Calcium entry through voltage-sensitive Ca²⁺ channels mediates several physiologic functions, including muscle contraction and neurotransmitter and hormone release in muscle, secretory and neuronal cells. We have recently cloned a rat brain cDNA (prBCCA1) encoding an α_1 subunit of L-type Ca²⁺ channel, and have shown that this channel is predominantly localized in neuroendocrine tissues. Although overall structural features are well conserved, the deduced primary structure of prBCCA1 indicated that amino and carboxy termini as well as cytoplasmic loops are significantly different from those of the α_1 subunits of skeletal and cardiac L-type Ca²⁺ channels. To investigate the gene products of three types of Ca²⁺ channel α_1 subunits cloned so far, we prepared antisera against various regions of the Ca²⁺ channel α_1 subunit. Bacterial expression plasmids (pET and pGEX) were used to construct recombinant plasmids that encode the fusion proteins containing the unique and homologous regions of the Ca²⁺ channel α_1 subunit. The fusion proteins were expressed in *E. coli* and used to produce rabbit polyclonal antisera. ELISA and Western blot analysis showed that the antisera were highly specific for the fusion proteins. Further functional characterization of the antisera is in progress.

MRNA FOR THE CARDIAC CALCIUM CHANNEL IS EXPRESSED DURING DEVELOPMENT OF SKELETAL MUSCLE. N. Chaudhuri and K.G. Beam. Dept. of Physiology, Colorado State University, Fort Collins, CO 80523.

Voltage-gated (L-type) calcium channels in skeletal and cardiac muscle cells are intimately involved in coupling nerve-induced excitation to contraction. Skeletal and cardiac muscle each possess L-type calcium channels with distinct functional properties and which are encoded by separate genes.

We have found that mRNA similar (in size, hybridization characteristics and sequence) to the cardiac calcium channel mRNA is detectable during early skeletal myogenesis. The cardiac-like mRNA is found at high concentration in early skeletal myotubes and precedes the expression of mRNA encoding the skeletal calcium channel. As skeletal myotubes mature, the concentration of the cardiac calcium channel mRNA decreases rapidly. The cardiac-like mRNA present in skeletal cells is probably transcribed from the same gene as the mRNA in heart cells, as evidenced by similarly sized protection fragments in RNase protection assays. The cardiac calcium channel mRNA in fetal skeletal muscle is not derived solely from vascular tissue since a similar mRNA is detectable also in tissue cultures of skeletal myotubes. Certain established lines of fibroblasts (e.g. 3T3) also express this cardiac calcium channel mRNA, in keeping with reports of cardiac-type calcium current in such cells (Chen et al., 1988). At present, we have no evidence whether the mRNA is translated and yields a functional channel in immature skeletal myotubes. Supported by NIH grant GM42652.

IN SITU LOCALIZATION OF CALCIUM CHANNEL mRNA. ^WW.J. Tomlinson, ^ΦS.R. Vincent, and ^ΨT.P. Snutch. Division of Neurological Sciences, ^ΦDept of Psychiatry, and ^ΨBiotechnology Laboratory, University of British Columbia, Vancouver, B.C., Canada V6T 1W5.

Previously, we have cloned a family of Ca²⁺ channel α₁-subunits from rat brain. Utilizing Northern blot and PCR analysis we have determined the regional distribution of distinct Ca²⁺ channel α₁-subunit isoforms in the rat CNS and in nonneuronal tissues.

To examine the cellular distribution of Ca²⁺ channel expression, we have performed *in situ* hybridization on rat brain sections using antisense oligonucleotide probes radiolabelled with [³⁵S] dATP. The oligonucleotides were directed to distinct coding regions of each of the rat brain class A and class C Ca²⁺ channel cDNAs. Specificity of the probes was determined by using variable hybridization and post-hybridization stringencies and control oligonucleotide probes. Autoradiography revealed that the class A and class C Ca²⁺ channel mRNAs overlap somewhat in their distribution, both being highly expressed in the cerebellar cortex. However, the C type Ca²⁺ channel transcripts showed a much broader distribution, being highly expressed in the hippocampus, hypothalamus, piriform cortex, neocortex, olfactory bulb, locus ceruleus, pontine nuclei and the sensory ganglia. These results indicate that the class A and class C type Ca²⁺ channels are differentially expressed in the nervous system.

FUNCTIONAL EXPRESSION OF A RAT BRAIN CALCIUM CHANNEL IN XENOPUS OOCYTES J.P. Leonard, T.V. Starr¹, B.P. Schmidt, M. Pragnell², S.B. Ellis³, M. Williams³, M.M. Harpold³, K.P. Campbell², and T.P. Snutch¹. Dept. of Biology, Univ. of Illinois at Chicago, Chicago, IL, 60680; ²Biotechnology Laboratory, Univ. of British Columbia, Vancouver, B.C., Canada V6T 1W5; ³H.H.M.I., Univ. of Iowa, Iowa City IA, 52242; ³S.I.B.I.A., La Jolla CA, 92037.

The rat brain Class A calcium channel α₁ subunit encodes a 2,212 amino acid protein that is 33% homologous to muscle DHP-sensitive channels. Upon microinjection into *Xenopus* oocytes this principle pore-forming unit only produces functional calcium channels when co-expressed with the neuronal β and α₂ subunits. Under standard two-electrode voltage clamp in Ba saline the channels expressed from the cloned cDNAs remarkably resemble currents from total rat brain mRNA. The I_{Ba} is activated at high voltages (-30 to -20 mV), peaks at +10 to +20 mV, and is still inward at +50 mV. The current inactivates substantially but incompletely during a 1 sec depolarization. Positive changes in holding potential caused inactivation of I_{Ba} (50% at -20 mV). The pharmacological profile of the channel is also similar to that seen by expression of total rat brain mRNA. The I_{Ba} is insensitive to 10 μM nifedipine, or 1 μM TTX, but is blocked by low μM Cd²⁺. Conotoxin GVIA and *Agelenopsis aperta* venom sensitivity are currently under investigation. (Supported by the MRC of Canada, H.H.M.I., and the NIH)

CALCIUM CHANNELS: PHOSPHORYLATION

310.1

CYCLIC AMP MODULATION OF L-TYPE CALCIUM CURRENTS IN NON-DISSOCIATED HIPPOCAMPAL NEURONS. O. Thibault, L.W. Campbell and P.W. Landfield. Dept. Pharmacol., Univ. Kentucky College of Medicine, Lexington, KY, 40536-0084.

There is increasing evidence that cAMP can counteract "rundown" and calcium (Ca)-dependent inactivation of dihydropyridine (DHP)-sensitive Ca channels in molluscan neurons and other excitable tissues (e.g., Armstrong and Eckert, 1987, PNAS). However, it is unclear whether DHP-sensitive, or L-type, Ca currents in the mammalian CNS can be modulated by cAMP.

We, and others, have described DHP-sensitive currents in adult hippocampal slice neurons, using single electrode voltage clamp (SEVC). Because the cells are not disrupted or dissociated, Ca currents exhibit little "rundown" and remain viable for many hours. However, they are highly sensitive to Ca-dependent inactivation (Pitler and Landfield, 1987, Brain Res.; Campbell et al, 1990, Soc. Neurosci. Abstr.).

In the present studies, we impaled TTX and TEA-treated CA1 pyramidal neurons with pipettes filled with 1-10 mM dibutyl cAMP, and 2 M CsCl (pH 7.1) to study inward Ca currents with SEVC.

Cells (n=16) loaded with db cAMP exhibited significantly stronger L-type currents in comparison to control cells (n=16), both during a depolarizing step and during the long post-activation "tail-like" currents that we have described previously (cf. references above). The amplitude increases were 25-30%, but were highly significant (p<.005). Input resistance did not differ between control and db cAMP cells. This effect may be mediated by reducing Ca-dependent inactivation, as in non-CNS cells. (Supported by AG04542).

310.3

BIOCHEMICAL CHARACTERIZATION OF L-TYPE CALCIUM CHANNELS IN A1T-20 CELLS. G.A. Stafford* and G.A. Weiland. Dept. Pharmacology, Cornell Univ., Ithaca, NY 14853.

Membrane binding studies have demonstrated a single population of high affinity dihydropyridine (DHP) binding sites in A1T-20/D16v-F2 (mouse corticotrophic pituitary tumor) cells. We have shown that in intact cells, the binding is dependent upon membrane potential. Functional studies correlate the binding with calcium influx, suggesting that these binding sites represent L-type voltage-gated calcium channels.

This class of calcium channels has been most extensively studied in skeletal and cardiac muscle, where it has been shown that phosphorylation of the channel protein regulates function. We have found that the channel in A1T-20 cells shares at least some epitopes of the L-type channel from skeletal muscle. Monoclonal antibodies directed against the α₁ subunit of the rabbit skeletal muscle calcium channel specifically immunoprecipitate DHP binding from pre-labelled, solubilized A1T-20 cell membranes. Western blots indicate that the precipitated protein has a molecular weight of approximately 100 K, significantly smaller than its muscle counterpart. In cells loaded with ³²P-orthophosphate, the 100 KDa protein is phosphorylated in the basal state. Preliminary results indicate that activation of cAMP-dependent kinase increases the incorporation of ³²P. Continuing experiments will use back-phosphorylation to attempt to quantify the increase. Correlation will be made with alterations in function of the channel. (Supported by Cornell Biotechnology Program.)

310.2

cAMP-DEPENDENT PHOSPHORYLATION OF RYANODINE RECEPTOR OF RAT BRAIN. M. Takahashi, A. Yoshida, A. Ogura, T. Imagawa* and M. Shigeokawa. ¹Mitsubishi Kasei Institute of Life Sciences, Tokyo, Japan and ²National Cardiovascular Center Research Institute, Osaka, Japan

Ryanodine receptor was solubilized from rat brain microsomal membranes with CHAPS. A monoclonal antibody Ry-1 against cardiac ryanodine receptor immunoprecipitated more than 85% of the solubilized receptor. By immunoblotting with Ry-1, a large polypeptide having the same mobility in SDS-PAGE as that of cardiac ryanodine receptor was detected in the brain microsomal proteins. The brain ryanodine receptor, which was immunoprecipitated by Ry-1, was phosphorylated by cAMP-dependent protein kinase. The ryanodine receptor was expressed in cultured rat brain neurons and the phosphorylation of the receptor was markedly increased by a treatment with Bt₂-cAMP. The number of neurons showing the caffeine-induced Ca²⁺ transient was increased by the treatment. These results suggest that the Ca channel activity of brain ryanodine receptor is regulated by cAMP-dependent phosphorylation.

310.4

OKADAIC ACID AND HEPARIN HELP SUSTAIN THE ACTIVITY OF L-TYPE CALCIUM CHANNELS IN PLANAR LIPID BILAYERS. C. Townsend*, Y. Wang*, K. Fecho*, P.A. Koplas, & R.L. Rosenberg. Pharmacology and Neurobiology, Univ. of N. Carolina at Chapel Hill, NC

The activity of L-type Ca channels "runs down" in dialysed cells, excised patches, and planar lipid bilayers. Activated G_{SCA} reduces the rate of Ca channel rundown, possibly due to a direct G-protein/channel interaction (Yatani et al., 1987, Science 238; 1288). We have been studying the activity of L-type Ca channels incorporated from cardiac sarcolemma into planar lipid bilayers in the presence of the DHP agonist (+)202-791. In the absence of G_{SCA}, Ca channels disappeared in less than 3 min. Intracellular G_{SCA} caused channel activity to persist, with a mean "lifespan" of ~15 min (n>50). Channel lifespan was also dramatically improved by other additions in the absence of G_{SCA}. Treatment of the sarcolemma with okadaic acid, a potent phosphatase inhibitor, caused sustained channel activity in 14/19 experiments, with lifespans of 10-120 min. Incubation of the membranes with ATPγS, presumably leading to poorly-reversible thiophosphorylation, caused channel activity to be sustained for >10 min (4/5 experiments). Intracellular additions of heparin also inhibited channel rundown in 9/13 experiments. In the presence of G_{SCA}, the addition of heparin after channel incorporation caused an increase in channel activity above that seen with G_{SCA} alone (20/32 experiments). This increase is unlikely to result from phosphorylation, because of the absence of added ATP. These results (1) support the idea that a dephosphorylation of the Ca channel is a mechanism for the rundown process, (2) indicate that heparin increases channel activity, but probably not only by acting as a phosphatase inhibitor, and (3) suggest that G_{SCA} might improve channel lifespan by modulating G-protein-sensitive phosphatases or interfering with phosphatase/channel interactions.

310.5

FACILITATION OF LONG-LASTING (TYPE II) Ca CHANNEL CURRENTS BY A COGNITIVE ENHANCER DM-9384 REQUIRES A PHOSPHORYLATION PROCESS IN NG108-15 CELLS. M. Yoshii¹, S. Watabe², Y. L. Murashima^{1*} and Y. Nakamoto^{1*} ¹Dept. of Neurophysiology, Psychiatric Res. Inst. of Tokyo, Tokyo 156, Japan and ²Exploratory Res. Lab. II, Daiichi Pharmaceutical Co., Ltd., Tokyo 134, Japan.

A cognitive enhancer DM-9384 (a pyrrolidone derivative) causes an increase in the transmitter release in the brain (Watabe et al., Soc. Neurosci. Abstr. 15, 601, 1989; 16, 137, 1990). To examine a possibility that the drug might potentiate Ca channels responsible for the transmitter release, we have recorded Ca channel currents from neuroblastoma x glioma hybrid (NG108-15) cells using the whole-cell clamp technique. It has recently been found that DM-9384 markedly increases long-lasting (type II) Ca channel currents in a manner similar to the effect of dibutyryl cAMP (Yoshii and Watabe, Biophys. J. 59, 82a, 1991). In the present study, we have further examined whether cAMP-dependent mechanisms are involved in the DM-9384 action. Leu-enkephalin (50 nM), which activates an inhibitory G protein, caused a time- and voltage-dependent reduction in the type II current, which was antagonized by 1 μ M DM-9384 as well as by 1 mM dibutyryl cAMP. H-7(100 μ M), a protein kinase inhibitor, prevented the facilitatory effects of DM-9384 and dibutyryl cAMP. It is concluded that the facilitatory action of DM-9384 requires a phosphorylation process, which is probably mediated by cAMP.

310.7

MODIFICATION OF CALCIUM CURRENT BY HYPEROSMOTIC MEDIA IN CONTROL AND PHORBOL ESTER TREATED NEURONS. K.J. Loechner, R.J. Knox, J.A. Connor, L.K. Kaczmarek. Dept. of Pharmacology, Yale Univ. Sch. Med., New Haven, CT 06510, and Dept. Neurosciences, Roche Institute of Molec. Biol., Nutley, NJ 07110.

Alterations in extracellular osmolality have been shown to affect calcium-dependent secretion. We have reported previously that hyperosmotic media (H-M) (artificial sea water made hyperosmotic with mannitol, sucrose, NaCl, or choline chloride) inhibit KCl-induced release of peptides and terminate ongoing electrical activity (afterdischarge) in the bag cell neurons (BCNs) of *Aplysia*. We have now investigated the effects of H-M on the electrical properties of isolated BCNs. We have found that H-M inhibit action potentials elicited by depolarizing current injection in these neurons. This is associated with an attenuation of voltage-dependent calcium current measured using single microelectrode voltage clamp with either barium or calcium as the charge carrier. Furthermore, in BCNs loaded with fura-2, H-M inhibit the rise in intracellular calcium levels that normally occurs in response to depolarizing current injection. Basal levels of calcium, however, are not altered. Interestingly, the inhibition of the rise in intracellular calcium can be partially overcome by pre-treatment of the BCNs with the phorbol ester, TPA, which has been shown to recruit a new population of calcium channel in the plasma membrane (Strong et al., 1987). It appears, therefore, that H-M inhibit a portion of the voltage-dependent calcium channels in BCNs, an effect that may underlie the ability of H-M to inhibit afterdischarges and secretion.

310.6

PHOSPHORYLATION OF AN α 1-LIKE SUBUNIT OF AN ω -CONOTOXIN-SENSITIVE BRAIN CALCIUM CHANNEL BY cAMP-DEPENDENT PROTEIN KINASE AND PROTEIN KINASE C. Michael K. Ahljianian, Jörg Striessnig and William A. Catterall. Dept. of Pharmacology, SJ-30, University of Washington, Seattle, WA 98195.

Voltage-dependent calcium channels are responsible for rapid increases in intracellular calcium during depolarization in neurons. Electrophysiological evidence suggests that neuronal N- and L-type calcium channel function is regulated by phosphorylation, however, direct phosphorylation of subunits of neuronal calcium channels has yet to be demonstrated. We have used antibodies which recognize the α 2 δ and α 1 subunits of skeletal muscle L-type calcium channels to investigate the subunit components and phosphorylation of ω -conotoxin (ω -CgTx)-sensitive N-type calcium channels from rabbit brain. Photolabeling of the N-type channel with a photoreactive derivative of ¹²⁵I- ω -CgTx results in the identification of a single polypeptide of 240 kDa. MANC-1, a monoclonal antibody recognizing α 2 δ subunits of L-type calcium channels from skeletal muscle, immunoprecipitates the ω -CgTx-labeled 240 kDa polypeptide and approximately 6% of the digitonin-solubilized ¹²⁵I- ω -CgTx-labeled N-type channels. MANC-1 also immunoprecipitates a phosphoprotein of 240 kDa which comigrates with ¹²⁵I- ω -CgTx-labeled N-type calcium channels, but not with L-type calcium channels, in sucrose gradients. Both cAMP-dependent protein kinase and protein kinase C are effective in the phosphorylation of this polypeptide. Similar to the α 1 subunits of skeletal muscle L-type calcium channels, the immunoprecipitation of the 240 kDa phosphoprotein by MANC-1 is prevented by the detergent Triton X-100. Anti-CP(1382-1400), an anti-peptide antibody against a highly conserved segment of the α 1 subunits of calcium channels, immunoprecipitates the 240 kDa phosphoprotein in Triton X-100. The 240 kDa protein is phosphorylated to a stoichiometry of approximately 1 mole of phosphate per mole of ω -CgTx-binding N-type calcium channels by both cAMP-dependent protein kinase and protein kinase C. The results suggest that the 240 kDa polypeptide is an α 1-like subunit of an ω -CgTx-sensitive N-type calcium channel. The N-type calcium channels containing this subunit are phosphorylated by cAMP-dependent protein kinase and protein kinase C and contain noncovalently associated α 1-like and α 2 δ -like subunits as part of their oligomeric structure.

OKADAIC ACID PROLONGS K-INDUCED INCREASES IN [Ca]_i IN LEECH RETZIUS CELLS. A.L. Kleinhaus, K.M. Lerea & R.J. Zeman. Dept. Cell Bio. & Anat., NYMC, Valhalla, NY 10595

The Retzius cell (R) of the leech is a multifunction neuron implicated in the control of essential behaviors. During excitation its membrane admits Ca through divalent cation channels. Apart from the existence of a Na/Ca exchange mechanism, there is no information regarding the processes involved in the control of [Ca]_i in this neuron. Recent evidence suggests that protein phosphatases may influence Ca currents in other neurons. Therefore, we examined the effect of okadaic acid (OA), an inhibitor of type 1 and 2A protein phosphatases, on Ca transients induced by KCl depolarization in R cells. The average [Ca]_i was calculated by ratioing of fura-2 fluorescence excited at 340 and 380 nm. Following exposure to 120 mM KCl (substituting for NaCl) [Ca]_i rose from 64.7 ± 6.0 nM to 122.0 ± 13.9 nM. Recovery towards basal levels occurred rapidly after washout in normal (4 mM KCl) solution. In contrast, in the presence of OA (10⁻⁶M) recovery was significantly slower. The time constant of recovery was 1.79 min. in the control as compared to 7.50 min. in the presence of OA (P < 0.02). Assays of OA-sensitive phosphatases demonstrated the presence of approximately equal activities of PP1 and PP2A in lysates of leech ganglia.

These results suggest a role for PP1 and/or PP2A in the regulation of [Ca]_i in leech neurons.

POTASSIUM CHANNELS: MOLECULAR BIOLOGY I

311.1

TEMPERATURE-SENSITIVE, LONG-LASTING PLATEAU POTENTIALS IN CULTURED NEURONS FROM THE *DROSOPHILA* MUTANT *SEIZURE*^{TS}. M. Saito and C.-F. Wu, Dept. of Biology, Univ. of Iowa, Iowa City, IA 52242

At non-permissive temperatures (>38°C), *seizure* flies undergo hyperactive behavior followed by paralysis. Previous toxin-binding studies show altered Kd and Bmax for STX binding in *seizure* head extracts, suggesting abnormal Na⁺ channel properties (Jackson et al., 1984). However, neural activity in the adult cervical giant fiber path way was found to be elevated in *seizure* at 40°C (Elkins and Ganetzky, 1990). Recently voltage-clamp studies performed at room temperature detected no striking differences in cultured *seizure* neurons, except for a reduction in Na⁺ current density in one of the alleles, *seizure*¹ (O'Dowd and Aldrich, 1988). However, intracellular recording of action potentials in *seizure* at different temperatures have not yet been examined. We have carried out such studies by using "giant" *Drosophila* neurons derived from cell-division arrested embryonic neuroblasts. These large neurons allow both current- and voltage-clamp recordings performed on the same cell (Wu et al., 1990, Saito and Wu, 1991). Cells generating all-or-none action potentials were studied under current clamp. When temperature was raised to >35°C, action potentials in neurons from both wild-type and *seizure*¹ became sustained depolarization as long as current injection was maintained. However, this plateau potential in *seizure*² outlasted the depolarizing current pulse (800 ms) for several seconds. This response pattern could be seen in wild-type neurons when treated with the K⁺ channel blocker, TEA. This temperature-induced phenotype could be explained by an enhancement in Na⁺ current, a reduction in K⁺ currents, or both. Further voltage-clamp analyses is underway to identify the current component(s) affected by the *sei* mutation.

311.2

EFFECTS OF FOUR POTASSIUM CURRENT MUTATIONS ON ONGOING ACTIVITY IN A *DROSOPHILA* NEURON. L. M. Hurley and J. Paika. Department of Zoology, University of Washington, Seattle, WA 98195.

A number of mutations affect potassium (K⁺) currents in *Drosophila melanogaster*. Different mutations affect different currents, and the genes coding for them may also be expressed differentially in tissues. We examined the effects of four mutations affecting K⁺ currents on ongoing neuronal activity associated with the posterior scutellar bristle, a mechanosensory structure located on the thorax of the fly.

A broken off glass capillary microelectrode filled with a receptor lymph approximating high K⁺ saline was used both to maintain electrical contact with the neuron and to deflect the bristle. The mutations investigated were two alleles of *Shaker* (*Sh*), a deficiency (*DfSh^{B55-W32}*) and *Shaker K5133* (*Sh^{K5133}*), *ether-a-go-go* (*eag^{K-6}*), *slowpoke* (*slo¹*), and *Hyperkinetic* (*Hk¹*). Canton S (C-S) was used as the wild-type control.

Sh flies showed no significant differences in ongoing activity (spikes/sec.) from wild type. The average spike rate for C-S was 3.7 ± 541 spikes/sec. (n=19), for *DfSh^{B55-W32}* 0.98 ± 384 spikes/sec. (n=10), and for *Sh^{K5133}* 3.87 ± 353 spikes/sec. (n=14). *eag^{K-6}*, *slo¹*, and *Hk¹* flies, however, all showed approximately four times as much ongoing activity as wild-type flies. The average spike rate for *eag^{K-6}* was 15.4 ± 1.067 spikes/sec (n=10), for *slo¹* 17.5 ± 1.300 spikes/sec. (n=10), and for *Hk¹* 22.1 ± 1.861 spikes/sec. (n=9). These results indicate that the currents affected by *eag*, *slo*, and *Hk* all play a role in determining the ongoing activity of this mechanosensory neuron, while those affected by *Sh* may not.

This research was supported by a NSF Graduate Fellowship (LMH) and by NSF Research Grant BNS-9011028 (JP).

311.3

Mutations in the S5-S6 Segment of K_v3 Affect Charybdotoxin Blockade and the Rate of Slow Inactivation. C. Oliva, R. Wiedmann, C. Bennett, K. Folander, R. Swanson, and J. Smith Merck Sharp and Dohme Research Labs, West Point PA 19486

Despite extensive sequence homology, *Shaker* H4 and a mammalian homologue, K_v3 , display marked differences in their sensitivities to blockade by charybdotoxin (CTX). K_v3 is blocked with an IC_{50} of ~1 nM; *Shaker* H4 is relatively insensitive (IC_{50} ~300 nM). The putative pore-forming domain of these proteins (the S5-S6 region) differ by 10 of 37 amino acids and substitution of this entire region in K_v3 by the corresponding sequence from *Shaker* converts the channel to a toxin insensitive form (Oliva *et al.* 1991). A chimera containing changes at the 4 most distal residues that differ between the two channels (residues 401, and 404-406 in K_v3) displayed wt CTX sensitivity. Individual point mutations at the 6 remaining residues that differ have, therefore, been constructed in attempts to define the CTX binding site in more detail. The G377F mutant of K_v3 decreased the sensitivity of the channel to CTX by > 2 orders of magnitude. Interestingly, the corresponding mutation in H4, F425G, converts the *Shaker* channel from the wt (toxin-insensitive) form to a channel that is blocked with an IC_{50} = 1 nM. None of the other point mutants in this domain of K_v3 had any effects on CTX affinity.

When expressed in *Xenopus* oocytes, K_v3 activates rapidly and inactivates very slowly (τ_i = 751 +/- 40 ms). Some of the mutations in the pore forming domain had selective effects on the rate of slow inactivation. G377F eliminates slow inactivation, resulting in a noninactivating, toxin-insensitive current. D372G and D373S increase the rate of slow inactivation ~2X (τ_i = 440 +/- 44 ms) without changing CTX sensitivity. The chimeric channel (containing the H401T, T404G, I405V, and G406W mutations) also displays no inactivation.

311.5

ION REPULSION IN CLONED VOLTAGE GATED K^+ CHANNELS C.F. Newland¹, J.P. Adelman², B.L. Tempel³, E.W. McCleskey⁴, W. Almers¹.

¹Dept. Physiol & Biophys, and ³Dept. Pharmacol & Medicine U. Washington, Seattle WA 98195. ²Vollum Institute, Oregon Health Sciences U., Portland OR 97201. ⁴Dept of Cell Biol & Physiol, Washington Univ, St Louis MO 63110.

Both internal and external tetraethylammonium (TEA⁺) block voltage-gated K^+ channels by acting at two functionally and molecularly distinct sites. We have tested two predictions of models explaining ion permeation, namely that ion channels can be simultaneously occupied by multiple ions, and that these ions repel each other. Currents were measured by patch-clamp in *Xenopus* oocytes injected with specific mRNA for RBK1, RBK2 and *Shaker* B. In *Shaker* B and RBK1, both TEA⁺ sites lie within the aqueous pore because block by internal and external TEA⁺ is voltage-dependent and antagonized by K^+ on the opposite side of the membrane. External TEA⁺ antagonized block by internal TEA⁺ and internal TEA⁺ antagonized block by external TEA⁺. For example, with 1.5 mM external TEA⁺, 1.04 mM internal TEA⁺ was required to block half the remaining current of RBK1, while without external TEA⁺, 0.31 mM internal TEA⁺ was sufficient. The antagonism was less than predicted for competition (*i.e.* K_d = 1.76mM for the above), hence both sites may be simultaneously occupied by TEA⁺, and external and internal TEA⁺ reduce each others affinity about tenfold. The strong antagonism suggests that the two sites are in close proximity. For RBK2, a clone 1000 times less sensitive to external TEA⁺, 100mM external TEA⁺ was ineffective in reducing block by internal TEA⁺, hence TEA⁺ must bind to antagonize block. External TEA⁺ also antagonized block by another cationic blocker, virtually abolishing the inactivation induced by internal Ba²⁺. This suggests an electrostatic contribution to the antagonism.

311.7

PEPTIDE TOXIN BLOCK OF K^+ CHANNELS EXPRESSED IN FIBROBLAST CELLS STABLY TRANSFECTED WITH THE NGK1 GENE: COMPARISON WITH CONVENTIONAL K^+ CHANNEL ANTAGONISTS. T.R. Werkman¹, T. Kawamura², S. Yokoyama², H. Higashida² and M.A. Rogawski¹. ¹Neuronal Excitability Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892, and ²Neuroinformatics Research Institute, Kanazawa University, Japan.

Voltage-dependent K^+ currents with delayed rectifying properties were recorded in CL1023 fibroblast cells stably transfected with a K^+ channel gene (NGK1) from the NG108-15 neuroblastoma-glioma hybrid cell line (Kawamura *et al.*, *Soc. Neurosci. Abst.* 16: 670, 1990). NGK1 is identical to the rat brain K^+ channel protein BK2 and nearly identical to another rat brain K^+ channel protein RCK5. The blocking effects of three peptide toxins—charybdotoxin (CTX), dendrotoxin (DTX) and mast cell degranulating (MCD) peptide—were compared with the conventional K^+ channel blockers 4-aminopyridine (4-AP) and tetraethylammonium (TEA) using discontinuous whole-cell voltage clamp. All three toxins produced a concentration-dependent block of the K^+ current with IC_{50} 's in the nanomolar range (CTX, 2 nM; DTX, 3 nM; MCD peptide, 180 nM). The toxins were inactive when added to the patch electrode solution, indicating that they block from the outside of the channel. 4-AP was active either from the outside (IC_{50} , 0.3 mM) or the inside (1 mM), whereas TEA was nearly inactive when applied extracellularly but substantially reduced the current from the inside (5 mM). The blocking effect of 4-AP was strongly diminished at depolarized potentials, whereas the block induced by the toxins showed only a weak voltage dependence. We conclude that the peptide toxins are potent antagonists of the NGK1 delayed rectifier K^+ channel expressed in mammalian cells (as is the case in *Xenopus* oocytes; Stühmer *et al.*, *EMBO J.* 8: 3244, 1989) and that they act by binding to an extracellular site.

311.4

MUTATIONAL ANALYSIS EXAMINING THE INTERNAL MOUTH OF THE SHAKER POTASSIUM CHANNEL. G.A. Lopez, E.Y. Isacoff*, Y.N. Jan & L.Y. Jan. Howard Hughes Medical Institute and Departments of Physiology and Biochemistry, Univ. of California, San Francisco, San Francisco, CA 94143

In order to identify regions of the protein which may contribute to the internal mouth and pore lining structure of the *Shaker* potassium channel, we have made multiple point mutations in several of the proposed transmembrane and intracellular regions of the protein. The approach taken in this study is to examine the potential function served by those residues that are highly conserved. Mutations were restricted to the fifth and sixth proposed transmembrane domains S5 and S6 since these domains are the most conserved among the various potassium channels cloned to date. Sequence comparison reveals that many of the residues in the S5 and S6 domain are 100% conserved in all cloned potassium channels. Mutated channels were expressed in *Xenopus* oocytes and analyzed using the two-electrode voltage clamp technique. Mutant channels were then further characterized at the single-channel level using inside-out patches in order to determine if the single-channel conductance and/or selectivity profile of the channel had been altered.

POTASSIUM CHANNELS CLONED FROM NEUROBLASTOMA CELLS DISPLAY SLOWLY INACTIVATING OUTWARD CURRENTS IN *XENOPUS* OOCYTES. Y. Ito, S. Yokoyama & H. Higashida. Dep. of Biophys., Neuroinformatics Res. Ins., Kanazawa Univ. Sch. of Med., Kanazawa 920, Japan.

Oocytes injected with specific mRNA for NGK1 and NGK2 display outward K^+ currents (FEBS Lett. 259, 37, 1989). In previous reports in the literature it has not been possible to make direct physiological correlations between the currents expressed in oocytes and those from particular cell types. However, in this case NGK1 and NGK2 have been isolated from NG108-15 cells, enabling a direct comparison of the currents generated by the channels of these genes when expressed in oocytes with the native K^+ current in NG108-15 cells. The half activation potential of the NGK2 current (+29 mV) was more positive than that for the NGK1 (-8 mV). External tetraethylammonium chloride (TEA) was 1000 times more potent on the NGK2 current than the NGK1 current. The NGK2 currents showed faster inactivation during a 5 s depolarising pulse than did the NGK1 currents. These findings suggest that both NGK1 and NGK2 proteins form homomultimeric K^+ channels. Furthermore, NGK2 channels may be responsible for the native transient outward current with slow inactivation and underlying action potential repolarisation in NG108-15 hybrid cells, which was described by Robbins and Sim (Pflüger Archiv 416, 130, 1990).

311.8

LOCALIZATION IN RAT BRAIN OF mRNA FOR THE K_v4 POTASSIUM CHANNEL BY *IN SITU* HYBRIDIZATION HISTOCHEMISTRY. J.M. Perney, J. Marshall¹, K.A. Martin, S. Hockfield and L.K. Kaczmarek. Dept. of Pharmacology and Sect. of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Recently, it has been demonstrated that two different mammalian *Shaw*-type K^+ channels, K_v4 and NGK2, can arise by alternative splicing of transcripts from the same gene (Luneau *et al.*, *PNAS*, in press). We have demonstrated that both splice variants are present in rat brain by RNAase protection assay, but that K_v4 mRNA was the more abundant message. To examine the distribution of these two mRNAs in rat brain, *in situ* hybridization histochemistry was performed using K_v4 or NGK2 specific oligonucleotide probes. No specific NGK2 hybridization was detected. In contrast, a heterogeneous expression of K_v4 mRNA was observed throughout the brain. Highest K_v4 mRNA levels were expressed in the cerebellum. High levels of hybridization were also detected in the globus pallidus, subthalamus, and substantia nigra reticulata. Many thalamic nuclei, but in particular the reticular thalamic nucleus, hybridized well to K_v4 specific probes. A subpopulation of cells in the cortex and hippocampus, which by their distribution and number may represent interneurons, were also found to contain high levels of K_v4 mRNA. In the brainstem, many nuclei including the inferior colliculus and the cochlear and vestibular nuclei also express K_v4 mRNA. Low or undetectable levels of K_v4 mRNA were found in the caudate-putamen, olfactory tubercle, amygdala, and hypothalamus. Interestingly, most of the neurons that hybridize with K_v4 specific probes have been characterized electrophysiologically to have narrow action potentials and display high frequency firing rates with little or no spike adaptation. It seems likely that the expression of the delayed rectifier-like K_v4 current in these neurons would allow for rapid repolarization following an action potential and thereby contribute to their firing patterns.

A COMPARISON OF MACROSCOPIC KINETIC PROPERTIES IN THREE CLONED AND EXPRESSED RAT BRAIN POTASSIUM CHANNELS. L.D. Chabala¹ & R.G. Sorensen², Depts. of Medicine^{1,2} & Pharmacology², Jefferson Medical College, Phila., PA 19107.

We further characterized the macroscopic kinetic properties of three cloned rat brain potassium channels (Kv1, Kv2, & Kv3; Swanson et al., 1990, *Neuron* 4:929) with identical S4, S5, and S6 regions, nearly identical S4-S5 and H5 linker regions, but different S5-S6 loops. The expressed currents were studied with a two-electrode voltage clamp following injections of cRNA in *Xenopus* oocytes. [cRNA] was adjusted so that currents were usually less than 5 μ A, and series resistance compensation was employed. The currents are quite distinct and differ both with respect to activation and inactivation properties. Currents induced by cRNA from Kv1 show rapid voltage-dependent activation (positive to 0 mV) followed by only modest (<10%) inactivation during a 1 s pulse (+50 mV); those from Kv2 have slower activation rates and show less inactivation; while those from Kv3 are somewhat intermediate with respect to activation but show much stronger inactivation, which is about 40% complete in 1 s at +50 mV (at 24°C). Each clone also shows different conductance-voltage relations and prepulse-induced inactivation properties. Steady-state gating parameters were estimated from the prepulse-inactivation experiments using the assumption that the kinetic transitions after channel opening are voltage independent.

MOLECULAR CLONING OF TWO HUMAN BRAIN K⁺ CHANNELS.

F. Soler*, D. Arvey* and R. Joho, Department of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.

Voltage-gated K⁺ channels are essential for a variety of electrical events in the mammalian brain. They terminate the action potential, repolarize the neuron, set its resting potential, and regulate neurotransmitter release from the presynaptic terminal. This versatility and importance may be the reason for the impressive diversity and number of K⁺ channels in the brain. We have screened a human cortex cDNA library using a mixture of cDNA probes from different subfamilies of voltage-gated K⁺ channels that have been cloned and characterized in our laboratory. We have assembled two full length clones of 3.8 kb and 2.8 kb. One encodes the human homolog of *drk1* and the other a new human homolog of the *rk* family. The deduced amino acid sequence of the rat *drk1* and its human homolog is 95% identical with most of the amino acid substitutions occurring in the putative C-terminal tail. Expression of the isolated clones in the *Xenopus* oocytes system is now in progress.

311.13

CDNA ANALYSIS OF A LEECH SHAKER K-CHANNEL HOMOLOGY. K.M. Johansen, A. Wael[†], L. Salkoff[†], and J. Johansen, Department of Zoology and Genetics, Iowa State University, Ames, Iowa 50011 and [†]Department of Anatomy & Neurobiology, Washington University School of Medicine 63110.

We have cloned the *Shaker* K-channel homolog from leech with the polymerase chain reaction. Using degenerate oligonucleotides synthesized based on sequences conserved between *Drosophila* and mammals, we amplified and subcloned the core region encompassing transmembrane domains S1 through S5 from genomic DNA. We have used the genomic clone to screen a cDNA library and have isolated a cDNA clone extending from S1 through the poly A tail. We are currently primer extending and screening to isolate the 5' cDNA sequences. Analysis of both genomic and cDNA sequences reveal some very striking features. For example, while all the other characterized *Shaker* K-channels contain 7 positively charged amino acids in the S4 domain, the leech *Shaker* homolog contains only 5. Homology between leech *Shaker* and *Drosophila Shaker* within the currently analyzed domains is 58%, whereas homology with the other K-channel families *Shab*, *Shal*, and *Shaw* is only 28, 31, and 32%, respectively. Although several uniquely characteristic features of *Shaker* homologs are conserved within the leech sequence, the much higher degree of divergence (*Drosophila*-mouse *Shaker* homologs are 85% homologous in this region) will allow us to identify essential amino acids and motifs likely to be important for the structure-function relationship of the channel molecule. The structure-function of the leech *Shaker* K-channel will be further characterized by oocyte expression studies. In addition, by *in situ* hybridization and by using antibodies made to the cloned *Shaker* channel protein we plan to correlate and compare the expression, distribution, and subcellular localization of the *Shaker* K-channel among functionally identified neurons involved in known behavioral networks. Supported by an Iowa State Biotechnology grant and an Iowa State University grant.

311.10

NEUROTOXIN SENSITIVITY IN THREE CLONED AND EXPRESSED RAT BRAIN POTASSIUM CHANNELS. R.G. Sorensen¹ & L.D. Chabala², Depts. of Medicine^{1,2} & Pharmacology¹, Jefferson Medical College, Phila., PA 19107.

We studied neurotoxin sensitivity in three cloned rat brain potassium channels (Kv1, Kv2, & Kv3; Swanson et al., 1990, *Neuron* 4:929). We measured IC₅₀ values of each clone expressed in *Xenopus* oocytes to five dendrotoxin (DaTX) homologues and to β -bungarotoxin (β -BuTX, the holotoxin) using a two-electrode voltage clamp. We find that both Kv2 and Kv3 clones are sensitive to some of the toxins. Kv3 clones show IC₅₀ values of about 20 nM (at +40 mV) for α -DaTX and β -BuTX, and the inhibition is voltage dependent with tighter binding at positive potentials. Kv2 clones are also sensitive to those toxins, but the affinities seem to be somewhat reduced. This may be the first voltage-clamp evidence that some CNS potassium channels have receptor sites for phospholipase A₂ toxins. Other groups, however, have reported that Kv3 (cf. RCK3 or RCK5) channels are not sensitive to α -DaTX and that Kv2 (cf. RCK2) channels are not sensitive to β -BuTX. The reasons for these differences are not clear. One possibility is that the vitelline envelope represents a diffusion barrier to the bulky polypeptide neurotoxins, and it may be necessary to strip, tear, or digest it for quantitative studies. We are further characterizing the toxin binding site(s) by preparing chimeric channels and by using site-directed mutagenesis.

311.12

A SHAW SUBFAMILY K⁺ CHANNEL EXPRESSED IN HUMAN HEART. A. Butler*, D. P. McCobb, and L. Salkoff, Dept. of Anatomy and Neurobiology, and Dept. of Genetics, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Four voltage-gated potassium channel gene subfamilies defined by the *Drosophila* K⁺ channel genes *Shaker*, *Shal*, *Shab*, and *Shaw* are conserved in mammals. In mammals, *Shaker*, *Shal* and *Shaw* are represented as multigene subfamilies, while *Shab* may be present only as a single gene. In the mammalian heart, recent reports indicate that at least four *Shaker* and one *Shal* subfamily genes are expressed (Roberds & Tamkun, 1991). We now report that a third subfamily, *Shaw*, is represented in the heart. We have isolated a cDNA (*HHShaw1*) from a human fetal heart cDNA library which has high sequence homology to Raw3, a *Shaw* subfamily member cloned from rat brain by Schroter et al., (1991). Unlike previously described *Shaw* subfamily members, Raw3 produces a transient (A-type) potassium current when expressed in *Xenopus* oocytes. (One *Shaker* subfamily gene and the *Shal* gene probably also produce transient currents.) We are expressing *HHShaw1* in oocytes to determine whether a similar transient current is produced. If so, there may be transient K⁺ currents representing three potassium channel subfamilies expressed in heart. (Supported by NIH ROINS24785-01 and a research grant from Monsanto-Searle.)

HETEROLOGOUS EXPRESSION OF MODULATABLE CALCIUM-DEPENDENT POTASSIUM CHANNELS FROM RAT BRAIN. P.H. Reinhart, F.M. Schmalz* and L.B. Levitan, Dept. of Biochemistry and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

We have shown previously that rat brain cortex plasma membrane vesicles contain at least four distinct calcium-dependent potassium channels that can be reconstituted in planar lipid bilayers (Reinhart et al., *Neuron* 2(1989)1031-1041). Two of these channels exhibit large single channel conductance (maxi-K channels). Both of these maxi-K channels can be modulated by cyclic AMP-dependent protein phosphorylation, and one is also modulated by a protein kinase activity closely associated with the reconstituted channel. We have now expressed potassium currents in *Xenopus* oocytes by injection of messenger RNA from the brains of adult and 21 day old rats. A portion of this current is blocked by BAPTA-AM and low concentrations of tetraethylammonium, indicating that it is a calcium-dependent potassium current. Size-selection of messenger RNA from 21 day old rat cortex demonstrates that most of the message coding for calcium-dependent potassium current is larger than 5.5 kilobases. Patch clamp analysis has demonstrated the presence of single maxi-K channels in the plasma membrane of oocytes injected with size-selected brain messenger RNA. The expression and cloning of members of the family of calcium-dependent potassium channels should allow the elucidation of structural features involved in channel modulation. Supported by NS17910 to I.B.L.

SYNTHETIC N-TERMINAL PEPTIDES OF DIFFERENT SHAKER K CHANNEL VARIANTS INDUCE INACTIVATION IN NONINACTIVATING MUTANT CHANNELS. B.D. Murrell-Lagnado and R.W. Aldrich. HHMI, Mol. and Cel. Physiology, Stanford University Sch. of Med., Stanford, CA 94305.

Fast inactivation in *Shaker* potassium channels involves the interaction of the NH₂-terminal cytoplasmic domain with a region of the open channel. A "ball and chain" model for inactivation has been proposed for the ShB alternatively spliced variant whereby the first 20 residues form a structural domain that acts like a ball tethered to the rest of the channel protein which is able to bind within the channel pore thereby blocking ion flux. The *Shaker* variants C,D and H37 also inactivate even though their NH₂-termini show no sequence homology with the ShB NH₂-terminus. To determine whether the mechanism of fast inactivation is similar for all *Shaker* variants we applied synthetic peptides with the sequence of the amino terminal domains of ShB,C,D and H37, to the internal side of noninactivating mutant channels expressed in oocytes and in transiently transfected Cos7 cells. These peptides produced a time-dependent block of macroscopic currents in a concentration-dependent manner. The rate and steady-state level of block produced by the peptides were consistent with what one would predict from the time course of fast inactivation of the corresponding variants. To investigate the importance of structural features in the ball for inactivation point mutations were made in the ShB peptide. The two negatively charged residues at positions 12 and 13 were neutralised (ShB:E12QD13Q) and the positive charges at positions 16,17,18 and 19 were also neutralised. ShB:E12Q,D13Q had a higher binding affinity than the wild-type ShB peptide whereas neutralising the positive charges caused a decrease in binding affinity, suggesting that the inactivation receptor has a negatively charged region with which the positive charges interact electrostatically.

SHAKER INACTIVATING PEPTIDE ALTERS MAXI K_{Ca} SINGLE CHANNEL GATING. L. Toro*, E. Stefani & R. Latorre*^f. Dept. Molec. Physiol. & Biophys, BCM, Houston, TX 77030, ^fDept. Biol. Univ. Chile, & CECS Santiago 9, Chile.

In shaker A-type K channels the segment defined by the first 20 aminoacids of the amino terminus has been recognized to be an essential structural component of the inactivation gate (the "ball" in the ball-and chain model) (Hoshi et al., Science 250:533, 1990). Given the great similarities among the ion conduction domain of different K channels, it was interesting to ask if the "ball" receptor was present in the inner mouth of Ca²⁺-activated K (K_{Ca}) channels as well. K_{Ca} channels from coronary smooth muscle incorporated into lipid bilayers were studied (270 pS in 250 KCl). Internally (10-100 μM) but not externally (80 μM) applied inactivating peptide dramatically altered the electrical behavior of K_{Ca} channels. The most salient features of the peptide effect were: 1) Induction of long-lived closed events. Their mean time was dose-dependent (1.5 s at 40 μM and 3.5 s at 80 μM, 20 mV) as well as the mean burst time (12 s at 40 μM and 5 s at 80 μM, 20 mV). 2) Reduction of the open probability during a burst (P_o) in a dose-dependent manner (P_o control = 0.9; P_o 40 μM peptide = 0.6; P_o 80 μM peptide = 0.3, at 20 mV). 3) Stabilization of a number of conductance substates (up to eight). 4) Internal TEA (30-60 mM) inhibited the peptide action in a competitive manner. These results suggest that the "ball" inactivating peptide is able to interact with the internal mouth of the maxi K_{Ca} channel in the same concentration range where it is able to functionally reconstitute the inactivation process in non-inactivating Shaker A-type channels. Authors thank Dr. R. Aldrich for the "ball" peptide. Supported by NIH, HD-25616 (E.S.), GM-35981 (R.L.) and Grant-in-Aid 900963 AHA-National Center (L.T.)

311.16

INDUCTION OF SUB-CONDUCTANCE STATES IN A RAT BRAIN CALCIUM-DEPENDENT POTASSIUM CHANNEL BY A "BALL" PEPTIDE DERIVED FROM THE SHAKER POTASSIUM CHANNEL. S. K. Chung*¹, W.N. Zagotta², R.W. Aldrich² and I.B. Levitan¹. ¹Dept. of Biochemistry and Center for Complex Systems, Brandeis University, Waltham, MA 02254 and ²Dept. of Molecular and Cellular Physiology, School of Medicine, Stanford University, Stanford, CA 94305.

The amino terminal 20 amino acid residues of the *Shaker* potassium channel from *Drosophila* interact with the open channel to cause inactivation. Application of a synthetic peptide comprising these 20 amino acids, termed the *Shaker* "ball", to the intracellular side of non-inactivating mutant channels restores inactivation. We tested the actions of the ball on another potassium channel, a noninactivating large conductance calcium-dependent potassium channel reconstituted into lipid bilayers from rat brain plasma membrane vesicles. Two effects were observed. The ball causes blocks of channel activity lasting several hundred msec. In addition the ball induces the appearance of multiple sub-conductance states, lasting 10 msec - 10 sec. This latter effect is not mimicked by a single amino acid mutant ball that also fails to restore inactivation in *Shaker*. Thus the *Shaker* ball binds to some site on the calcium-dependent potassium channel that mediates the appearance of sub-conductance states. This site resembles the ball receptor in *Shaker* because it binds native but not mutant ball. Supported by NS17910 to I.B.L.

POTASSIUM CHANNELS: PHYSIOLOGY AND REGULATION II

312.1

KINETICS AND VOLTAGE DEPENDENCE OF SODIUM-DEPENDENT POTASSIUM CHANNELS IN RAT OLFACTORY BULB NEURONS. T. M. Egan, J. Kupper* and I. B. Levitan. Dept. of Biochemistry and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Among the multiple classes of potassium channels are those whose gating is regulated by intracellular ions, including calcium and sodium. We have recorded the activity of sodium-activated potassium channels (K_{Na}) from olfactory bulb neurons in culture, and in *in vitro* slices. In inside-out membrane patches exposed to symmetrical 150 mM [K⁺]_i, K_{Na} has a mean E_{rev} of 0 mV, a mean conductance of 172 pS, and a linear current-voltage relationship over the V_m range of -100 to 0 mV. At positive V_m, single channel currents show inward rectification, the degree of which is determined by [Na⁺]_i. Channel gating is voltage-dependent, so that the channel is more likely to be in the open state at positive V_m. Because of this voltage-dependence, the K_{Na} channel may be more sensitive to [Na⁺]_i than has previously been suggested. The channel opens in bursts. Within a burst the channel alternates between the fully open state, multiple substates, and the fully closed state. Between bursts, the channel sometimes enters a very long-lived inactive state which can last for up to several minutes. These findings suggest that K_{Na} may be subject to modulation by intracellular factors yet to be identified. Supported by NS17910 to I.B.L.

312.2

A SODIUM-DEPENDENT POTASSIUM CURRENT IN SPINAL NEURONS OF THE *XENOPUS* EMBRYO. N. Dale. Department of Zoology, University of Bristol, Bristol, BS8 1UG, U.K.

The potassium currents of neurons acutely isolated from the spinal cord of the stage 37/38 *Xenopus* embryo have been studied using whole cell recordings. About half of the total outward current was blocked by substitution of extracellular Na⁺ with N-methyl-glucamine or lysine chloride. Using Li⁺ as a substitute for Na⁺ caused a lesser reduction in the outward current. The Na⁺-sensitive current activated in a voltage dependent manner and was sustained. Its reversal potential was close to E_K and depended on external K⁺, suggesting that the current was carried by K⁺. The amplitude of the Na⁺-dependent K⁺ current was progressively reduced as the neuron was depolarized to command potentials above E_{Na}. Activation of the Na⁺-dependent K⁺ current therefore requires the presence of internal Na⁺. While the neurons do not possess a sustained voltage-dependent Na⁺ current, they do have a steady state leakage current that is reduced by removal of external Na⁺. Presumably lowering external Na⁺ allows pumps to reduce the intracellular levels of Na⁺ adjacent to the membrane and hence activation of the Na⁺-sensitive current. The Na⁺-dependent K⁺ current possessed by *Xenopus* embryo spinal neurons appears to differ from those previously described in other vertebrate neurons which are transient, lack voltage sensitivity, and are not activated by Li⁺.

312.3

CHARACTERIZATION OF A DELAYED RECTIFIER POTASSIUM CURRENT IN MUSCLE CELLS ISOLATED FROM THE FLATWORM SCHISTOSOMA MANSONI. T.A. Day*, R.A. Pax and J.L. Bennett*. Departments of Zoology and Pharmacology & Toxicology, Michigan State University, East Lansing, MI, 48824.

Whole-cell voltage clamp techniques have been applied to individual dispersed muscle fibers of the parasite *Schistosoma mansoni* (Phylum Platyhelminthes). The predominant current activated upon depolarization of these fibers is a large outward K^+ flux. The current activates when the voltage is pulsed from a resting potential of -40 mV to > -15 mV, displays very slow inactivation, and is blocked by high extracellular concentrations of Ba^{2+} . In outside-out patches of membrane pulled from these muscles, the unitary conductance of the channels is 20-30 pS. On the basis of these characteristics this current is similar to delayed rectifier currents which are widespread in the animal kingdom. With the delayed rectifier current suppressed by extracellular Ba^{2+} , other voltage-gated currents also appear to be present.

312.5

K⁺ CHANNEL OPENERS INHIBIT VOLTAGE-ACTIVATED OUTWARD CURRENTS IN DORSAL ROOT GANGLION CELLS. D.G. Owen. Wyeth Research (UK) Ltd, Huntercombe Lane South, Taplow, BERKS, SL6 0PH, UK.

In addition to their established activity in a variety of peripheral tissues, K^+ channel openers (KCO), such as cromakalim, activate ATP-sensitive K^+ channels and reportedly can also enhance voltage-activated K^+ currents in central neurones (eg hippocampal cells). Accordingly, I have examined the effects of a number of KCOs, including the novel KCO, WAY-120491, on voltage-activated K^+ currents in rat sensory neurones.

Dorsal root ganglion cells were obtained from 1-3 day old rat pups and cultured according to established methods. Whole cell patch clamp recordings were made after 3-8 days in culture using a switching voltage clamp. In most cases cells were 'replated' 1-3 hours prior to use to reduce the extent of process outgrowth and thus facilitate adequate voltage clamping. Patch electrodes of 5-8M Ω were filled with (mM): 140 Kgluconate, 2MgCl₂, 5HEPES, 1.1EGTA/KOH, sucrose to 310mOsm, pH 7.2 and cells were bathed in (mM): 124NaCl, 2.5KCl, 4MgCl₂, 5HEPES, 10glucose, 1 μ M TTX, sucrose to 320mOsm, pH 7.4. KCOs, excepting somatostatin (SS), were dissolved in DMSO or EtOH (final concentration $\leq 0.1\%$) and applied via microperfusion system to individual cells. WAY-120491 (10 μ M) blocked about 20% of the total outward current activated by voltage steps from -100 mV to $+60$ mV. Proportionally more block was evident at the end of depolarizing voltage steps (1s) than at the start, with a marked acceleration of the decay. WAY-124903, a structural analogue, blocked total outward current to a similar degree (ca 20% at 10 μ M), showing some selectivity for non-inactivating current (30% block) over transient outward current (15% block). Cromakalim (10 μ M) blocked relatively less outward current but, like WAY-120491, accelerated the decay with little effect on peak current. Inhibition of non-inactivating current from -30 mV showed no such time-dependence, suggesting an open-channel type of block. SS which activates K_{ATP} channels in peripheral tissue also reduced outward current but only after relatively prolonged application (ca 4 min). Non-inactivating current was preferentially blocked.

312.7

A PARADOX CONCERNING BLOCKADE OF THE DELAYED RECTIFIER CHANNEL (I_K) BY CESIUM IONS. J.R. Clay and V. Kowrha. NIH, Bethesda, MD 20892

A comparison of the effects of Cs_1^+ with the effects of Cs_e^+ on I_K in squid axons reveals a paradox. Cs_e^+ blocks inward current in a voltage-dependent manner resulting in an N-shaped current-voltage (IV) curve. Blockade is complete at ~ -150 mV with 100 mM Cs_e^+ . A slight secondary increase in inward current occurs for $V < -220$ mV. The concentration dependence of Cs_e^+ block is consistent with a 2:1 stoichiometry, especially for $V < -100$ mV (Adelman and French, 1978: J Physiol 278:13). Blockade of outward current by Cs_1^+ is also voltage dependent (N-shaped IV). However, the block is not complete at any potential, even with 300 mM Cs_1^+ . A marked secondary increase in outward current occurs for $V > 150$ mV, which is blocked by TEA. Blockade of I_K by Cs_1^+ is consistent with a 1:1 stoichiometry. The electrical distance, s , of block with Cs_e^+ is ~ 0.9 , whereas $s \sim 0.5$ for Cs_1^+ . That is, Cs^+ can more readily pass through the channel from the inside than from the outside; 2 ions enter the channel from the outside, only 1 from the inside; and the blocker moves a considerable way through the electric field from either side. These results constitute a paradox.

312.4

GALANIN- AND BETHANECHOL-INDUCED POTASSIUM CURRENTS IN MUDPUPPY PARASYMPATHETIC NEURONS. L.A. Merriam and R.L. Parsons. Dept. of Anat. & Neuro., Univ. of Vermont Coll. Med., Burlington, VT 05405.

Galanin and bethanechol hyperpolarize parasympathetic postganglionic neurons in the mudpuppy cardiac ganglion by activating a membrane potassium conductance. In the present study, whole cell voltage clamp recordings of galanin- and bethanechol-induced currents have been compared in dissociated mudpuppy cardiac neurons maintained in a solution containing 12.5mM external potassium. In cells voltage clamped to -60 mV, brief galanin applications (0.5 to 1 sec) initiated an inward current which lasted for tens to hundreds of seconds. In contrast, similar duration applications of bethanechol initiated inward currents which were shorter with the duration determined by the duration of the agonist application. The time- and voltage-dependence of agonist-induced inward currents were determined using 300 msec hyperpolarizing voltage steps from a V_H of -40 mV. The shape of the I-V relationship was similar for the currents activated by either agonist. The reversal potential for the currents activated by either agonist was approx. -44 mV. The inward currents activated by either agonist were time dependent with the time course generally fit as the sum of two exponentials. In summary, both galanin and bethanechol activate a time-dependent potassium current which is kinetically different from the background membrane currents recorded during hyperpolarizing voltage clamp steps in the absence of agonist. Supported by NIH Grants NS-23978 and NS-25973.

312.6

ACTION POTENTIALS ACTIVATE AN INTERNODAL POTASSIUM CONDUCTANCE IN LIZARD MYELINATED AXONS. G.David*, J.N. Barrett and E.F. Barrett. Dept. of Physiology & Biophysics, Univ. of Miami Med. Sch., P.O. Box 016430, Miami, Fla. 33101.

Action potentials and afterpotentials in motor axons innervating the ceratohandibularis muscle of lizards (*Anolis sagrei*) were recorded with microelectrodes inserted into axons (intra-axonal) and/or under the myelin sheath (peri-internodal). The contribution of internodal K currents to potentials across the internodal axolemma was studied in normal bath [K], and in high peri-internodal [K]_o achieved by ionophoresis from peri-internodal microelectrodes.

Peri-internodal recordings exhibited a negligible (< 2 mV) resting potential but showed action potentials with peak amplitudes of up to 78 mV. High peri-internodal [K] (favoring K influx into the axon) resulted in: (1) a prolonged (hundreds of msec) negative afterpotential (PNP) recorded peri-internodally from the K-injected internode, (2) a simultaneous intra-axonal positive afterpotential accompanied by increased conductance of the internodal axolemma and (3) no significant changes in the axonal resting potential. PNPs could also be evoked by depolarizing the internodal axolemma in the presence of tetrodotoxin (10 μ M). PNPs were blocked by tetraethylammonium (TEA, 10 mM), but not by 3,4-diaminopyridine (DAP). In normal peri-internodal [K] (favoring K efflux from the axon), a brief positive afterpotential, sensitive to TEA but not to DAP, was recorded in the peri-internodal region. These results indicate that depolarization of the internodal axolemma by an action potential activates an internodal K conductance. The activation of this conductance limits the peak amplitude of the passive depolarizing afterpotential, and thereby helps to prevent progressive depolarization of the axon during high frequency activity.

312.8

NON-NEURONAL CELLS INFLUENCE THE EXPRESSION OF K CURRENTS ON CULTURED SCG NEURONS. S.McFarlane, E.Cooper. Dept. of Physiol., McGill Univ., Montr al, Qu . H3G 1Y6.

We have been investigating voltage-gated K currents on rat neonatal superior cervical ganglion (SCG) neurons to learn more about factors that influence K current expression. SCG neurons express 3 voltage-gated K currents: a non-inactivating current (IK); a rapidly inactivating A-current (IAf); and a slowly inactivating A-current (IAS). Using whole cell recording we have shown that the mean current densities change during post-natal development. On neurons (n=45) from day one animals (P1) IAf=27pA/pF, IAS=67pA/pF and IK=15pA/pF, whereas on P14 neurons (n=48) IAf increases to 64pA/pF, IAS decreases to 34pA/pF, and IK stays constant. In contrast, when P1 neurons develop in culture without other cell types, the mean current density of IK increases, while the densities of IAf and IAS decrease: by day 28, cultured neurons express IAS at low levels (9pA/pF, n=20), IK at higher levels (60pA/pF, n=20) and express no detectable IAf. These results suggest that some factor(s) required for the maintenance of A-current expression on SCG neurons is missing in culture. To test whether this factor is provided by the ganglionic non-neuronal cells, we grew SCG neurons for 4 weeks in the presence of ganglionic non-neuronal cells. In these conditions, SCG neurons express IAf (25.1pA/pF, n=40) and IAS (39.7pA/pF, n=41), and show no increase in IK (18.7pA/pF, n=41). These results show that a factor(s) provided by non-neuronal ganglionic cells is able to influence the expression of K currents. The nature of this factor is presently being investigated. THE SLOWLY ACTIVATING, VOLTAGE-DEPENDENT POTASSIUM CURRENT (I_{SK}) EXPRESSED IN XENOPUS OOCYTES IS REGULATED BY OSMOTIC PRESSURE. A. E. Busch, J. P. Adelman and R. A. North Vollum Institute, Oregon Health Sciences University, Portland, Oregon 97201

The potassium channel I_{SK} has been cloned from rat kidney, where it is expressed in the apical membrane of proximal tubule cells (Takumi et al., Science 242: 1042, 1988; Sugimoto et al., J. Membr. Biol. 113: 39, 1990). Kidney cells have been shown to regulate their volume in hypotonic shock by activation of potassium conductances (Uhl et al., Pfluegers Arch. 104: 223, 1988): therefore we studied the effects of changes in the osmolarity of the superfusion solution on I_{SK} expressed in Xenopus oocytes. Currents were evoked by depolarizing the oocyte from a holding potential of -80 mV, and measured by two-electrode voltage-clamp. A decrease in osmolarity from 220 mOsm to 160 mOsm caused an increase in I_{SK} : the current activated more rapidly and the threshold for current activation was shifted in a hyperpolarizing direction (to about -80 mV). The effects of hypotonic solution were mimicked by superfusion with the calcium ionophore A23187 (1 μ M). Injection of BAPTA (2.5 nmoles/oocyte) reduced I_{SK} and prevented the effect of hypotonic solutions. The results suggest that hypotonic shock leads to an increase of an intracellular calcium and that this in turn increases I_{SK} .

QX-222 BLOCKS A FAST TRANSIENT POTASSIUM CURRENT IN NEOCORTICAL NEURONS. M. Andreassen* and J.J. Hablitz. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL. 35294.

The quaternary derivatives of lidocaine, such as QX-222, block voltage-dependent sodium currents thereby inhibiting the generation of action potentials. Studies have indicated that these compounds may also reduce potassium currents. Since the fast transient potassium current, known as I_A , has many properties similar to the fast voltage-dependent sodium current, we examined the effect of QX-222 on I_A .

The experiments were performed on neocortical neurons maintained in dissociated cell culture for 5-10 days. Whole-cell patch clamp techniques were used for recording. I_A was pharmacologically isolated by using an extracellular saline containing 1 μ M TTX, 20 mM TEA and 200 μ M CdCl₂. QX-222 (1-2 mM) was added to the K-gluconate containing intracellular saline.

QX-222 reduced I_A in a dose-dependent manner; 2 mM QX-222 completely blocked I_A while 0.5 mM reduced it by 25-30%. Depending on the concentration of QX-222 used, a steady-state reduction was obtained within 1 to 2 minutes after the membrane was broken. Concentrations of QX-222 that only partially blocked I_A had no apparent effect on steady-state activation or inactivation kinetics. These results indicate that QX-222 has a direct blocking effect on the channels generating I_A (NS-18145)

312.13

PROPERTIES OF THE TRANSIENT OUTWARD POTASSIUM CURRENT IN GH₃ CELLS. B. Robertson Electrophysiology Lab, Wyeth Research, Taplow, Maidenhead SL6 0PH, U.K.

Transient outward currents (TOCs) are found in a wide variety of cell types and it is envisaged that TOCs may be an important therapeutic target, since blockers of this potassium current are proving useful in the treatment of cardiovascular and perhaps also CNS disorders. The TOC in the GH₃ cell line provides a convenient model for physiological and pharmacological study (Oxford & Wagoner (1989) *J. Physiol.* 410, 587).

TOCs were recorded using whole-cell voltage clamp techniques after precluding contaminating ionic conductances with blockers or by ion substitution. Experiments were performed at room temperature and drugs applied via a U tube rapid delivery system. TOC activates at potentials positive to -40mV and double-pulse protocol experiments show that steady-state half inactivation occurs at -40mV. The current activates more rapidly with increasing depolarization, and is best described by third power kinetics. Activation time constants are 3ms at -20mV, decreasing to 0.8ms at +100mV. The TOC typically inactivates with two exponentials, with mean τ 's of 35ms (\pm 1.7, s.e.m.) and 164ms (\pm 8.3, s.e.m.) at +60mV. Deactivation of the current followed a single exponential. The TOC in GH₃ cells is similar to that seen in freshly isolated pituitary terminals (Thorn et al. *J. Physiol.* 432 313)

TOC decay is slowed by extracellular application of N-bromoacetamide (100 μ M) and by including trypsin or papain in the internal solution. The current is blocked by 4-aminopyridine (1-5mM), but is unaffected by: toxin I (100nM), adenosine (1mM), pentobarbitone (100 μ M), baclofen (500 μ M), decanol (50 μ M) or ruthenium red (100 μ M). However, the TOC is inhibited by two compounds designed to treat cardiovascular disorders, albeit at very high concentrations. The antiarrhythmic tedisamil (50-200 μ M) reduces peak current only a little, but markedly accelerates TOC decay. Sparteine (5mM), a natural precursor of tedisamil, also inhibits. The novel antihypertensive WAY 120491 (10-100 μ M) reduces TOC, principally by accelerating decay. The related compound cromakalim has no effect on TOC at 200 μ M.

312.10

THE EFFECTS OF PROTEIN MODIFYING AGENTS ON THE TRANSIENT OUTWARD K⁺ CURRENT ($I_K(f)$) IN RAT PITUITARY MELANOTROPHS. J. Davidson*, T. Warren* and S.J. Kehl. Dept. of Physiology, University of British Columbia, Vancouver, B.C., V6T 1Z3

The $I_K(f)$ of melanotrophs is a voltage-gated K current which activates and inactivates rapidly. Since protein modifying agents have been shown selectively to remove inactivation both from a similar current in clonal pituitary cells and from Na channels in the squid axon, we examined the effects on $I_K(f)$ of internal or external applications of N-bromoacetamide (NBA), N-bromosuccinimide (NBS), chloramine-T, trypsin, papain and pronase. Whole-cell currents were recorded using conventional patch-clamp techniques. Internal trypsin (2 mg/ml), pronase (1 mg/ml), NBA (100 μ M) or NBS (100 μ M) did not alter $I_K(f)$. Internal chloramine-T (3.55 mM) or papain (1.25 mg/ml) caused a time-dependent decline of the peak amplitude of $I_K(f)$ but did not affect inactivation. External NBA (100 μ M) rapidly and irreversibly reduced the amplitude of $I_K(f)$ but did not change its kinetics.

Protein modifying agents have no effect on or eliminate the $I_K(f)$ in melanotrophs.

312.12

TWO TRANSIENT VOLTAGE ACTIVATED POTASSIUM CURRENTS IN CULTURED RAT HIPPOCAMPAL CELLS. E. Ficker, H. J. Luhmann, U. Heinemann. Department of Neurophysiology, Univ. of Cologne, 5000 Cologne 41, FRG.

Slowly inactivating K⁺ currents have been proposed to determine the firing properties of neurons in the time scale of seconds (Storm, Nature 336, 379-381, 1988). We used the whole cell version of the patch clamp technique to extend our understanding of the A-current and to study in more detail a slowly inactivating potassium current in cultured rat hippocampal cells.

The two components are distinguished on the basis of voltage sensitivity and kinetics. The fast transient current decayed monoexponentially with a time constant of about 10 ms. The slow transient current decayed with two time constants in the order of 500 ms and of 3.4 ms. The reversal potential of the slow component shifted by 54 mV for a tenfold change in extracellular potassium concentration. The inactivation curve showed half maximal inactivation at -61 mV. The threshold for activation was determined between -40 and -30 mV. For the fast transient current half maximal inactivation occurred at -81 mV, half maximal activation was reached at -19 mV. Studies on the removal of inactivation for the two currents revealed a time constant of 29 ms and of 107 ms for the fast and slow current.

Both currents were sensitive to 4AP. Most prominent was the ability of 4AP to speed up the inactivation process of both currents. TEA did not affect the fast transient current but reduced the slow transient in a dose dependent manner. In case of the slow transient also an acceleration in the time course of current decay by TEA could be observed. To our surprise, dendrotoxin applied in concentrations up to 600 nM was completely ineffective on both transient currents.

312.14

EFFECT OF QUININE ON 'BASELINE CURRENT' IN BOVINE CHROMAFFIN CELL MEMBRANES. M.I. Glavinovic and J.M. Trifaro. Department of Anaesthesia Research and Physiology McGill University, Montreal, P.Q., Canada H3G 1Y6 and Department of Pharmacology, University of Ottawa, Ottawa, Ont., Canada K1H 8M5.

Cellular membranes are known to contain ion pumps - the transport systems that extrude or accumulate ions against an electro-chemical gradient. The molecular mechanism of active ion transport appears to involve a sequence of elementary steps (binding, dissociation and translocation) which are stochastic in nature. The baseline current in patch-clamp experiments, in addition to a contribution from the seal, can have a large contribution, blocked by quinine, which was suggested to be due to transport system (Christensen & Zeuthen, *J. Physiol.*, 387, 34P, 1987). This is an attempt to determine whether this current is due to a transport mechanism or due to a very small channel.

Both mean values and the variances of 'baseline current' are reduced after addition of quinine (0.5-1.5 mM) to the solution bathing the internal membrane. Power spectra of quinine-inhibited currents are white at low and high frequencies with transition intervals that typically occur at \approx .5-1 kHz, as is expected for a transport mechanism or a pump (Lauger, *Eur. Biophys. J.*, 11, 117-128, 1984) but not for a channel. Supported by MRC (Canada).

312.15

OUTWARD CURRENTS IN HEART MOTOR NEURONS OF THE MEDICINAL LEECH. C.A. Opdyke & R.L. Calabrese. Dept. of Biology, Emory University, Atlanta GA 30322

Heart motor neurons exist as bilateral pairs in ganglia 3 through 18 of the nerve cord of the medicinal leech. These motor neurons which innervate the hearts directly are rhythmically inhibited by heart interneurons which comprise the motor pattern generator for the heartbeat.

Heart motor neurons were voltage clamped using switching single electrode techniques to examine outward currents. We have found evidence for three distinct outward currents in the heart motor neurons: a fast transient current (I_A), a slowly inactivating current (I_K), and a calcium dependent outward current ($I_{K(Ca)}$). I_A and I_K were separated by their voltage sensitivity in external saline containing 0mM Na⁺ and 0mM Ca²⁺ and 1.8mM Co²⁺, and are in the process of being kinetically characterized. Depolarizing voltage steps from a holding potential of -80mV elicited both I_A and I_K currents whereas depolarizing voltage steps from -40 mV activates I_K only. I_A is activated at potentials positive to -45mV, I_K at potentials above -30mV. Steady state inactivation of I_A varies with holding potential and is nearly complete at -40mV. When the external saline contained 1.8mM Ca²⁺ and no Co²⁺ depolarizing voltage steps revealed a large increase in outward current that is presumably contributed by a calcium sensitive K⁺ current. The calcium sensitive K⁺ current is almost completely blocked by 25mM external TEA⁺.

312.17

MODULATION OF CRAYFISH MOTONEURON EXCITABILITY AFTER A SINGLE ACTION POTENTIAL. M. Roux-Bruyelle, G. Czernasty and J. Bruner. Lab. Neurobiol. Cell., Faculté des Sciences, 80039-AMIENS CEDEX, Lab. Neurobiol. Cell. Moléc., C.N.R.S., 91198-GIF/YVETTE, CEDEX, FRANCE

In the abdominal motor giant soma of the crayfish *Procambarus clarkii* a single Ca²⁺-dependent action potential (AP) induced, for about 10 min, marked shortening of a subsequent AP. The present study aimed to determine the origin of such a long-lasting effect. Two microelectrode current or voltage clamp experiments were performed in modified crayfish saline containing 60 mM TEACl (substituted for NaCl), 1 mM 4-AP and 0.1 μM TTX. After a single AP the input resistance of the cell decreased from 0.6-0.8 MΩ to 0.1-0.2 MΩ and a hyperpolarization developed (about 10 mV, at a resting potential ≈ -72 mV). These effects became maximal 30 s to 1 min after an AP and recovered in 10-15 min. Similar changes were obtained after the membrane was clamped for 200 ms at 0 mV. Their magnitude and duration depended upon [Ca²⁺]_o. Calcium current block by Cd²⁺ (1 mM) or replacement of Ca²⁺ by Ba²⁺ suppressed both effects. In voltage clamp experiments similar voltage pulses produced an outward current which lasted 10-15 min and reversed at about -80 mV, suggesting K⁺ as a carrier. Such a long-lasting Ca²⁺-dependent outward current would be responsible for the observed decreased excitability.

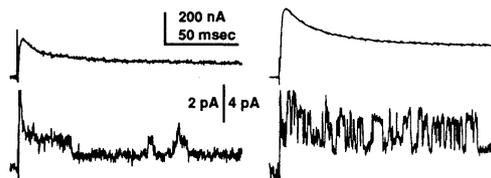

312.16

SIMULTANEOUS MACROSCOPIC AND SINGLE-CHANNEL CURRENTS IN LOBSTER STOMATOGASTRIC NEURONS.

B.R. Jones, M.C. Bieda* and D.K. Hartline. Békésy Laboratory of Neurobiology, University of Hawaii, Honolulu, Hawaii 96822

We used simultaneous two-microelectrode voltage clamp and cell-attached patch clamp to study the ion channels underlying macroscopic currents in intact, enzyme-cleaned neurons from the lobster, *Homarus americanus* (21°C). Intact ganglia were used for all experiments. Somata impaled with 3 M KCl-filled microelectrodes (3-15 MΩ) exhibited normal resting potentials (ca. -50 mV), action potentials, and macroscopic currents after enzyme treatment. Patch pipettes (2-10 MΩ) were filled with *Homarus* saline (seal resistance 10-40 GΩ).

Two types of channels were commonly observed. A low conductance channel (~7 pS), having a roughly linear I(V) relation, exhibited voltage-dependence characteristic of the fast, transient K⁺ current (I_A , left fig.). A larger channel (~30 pS), with an outwardly rectifying I(V) relation, showed a current reversal at -65 mV. In some cells this channel exhibited frequent spontaneous openings at rest (-50 mV). Preliminary evidence suggests that this channel may be associated with the transient, Ca²⁺-dependent outward current that is activated by depolarization in these neurons (I_1 , right fig.). (Figs: V_{hold} = -50 mV, V_{cmd} = 0 mV, I_A = difference current with and without V_{cmd} = -100 mV). Supported by NSF BNS-8920698.

ACETYLCHOLINE: RELEASE

313.1

A Novel Technique For the Determination of Acetylcholine Release by Microdialysis in Electrically Stimulated Rat Striatum. U. Kischka*, S.A. Farber, J.K. Blusztajn* & R. J. Wurtman. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139, *Dept. of Pathology, Boston Univ. School of Medicine Boston, MA 02118.

We have established a method for assessing the electrically-stimulated release of acetylcholine (ACh) from anesthetized rat striatal neurons in vivo. A teflon-coated tungsten wire (50 μm) is attached to a standard microdialysis probe. This hybrid probe is used to stimulate electrically the neurons in the direct vicinity of the dialysis membrane. Maximal release of ACh during a 10 minute stimulation period (a dialysis flow rate of 2.0 ul/min) was found to be 600% (n=6, p<.01) greater than basal levels. Maximal stimulation (200 μA; 20-60 Hz; 0.5 msec duration) was often followed by a prolonged increase in basal ACh release, as well as an inhibition of subsequent, electrically-evoked release. By characterizing the electrical responses of these neurons we identified stimulation parameters (150 μA; 20 Hz; 0.2 msec duration) which induced a 158% increase (n=5, p<.01) in ACh release while minimally affecting basal levels and subsequent responsiveness to further stimulation. At pulse durations less than 0.1 msec we were unable to evoke release reliably, even using higher currents and stimulation frequencies. Supported by NIMH grant MH-28783.

313.2

CHOLINE ENHANCES SCOPOLAMINE-INDUCED RELEASE OF ACETYLCHOLINE IN THE DORSAL HIPPOCAMPUS OF CONSCIOUS FREELY MOVING RATS. D.A. Jackson, U. Kischka* and R.J. Wurtman. Dept. of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139

Peripheral administration of choline has been shown to elevate hippocampal tissue levels of choline and acetylcholine in the rat (Cohen and Wurtman, 1976). In addition, recent findings have suggested that increasing available free choline may enhance brain acetylcholine release (Wecker, 1989). In this study we used *in vivo* microdialysis to investigate whether peripheral administration of choline can enhance basal levels or evoked release of acetylcholine in the dorsal hippocampus of awake freely moving rats. Microdialysis probes were chronically implanted in the dorsal hippocampus and perfused with artificial CSF containing 10 μM of neostigmine. An intraperitoneal catheter was also chronically implanted for administration of choline and other drugs. The animals were allowed to recover for twenty-four hours prior to experimentation. Within 15 minutes of choline administration, choline dialysate levels were significantly elevated. However, there was no effect on basal acetylcholine levels. Administration of the muscarinic antagonist scopolamine (0.5 mg/kg, ip.) 60 minutes after vehicle injection caused a 5-8 fold elevation in acetylcholine release at thirty minutes post-injection. In animals pretreated with choline, the effect of scopolamine on acetylcholine release was further enhanced by 3-12 fold at thirty minutes post-injection. These results suggest that increasing free choline availability can enhance scopolamine-induced acetylcholine release in the dorsal hippocampus of conscious freely moving rats. (Supported by NIMH grant MH-28783)

313.3

MUSCARINIC M2 NEGATIVE AUTORECEPTORS REGULATE ACETYLCHOLINE RELEASE IN CORTEX AND HIPPOCAMPUS: A MICRODIALYSIS STUDY IN FREELY MOVING RATS. J.W. Richard, A. Wilson, R. Quirion, Douglas Hospital Research Centre and Department of Psychiatry, McGill University, 6875 Blvd LaSalle, Verdun Quebec, Canada, H4H 9R3.

We have previously reported that atropine markedly stimulated the in vivo release of acetylcholine (ACh) in the rat cortex. In order to further investigate the pharmacological nature of the muscarinic autoreceptors involved, we studied the effects of M1 and M2 receptor antagonists on cortical and hippocampal ACh release using in vivo dialysis in behaving animals. 2-3 days after stereotaxic implantation of dialysis probes, male Sprague Dawley rats were dialyzed using Ungerstedt ringer buffer containing physostigmine and various muscarinic blockers. ACh levels were determined by GC/MS (PCI). In both cases, putatively selective M2 receptor antagonists such as AF-DX 116, AF-DX 384 and AQ-RA 741 markedly stimulated, in a dose dependent manner, ACh release. At 40 μ M, AF-DX 384 and AQ-RA 741 were especially potent, increasing cortical release by 7 and 7.5 fold over basal level. Pirenzepine, a purported M1 antagonist, was less potent at equimolar concentrations. Interestingly, the combination with nicotine (5 mg/kg s.c.) further increased ACh release induced by M2 blockers (10 times over baseline). Thus, negative muscarinic autoreceptors are most likely of the M2 sub-type in rat cortex and hippocampus. Moreover, the simultaneous blockade of these receptors and the activation of nicotinic sites synergically act to greatly increase ACh release. Supported by the MRCC.

313.5

SYSTEMIC CYSTEAMINE ADMINISTRATION INCREASES 3 H-ACETYLCHOLINE RELEASE IN RAT STRIATUM. M.A. Musgrave*, R.J. Boegman, J.V. Milligan, Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Cysteamine (2-mercaptoethylamine) a natural product, constitutes part of the pantothenic acid moiety of Acetyl CoA. Studies utilizing radioimmunoassay and immunohistochemical techniques have shown that systemic administration of cysteamine selectively depletes somatostatin-like immunoreactivity in several brain regions including the striatum and cortex. The consequence of this loss in terms of neurotransmitter release has not been investigated. The purpose of this study was to determine the effect of cysteamine administration on 3 H-Acetylcholine (3 H-ACh) release stimulated by 25mM potassium (K^+). Rats received a subcutaneous injection of cysteamine (480 or 806 or 1050 mg/kg) four hours prior to sacrifice. In the cortex, no significant difference in K^+ stimulated 3 H-ACh release was observed between control and cysteamine treated rats at any dosage. However, in the striatum the highest dose of cysteamine resulted in a significant increase in K^+ stimulated 3 H-ACh release of 40% above control levels. Immunohistochemistry was used to verify cysteamine induced changes in somatostatin-like reactivity. The results of the study suggest a differential neuromodulatory effect of cysteamine in cortical versus striatal cholinergic neurons. (Supported by the Medical Research Council of Canada).

313.7

PERTUSSIS TOXIN-SENSITIVE G-PROTEIN MEDIATES GALANIN'S INHIBITION OF SCOPOLAMINE EVOKED ACETYLCHOLINE RELEASE IN VIVO AND CARBACHOL STIMULATED PHOSPHOINOSITIDE TURNOVER IN RAT VENTRAL HIPPOCAMPUS. S. Consolo, R. Bertorelli*, P. Girotti*, C. La Porta*, T. Bartfai*, M. Parenti*, M. Zambelli*; Istituto "Mario Negri", Milan, Italy; *Dept. of Pharmacology, Univ. of Milan, Italy; †Dept. Biochemistry, Arrhenius Labs, Stockholm, Sweden.

The effects of intracerebroventricular (i.c.v.) injections of pertussis toxin were investigated on the inhibitory action of the 29-amino-acid peptide galanin on acetylcholine (ACh) release and phosphoinositide breakdown stimulated by muscarinic agents in rat ventral hippocampus. Pertussis toxin (0.6 μ g, i.c.v., 96h) counteracted the *in vivo* inhibitory effect of galanin (3.1 nmol) on phosphoinositide breakdown stimulated by carbachol without altering the stimulatory action of the cholinergic agonist on signal transduction, in miniprisms from rat ventral hippocampus. Pertussis toxin also abolished the *in vivo* effect of galanin on scopolamine-stimulated ACh release *in vivo* but did not affect basal ACh release. The results indicate that pertussis toxin-sensitive G-protein(s) mediates the galanin receptor regulation of pre- and postsynaptic cholinergic functions in the ventral hippocampus.

313.4

CONTROL OF THE BASAL FOREBRAIN CHOLINERGIC SYSTEM: A MICRODIALYSIS STUDY. Gary L. Wenk, Cheryl A. Harrington, and Paul E. Gold. Div. of Neural Systems, Memory & Aging, Univ. of AZ, Tucson, AZ 85724, and Dept. of Psychology, Univ. of Virginia, Charlottesville, VA 22903.

The basal forebrain cholinergic system (BFCS), includes the medial septal area and nucleus basalis magnocellularis, which project to the hippocampus and cortex, respectively. Drugs that alter the function of the BFCS also alter performance in tasks that require learning and memory. We investigated the neurochemical effects of pharmacological manipulation of BFCS activity. Various drugs and putative neurotransmitters were administered to rats. Extracellular acetylcholine (ACh) in hippocampus and cortex was collected by microdialysis. ACh was analyzed by HPLC and electrochemistry. Among those drugs examined, scopolamine and glucose increased ACh release, enkephalin and barbiturates decreased ACh release and neurotensin had no significant effect. The pattern of results fits other, less direct, findings regarding control of ACh release by drugs and neuromodulators. Supported by the NSF (BNS 89-14941 & 90-12239).

313.6

EFFECTS OF DOPAMINE AGONISTS AND ANTAGONISTS ON CAUDATE ACETYLCHOLINE: BEHAVIORAL CORRELATES FOLLOWING AMPHETAMINE. S.M. Florin, D.S. Segal, R. Kuczenski. Dept. of Psychiatry, Univ. of California, San Diego, La Jolla, CA 92093-0603.

In vivo dialysis in rats was used to study the effects of systemically administered dopamine (DA) agonists and antagonists on behavior and extracellular acetylcholine (ACh) concentration in the caudate. Measurable ACh was obtained by intracaudate infusion of buffer (147mM NaCl, 1.2mM CaCl₂, 0.9mM MgCl₂, 4.0mM KCl) containing 0.25 μ M neostigmine bromide. Apomorphine (1.0 mg/kg) decreased, while haloperidol (1.0 mg/kg) increased ACh concentrations. A behaviorally transitional dose (1.75 mg/kg) of amphetamine (AMPH) had no significant effect on ACh. However, concentrations of the transmitter were positively correlated with the intensity of stereotyped behaviors. A higher dose of AMPH (5.0 mg/kg) significantly increased ACh concentrations. The divergent responses to the various DA agents suggest the absence of a simple relationship between ACh concentration and behavior. Furthermore, these results suggest other mechanisms in addition to DA receptor activation are involved in AMPH-induced effects on ACh. (Supported by DA04157 and DA01568).

313.8

INFUSION OF FENFLURAMINE INTO THE HIPPOCAMPUS OF RATS DECREASES POTASSIUM STIMULATED RELEASE OF EXTRACELLULAR ACETYLCHOLINE AS MEASURED BY IN VIVO MICRODIALYSIS. P. A. Shea, S. T. Ahlers, and A. C. Santucci¹. Naval Medical Research Institute, Bethesda, MD 20889 and ²Manhattanville College, Purchase, NY 10577.

In vitro experiments have shown that serotonin (5-HT) will inhibit potassium (K^+) evoked release of acetylcholine (ACh) in hippocampal tissue. In the present study dl-fenfluramine was used to examine the effects of serotonin release on both basal and K^+ stimulated extracellular levels of ACh and Choline (Ch) in the hippocampus using in vivo microdialysis. Male Long-Evans rats were implanted with a guide cannula into the dentate gyrus region of the hippocampus (AP: -5.0; L: + 2.6; V: - 2.0) one week prior to the beginning of the experiment. Dialysis was performed on awake, unrestrained rats using 2mm Carnegie Medicine microdialysis probes. The dialysis probe was perfused with artificial CSF at a rate of 2.6 μ l/min; the esterase inhibitor neostigmine (10 μ M) was used in the perfusion medium in order to obtain measurable baseline levels of ACh. When 40mM of fenfluramine was infused through the microdialysis probe slight increases in the basal levels of extracellular ACh and Ch were observed. Infusion of 60mM K^+ without fenfluramine produced a 400% increase in extracellular ACh and virtually no change in Ch levels. When fenfluramine was infused a substantial decrease in K^+ elicited extracellular ACh release was observed. These results are consistent with a neuromodulatory role of serotonin on ACh release in the hippocampus.

313.9

EFFECTS OF FEEDING, DRINKING AND LEARNED TASTE AVERSION ON ACETYLCHOLINE RELEASE IN THE NUCLEUS ACCUMBENS OF FREELY-MOVING RATS. G. P. Mark, P. Rada*, J. B. Weinberg*, E. Pothos & B. G. Hoebel. Dept. of Psychology, Princeton Univ., Princeton, NJ 08544.

Microdialysis with a neostigmine Ringer (0.5 μ M) was used to monitor extracellular acetylcholine (ACh) in the nucleus accumbens (NAC), striatum (STR) and hippocampus in 30 min intervals before, during and after free-feeding in 20 hr food-deprived rats. The effects on ACh in the NAC and STR were also observed in response to water intake in water-deprived animals. Feeding caused a 38% increase in extracellular ACh in the NAC ($P < .05$), 18% in the STR (n.s.), and no change in the hippocampus. Drinking caused statistically reliable 18-20% increases in both the NAC and STR ($P < .05$). To determine if ACh was released in the accumbens to promote feeding in response to deprivation or inhibit it in response to satiety, two additional experiments were performed. First, neostigmine (1mM) bilaterally infused into the NAC via reverse dialysis caused a reduction in food intake in food-deprived rats. Second, the conditioned taste aversion (CTA) paradigm was used to develop an aversion to a previously appetitive taste (2.5 mM saccharin). Intraoral infusions of the aversive taste stimulus resulted in a 40% increase in extracellular ACh. These results suggest a site specific increase in ACh release during feeding that may be related to the inhibition of food intake.

Supported by USPHS grant DA-03597 and Eli Lilly Inc.

313.11

IN VIVO CHARACTERIZATION OF THE EFFECT OF AMPHETAMINE ON ACETYLCHOLINE RELEASE IN THE FRONTAL CORTEX. I. DAY and H.C. FIBIGER. Div. of Neurological Sciences, Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C. V6T 1Z3

Basal forebrain cholinergic neurons project diffusely to the cortex and have been proposed to be part of the reticular activating system. The present experiments sought to characterize the effects of the psychomotor stimulant *d*-amphetamine (AMPH) on ACh release in the frontal cortex using *in vivo* brain microdialysis. AMPH (2mg/kg) increased ACh release in the frontal cortex of rats to approximately 280% of baseline values. Local application of AMPH (10^{-5} M) in the frontal cortex did not affect ACh release; AMPH does not therefore appear to produce this effect locally in the cortex. The nonselective dopamine receptor agonist apomorphine (1mg/kg) increased dialysate concentrations of ACh to 220%. This suggests that AMPH's effect on cortical ACh release may be dopaminergically mediated. When given alone, the D_1 antagonist SCH23390 (0.3mg/kg) did not affect cortical ACh release. However, it completely blocked AMPH-induced increases in both cortical ACh release and locomotor activity. The D_2 antagonist haloperidol (0.15mg/kg) also did not itself affect cortical ACh. This neuroleptic only partially attenuated the effect of AMPH on cortical ACh (to 60% over baseline) while it completely blocked the drug's locomotor stimulant effect. These results suggest that in the awake, freely moving animal both D_1 and D_2 dopamine receptors mediate AMPH-induced increases in frontal cortical ACh release.

313.13

EVOKED EFFLUX OF ENDOGENOUS ACETYLCHOLINE FROM RAT BRAIN SLICES: EFFECT OF INTERLEUKIN-2. D. Seto, U. K. Hanisch*, J. G. Chabot and R. Quirion. Douglas Hospital Research Centre, Departments of Psychiatry and Pharmacology, McGill University, Montreal, Quebec H4H 1R3 Canada.

It was shown earlier by our group that interleukin-2 (IL-2, 1-100 nM) inhibits the high- K^+ (25mM) evoked efflux of endogenous acetylcholine (ACh) using a model of static incubation. This effect was more pronounced in the rat hippocampus than in the cortex or striatum. Here we present data obtained in a time-course study using a model of superfusion of brain slices. Hippocampal slices were superfused for 60 minutes in normal Krebs buffer (NKB), followed by a first stimulation (S_1) with high- K^+ Krebs (25mM) buffer (HKB) for 30 minutes, another 20 to 30 minutes of NKB, a second stimulation (S_2) with HKB for 30 minutes, and finally, by a 20- to 30-minute exposure to NKB. IL-2 (1-100nM) was present during either S_1 or S_2 in experimental groups and the effects were compared to the response of controls untreated with IL-2. The superfusate was collected over the entire duration and analysed for ACh using a radioenzymatic assay. Results suggest that IL-2 present during S_2 reduced the evoked ACh efflux similarly as described for static incubation. Moreover, inhibition of evoked ACh efflux was observed not only during S_1 , but also during S_2 in the group that have undergone IL-2 exposure during S_1 , suggesting a long-lasting effect of IL-2 in this model. ACETYLCHOLINE RELEASE IN THE NUCLEUS ACCUMBENS IS CORRELATED WITH OPIATE WITHDRAWAL SYMPTOMS. P. Rada*, E. Pothos, G. P. Mark & B. G. Hoebel. Department of Psychology, Princeton Univ., Princeton NJ 08544-1010.

Microdialysis with a neostigmine Ringer (0.5 μ M) was used to measure changes in extracellular ACh in the nucleus accumbens (NAC) of freely moving rats during acute and chronic morphine treatment, and following naloxone-precipitated withdrawal with and without clonidine treatment. Basal recovery of ACh was not affected by chronic morphine treatment. Acute morphine (20 mg/kg, i.p.) caused a decrease in extracellular ACh ($F(6,42) = 7.02$; $p < 0.001$) which was not apparent after 7 days of exposure to this opiate. The effect of naloxone (20 mg/kg, i.p.) was identical to that of saline in the non-dependent state but naloxone caused an exaggerated increase in ACh levels after morphine dependence had been established ($F(6,48) = 2.984$; $p < 0.02$). The increase in ACh following naloxone-precipitated withdrawal was eliminated by pretreatment with clonidine (200 μ g/kg, i.p.). To study the possibility that the changes in ACh levels were due to general activity or arousal, a different group of rats received cocaine (20 mg/kg, i.p.). After the administration of this drug, accumbens ACh decreased 28% ($F(6,66) = 3.752$, $p < .005$). These results suggest involvement of the NAC cholinergic system in the aversive aspects of opiate withdrawal and therefore an important role in opiate addiction.

EFFECTS OF DELTA-9-TETRAHYDROCANNABINOL ON ACETYLCHOLINE LEVELS IN THE PRIMATE HIPPOCAMPUS: AN IN VIVO MICRODIALYSIS STUDY. H. Ogura*, C. Chavoix, and T. Aigner. Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892.

Delta-9-tetrahydrocannabinol (THC) is known to impair memory in monkeys and humans. One possible mechanism is that THC may affect acetylcholine (ACh), which is known to play a critical role in mnemonic processes. In vivo microdialysis was used to study the effects of THC on ACh in the rhesus monkey hippocampus, a structure rich in cholinergic innervation and thought to contribute to certain forms of memory. Magnetic resonance imaging was used to determine stereotactic coordinates for the target sites in the hippocampus. The monkeys (n=4) were anesthetized with isoflurane and 1-3 probes were then inserted into the dentate gyrus and perfused with Ringer's solution containing 10 μ M neostigmine at a flow rate of 1 μ l/min. Samples were collected every 15 min. ACh levels were measured by HPLC using isopropylhomocholine as an internal standard (detection limit: 100 fmol). THC (4, 6, & 8 mg/kg, i.m.) initially produced a significant rise (as much as 243%) in the extracellular ACh levels, with a peak effect 15-30 min after injection, which returned to baseline levels within 60 min. At that time, a second administration of the same dose had little or no effect on levels of ACh, suggesting that some form of acute tolerance had occurred.

Although the relationship of these findings to the THC-induced memory impairment remains to be determined, the microdialysis technique used here shows promise for studying compounds that affect cholinergic transmission in primates.

AMINO ALCOHOLS MODULATE THE RELEASE OF NEWLY SYNTHESIZED ACETYLCHOLINE IN RAT HIPPOCAMPAL SLICES. J.R. Bostwick, J. Surr and S.H. Appel. Dept. Neurology, Baylor Col. Med., Houston, TX 77030

A search for endogenous brain trophic factors which influence *in vitro* cholinergic development led to the discovery that phosphoethanolamine and ethanolamine enhance acetylcholine formation. Since the function of a cholinergic neuron is predicated on its ability to release ACh, we measured the effects of these and 36 other amino alcohols on the release of newly synthesized ACh in hippocampal slices. Ten compounds were found to significantly increase ACh release. A short (20 minute) exposure to the compounds followed by a wash and incubation with 3H -choline resulted in an effect which persisted for at least 3 hours. This acute effect was not due to enhanced synthesis because the total ACh content, amount of 3H -ACh formed or the specific activity of the total 3H -ACh pool were not increased. To further confirm this finding, slices were incubated in 3H -choline and allowed to synthesize ACh prior to any treatment. We measured 3H -ACh subsequently released during brief depolarizations both before (S_1) and during (S_2) perfusion with test compounds. Active amino alcohols increased the ratio of the fractional ACh released (S_2/S_1). The action appeared to be unique to hippocampal cholinergic nerve terminals because amino alcohols did not modulate evoked release of ACh from cortical or striatal slices, dopamine from striatal slices or norepinephrine from hippocampal slices. Bay K 8644, a dihydropyridine calcium L-channel agonist, exhibited a release profile identical to amino alcohols. Bay K 8644 decreased the EC_{50} of amino alcohols without changing the maximal response, indicating that their actions converge through the same mechanism. Diltiazem, a benzothiazepine L-channel antagonist, blocked the amino alcohol induced effect whereas nifedipine, a dihydropyridine L-channel antagonist, did not. Thus, the modulatory action of amino alcohols appears to be mediated by a change in the mechanism which underlies the recruitment of ACh for release in the hippocampus and may involve an elevation of intra-terminal calcium concentrations through a specific activation of presynaptic L-channels. THE HEAT-SHOCK RESPONSE PROTECTS NEURONS FROM Ca^{++} -MEDIATED GLUTAMATE TOXICITY IN VITRO. W.J. Koroshetz, G. Rordorf, J.V. Bonventre. Stroke Res. Ctr. Massachusetts Gen Hospital, Boston Ma. 02114.

Most cells synthesize a specific array of proteins after various stresses; heat stress has been especially well studied. In many cells this "heat-shock response" improves cellular tolerance to repeated stress. Expression of "heat-shock proteins" (HSPs) occurs in brain after ischemic or severe epileptic insults though a functional role of brain expression has not been shown. We demonstrate that the heat shock response can be induced by heating neuronal/glial cultures of rat cortex to 42.2 °C for 20 minutes. This heat protocol increased the expression of mRNA for the 72kD HSP and increased the synthesis of proteins of approximately 72 and 83 kD, the approximate m.w.'s of the most highly conserved HSPs. Though less dense, these protein bands were present in non-heated cultures. However their density was much decreased by pretreating with glutamate antagonists.

Cultures heated to induce the heat-shock response demonstrated increased neuronal survival after exposure to toxic levels of glutamate in media with low $[Cl^-]$, a model of Ca^{++} dependent excitotoxicity. Consistent with a heat-induced expression of HSPs, this protective effect occurred only with a delay after the heating and was blocked by inhibitors of RNA and protein synthesis. The protective effect of heat-shock lasted 24 but not 48 hours. It was not the result of heat-induced glutamate release because heating in the presence of glutamate antagonist still conferred protection. These data indicate that glutamatergic processes induce HSP synthesis and that the heat-shock response protects neurons from Ca^{++} mediated excitotoxicity. HSPs may play a similar protective role in brain after ischemia or status epilepticus.

OPENING OF NMDA-GATED IONIC CHANNELS STIMULATES cGMP FORMATION IN CA1 MINISLICES. K.L. Panizzon, R.A. Wallis, E. Csizsar* and C.G. Wasterlain. Dept. of Neurology, Sepulveda VAMC and UCLA Sch. of Medicine, Sepulveda, CA 91343.

Stimulation of second messengers and protein kinases plays an important role in the brain's adaptive responses to excitotoxic injuries encountered in seizures, ischemia, trauma and hypoglycemia. We examined the stimulation of cyclic GMP and cAMP formation, assayed by radioimmunoassay, by NMDA in superfused CA1 hippocampal minislices, in which CA3 and dentate gyrus were trimmed. Exposure to NMDA caused rapid, dose-dependent CA1 injury (60 min. recovery after 8 min. at 20 μ M = 0%). 20 μ M NMDA raised cGMP concentration 2-fold after 3 min., 3-fold after 5 min. and nearly 4-fold after 10 min., without altering cAMP concentrations. However, 5 μ M NMDA (8 min.) was not toxic but raised cGMP concentration by 53%. Both the cGMP increase and the neuronal injury induced by 8 min. exposure to 20 μ M NMDA were completely blocked by 32 μ M MK-801. These data suggest that the cGMP response to NMDA is mediated through opening of receptor-gated ionic channels and may play a role in neuronal injury.

FAILURE OF A PROTEIN SYNTHESIS INHIBITOR TO MODIFY GLUTAMATE RECEPTOR MEDIATED NEUROTOXICITY IN VIVO. C. Leppin*, F. Finiels-Marlier*, J.N. Crawley, P. Montpied and S.M. Paul. NSB, NIMH, Beth., MD 20892.

It has recently been reported that the protein synthesis inhibitor anisomycin administered before and after experimentally-induced CNS ischemia reduces the development of delayed neuronal death (DND) in hippocampal (CA1) neurons (Neurosci. Lett. 120:117, 1990). Given the postulated role of excitatory amino acids (EAA's) in mediating DND, we tested whether anisomycin, could modify DND induced by unilateral intra-caudate administration of excitotoxins. Neuronal survival was assessed 7-12 days later by comparing glutamatic acid decarboxylase activity in the ipsilateral vs. contralateral caudate. Excitotoxic lesions were induced by N-methyl-D-aspartate (NMDA; 100, 150, 200 nmol), α -amino-3-hydroxy-5-methylisoxasole-4-propionate (AMPA; 50 nmol) or kainate (5 nmol). Anisomycin (50 mg/kg i.p.) was given 1-2 hours before as well as 12 and 36 hrs after EEA administration. Intra-caudate injection of NMDA, AMPA and kainate resulted in a marked reduction in GAD activity. Anisomycin administration did not alter DND following any of the three excitotoxins although there was a trend ($t[11] = 2.01$; $p < 0.07$) towards a reduction in neurotoxicity induced by AMPA. These data should be interpreted cautiously, given the limited number of AMPA-treated animals. It appears that the synthesis of a "killer protein(s)" does not underlie neurotoxicity induced by NMDA or kainate acid.

KAINIC ACID INJECTIONS INTO VENTROBASAL THALAMUS INDUCE THE EXPRESSION OF HEAT SHOCK PROTEIN IN THE CORTEX AND AMYGDALA OF THE RAT. M.F. Gonzalez, and E. Wron. Department of Psychology, UCSD, La Jolla, CA 92093

Previous work has shown that systemic injections of kainic acid induce the expression of heat shock proteins of a 72 kD molecular weight (HSP72) in many structures of the rat's brain. In the present work the expression of HSP72-like immunoreactivity was examined following intrathalamic injections of 0.1 and 0.2 μ g of KA. Sprague-Dawley rats were anesthetized and injections were aimed to the center of either the mediodorsal (MD) or the ventrobasal (VB) nuclear complex. Three days later the rats were sacrificed and their brains immunocytochemically reacted for the expression of HSP72 using commercially available HSP72 antibody (Amersham) and an ABC reagent kit (Vector Lab). Subjects injected in VB exhibited necrosis of the ipsilateral piriform cortex and basolateral amygdaloid complex. In the contralateral side, HSP72 positive neurons, mostly of a pyramidal type, were present in layers III, V and VI of perirhinal and parietal cortex and in the upper layers of hindlimb sensorimotor cortex. In the ipsilateral side, HSP72 positive neurons were present layer III of the parietal cortex above the ablated piriform cortex. The expression of HSP72 was more intense using the higher dose of kainic acid, but the regions affected were similar. Following kainic acid injections into the MD complex, many HSP72 positive non-pyramidal neurons were present in the deeper layers of parietal cortex, but the overall expression of HSP72 was less intense. These results suggest that thalamic nuclei participate in the induction of HSP72 following systemic injections of kainic acid, and that the level of receptors sensitive to the excitotoxin in different areas of thalamus influence the expression of the protein in distant brain sites.

GLUTAMATE-INDUCED EXCITOTOXICITY RESULTS IN DECREASED CAM KINASE II ACTIVITY IN CULTURED RAT CORTICAL NEURONS. S.B. Churn, S. Sombatii, W.C. Taft, *A.L. Willey and R.J. DeLorenzo. Department of Neurology, Medical College of Virginia, Richmond, VA 23298.

Exposure of neurons to excitotoxic levels of Glutamate results in extensive delayed neuronal cell death, 24 hr. later. The delayed cell death is thought to be a calcium dependent phenomenon (Choi et al. (1987) J. Neurosci. 7:369), however, the tertiary mechanisms whereby the glutamate-induced calcium increase causes delayed neuronal death are not understood. We utilized primary cortical neuronal culture to study the effects of glutamate toxicity on CaM kinase II activity. Cortical cells cultured for 14 days from embryonic (E15) rats were exposed to 500 μ M Glutamate for 10 min. Following 60 min recovery, the cells were harvested and studied for CaM kinase II activity under standard conditions (Goldenberg et al. (1983) J. Biol. Chem. 258:12632). The results show that glutamate exposure results in greater than 50% inhibition of CaM kinase II activity. The decrease in CaM kinase II activity occurred at a time prior to extensive cell loss and was not reversible with phosphatases shown to be active towards CaM kinase II auto-phosphorylation. In addition, inclusion of the NMDA antagonist MK-801 (20 μ M) completely protected both CaM kinase II activity and neurons from the effects of 500 μ M glutamate exposure, suggesting that the inhibition of CaM kinase II activity is due to activation of NMDA channels. The results are consistent with the hypothesis that CaM kinase II may be involved in the glutamate-induced neuronal excitotoxicity.

GLUTAMATE NEUROTOXICITY IS MEDIATED BY NITRIC OXIDE. V.L. Dawson, T.M. Dawson#, E.D. London, D.S. Bredt#, and S.H. Snyder#. *Neuropharmacology Lab., NIDA/ARC, Balto., MD 21224, #Dept. Neurosci., Pharmacol. and Mol. Sci., and Psychiatry, Johns Hopkins Med. Sch., Balto., MD 21205.

Several biological actions are mediated by nitric oxide (NO) including relaxation of blood vessels, formation of cGMP by glutamate receptor activation in cerebellar slices, and cytotoxicity produced by activated macrophages. Nitric oxide synthase (NOS) activity accounts for nicotinamide adenine dinucleotide phosphate (NADPH) diaphorase staining. NADPH diaphorase neurons are uniquely resistant to toxic or ischemic insult, therefore NO may play a role in neurotoxicity. N-methyl-D-aspartate (NMDA) neurotoxicity in primary cortical cultures, 24 hrs after a 5-minute exposure, is prevented by the NOS inhibitors N^G -nitro-L-arginine (EC₅₀=20 μ M) and N^G -monomethyl-L-arginine (EC₅₀=170 μ M). This effect is competitively reversed by L-arginine. NO is formed from the conversion of L-arginine to citrulline by NOS. In arginine-free media the LD₅₀ of NMDA neurotoxicity is shifted from 280 μ M to 7.5 mM. Sodium nitroprusside (SNP) which spontaneously releases NO, produces dose-dependent cell death which parallels cGMP formation and NMDA cytotoxicity. Hemoglobin complexes NO and prevents the neurotoxicity of both NMDA and SNP. These data establish that NO mediates glutamate neurotoxicity.

NITRIC OXIDE SYNTHASE/NADPH DIAPHORASE NEURONS: ROLE IN NEUROTOXICITY. T.M. DAWSON¹, V.L. DAWSON², D.S. BREDT¹, M. FOTUHI¹, P.M. HWANG¹, G.R. UHL^{1,2} AND S.H. SNYDER¹.

¹Johns Hopkins University School of Medicine, Dept. of Neuroscience, Baltimore, MD, 21205; ²Lab. Mol. Neurobiol. ARC, NIDA, Baltimore, MD 21224

Nitric oxide synthase (NOS), generates a novel neuronal messenger molecule, nitric oxide (NO), and is co-localized with neuronal NADPH diaphorase in brain and peripheral tissues. Transfection of human kidney cells with NOS cDNA elicits NADPH diaphorase staining, thus NOS catalytic activity accounts for neuronal diaphorase. We show that striatal and cortical somatostatin and NPY containing neurons co-localize with NOS/NADPH diaphorase staining neurons, neurons which are uniquely resistant to several neurodegenerative disorders and excitotoxins. Since NO can mediate glutamate neurotoxicity, we have evaluated NOS/NADPH diaphorase neurons as a potential source of cytotoxic NO. In neuronal cultures NOS/NADPH diaphorase neurons are resistant to NMDA neurotoxicity, but are exquisitely vulnerable to quisqualate or kainate neurotoxicity. Utilizing the susceptibility of NOS/NADPH diaphorase neurons to quisqualate we were able to kill >90% of these neurons while the remaining neurons stayed viable. Under these conditions subsequent NMDA neurotoxicity was attenuated. These data suggest that the NOS/NADPH diaphorase neurons are the source of NO and in situations of excess glutamate, they may become "killer neurons."

NORDIHYDROGUAIARETIC ACID POTENTIATES RAPIDLY TRIGGERED EXCITOTOXIC INJURY IN MURINE CORTICAL CELL CULTURES. K. Rose, L.L. Dugan, L. Bjerknes, and D.W. Choi Dept. of Neurology, Stanford Univ. Med. Sch., Stanford CA 94305.

We have previously found that nordihydroguaiaretic acid (NDGA) and other lipoxygenase inhibitors attenuate the slowly-triggered neuronal injury induced by 24 hr exposure to AMPA, kainate, NMDA, or quinolinic acid (Soc. Neurosci. Abstr. 16: 288, 1990). In contrast, NDGA potentiates rapidly-triggered excitotoxic injury.

The neuronal degeneration induced by brief (5-10 minute) exposure to 150 μ M glutamate is significantly potentiated (20%) by the addition of 30 μ M NDGA. 45-Calcium influx studies with 100 μ M NMDA and 30 μ M NDGA suggest that this injury is not mediated by an increase in calcium through the NMDA receptor. Furthermore, NDGA addition produced a marked increase in the injury induced by combined oxygen and glucose deprivation. A similar increase in oxygen and glucose deprivation injury was also produced by 30 μ M baicalin.

While further studies will be needed to determine the basis of these observations, one possibility is a toxic buildup of arachidonic acid, due to inhibition of lipoxygenase pathway metabolism during intense NMDA receptor-mediated excitotoxic injury. Twenty-four hour exposure to exogenously administered arachidonic acid (100-200 μ M) induces neuronal, and to a lesser extent, glial degeneration.

314.11

PHYSIOLOGICAL RESPONSES OF TURTLE CORTICAL NEURONS TO PROLONGED N-METHYL-D-ASPARTATE EXPOSURE. Herman C. Sullivan and Arnold R. Kriegstein, Department of Neurology and Neurological Sciences, Stanford University Medical Center, Stanford, CA 94305

We have demonstrated in an *in vitro* slice model that turtle cortical neurons exposed to excitatory amino acids undergo delayed neuronal degeneration, although a prolonged exposure is necessary to elicit this phenomenon when compared to mammalian cortical neurons (Sullivan and Kriegstein, Soc. Neurosci. Abstr. 16:1123). We have recorded from turtle cortical neurons using the whole cell, patch clamp method, during and after exposure (5-25 minutes) to 50 μ M N-methyl-D-aspartate (NMDA).

Several sequential phases of physiological activity have been identified that correlate with receptor-ligand interaction: 1. increased synaptic activity, 2. massive increase in conductance, 3. depolarization, and after washout, 4. a prolonged and sustained hyperpolarization of 15-25 mV. The pattern of response is dependent on the length of exposure to NMDA. In those cells that undergo prolonged exposure of 15-25 minutes, the sustained after-hyperpolarization does not occur after washout; an intermediate exposure of 8-12 minutes results in a return to resting membrane potential followed by a variable phase of brief hyperpolarization and spontaneous depolarization. During brief exposure of less than 5 minutes, a sustained after-hyperpolarization occurs after washout but no spontaneous depolarization.

The after-hyperpolarization is characterized by an increase in resistance (decrease in conductance). This would occur if leak currents are turned off with or without an increase in ionic pump activity (Na-K, Na-Ca). Therefore, we postulate that depolarizing leak currents are impaired following exposure to the excitatory amino acid NMDA, and the abolition of this leak current may be an important factor in protecting neurons from cell death.

314.8

POTENTIATION OF QUINOLINATE-INDUCED HIPPOCAMPAL LESIONS BY AN INHIBITOR OF THE EDRF/NO PATHWAY. K. A. Haberny and C.U. Eccles, Dept. of Pharmacol. and Toxicol., Sch. of Pharmacy, University of Maryland, Baltimore, MD 21201.

An EDRF/NO generating system similar to that described in vascular tissue and other cell types has been identified in brain. The NO is formed via a calcium/calmodulin-dependent enzymatic conversion of L-arginine to L-citrulline (Bredt and Snyder, PNAS 87:682-685, 1990). Despite much speculation, no physiological function for an NO-generating system in the central nervous system has been demonstrated. We undertook the present study to determine whether the EDRF/NO pathway could play a role in modulating cytotoxicity produced *in vivo* by the excitotoxin quinolinic acid (QA).

Intracerebroventricular (ICV) administration of L-N^o-nitroarginine (NARG), a specific inhibitor of the EDRF/NO pathway, while not toxic when given alone, markedly potentiates the toxicity of quinolinic acid in the hippocampus when given 15 min prior to QA. Administration of QA only (225 nmoles ICV; N=10) was accompanied by mild (7/10) or, in some cases, severe (3/10) seizures and produced minimal to moderate damage in the pyramidal cell layer of the hippocampus. Administration of QA following pretreatment with NARG (120 nmoles; N=11) resulted in severe seizures (9/11) and death in some cases (3/11) as well as severe hippocampal damage in the surviving animals which was manifested as complete loss of the pyramidal cell layer. Administration of NARG only (N=4) produced no remarkable behavior signs and no evidence of hippocampal damage. In conclusion, the endogenous EDRF/NO system in rat brain appears to exert a protective influence in the case of cytotoxicity produced by QA. We have not yet determined whether this protection is mediated via vascular or neuronal mechanisms.

314.10

OUABAIN POTENTIATES GLUTAMATE TOXICITY IN NEURONAL CULTURES. Michael L. Brines and Richard J. Robbins, Neuroendocrine Program, Yale University School of Medicine, New Haven, CT 06510

Excitatory amino acids (EAA) kill sensitive neurons through ionic fluxes, resulting in increased intracellular calcium, and associated cellular swelling. The activation and effectiveness of homeostatic mechanisms to buffer these changes are largely unexamined. The sodium pump (Na,K-ATPase) is a family of proteins which maintain the transmembrane gradients necessary for regulation of many ions and small molecules. We hypothesized that this pump buffers ionic perturbations induced by EAA and that decreased activity would result in amplified toxicity. To test this idea, we used 10 μ M ouabain to inhibit specifically the high-affinity (α 2 and α 3) but not the low-affinity (α 1) isoforms of the pump in monolayer cultures of rat telencephalic cells. This decreased total ouabain sensitive flux by =50% in ⁸⁶Rb studies. Cultures were exposed to agents for 5 min and the degree of toxicity assessed by measuring LDH released over 24 hr. Inactivation of the high-affinity pumps alone did not increase LDH release above control. Inhibition of both high- and low-affinity pumps, however, was very toxic to neurons. Exposure to 100 μ M glutamic acid (GLU) released only 5% of the total GLU sensitive neuronal LDH pool, but simultaneous exposure to 100 μ M GLU and 10 μ M ouabain increased this to 30% (n=18; p<0.001). Similar treatment of glial cells alone did not release LDH. Thus, in this paradigm inhibition of high affinity sodium pumps significantly increases the neurotoxicity of GLU. We conclude that high affinity sodium pumps are an important element in the overall homeostatic response of neurons to EAA.

314.12

PHYSIOLOGICAL PROCESSES UNDERLYING INDUCTION OF THE EXTENDED NEURONAL DEPOLARIZATION ELICITED BY PROLONGED GLUTAMATE EXPOSURE. Douglas A. Coulter, Sompong Sombati, and Robert J. Delorenzo Department of Neurology, Medical College of Virginia, Richmond, VA 23298.

We have previously shown that excitotoxic exposure to glutamate (GLU) elicits an extended neuronal depolarization (END) after washout of GLU, which lasts for hours (Sombati, et al. Soc. Neurosci. Abstr., 1990). We employed whole-cell current-clamp recordings of 2-3 week old neonatal cultured hippocampal neurons to study processes involved in the induction of the END.

ENDs were induced following exposure to 500 μ M GLU for 10 minutes in 100% of the neurons (7/7) recorded using an electrode solution in which calcium was unbuffered. ENDs, defined as a prolonged depolarization of at least 20 mV from rest, persisted for the duration of the recording with no sign of recovery, in some cases for over 4 hours. During the END, cells remained responsive to GLU, and retained electrical excitability, as evidenced by their ability to fire sodium spikes if repolarized by current-clamp. ENDs were never (0/6) elicited in neurons recorded with intracellular calcium strongly buffered by BAPTA (11 mM). This was true even with extended GLU exposure (20 min, n=2). In recordings where calcium was buffered less strongly (by 1.1 mM EGTA), ENDs were elicited in 60% of the experiments (15/25). Concurrent application of MK-801 (10-30 μ M) with GLU blocked induction of the END in cells recorded without calcium buffer in the electrode solution (0/5).

We therefore conclude that excitotoxic activation of glutamate receptors constantly produces an extended neuronal depolarization in hippocampal neurons in culture and that a rise in intracellular free calcium concentration, elicited by activation of excitatory amino acid receptors, is involved in initiation of this phenomenon. 314.13

HIGH DENSITY HIPPOCAMPAL NEURON POPULATION IN CULTURE INCREASES VULNERABILITY TO GLUTAMATE EXCITOTOXICITY.

S. Sombati, D.A. Coulter, E.R. Jakoi* and R.J. DeLorenzo. Dept. of Neurology, Medical College of Virginia, Richmond, VA 23298.

Glutamate (GLU) excitotoxicity has been implicated in various neurodegenerative diseases. We were interested in whether neuronal population density may affect cellular vulnerability to GLU toxicity. We report here a correlation between neuronal plating density and susceptibility to GLU excitotoxicity. Dissociated hippocampal cells from 1 day old rat were grown at low and high density (LDC and HDC, 100,000 and 600,000 cells/dish) with added conditioned medium. Non-neuronal proliferation was inhibited one day after plating. Experiments were performed on 10 day old cultures.

Intracellular recordings from LDC neurons revealed discreet synaptic potentials and some sporadic activity while those from HDC neurons showed barrages of synaptic potentials, accompanied by rhythmic spike activity, indicating increased synaptic connections and activity in HDC vs LDC conditions. Neurons from both culture conditions were exposed to 500 μ M GLU plus 10 μ M glycine for 5 min. GLU caused membrane depolarization to -15 to -5 mV without marked receptor desensitization in either culture density. In separate experiments cell viability was assessed using trypan blue stain pre and post GLU treatment. Under these conditions 58.81 \pm 4.26 % (n=12, 4 experiments) of neurons from LDC survived while only 15.03 \pm 1.78% (n=8, 4 experiments) from HDC survived 24 hours post GLU treatment. Neurons in groups or clusters were more affected. These results suggest that the density of neuronal cultures affect endogenous release of neurotransmitter, which may augment the excitotoxic effects of exogenously applied GLU.

REPEATED NMDA RECEPTOR ACTIVATION INDUCES DISTINCT INTRACELLULAR CALCIUM CHANGES IN SUBPOPULATIONS OF STRIATAL NEURONS IN VITRO.

B.A. MacVicar, D. Hochman and S. Weiss. Neuroscience Research Group, University of Calgary, Calgary, AB, Canada.

We used imaging analysis of fura-2 fluorescence to examine changes in the concentrations of intracellular calcium ($[Ca^{2+}]_i$) in striatal neurons in primary culture. We examined > 700 NMDA-responsive striatal neurons (15-25 neurons/field) in separate coverslips from 8 independent culture preparations. Neurons were exposed to three pulses of NMDA (200 μ M; 2 min) separated by 7 min intervals. A subset (17%) of the NMDA-responsive neurons displayed uncontrolled increases in $[Ca^{2+}]_i$ (final $[Ca^{2+}]_i$ \geq peak response), usually after the second or third application. The rest of the NMDA-responsive neurons displayed either a persistent increase in $[Ca^{2+}]_i$ (33%; 150% of baseline \leq final $[Ca^{2+}]_i$ < peak response) or no long term changes in $[Ca^{2+}]_i$ (50%). After 3 NMDA applications, $OCa^{2+}/EGTA$ aCSF was superfused and this resulted in a significant reduction in only the persistent increases in $[Ca^{2+}]_i$, but not uncontrolled increases. In addition, while some persistent increases in $[Ca^{2+}]_i$ were attenuated in the presence of 1 μ M MK-801 or 100 μ M verapamil, uncontrolled increases were unaffected. This work indicates that the uncontrolled $[Ca^{2+}]_i$ increases may be principally due to increased intracellular Ca^{2+} release whereas the persistent increases may be due to Ca^{2+} influx.

Protection Against Kainic Acid Toxicity With Lipophilic Antioxidants in Cerebellar Granule Cell Cultures. W.E. Lyons, P.S. Puttfarcken, and J.T. Coyle. Depts. of Toxicol. and Psychiatry, The Johns Hopkins University, Baltimore, MD 21205.

Previous evidence from this laboratory indicates that treatment with the antioxidant idebenone provides significant protection against neuronal degeneration induced by intrastriatal injections of kainic acid (KA). We now report that treatment of cerebellar granule cell cultures with lipophilic antioxidants significantly attenuates the neurotoxic effects of KA. Thirty min. exposures to KA produces an acute NaCl dependent neuronal swelling which leads to rapid lysis of approximately 50% of the neurons during the exposure period, followed by degeneration of the remaining neurons over the next 12 hours. However, if the cells are exposed to KA for 30 min. in the absence of extracellular Na^+ , the acute swelling phase is alleviated and the cells degenerate more slowly over an 18 to 24 hour period. Using (-) Na^+ exposure conditions as a model for delayed KA mediated toxicity, we have found that addition of the lipophilic antioxidants idebenone and vitamin E (α -tocopherol) provides significant protection against KA toxicity. KA dose response curves were constructed in the presence and absence of either 3 μ M idebenone or 50 μ M vitamin E. Idebenone produces a rightward shift in the KA dose response curve with complete reversal of toxicity at low doses of KA (50-300 μ M). At maximal doses of KA (500-1000 μ M) idebenone reduced cytotoxicity by 50%. Vitamin E was less effective in preventing toxicity but provided from 20 to 40% protection. These data suggest that generation of free radicals may be involved in the process of KA mediated delayed neurotoxicity.

RELATIONSHIP BETWEEN CHANGES IN INTRACELLULAR FREE CALCIUM ($[Ca^{2+}]_i$) AND NEUROTOXICITY. S. Rajdev, K. Rothermund* and I.J. Reynolds. Dept. of Pharmacology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

An increase in ($[Ca^{2+}]_i$) has been proposed to be the major cause of excitotoxic neuronal death. Using fura-2, we measured $[Ca^{2+}]_i$ changes in single fetal rat forebrain neurons exposed to various agonists at concentrations which produce little or no toxicity after 24 hr for 5 min.: 100 μ M glu (+1 μ M gly), 30 μ M NMDA (+1 μ M gly), 100 μ M kainate and 50mM K^+ , under control and ischemic (agonist with 5mM KCN in glucose free HBSS) conditions. The $[Ca^{2+}]_i$ changes were characterized in terms of rise in $[Ca^{2+}]_i$, level of $[Ca^{2+}]_i$ at the time agonist was washed out (plateau), the time taken by cells to recover by 90% of peak rise in $[Ca^{2+}]_i$, and area under the curve (AUC).

Parameter	Glu/gly	NMDA/gly	Kainate	K^+
Rise, nM	606 \pm 53	242 \pm 23	587 \pm 28	462 \pm 49
Plateau, nM	536 \pm 56	173 \pm 20	410 \pm 59	179 \pm 23
AUC, μ M.sec	381 \pm 68	52 \pm 6	165 \pm 30	62 \pm 8
Recovery, min	17 \pm 2	3 \pm 0.5	6 \pm 1	0.9 \pm 0.1

Addition of KCN significantly increased the $[Ca^{2+}]_i$ changes induced by NMDA, kainate and K^+ . However, only NMDA induced neurotoxicity was potentiated by KCN. Thus, in addition to increase in $[Ca^{2+}]_i$, excitotoxic cell death also depends on other factors linked to NMDA receptor activation.

RELEASE OF GLUTAMATE AND TAURINE INDUCED BY ALTERED SODIUM GRADIENTS. J.E. Madl, K. Burgesser* and P.C. Mishra*. Dept. Anatomy & Neurobiology, Colorado State University, Ft. Collins, CO 80521.

Release of glutamate (Glu) and other transmitters may mediate neuronal damage produced by metabolic insults. Most of the oxidative metabolism of the CNS is used to maintain Na^+ gradients, suggesting release of transmitters during metabolic insults could involve altered Na^+ concentrations. Rat hippocampal slices were incubated in Hank's balanced salt solution with additional HEPES and glucose and amino acids were measured in supernatants and homogenates by HPLC. Monoclonal antibodies were used for immunocytochemical localization of Glu or taurine (Tau). Glu was released in a Ca -independent manner when intracellular Na^+ was increased by treatment with ouabain or monensin. Treatment with tetrodotoxin blocked the ouabain-induced release, suggesting the release was primarily from neurons. Na^+ replacement with N-methyl-D-glucamine decreased both intra- and extracellular Glu and resulted in little Glu-like immunoreactivity (IR) remaining in slices, suggesting increased catabolism of Glu. In contrast to Glu, Tau release was increased by Na^+ replacement. Hypotonic removal of NaCl resulted in release of both Glu and Tau and in strong Glu-like IR in glia while little Tau-like IR remained in slices. These results suggest that Glu and Tau may be released from neurons by reversal of their Na^+ -amino acid cotransporters during Na^+ influx, while replacement of Na^+ depletes intracellular Glu and leads to decreased release of Glu. In contrast to Na^+ replacement, Na^+ removal results in increased release of Glu and in Glu accumulation in glia.

314.18

DISSOCIATION OF NITRIC OXIDE GENERATION AND KAINATE MEDIATED NEURONAL DEGENERATION IN CEREBELLAR GRANULE CELLS. P.S. Puttfarcken, W.E. Lyons and J.T. Coyle. Dept. of Psychiatry, The Johns Hopkins School of Medicine, Baltimore, MD 21205.

The mechanism by which kainate (KA) kills neurons in response to persistent activation of its receptors remains poorly defined. Recent studies have demonstrated that stimulation of the KA receptor leads to formation of nitric oxide (NO) from L-arginine, and that subsequent activation of soluble guanylate cyclase by NO accounts for cGMP generation in slices of rat cerebellum. In light of growing evidence that KA-mediated neurotoxicity may involve oxidative stress as the cause of membrane disruption and that NO can lead to oxidative stress, we investigated the relationship between KA-mediated NO generation and neurotoxicity in rat cerebellar granule cell cultures. Neither NO nor cGMP appear to be directly involved in the mechanism(s) underlying KA mediated-toxicity. This conclusion is based on the fact that the neuronal damage elicited by KA was not L-arginine-dependent, and treatment with competitive NO synthase inhibitors did not provide protection against KA toxicity. However, we conclude that the generation of free radicals may be involved in the process of KA-elicited neuronal death in cultures of cerebellar granule cells (see accompanying abstract by Lyons et al., 1991). Protection provided by preincubation with MA(hbs), appeared to be due to the counterion, HBS, whose structure resembles lipophilic antioxidants.

PEROXIDE ALTERS [³H]GLUTAMATE RELEASE BY CEREBRAL CORTICAL SYNAPTOSOMES. S.C. Gilman* and T.C. Pellmar. Physiology Dept., Armed Forces Radiobiology Research Institute, Bethesda, MD 20889-5145.

Hydrogen peroxide (H₂O₂) is a by-product of oxidative metabolism normally maintained at low levels in the CNS. Certain conditions, such as aging, ischemia or radiation exposure, elevate H₂O₂ levels causing increased oxidative stress to the neuron and hydroxyl free radical generation. Previous studies in our laboratory have shown that H₂O₂ reduces synaptic potentials. In an effort to define the mechanisms of H₂O₂ damage, we examined its effect on [³H]glutamate release by guinea pig cerebral cortical synaptosomes. Glutamate is a major excitatory neurotransmitter in the CNS, but can be neurotoxic in high concentrations, suggesting a role in H₂O₂ induced pathophysiology.

Basal and high [K⁺]-stimulated [³H]glutamate release were assessed. Basal release was Ca²⁺-independent. Pretreatment with H₂O₂ substantially increased the basal release, while producing a 25% depression in high K⁺-evoked release in the presence of Ca²⁺. Evoked release in the absence of Ca²⁺ was unaffected. Subtraction of Ca²⁺-independent curves from Ca²⁺-dependent showed that H₂O₂ completely blocked Ca²⁺-dependent high K⁺-evoked release. We hypothesize that under non-depolarized conditions, H₂O₂ is affecting a high-affinity Na⁺-dependent glutamate transporter, while under depolarized conditions, H₂O₂ is interfering with exocytosis.

EFFECTS OF A SYNTHETIC CATALYTIC SCAVENGER OF OXYGEN FREE RADICALS ON KAINIC ACID-INDUCED PATHOLOGY IN RAT LIMBIC SYSTEM. A. Bruce, I. Najm, B. Malfroy*, and M. Baudry. Neuroscience Program, USC, Los Angeles, CA; *Eukarion, Inc. Arlington, MA.

Oxygen free radicals have been implicated in many types of neuronal injury, such as ischemia and excitotoxicity. Transgenic mice expressing high levels of superoxide dismutase (SOD) exhibit reduced degrees of brain pathology following ischemia or MPTP treatment, suggesting that exogenously administered SOD could be used to protect neurons against free radicals. However, the large size and rapid clearance of recombinant SOD may account for the limited success of this approach. A small molecule consisting of a complex of desferrioxamine and manganese (DFn-Mn) has been shown to have catalytic SOD activity. We report our initial attempts to test this compound on neuronal damage. We selected the model of kainic acid (KA)-induced seizure activity which results in widespread neuronal damage in hippocampus and piriform cortex. Rats were first treated with DFn-Mn (40 mg/kg; i.v.) before receiving KA (10 mg/kg; i.p.), and were sacrificed 7 days after KA injection. The extent of neuronal damage was determined by quantifying the amount of binding of 3H-Ro5-4864, a ligand for the peripheral type benzodiazepine receptors, which has been shown to be a good marker of reactive gliosis. Pretreatment of rats with DFn-Mn almost totally suppressed the increase in 3H-Ro5-4864 binding elicited by KA treatment in hippocampus and piriform cortex. Other markers of neuronal damage (cell counts, spectrin breakdown) will be determined to further evaluate the protective capability of this catalytic scavenger.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY III

315.1

EXCITOTOXIC ACTIONS OF THE CYANIDE METABOLITE, 2-ICA (2-IMIDOTHIAZOLIDINE-4-CARBOXYLIC ACID). R.S. Bitner*, M.N. Patel, L. Cintron*, A. Kanthasamy*, G.E. Isom* and G.K.W. Yin, Dept. Pharmacology & Toxicology, School of Pharmacy, Purdue Univ., W. Lafayette, IN 47907.

Rosling (1989) suggested that the reaction product of cyanide with cystine, 2-ICA (2-Imidothiazolidine-4-Carboxylic Acid) might be an excitotoxin responsible for cassava-induced neurotoxicity (CIN). Hence 2-ICA was synthesized and examined for neuroexcitatory actions. After icv injection in mice, 2-ICA (0.4 -3.4 μM) caused ear scratching, wild running accompanied by clonic and tonic seizures that was blocked by PCP but not by diazepam. NMDA caused a similar excitatory syndrome that was also selectively blocked by PCP. In primary cultured hippocampal cells, 2-ICA (500 μM) and glutamate (200-500 μM) caused comparable increases in intracellular calcium levels. These results indicate that the possible role of cyanide-related excitotoxins in motoneuron diseases deserve further study. (Supported by NIH Grants EB04140, RR05586, & Marc fellowship to L.C.)

315.2

CHRONIC INTRASTRIATAL APPLICATION OF KYNURENINES PRODUCE A PATTERN OF NERVE CELL LOSS SIMILAR TO HUNTINGTON'S DISEASE. G.K. Rieke. Dept. Anat. & Cell Biol., Sch. of Med., Univ. of North Dakota, Grand Forks, ND 58202.

The kynurenines are neuroactive metabolites of tryptophan and are present within the brain. Chronic intrastriatal injection of L-kynurenic acid, 3-hydroxykynurenine or quinolinic acid selectively destroyed GABA-ergic neurons, while sparing NADPH-diaphorase positive cells. The spared neurons were located in the spongiose zone of the lesion. Each compound was delivered through an indwelling cannula coupled to an osmotic pump filled with buffered (pH 7.4-7.8) test compounds at concentrations 2-5 times the normal levels per gram wet weight rat forebrain. Whether 3-hydroxyanthranilic acid, xanthurenic acid or kynurenine are neurotoxic remains to be determined. If the kynurenines and their metabolic side products (viz., L-kynurenic acid, xanthurenic acid, anthranilic acid) prove to be neurotoxic, they may represent a chain of inter-related brain chemicals with a potential role in HD, as brain levels of some of these compounds are elevated in HD.

315.3

SYSTEMIC LOADING WITH KYNURENINE AND PROBENECID MARKEDLY INCREASES STRIATAL KYNURENIC ACID LEVELS AS MEASURED BY IN VIVO MICRODIALYSIS.

J.M. Miller, U. MacGarvey* and M.F. Beal. Department of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Kynurenic acid (KYA) is the only endogenous NMDA receptor antagonist currently identified in mammalian brain. To pharmacologically maximize brain concentrations of this compound peripheral injections of the combination of its immediate precursor, kynurenine (KYN) with probenecid, a known inhibitor of membrane transport were administered and KYA levels measured in striatal dialysates of freely moving rats.

Baseline KYA levels in striatal dialysates were found to be 1.6 ± 0.3 pmol/ml (mean ± SEM). Peripheral injections of KYN 150 mg/kg increased KYA levels to 30.9 ± 7.8 pmol/ml 2 hr after injection. Administration of the combination of KYN 150 mg/kg with probenecid 100, 150, 200 and 250 mg/kg resulted in significant increases compared with KYN alone at each dose. The largest KYA increases were with 200 mg/kg probenecid (945 ± 210 pmol/ml KYA 3 hr after injection) and no further increase was observed with 250 mg/kg. Probenecid alone at 200 mg/kg slowly increased KYA levels to 16.0 ± 5.2 pmol/ml 5 hr after injection. Using 200 mg/kg probenecid in combination with KYN 150, 300 and 450 mg/kg, striatal KYA levels were maximally increased to 2085 ± 391 pmol/ml 3 hr and 20 min after injection with the highest KYN dose. These data show that kynurenic acid concentrations in striatal dialysates can be modestly increased with kynurenine alone but increases of several orders of magnitude can be achieved with the combination of probenecid and kynurenine.

315.4

QUINOLINIC ACID INDUCED NEUROTOXICITY ANTAGONIZED BY INDOLE-2-CARBOXYLIC ACID C.M. WRAY*, R.J. BOEGMAN AND C. ROMERO-SIERRA. DEPT. PHARMACOLOGY AND TOXICOLOGY, QUEEN'S UNIVERSITY, KINGSTON, ONTARIO, K7L 3N6

It has been demonstrated in *Xenopus* oocytes that glycine may be absolutely required for NMDA activity. In cell culture, indole-2-carboxylic acid (I2CA) has been shown to competitively inhibit the potentiation by glycine at the NMDA receptor. The ability of I2CA to protect against the neurotoxicity induced by the NMDA receptor agonist QUIN when co-injected into the rat striatum was evaluated. When co-injected with 200 nmol/ul I2CA, QUIN (15nmol/ul), which is neurotoxic to the NADPH-diaphorase (NADPH-d) neurons while sparing the acetylcholinesterase (AChE) neurons resulted in approximately 50% cell survival of the NADPH-d neurons. 60 nmol/ul QUIN, which is neurotoxic to both NADPH-d and AChE neurons, resulted in significant protection of the AChE neurons as determined morphologically and from studies measuring choline acetyltransferase (ChAT) activity. There was no decrease in ChAT activity when I2CA was co-injected with QUIN. In contrast a 35% decrease in ChAT activity was obtained with QUIN alone. No sparing of the NADPH-d neurons was seen at this dose of QUIN. Our studies indicate that inhibiting the action of glycine on the NMDA receptor decreases the neurotoxicity induced by QUIN. Supported by the Medical Research Council of Canada and the Huntington's Society of Canada.

INCREASED STRIATAL AND PALLIDAL MET-ENKEPHALIN LEVELS AFTER MICROINJECTIONS OF QUINOLINATE. B.B. Ruzicka & K. Ihamandas, Dept. Pharmacology & Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

In an attempt to develop a model of the striatopallidal enkephalin deficit associated with Huntington's disease, we examined the sensitivity of the enkephalinergic neurons to quinolinate (QUIN, 18-288 nmol), an excitatory amino acid (EAA) which activates the NMDA receptor. At specific times (2 hr - 14 days) after a single, unilateral QUIN-injection into the rat striatum, the levels of met-enkephalin-like immunoreactivity (ME-i.r.) in the striatum and globus pallidus were estimated by RIA. At 7 days postinjection, QUIN produced dose-related and bilateral elevations in the striatal and pallidal ME-i.r.. The maximal responses, representing 3- and 4-fold increases in the ME-i.r., respectively, occurred at a dose of 72 nmol. The peak pallidal response was attenuated by the coinjection of QUIN with kynurenic acid (KYN, 36 nmol), a non-selective EAA receptor antagonist, or CPP (1.8 nmol), a selective NMDA receptor antagonist. The injection of KYN into the striatum contralateral to the QUIN-injection attenuated the QUIN-induced response in both the contralateral and the ipsilateral pallidum, suggesting that the contralateral changes in ME-i.r. may involve the mobilization of an endogenous EAA. Experiments conducted with the QUIN-injected tissues revealed that the elevations in ME-i.r. were not associated with an increased basal or K+-evoked ME-i.r. release. These results suggest that at 7 days following the intrastriatal QUIN injection, the striatopallidal enkephalinergic neurons surviving the EAA exposure contain an enhanced level of ME-i.r., a response that may reflect neuronal adaptation to injury. (Supported by the MRC of Canada).

TOPOGRAPHICAL EXPOSURE OF ENDOGENOUS GM1 AFTER GLUTAMATE TOXICITY: EXOGENOUS GM1 PROTECTIVE EFFECTS.

H. Laev, B. Williams*, J. Bonheur*, S.E. Karpiak and S.P. Mahadik, NYS Psychiatric Inst., Neuroscience, Dept. Psychiatry, Columbia U (Physicians & Surgeons) NY, NY 10032.

Reports describing the neuroprotective effects of exogenous GM1 (monosialoganglioside) and their possible interaction with trophic factors suggests that the endogenous molecule may itself play a critical role in CNS injury and recovery processes. In order to begin to study these possible relationships we have begun a series of experiments which assess the topographical localization of GM1 during injury since membrane surface exposure of GM1 is indicative of membrane integrity. Cortical neuronal cultures (± 14 days) from fetal (15 day gestation) and postnatal day 0-1 were subjected to glutamate (0.5-10 μ M) for 30 min with and without preincubation with GM1 (80 μ M for 90 min). Following fixation the effects on the distribution of endogenous GM1 were studied using cholera toxin (ligand for GM1) and anti-toxin immunohistochemical analysis. No significant differences were seen in the distribution of GM1 in the cultures when comparing untreated and 1 hr post-challenged cultures. In unchallenged cultures GM1 is localized continuously along the entire cellular plasma membrane surface. The highest intensity of staining is associated with synaptic structures (soma and fiber connections). In challenged cultures (24 hrs) there is a significant loss of staining, indicating primarily a disappearance of cell processes. This staining is markedly preserved in cultures challenged with glutamate but pretreated with GM1. Dye exclusion studies and LDH measurements confirm these assessments.

This work was supported in part by a grant from the FIDIA Research Foundation.

315.9

AGE RELATED SUSCEPTIBILITY OF VENTRAL HORN NEURONS TO N-METHYL-D-ASPARTATE (NMDA) IN ORGANOTYPIC EXPLANT CULTURES OF SPINAL CORD (OTC-SCs). Y. Nishida, D.M. Saroff* and J.R. Delfs, Lab. of Neurodegenerative and Aging Studies, Beth Israel Hosp., Boston, MA 02215.

To elucidate developmental changes in neuronal sensitivity to NMDA, we examined the effect of NMDA on ventral horn acetylcholinesterase (AChE)-positive neurons (VHANS) in OTC-SCs from neonatal rats. OTC-SCs were performed as previously described (Delfs, et al. Brain Res 1989;488:31-42). After 1, 2, and 3 weeks *in vitro*, each culture was incubated in control medium or 100 μ M NMDA. After 72 hours, cultures were stained for AChE and analyzed by histochemical and morphometric evaluation.

Decreases in AChE staining were observed in NMDA treated groups as compared with control cultures. In both control and treatment group, mean area of VHANS increased while mean numbers of VHANS decreased over 3 weeks. That decrease was especially remarkable in the smaller size groups (neuronal area less than 500 μ m²). At each age *in vitro*, NMDA affected mainly smaller VHANS. Survival rates of VHANS (NMDA vs control) in each size group was not obviously different between age groups.

Our results show that VHANS are susceptible to NMDA neurotoxicity by the first week *in vitro*. The relatively selective decrease in neurons in the smaller size groups could be related to a differential susceptibility to NMDA.

315.6

Chronic intrastriatal administration of high and low dose quinolinic acid using a novel device for dialytic delivery

T. Bazzett¹, J.B. Becker¹, R.L. Albin², Depts of ¹Psychology and ²Neurology, University of Michigan, Ann Arbor, MI 48104

We employed a microdialysis probe mated to an Alzet 2002 osmotic minipump to administer a high (40 mM) or a low (4 mM) dose of the excitotoxin quinolinic acid (QA) over a 3 week period. *In vitro* experiments showed >93% delivery of QA via the dialysis apparatus. The effects of chronic unilateral QA delivery to the striatum were evaluated with behavioral tests, routine histology and histochemistry for NADPH diaphorase and cholinesterase containing neurons, and D1/D2 receptor autoradiography.

Chronic delivery of 40 mM QA produced near total striatal necrosis with some damage to adjacent regions. This dose of QA also produced a significant increase in ipsilateral rotation in response to a 3 mg/kg challenge of amphetamine. By contrast, with both young (<3 months) and old (18-24 months) rats, 4 mM QA did not produce significant lesions or changes in D1/D2 receptor binding. After receiving the low dose of QA, animals did not rotate in response to amphetamine, nor was there a change in nocturnal activity.

The dialysis device used appears to increase total area of drug delivery while eliminating nonspecific damage seen after pressure injection techniques. Further experiments using this device are now in progress using an intermediate dose of QA.

ANTAGONISTS OF N-METHYL-D-ASPARTIC ACID (NMDA) DEMONSTRATE TOXIC EFFECTS IN ORGANOTYPIC ROLLER TUBE CULTURES OF SPINAL CORD (OTC-SC). D.M. Saroff*, Y. Nishida and J.R. Delfs, Lab. of Neurodegenerative and Aging Studies, Beth Israel Hosp., Boston, MA. 02215

We have previously shown the toxic effects of NMDA on ventral horn acetylcholinesterase-positive neurons (VHANS) could be attenuated by the competitive receptor antagonist DL-2-amino-5-phosphonovaleric acid (DL-AP5). (Delfs et al. *New Adv. in Tox. and Epidem.* 1990; Chap. 35:273-281) Besides partially protecting neurons from the effects of NMDA, addition of DL-AP5 was associated with a shift in the distribution of neuron sizes.

In this study, OTCs were used to examine the effects of NMDA antagonists, including DL-AP5, D-2-amino-5-phosphonovaleric acid (D-AP5), and 3-((\pm)-2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP). These effects were quantified by performing morphometry on the neurons in OTCs stained for acetylcholinesterase activity. Each antagonist studied caused a depression in the number of VHANS. The racemic mixture of AP5 (DL-AP5) demonstrated a lesser toxic effect than did its Dextro component (D-AP5) or CPP. While demonstrating toxicity, each of the three antagonists was less toxic than NMDA. These results indicate that the decrease in neurons observed in cultures with NMDA plus an antagonist was not the result of partial excitotoxic blockade, rather that the antagonist was having a toxic effect of its own.

315.10

HOMOCYSTEATE, KAINATE AND AMPA INDUCE SPINAL CORD LESIONS WHEN ADMINISTERED SUBCUTANEOUSLY TO INFANT RATS. G.J. Wang, Y.Q. Qin*, M.T. Price, J.W. Olney, Washington University Medical School, St. Louis MO, 63110

Experiments were undertaken to explore an unpublished observation (JWO, circa 1970) that sc administration of DL-homocysteic acid (DL-HCA) to infant rats damages the developing spinal cord. We found that DL-HCA induces acute massive degeneration of neurons in both ventral and dorsal portions of the spinal cord, predominantly at lumbar and lower thoracic levels. Sacral, upper thoracic and cervical levels were relatively spared. Dose response studies at various ages revealed a definite developmental time window when spinal neurons are particularly sensitive. Vulnerability to a fixed dose (150 mg/kg sc) was negligible from postnatal days 1 to 3 but then progressively increased to reach a peak at 7-9 days followed by a gradual decline to zero vulnerability by the 15th postnatal day. Administering the D and L isomers separately to 7 day old rat pups revealed the D isomer to be about twice as potent as the L isomer. In part, this may reflect the more efficient uptake/inactivation system for L-HCA. Also relevant may be our observation that in the isolated chick embryo retina, the D isomer activates both NMDA and non-NMDA receptors, whereas the L isomer activates only NMDA receptors. To explore the role of each receptor type, we administered AMPA and kainate, which are selective agonists for the two major subtypes of non-NMDA ionotropic receptors, and found that each induces a spinal lesion. However, it was difficult to keep the pups alive long enough for a full lesion to develop because each of these agents induces respiratory failure at doses (2-4 mg/kg sc) required to induce spinal pathology. All three of the agonists studied, DL-HCA, AMPA and kainate, caused typical excitotoxic cytopathology which was accompanied by conspicuous bleeding at multiple foci within the spinal cord; however, there did not appear to be any correlation between locus or degree of bleeding and severity of spinal cord damage. Intermediolateral and ventral horn motor neurons were comparably sensitive to all three agents, whereas dorsal horn neurons were differentially more sensitive to DL-HCA than to AMPA or kainate. Supported by HD24237, DA05072, AG05681 and RSA MH 38894 (JWO).

COMPARATIVE EFFECTS OF EXCITOTOXINS ON BASAL FOREBRAIN CHOLINERGIC NEURONS. R.J. Boegman, J. Cockhill, K. Jhamandas and R.J. Beninger. Dept. Pharmacology & Toxicology, Queen's University, Kingston, Canada K7L 3N6.

Large neurons of the nucleus basalis magnocellularis (nbm) provide a major cholinergic input to the cerebral cortex and amygdala. While excitotoxic lesions of cholinergic projections to the cortex have implicated it in memory, little emphasis has been placed on the projection to the amygdala. We compared the response of the cholinergic projections to the cortex and amygdala to excitotoxin-induced damage. Unilateral (0.5 μ l) stereotaxic injections of quinolinate (Quin), quisqualate (Quis), ibotenate (Ibo), NMDA or AMPA into the nbm of rats. Five days later animals were sacrificed and choline acetyltransferase (ChAT) activity measured in the cortex and amygdala. Our dose response results show that Quis and AMPA are preferentially neurotoxic to cholinergic neurons projecting to the cortex with an IC_{50} for AMPA of 0.75 nmoles. Quin was preferentially neurotoxic to the cholinergic neurons projecting to the amygdala with an IC_{50} of 18 nmoles. In contrast Ibo and NMDA did not discriminate between the cortical and amygdala projection. Our results offer an explanation for the lack of correlation reported between cortical cholinergic deficit and behavioural impairment observed with different neurotoxins. Supplied by M.R.C./N.C.E.

EFFECT OF KAINIC ACID ON BRAINSTEM RESPIRATORY CHEMOSENSITIVE ZONES. R.M. Douglas*, D.G. Bernard, Y. Pan, L.M. Sexcius*, J.A. Holloway, R.M. Millis*, and C.O. Trouth. Dept. of Physiol. & Biophysics, Coll. of Med., Howard University, Washington, D.C. 20059.

Central respiratory chemosensitivity has been attributed to specialized neurons located on the ventrolateral medullary surface (VMS). In this investigation, the response of rat VMS chemosensitive neurons to inspired CO_2 and topically applied acetylcholine (ACh) were examined before and after topical application of 1% Kainic Acid (KA). Inspired CO_2 and ACh increased medullary neuronal activity (MNA) as well as diaphragmatic activity (DA). KA, an excitotoxic amino acid, caused a marked and prolonged increase in both MNA and DA, followed by depression to extinction and respiratory arrest. This experiment shows that: 1) KA may have destroyed superficial chemosensitive VMS cell bodies. 2) Due to VMS neuronal destruction, it was not possible to effectively assess the effect of KA on the central chemosensory response. 3) The integrity of chemosensitive VMS neurons in the anesthetized rat appears essential to the maintenance of the central drive to respiration. **SUPPORT:--NIH-NIGMS Grant # S06GM08016 AND NIH Grant PH 55-T 32 GM-07800.**

UNILATERAL FOCAL NEURONAL DEATH INDUCED BY INTRA-ARTERIAL INFUSION OF KAINATE IN THE RAT. K. Shiraishi and H. Shinokaki. The Tokyo Metro. Inst. Med. Sci., Tokyo 113, Japan.

Systemic administration of kainate to the rat induces characteristic neuronal damages in the CA1 area of the hippocampus, which are similar to the delayed neuronal death caused by transient global ischemia. We intended to induce unilateral focal neuronal death in the rat by intra-arterial infusion of kainate with the Harvard pump through a thin catheter introduced into the left common carotid artery without affecting cerebral blood flow. 72 hours after the infusion of kainate, mild hemiparesis and slight decrease in muscle tone developed in all rats without demonstrating generalized convulsions, and pathological examination demonstrated unilateral focal neuronal death in the cortex and the CA3 area of the hippocampus. Infusion doses of kainate were significantly lower than those of systemic administration, and there was no case of death. When a bolus of kainate was given, generalized convulsions and bilateral neuronal damages were observed, like systemic administration. It is of great interest that there is a considerable difference in anatomical distribution of neuronal damages induced by systemic and intra-arterial administrations. The present case would be expected to be a valuable model for inducing focal neuronal death under preserving cerebral blood flow in rats. Supported by Seijin-byo Institute Memorial Foundation.

RECEPTOR ABUSE-DEPENDENT ANTAGONISM (RADA): IN VITRO AND IN VIVO EVIDENCE FOR AN ANTIEXCITOTOXIC ACTION OF NATURAL AND SYNTHETIC GLYCOSPHINGOLIPIDS. H. Manev, G. Lombardi, S. Francioni, D.M. Armstrong, A. Guidotti and E. Costa. F.G.I.N., Georgetown Univ., Washington, DC 20007.

RADA is a therapeutic strategy of selectively targeting drugs to the site where homeostasis is destabilized by paroxysmal receptor stimulation (FASEB J, 1990, 4: 2789). RADA strategy avoids that the same receptor is blocked indiscriminately throughout the brain. In vitro, natural (GM1, GD1a, GD1b, GT1b), and synthetic (LIGA4, LIGA20), glycosphingolipids protected rat cerebellar granule neurons in primary culture against glutamate-induced neuronal death (measured by MTT or fluorescein diacetate/propidium iodide staining). LIGA 4 and LIGA 20 acted faster and more persistently than natural gangliosides. The neuroprotection correlated with the ability of glycosphingolipids to prevent the protracted protein kinase C translocation and intraneuronal destabilization of Ca^{2+} homeostasis. In vivo, unilateral thrombotic stroke of the sensorimotor cortex (lesion 3-4 mm in diameter) induced by injecting the rats intravenously with 80 mg/kg rose bengal, and focally illuminating the skull, caused a behavioral deficit, quantitated by a battery of tests (vertical grid, inclined plane, patch removal, computer-assessed open field behavior). Pretreatment (1 day) with GM1 or LIGA 4 (50 and 10 mg/kg.i.v., respectively), followed by a subcutaneous post-treatment (4 days) resulted in behavioral recovery, giving the first evidence of the in vivo RADA profile of these drugs.

315.14

EFFECT OF INTRACEREBROVENTRICULAR INFUSION OF EXCITATORY AMINO ACIDS ON NEUROPEPTIDES IN RAT BRAIN. H. Kaneda, E. Kawata*, Y. Komurasaki*, K. Sakai*, K. Maeda and K. Chihara*. Dept. of Psychiat., Kobe Univ. Sch. of Med., Kobe 650, Japan.

Recently roles of excitatory amino acids (EAAs) on neurodegenerative diseases have been investigated biochemically and histologically. "Axon-Sparing lesion" is the one of the characteristic changes induced by EAAs. On the other hand, there are many findings about alterations of neuropeptides in postmortem brains or cerebrospinal fluids with such diseases in clinical study. Then, in this study, we have examined effects of three excitotoxins, ibotenic acid (IA), kainic acid (KA) and quinolinic acid (QA) on somatostatin (SS), neuropeptide Y (NPY) and arginine-vasopressin (AVP) levels in the discrete regions of rat brain. Male Wistar rats were used (300-350 g). The excitotoxins were infused into the right lateral ventricle for 14 days using an osmotic minipump (Alzet 2002). Each dose of excitotoxins was 500 nmol IA, 5000 nmol QA or 5 nmol KA for 14 days. After the infusion the brain was taken out and dissected with modulated Palkovits' punch technique. Neuropeptides were measured by radioimmunoassay.

IA infusion resulted in a significant decrease in SS levels in the anterior cortex (AC), septum (SE), amygdala (AM), hippocampus (HC) and posterior cortex (PC), compared to those in control animals which were infused the vehicle. NPY and AVP in AM and HC, respectively, were reduced following IA administration. On the other hand, these neuropeptide levels in some discrete regions of the brain were elevated by either KA or QA infusion.

This result suggests that there exists a difference in the effects on brain neuropeptide metabolism among these excitotoxins. Small amount of IA infusion into rat lateral ventricle for long term may produce closely resembling pathophysiology to Alzheimer's disease in human.

315.16

LOSS OF VISION AND SUBSEQUENT RECOVERY AFTER EXPOSURE OF ADULT RAT RETINA TO N-METHYL-D-ASPARTATE (NMDA).

R. Siliprandi, R. Canella*, J. Sautter*, K. McDonald*, G. Carmignoto and B. Sabell*. Fidia Research Laboratories, Abano Terme, Italy and ¹Inst. of Med. Psychology, Univ. of Munich, 8000 Munich, FRG.

We studied the effects of a single intraocular (i.o.) injection of varying doses of NMDA on visual performance of adult rats. Rats were trained for a week to orient towards visual stimuli (Duvdevani et al., Restor. Neurol. Neurosci. 2: 31, 1990), and then received a unilateral i.o. injection of NMDA (2, 20, 100 nmoles, each n=5) or PBS. Loss of vision was quantified by assessing the size of the visual field ipsilateral to the NMDA injection. Rats receiving 2 nmoles of NMDA did not show deficits compared to control-injected counterparts. However, when receiving 20 or 100 nmoles NMDA, they showed near-complete blindness followed by significant recovery of vision which was almost complete 10 days post-lesion. Anatomical correlates were obtained after a combined Nissl and retrograde HRP-stain, with the 20 nmoles group displaying a loss of about 80% of the retinal ganglion cells. Thus rats can significantly recover visual function, despite a severe cell loss. This system provides a standardized behavioral assessment of excitotoxicity applicable to the evaluation of drugs effective on CNS functional recovery.

315.17

HIGH EXTRACELLULAR POTASSIUM INDUCES MARKED CHANGES IN EXTRACELLULAR AMINO ACID LEVELS AND NEURONAL NECROSIS IN THE RAT AMYGDALA. D.G. Fujikawa, A.F. Alcaraz, and N.C. Phan. Exp. Neurol. Lab., VA Med. Ctr., Sepulveda, CA 91343 and Dept. of Neurology and Brain Res. Inst., UCLA Sch. of Med., Los Angeles, CA 90024.

We used *in vivo* microdialysis and high-performance liquid chromatography (HPLC) to determine the effects of high extracellular K^+ ($[K^+]_o$) on extracellular amino acid concentrations in the rat amygdala, and correlated this with a histological assessment of neuronal viability.

Bilateral guide cannulae were positioned to place microdialysis probes within the basolateral amygdaloid nuclei of adult Wistar rats ($n=3$). The next day the probes were inserted and perfused with Krebs-Ringer-bicarbonate (KRB) solution for 2 h. One side was switched to 100 mM KCl in modified KRB for 3 h, after which rats underwent brain perfusion-fixation for histological examination. The dialysate was analyzed by HPLC.

100 mM KCl induced sustained 3-h increases in aspartate (251-503%) and taurine (447-629%) and decreases in glutamine (down 82-88%) compared to the side perfused with KRB. Glutamate was elevated during the first 60 min of 100 mM KCl perfusion (365% at 30 min and 202% at 1 h) but subsequently declined. Glycine increased only at 2 h (367%). Serine levels did not change. The side perfused with 100 mM KCl showed extensive edema and necrotic neurons up to 500 μ m from the probes. Cell loss (primarily neurons) was most pronounced in the first 100 μ m. The side perfused with KRB showed minimal changes. Thus, large, prolonged increases in extracellular aspartate, glutamate and taurine are produced by high $[K^+]_o$ and are associated with neuronal necrosis.

315.19

INTRAVENTRICULAR INFUSION OF N-METHYL-D-ASPARTATE LEADS TO ACUTE HYPERTENSION, INCREASED VASCULAR PERMEABILITY AND NEURONAL INJURY. W.D. Dietrich, O. Alonso, R. Busto, M. Halley, and M.Y.-T. Globus. Dept. Neurology, Univ. Miami School Medicine, Miami, FL 33101.

N-methyl-D-aspartate (NMDA) receptor activation has been implicated in a variety of neurotoxic processes. This study determined whether excessive NMDA receptor activation would produce blood-brain barrier (BBB) dysfunction and neuronal injury in the acute experimental setting. NMDA (20 μ g/min) or vehicle was infused over a 30 min period into the lateral ventricle of rats. At 15 min into the infusion period, the protein tracer horseradish peroxidase (HRP) was injected and perfusion-fixation conducted 15 min later. NMDA infusion ($n=6$) increased arterial blood pressure (mean 54 ± 5 mmHg). In NMDA infused rats, multifocal regions of HRP extravasation were observed bilaterally throughout the neuraxis. Sites of BBB disruption included the cerebral cortex, hippocampus, thalamus, septum, hypothalamus, and cerebellum. HRP was also detected bordering the lateral and third ventricles. Both swollen and dark-shrunken neuronal cell bodies and processes were seen at leaky sites. Pretreatment with MK-801 (2 mg/kg) attenuated the hypertensive and BBB response to NMDA. In experimental settings where extracellular levels of glutamate are elevated, excessive NMDA receptor activation may contribute to acute vascular and neuronal injury.

315.18

HYPOXIC AND EXCITOTOXIC LESIONS IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES. N. Tønder and J. Zimmer. Pharma-Biotech, Inst. of Neurobiology, Univ. Aarhus, Denmark.

Slices of hippocampal tissue (350 μ m) from 5 day old rats, were grown in culture using the roller-tube technique. After 4 weeks *in vitro*, cultures with a complete, organotypic appearance were selected for either hypoxia ($1/2$ - 4 hrs at 36°C in 3% O_2 and 5% CO_2) or addition of excitotoxins (kainic acid, 3 μ M for 48 hrs; NMDA, 10 μ M for 1 to 11 hrs; AMPA, 10 μ M for 5 or 10 hrs), after which they were returned to normal medium for up to 14 days.

After 45 min hypoxia hippocampal CA1 and CA3c pyramidal cells and dentate granule cells degenerated, while CA3a,b pyramidal cells and somatostatinergic (SS) neurons in all areas appeared intact. Exposure to NMDA for 10 hrs resulted in a similar lesion. Cultures exposed to AMPA for 10 hrs showed additional degeneration of SS neurons. Kainic acid selectively damaged CA3 pyramidal cells.

The results demonstrate that hypoxic and excitotoxic lesions in organotypic hippocampal slice cultures, with some differences (granule cell degeneration), resemble the lesions *in vivo*. The method may, accordingly, be used for experimental analysis of cellular mechanisms, and testing of pharmacologically active substances, in relation to cerebral ischemia.

ABNORMAL GLUTAMATE TRANSPORT IN AMYOTROPHIC LATERAL SCLEROSIS: PATHOPHYSIOLOGICAL IMPLICATIONS. RW Kuncl and JD Rothstein. Dept of Neurology, Johns Hopkins Univ. Baltimore, MD 21205

A number of studies have suggested abnormal glutamate metabolism in ALS. Glutamate and glutamate analogs can induce neuronal degeneration *in vivo* and *in vitro*, and could be responsible for chronic human neuronal degenerations. Recently we demonstrated marked increases in CSF glutamate in ALS. Of the various explanations for these findings, it is possible that the pathophysiology of glutamate neurotoxicity in ALS could be excessive synaptic glutamate due to defective glutamate uptake. Therefore, we measured high affinity glutamate uptake in postmortem brain and spinal cord tissue from ALS and control patients. Uptake could be reliably measured up to 12 hours postmortem. Mean age and postmortem delay were similar for both groups. High affinity, sodium-dependent uptake was reliably measured in all specimens. In ALS cervical spinal cord there was a 65% decrease in the V_{max} for glutamate uptake [0.34 ± 0.06 (SEM) nmoles/min/mg protein, $n=8$] compared to control [0.98 ± 0.01 nmoles/min/mg protein, $n=8$]. In some ALS spinal cord tissue, glutamate uptake was decreased as much as 90% compared to control. Motor, sensory, and visual cortex were also assayed. The mean V_{max} for glutamate uptake was significantly decreased 75% in ALS motor cortex compared to control motor cortex. Glutamate uptake in sensory cortex was slightly (but significantly) decreased, but not changed in occipital cortex. The affinity for glutamate was similar, both in ALS and control specimens, whether from spinal cord, motor cortex, sensory cortex, or occipital cortex. These changes were specific for glutamate, since GABA and phenylalanine transport in ALS cortex did not differ from control. These studies provide the first physiological evidence for dysfunction of glutamatergic systems in ALS and have important therapeutic implications.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY IV

316.1

THE ROLE OF GLIAL CELLS IN KAINATE-INDUCED NEURODEGENERATION. Y. Cheng, Q. Bu, P. Wixom and A.Y. Sun. Department of Pharmacology, University of Missouri, Columbia, MO 65212.

Excessive release of excitatory amino acids, such as glutamates can lead to the development of excitotoxicity. Recently, we have demonstrated that the action of glutamate at its presynaptic KA receptor provokes the calcium influx and the release of more glutamate. It is possible that glutamate released from terminals not only binds to postsynaptic receptors, but also feeds back onto presynaptic receptors and thus increases glutamate release. We have used kainate to study this amplification mechanism as caused by glutamate excitotoxicity. Since the glutamate uptake by glial cells and by their surrounding glial cells is the important mechanism for removing glutamate from continuing action at the postsynaptic receptor, the possible interaction of neuron and glial cells on the glutamate excitotoxicity was also investigated. Results indicate that kainate can induce the release of free fatty acids, which are potent inhibitors of both synaptosomal and glial uptake of glutamate. Thus, the neurotoxicity of kainate may involve the potentiation of glutamate acting on the postsynaptic receptor by stimulating glutamate release and inhibiting the high affinity uptake of this excitatory neurotransmitter.

316.2

Differential vulnerability of Ts16 neurons to excitotoxic damage. Paul J. Schwartz and Joseph T. Coyle. Depts. of Neuroscience and Psychiatry, The Johns Hopkins School of Medicine, Baltimore MD 21205

The homology between the 16th mouse and 21st human chromosomes has led to the use of mice trisomic for chromosome 16 (Ts16) as a model of human trisomy 21 (Down syndrome, DS). A consequence of DS is the appearance of pathological and behavioral changes associated with Alzheimer's disease. There are indications that a common pathway for many neurodegenerative disorders is the failure to regulate reactive oxygen species such as the superoxide anion and hydrogen peroxide. Since both the murine 16th and the human 21st chromosomes contain the gene for superoxide dismutase-1 (SOD-1), we have investigated potential differences in the vulnerability of neurons from Ts16 and euploid embryos. We have used both "acute" excitotoxic and long term survival studies to determine the direction and mechanisms of such differences.

Mature (14DIV+) cultures grown on glial monolayers were used for "acute" studies. Long (12h) exposures to kainic acid (KA) showed a subtle dose response shift (trisomic less vulnerable to KA), and initial studies indicate that NMDA affects Ts16 cells less than euploid cells.

Cultures prepared for long term survival were not plated on glial monolayer and drugs were added the day after plating. After 7 days, the trisomic neurons began an accelerated attrition until, at three weeks, the number of Ts16 neurons in untreated cultures was 50% that of euploid controls. This effect could be reversed entirely by 3 μ M idebenone (a lipophilic antioxidant) and partially with 10 μ M MK801. The control cultures also exhibited some attrition; while maximum survival with idebenone was the same for both trisomic and euploid cells, MK801 was much more efficacious in saving euploid neurons.

316.3

UPTAKE AND DISTRIBUTION OF THE EXCITOTOXIN L-BMAA IN RODENT BRAIN TISSUE. G.E. Kisby, V. Nottingham*, R. Kayton* and P.S. Spencer, Center for Research on Occupational and Environmental Toxicology, Oregon Health Sciences University, Portland, OR 97201.

β -N-Methylamino-L-alanine (BMAA), a weak glutamate-like excitotoxic amino acid, is one of the many potentially toxic agents in cycad seed which is under study as a possible etiological factor for western Pacific ALS/P-D. Studies were initiated to determine if L-BMAA, unlike other excitotoxins, is taken up by CNS tissue *in vitro* and *in vivo*. Mouse cortical explants were treated with 1.6 mM BMAA and L-[-N-¹⁴CH₃]-BMAA (sp. activity 265 μ Ci/mmol) and tissue levels determined by HPLC and LSC, respectively. BMAA uptake was time-dependent, an indication that the neurotoxicity of this compound may in part be due to its intracellular effects. Similarly, linear uptake of [³H]-BMAA (sp. activity 4.4 mCi/mmol) into mouse brain synaptosomes was sodium, protein, and pH dependent. To determine the regional brain distribution of BMAA, [¹⁴C]-BMAA (2.0 μ Ci) was injected in the right common carotid artery of adult male Sprague-Dawley rats (n = 6) and the radioactivity determined in brain (hippocampus, cortex, striatum, sub-cortex, midbrain, cerebellum) and spinal cord tissue. BMAA differentially distributed within the CNS of rats. These studies demonstrate that BMAA is rapidly taken up by CNS tissue. The intracellular fate of this foreign amino acid is presently under study and preliminary results indicate production of a toxic metabolite. Further study is critically needed before conclusions can be drawn about the potential role of this agent in western Pacific ALS/P-D. [Supported by a grant from AHAF and NS19611]

NEURONAL DEATH IN THE HIPPOCAMPUS INDUCED BY INTRACEREBRAL INJECTION WITH AN NMDA RECEPTOR AGONIST, L-CCG-IV BUT NOT WITH A METABOTROPIC RECEPTOR AGONIST, L-CCG-I.

T. Shigeno¹, G. Kato², T. Murakoshi¹, M. Ishida¹, and H. Shinozaki¹.

¹Neurosurgery, Saitama Medical Center, ²Anatomy, Chiba College of Medical Science, ³Pharmacology, Tokyo Medical and Dental University, ⁴Pharmacology, The Tokyo Metropolitan Institute of Medical Science, Bunkyo, Tokyo 113, JAPAN

Neurons in the CA1 sector of the hippocampus are susceptible to die several days after cerebral ischemia known as delayed neuronal death (DND). The excitatory neurotoxicity by glutamate has been surmised in the pathogenesis of DND. Here we report that intracerebral injection with a potent NMDA receptor agonist, the (2R,3R,4S) isomer of α -(carboxycyclopropyl)glycine (L-CCG-IV) induced death of the CA1 neurons. Using adult rats under halothane anesthesia, we injected either L-CCG-IV or a metabotropic receptor agonist, the (2S,3S,4S) isomer (L-CCG-I) into the unilateral cortex, CA1 or CA3. In the contralateral side, we injected vehicle for controls. The dose was 50nmole in 1 μ l vehicle. After L-CCG-I injection and discontinuation of anesthesia, the rats remained calm for several hours. By contrast, L-CCG-IV injection caused clonic twitching of both legs for around one hour. All rats survived for one week and served for histological examinations. The vehicle injection did not cause any neuronal damage except for local gliosis along the needle track. The cerebral cortex, CA1 and CA3 sector injected with L-CCG-I did not show any change, either. However, when L-CCG-IV was injected into either CA1 or CA3 sector, we observed complete loss of neurons and marked gliosis in the CA1 sector. Neurons in the CA3 sector appeared intact but with slight local gliosis even when the agent was injected into the CA3 sector. There was no damage in the cortex. Thus, the pathogenesis of DND might be related with neuroexcitatory damage via the NMDA receptor.

316.7

A HIGH THROUGHPUT *IN VITRO* BIOASSAY FOR ANTAGONISM AT THE GLYCINE SITE OF THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR. Dwight L. Needels, Brenda J. McKinley*, Joseph A. Cipollina* and Andrew D. Williams*, Cell & Molecular Neurobiology and CNS Chemistry, Bristol-Myers Squibb Co., Wallingford, CT 06492.

The damage to the hippocampus by an ischemic/hypoxic event is thought to be mediated by overstimulation of the postsynaptic NMDA receptor complex and its regulatory glycine site caused by accumulation of glutamate or other excitotoxins. [For review: Choi and Rothman (1990) *Ann. Rev. Neurosci.* 13:171-182].

Cultured hippocampal neurons have been used for some time as an *in vitro* model for stroke. We describe here the adaptation of such cultures to a specific, high throughput screen for the evaluation of glycine antagonists. Hippocampal neurons were dissected from E18 rat and cultured under serum-free conditions with low endogenous glycine. On day 11 (after neurons had developed sensitivity to NMDA) cultures were exposed to a continuous toxic dose of NMDA in the presence of various concentrations of test drug. Neuronal survival was evaluated 24 hr later by cell counting, which is both labor and time intensive. As neurons die in response to NMDA they lyse, releasing the enzyme lactate dehydrogenase (LDH) which was assayed in parallel to cell counts using a high throughput 96 well plate procedure.

A series of 7-Cl-kynurenic acid analogs were synthesized and used to evaluate this bioassay for generation of structure/activity relationship (SAR) data for glycine antagonists. A parallel shift in the dose-response curve upon addition of 50 μ M glycine is indicative of competitive antagonism. Cell count and LDH release data gave very similar results, but the LDH method was found to provide a more sensitive (and convenient) measure of protection from NMDA toxicity. This neuroprotective bioassay provides a consistently reliable method for evaluation of antagonists at the glycine site of the NMDA receptor.

316.4

β -N-OXALYL-L- α -DIAMINOPROPIONIC ACID (β -L-ODAP) INCREASES GLUTAMINE SYNTHETASE ACTIVITY IN CULTURED RAT ASTROCYTES. S.E. Miller¹, P.B. Nunn^{2*}, and R.J. Bridges³, Depts. of Psychobiology¹ and Neurology³, Univ. of California, Irvine, CA 92717 and Dept. of Biochemistry², King's College, London WC2R 2LS England.

β -L-ODAP, an amino acid found in the seeds of *Lathyrus sativus*, is believed to be the causative agent of human lathyrism, a disease characterized by a permanent bilateral spastic paralysis. Studies have shown that β -L-ODAP is a potent non-NMDA agonist and is toxic to both neurons and glia. In the present study we have examined glutamine synthetase (GS) activity in astrocytes exposed to β -L-ODAP. This glial-specific enzyme catalyzes the conversion of glutamate and ammonia to glutamine, thus playing a critical role in regulating the levels of two potential CNS toxins.

Type I astrocytes were cultured from 4 day old rats and GS activity was quantitated on the basis of the L- γ -glutamyl hydroxymate transfer reaction. 24 hours after adding β -L-ODAP to the cultures (100 μ M initial concentration), GS activity was increased to approximately 140-160% of control activity. This effect was stereospecific, as β -D-ODAP produced no increase. Studies in cell-free preparations with purified GS failed to show any direct activation of GS by β -L-ODAP. When homogenates of β -L-ODAP treated cells were combined with homogenates of untreated cells the resulting GS activity was an average of the two, suggesting that the increased GS activity was not due to the production of an activating factor which modified the existing enzyme. Importantly, this dose of β -L-ODAP did not appear to be gliotoxic as measured by LDH release, suggesting the increased GS activity was not dependent upon astrocyte degeneration. These results imply that the induction of GS activity by β -L-ODAP involves upregulation at the transcriptional or translational level, and may represent an early event in the astrocytic response to high levels of excitatory amino acids.

316.6

GLUTAMATE-INDUCED SEIZURES IN ANOXIC AND NORMAL MICE: EFFECT OF NMDA AND AMPA ANTAGONISTS. H. Kitgaard¹, U.B. Olesen¹ and E.B. Nielsen, CNS Division, Novo Nordisk A/S, DK-2880 Bagsvaerd, Denmark.

The mammalian cortex is exquisitely sensitive to anoxia. Recently, excessive release of glutamate has been postulated to be involved in neuronal cell death by generating a lethal extracellular concentration of glutamate. This process is known to be counteracted by NMDA and AMPA antagonists. Therefore, the present study investigated the protective effect of these compounds against glutamate-induced seizures in normal and anoxic mice.

Male NMRI mice (25 \pm 2 g) were exposed to 100% nitrogen for 30 sec. After 14-22 sec, the animals became unconscious and after about 45 sec, respiratory movements terminated. After 75 sec, artificial respiration was started resulting in normal respiration and consciousness after about 120 sec and 3-5 min, respectively. Glutamate-induced seizures were evoked in normal and anoxic mice, 30 min after nitrogen treatment, by i.c.v. infusion of 100 μ g L-glutamate pr. min according to the i.c.v. infusion method of Steppuhn and Turski (Naunyn-Schmiedeberg's Arch. Pharmacol. 344, 1991). MK-801, CGP 39551 and NBQX were evaluated by co-infusion i.c.v. in a dose range of 0.03-1.0 μ g/min.

In general, all three compounds were markedly more potent against glutamate-induced seizures in anoxic mice than in normal mice. In all experiments, NBQX was the most potent compound. Thus, in the anoxic mice, NBQX had an ED₅₀ value of 0.08 μ g/min against glutamate-induced seizures. This was about ten times lower than the ED₅₀ values of MK-801 (0.82 μ g/min) and CGP 39551 (0.69 μ g/min). In conclusion, anoxia increases to potentiate the protective effect of NMDA and AMPA antagonists against glutamate-induced seizures. Of the compounds tested, the AMPA antagonist NBQX was markedly more potent than the NMDA antagonists MK-801 and CGP 39551.

316.8

GLUCOCORTICOID DOES NOT EXACERBATE EXCITOTOXIC DAMAGE IN THE IMMATURE RAT BRAIN. J.D.E. Barks, Dept of Pediatrics, Section of Newborn Services, Univ. of Michigan, Ann Arbor, MI 48109-0254.

Damage to mature neurons due to a variety of insults is exacerbated by glucocorticoid (GC) exposure. The purpose of this study was to determine whether administration of the synthetic GC dexamethasone (DEX) to infant rats increased the extent of damage due to intrastriatal injection of N-methyl-D-aspartate (NMDA). DEX 0.1 mg/kg (n=13) or vehicle (n=13) was administered i.p. on day 6 of life. Twenty four hours later NMDA 12.5 nmol was injected into the right posterior striatum (CPU) under ether anesthesia. Brains were removed on day 12 of life. Cross sectional areas of CPU, hippocampal formation (HIP), neocortex (CX), and hemisphere (HEMI) ipsi- and contralateral to NMDA injection were measured from Nissl stained sections with a microcomputer image analysis system. Left-right area differences [(L-R)/L] were calculated for all regions and treatment groups were compared using analysis of variance.

Lesions consisting of neuronal loss, gliosis and reduced cross-sectional area of the right CPU as well as overlying HIP and CX resulted in all animals. The reduction in regional cross sectional areas ipsilateral to NMDA injection was not significantly greater in animals pretreated with DEX compared to controls (reduction on right side, DEX vs. control: CPU 30% vs. 33%; HIP 47% vs. 45%; CX 26% vs. 20%; HEMI 14% vs. 14%). Although DEX pretreatment protects the infant rat brain from hypoxic-ischemic damage (Pediatr. Res., in press, June 1991) this benefit does not extend to excitotoxic injury due to NMDA injection. Nevertheless, glucocorticoids do not appear to enhance the vulnerability of the immature brain to excitotoxic injury.

316.9

Effects of N-methyl-D-aspartic acid in neonatal monosodium glutamate treated rats. C. Ryan¹*, C. Smythe²*, R. Brown^{1,2}, and M. Wilkinson². Depts. Psychology¹ and Physiology & Biophysics², Dalhousie Univ., Halifax, N.S., Canada, B3H 4J1.

Neonatal treatment of rats with acute doses of monosodium glutamate (MSG) accelerates sexual maturation (MacDonald & Wilkinson, *Neuroendocrin.*, 1990, **52**, 143-149). In the young rat, antagonists of the glutamate analogue N-methyl-D-aspartate (NMDA) exhibit anxiolytic action, while NMDA itself reportedly increases isolation stress in rat pups as measured by ultrasonic vocalization (UV) rate (Windsor et al., *Eur. J. Pharmacol.*, 1990, **190**, 11-21). We have investigated the disruptive effect of MSG on behavioral development by giving neonatally MSG treated pups a pharmacological challenge of NMDA. We were interested in whether earlier treatment with MSG would modify the pups response to an NMDA challenge.

At two days of age rat pups (Sprague Dawley) from two sources (Charles River and Canadian Hybrid Farms) received a single s.c. dose of 2.0 mg/kg MSG or saline vehicle. At ten days of age, these two groups were split, half of each receiving a single s.c. dose of NMDA (2.5 mg/kg) or saline. 30 minutes later, pups were assessed on a number of parameters including, ultrasonic vocalizations, core temperature, activity, movement, and negative geotaxis. Animals treated with NMDA showed signs of increased stress including hyperlocomotion, lowered core temperature, and stiff hyperextension of the tail. However, UV rates were not altered. With the exception of UV, NMDA increased behavioral stress responses, confirming its anxiogenic potential and this effect was modified by neonatal MSG treatment, particularly in the CHF strain.

316.11

UBIQUINONE PROTECTS CEREBELLAR GRANULE CELLS AGAINST GLUTAMATE-INDUCED CYTOTOXICITY. A. Favit*, F. Nicoletti, U. Scapagnini* and P.L. Canonico. Institute of Pharmacology, University of Catania, 95100, Catania, Italy.

Ubiquinone (UBI) or coenzyme Q is an endogenous quinone with pharmacological actions probably related to its antioxidant properties. Here we report that UBI protects cultured cerebellar granule cells against glutamate-induced neurotoxicity. In control cultures at 8-9 DIV, a 20-min exposure to 100 μ M glutamate induced neuronal degeneration, as reflected by the high percentage of cells labelled with propidium iodide (>90%) 24 hours after the exposure. Glutamate-induced neuronal death was dramatically reduced in cultures treated daily with UBI (1 μ M) since the 1st day of maturation. In these cultures, glutamate failed to induce a "delayed" increase in the basal influx of ⁴⁵Ca²⁺, an established parameter of excitotoxicity. Similarly, repeated addition of UBI attenuated the age-dependent degeneration of granule cells that occurs after 10-12 days of maturation in culture, due to the toxic action of endogenous glutamate progressively released into the medium. These results suggest that UBI may be a useful drug in the therapy of acute and chronic degenerative diseases of the Central Nervous System.

316.13

THE PUTATIVE ESSENTIAL NUTRIENT PQQ PROTECTS AGAINST NMDA NEUROTOXICITY IN ASTROCYTE-POOR CORTICAL CULTURES. P.A. Rosenberg, C. Zhong*, P.M. Gallop*, and E. Aizenman. Children's Hosp. & Harvard Med. Sch., Boston, MA 02115; Dept. Phys., U. Pittsburgh Med. Sch., Pgh, PA 15261.

We have examined the actions of the soluble redox cofactor pyrroloquinoline quinone (PQQ) upon NMDA neurotoxicity in astrocyte-poor rat cortical cultures in which drugs and enzymes in the medium have free access to dendrites. Exposure of cultures to the reducing agent dithiothreitol (DTT; 1-2 mM) increased the sensitivity of cortical neurons to a thirty minute exposure to 50-75 μ M NMDA. Exposure to 50 μ M PQQ protected neurons exposed to DTT against NMDA toxicity. This effect of PQQ could not be blocked by superoxide dismutase (SOD; 10 μ g/ml) and catalase (CAT; 10 μ g/ml). Exposure to PQQ following DTT, without extensive washing between these steps, resulted in delayed neurotoxicity independent of NMDA receptor activation which could be blocked by SOD and CAT. We conclude that one mechanism of action of PQQ involves direct interaction with the redox modulatory site. The possibility of an indirect action, e.g. via formation of oxygen-derived free radicals, has not been excluded, and would be expected in the presence of a suitable electron donor.

MK-801 PREVENTS BODY AND ORGAN WEIGHT REDUCTIONS IN THE ADULT RAT RESULTING FROM NEONATAL ADMINISTRATION OF MONOSODIUM GLUTAMATE. J. Kleim*, M. Saari, K. Fisher*, R. Turner*, M. McIsaac*, & E. Bowen*. Neuroscience Research Unit, Nipissing University, North Bay, Ont. Canada.

On day 4 postpartum, half of 48 male rat pups were injected (s.c.) with 1mg/kg of MK-801 and the other half with an equivalent volume of physiological saline. Thirty minutes later, half of each group were then injected with 4g/kg of MSG (s.c.) and the other half with an equivalent volume of physiological saline, yielding 4 treatment groups: MK/MSG, MK/SAL, SAL/MSG and SAL/SAL. On day 70 postpartum, the animals were sacrificed via CO₂ asphyxiation and the carcasses immediately dissected. Results show that MK-801 blocks the reduction in brain, liver, testis and body weights associated with neonatal exposure to MSG. The possible adverse effects of MK-801 on organ development are discussed.

316.12

OXIDATION OF THE NMDA RECEPTOR REDOX MODULATORY SITE BY PYRROLOQUINOLINE QUINONE (PQQ).

E. Aizenman, K.A. Hartnett, C. Zhong*, P.M. Gallop* & P.A. Rosenberg U. of Pittsburgh Sch. of Med., Pgh, PA 15261 and Children's Hosp. and Harvard Med. Sch., Boston, MA 02115.

The putative nutrient PQQ can efficiently mediate reduction and oxidation reactions in a variety of systems. Therefore, we investigated whether this compound could alter the function of the N-methyl-D-aspartate (NMDA) receptor via its redox modulatory site (Aizenman et al., *Neuron* 2:1257; 1989). In rat cortical neurons *in vitro* PQQ (50 μ M) could reverse the enhancement of NMDA-induced whole-cell ionic currents produced by the reducing agent dithiothreitol (DTT; 2-4 mM), as well as depress native responses in a DTT-reversible fashion. PQQ mediated oxidation may occur via the generation of oxygen free radicals and we have observed that these species are effective at oxidizing the NMDA receptor redox site (Aizenman et al., *Neuron* 5:841; 1990). However, inclusion of 20 μ g/ml each of superoxide dismutase and catalase did not prevent the oxidizing actions of PQQ. Finally, 50-200 μ M PQQ was also observed to produce a significant degree of neuroprotection in an acute model of NMDA-mediated neurotoxicity in astrocyte-rich cultures of rat cerebral cortex. These results suggest a novel role for PQQ, PQQ-like substances, and for quinone containing proteins in the brain, and may represent a novel therapeutic approach for the amelioration of NMDA receptor-mediated neurotoxic injury.

316.14

AMELIORATION OF GLUTAMATE TOXICITY BY KYNURENIC ACID:

³¹P NMR SPECTROSCOPY STUDIES OF PERFUSED, LIVE RAT CEREBROCORTICAL SLICES. M.T. Espanol*, G.Y. Yang*, L. Litt, P.B. Weinstein, P. Chan and T.L. James*. Departments of Pharmaceutical Chemistry, Anesthesia, Neurosurgery, Radiology, and CVRI, University of California, San Francisco, CA 94143.

Glutamate (glu) is toxic to neurons in acute ischemia. Metabolic toxicity of 60 min exposures to glu was studied with ³¹P NMR spectroscopy in live, normoxic cerebrocortical slices (350 μ) obtained from neonatal Sprague Dawley rats. Within 5 min after initiating exposures to glutamate concentrations above 1 mM, intracellular decreases were seen in pH, phosphocreatine (PCr), and adenosine triphosphate (ATP), while an increase was seen in inorganic phosphate (Pi). After discontinuation of glu \leq 1 mM, ³¹P metabolites recovered to control levels. In contrast, after 60 min exposure to \geq 5 mM glu, no recovery was observed during or after 60 min reperfusion with normal medium. Partial recovery of ³¹P metabolites was observed for brain slices exposed to 2 and 3 mM glu. Kynurenic acid (kynu), a glu receptor antagonist, was administered with the same glu protocols. Exposure of slices to both 3 mM glu and 1 mM kynu produced delays in the rates of decrease of pH, PCr, and ATP and a delay in the rate of increase of Pi. The results demonstrate that deleterious changes to the ³¹P NMR energy profile of slices occurs with administration of glu, and that addition of a glu receptor antagonist has protective effects. The study directly links dysfunctions in brain energy metabolism with glu neurotoxicity, which is widely acknowledged to be associated with Ca²⁺ influx and subsequent amplification of Ca²⁺-associated events.

NMDA NEUROTOXICITY AND ITS ENHANCEMENT BY DITHIOHREITOL IS ANTAGONIZED BY CGS-19755.

Karen A. Hartnett, Hai N. Vo and Elias Aizenman, Dept. of Physiology, Univ. of Pittsburgh Sch. Med. Pittsburgh, PA 15216.

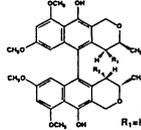

The neuroprotective properties of the novel NMDA receptor antagonist CGS-19755 (*cis*-4-phosphonomethyl-2-piperidine carboxylic acid) were studied in cultures of rat cerebral cortex under normal and altered redox conditions (Aizenman et al., *Neuron* 2: 1257, 1989). This antagonist was effective in preventing neurotoxicity induced by a prolonged (24-72 hr) exposure to 500 μ M glutamate with an EC₅₀ near 5 μ M. Furthermore, 100 μ M CGS-19755 was also effective in preventing delayed neuronal death produced by an acute (5 min) exposure to either glutamate (500 μ M) or NMDA (500 μ M). In contrast, toxicity induced by a prolonged exposure to kainate (500 μ M) was not blocked by 100 μ M of this antagonist. We observed that the reducing agent dithiothreitol (DTT; 500 μ M), but not oxidized DTT, could dramatically enhance the toxicity and electrophysiological responses produced by 50 μ M NMDA, and that CGS-19755 (100 μ M) was effective in blocking these effects. Any toxicity produced by higher concentrations of DTT alone were also antagonized by CGS-19755. These results indicate that CGS-19755 is an effective and specific neuroprotectant acting at the NMDA receptor, and that the enhancement in toxicity induced by DTT is mediated by an increase in activity at this receptor complex. Supported by NIH grant NS29365.

THE DISCOVERY OF ES-242-1 FROM A MICROBIAL SOURCE AND ITS CHARACTERIZATION AS A NOVEL TYPE OF NMDA ANTAGONIST.

Y. Matsuda, S. Toki, M. Nozawa, M. Yoshida, H. Sano, K. Ando, and I. Kawamoto, Kyowa Hakko Kogyo Co., 3-6-6 Asahimachi, Machida-shi, Tokyo 194, Japan.

We isolated ES-242-1, a novel bioanthracene, from the culture broth of *Verticillium* sp. ES-242-1 competitively inhibited the binding of [³H]MK-801 to NMDA receptor complex in rat brain synaptic membrane fractions with an IC₅₀=66nM. It also competitively inhibited the binding of [³H]CGS19755 with an IC₅₀=1.1 μ M, while it did not inhibit the binding of [³H]glycine, [³H]kainate, [³H]AMPA, or [³H]3-PPP. These data show that HS-142-1 specifically interacts with both the glutamate recognition site and the channel domain. Using a histofluorescence staining method, we examined the protective effects of ES-242-1 on glutamate-induced neuronal death in primary cultures of hippocampal neurons prepared from fetal mice. ES-242-1 significantly blocked the glutamate-induced neurotoxicity to a similar extent as MK-801, but not neurotoxicity induced by kainate or quisqualate. ES-242-1 is a new chemical existence with a novel mechanism of action at the NMDA receptor, and as such may provide a new tool for understanding the molecular pharmacology of this receptor and may possess neuroprotective properties useful in the treatment of disease involving glutamate toxicity.

316.19

SELECTIVE DESTRUCTION OF THE THALAMIC RETICULAR NUCLEUS BY DOMOIC OR KAINIC ACID

E.B. Friedberg*, and D.T. Ross, Head Injury Center, Division of Neurosurgery, University of Pennsylvania, and Hahnemann University School of Medicine, Philadelphia, PA 19104

Domoic acid (DA), a potent analogue of the excitatory amino acid kainic acid (KA), produces memory and attentional deficits in humans who have ingested shell fish contaminated with this excitotoxin. The thalamic reticular nucleus (RT), by virtue of its location, connections and intrinsic properties, has been implicated as playing a major role in attentional processes. This study was designed to establish 1) whether the RT was vulnerable to DA toxicity and 2) whether complete and selective lesions of the RT could be produced with intrathalamic KA or DA injections.

Adult Long Evans rats anesthetized with chloral hydrate were given stereotaxic injections (4 x 0.025 μ l each) of either 0.1% DA or 0.5% KA at the coordinates of their RT and allowed to survive for 7 days. RT lesions were characterized by almost total neuronal loss and dense microglial proliferation throughout the entire RT. In most cases neuronal loss was restricted entirely to the RT and relay neurons in adjacent regions of the VPL were spared. In a few cases where the injections were too large, too fast, or too medial the lesions extended into the VPL or VPM.

Upon awakening from anesthesia the rats exhibited hyperactive-stereotyped paddling movements that evolved into brief episodes of ballistic jumping followed by periods of hypoactivity with intermittent bursts of vigorous-awkward grooming and wet dog shakes. The rats were disoriented and nonresponsive to vibrissal stimulation. One day later rats were hypoactive with decreased whisking and exploratory behavior, and a diminished responsiveness to visual and tactile stimulation.

The death of RT neurons has been postulated to be the organic basis for some types of post traumatic and post ischemic attentional and sensory processing deficits. Selective RT lesions produced by either KA or DA may be an efficacious means with which to study the neurobehavioral role of the RT (Supported by NIH Grant 5-T32-MH 18902 (EBF); NIH BRSG 2-507-RR05415-29, and R01 NS-28852 (DTR))

ANIRACETAM PREVENTS GLUTAMATE-INDUCED NEUROTOXICITY.

M.Pizzi, C.Fallacara*, M.Memo, P.F.Spano, Dept. Biom. Sci. & Biotech., Section Pharmacol. Exper. Ther. School of Medicine, Univ. Brescia, I-25124

The effect of aniracetam, a novel nootropic drug, was studied on the neuronal damage induced by different glutamate receptor activation in a preparation of rat cerebellar granule cells. We observed that the rapid cell loss induced by 15 min application of 50 μ M glutamate was significantly prevented by the addition of aniracetam at concentrations higher than 1 μ M. Moreover, aniracetam counteracted the glutamate-mediated slow neurotoxicity reproduced by 24 h application of 20 μ M AMPA or 60 μ M kainate. The maximal effect for neuroprotection was obtained with 7 μ M aniracetam. Higher concentrations were less effective.

Finally, aniracetam greatly potentiated the protective effect elicited by quisqualate on both AMPA- and kainate-induced neuronal death. A role for aniracetam in potentiating the quisqualate metabotropic receptor transmission will be discussed.

316.18

Mg²⁺ AND ACUTE EXCITOTOXICITY ASSOCIATED WITH METABOLIC STRESS. G.D. Zeevalk and W.J. Nicklas, Dept. Neurology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854

Several laboratories have demonstrated the involvement of the NMDA receptor during metabolic stress. Data from our laboratory indicate that changes in the physiological state of the receptor rather than increases in extracellular glutamate or aspartate (EAAs) may be responsible for activation of the receptor such that the receptor could become activated by low endogenous or ambient levels of EAAs when energy stores are compromised. One hypothesis for the mechanism by which this may occur is by mitigation of the voltage dependent Mg²⁺ blockage of the NMDA channel caused by a deteriorating membrane potential (MP). Previous studies in which MP was titrated with increasing extracellular K⁺ supported this proposal since gradually decreasing the MP caused NMDA-mediated acute excitotoxic cell swelling and GABA release in embryonic chick retina without any net increase in extracellular EAAs (JPET 253, 1991). The above hypothesis was further tested in the present study by examining the dose response characteristics for NMDA, glutamate and kainate in the presence or absence of Mg²⁺ and by examining the effects of 0 Mg²⁺ on pharmacologically induced metabolic inhibition. The studies showed that removal of Mg²⁺ greatly decreased the minimal concentration needed to produce acute excitotoxicity in retina; 25 versus 5 μ M for NMDA and 300 versus 10 μ M for glutamate in 1.2 and 0 mM Mg²⁺, respectively, and shifted the EC₅₀ for swelling induced GABA release to the left for both agonists. Mg²⁺ removal had no effect on kainate induced toxicity. Acute swelling and GABA release caused by pharmacological inhibition of metabolism was not potentiated in the absence of Mg²⁺ and was attenuated by high Mg²⁺ (20 mM) consistent with the proposal that the Mg²⁺ block is lifted during metabolic inhibition.

ANTAGONISM OF Ca²⁺-DEPENDENT GLUTAMATE RELEASE BY SUBSTITUTED GUANIDINES. S. Katragadda, J.B. Fischer, D. Daly, N.I. Reddy, J.F. Keana, D.J. Adams, and S.M. Goldin, Cambridge Neuroscience, Cambridge MA; Chem. Dept., U. of Oregon; Pharmacol. Dept., U. of Miami Med. Sch., Miami Fla.; Camb. NeuroSci. & Dept. of Biol. Chem., Harvard Med. Sch., Boston MA.

³H-glutamate (GLU) release from rat brain synaptosomes was resolved with ~60 msec time resolution by rapid superfusion (c.f. Turner et al. [1989] Anal. Biochem. 178, 8). Three distinct components of GLU release stimulated by K⁺-depolarization were observed: a rapidly decaying ("phasic") Ca-dependent component (decay constant <100 msec), a more persistent Ca-dependent component, and a Ca-independent component that may result from reversal of the Na-dependent GLU uptake system. Several substituted guanidines were found to selectively block Ca-dependent GLU release at 10 μ M concentrations. The ability of these compounds to block K⁺-stimulated synaptosomal ³Ca uptake, correlated well with their ability to block the persistent (r²=0.965) but not the phasic (r²=0.364) component of Ca-dependent GLU release. CNS 1029 (10 μ M) selectively blocked persistent vs phasic GLU release. Whole cell recordings from cultured neurons from rat parasympathetic ganglia during extracellular perfusion with CNS 1029 revealed inhibition of depolarization-activated high threshold Ca currents, with a K_{1/2} of ~10 μ M; in the same preparation, no significant effect of CNS 1029 on voltage-gated Na or K currents were observed. We hypothesize that blockade of GLU release in the synaptosomal preparation is due to antagonism of a subclass of Ca channels present in glutamatergic nerve terminals. These compounds are potential attenuators of glutamate excitotoxicity *in vivo*. Selective block of the persistent vs. the phasic component of GLU release may be a desirable characteristic for a neuroprotective agent.

317.1

LOCALIZATION OF GLUTAMATE RECEPTOR TYPES IN THE RAT BRAIN USING CHARACTERIZED ANTIPEPTIDE ANTIBODIES. R.S. Petralia and R.L. Wenthold, Lab. of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

Antibodies were made to synthetic peptides corresponding to the C-terminal segments of the glutamate receptor (GluR). These peptides were SHSSGMPLGATGL, EGYNVYIGIESVKI, and RQSSGLAVIASDLP for GluR A, B/C, and D, respectively. Peptides were conjugated to BSA with glutaraldehyde and injected into rabbits. The antibodies were affinity purified using the peptides, either the entire peptide or shorter portions of it, covalently attached to agarose. Antibodies were characterized with respect to their immunoprecipitation of solubilized ³H-AMPA binding activity and their staining patterns on western blots. Antibodies to GluR A, B/C, and D immunoprecipitated 28%, 56%, and 13% of solubilized ³H-AMPA binding activity, respectively. On immunoblots of rat brain samples separated on SDS polyacrylamide gels, each antibody showed an immunoreactive band corresponding to the GluR subunit. Antibodies to GluR B/C often showed a poorly resolved dimer.

Immunocytochemistry was carried out on vibratome sections of rat brain fixed with 4% paraformaldehyde with or without 0.1% glutaraldehyde using avidin-biotin-peroxidase visualization. Highest labelling was found in the hippocampus, olfactory bulb and cerebellum. In contrast, labelling was moderate to low in many regions of the brainstem. Often, distinct differences in staining were evident among the 3 antibodies. For example, in the cerebellum, antibodies to A and D stained Bergmann glia, while the granule cell layer stained with antibodies to B/C and D.

Ultrastructural studies in the cerebrum and hippocampus revealed antibody labelling for all 3 receptor types localized in the postsynaptic densities, as well as in the cytoplasm of the dendritic processes. Typically, labelled synapses contained asymmetric densities and round vesicles. No presynaptic labelling was evident.

317.3

LOCALISATION OF A RAT METABOTROPIC GLUTAMATE RECEPTOR mRNA IN RAT BRAIN BY *IN SITU* HYBRIDIZATION. Peter Kristensen*#, Eileen Mulvihill*\$, Betty Haldeman*\$, Teresa Gilbert*\$ and Birgitte Guldhalmmer#. #CNS Division, Novo Nordisk, Måløv, Denmark. \$ZymoGenetics Inc., Seattle, WA 98105.

A cDNA coding for a G-protein coupled (metabotropic) glutamate receptor was isolated by expression cloning in frog oocytes (Houamed *et al.*, Science, in press (1991)). Two non-overlapping subclones of this cDNA was used to prepare RNA probes for *in situ* hybridization. 35-S labeled anti-sense and sense probes was employed on adjacent sections of rat brain. Expression was found in cerebellum, olfactory bulb, tenia tecta, hippocampus, diagonal band nucleus, caudate putamen, lateral septal nucleus, medial geniculate nucleus, reticular part of substantia nigra, the red nucleus and a number of brain stem and thalamic nuclei. Lower, but definite expression was seen in cerebral cortex.

317.5

GLUTAMATE RECEPTOR GENE EXPRESSION IN DEVELOPING RAT BRAIN: AN *IN SITU* HYBRIDIZATION STUDY. R.S. Zukin, M.Y.L. Bennett and D.E. Pellegrini-Giampietro, Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461.

Glutamate receptors are thought to play a major role in synaptic plasticity, neuronal survival and excitotoxicity in the developing brain. The present study examined the developmental pattern of GluR-1, -2, and -3 gene expression in rat brain. *In situ* hybridization revealed different spatial patterns throughout the brain for the related mRNAs at all ages examined, as well as different temporal patterns during development. In adult all mRNAs were expressed prominently in the pyramidal and granule layers of hippocampus and in the Purkinje cell layer of cerebellum, where detailed differences among probes were apparent at the cellular level. In neocortex, GluR-2 mRNA exhibited prominent lamination and regional differences which were less marked for GluR-1 and -3 mRNAs. In caudate-putamen GluR-2 mRNA was at high levels; but GluR-1 and -3 were not. At early ages transcripts were transiently elevated relative to adult levels. GluR-1 mRNA reached peak expression in cortex at P14 (225% of adult), striatum at P4 (255% of adult), hippocampus at P14 (195% of adult), and cerebellum at P21 (150% of adult). GluR-3 exhibited more modest peaks in neocortex and hippocampus. In contrast, GluR-2 message was at near adult levels at P4 and exhibited a peak only in cerebellum at P14 (168% of adult). GluR-1 and -3 homomeric channels are permeable to Ca²⁺, heteromers with the GluR-2 subunit are not (McGurk *et al.*, this meeting). Thus, cells in specific brain regions may contain glutamate receptors that differ significantly in their functional properties at different stages in development depending on whether they express GluR-2 mRNA.

317.2

BIOCHEMICAL CHARACTERIZATION AND LOCALIZATION OF NON-NMDA GLUTAMATE RECEPTOR IN THE RAT BRAIN.

C.D. Blackstone, S.J. Moss, L.J. Martin, A.I. Levey, D.L. Price and R.L. Huganir, Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

The structure and distribution of non-NMDA glutamate receptors in the rat brain were studied using subunit-specific antibodies for the receptor subunit GluR1. This subunit is found to be a 106 kD glycoprotein in human 293 cells transfected with the GluR1 cDNA as well as the rat brain. Immunoblotting of dissected brain regions shows an enrichment in the hippocampus and cerebellum. Immunocytochemical localization demonstrates a heterogeneous distribution on neurons within the CNS, closely matching the results of [³H]AMPA autoradiography. Interestingly, in the cerebellum GluR1 is localized to the Bergmann glial processes. When GluR1 is solubilized with CHAPS, both high-affinity AMPA binding and GluR1 immunoreactivity comigrate at a M_r = 610,000 by gel-exclusion chromatography and sucrose gradient density centrifugation. Purification of a non-NMDA glutamate receptor by domoic acid affinity chromatography reveals a single band at 106 kD on SDS-PAGE by silver staining. This protein band is recognized by the specific GluR1 antibodies. These data suggest that GluR1 is a subunit of an oligomeric AMPA-preferring glutamate receptor, most likely a pentamer of similarly-sized subunits, which has roles in neuronal and glial signaling.

317.4

LOCALIZATION OF GLU-A RECEPTOR mRNA IN THE SUBSTANTIA NIGRA AND VENTRAL TEGMENTAL AREA. Ma-Li Wong and Ariel Y. Deutch, Department of Psychiatry, Yale University School of Medicine, New Haven, CT 06510 and Psychiatry Service, Veterans Affairs Medical Center, West Haven, CT 06516.

Transmitter release from dopamine (DA) neurons innervating the striatal complex can occur secondary to an increase in the firing rate of DA neurons, or alternatively can occur via presynaptic (impulse-independent) regulation at the axon terminal. An example of the latter mode is the release of striatal DA in response to excitatory amino acids such as glutamate. In an effort to determine the localization of excitatory amino acid receptors in the striatal complex, we have examined the distribution of an AMPA family receptor (Glu A) mRNA. Oligonucleotide probes complementary to the Glu A receptor mRNA (flop) were used for *in situ* hybridization histochemistry. This Glu A mRNA was localized to a variety of CNS sites, including the ventral mesencephalon. Glu A receptor gene expression was observed throughout the pars compacta of the substantia nigra. In addition, Glu A mRNA was present in the ventral tegmental area, particularly within the dorsolateral (nuc. parabrachialis pigmentosus) region. Studies are under way to confirm that this receptor is expressed specifically in DA neurons. These data suggest that glutamate and other excitatory amino acids may presynaptically elicit DA release via interactions with a KA/quisqualate type excitatory amino acid. Supported by MH-45124, the Schizophrenia Res. Ctr. of the West Haven VAMC, and the Natl. Parkinson Foundation Center at Yale Univ.

317.6

GLUTAMATE RECEPTOR GENE EXPRESSION IN KINDLED RATS. S.L. Moshé, D.E. Pellegrini-Giampietro, E.F. Sperber, S.G. Xu, M.Y.L. Bennett and R.S. Zukin, Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Glutamate receptors have been implicated in the establishment of kindling, an animal model of chronic epilepsy. Glutamate receptor antagonists can retard the development and block the expression of kindling, and receptor binding studies indicate that both NMDA and non-NMDA type glutamate receptors are altered in the hippocampus following kindling. This study was conducted to determine whether the receptor changes are associated with alterations in non-NMDA glutamate receptor gene expression. *In situ* hybridization was used to examine the levels of GluR-1, -2 and -3 mRNAs (encoding channels activated by both kainate and AMPA) in amygdala kindled as compared to control rats. Kindling was produced with stimulations (1 sec train, 400 μ A peak to peak, 60 Hz sine wave current) administered 3 times daily. Upon acquisition of three stage 5 kindled seizures, stimulations were terminated and rats were sacrificed 3 or 15 days later. Sections (20 μ m) from the brains of kindled and control rats were hybridized at high stringency with ³⁵S-labeled riboprobes transcribed from GluR-1, -2, and -3 cDNAs (10⁶cpm/section). Three days after development of kindling, the levels of all 3 mRNAs were increased in the granule cells of the dentate gyrus relative to levels in control rats. Conversely, after 15 days, labeling (especially for GluR-2) was decreased markedly in all regions studied, including hippocampus and neocortex. These results indicate that alterations in kainate/AMPA-type glutamate receptor expression may play a causal role in kindling.

317.7

GLUTAMATE RECEPTOR GENE EXPRESSION IN NEONATE AND ADULT RATS FOLLOWING FLUROTHYL- AND KAINATE-INDUCED SEIZURES. L.K. Friedman, D.E. Pellegrini-Giampietro, E.F. Sperber, M.V.L. Bennett, S.L. Moshe and R.S. Zukin. Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Glutamate receptors are thought to play a role in epilepsy. NMDA and non-NMDA receptor blockers possess anticonvulsant properties and can prevent seizure-induced brain damage. Moreover, seizures induced in adult animals by any of a number of agents result in brain damage resembling glutamate cytopathology and in glutamate receptor loss. An important question is whether these changes are associated with altered glutamate receptor gene expression. *In situ* hybridization was used to measure levels of GluR-1, -2 and -3 mRNAs (which encode channels activated by both kainate and AMPA) in status epilepticus induced by systemic administration of (i) flurothyl in 15 day old rat pups and by (ii) kainate in pups and adults. Brain sections from control and seizure-induced animals were hybridized with ³⁵S-labeled riboprobes transcribed from GluR-1, -2 and, -3 cDNAs. Morphological lesions and levels of mRNAs were monitored in film autoradiograms and emulsion-dipped sections. No morphological or mRNA changes were seen in brain sections from flurothyl- or kainate-treated neonates. Selective brain damage was observed in limbic regions of adult rats following kainate-induced seizures. In these animals all 3 receptor mRNAs were virtually absent in the CA3 field of the hippocampus, presumably due to cell loss. However, increased labeling (most prominent for GluR-3) was observed in granule cells of the dentate gyrus, which project to CA3. This increase in expression may be related to kainate-induced destruction of CA3 cells and may lead to synaptic reorganization. Thus, the different patterns of neurodegeneration in adults vs. neonates after seizure may lead to differences in glutamate receptor gene expression.

317.9

GLUTAMATE RECEPTOR GENE EXPRESSION IN DEVELOPING RAT BRAIN: A NORTHERN ANALYSIS STUDY. G.M. Durand, M.V.L. Bennett and R.S. Zukin. Dept. of Neuroscience, Albert Einstein College of Med., Bronx, NY 10461.

The recent cloning and sequencing of cDNAs encoding a family of non-N-methyl-D-aspartate (NMDA) glutamate receptors indicate that these belong to the large superfamily of ion channel forming receptors. We examined the developmental pattern of GluR-1, -2, and -3 gene expression in embryonic and neonatal rat brain by Northern analysis using full-length ³²P-labeled riboprobes under conditions of high stringency. Northern analysis with GluR-1 and -3 riboprobes revealed the presence of an abundant 5.2 kb RNA species and minor bands of ~ 3.2 and ~ 3.9 kb in poly(A)⁺RNA isolated from all ages and regions examined. In contrast, hybridization of these same samples with the GluR-2 riboprobe revealed two RNA species, ~ 5.9 and ~ 3.9 kb, of about equal abundance. The ratio of the 5.9 to 3.9 kb species labeled by GluR-2 remained nearly constant in all tissues and all ages examined. In the developing animal the GluR-1 5.2 kb species was first detected in whole brain mRNA at embryonic day 16; highest expression (normalized to 18s rRNA) was observed at postnatal day 28 (P28) (133% adult level). GluR-1 mRNA reached peak expression at P28 in hippocampus (~ 200% of adult) and in cerebellum (~ 300% of adult). GluR-2 and GluR-3 mRNAs reached their peak expression (>200% of adult) at P28 in hippocampus and neocortex. These findings show differential regulation of GluR mRNAs during development with transient elevation of specific mRNAs in specific regions.

317.11

EXCITATORY AMINO ACID BINDING SITES IN THE SPINAL TRIGEMINAL NUCLEUS OF RAT AND HUMAN. S.J. Tallaksen-Greene¹, A.B. Young¹, J.B. Penney¹, and A.J. Beitz² ¹Department of Neurology, University of Michigan, Ann Arbor, MI 48104-1687 and ²Department of Veterinary Biology, University of Minnesota, St. Paul, MN 55108.

The spinal trigeminal nucleus (STN) is involved in the processing of orofacial sensory information. Previous studies suggest that excitatory amino acids (EAAs) are contained within trigeminal primary afferent neurons and may play an important transmitter role in the processing of nociceptive information. We have examined the distribution of excitatory amino acid binding sites in the STN of rat and human using *in vitro* autoradiography.

Within the subnucleus caudalis of both rat and human, the outer laminae (I and II) contained a high density of NMDA, ionotropic-quisqualate (AMPA), metabotropic-quisqualate and kainate binding sites. This region has been shown to receive a major input from nociceptive and thermal receptors. In contrast, the density of EAA receptors was generally very low within the inner magnocellular portion of nucleus caudalis (laminae III and IV), regions known to contain wide-dynamic range neurons and low-threshold mechanoreceptive neurons. Likewise, low densities of EAA binding sites were observed in rat STN subnuclei interpolaris and oralis. These findings support the hypothesis that excitatory amino acids are neurotransmitters involved in the processing of orofacial nociceptive information.

Supported by USPHS grants DE 06682, DA 06687 and AG 08671.

317.8

GLUTAMATE RECEPTOR GENE EXPRESSION IN NEURODEGENERATIVE DISEASES. D.E. Pellegrini-Giampietro, Bennet M.V.L. and R.S. Zukin. Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461.

Excitatory amino acid (EAA) systems are thought to play a major role in the pathogenesis of neurodegenerative diseases such as Huntington's disease (HD) and Alzheimer's disease (AD). Neurotoxins acting at EAA receptors produce lesions closely resembling those seen in these pathologies, and EAA receptor numbers are altered in autopsy tissue from HD and AD patients. *In situ* hybridization experiments were undertaken to examine the levels of GluR-1, -2, and -3 mRNAs (encoding channels activated by kainate and AMPA) in normal and diseased human brain. Sections (20 μm) of human autopsy material were hybridized under conditions of high stringency with ³⁵S-labeled GluR-1, -2, and -3 riboprobes transcribed from rat brain cDNA. Autoradiograms of human brain hippocampal sections hybridized with riboprobes for GluR-1, -2, and -3 mRNAs displayed selective labeling over dentate gyrus, pyramidal cells of Ammon's horn, subiculum, and entorhinal cortex. Striatal sections also displayed specific glutamate receptor mRNA hybridization. In emulsion dipped sections labeling was observed at the cellular level in dentate gyrus granule cells and in CA1 and CA3 pyramidal cells. Competition experiments indicated the virtual absence of cross-hybridization under these labeling conditions. Brain tissue from HD and AD patients is also being examined. To date, labeling was found to be significantly lower in AD hippocampal sections relative to control autopsy tissue from age- and sex-matched controls. These studies should provide new insights into mechanisms underlying these neurodegenerative diseases.

317.10

GLUTAMATE RECEPTOR BINDING IN THE FROG BRAIN. H.T. Cline, J. McDonald, M. Constantine-Paton. Dept Physiology & Biophysics, Univ. Iowa; Dept Neuroscience, U. Michigan; Dept Biology, Yale Univ. We used receptor binding techniques to map the presence of Quis and NMDA type glutamate receptors in the brains of postmetamorphic and adult frogs. The highest Q binding was seen in telencephalon, pallium (the frog's version of the hippocampus), ventral hypothalamus, basal optic nucleus, preoptic area and cerebellum, all of which have 25-33 pmol/mg protein. The highest N binding was seen in telencephalon, cerebellum and preoptic area, which have 2.4 - 3.9 pmol/mg protein. We determined to ratio of N binding to Q binding for postmets and adults as a possible indicator of the relative degree of plasticity of the structure. In most brain regions (ie telencephalon, torus, optic nerve, layer 6 of optic tectum) the N/Q binding ratio is about 0.1 in both postmets and adults. However, in the superficial neuropil layer of the optic tectum, where NMDA receptor-mediated plasticity has been shown to occur, N binding is enriched relative to Q binding in postmets. Here the N/Q ratio is .256. In the adult the tectal neuropil and the lower rim cortex of the nucleus isthmi both share the highest N/Q ratios of .18. The deep layers of the tectum, which receive auditory input, display an elevated N/Q ratio of .18 in postmets. This value returns to about 0.1 in adults. Interestingly, significant Q binding is detected in several axon pathways, including the optic nerve (18.2 pmol/mg protein), tectal commissure (5.6 pmol/mg protein) and tecto-bulbar commissure (19 pmol/mg protein). NMDA binding could not be detected in these regions. Supported by NIH EY05818 (HTC), EY06039 (MCP), MSTP Grant 5 T326M07863-07 (JM).

DENSITY AND DISTRIBUTION OF GLUTAMATE RECEPTORS IN THE DEVELOPING HUMAN BRAIN: A QUANTITATIVE AUTORADIOGRAPHIC STUDY. Haesung Lee* and Ben H. Choi. Ewha Women's University, Seoul, Korea and University of California, Irvine, CA 92717.

Developmental changes in glutamatergic innervation of the CNS would provide valuable information not only of normal maturation but also of age-dependent selective vulnerability of the CNS to various insults. Using *in vitro* autoradiography, we have examined the status of the N-methyl-D-aspartate (NMDA), kainate (KA), and α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors in the brains of 18- and 26-week-old aborted human fetuses. Densities in outer and inner layers of 6 cortical regions including hippocampus, basal ganglia and thalamus were quantified (fmol/mg protein) using computer-assisted image analysis system. Regional heterogeneity and age-related changes in each receptor subtype were apparent. For example, AMPA densities were highest as compared to KA or NMDA at both ages. Highest labeling of all receptor subtypes was noted in the hippocampus at both ages. By 26 weeks, there was a significant increase in AMPA receptor densities in all regions, however, both NMDA and KA receptor densities were significantly lower as compared to those in 18-week-old fetus. In 18-week-old fetus, both KA and AMPA were prominently labeled in the basal ganglia, subthalamic nucleus and external lamina of the thalamus. NMDA densities, on the other hand, were prominent only in the ventral nuclei of the thalamus. In 26-week-old fetus, AMPA labeling was more in the outer cortical layers whereas NMDA and KA densities were significantly higher in the deeper cortical layers. These results provide essential baseline data for our understanding of the developmental plasticity as well as excitotoxic damage in the CNS. (Supported in part by NIH grant ES02928).

AUTORADIOGRAPHIC LOCALIZATION OF ^3H -MK 801 BINDING SITES IN THE RAT BRAIN. S. Kito, R. Miyoshi and T. Nomoto*. Division of Health Sciences, University of the Air, Chiba 260 and Department of Pharmacology, Tokyo Women's Medical College, Tokyo 162, Japan.

It has been advocated that the N-methyl-D-aspartate (NMDA) receptor complex consists of an agonist recognition site, a strychnine-insensitive glycine modulatory site and a cation channel. To detect the channel activity, MK 801 has become a useful tool. In the present study, in vitro autoradiographic studies of ^3H -MK 801 binding sites were done using the rat brain. ^3H -MK 801 binding were increased dose-dependently by L-glutamate, glycine and spermidine, when Triton X-100 treated sections were used. Distribution patterns of ^3H -MK 801 binding sites in the presence of either amino acids or spermidine were similar to those of binding sites for glycine and an NMDA antagonist, CPP. However, in the cerebellum, low but specific ^3H -MK 801 binding sites were detected when stimulated by either L-glutamate or glycine, although no specific binding sites were observed by adding spermidine. It has been reported that H-spermidine binding sites are more richly contained in the cerebellum than the hippocampus and cerebral cortex. Since an enhancing effect of ^3H -MK 801 binding by spermidine was not found in the cerebellum, it was considered that spermidine binding sites in this brain area had no relation with the NMDA receptor complex.

PHOSPHOLIPASE A₂ PRETREATMENT MODULATES DIFFERENT SUBTYPES OF NON-NMDA RECEPTORS: AN AUTORADIOGRAPHIC STUDY. M.Y. Catania*, J.B. Penney and A.B. Young. Dept. of Neurology, U. of MI., Ann Arbor, MI 48109.

Increasing evidence suggests that phospholipase A₂ (PLA₂) is involved in mechanisms underlying synaptic plasticity. We used in vitro quantitative autoradiography to evaluate the effect of PLA₂ pretreatment on NMDA and non-NMDA glutamate receptors in rat brain. Slices were pretreated with various concentrations (0.06-600 U/mg prot.) of PLA₂ from porcine pancreas and bee venom at 37° for 20' in presence of CaCl₂ (25 mM). In all regions examined, the pretreatment with concentrations equal or greater than 0.6 U/mg prot. of phospholipase A₂ increased [^3H]AMPA binding by 30-40 %, without affecting NMDA sensitive [^3H]glutamate and [^3H]kainate binding, in accord with other previous results performed in homogenates (Massicotte and Baudry, *Neurosci Lett* 118, 1990). In addition, in the pretreated slices, [^3H]Glutamate binding, to the metabotropic receptors was significantly increased by 25-30 % in CA1 of hippocampus (p<0.05). A significant increase in non-NMDA, non-Kain, non-Quis [^3H] glutamate binding was also observed in the dentate gyrus and in CA1 of the hippocampus.

Our results support the hypothesis that modification of different non-NMDA receptor binding properties by the activation of PLA₂, may play an important role in the mechanisms that regulate synaptic plasticity. Supported by CNR-Italy n. 224.04.10 cod. 24.04.10 and USPHS NS19613.

IN VIVO [^3H]MK-801 BINDING: NMDA-ASSOCIATED ION CHANNEL STATUS. C. Arons¹*, M. Thomas², T. McIntosh² and W. Shoemaker¹. Dept. Psychiatry¹ and Dept. Surgery², UConn Health Center, Farmington, CT 06030.

In vitro binding studies have shown that binding of MK-801 (N-methyl-D-aspartate noncompetitive antagonist) is dependent on the configurational state of the NMDA receptor. MK-801 binding increases if the NMDA receptor associated ion channel is open. Activation of both the glutamate and glycine binding sites of the receptor complex potentiate channel opening. We examined [^3H]MK-801 binding using in vivo binding methods. A tracer dose of [^3H]MK-801 was injected into the tail vein of anesthetized rats. After a 25 minute labelling period, animals were decapitated, and brains dissected. Tissue was homogenized, filtered, and radioactivity counted. The highest concentrations of specifically bound [^3H]MK-801 were detected in hippocampus and cortex, less in thalamus and hypothalamus, and very little in cerebellum. MK-801 binding increased in some regions following administration of NMDA and decreased following administration of CGS-19755 (NMDA competitive antagonist). These results suggest that in the anesthetized animal, the NMDA receptor complex may be active (open channel) in some regions, while in other regions it may be inactive (channel closed).

GLUTAMATE RECEPTOR ACTIVATION IS EVALUATED IN VIVO BY POSITRON EMISSION TOMOGRAPHY

C. Ferrarese, R.S. Miletich, J. Linfante, R. Brooks, D. Kiesewetter, A. Guidotti, E. Costa, R.E. Carson, M. Fulham, K.C. Rice, B.R. de Costa, K. Hayashida, K. Borbey and G. Di Chiro, N.I.H., Bethesda, MD and F.G.I.N., Georgetown University, Washington, DC.

The phencyclidine (PCP) derivative fluorothienylcyclohexylpiperidine (FTCP) binds in vivo to the PCP site of the NMDA-selective glutamate receptor (*Soc. Neurosci. Abst.* 1990, 16:396.5). Using [^{18}F] FTCP we performed eight PET experiments in four rhesus monkeys under curare immobilization. Heart rate, blood pressure, ECG, and EEG were recorded continuously. Serial arterial plasma samples were withdrawn to calculate the kinetics of drug disposal and metabolism. To date, PET and blood data were fully analyzed by the multiple-time graphical method and by compartmental analysis in two studies. In the control experiment, FTCP influx constants were greater in the cerebral cortex than in the cerebellum. N-methyl-D-aspartate, (NMDA) 150 mg/kg iv, induced prolonged EEG epileptic abnormalities and a parallel increase in FTCP influx in the temporal cortex. This suggests that activation of NMDA-selective glutamate receptors may be monitored in vivo by PET. This may be clinically useful in disorders involving glutamate receptor overstimulation, such as epilepsy, stroke, and neurodegenerative diseases.

EXCITATORY AMINO ACID RECEPTORS IN CONTROL AND ALZHEIMER'S AMYGDALA. W.F. Maragos, S.W. Newman, R.W. Price, A.B. Young and J.B. Penney. Depts. of Neurology and Anatomy and Cell Biology, Univ. Michigan, Ann Arbor, MI 48105.

The basolateral (BL) subdivision of the amygdaloid complex has properties in common with the cerebral cortex. This limbic structure has strong reciprocal connections with entorhinal and subicular cortices, regions with marked pathological changes in Alzheimer's disease. Using quantitative autoradiography, we analyzed ligand binding to the NMDA, AMPA and kainate receptor subtypes in the amygdala obtained post-mortem. Nuclear boundaries were determined using cholinesterase and cresyl violet stained sections. Thioflavin-S staining was also performed. In control tissue, 3H-glutamate binding to the NMDA receptor was highest in the basal medial and lateral nuclei, with moderate binding in the basolateral, accessory basal and basal central nuclei. 3H-AMPA binding was highest in the basal medial nucleus with moderate binding in the accessory basal, basal lateral, basal central and lateral medial nuclei. Binding was lowest in the lateral division of the lateral nucleus. 3H-kainate binding displayed little regional variation in binding. In Alzheimer's disease tissue, reductions of NMDA and AMPA receptors were confined to several of the basal nuclei, sparing the lateral nuclei. It may be significant that several subdivisions of the basolateral complex that have the greatest number of both NMDA and AMPA receptors are the same nuclei that send and receive projections to the entorhinal and subicular cortices. Supported by USPHS Grant AG08671

METABOTROPIC GLUTAMATE RECEPTORS AND REGULATION OF NEURONAL PLASTICITY. F. Nicoletti, G. Casabona*, G. Aleppo*, P. Dell'Albani#, C. Amico#, E. Aronica*, V. Perciavalle, K.G. Revmann* and D.F. Condorelli#. Institutes of Pharmacology, #Biochemistry and *Physiology, University of Catania, Italy; and #Institute for Neurobiology and Brain Research, University of Magdeburg, Germany.

Specific glutamate receptors coupled to polyphosphoinositide hydrolysis (metabotropic receptors) are present in neurons and astrocytes. Activation of metabotropic receptors in both cell types leads to a rapid and transient increase in the expression of immediate early genes, including zif/268, c-fos and c-jun. The activation of a coordinated transcriptional program implicates a role for metabotropic receptors in the regulation of neuronal plasticity. The antagonist L-2-amino-3-phosphonopropionate (AP3), shortens the duration of long-term potentiation (LTP) in the Schaffer collateral-CA1 synapse in the hippocampus, suggesting that activation of metabotropic receptors contributes to the series of events enabling the late expression of LTP. We are currently studying the activation of the specific transcriptional program that follows the induction of LTP in hippocampal slices incubated in the absence or presence of L-AP3.

NOOTROPIC DRUGS AS POSITIVE MODULATORS OF AMPA RECEPTORS. A.A. Genazzani*, A. Copani*, G. Aleppo*, P.L. Canonico and F. Nicoletti. Inst. Pharmacology, Univ. Catania, Italy.

Micromolar concentrations of piracetam, aniracetam, and oxiracetam enhanced AMPA-stimulated $^{45}\text{Ca}^{2+}$ influx in primary cultures of cerebellar granule cells. Nootropic drugs increased the efficacy, but not the potency, of AMPA and their action persisted in the presence of the voltage-sensitive calcium channel blocker, nifedipine. Oxiracetam and aniracetam had no effect on the stimulation of $^{45}\text{Ca}^{2+}$ influx induced by NMDA or kainate. Nootropics did not affect the stimulation of inositol phospholipid hydrolysis induced by quisqualate in cultured cerebellar neurons or by trans-ACPD in hippocampal slices, indicating that piracetam and its derivatives are devoid of activity on metabotropic receptors. To characterize further the mechanism of action of nootropics, we have studied [^3H]AMPA binding in membranes from rat cerebral cortex. All nootropic drugs increased the maximal density of low affinity [^3H]AMPA binding sites, without affecting the high affinity component of the binding. These results support the view (Ito et al., J. Physiol., 424, 1990) that nootropic drugs positively modulate AMPA receptors in neurons.

GABA RECEPTORS: FUNCTION III

318.1

SINGLE CHANNEL GATING KINETICS OF GABA_A RECEPTORS ACTIVATED BY DESENSITIZING CONCENTRATIONS OF GABA.

R.A. Gross and R.E. Twyman. Dept. of Neurology, Univ. of Michigan, Ann Arbor, MI.

When exposed to high agonist concentrations, ligand gated ion channels exhibit desensitization or a decline in evoked current over time to a smaller equilibrium value. During desensitization, bursts and clusters of channel openings can occur after irregular long closed periods. We studied processes involved in GABA_A receptor regulation and desensitization by analyzing single channel equilibrium kinetic properties of GABA receptors exposed to high concentrations of GABA (10-1000 μM).

In 0.1-1.0 μM strychnine and symmetric chloride solutions, excised outside-out patches were obtained from mouse spinal cord neurons in culture and voltage clamped at -75 mV. Average open durations increased with concentration up to 75 μM GABA. Open duration time constants were concentration independent. However, several burst and cluster properties were concentration dependent over the entire range tested. At the highest GABA concentrations, open channel block was occasionally observed and there were excess numbers of isolated brief openings that were independent of bursts and clusters. Two brief intraburst closed duration time constants and their ratios were concentration independent.

These results suggest that the closing (open state) properties of the GABA receptor were saturable at low concentrations, but opening (burst and cluster) properties were affected by a concentration dependent desensitization process. This suggests that the kinetic processes involved with GABA binding and the regulation of open state gating may be different from those regulating GABA binding and desensitization of the GABA receptor.

This work was performed in the laboratory of Dr. Robert L. Macdonald.

DESENSITIZATION OF GABA INDUCED CURRENT IN CULTURED RAT HIPPOCAMPAL NEURONS. D.J. Oh and M.A. Dichter. Dept. of Neurology, University of Pennsylvania School of Medicine and Graduate Hospital, Philadelphia, PA 19104.

Basic characteristics of desensitization were investigated in cultured rat hippocampal neurons (3 days- 4 weeks in vitro) using whole cell patch clamp techniques. 10 to 500 μM GABA was perfused for 30 or 60 seconds with 60 second intervals. Between applications neurons were washed with control bath solution.

Desensitization, evaluated by peak to plateau ratio (PPR) and time constants of current decay (τ), was dose-dependent and culture age-dependent. Higher concentrations of GABA induced larger and faster desensitization, which was more prominent in older cells. Membrane potential influenced both desensitization and resensitization. Desensitization decreased with membrane depolarization; PPR went from 6.3 to 1.4 and τ went from 4.6 to 26.8 seconds at -80 mV and +30 mV, respectively. Resensitization, studied with brief applications of 20 μM GABA at different membrane potentials after 200 μM GABA-induced desensitization at -80 mV, occurred faster at +30 mV than at -80 mV in older cells.

Low concentrations of GABA (1-2 μM) perfused for 2 to 60 seconds, which did not induce any current, had no effect on the maximal response nor desensitization produced by a subsequent application of 100 μM GABA. This finding suggests that GABA receptors were not desensitized without first being activated, as has been demonstrated for AMPA receptor/channels. This work was supported by NS 24927.

318.2

DITHIOHREITOL ENHANCES GABA_A RECEPTOR CURRENT IN MOUSE NEURONS IN CULTURE. N.M. Porter*, R.E. Twyman*, and R.L. Macdonald*. Depts. of Neurology+ and Physiology#, Univ. of Michigan, Ann Arbor, MI 48104

The predicted structure of the neuronal GABA_A receptor places cysteine disulfide loops on extracellular domains of the receptor. Sulfhydryl reducing agents, such as dithiothreitol (DTT), have been shown to enhance NMDA receptor currents in neurons. To determine the role of disulfide loops on GABA receptor function, we measured GABA receptor chloride currents in the presence of DTT or oxidized DTT (an inactive form) in mouse spinal neurons using the whole cell and excised patch clamp techniques.

Whole cell recordings were obtained and GABA (5 μM) + oxidized DTT (5 mM) or GABA + DTT (5 mM) were applied at regular intervals for 7-10 min. Peak GABA-evoked inward chloride current was reduced by 50% at 3 min in the presence of oxidized DTT. Replacement of oxidized DTT with DTT resulted in a recovery to within 86% of the initial GABA-evoked current. In excised outside-out patches, externally applied DTT enhanced GABA receptor channel opening frequency. The effects of DTT on the inside surface of the receptor also were examined. DTT included in the recording pipette reduced the time-dependent decrease in channel opening frequency typically observed upon repeated application of GABA to patches. This "run down" was not reduced when either oxidized DTT or DTNB (5-5-dithio-bis-2-nitrobenzoic acid, an oxidizing agent) were included in recording pipettes.

We conclude that DTT may affect GABA receptor function when exposed to either the inside or outside surface of the receptor. DTT enhanced current primarily via an increase in channel opening frequency. These results suggest that activity of the GABA receptor may be dependent on the redox state of the receptor and/or of a closely associated regulatory protein.

318.4

Current source-density (CSD) analysis of GABA-mediated monosynaptic responses in area CA1 of hippocampus and supragranular neocortex. A.M. Borroni, N.A. Lambert and T.J. Teyler. Department of Neurobiology, NE Ohio Universities College of Medicine, Rootstown, OH 44272.

Monosynaptic GABA-mediated population synaptic responses were recorded using a 16-channel multielectrode array in area CA1 of hippocampal and area Oc2 of visual cortical slices in the presence of DNQX and APV. The laminar distribution of inhibitory synaptic current evoked at several stimulation sites was analyzed. In area CA1, stimulation in any layer evoked maximal current sources horizontal to the stimulation site that were blocked by bicuculline-methiodide (BMI; 30 μM). Stimulation in stratum pyramidale evoked larger BMI-sensitive current sources than did stimulation in other layers, consistent with dense GABAergic innervation of pyramidal cell bodies. BMI-sensitive sources in both preparations displayed use-dependent depression that was antagonized by the GABA_B receptor antagonist CGP 35348 (0.8mM). In both preparations, in the presence of 4-aminopyridine (100 μM), BMI-sensitive dendritic current sinks occurred spontaneously or could be evoked. The distribution of BMI-sensitive current sources and sinks was similar in both preparations. These results suggest that activation of dendritic GABA_A receptors in areas CA1 of hippocampus and Oc2 of neocortex elicits outward chloride current that can be detected using extracellular recording. ATYPICAL EFFECTS OF GABA ON FROG TECTAL CELLS IN VITRO. L. Sivilotti¹ and A. Nistri². Dept. Pharmacology, Queen Mary and Westfield College, London E1 4NS, U.K.

GABA enhances excitatory neurotransmission evoked by optic nerve stimuli on neurones of the frog optic tectum. The present study, employing intracellular recording from deep tectal neurones of an *in vitro* slice preparation kept at 10°C, sought to clarify the mechanism of this unusual action of GABA. The membrane potential of these cells was -50 ± 2 mV (with either KCl or K-acetate microelectrodes). About 50% of cells were depolarized (6 ± 1 mV) by 1 mM GABA while the remaining ones were hyperpolarized (6 ± 1 mV). Regardless of their response polarity, cells displayed either decreases ($20 \pm 3\%$) or increases ($23 \pm 6\%$) in input resistance in the presence of GABA. Only in a minority of neurones these responses were associated with inhibition of spontaneous activity. In most cells the effects of GABA persisted in TTX ($1 \mu\text{M}$) medium. The peak mean amplitude of EPSPs elicited by electrical stimulation of afferent axons was reversibly enhanced from 8 ± 1 mV to 11 ± 2 mV by GABA; a prolongation of the EPSP decay time was also apparent. These data suggest that GABA facilitates excitatory neurotransmission by a combination of pre- and postsynaptic actions which include disinhibition coupled with postsynaptic changes in membrane potential and resistance.

CHARACTERIZATION OF GABA-MEDIATED CHLORIDE INFLUX INTO CEREBELLAR MICROSACS - MODULATION BY BENZODIAZEPINES THROUGH THE TYPE I RECEPTOR. M.F. Davies, P.A. Maguire, N.F. Tsai* and G.H. Loew*. Molecular Research Institute, Palo Alto, CA 94304

In order to investigate benzodiazepine actions at one a single receptor subtype, modulation of GABA-mediated ³⁶Cl influx was studied in rat cerebellar microsacs, which we have shown to contain only the Type I benzodiazepine receptor. The sensitivity of the GABA_A receptor complex to GABA and muscimol was similar, with IC₅₀ of $7.9 \pm 1.4 \mu\text{M}$ (n=10), reaching a maximal stimulation at 100 μM GABA or muscimol. The response to each ligand was biphasic, decreasing chloride flux at concentrations above 100 μM . Pentobarbital (20 μM) produced an increase in the maximal response to GABA. Flunitrazepam (1 μM) enhanced GABA stimulation of ³⁶Cl influx at GABA concentrations below the IC₅₀ but had no effect at high concentrations. The inverse agonist, DMCM (1 μM), shifted the GABA dose-response curve to the right. This system will be used to assess the modulation of the native GABA_A/BDZ Type I receptor complex by benzodiazepine receptor ligands with different chemical structures.

318.9

HETEROGENEITY OF GABA_A RECEPTOR PHYSIOLOGY AND PHARMACOLOGY IN DORSAL ROOT GANGLION NEURONS FRESHLY ISOLATED FROM ADULT RATS. G. WHITE, Neurogen Corporation, 35 Northeast Industrial Rd., Branford, CT 06405.

Electrophysiological and pharmacological heterogeneity of GABA_A receptor/ionophore function has been demonstrated using combinations of cloned GABA_A subunit cDNAs in a variety of expression systems. A systematic demonstration of such heterogeneity within a group of neurons has yet to be reported. Because dorsal root ganglia (DRG) have a heterogeneous population of neurons as defined by voltage gated ion currents, sensitivity to pharmacological agents, presence of peptides, and antigenic expression, I examined this category of neuron for heterogeneity in properties of the GABA_A receptor/ionophore complex. DRGs were dissected and neurons were isolated using 2/1.5/0.5 mg trypsin/collagenase/DNase (respectively) in 5 ml DMEM in a shaking water bath at 35°C for 45-60 minutes. Electrophysiological responses were recorded using the whole-cell patch clamp technique. External solution contained (mM): 150 NaCl, 5 KCl, 2 CaCl₂, 1 MgCl₂, 10 HEPES (pH 7.4) and 10 glucose. Recording electrode solution contained (mM): 130 KCl, 1 CaCl₂, 2 MgCl₂, 11 EGTA, and 10 HEPES (pH 7.4). Using the logistic equation, EC₅₀s for GABA ranged from 28 μM to >100 μM between neurons. Pseudo-Hill coefficients ranged from 1 to 2. In addition, a large degree of variability was found in current/voltage rectification. Finally, responses to a given benzodiazepine ligand varied in amplitude between neurons by up to 4 fold while the EC₅₀ for that ligand remained constant and pseudo-Hill coefficients varied between 1 and 2 for individual ligands. As determined by PCR (C. Hartnett et al., this meeting), DRGs contain messenger RNA for the following GABA_A subunits: $\alpha 1$, $\alpha 2$, $\alpha 4$, $\beta 2$, $\beta 3$, $\gamma 10$, but not $\alpha 3$, $\alpha 6$, $\beta 1$, $\gamma 8$ or δ . Thus the substrate exists for many different combinations of subunits in this category of neuron. This data suggests that DRG neurons do express diverse GABA_A subunit combinations and that such combinations can alter molecular interactions at benzodiazepine receptors without greatly altering affinity.

318.6

GABA CAUSES ELEVATION OF INTRACELLULAR CALCIUM ION CONCENTRATION IN SOME DORSAL HORN NEURONS. J. Wang*, D. B. Reichling, and A.B. MacDermott. Dept. Physiology & Cellular Biophysics and Center for Neurobiology and Behavior, Columbia Univ., New York, NY 10032.

In these experiments, we have examined the effects of GABA on the intracellular concentration of calcium ions ($[\text{Ca}^{2+}]_i$) in neurons isolated from the spinal cord dorsal horn of embryonic rats. Neurons were cultured on a glass coverslip and loaded with the calcium indicator dye, indo-1. GABA (100 μM) was rapidly applied for a period of 3 sec while indo-1 fluorescence was continuously monitored. In most neurons tested, $[\text{Ca}^{2+}]_i$ did not change from the normal resting level of approximately 50 nM during GABA application. Approximately 30% of neurons, however, responded to GABA with fast increases in $[\text{Ca}^{2+}]_i$ to concentrations between 5 and 50 nM above resting levels. The GABA_A receptor subtype is involved in this action since the amplitude of $[\text{Ca}^{2+}]_i$ transients evoked by GABA was reduced by co-application of 50 μM bicuculline, and $[\text{Ca}^{2+}]_i$ transients could be evoked by 10 μM muscimol, a GABA_A agonist. It has been reported that activation of the GABA_A receptor can depolarize some types of neurons, and suggests the possibility that GABA might elevate $[\text{Ca}^{2+}]_i$ by activating voltage-gated calcium channels. This possibility is now being tested using antagonists of voltage-gated calcium channels. In contrast to the relatively fast inhibitory postsynaptic potentials usually associated with GABA transmission, GABA-stimulated increases in $[\text{Ca}^{2+}]_i$ might cause relatively long-term changes in sensory transmission in the dorsal horn.

318.8

ANTAGONISM OF GLYCINE AND TAURINE INDUCED ION CHANNELS BY TAG IN CULTURED MOUSE SPINAL NEURONS. DA. Mathers. Department of Physiology, University of British Columbia, Vancouver, B.C. V6T 1Z3 Canada.

We studied the blocking action of 6-(aminomethyl)-3-methyl-4H-1,2,4-benzothiadiazine 1,1-dioxide (TAG) on single chloride channels activated by glycine and taurine in mouse spinal cord cell membranes. This agent is regarded as a selective taurine antagonist at some central synapses. (Girard et al., J. Med. Chem. [1982] 25: 113-116). Neurons were dissociated from CD1 white embryos at day E12 and cultured at 37°C in Minimum Essential Medium with 10% horse serum for 2-3 weeks prior to use. Voltage-clamp recordings were made at 21-23°C in the outside-out patch configuration using a List EPC-7 amplifier (bandwidth DC-2 kHz). Patch electrodes contained a solution of composition (mM): 140 Tris-Cl, 3 NaCl, 1 MgCl₂, 11 EGTA, 10 HEPES, pH 7.2. The external membrane face was exposed to a solution containing (mM): 140 Tris-Cl, 4 KCl, 1 CaCl₂, 1 MgCl₂, 10 HEPES, pH 7.2. At concentrations up to 200 μM , TAG did not alter the conductance or reversal potential of multi-conductance chloride channels activated by glycine or taurine. At concentrations above 50 μM , TAG reduced the probability, P of these channels being in the open state. 100 μM TAG reduced P by $94 \pm 2.7\%$ (mean \pm S.E.M., 5 patches) in the case of channels activated by 80 μM taurine. However, TAG was considerably less effective in antagonising channels activated by glycine. 200 μM TAG was required to produce $85 \pm 6.1\%$ reduction in P during channel activation by 20 μM glycine.

318.10

DETECTION BY PCR OF GABA_A RECEPTOR SUBTYPES EXPRESSED IN DORSAL ROOT GANGLIA OF THE ADULT RAT. C. Hartnett. Neurogen Corporation, Branford, CT. 06405

Molecular characterization of the GABA_A receptor has demonstrated the existence of multiple subtypes, leading to the speculation that receptor subtype heterogeneity can be correlated with distinct clinical properties. To determine which subtypes are present in small numbers of cells, a modified PCR protocol was used to detect mRNA expressed in dorsal root ganglia of the adult rat. Using subtype specific oligonucleotides as PCR primers, the presence of the following subtypes has been demonstrated: $\alpha 1$, $\alpha 2$, $\alpha 4$, $\beta 2$, $\beta 3$, and the long form of $\gamma 2$. The $\alpha 3$, $\alpha 6$, $\beta 1$, δ , and the short form of the $\gamma 2$ subtypes were not found. The PCR protocol included incorporation of digoxigenin-labelled dUTP in the amplified product. The labelled DNA can then be linked to an alkaline phosphatase conjugated antibody, and detected with a chemiluminescent substrate. This method allows detection of mRNAs with several-fold more sensitivity than ethidium bromide staining, without using radioisotopes. Based on the data presented here, it is possible to quickly detect the presence or absence of mRNAs coding for specific receptor subtypes in a small number of cells.

LOCALLY-APPLIED ETHANOL ATTENUATES NMDA-EVOKED NEURONAL ACTIVITY WHILE POTENTIATING INHIBITION BY GABA IN THE INFERIOR COLLICULUS. P.E. Simson, H.E. Criswell, and G.R. Breese. Dept. of Psychiatry, University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC 27599.

Systemically administered ethanol (ETOH) inhibits NMDA-evoked activity in only a subpopulation of neurons in the medial septum (Simson et al., *J. Pharmacol. Exp. Therap.*, 1991), a site where systemically-administered ETOH potentiates the behavioral and electrophysiological effects of GABA (Givens and Breese, *J. Pharmacol. Exp. Therap.*, 1990). Another brain site where ETOH has behavioral effects is the cortex of the inferior colliculus (IC), where ETOH withdrawal is related to seizure production (McCown and Breese, *Alcoholism*, 1990). In the present study, the effects of electro-osmotically-applied ETOH on NMDA-evoked and GABA-inhibited activity of IC neurons were investigated. As with systemic administration of ETOH in the medial septum, locally-applied ETOH potentially inhibited NMDA-evoked activity in only a portion of IC neurons tested (75%), while having no effect on NMDA-evoked activity in the remaining neurons. Local application of ETOH also potentiated, in a dose-dependent manner, the inhibitory effects of GABA on IC neuronal activity. In contrast, locally-applied ETOH failed to potentiate the inhibition by glycine of IC activity, as well as the inhibition by GABA in the lateral septum, a site where systemically-administered ETOH has no effect on spontaneous and GABA-inhibited activity. These findings suggest that ETOH has actions on specific brain areas, and that these differences may be related to actions on specific receptor subtypes. Supported by NS26595 and AA-08024.

GENERAL ANESTHETICS POTENTIATE GABA ACTIONS ON GABA_A RECEPTORS EXPRESSED BY XENOPUS OOCYTES: LACK OF INVOLVEMENT OF INTRACELLULAR CALCIUM. L. H. Lin and R. A. Harris. Dept. of Pharmacology, UCHSC, Denver, CO 80262; Veterans Admin. Med. Res. Serv., Denver, CO 80222.

Potential of GABA_A receptor channel response may be a primary action of general anesthetics (GAs). Enhancement of GABA_A-induced synaptic inhibition by halothane was suggested to be mediated through the release of intraneuronal Ca²⁺ (Mody et al., *Brain Res.*, 538:319, 1991). Effects of GAs on GABA receptor-gated Cl⁻ channels and the participation of intracellular Ca²⁺ were assessed in *Xenopus* oocytes microinjected with mouse cortex mRNA. GABA-activated Cl⁻ current was measured using 2-electrode voltage clamping. Anesthetic concentrations of GAs (diethylether, halothane, isoflurane, enflurane, 3 α -hydroxy-5 α -dihydroprogesterone and propofol) enhanced the GABA-activated current by 100-300%. This supports the hypothesis that the potentiation of GABA_A response is a common action of GAs. Potentiation produced by these drugs was not suppressed by an intracellular injection of the Ca²⁺ chelator, EGTA (intracellular concentration: about 500 μ M). This EGTA treatment completely blocked the 5HT-induced Ca²⁺-dependent Cl⁻ current in the same oocytes. In addition, GAs alone did not induce significant current (< 5 nA), suggesting that anesthetic concentrations of GAs did not activate endogenous Ca²⁺-dependent Cl⁻ channels in oocytes. These results indicated that GAs' enhancement effects of GABA-activated Cl⁻ current in oocytes did not require changes of intracellular Ca²⁺ concentration. However, it is possible that GAs produce actions on neuronal [Ca²⁺] that are not observed in oocytes.

CORRELATION OF IMMUNOCYTOCHEMICAL PROPERTIES WITH GABA RESPONSES IN CULTURED SUBSTANTIA NIGRA NEURONS.

K.M. Kim, Y. Nakajima and S. Nakajima. Dept. of Pharmacology and Dept. of Anatomy and Cell Biology, Univ. of Illinois College of Medicine, Chicago, IL 60612.

We separately cultured the pars compacta and the pars reticulata of the substantia nigra of 2 to 4-day old postnatal rats. The cell cultures were double-labelled with antibodies to tyrosine hydroxylase (to show dopaminergic (DA) cells) and GABA. Previously, we have reported that D₂ receptors are located on DA neurons and activate K-channels, whereas D₁ receptors are located on non-DA/non-GABAergic neurons and decrease K-conductance (Kim et al., *Biophysical J.* 59: 20A, 1991).

Using the whole-cell clamp technique, we have conducted electrophysiological studies. By applying GABA and baclofen, we have tested for the presence of GABA receptor subtypes in cultured substantia nigra neurons. For example, some cells responded to GABA with an increase in Cl⁻ conductance but did not respond to baclofen, suggesting the presence of GABA_A receptors and the absence of GABA_B receptors. After electrophysiological experiments, the same neuron was immunocytochemically treated. GABA_A receptors seemed to be present in all types of cells including GABAergic cells. On the other hand, GABA_B receptors were mostly located on DA neurons. Supported by PHS grants, DA05701 and NS24711.

SPECT IMAGING OF THE BENZODIAZEPINE RECEPTOR: FEASIBILITY OF *IN VIVO* POTENCY MEASUREMENTS FROM STEPWISE DISPLACEMENT CURVES. R.B. Innis, E. Sybirska, M. Al-Tikriti, S.S. Zoghbi*, R.M. Baldwin*, M. Laruelle, S.W. Woods, J. Seibyl, R. Malison, P.B. Hoffer*, D.S. Charney, and G.R. Heninger. Dept. Psychiatry, VA Medical Center and Yale Univ., West Haven, CT 06516.

Ro16-0154 is a high affinity, iodine-containing antagonist of the benzodiazepine (BZ) receptor. We have examined the pharmacological specificity of ¹²³I-Ro16-0154 as a BZ receptor probe with SPECT (single photon emission computed tomography) and show the feasibility of measuring potency of BZ agents from an *in vivo* stepwise displacement curve.

In a series of 28 SPECT studies, baboons were injected with 1-18 mCi ¹²³I-Ro16-0154 and scanned for 2-6 hours in the Strichman 810X. Radiolabel uptake was concentrated in cortical areas with highest density in occipital cortex. Maximum uptake was reached within 30-90 min and was relatively stable for the following 180 min. Repeated injections of increasing doses of each of five BZ drugs (Ro 16-0154, Ro 15-1788, clonazepam, alprazolam, and diazepam) yielded stepwise displacement curves, which were analyzed to measure the *in vivo* potencies of these agents. The relatively long half-life of ¹²³I and the stable biological uptake of the radiotracer allowed such potency estimations in just one experiment. The *in vivo* potencies of these five agents were highly correlated with their affinities for the BZ receptor determined with homogenate binding.

In conclusion, stepwise displacement by agents administered following the injection of the radioligand ¹²³I-Ro 16-0154 provided a reliable means of measuring the *in vivo* potencies of BZ receptor agents. This *in vivo* determination may better predict the clinical potency of BZ drugs than *in vitro* homogenate estimations, because the *in vivo* measure provides the summed effects of receptor affinity, plasma protein binding, penetration of the blood brain barrier, and metabolism of the agent.

POSTNATAL RAT HIPPOCAMPAL GABA_A RECEPTORS WITH DIFFERENTIAL SENSITIVITY TO BENZODIAZEPINE RECEPTOR LIGANDS. J. Bormann and B. Schönrock*. Max-Planck-Institut für Hirnforschung, W-6000 Frankfurt / M. 71, Germany.

We examined the benzodiazepine pharmacology of neuronal GABA_A receptors in primary cultures of newborn rat hippocampus by using the whole-cell configuration of the patch-clamp technique. After 1-7 days in culture, recordings were made from neurons with equal intra and extracellular Cl⁻ concentrations of 145 mM. The rapid application of GABA (10 μ M) elicited inward currents at a holding potential of -70 mV. Sequentiell application of the benzodiazepine agonist flunitrazepam (FNZ) and the inverse agonist DMCM (both 1 μ M) revealed different response patterns to GABA. In one set of cells, FNZ augmented the GABA response by 114%, whereas DMCM reduced the currents by 53%. This well-established effect of benzodiazepine receptor ligands on neuronal GABA_A receptor channels contrasts with the observation that in some cells DMCM inhibited the GABA-induced currents, whereas FNZ was almost ineffective.

These results suggest that several isoforms of the GABA_A receptor complex exist in the postnatal rat hippocampus, and that their subunit composition may change during development.

FUNCTIONAL RECONSTITUTION OF THE GABA_A RECEPTOR PURIFIED FROM BOVINE BRAIN. R.P. Thuymsma*, L.L. Duncalfe*, C. Bladen* & S.M.J. Dunn. Dept. of Pharmacology, Univ. of Alberta, Edmonton, Alberta T6G 2H7.

The GABA_A/benzodiazepine receptor complex has been purified from bovine cerebral cortex by benzodiazepine (1012S) affinity chromatography. Polyacrylamide gel electrophoresis in the presence of SDS revealed major protein species with apparent molecular weights of 55 and 59K. The purified protein was reconstituted into phospholipid vesicles with retention of many of the functional properties of a native GABA_A receptor. The ability of the reconstituted preparation to mediate rapid chloride flux has been investigated by monitoring the fluorescence of a chloride-sensitive probe (6-methoxy-N-(3-sulfo-propyl) quinolinium) trapped within the vesicles. Chloride influx was stimulated in the presence of micromolar concentrations of muscimol and was blocked by pretreatment of the vesicles with muscimol (desensitization), a competitive antagonist (bicuculline) or by the channel blocker (picrotoxin). The muscimol-stimulated response was potentiated in the presence of 10 μ M diazepam. This reconstituted system will prove useful in the study of structure-function relationships of the GABA_A receptor. (Supported by the AHFMR and the MRC of Canada).

SEQUENCE AND EXPRESSION OF A NEUROPEPTIDE Y RECEPTOR cDNA
J.R. Rimland, W. Xin, P.M. Sweetnam*, K. Saijoh*, E.J. Nestler, and R.S. Duman. Lab. of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508; *NOVA Pharmaceutical, Baltimore, MD 21224; †Kobe Univ., Japan.

Neuropeptide Y (NPY) is widely distributed in the peripheral nervous system and in brain where it has been shown to influence a variety of cardiovascular, gastrointestinal, neuroendocrine, and behavioral processes. NPY ligand binding and consequent regulation of adenylate cyclase and ion channels is sensitive to guanine nucleotides and pertussis toxin treatment, suggesting that NPY receptors belong to the G protein-coupled receptor superfamily.

As a strategy to clone the NPY receptor, we have used the polymerase chain reaction to isolate cDNAs for novel members of this receptor family from locus coeruleus, a brain region enriched in the NPY system. We now report the isolation and characterization of an NPY receptor cDNA clone, referred to as LCR1, from bovine locus coeruleus. LCR1 cDNA encodes a predicted protein of 353 amino acids with a membrane topology similar to that of other G protein-coupled receptors. Expression of LCR1 in mammalian cells results in specific and high affinity (< nM) NPY ligand binding. Northern blot analysis reveals that NPY receptor mRNA is regionally distributed in both brain and peripheral tissues. This cDNA clone will be useful for studies of the regulation and function of NPY receptors and for the isolation of related NPY receptor subtypes.

319.3

THE NEUROPEPTIDE Y BINDING PROTEIN IN BOVINE ADRENAL MEDULLA IS LINKED TO A G-PROTEIN. T.D. Hexum and W. Li*, Dept. of Pharmacol., Univ. Neb. Med. Ctr., Omaha, NE 68198-6260.

Neuropeptide Y (NPY), a 36 amino acid messenger, has been shown to decrease catecholamine secretion from bovine chromaffin cells (Higuchi et al., *JPET* 244 468, 1988). To more fully understand this phenomenon we have investigated NPY receptor structure. NPY receptors present in bovine adrenal medulla membranes were covalently cross-linked to [¹²⁵I]NPY via disuccinimidyl suberate (DSS, 1 mM). SDS-polyacrylamide gel electrophoresis followed by autoradiography revealed the presence of a 90 kDa NPY binding protein in crude membranes with an IC₅₀ of 1.1 x 10⁻⁷ M for unlabeled NPY. The membranes were further purified by continuous sucrose gradient centrifugation. Binding studies indicated that the majority of the binding sites co-purified with the plasma membranes and few binding sites existed on microsomal membranes. Competitive inhibition studies indicated that purified plasma membranes have two NPY binding sites with IC₅₀'s of 1.4 x 10⁻⁷ M and 1.7 x 10⁻¹¹ M. However, in the presence of 1 mM GTP, plasma membranes have only a low affinity binding site. Affinity labeling revealed the same 90 kDa binding protein in purified plasma membranes. These data suggest that the 90 kDa binding protein is a plasma membrane protein associated with a G-protein and may be the NPY receptor in this tissue. (Supported by Amer. Heart Assoc., Neb. Affil.)

SK-N-MC: MODEL SYSTEM FOR MOLECULAR STUDIES OF THE NEUROPEPTIDE (NPY) Y1-RECEPTOR. F. Yee*, A.G. Blomqvist*, D. Larhammar*, D.J. Reis* and C. Wahlestedt†. ¹Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021; ²Dept. of Med. Genetics, Uppsala Univ., S-751 23 Uppsala, Sweden.

The Y1-receptor is the principal NPY receptor subtype in blood vessels and frontoparietal cortex. It is the only NPY receptor expressed in the human neuroblastoma cell line, SK-N-MC, making it a suitable model system to study Y1-receptor biology (Wahlestedt, et al., *Ann. NY Acad. Sci.* 611:7, 1990). In SK-N-MC cells, the Y1-receptor appears to be G-protein coupled since the number of specific [¹²⁵I]-NPY binding sites (95,000 sites/cell) was reduced to 50% by GTP in a concentration-dependent manner. In addition, NPY and the Y1-selective agonist, [Pro³⁴]NPY, attenuated forskolin-stimulated cAMP levels, along with eliciting Ca²⁺ release from a thapsigargin-sensitive pool with potencies in the nM range. The Ca²⁺ mobilization evoked by NPY and carbachol (an Ins[1,4,5]P₃-generating agonist) do not cross-desensitize, suggesting that the two agonists liberate Ca²⁺ from distinct intracellular pools.

The G-protein-coupled receptors have conserved transmembrane (TM) domains, and on the basis of these homologies, combinations of degenerate primers corresponding to the TM2, TM3, TM6 and TM7 regions, were used to clone the Y1-receptor from SK-N-MC cells by PCR. We have selected 33 PCR-generated fragments (350-600 bp) as potential receptor candidates and these are currently in the process of being characterized.

319.2

ISOLATION OF NOVEL NEUROPEPTIDE RECEPTOR cDNAs FROM LOCUS COERULEUS (LC) W.W. Xin, J.M. Rimland, E.J. Nestler, and R.S. Duman. Lab. of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508

Receptors for NPY, opiates, CRF, VIP, and substance P, as well as for other neurotransmitters have been located in LC, the major noradrenergic nucleus in brain. These receptors are thought to belong to the G protein-coupled receptor superfamily. We have used PCR and primers derived from the third and sixth transmembrane domains of previously isolated members of this receptor family in an attempt to isolate cDNA clones for these receptors. PCR amplification of bovine LC cDNA resulted in nine major amplified DNA bands which were subsequently cloned into pBluescript. These PCR clones were then used to screen an LC cDNA library to isolate full-length cDNA clones. One of these clones has been sequenced and expressed and encodes an NPY receptor (see Rimland et al., 1991, this volume). This clone, referred as LCR1, is being used as a probe to screen a randomly primed rat brain cDNA library to isolate the rat homologue of this NPY receptor and other NPY receptor subtypes. In addition, we have isolated and sequenced another cDNA clone from the bovine LC cDNA library, LCR9, which appears to be a novel G protein-coupled receptor. Northern blot analysis demonstrates a regional distribution of LCR9 mRNA in brain. Full-length cDNAs of the above clones will be subcloned and expressed in mammalian cell lines to study their functional properties.

Application of PCR to discrete brain regions like the LC offers a particular advantage in the isolation and cloning of neurotransmitter receptors.

319.4

VASCULAR RECEPTORS FOR NEUROPEPTIDE Y (NPY) L. Grundemar, J. Mörner*, E. Högestätt*, C. Wahlestedt and R. Häkanson*, Dept. of Pharmacol. Univ. of Lund, Sweden and Div. of Neurobiol. Cornell Univ. Med. Coll. NY, NT 10021 USA.

We compared NPY and NPY-related analogs with respect to their ability to activate or bind to vascular NPY receptors in four experimental set-ups. Previous results have suggested the existence of: Y1 receptors requiring full-length NPY (1-36) or [Pro³⁴]NPY, and Y2 receptors recognizing also N-terminally truncated forms of NPY but not [Pro³⁴]NPY. NPY and [Pro³⁴]NPY increased arterial pressure in the anesthetized rat with a similar magnitude and potency. NPY 2-36 was much less potent than NPY. NPY 4-36 was inactive. NPY, [Pro³⁴]NPY, NPY 2-36 and NPY 5-36 increased the coronary resistance in the perfused rat heart. NPY and [Pro³⁴]NPY were equipotent, while NPY 2-36 and NPY 5-36 were 7 and 20 times less potent. At 0.3 μM, NPY 11-36 and NPY 22-36 induced a slight contraction while NPY 23-36 was inactive. NPY, [Pro³⁴]NPY, NPY 2-36, NPY 4-36, NPY 5-36 and NPY 11-36 evoked contractions in the inferior caval vein of the rat and guinea pig. [Pro³⁴]NPY was more potent than NPY. NPY 2-36 was equipotent with NPY, while NPY 4-36, NPY 5-36 and NPY 11-36 were 30 times less potent. [Pro³⁴]NPY was equipotent with NPY 1-36 in displacing [¹²⁵I]-PYY from rat aortic smooth muscle cells, while NPY 2-36 and shorter forms were much less potent. In caval vein smooth muscle cells, the displacement pattern was more complex, in that both [Pro³⁴]NPY and NPY 13-36 displaced the radioligand, albeit none of them completely. The bioactivity and the binding affinity of the NPY-related peptides suggest the presence of Y1 receptors in all vascular systems studied. In addition, contraction-coupled Y2 receptors seems to be present in the caval vein.

319.6

2-NAPHTHYLBENEXTRAMINE (2-NapBXT): A PRELUDE TO THE DEVELOPMENT OF SELECTIVE AND POTENT NON-PEPTIDE NEUROPEPTIDE-Y (NPY) ANTAGONISTS. C.S. Chaurasia, K. Li* and M. B. Doughty*, Dept. of Medicinal Chemistry, Univ. of Kansas, Lawrence, KS 66045.

NPY is a 36-amino acid peptide messenger that has been implicated in a variety of physiological and pharmacological actions including vasoconstriction and norepinephrine modulation. However, lack of a selective NPY antagonist has hampered evaluation of the functional role of NPY's central and peripheral-mediated actions. Benextramine (BXT), an irreversible α-adrenoceptor antagonist, has been shown to exhibit binding affinity to NPY receptors, and to inhibit in vivo NPY's pressor activity (Doughty et al. *Eur J. Pharmacol.* 185, 1990, 113). However, its affinity is rather low, and it is not selective for the NPY receptor. Based on the structural features shared between BXT and NPY, we have hypothesized common sites of interaction for these molecules at the NPY receptor. Furthermore, based on the existing structure-activity relationship studies of BXT analogs at the α-adrenoceptor, we synthesized a number of BXT derivatives in our quest to develop more selective and potent NPY receptor antagonists. The pharmacological evaluation of these analogs were performed using [³H]NPY bound to rat brain membranes. Result of our studies indicates a 2-fold higher affinity for 2-NapBXT at NPY sites as compared to that of BXT. A significantly lower α-adrenoceptor antagonist potency of 2-NapBXT makes this compound a potential candidate for the development of selective and potent non-peptide NPY antagonist (supported in part by the American Heart Association, National Center).

319.7

LOCALIZATION OF NEUROPEPTIDE Y BINDING SITES TO SMALL ARTERIOLES OF THE HEART, DORSAL ROOT GANGLIA NEURONS, AND POST-GANGLIONIC SYMPATHETIC NEURONS SUGGESTS POSSIBLE NPY ACTIONS ON ALL THREE CELL TYPES DURING MYOCARDIAL ISCHEMIA. C. Allen, M. Labenski, J. Ghilardi, M. Catton, P. J. Mannon, I. L. Taylor, S. R. Vigna, J. E. Maggio, P. W. Mantyh. Mol. Neurobiology Lab (151) VA Medical Center, Mpls., MN 55417; Gastroenterology Div., VA Medical Center, Durham, N.C. 27705; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115.

Neuropeptide Y (NPY) is a 36 amino acid peptide that is synthesized and released by post-ganglionic sympathetic neurons and several reports have suggested that the peptides may exert potent direct and indirect effects on the heart. To identify possible sites of NPY actions on the heart and peripheral neurons which innervate the heart we have used receptor autoradiography to examine the localization of NPY receptor binding sites in the dorsal root ganglion, sympathetic ganglion and heart. Standard receptor autoradiographic methods were used along with an ^{125}I -PYY ligand which has been shown to bind to both NPY and PYY receptor binding sites. NPY receptor binding sites were found to be expressed by a substantial population of dorsal root ganglion neurons, by post-ganglionic sympathetic neurons and by small arterioles throughout the rat heart.

These results suggest that NPY released by post-ganglionic sympathetic neurons could act through these specific binding sites to mediate; dorsal root ganglion activity which is known to convey nociceptive information from the heart, vasoconstriction of myocardial arterioles, and sympathetic tone in the heart.

NEUROMEDIN B STIMULATES THE GROWTH OF C6 GLIOBLASTOMA CELLS. P. Duncan, J. Rosenstein, R. T. Jensen, J. Battey and T. W. Moody. Depts. Anatomy, Neuroscience, Biochemistry and Molecular Biology, George Washington Univ. Med. Ctr., Washington, D.C. 20037, Digestive Disease Branch, NIDDK and Lab. Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

Two bombesin (BN) receptor subtypes have been identified which prefer gastrin releasing peptide (GRP) or neuromedin B (NMB). These G-protein coupled receptors have been cloned and have 54% sequence homology (Wada et al., Neuron, 6:421, 1991). Previously, we found that human U118 glioblastoma cells have GRP receptors (Moody et al., J. Mol. Neurosci. 1:235, 1989) and here we report that C6 cells have NMB receptors. Radioreceptor assays indicated that (^{125}I -Tyr⁴)BN bound with high affinity ($K_d = 3$ nM) to a single class of sites ($B_{max} = 11,000/\text{cell}$) using C6 cells. Specific (^{125}I -Tyr⁴)BN binding was inhibited with high affinity by NMB, GRP and BN ($IC_{50} = 0.3, 100$ and 50 nM respectively) but not (D-Phe⁶)BN⁶⁻¹³ methyl ester, (Psi^{13,14}, Leu¹⁴)BN or GRP¹⁻¹⁶ ($IC_{50} = 3, 3$ and >10 μM). Also, C6 cells formed grafts when transplanted into the adult rat cortex. NMB elevated the cytosolic Ca^{2+} and stimulated the growth of C6 cells in a dose dependent manner. These data indicate that NMB receptors may have signal transduction mechanisms similar to GRP receptors resulting in cellular proliferation. Supported in part by NSF grant BNS88-15133 and NIH grant NS-17468.

319.11

SPECIFIC ANTAGONISTS AND AGONISTS DIFFERENTIATE BOMBESIN RECEPTOR SUBTYPES IN THE RAT BRAIN. E. E. Ladenheim, R. T. Jensen, D. H. Coy, S. A. Mantey, and T. H. Moran. Dept. Psychiatry, Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205, NIDDK, NIH, Bethesda, MD 20892 & Peptide Res. Lab., Tulane Univ. Med. Ctr., New Orleans, LA 70112.

The rat CNS contains two distinct bombesin (BN) receptor subtypes. One, similar to the pancreatic BN subtype, has a high affinity for gastrin-releasing peptide (GRP) and the other has a high affinity for neuromedin B (NMB). In this study, we used *in vitro* receptor autoradiography to examine the ability of NMB, GRP, selective antagonists [D-Phe⁶]BN(6-13)ethyl ester, [D-Phe⁶, Cpa¹⁴, Ψ 13-14]BN(6-14) and a selective agonist [D-Phe⁶]BN(6-13)butyl amide to inhibit binding of ^{125}I -(Tyr⁴)BN to the anterior olfactory nucleus (AON), a brain region we have previously characterized as containing the BN receptor subtype with a high affinity for NMB. Our results indicate that NMB was the most potent in inhibiting binding of ^{125}I -(Tyr⁴)BN to this receptor subtype, causing half-maximal inhibition at 8.1 nM and was 50-fold more potent than GRP, with half-maximal inhibition at 420 nM. The agonist and antagonists selective for the pancreatic BN receptor subtype were extremely ineffective in inhibiting binding of the BN radioligand to the AON with half-maximal inhibition occurring at >5500 nM. This binding profile strongly contrasts that previously reported for the pancreatic BN receptor subtype (von Schrenck et al., 1990). As with peripheral receptors, the use of these potent and specific BN antagonists and agonists will be useful in defining the binding characteristics of BN receptor subtypes in the rat CNS.

POLYMERASE CHAIN REACTION (PCR) AMPLIFICATION OF mRNA ISOLATED FROM AIT-20/D16 CELLS USING GUANINE NUCLEOTIDE BINDING PROTEIN-LINKED RECEPTOR OLIGONUCLEOTIDE PRIMERS: PRELIMINARY ISOLATION AND CHARACTERIZATION. R.C. Thompson, and S.J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

Our laboratory has a long standing interest in the anatomy, physiology and function of neuropeptides in the central nervous system particularly those involved in the regulation of hypothalamic-pituitary-adrenal functions. Many of these neuropeptides are thought to exert their function on postsynaptic elements and/or target cells by interacting with membrane bound receptors. These receptors in turn interact with guanine nucleotide binding proteins (G-proteins) which link ligand/receptor binding to activation of intercellular second messenger systems. AIT-20 cells, mouse corticotrophic tumor cells, have been extensively studied as a model system of Proopiomelanocortin (POMC) peptide (ACTH, β -LPH, and some β -endorphin) secretion and gene regulation. These cells appear to respond to many of the same secretagogues as endogenous anterior pituitary corticotroph cells and thus express many of the receptors for these ligands. Libert, et al. in 1989 described a PCR process and the use of degenerate oligonucleotide primers to isolate cDNA clones encoding G-protein linked receptors. Using these primers, we have begun to investigate the G-protein linked receptors expressed in AIT-20 cells. In this report, we present our data on two PCR clones which have homology to other members of the G-protein receptor superfamily. The cellular and regional distribution of the mRNAs encoding these two clones is also presented as analyzed by Northern blot and *in situ* hybridization. R.C.T. is supported by MH09904-02. This work supported in part by MH422251-04 (to S.J.W.).

EFFECTS OF REDUCED PEPTIDE BOND AND DesMet ANALOGUES OF BOMBESIN (Bn) IN ANTAGONIZING THE CNS EFFECTS OF Bn. Z. Merall^{1,2} and H. Plamondon¹. ¹School of Psychology and ²Dept. of Pharmacology, University of Ottawa, Ottawa, Ont. Canada. K1N 9A9.

This study assessed the potency and efficacy of [D-Phe⁶, Cpa¹⁴, Ψ 13-14]BN₆₋₁₄ (Ψ CpaBn) and [D-Phe⁶]BN₆₋₁₃ methyl ester (DesMetBn), two of the most potent Bn antagonists at the pancreatic acini, in blocking some of the centrally mediated effects of Bn. The *in vitro* receptor binding studies on rat brain membranes revealed that both the antagonists displaced (^{125}I -Tyr⁴)Bn with IC_{50} values in the nano molar range, with DesMet Bn being more potent than Ψ CpaBn. For the *in vivo* studies, male Sprague-Dawley rats (300-400g) implanted with 3rd ventricular cannulae were pretreated with Ψ CpaBn (0, 0.5, 2.5 or 5.0 μg ; i.c.v.) or DesMetBn (0, 0.1, 0.5 or 1.0 μg ; i.c.v.), and then injected with Bn (0.5 μg ; i.c.v.) 15 min later. The most dominant behavior elicited by Bn was scratching directed at the head/nappe region. This was antagonized more potently by DesMetBn however, in terms of efficacy, Ψ CpaBn was superior as it completely blocked Bn-elicited scratching. Bn reduced the core body temperature and this effect was antagonized by the lower (0.1 and 0.5 μg) but not the higher (1.0 μg) doses of DesMetBn. At the doses used, Ψ CpaBn failed to alter Bn-induced hypothermia. DesMetBn only partially antagonized Bn-induced satiety and only at the 1.0 μg dose. The effects of Ψ CpaBn on ingestion are currently being assessed. Whereas DesMetBn failed to affect Bn-induced exploratory activity, Ψ CpaBn potentiated this effect of Bn. These data demonstrate that various physiological and behavioral end points were differentially affected by the two antagonists. The dose-response curves obtained with DesMetBn were bell-shaped with Bn-antagonism usually being apparent at the lower doses. Since these antagonists do not have a high affinity for the neuromedin B-type receptors, these data may suggest subtype(s) within the Bn/GRP-type receptors. (Supported by MRC).

COMPARATIVE DISTRIBUTION OF GRP-PREFERRING AND NMB-PREFERRING BOMBESIN RECEPTOR mRNAs IN ADULT AND EMBRYONIC RAT. E. Wada, J. Way, S. Key, S. Gray, and J. Battey, Laboratory of Neurochemistry, NINDS, NIH Bethesda, MD 20892

Two bombesin-like peptides, gastrin releasing peptide (GRP) and neuromedin B (NMB), have been identified in mammalian neural and neuroendocrine cells. In previous studies, cDNA clones were isolated for two distinct mammalian bombesin receptors, one from mouse fibroblasts which has higher affinity for GRP than NMB (GRP-R) (Battey et al., Proc. Natl. Acad. Sci. USA 88:395, 1991) and a distinct receptor from rat esophagus with higher affinity for NMB than GRP (NMB-R) (Wada et al., Neuron 6:421, 1991). In this study, we analyzed and compared the distribution of GRP-R and NMB-R mRNA at various developmental stages in both brain and peripheral tissues by *in situ* hybridization. In the adult rat brain, GRP-R was expressed at highest levels in hypothalamic regions including the paraventricular nucleus, supraoptic nucleus, mesocellular preoptic nucleus. In contrast, NMB-R mRNA was prominent in olfactory regions including the anterior olfactory nucleus, piriform cortex, tenia tecta, as well as in the thalamic regions (paraventricular, mediodorsal, centrolateral, and centromedial thalamic nuclei). Both GRP-R and NMB-R expression was observed in the gastrointestinal tract, including stomach, small intestine, and colon. At late embryonic stages (E18), both GRP-R and NMB-R mRNA was expressed in the brain, while only GRP-R is observed in the gastrointestinal tract. The distinct distribution of GRP-R and NMB-R mRNAs suggests that these two bombesin receptor subtypes play independent roles in mediating the biological effects associated with bombesin peptide agonists in different organs.

THE DISTRIBUTION OF VASOPRESSIN V₁ RECEPTOR mRNA IN RAT BRAIN. N.L. Ostrowski, W.S. Young, III, A.-M. O'Carroll*, and S.J. Lolait*. Lab Cell Biology, NIMH, Bethesda, MD 20892

A pressor-type vasopressin receptor (V₁) cDNA has been cloned from a liver library (Lolait et al., in preparation). In order to study the distribution of the V₁ receptor's expression in the rat brain, a 650bp fragment from the 5' end of the V₁ cDNA was subcloned into pGEM3Z from which [³²S]-riboprobes (sense and antisense) were generated for use in hybridization histochemistry. Preliminary studies with male rat brain sections revealed V₁ receptor transcripts in brain regions including olfactory bulb, hypothalamus, lateral septal area, habenula, pineal, and neocortex. Liver sections showed very high levels of V₁ transcripts, whereas kidney sections showed lower levels, especially in the medulla.

These studies confirm the presence of V₁ receptors in some areas of the rat brain, such as the septum, and raise questions about their role in other areas. Further studies are in progress to investigate the expression of this receptor gene in female and Brattleboro rats, and in rats undergoing hormonal manipulations.

ACTH/MSH-LIKE PEPTIDES STIMULATE [³H]DOPAMINE RELEASE AND cAMP PRODUCTION IN BRAIN SLICES; EVIDENCE FOR A MSH RECEPTOR-COUPLED MECHANISM. W.J. Florijn*, A.H. Mulder*, A.B.A. Kroese and D.H.G. Versteeg*. Dept. of Pharmacol., Med. Fac., Free University Amsterdam, Agricultural Univ. Wageningen and Rudolf Magnus Inst., Univ. of Utrecht, Vondellaan 6, 3521 GD, Utrecht, NL.

ACTH-(1-24) and related peptides potently stimulate grooming behavior after intra ventricular administration, an effect thought to involve the dopamine system. The present study was designed to study the effect of ACTH-(1-24) on transmitter release and second messenger formation in vitro using a superfusion technique. ACTH-(1-24) concentration-dependently (IC₅₀ value = 10 nM) enhanced the electrically stimulated release of [³H]dopamine, but not of [³H]noradrenaline, from rat septal slices with approximately 20%.

ACTH-(1-24) enhanced the basal and forskolin-stimulated cAMP production in septal and striatal slices, also with an IC₅₀ value of 10 nM and a maximal effect of 20%, but not the dopamine-stimulated cAMP production. Preliminary data suggest that α-MSH and ACTH-(1-24) are equipotent in enhancing cAMP formation. The structure-activity relationship resembles the one found for excessive grooming.

319.17

BIOCHEMICAL CHARACTERISTICS OF [¹²⁵I]hCGRPα BINDING SITES IN RAT BRAIN AND PERIPHERAL TISSUES: FOCUS ON DISULFIDE BRIDGES AND MODULATION BY GTP ANALOGUE. D. van Rossum¹, Y. Dumont¹, A. Fournier², S. St-Pierre² and R. Ouirion¹. (1) Douglas Hosp. Res. Ctr. and Dept. Pharmacol. & Therap., McGill University, Montreal, Que., Canada (2) INRS-Santé, Pointe-Claire, Que., Canada.

The purpose of the following study was to better determine the biochemical characteristics of the putative calcitonin gene-related peptide (CGRP) receptor subtypes present in rat brain and lung and guinea pig atria and vas deferens. The effects of the reducing agent dithiothreitol (DTT) (0.1 to 10000 μM) and of the non-hydrolysable GTP analogue, Gpp(NH)p (100 μM), on the binding of [¹²⁵I]hCGRPα (40 pM) were evaluated in these tissues. Treatment with DTT markedly decreased, in a concentration dependent manner, specific [¹²⁵I]hCGRPα binding in all preparations. Decrements were associated with losses in maximal binding capacities without apparent alterations of binding affinities. However, DTT did not completely inhibit [¹²⁵I]hCGRPα binding even at very high concentrations (10 mM). Treatment of membrane preparations with Gpp(NH)p decreased [¹²⁵I]hCGRPα binding in rat lung. In contrast, Gpp(NH)p was totally ineffective on [¹²⁵I]hCGRPα binding in rat brain, and guinea pig atria and vas deferens. Globally, our results suggest the presence of disulfide bridges on CGRP receptor in all these preparations. However, except for the rat lung, it appears that CGRP receptors are not directly coupled to a GTP-binding protein, in contrast to most other peptide receptor subtypes studied thus far. Supported by the MRC of Canada.

GALANIN RECEPTOR AGONISTS AND ANTAGONIST REGULATE THE RELEASE OF ACETYLCHOLINE IN THE RAT HIPPOCAMPUS. G. Fisone, T. Land*, Ü. Langel*, T. Bartfai, S. Consolo*, R. Bertorelli*, P. Girotti* and T. Hökfelt. Dept. of Biochemistry, University of Stockholm, S-106 91 Stockholm, Sweden; "Mario Negri" Institute for Pharmacological Research, Milan, Italy and Dept. of Histology and Neurobiology, Karolinska Institute, Stockholm, Sweden.

The 29 amino acid long neuropeptide galanin (GAL) coexists with the classical neurotransmitter acetylcholine (ACh) in septo-hippocampal neurons of rat and monkey brain. In the rat and monkey ventral hippocampus, GAL, acting on specific pre- and postsynaptic receptors, inhibits the evoked release of ACh (*Proc. Natl. Acad. Sci. USA* 84: 7339, 1987; *Eur. J. Pharmacol.* 164: 355, 1989) and the carbachol-stimulated phosphoinositide turnover (*Eur. J. Pharmacol.* 148: 479, 1988).

We have identified the N-terminal fragments of GAL (1-9, 1-12 and 1-16) as the part of the molecule responsible for the expression of biological activity (*cf. Proc. Natl. Acad. Sci. USA* 86: 9588, 1989). When applied intracerebroventricularly (i.c.v.), the short N-terminal fragments GAL(1-9) and GAL(1-12) potently inhibit the evoked release of ACh, acting as GAL agonists. We have also synthesized a peptide which possesses the properties of a GAL receptor antagonist, i.e. it binds with high affinity to the hippocampal GAL receptors (IC₅₀ < 0.5 nM), it does not inhibit the evoked ACh release, but it antagonizes the effects of GAL applied i.c.v.

These findings represent a first step in the design of GAL receptor antagonists of possible therapeutical value in the treatment of neurodegenerative disorders, like Alzheimer's disease (*cf. Experientia* 43: 768, 1987). (Supported by grants from the Swedish Medical Research Council).

Stimulation of [³²P]GDP release from G proteins in the rat anterior pituitary lobe by gonadotropin-releasing hormone. R. Ravindra and R. S. Aronstam, Department of Pharmacology & Toxicology, Medical College of Georgia, Augusta, GA 30912-2300.

The release of GDP is the rate limiting step of the G protein cycle, and it is this step that is catalyzed by an interaction with hormonal receptors. Gonadotropin-releasing hormone (GnRH) stimulation of [³²P]GDP release from G proteins was studied in plasma membranes purified from the anterior pituitary lobes of adult male rats. Membranes (1-2 mg protein) were incubated with 0.6 μM α-³²P]GTP for 60 min at 37°C. Following this incubation, the predominant form of labelled nucleotide bound to the membranes was [³²P]GDP. The release of [³²P]GDP from the membranes was monitored at 37°C using thin layer chromatography. The amount of [³²P]GDP released was proportional to the protein concentration and increased as a function of time. GnRH agonist (0.1 μM) maximally stimulated the [³²P]GDP release by 31-38%. The GnRH agonist (0.1 μM) stimulated GDP release by 21%, 24%, 17%, and 14% at 30 sec, 1, 2, and 5 min, respectively. A GnRH antagonist also stimulated [³²P]GDP release, albeit to a somewhat lesser extent than the GnRH agonist. The antagonist did not inhibit agonist stimulation of GDP release. These results indicate that ligand binding to the GnRH receptors promotes an interaction of the receptor with a G protein and activation of a GTP/GDP exchange. This GDP release represents an early biochemical marker of GnRH receptor stimulation. (Supported by USPHS grants GM-37948 and AA-07698).

EFFECT OF 5'-GUANYLYLIMIDODIPHOSPHATE AND SULFHYDRYL-MODIFYING REAGENTS ON [¹²⁵I-TYR¹⁰]H GROWTH HORMONE-RELEASING FACTOR (1-44)NH₂ BINDING IN RAT PITUITARY. L. Lefrançois*, T. Abridat, L. Boulanger and P. Gaudreau. Neuroendocrinology Laboratory, Notre-Dame Hospital Research Center, Montreal, Canada, H2L 4M1.

High and low affinity binding sites for GRF have been identified in young rat anterior pituitaries. Binding of GRF to its cell surface receptors results in the activation of adenylate cyclase, presumably, through a guanine nucleotide-binding protein. In old rat pituitaries, a diminution of GRF-induced adenylate cyclase activity and an alteration of GRF binding parameters have been documented. To reproduce such a condition in young pituitaries and to investigate possible biochemical receptor modifications that could prevent G-protein-receptor coupling, modulation of GRF receptor affinity was evaluated in presence of Gpp(NH)p, DTT and glutathione. Gpp(NH)p (0.01-1mM), DTT and glutathione (1-50 mM), inhibited GRF specific binding in a concentration-dependent manner. Saturation experiments with 1 mM Gpp (NH)p, 1mM DTT or 10 mM glutathione revealed only one class of GRF binding sites, exhibiting a similar affinity to that found in old pituitaries. Interestingly, 1mM Gpp(NH)p did not modify GRF affinity in old pituitaries. It is suggested that G-protein-GRF receptor uncoupling is responsible for the decreased GRF receptor affinity observed in aged rats, however, the biochemical nature of receptor alterations involved in that phenomenon remains to be elucidated.

MODULATION OF ATRIAL NATRIURETIC PEPTIDE B RECEPTOR FUNCTION BY PROTEIN KINASE C. A. Rathinavelu, G. Pavlakovic, P.-W. Sun, R.P. Maickel and G.E. Isom. Dept. of Pharmacol. & Toxicol., Sch. of Pharm. & Pharmacol. Sci., Purdue Univ., West Lafayette, IN 47907.

ANP acts by binding to specific receptors in the periphery and central nervous system. cGMP is the second messenger for ANP-B receptors which are guanylate cyclase coupled, bifunctional proteins. Involvement of protein kinase C (PKC) in modulating ANP-B receptor function was explored in rat diencephalon slices and in PC12 cells. When slices were treated with a saturating concentration of (5 μ M) ANP (99-126) for 60 min, PKC activity in the cytosolic fraction increased significantly (28.2%). This increase was not observed when slices were treated with the same concentration of ANP for a shorter time (15 min). A similar increase in the cytosolic PKC activity was observed in PC12 cells treated with 5 μ M ANP. Increase in PKC activity did not occur when the slices and cells were treated with lower concentrations (0.5 and 1.0 μ M) of ANP. Quantitation of cGMP, by HPLC method, following the above treatments indicated that 0.5 μ M ANP elevated cGMP level by 321% and the increase was 85.6% with 1.0 μ M ANP. 5 μ M ANP treatment showed only 38.0% increase in the cGMP content. These results indicate PKC is induced when the ANP receptors are over stimulated and this may negatively modulate function of the ANP-B receptor.

SIGNALLING PATHWAYS OF THE EPIDERMAL GROWTH FACTOR RECEPTOR IN RAT HIPPOCAMPAL CELL LINES. M.S. Tucker and M.R. Rosner. The University of Chicago, Chicago, IL 60637.

Epidermal growth factor (EGF) receptor has been identified in hippocampal pyramidal neurons. To investigate EGF receptor function during hippocampal neuron development, we utilized two hippocampal cell lines, H19-7 and WH19-4. Differentiation of H19-7 and WH19-4 cells coincides with an increase and decrease in EGF receptor number, respectively. MAP-2 kinase is also expressed in both cell lines. EGF strongly stimulates phosphorylation of myelin basic protein (MBP), a substrate for MAP-2 kinase, in undifferentiated cells of both lines. In the differentiated cell line that expresses lower EGF receptor levels, EGF induces a low level of MBP phosphorylation. In contrast, no induction of MBP phosphorylation by EGF is observed in either the differentiated line expressing higher EGF receptor levels or in primary hippocampal neurons, which both contain a constitutively activated MBP kinase. Thus, the different levels of EGF receptor expression and the different abilities of EGF to stimulate MBP phosphorylation in the cell lines suggest that the EGF receptor may have alternate signalling pathways in developing and mature neurons as well as in different CNS cell types. 6-HYDROXYDOPAMINE (6-OHDA) LESIONS OF THE NIGROSTRIATAL DOPAMINE PATHWAY DIFFERENTIALLY REGULATE SOMATOSTATIN RECEPTOR SUBTYPES IN RAT STRIATUM. J. Zhong, K. Raynor, J.J. Soghomonian, M.F. Chesselet and T. Reisine. Dept. Pharmacol., Univ. Pennsylvania, Philadelphia, PA 19104.

Somatostatin (SRIF) is a neurotransmitter. It induces its biological effects by interacting with multiple receptor subtypes. Two SRIF receptor subtypes can be selectively labeled with the SRIF agonists [125I] MK 678 and [125I] CGP 23996. To explore the interaction of the dopamine-SRIF transmitter systems in the basal ganglia, we have investigated the effect of depletion of dopamine in the striatum on the expression of SRIF receptors in this brain region. Unilateral destruction of the nigrostriatal dopamine pathway with 6-OHDA did not alter [125I] CGP 23996 binding sites in the striatum. However, such lesions increased the level of [125I] MK 678 binding sites in the ipsilateral striatum. The elevated binding is due to an increase in density of [125I] MK 678 binding sites. Analysis of the distribution of [125I] MK 678 binding sites in the striatum of control animals indicated that a gradient of binding sites exists with ventromedial aspects of the striatum exhibiting the highest levels of MK 678-sensitive SRIF receptors and dorsolateral regions having the lowest. Following 6-OHDA lesions, the distribution of [125I] MK 678 binding sites was more homogeneous in the ipsilateral striatum suggesting that the greatest increases in SRIF receptor expression occurred in dorsolateral aspects of the striatum. The enhanced expression of the [125I] MK 678 binding sites may be an adaptive response to diminished synthesis of SRIF in the striatum since similar lesions decrease SRIF mRNA levels in the ipsilateral striatum. The results of these studies indicate that the expression of SRIF receptor subtypes can be differentially regulated and further reveal the close interaction of SRIF and dopamine transmitter systems in the basal ganglia. MAPPING THE "CLEARANCE" ANP RECEPTORS IN WISTAR KYOTO RAT BRAIN. S. Zorad, K. Tsutsumi and J.M. Saavedra. Section on Pharmacology, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

New conditions for quantitative autoradiographic determination of atrial natriuretic peptide (ANP) binding in rat brain were developed in order to block hormone degradation during incubation without the use of proteinase inhibitors. These conditions comprise 1 hr preincubation of brain slices in hypotonic solution in the presence of 2% protease-free bovine serum albumin (pfBSA) and incubation in isotonic buffer at 4°C in the presence of 4% pfBSA. HPLC revealed only 2% degraded ANP after 90 min incubation when the binding to choroid plexus and subfornical organ of Wistar Kyoto rats (WKY) had reached equilibrium. Using above conditions and the C-ANP(4-23) a truncated ANP analog selective for C (clearance) ANP receptors, we were able to displace about 30% ¹²⁵I-ANP binding to choroid plexus at 10⁻¹⁰M concentration of C-ANP. The competition curve reached plateau at the 6x10⁻¹⁰M concentration of C-ANP. Consequently the concentration 10⁻¹⁰M of C-ANP was used for mapping the presence of C receptors in rat brain. C-ANP competed for ANP binding only in external plexiform layer of the olfactory bulb, arachnoid mater and the choroid plexus. Apparent amounts of C receptors in these brain structures were 40, 76 and 30% respectively of the total ANP receptors. Other studied brain structures in adult (14 weeks old) WKY rats contained only B ANP receptors.

MECHANICAL AND CHEMICAL LESIONS INDUCE INSULIN-LIKE GROWTH FACTOR-2 (IGF-2) BUT NOT IGF-1 RECEPTOR BINDING IN THE ADULT RAT BRAIN. C.R. Brees, A. D'Costa, R.L. Boyd, J.E. Lenham, R.M. Booze, and W.E. Sonntag. Department of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27103.

The IGF-2 receptor is a single chain glycoprotein (~250kDa) which has been shown to be identical to the cation independent mannose-6-phosphate receptor. Previous reports have shown that regenerating hepatocytes (Scott) and glioblastoma cells (Sara) have increased numbers of IGF-2/Man-6-P receptors. It was therefore hypothesized that IGF-2 receptor binding would be increased in the brain following insult. Unilateral knife lesions to cortical regions or colchicine lesions to the dentate gyrus of the hippocampus were performed and the animals sacrificed after 4 days. Brains were removed and cryostat cut for receptor autoradiography. Mounted sections were incubated in ¹²⁵I-IGF-1 and ¹²⁵I-IGF-2, washed, and apposed to film. Nissl stained sections revealed an ablation of the granular cell layer of the dentate gyrus, and extensive glial ingrowth into both lesioned regions. IGF-1 receptor autoradiography revealed an absence of normal binding in the dentate molecular layers, further supporting a loss of dentate granular cells. IGF-1 binding in the lesioned regions of the cortex was not increased as compared to the contralateral side. Conversely, IGF-2 binding was dramatically increased in lesioned areas. In the dentate gyrus, IGF-2 binding was increased 42% over normal binding, in spite of a complete loss of granular cells. In the lesioned cortical areas, IGF-2 binding was increased 350% over that normally seen in this region. While it unclear at this time the nature of the increased binding, it is clear that expression of IGF-2 receptors by astroglia following neuronal insult is important to tissue remodelling seen following brain injury. (supported by NIH grant AG07752 to WES).

319.24

COMPARTMENTAL LOCALIZATION OF SOMATOSTATIN (SRIF) RECEPTORS IN THE STRIATUM. H. Kong, J. Zhong, K. Raynor, C. Gonzales, Y. Qin, M.F. Chesselet and T. Reisine. Dept. Pharmacol., Univ. Pennsylvania, Philadelphia, PA 19104.

The distribution of SRIF receptors in the striatum was measured by autoradiography using the highly selective SRIF agonist [125I] MK 678. [125I] MK 678 binding sites were expressed in an uneven pattern within the rat striatum similar to the distribution of SRIF-like immunoreactivity. To determine whether the distribution of SRIF receptors corresponded to a localization to striosomes or extrasstriosomal matrix compartments of the striatum, adjacent sections of rat striatum were analyzed for [125I] MK 678 binding or [³H] naloxone binding, which is a marker for the striosomal compartment of the rat striatum. From these studies it was determined that SRIF receptors are more highly expressed in the extrasstriosomal matrix compartment than striosomes in rat striatum. A similar localization of SRIF receptors was observed in the cat caudate nucleus, that is [125I] MK 678 binding sites were predominantly localized to acetylcholinesterase-rich areas, consistent with an extrasstriosomal matrix localization. In contrast, [125I] MK 678 binding sites exhibited a patchy distribution in Rhesus monkey caudate nucleus and may be predominantly expressed in striosomes in this species. These species variations in the distribution of SRIF receptors in the striatum may be related to differences in the expression of SRIF. The findings of these studies suggest that SRIF receptors have a compartmental localization in the striatum which may contribute to specifying the functions mediated by SRIF in the striatum. This work was supported by NIMH grants 45533 (TR) and 44894 (MFC).

319.25

ANALOGS OF SOMATOSTATIN SELECTIVELY INTERACT WITH SUBTYPES OF SRIF RECEPTORS IN THE CNS. Karen Raynor and Terry Reisine. Department of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Somatostatin (SRIF) is a neurotransmitter which produces its multiple biological effects in the central nervous system (CNS) through interactions with membrane-bound receptors. Subtypes of SRIF receptors are found in the CNS which are distinguished by their sensitivities to the cyclic hexapeptide MK 678, as the displacement of [125I]Tyr11SRIF binding by MK 678 was incomplete. The inhibition of [125I]MK 678 binding by SRIF, CGP 23996 and MK 678 was monophasic, consistent with the highly selective labeling of a subtype of SRIF receptor. The inhibition of the binding of [125I]Tyr11SRIF and [125I]CGP 23996 by CGP 23996 was biphasic, indicating that CGP 23996 has differing affinities for subtypes of SRIF receptors. The MK 678-sensitive receptor subtype was labeled with [125I]MK 678 and the binding was potently and monophasically displaced by disulphide bridge-containing octapeptides, such as SMS 201-995, and by other cyclic hexapeptide analogs. The binding was unaffected by dicarba-containing analogs, indicating they do not interact with the MK 678-sensitive receptor. The displacement of [125I]CGP 23996 binding by the octapeptides was biphasic, consistent with the labeling of multiple SRIF receptor subpopulations. The displacement of [125I]CGP 23996 binding by either the hexapeptides or the dicarba-containing analogs was incomplete. The results of inhibition studies showed that the hexapeptides and dicarba-containing compounds were additive in displacing [125I] CGP 23996 binding indicating selective interaction of these compounds with different receptor subpopulations. [125I]MK 678 binding was abolished by 100 μ M GTP γ S, but [125I]CGP 23996 binding was only partially affected and this corresponded to that component of labeling which was MK 678-sensitive. Thus, two SRIF receptor subpopulations exist in the CNS which are differentially sensitive to the cyclic hexapeptides and dicarba-containing analogs. They are further differentiated by their sensitivities to GTP γ S. These peptide analogs will be useful in the future characterization of the functions mediated by SRIF receptor subtypes in the CNS. Supported by MH45533.

Interactions of Alpha, Beta, and Gamma Subunits of GTP Binding Regulatory (G) Proteins. H.M. Juul, S.F. Law, and T. Reisine. Dept. of Pharmacology and Graduate Group in Cell Biol. Univ. of Pennsylvania, Phila. Pa. 19104

The heterotrimeric G proteins serve to transduce signals from membrane bound receptors to intracellular second messenger systems. Multiple forms of each of the three subunits are known to exist in rat brain. Our lab is investigating the specificity of associations between the alpha, beta, and gamma subtypes of G proteins using methods developed for the elucidation of G protein coupling to the somatostatin receptor. Rat brain homogenates were solubilized with the nonionic detergent CHAPS and then size fractionated on a gel exclusion column. Fractions enriched for somatostatin receptor binding were concentrated and subjected to immunoprecipitation with G protein subtype specific antisera. The resulting immune complexes were then screened by western analysis with antisera directed against a variety of subunits of G proteins to determine the ability of the different subunits to associate. By immunoprecipitating with antisera directed against $G_{i\alpha}$, and screening the immune complexes using western analysis with antisera against beta 35 and beta 36, it was determined that both forms of beta subunits are capable of associating with $G_{i\alpha}$. Furthermore, by using antisera specific for each of the $G_{i\alpha}$ subtypes, as well as Gao, we demonstrate that $G_{i\alpha}$ subtypes 1, 2, and 3, and Gao, can associate with beta 35 and beta 36. Beta-gamma associations were investigated by immunoprecipitating with beta specific antisera and then screening immune complexes by western analysis with antisera against gamma 2 and gamma 3. It was found that both gamma 2 and gamma 3 coimmunoprecipitate with beta 35 and beta 36, although differences were observed between the amounts of gamma 2 and gamma 3 which complex with the beta subtypes. Supported by grants MH45533 and GM08076

DEVELOPMENT OF ANTIBODIES AGAINST THE SOMATOSTATIN RECEPTOR

Maqali Théveniau, Stephanie Rens-Domiano, Susan F. Law, Geneviève Rougon and Terry Reisine. Dept. Pharmacol. Univ. of Pennsylvania, PA and URA CNRS 179, Marseille France.

Somatostatin (SRIF) is a neuroregulator of pituitary secretion and in the brain a mediator of different behaviors such as cognition and motor activity. Its effect are triggered through specific G-protein coupled receptors. Polyclonal antibodies directed against the active form of the solubilized brain SRIF receptor have been developed to investigate the molecular mechanisms responsible for the physiological actions of SRIF. These antibodies were purified from immunoblots and characterized. The antibodies are able to immunoprecipitate SRIF receptors from rat brain as well as the pituitary cell line AtT20. In tissues and cell lines that express the SRIF receptor, such as rat brain, AtT20 and GH3, a 55 kDa protein band is specifically detected with the anti-SRIF receptor antibodies by immunoblotting. A similar size protein is also immunoprecipitated from AtT20 cells prelabeled with 35 S-methionine. This protein is absent from membrane preparations of cells which do not express the SRIF receptor.

Since the antibodies specifically react with the SRIF receptor and are able to immunoprecipitate it, they are useful in studying the physical properties of the receptor and its coupling to G-proteins. Furthermore, these antibodies may allow for the cloning of the gene(s) encoding the SRIF receptors.

Supported by NIMH grant 45533 and grants from the Human Frontiers in Science Found. and NATO.

ANTISERUM AGAINST $G_{i\alpha}$ BLOCKS SOMATOSTATIN INHIBITION OF ADENYLYL CYCLASE ACTIVITY Melanie Tallent and Terry Reisine. Inst. of Neurol. Sci. and Dept. Pharmacol., Univ. Pennsylvania, Philadelphia, PA 19104

The neuropeptide somatostatin (SRIF) is a major inhibitor of hormone secretion from the anterior pituitary. It induces its effects, in part, by reducing the synthesis of the second messenger, cAMP. SRIF receptors are believed to be coupled in an inhibitory fashion to the catalytic subunit of adenylyl cyclase via the GTP binding regulatory (G) protein, G_i . In previous studies, we have shown that SRIF receptor/ G_i complexes from the pituitary cell line AtT-20 can be immunoprecipitated with an antiserum (8730) directed against the C-terminal region of the alpha subunit of G_i ($G_{i\alpha}$). In the present study, we show that antiserum 8730 can also disrupt functional coupling of the SRIF receptor/ $G_{i\alpha}$ complex with the catalytic subunit of adenylyl cyclase. In membranes pretreated with antiserum 8730, the inhibitory effect of SRIF on adenylyl cyclase activity was attenuated by 42%. The blockade by antiserum 8730 was specific since it could be prevented by the peptide to which the antiserum was generated. Since antiserum 8730 is directed against the C-terminal region of $G_{i\alpha}$, these results suggest that this region of the alpha subunit is critical for G protein/adenylyl cyclase coupling. Studies are in progress using antiserum directed against different subtypes of $G_{i\alpha}$ to investigate whether different $G_{i\alpha}$'s direct the receptor to divergent cellular effector systems. Supported by grant MH 45533.

Beta and Gamma Subunits of G Proteins Couple to the Somatostatin Receptor. S.F. Law and T. Reisine. Dept. of Pharmacology and Graduate Group in Cell Biol. University of Pennsylvania, Phila. Pa. 19104.

SRIF is a neuropeptide that inhibits growth hormone secretion from the anterior pituitary and is involved in the control neuronal activity. SRIF acts through its receptor to inhibit adenylyl cyclase, Ca^{2+} conductance and increases K^+ conductance. SRIF receptors couple to their cellular effector systems via G proteins. We have previously shown in immunoprecipitation studies utilizing peptide directed antisera against the alpha subunit of G proteins, that $G_{i\alpha 1}$ and $G_{i\alpha 3}$ are associated with the SRIF receptor from rat brain, but $G_{i\alpha 2}$ was not. This same immunoprecipitation protocol was used to study the beta and gamma subunits associated with the SRIF receptor. The SRIF receptor was solubilized from rat brain with the nonionic detergent CHAPS and fractionated by gel exclusion chromatography. The solubilized fractionated SRIF receptor was exposed to peptide directed antisera against the beta subunits of G proteins and precipitated with protein A sepharose. SRIF receptors in the immune complex were detected by the high affinity SRIF agonist 125I MK678. Antisera directed against beta36 specifically immunoprecipitated 40% of 125I MK678 sensitive SRIF receptors whereas antisera directed against beta35 did not. The ability of the alpha36 antisera to immunoprecipitate SRIF receptor binding was selectively blocked by the peptide to which they were directed. Along with beta36, gamma2 and gamma3 but not gamma1 immunoreactivity was coimmunoprecipitated with the SRIF receptor. These results indicate that the SRIF receptor from rat brain is associated with beta36 and gamma2 and/or gamma3. Work supported by grant MH45533.

FUNCTIONAL ROLE OF SIALIC ACID RESIDUES ON SOMATOSTATIN (SRIF) RECEPTORS. S. Rens-Domiano and T. Reisine. Dept. of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

SRIF is a neurotransmitter in the brain whose physiological actions are mediated by cell surface receptors. We have previously shown SRIF receptors to be glycoproteins and that treatment of solubilized SRIF receptors with neuraminidase removes sialic acid residues from the receptor and diminishes high affinity agonist binding to the receptor. Further studies have been conducted to understand the functional role of sialic acid residues on SRIF receptors. Overnight treatment of intact AtT20 cells, a pituitary tumor cell line, with neuraminidase resulted in the reduction of high affinity binding of the stable SRIF agonist [125I]MK 678 to SRIF receptors. This treatment did not effect the maximal ability of SRIF to inhibit forskolin-stimulated cAMP production in AtT20 cells. Treatment of AtT20 cell membranes with neuraminidase for 5 hours resulted in a 75% decrease in specific, high affinity [125I]MK 678 binding sites. However, when the membranes were pretreated with SRIF agonist, neuraminidase was only able to decrease high affinity binding by 24%. These data would suggest that the desialylated SRIF receptors are functionally active and remain coupled with G-proteins, but exhibit a reduced affinity for agonist. The protection from the effects of neuraminidase on SRIF receptors afforded by SRIF agonist occupancy suggests that the sialic acids may be associated with the ligand bind site of SRIF receptors. Specifically, the negatively charged sialic acid residues may promote high affinity agonist binding to SRIF receptors through electrostatic interactions since SRIF contains a charged lysine residue critical for high affinity binding. REGULATION OF SOMATOSTATIN RECEPTORS BY BETA-ADRENERGIC RECEPTOR KINASE (BARK). J. Delfs, S. Rens-Domiano, J. Benovic* and T. Reisine. Dept. Pharmacol. and Inst. Neurol. Sci., Univ. Pennsylvania, Philadelphia PA, 19104 and the Fels Research Inst., Philadelphia, PA, 19140.

The neuropeptide somatostatin (SRIF) is an important physiological regulator of hormone secretion from the pituitary. It induces its actions by stimulating membrane associated receptors. Continuous application of SRIF to pituitary cells desensitizes SRIF receptors. It has been postulated that SRIF desensitization may involve the phosphorylation of the receptor and that this phosphorylation may be catalyzed by the enzyme BARK. To test this hypothesis, SRIF receptors from the pituitary cell line AtT-20 were reacted with purified BARK, SRIF agonist and ATP and the loss of specific agonist binding to the receptor due to phosphorylation was measured. BARK caused a decrease (20%) in the binding of the high affinity, SRIF agonist [¹²⁵I] MK 678 to SRIF receptors. This effect was blocked by an inhibitor of BARK, dextran sulfate, and required that the receptor be occupied by agonist. These findings are the first direct evidence that BARK may have a role in SRIF desensitization and support the hypothesis that SRIF desensitization may involve the phosphorylation of the SRIF receptor. This work was supported by grants MH 45533, GM 34781, GM 44944 and training grant MH 17168.

PEPTIDES: RECEPTORS III

CP-96,345 A SELECTIVE NONPEPTIDE TACHYKININ NK₁ RECEPTOR ANTAGONIST. A.H. Ganong, L.S. Reynolds, C.J. Siok, D.K. Bryce* and S. McLean. Dept. of Neuroscience, Central Research Division, Pfizer Inc., Groton, CT 06344.

CP-96,345 is a recently described nonpeptide NK₁ tachykinin receptor antagonist (*Science* 251:434-439,1991). Using radioligand binding assays and extracellular recordings from locus coeruleus (LC) neurons in a slice preparation, the selectivity and functional activity of CP-96,345 at the NK₁ receptor is described. For the binding assays, membranes (P₂) from guinea pig striatum (NK₁), hamster bladder (NK₂), and guinea pig cortex (NK₃) were incubated with ³H-SP (2.3 nM), ¹²⁵I-iodohistidyl-NKA (0.1 nM) and ¹²⁵I-BH-cleidoisin (0.1 nM), respectively.

The rank order of potency in displacing ³H-SP binding to the NK₁ receptor was CP-96,345>SP>phylalaemin>eledoisin>NKA>NKB. In contrast, the rank order for displacing ¹²⁵I-NKA binding was NKA>SP>eledoisin>CP-96,345. Similarly, CP-96,345 was relatively weak in displacing ¹²⁵I-BH-cleidoisin binding with the rank order of potency senktide>eledoisin>NKB>NKA>SP>CP-96,345. CP-96,345 is at least 100-fold selective for the NK₁ receptor with IC₅₀ values of 5 nM for the NK₁ receptor and >2000 nM at the NK₂ and NK₃ receptors.

The NK₁ agonist substance P produced a dose-dependent increase in firing rates of locus coeruleus neurons recorded extracellularly in guinea pig brainstem slices; maximal firing rate increases of ~500% were achieved with 1-10 μM SP. Excitations induced by 100 nM SP were inhibited dose-dependently by CP-96,345 with an IC₅₀ value of 90 nM. Excitations produced by the NK₃ agonist senktide were not significantly inhibited by 1 μM CP-96,345.

CP-96,345 will be a useful pharmacological tool for elucidating the role of tachykinin receptor subtypes in the physiological actions of endogenous tachykinin transmitter and the utility of NK₁ antagonists as therapeutic drugs.

320.3

HYPERLOCOMOTION INDUCED BY ICV [SAR⁹, MET(O₂)¹¹]-SP IS REVERSED BY THE SELECTIVE NK-1 ANTAGONIST, CP-96,345. P. A. Seymour, G. L. Robinson* and D. K. Bryce*. Dept. of Neuroscience, Central Research Division, Pfizer Inc., Groton, CT 06340.

Studies have shown that ICV administration of Substance P (SP) induces hyperlocomotion in rats (e.g. Elliot and Iversen, *Brain Res.* 381,1986, 68) and guinea pigs (Brent et al., *Neuropharm.* 27:7,1988, 743). Since the SP analog, [SAR⁹, MET(O₂)¹¹]-SP has been shown to be a potent and selective agonist at NK-1 receptors (Drapeau et al., *Neuropeptides* 10,1987, 43) these studies were aimed at elucidating the role of NK-1 receptors in the hyperactivity response to SP. Guide cannulae were implanted in the lateral ventricles of anesthetized guinea pigs and after recovery from surgery, animals were placed into automated behavioral chambers for overnight habituation. [SAR⁹, MET(O₂)¹¹]-SP was infused into the ventricles and activity was recorded for several hours. Data analysis showed that this compound significantly increased horizontal locomotor activity in a dose related manner (3.2-32 μg/side) for approximately 2 hours. In antagonism experiments compounds were given s.c. 30 minutes after ICV [SAR⁹, MET(O₂)¹¹]-SP (25 μg) and data were recorded for 1.5 hours. These studies showed that the nonpeptidic NK-1 antagonist, CP-96,345, significantly and completely antagonized the hyperactivity response with an ED₅₀ of 1.9 mg/kg. In contrast, the enantiomer of CP-96,345, which lacks appreciable NK-1 receptor affinity, was without effect. These results support the hypothesis that SP increases locomotor activity by agonist activity at NK-1 receptors, and demonstrate that CP-96,345 acts as an antagonist at brain NK-1 receptors *in vivo*.

320.2

DIFFERENTIAL BINDING OF CP-96345 ACROSS SPECIES: POSSIBLE HETEROGENEITY OF THE NK₁ TACHYKININ RECEPTOR. D. K. Bryce* and S. McLean. Dept. of Neuroscience, Central Research Division, Pfizer Inc., Groton, CT 06340.

The recent discovery of CP-96345, a potent and selective non-peptide NK₁ receptor antagonist provides a valuable tool for the study of the pharmacology of NK₁ receptors. As suggested by Snider et al. (*Science* 251: 435-437, 1991), species differences exist at the tachykinin NK₁ receptor. Investigation of this heterogeneity was carried out using [³H]-substance P (SP), [³H]-CP-96345, and [¹²⁵I]-Bolton-Hunter (BH) SP, in radioligand binding experiments using P₂ preparations of mouse, rat, guinea pig, and marmoset whole forebrain. Saturation studies indicated that the affinity and receptor density for [³H]-SP was similar across species, consistent with values reported previously (see Dam and Quirion, *Peptides*, 7: 855-864, 1986). In contrast, the binding affinity of [³H]-CP-96345 differed markedly across species. In the guinea pig and marmoset [³H]-CP-96345 bound with high affinity (K_d = ~1.0nM), while in the rat and mouse binding affinity was decreased 10-30 fold. Differences between species were also obtained in competition studies. CP-96345 was 10-20 fold more potent in displacing the binding of [¹²⁵I]-BH-SP to guinea pig and marmoset brain than to rat or mouse brain while SP did not discriminate among the species (IC₅₀s=1-2 nM). Although agonist binding does not differentiate among the species, the selective NK₁ receptor antagonist CP-96,345 exhibits marked differences in potency.

320.4

QUANTITATIVE AUTORADIOGRAPHY OF THE SUBSTANCE P (NK₁) RECEPTOR WITH A NEW NON-PEPTIDE ANTAGONIST LIGAND: ³H-CP-96,345. T. F. Seeger and K. G. Pratt*. Neuroscience Dept., Pfizer Central Research, Groton, CT 06340.

CP-96,345 is the first potent non-peptide antagonist of the Substance P (SP) NK₁ receptor (*Science* 251:435-439). CP-96,345 was tritiated and binding conditions optimized for autoradiography in hamster brain sections. ³H-CP-96,345 demonstrated saturable binding (K_d = 1.9 nM) to sections that was displaceable by SP, but not by Substance K or eledoisin at submicromolar concentrations, suggesting selective interaction with the NK₁ receptor. The distribution of ³H-CP-96,345 binding closely matched the pattern of ³H-SP binding visualized in adjacent sections. Dense binding was noted in striatum, nucleus accumbens, bed nucleus, cortical amygdala, habenula, and the septohippocampal, amygdalohippocampal and periventricular nuclei. Moderate levels were seen in hypothalamus, superior colliculus, medial geniculate, subiculum, and central gray. Little specific binding was noted in cortex, hippocampus, cerebellum, and most thalamic nuclei. Similar patterns of ³H-CP-96,345 binding were seen in guinea pig and marmoset brain. ³H-CP-96,345 provides a valuable tool for the study of the mammalian NK₁ tachykinin receptor.

320.5

NOVEL NON-PEPTIDE SUBSTANCE P ANTAGONISTS IN THE RAT. L.D. Aimone, K.C. Appell*, S.C. Chippari*, A.L. Harris* and S.J. Ward, Sterling Research Group, 81 Columbia Turnpike, Rensselaer, NY 12144, 9 Great Valley Parkway, Malvern, PA 19087

We describe the discovery of WIN 51708 and WIN 62577, novel non-peptide substance P (SP) antagonists with selectivity for the NK-1 receptor. NK-1 activity was defined against [¹²⁵I] SP in a rat forebrain binding assay. WIN 51708 and WIN 62577 both bind competitively at the NK-1 site with a K_i of 22 ± 5 nM ($n=3$) and 21 ± 4 nM ($n=3$), respectively. These compounds have K_{is} of 1.3 and 4.5 μ M against [¹²⁵I] neurokinin A binding at the NK-2 site in the rat duodenum.

Plasma extravasation (PE) of Evans Blue dye was induced by the intraplantar injection of SP (2.5 nM). Antagonists (0.1 to 3.0 mg/kg, IV) were administered 2 min prior to SP. WIN 51708 and WIN 62577 produced a dose-dependent inhibition of SP-induced PE with IC_{50} s of 0.9 ± 1.0 and 2.2 ± 0.8 mg/kg. Neither compound was effective in inhibiting PE induced by bradykinin (2.5 nM). An in-vivo time course revealed WIN 51708 to be active in the PE assay for greater than 45 min.

WIN 51708 and WIN 62577, novel non-peptide NK-1 selective antagonists, will be useful in defining the physiological role of NK-1 receptors.

320.7

CHARACTERIZATION OF ELECTROPHYSIOLOGICAL RESPONSE TO SUBSTANCE P IN HUMAN ASTROCYTOME CELL LINE U373. L. Pradier, S. Le Guern*, M. Laville*, A. Doble, Rhone-Poulenc Rorer, CRVA, 13 Quai J. Guesde, 94400 Vitry, France.

The neuropeptide substance P (SP) is a member of the tachykinin family. Its function in certain smooth muscle stimulation has long been known and its presence in sensory C afferent fibers and dorsal horn of the spinal cord has made SP a prime candidate as a pain neurotransmitter. However functions in the higher structures of the central nervous system have remained elusive. We report studies of SP responses in the human astrocytome cell line U373 using the whole-cell patch-clamp technique. Reproducible responses to brief application of SP (10 nM) could be obtained with little desensitization and were shown pharmacologically to be mediated by an NK1 type receptor. At -30 mV, the biphasic SP response was composed of an initial large outward current followed by a slow inward component. Both currents were carried by K ions as demonstrated by shifts in the reversal potential upon external [K⁺] modification. The two K channels could be differentiated pharmacologically, the first component being likely activated by the rise in internal [Ca²⁺]. Responses could be elicited in the absence of external Ca although they displayed a marked desensitization under those conditions. The human U373 cell line may thus represent a convenient system to study the pharmacology of the NK1 receptor in the human brain.

A NOVEL NK₂ RECEPTOR SUBTYPE IN FIBROBLASTS TRANSFECTED WITH BOVINE cDNA EXPRESSING NK₂ RECEPTORS A.K. Henderson, P.L.M. van Giersbergen^{1,2}, S.H. Buck¹, W.R. Roeske and H.I. Yamamura Departments of Pharmacology & Internal Medicine, University of Arizona, Tucson, AZ 85724; ¹Marion Merrell Dow Research Institute, Cincinnati, OH 45215; ²Department of Pharmacology & Cell Biophysics, University of Cincinnati, Cincinnati, OH 45267.

Tachykinin receptors have been classified into three distinct subtypes by their rank order of affinity to neurokinin agonists. Recently two antagonists for the neurokinin A receptor (NK₂), [Tyr², D-Trp^{6,8,9}, Arg¹⁰]-NKA(4-10) (MEN 10207) and [Tyr², D-Trp^{6,8,9}, Arg¹⁰]-NKA(3-10) (MEN 10208), demonstrated heterogeneity among NK₂ receptors in rabbit pulmonary artery (RPA) and hamster trachea (HT). Both antagonists had high affinity for NK₂ receptors in RPA and low affinity for these receptors in HT (Maggi, 1990). In contrast, these ligands had different binding affinities for NK₂ receptors expressed by SKLKB82#3 cells, fibroblasts transfected with bovine stomach cDNA encoding for this receptor. In competitive ligand/[¹²⁵I]NKA assays with SKLKB82#3 cells, the IC_{50} value was 21 nM for MEN 10207 and 691 nM for MEN 10208. This difference was also observed in bovine stomach membranes which had an IC_{50} value of 54 nM and 1560 nM, respectively. In addition, in the SKLKB82#3 cells the pA_2 values were 7.96 for MEN 10207 and 6.59 for MEN 10208 in inhibiting NKA induced [³H]IP₁ accumulation. The different affinities of MEN 10207 and MEN 10208 for the NK₂ receptor in RPA, HT or bovine stomach may be a result of a species difference or indicate distinct NK₂ receptor subtypes.

320.6

CHARACTERIZATION OF THE SUBSTANCE P RECEPTOR IN TUNICAMYCIN-TREATED TRANSFECTED CELLS USING A PHOTOAFFINITY ANALOG. R. Kage¹, A.D. Hershey², J.E. Krause², N.D. Boyd¹, S.E. Leeman¹. ¹Univ. of Mass. Medical Center, Worcester, MA 01655; ²Washington Univ. School of Medicine, St. Louis, MO 6311A

A photoaffinity analog of substance P (SP), p-benzoyl-L-phenylalanine-substance P [Phe⁸(pBz)]SP, has recently been described (Boyd et al., Biochemistry 30, 336, 1991). CHO cells transfected with the complete coding region of the rat substance P receptor (SPR) cDNA were treated with 5 μ g/ml tunicamycin for two days. Increasing concentrations of SP inhibited the binding of [¹²⁵I]-[Phe⁸(pBz)]SP to non-treated and tunicamycin-treated cells with the same IC_{50} (0.3 nM). Photolabelling of tunicamycin-treated CHO cells with [¹²⁵I]-[Phe⁸(pBz)]SP followed by SDS-PAGE and autoradiography showed two protein bands; one broad band centered at a mol.wt. of about 80,000 corresponding to the SPR in non-treated cells and a second narrower band with a mol.wt. of 48,000 corresponding to the mol.wt. of the photolabelled SPR which has been incubated with endoglycosidase F to remove N-linked oligosaccharides. Tunicamycin-treated CHO cells were photolabelled in the presence of increasing concentrations of SP and the radioactive SPR bands quantitatively analyzed after SDS-PAGE and autoradiography. These experiments give the first direct evidence that in CHO cells expressing the SPR the non-glycosylated receptor is able to bind SP with an affinity that is not significantly different from the glycosylated receptor. 320.8

NEUROKININ RECEPTOR-MEDIATED DEPOLARISATION OF NEURONES IN RAT SUPERIOR CERVICAL GANGLIA.

Seabrook G.R., Main M.J., Hill R.G., Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex, CM20 2QR, U.K.

At least 3 types of neurokinin receptors are present on neurones. It has been reported that the rank order of potency of neurokinin agonists at producing depolarisations in rat superior cervical ganglia (SCG) are inconsistent with described receptor subtypes (Brown et al 1983). Here we provide evidence for a heterogeneous population of neurokinin receptors in rat SCG which can account for this atypical agonist profile.

DC recordings were made from isolated rat SCG using grease-gap methodology in the presence of tetrodotoxin (0.1 μ M). The rank order of agonist potency was as follows (EC₅₀ in nM): senktide (4) > substance P (12) > substance P methyl ester (30) = eleodoisin (33) > neurokinin B (118) > neurokinin A (267). It was apparent that the maximal depolarisation induced by the NK3 selective agonist, senktide, was less than that of the other agonists (27% that of 1 μ M eleodoisin). Similarly, the NK1 selective ligands substance P and its methyl ester had submaximal efficacies of 72% and 77% respectively. The depolarisations elicited by senktide and eleodoisin were not blocked by atropine (1 μ M).

It is evident from the above data that rat SCG possess both NK1 and NK3 receptors. The need for determination of both agonist potency and efficacy in characterisation of neurokinin receptor subtypes is emphasised.

Brown et al. 1983 J. Physiol. (Lond.) 334; 91P

320.10

NEUROPEPTIDE γ -PREFERING SUBTYPES OF NK₂ RECEPTORS IN RAT FUNDUS AND DOG URINARY BLADDER. E. Burcher and C.J. Müssap, School of Physiology and Pharmacology, University of New South Wales, Sydney, NSW 2033, Australia.

Recent work with novel antagonists has suggested that subtypes of the tachykinin NK₂ receptor exist. L-659,877 and MDL 29,913 show preference for one postulated subtype; MEN 10207 shows preference for another. In this study, we have used radioligand binding and isolated organ techniques to characterize the NK₂ receptors found in rat fundus and dog bladder. In homogenates of rat fundus, binding of 100 pM [¹²⁵I]-iodohistidyl NKA (INKA) was inhibited by neuropeptide γ (NP γ) = neuropeptide K (NPK) > NKA > kassinin > MDL 29,913 > [Sar⁹,Met(O₂)¹¹]-SP \geq neurokinin B (NKB) \geq substance P (SP) > MEN 10207 >> senktide. The potency order for contraction of the isolated fundus strip was NP γ > kassinin \geq NKA \geq NPK \geq [Lys⁵,MeLeu⁹,Nle¹⁰]-NKA(4-10) > NKB, with senktide and [Sar⁹,Met(O₂)¹¹]-SP ineffective. MDL 29,913 competitively antagonized responses to NP γ (pA_2 7.2) and other tachykinins. In homogenates of dog bladder (minus mucosa), INKA binding was inhibited by NP γ > NKA > kassinin = NPK >> NKB \geq SP > L-659,877 > MDL 29,913 > MEN 10207 >> senktide. In isolated strips, the rank potency order was NP γ \geq kassinin \geq [Lys⁵,MeLeu⁹,Nle¹⁰]-NKA(4-10) = NPK = NKB. Contractile responses were diminished by atropine or mepyrmine and were enhanced by phosphoramidon. Responses to NP γ , NPK and [Lys⁵,MeLeu⁹,Nle¹⁰]-NKA(4-10) were antagonized by MDL 29,913 in a competitive manner (pA_2 6.4 - 6.6). Autoradiographic studies showed binding sites for INKA over the circular muscle and muscularis mucosae of rat fundus and over the muscularis and blood vessels of dog bladder. These data provide evidence for "classical" MDL 29,913-preferring NK₂ subtypes in rat fundus. The NK₂ receptors in dog bladder are less easy to categorize. NK₂ receptors in both tissues have high affinity for NP γ .

320.11

NEUROPEPTIDE RECEPTORS IN DEVELOPING AND ADULT RAT SPINAL CORD: AN *IN VITRO* QUANTITATIVE AUTORADIOGRAPHY STUDY. S. Kar, J.-G. Chabot and R. Quirion. Douglas Hospital Research Center, Department of Psychiatry, McGill University, Montreal, Canada H4H 1R3.

The spinal cord which forms a vital link in relaying information to and from the brain, is endowed with a number of neuropeptides. These peptides are considered to function as neurotransmitters/neuromodulators in spinal synaptic transmission and are localized primarily in the superficial layers of the dorsal horn, intermediolateral cell column and in the ventral horn of the spinal cord. To provide a substrate for better understanding of neuropeptide functions, we have studied the distribution as well as the postnatal development of calcitonin gene-related peptide (CGRP), neurokinin/substance P (NK-1 and NK-3), galanin (GAL), vasoactive intestinal polypeptide (VIP), neuropeptide Y (NPY), peptide YY (PYY) and μ opioid receptor binding sites in the spinal cord of rat using *in vitro* quantitative receptor autoradiography. The distribution of the receptor binding sites for each peptide demonstrated a characteristic pattern in the developing and adult spinal cord. At postnatal day 1, notwithstanding the variation in the density of labelling, the receptor binding sites of all the peptides studied were observed throughout the grey matter as well as the white matter of the spinal cord. Changes in the pattern of distribution of binding sites were not noticed until day 7 of postnatal development. However, the receptor binding sites of each neuropeptide subsequently exhibited dramatic alterations at all regions of the spinal cord and attained the adult pattern of distribution during third week of postnatal development. In the adult rat spinal cord, high density of receptor binding sites of all the peptides, except CGRP, were found primarily in the superficial layers (laminae I-II) of the dorsal horn. Labelling in areas around the central canal, intermediolateral cell column and in the ventral horn was relatively low and varies according to the neuropeptides as follows: NK-1>CGRP>GAL>PYY> μ opioid>NPY>NK-3>VIP. This study thus reveals that the receptor binding sites of the peptides differ in terms of their distribution and pattern of development. Early appearance of binding sites and their dramatic variation during the course of development suggest an important role for these peptides in early maturation and organization of the spinal cord. Furthermore, the presence of receptor binding sites in discrete areas of the adult spinal cord strongly support the implication of neuropeptides in various sensory, autonomic and motor functions of the spinal cord.

DISTRIBUTION OF NEUROKININ RECEPTOR GENE EXPRESSION IN THE RAT BRAIN. M. S. Poosch, D. J. Goebel and M. J. Bannon. Dept. of Psychiatry, Wayne State University, Detroit, MI 48201.

The neurokinin receptors NK1, NK2 and NK3 have been classified based on their differing affinities for various tachykinin peptide ligands. Recently, the expression of these receptor genes in the brain and peripheral tissues has been confirmed by solution hybridization techniques. NK1 and NK3 clones (obtained by PCR amplification of rat cortex cDNA) as well as an NK2 clone (courtesy of J. Krause) were used to detect gene expression of each receptor type by simultaneous solution hybridization using ³²P labeled probes. The rank order of NK1 receptor mRNA expression in selected areas of the rat brain was as follows: hypothalamus > striatum > olfactory bulb > substantia nigra = hippocampus > cortex > cerebellum. Expression of the NK2 receptor was limited to the hippocampus, hypothalamus and substantia nigra, accounting for only 1% of the total amount of neurokinin receptor mRNA in these regions. The NK3 receptor was the most predominantly expressed of the three receptor types, with substantia nigra and cerebellum exhibiting the highest concentration followed by the cortex, hypothalamus, striatum, hippocampus and olfactory bulb. The cellular localization of neurokinin receptor gene expression is under investigation using *in situ* hybridization and lesion experiments. Supported by: grant MH 43026.

AFFINITY CHANGES OF NEUROTENSIN RECEPTORS AFTER CHRONIC ETHANOL: CORRELATIONS WITH TOLERANCE. A. D. Campbell and V. G. Erwin. School of Pharmacy and Alcohol Research Center, University of Colorado, Boulder, CO 80309.

Neurotensin (NT), a tridecapeptide widely distributed in brain, acts as a neurotransmitter or neuromodulator, and may mediate some of the effects of ethanol. This laboratory has shown that NT produces a dose-dependent increase in ethanol sensitivity in short sleep (SS) but not long sleep (LS) mice, which were selectively bred for differences in ethanol sensitivity. The NT receptor system in these mice is best described by a two site model, with high (NT_H) and low (NT_L) affinity receptors being present, the latter being sensitive to the antihistamine, levocabastine. The LS and SS mice have been shown to differ in NT receptor density in several brain regions. The present study was conducted to determine the effects of chronic ethanol administration on NT receptor systems in these lines of mice. After two weeks of ethanol consumption, receptor binding was best described by a one site model, and effects at three or four weeks were not different from two weeks. Unlike control K_D values (0.3 and 3.5 nM), Scatchard analysis of [³H]NT binding in ventral midbrain and entorhinal cortex membranes from chronically treated mice revealed a one site model, with a K_D value of 1 nM. The B_{max} values, however, were not changed by this treatment. Additionally, the numbers of levocabastine-sensitive and insensitive receptors were not changed, suggesting a shift in the affinity of NT_H and/or NT_L receptors. The effects of ethanol administration on the affinity of NT receptors closely paralleled the development of behavioral tolerance and the disappearance of tolerance after withdrawal. Indeed, after four weeks of withdrawal from ethanol, the receptor characteristics appeared to return to control values. The finding that chronic ethanol markedly affects the NT receptor systems further supports the hypothesis that ethanol's actions may be mediated in part by neurotensinergic systems. (Supported by NIAAA Grants 00079, 30527, and 07330).

320.12

DISTRIBUTION OF SUBSTANCE P BINDING IN THE GASTROINTESTINAL TRACT OF BB RATS - AN ANIMAL MODEL OF DIABETES MELLITUS. Q. Yu*, D.H. Silberberg, and A. Ouyang. Gastrointestinal Section, School of Medicine, University of Pennsylvania, Philadelphia, PA 19104-6144, U.S.A.

Introduction: In patients with diabetes mellitus, neuropathy in the gastrointestinal tract is a common occurrence, and the disease is associated with gastroparesis and altered bowel habits. Previous reports have shown that the substance P (SP) content of the peripheral nerves was reduced in diabetic patients and in animal models of diabetes, e.g., the BioBreeding (BB) rats. The present study investigated the SP binding in the stomach, pylorus and antrum and the colon (proximal and distal regions)

Methods: BB rats (4 - 6 months old) were anesthetized with pentobarbital and the selected regions of the gut were dissected, cleaned and quick frozen in liquid nitrogen. Ten micron sections were cut and the binding assay was performed at room temperature with 100 pM [¹²⁵I]-SP for 2 hr and passed through 4 washes. HyperfilmTM 3H (Amersham) were then exposed to these dried [¹²⁵I]-SP bound gut slices for 7 days. The circular muscle layers of gut autoradiograms were analyzed.

Results: In the diabetic (D) BB rats, SP binding (nCi/mg protein \pm SEM) was found to be higher in the pyloric stomach and the distal colon than in the non-diabetic (ND) BB rats (Pyloric stomach: D: 110.47 \pm 2.65, N = 4; ND: 90.58 \pm 2.94, N = 5; P = 0.002, 2-tailed Student's t-test. Distal colon: D: 131.05 \pm 3.25, N = 4; ND: 97.638 \pm 7.14, N = 5; P = 0.006). There were no observable changes between the ND and the D rats in the antral stomach (D: 82.18 \pm 4.25, N=4; ND: 79.38 \pm 3.88, N = 3; P > 0.05) and the proximal colon (D: 112.01 \pm 7.25, N=4; ND: 123.64 \pm 2.96, N = 5; P > 0.05).

Conclusion: The present data suggest that, in the circular muscle layer of the gastrointestinal tract of the BB rats, there are regional differences in SP binding between ND and D rats, a condition which may be contributing to physiologic abnormalities of intestinal function in diabetes mellitus.

HYBRID CELLS DERIVED FROM SEPTAL CHOLINERGIC NEURONS EXPRESS NEUROTENSIN RECEPTORS. M-P. Faure*, J. Shaw*, D.N. Hammond, N.R. Cashman and A. Beaudet. Lab. of Neuroanatomy, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B4.

Autoradiographic studies from our laboratory have demonstrated a selective association of high affinity neurotensin (NT) binding sites with basal forebrain cholinergic neurons. In an attempt to establish an *in vitro* model for further characterization of these sites, the binding of 125-I-Tyr3 NT and of fluorescein isothiocyanate (FITC)-conjugated NT was examined in hybridomas SN6 and SN17, produced by fusion of embryonic murine septal cells with a murine neuroblastoma (Science, 1986). Both cell lines showed saturable, high affinity NT binding. Flow cytometric histograms indicated that 97.4% of cells in SN6 and 99.2% of cells in SN17 stained positively for NT-FITC. Scatchard analysis of 125-I-NT binding at 4°C yielded a linear plot for SN6 (K_d=1.7 nM; B_{max}=180 fmol/mg prot) and a biphasic plot for SN17 (K_d=1.5 and 5.0 nM; B_{max}=120 and 281 fmol/mg prot) suggesting that the SN17 cell line may be expressing two different types of binding sites. Whereas most of the radioactivity bound at 4°C was detached from either type of cells by an acidic wash, more than 50% of the ligand bound at 37°C resisted such treatment, suggesting that a large fraction of the radioactivity had been internalized. Confocal microscopic examination of cells incubated with NT-FITC at 37°C confirmed the presence of "hot spots" of internalized ligand molecules. These results indicate that both SN6 and SN17 cell lines express high affinity NT binding sites and that these sites may be internalized upon ligand interaction, suggesting that they correspond to functional receptors.

CHANGES IN NEUROTENSIN RECEPTOR DENSITY IN RATS CHRONICALLY TREATED WITH HALOPERIDOL AND SIGMA ANTAGONIST BMY 14802. J.T. Clapacs*, S.T. Cain, D.L. Knight, W.E. Smith and C.B. Nemeroff. Departments of Psychiatry and Pharmacology, Duke University Medical Center.

Neurotensin (NT) is an endogenous tridecapeptide found in the mammalian CNS which fulfills many of the neurotransmitter criteria. NT concentrations have been shown to be increased in the striatum and nucleus accumbens of rats treated chronically with clinically effective antipsychotic drugs. Similar changes in NT concentrations in the nucleus accumbens and caudate nucleus have been observed after treatment with the sigma receptor antagonist BMY 14802. Male Sprague-Dawley rats were treated daily with either haloperidol (1 mg/kg/day) or BMY 14802 (35 mg/kg/day) for 21 days. On day 22 all animals were killed by decapitation and their brains rapidly dissected and frozen. Frontal cortex, striatum, nucleus accumbens, hypothalamus and VTA-substantia nigra were later dissected from the frozen brains. Single-point binding was performed (at a concentration of 0.4 nM NT) on each sample using mono-iodinated [¹²⁵I]-Tyr³-NT prepared by the lactoperoxidase reaction. Incubation with 1 μ M unlabeled NT was used to define non-specific binding. Data was expressed as fmoles/mg protein. NT receptor binding was significantly decreased in frontal cortex of haloperidol treated animals compared to controls. A similar trend toward a decrease in frontal cortex NT binding was seen in BMY 14802 treated animals. No significant changes in NT binding were found in any other regions in either treatment group. These results indicate that the NT concentration increases observed after chronic antipsychotic drug treatment may not be associated with increased release of NT, because this would presumably result in NT receptor down regulation. Delineating the complex interactions between NT and dopamine systems remains a critical focus of investigation. Supported by NIMH MH-39415.

INJECTION OF MRNA FROM PANCREAS AND BRAIN INDUCE DIFFERENT TYPES OF CCK RECEPTORS IN XENOPUS OOCYTES. K.Kawasaki and Y.Shigeri*, Div. of Pharmacol., Shionogi Res. Labs., Shionogi & Co., Ltd., Osaka 553, Japan

Microinjection of mRNA from rabbit pancreas and rat hippocampus into *Xenopus* oocytes induced different types of CCK receptors, the peripheral- (CCK_A-R) and central-type (CCK_B-R) of CCK receptors. CCK-8 induced oscillating inward current mediated by CCK_A-R (CCK_A-responses) and CCK_B-R (CCK_B-responses). CCK_A- and CCK_B-responses were selectively antagonized by L-364718 and by L-365260, respectively. Non-sulphated CCK-8, CCK-4 and gastrin I had weak agonistic actions only in oocytes injected with hippocampal mRNA. Ramp clamp analysis showed that the equilibrium potential of CCK_A-responses was a little more positive (-15 ~ -20 mV) than that of CCK_B-responses. Although intracellular injection of EGTA completely abolished CCK_B-responses, slow inward current in CCK_A-responses remained after EGTA. The equilibrium potential of this slow current was -5 ~ 0 mV. Lowering [Ca²⁺]_i reduced CCK_A-responses, while CCK_B-responses were relatively resistant to [Ca²⁺]_i change. CCK_B-responses were more easily desensitized than CCK_A-responses. These results indicate that injection of mRNA from rabbit pancreas or from rat hippocampus induces pharmacologically different CCK receptors, CCK_A-R or CCK_B-R subtype, respectively. Activation of CCK_B-R opens Ca²⁺-dependent Cl⁻ channels, while that of CCK_A-R induces opening of non-specific cation channels as well as Ca²⁺-dependent Cl⁻ channels in mRNA injected *Xenopus* oocytes.

LOCALIZATION OF CHOLECYSTOKININ RECEPTORS IN THE BRAZILIAN OPOSSUM BRAIN. M. C. Kuehl, L. R. Ross, J. K. Elmquist, C. A. Fox and C. D. Jacobson. Department of Veterinary Anatomy, Iowa State University, Ames, IA 50011.

We have studied the anatomical distribution of cholecystokinin (CCK) receptors in the brain of the adult Brazilian short-tailed opossum, *Monodelphis domestica*. *Monodelphis* is a small marsupial whose young are born in an extremely immature state making them an excellent model for studying development. CCK receptors were localized in tissue sections with Bolton-Hunter I²⁵ labeled CCK. Adult Brazilian opossums were decapitated and the brains were rapidly isolated, frozen on dry ice, sectioned on a cryostat, and thaw-mounted onto slides. Sections were incubated with buffer containing I²⁵ CCK, washed, and subsequently exposed to LKB ultrafilm. Following film exposure, slides were processed for autoradiography. Brain regions were characterized as having CCK receptors if they contained greater densities of silver grains (on film & on the slides) compared to adjacent tissue sections that were exposed to I²⁵ CCK and unlabeled CCK. In the forebrain, CCK receptors were observed in the CA1 region of the hippocampus, neocortex, corpus striatum, medial preoptic area, posterior amygdaloid area, and ventromedial hypothalamic nucleus. In the brainstem, CCK receptors were observed in the nucleus of the solitary tract and in the spinal nucleus of the trigeminal nerve. The anatomical distribution of CCK receptors in *Monodelphis* is similar to the distribution patterns described for CCK receptors in other mammals and supports the use of *Monodelphis* in studies on the developmental expression of CCK receptors in the brain.

OPIOID RECEPTOR INTERACTION AS A MECHANISM OF CCK PEPTIDE ANALGESIC ACTIVITY. J. Slaninova, B.J. Knapp, S.-N. Fang, T. Kramer, T.F. Burks, V.J. Hruby and H.I. Yamamura. Univ. of AZ Coll. of Med, Pharmacol. and Chem. Depts, Tucson, AZ 85724.

The opioid receptor binding affinities of CCK-8 and four analogues having analgesic potency after i.c.v. administration and high affinity for CCK-B receptors were measured using the selective radioligands [³H]CTOP (μ), [³H][D-Pen², 4-CI-Phe⁴, D-Pen⁵]enkephalin (δ), and [³H]U-69,593 (κ). These analogues included nonsulfated [N-MeNle³, N-MeNle⁷]CCK-8, [threo-L-β-MePhe³, N-MeNle⁷]CCK-8, [D-Phe³, N-MeNle⁷]CCK-8 and bis-sulfated [threo-L-β-MePhe³, N-MeNle⁷]CCK-8. None of the peptides tested had high affinity for either μ- or κ-receptors (IC₅₀ values > 0.7 μM), but their IC₅₀ values for δ-receptors range from 29 to 1,023 nM. The analogue ([D-Phe³, N-MeNle⁷]CCK-8) with the greatest analgesic activity (A-50 = 0.5 nmole i.c.v.) has high affinity for δ opioid receptors (IC-50 = 29 nM and CCK-B receptors (IC-50 = 0.79 nM). Nonsulfated [threo-L-β-MePhe³, N-MeNle⁷]CCK-8 showed the lowest analgesic potency (A-50 = 232 nmole) but also had high CCK-B receptor affinity (IC-50 = 2.1 nM). Thus, distinct receptor mechanisms (CCK-B and opioid) may be responsible for the analgesia observed.

320.18

RABBIT VAGUS NERVE CONTAINS BOTH CCK-A AND CCK-B RECEPTORS. T. R. Miller*, D.G. Witte*, M. Holladay*, A.M. Nadzan, and C.W. Lin. Neuroscience Research, Abbott Laboratories, Abbott Park, IL 60064.

Cholecystokinin (CCK) receptors on vagal afferents have been implicated in mediating many of the actions of the brain-gut peptide, CCK, including satiety, release of pituitary hormones and enhancement of memory. CCK receptors have been classified as CCK-A and CCK-B based on affinities for CCK, gastrin and related peptides. Autoradiographic studies in rat have indicated the predominance of CCK-A receptors in vagus. Here, using [125I]-Bolton-Hunter(BH)-CCK-8 as the radioligand, we have characterized CCK receptors in membranes prepared from rabbit vagus nerve. [125I]-BH-CCK-8 binding was inhibited by the guanine nucleotide, Gpp(NH)p, with an IC₅₀ of 140 nM. Competition experiments showed that CCK-8 (IC₅₀ = 0.25 nM) was about 280-fold more potent than suggestive CCK-8, desferal of the CCK-A receptor. Competitive binding studies using A-71378, a selective CCK-A agonist, exhibited biphasic inhibition curves, with the high affinity portion (<10 nM) at ~60% and low affinity portion at ~40%. Conversely, competitive binding studies using A-63387, a selective CCK-B receptor agonist, also showed biphasic displacement curves with the high affinity portion at ~35% and low affinity portion at ~60%. These results suggest that rabbit vagal CCK receptors contain both A and B subtypes, at ~60 and ~40 %, respectively, which are linked to G protein. The presence of CCK-B/gastrin receptors on vagus may have implications for many of the behavioral effects of selective CCK-B peptides, such as anxiety.

320.20

PARTIAL PURIFICATION AND CHARACTERISATION OF THE CHOLECYSTOKININ TYPE B RECEPTOR FROM PORCINE CEREBRAL CORTEX. J.C. Hunter*, K. Forde*, J. Hughes*, E.A. Barnard* and S.H. Gut*. MRC Molecular Neurobiology Unit, MRC Center, Hills Road, Cambridge CB2 2QH, U.K.; * Parke-Davis Research Unit, Hills Road, Cambridge CB2 2QB, U.K.

Cholecystokinin (CCK) receptors can be divided into either CCK_A or CCK_B /gastrin on the basis of both anatomical localization and pattern of selectivity to agonists and antagonists. CCK_A receptors are predominant in peripheral tissues and show enhanced sensitivity to CCK-8S and L-364,718 while those of the CCK_B type predominate in the CNS and show particular affinity for pentagastrin, L-365,260 and PD 134308 (CI-988) (Hughes et al., PNAS 87, 6728-6732, 1990). CCK_B sites were digitonin (2%) solubilized from pig cerebral cortex membranes (Gut et al., Eur J Pharmacol 172, 339-346, 1989) and purified by a four-step chromatographic procedure involving 1) anion exchange (AEC, sepharose Q), 2) Wheat Germ Agglutinin sepharose, 3) Affigel-15-pentagastrin, 4) Phenyl-sepharose. Following this procedure a final purification was estimated at approximately 7000. The affinity purified protein was also re-chromatographed by AEC, separated into several individual fractions and, following SDS-PAGE and silver staining, identified as a major band of either 70kDa or the deglycosylated core protein of around 45kDa. The density of the band corresponded directly to the level of specific [¹²⁵I]-CCK-8S binding in each fraction. The rank order of potency for the inhibition of [¹²⁵I]-CCK-8S binding to this purified form of the receptor (CCK_B = gastrin [1-7] > CI-988 > L-365,260 >> L-364,718) confirmed its identity as the CCK_B receptor.

320.22

A-73559: A FIRST GENERATION IRREVERSIBLE CCK-A ANTAGONIST. J.F. Kerwin, Jr., C.W. Lin, F. Wagenaar*, D. Witte*, T. Miller*, A.M. Nadzan. Neuroscience Research Division, D-47H, Abbott Laboratories, Abbott Park, IL 60064.

We have developed selective and novel CCK-A antagonists (eg. A-65186, A-67396) and a model of the pharmacophores necessary for affinity and selectivity. We became interested in irreversible CCK antagonists as a tool for studying the pharmacology associated with CCK-A receptors in the CNS. Using the prototypical CCK-A antagonist A-69457 as a base structure, we prepared alkylative analogs. All of these possess affinities for the CCK-A receptor (guinea pig pancreatic acini) in the 100-200 nM range. Compound A-73539 (a disulfide) was studied further. At 20 μM (20 min) it reduced radioligand binding of [³H]-L-364,718 and [¹²⁵I]-BH-CCK-8 by 65%. This effect appears to be specific for CCK-A ligands since [³H] scopolamine binding was unaffected. In amylase release studies in guinea pig pancreatic acini response was reduced for 1 nM CCK-8 (>90%) but not for VIP, PMA, carbachol and bombesin. These studies suggest that A-73539 (20 μM, 20 min) is a selective CCK-A irreversible antagonist. However, A-73539 reduced PI breakdown in guinea pig pancreatic acini induced by CCK-8 (48%), carbachol (40%) and NaF. Alkylation of the CCK-A receptor by A-73539 (20 μM) could not be prevented with CCK-8 (5 μM). The specificity of A-73539 is condition dependent and further improvements are needed for a practical CCK-A irreversible antagonist.

320.23

L-365,260 BLOCKS CHOLECYSTOKININ-INDUCED DEPOLARIZATIONS IN SUPRAOPTIC MAGNOCELLULAR NEURONS. C.R. Jarvis, C.W. Bourque and L.P. Renaud, Neuroscience Unit, Loeb Research Institute, Ottawa Civic Hospital, 1053 Carling Ave., Ottawa, Ontario, Canada, K1Y 4E9.

Exogenous application of sulphated cholecystokinin octapeptide 26-33 (CCK-8S) or cholecystokinin tetrapeptide 30-33 (CCK-4) (Bachem) induces a prominent depolarization and an increase in a membrane cationic conductance in rat supraoptic magnocellular neurons. The present study sought to determine whether this depolarizing action of CCK is mediated by central (CCK-B) or peripheral (CCK-A) type CCK receptors. Intracellular recordings were obtained from supraoptic neurons in explants of basal hypothalamus superfused with oxygenated artificial cerebral spinal fluid and maintained at 34°C. Applications of CCK-4 (0.1-25 µM) induced reversible depolarizations, similar to those evoked by CCK-8S. Bath application of 200 nM L-365,260 (Merck Sharp and Dohme), a potent and selective antagonist for central (CCK-B) and gastrin receptors (Lotti and Chang, 1989 Eur. J. Pharmacol. 162:273-280), largely blocked the depolarizing response to CCK-8S (5-20 µM). The effectiveness of low concentrations of CCK-4 and L-365,260 in mimicking and antagonizing the effects of CCK-8S respectively suggests that the depolarizing action of CCK on magnocellular neurons is mediated by central (CCK-B/gastrin) receptors. Supported by MRC and FCAR.

SPECIES DIFFERENCES IN BRAIN NEUROPEPTIDE RECEPTOR BINDING. N.R. Mason, R.F. Bruns, J.J. Howbert, and M.J. Yu*, Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46285. In the course of comparing affinities of non-peptide CCK antagonists, for CCK-B and gastrin receptors, species differences in affinity were observed. Several quinazolinone CCK-B antagonists appeared to be highly selective for mouse brain 125I-CCK-8S binding (CCK-B receptor) compared to 125I-gastrin binding in the guinea pig stomach; however, in guinea pig brain CCK-B binding these compounds had about 1/10 the activity seen in mouse brain and little selectivity for the CCK-B receptor compared to the gastrin receptor. Neither CCK-8S or L-365,260 showed any significant difference in affinity between mouse and guinea pig brain CCK-B receptors. Several pyrazolidinone CCK antagonists had only 2-4 times more affinity for mouse brain CCK-B binding as compared to guinea pig brain. However, the affinity of these compounds was markedly affected by the pH of the medium. CCK-B and gastrin receptor affinities were similar at pH 7.4. Thus, the CCK-B and gastrin receptors appear to be very similar or identical. Species differences were also noted in the binding of non-peptide antagonists to brain NK-1 (Substance P) receptors. Although Substance P itself showed no difference between species, the non-peptide antagonist (±)CP-96,345 showed a marked species difference with high affinity versus 125I-Substance P binding in guinea pig, rabbit, bovine, and hamster brain membranes, but had 100-500 fold less affinity in rat, mouse or chicken brain. These results show that the affinities of non-peptide compounds for peptide receptors may be highly species-dependent. This should be taken into consideration when comparing results from different tissues and when choosing an appropriate species for *in vivo* experiments.

PEPTIDES: RECEPTORS IV

ANGIOTENSIN II DEPRESSES GLUTAMATE-INDUCED DEPOLARIZATION AND SYNAPTIC TRANSMISSION OF LOCUS COERULEUS NEURONS

H. Xiong and K. C. Marshall Department of Physiology, University of Ottawa, 451 Smyth Road, Ottawa, Ontario, Canada K1H 8M5

We have earlier shown that iontophoretically applied angiotensin II (AII) specifically depresses the depolarizing action of L-glutamate (Glu) on locus coeruleus (LC) neurons in a transverse brain stem slice preparation (Neurosci. Lett. 118:261, 1990). We have further studied the effect of AII on Glu in LC neurons recorded intracellularly from coronal pontine-medullary brain slices in which EPSPs can be readily evoked by electrical stimulation. Consistent with our previous observation, AII was found to depress Glu excitation by more than 30% in 77 out of 87 LC neurons, in the absence of other effects on membrane properties. Application of hydrogen ions (H⁺) from a pH control barrel depressed 40 out of 87 LC neurons. The correlation between H⁺ and AII effects on the same cells was poor, indicating that the AII effects are not attributable to actions of co-expressed H⁺. The effect of AII on Glu appears to be specific to the LC neurons since it had little or no effect when tested on non-LC neurons (e.g. neurons of Barrington's or lateral vestibular nuclei). Sar¹-AII, which is resistant to peptidase degradation, had similar effects to AII when iontophoretically applied, and with bath application it was also found to depress Glu excitation in the LC neurons in a dosage dependent manner (IC₅₀=10µM, n=14). In addition, when AII was tested by pressure ejection, the result was consistent with that observed using iontophoresis.

EPSPs evoked by electrical stimulation and blocked by an excitatory aminoacid antagonist (kynurenic acid) were also partially depressed by bath application or pressure ejection of AII (n = 8).

It has been reported that LC neurons contain three subtypes of Glu receptors, but we observed that AII can in some cases entirely eliminate the Glu response. Our tests to find which subtype of Glu receptors was affected by AII suggest that the mechanism is complex. (Supported by the Medical Research Council of Canada)

321.3

EFFECTS OF ANGIOTENSIN II (AII) ON NET OUTWARD CURRENT (i_{no}) IN CULTURED NEURONS FROM RAT BRAIN. J. Kang*, C. Summers, and P. Fosner*. (Spon: R.L. Casto) Dept. of Physiology, JHMHC, Gainesville, FL 32610

The hypothalamus and brainstem contain the major concentrations of AII neurons and receptors in the brain. In this study we have utilized standard whole cell voltage clamp techniques to study the effects of AII on the net outward current of neurons cultured from these brain regions of one day old rats. The i_{no} was elicited at room temperature by using 50 msec steps from a holding potential (HP) of -80 mV to +10 mV, every 10 seconds. The i_{no} was blocked with TTX (10µM). The i-v relationship was determined using 10 mV steps over a range of -100 mV to +90 mV, from a HP of -80 mV. We have identified two morphologically distinct populations of neurons (bipolar cells and multipolar cells) which respond to AII. Of 22 bipolar cells studied, 18 responded to AII with a reversible inhibition of i_{no}. Of 31 multipolar cells studied, 27 responded to AII with a reversible increase in i_{no}. Both types of neurons responded to AII in a dose-dependent manner. The threshold dose was 0.01 nM AII, while maximal responses occurred at 1 µM. The current changes were independent of shifts in the i-v curve. Further characterization of i_{no} is in progress.

321.2

ANGIOTENSIN II (AII) MODULATED NET OUTWARD CURRENT (i_{no}) IN CULTURED NEURONS FROM RAT BRAIN: EFFECTS OF NON-PEPTIDE AII RECEPTOR BLOCKERS. P. Fosner*, J. Kang* and C. Summers. Dept. of Physiology, JHMHC, Gainesville, FL 32610

The hypothalamus and brainstem contain the major concentrations of AII neurons and receptors in the brain. By using whole cell voltage clamp, we have found that AII modulates i_{no} in neurons cultured from these brain regions of 1 day old rats. Of 53 cells studied, AII (0.01nM-1µM) either caused an increase or a decrease in i_{no} in 83% of the cells. To characterize which AII receptor subtype(s) are involved, we tested the effects of non-peptide AII receptor blockers on these responses. The AII-1 (AT₁) receptor blocker DuP 753 (DuP, 1µM), but not the AII-2 (AT₂) receptor blocker PD 123177 (PD, 1µM) reversibly blocked the AII induced inhibition of i_{no}. Both PD and DuP were able to reversibly block the stimulatory effect of AII on i_{no}. However, PD was effective when given prior to, simultaneously with or after AII, while DuP was only effective when given before AII. DuP and PD alone had no effect on i_{no}. These data suggest that AT₁ receptors mediate the inhibitory effect of AII on i_{no}. The stimulatory effect is probably mediated by AT₂ receptors. The blocking action of DuP may be non-selective at these doses. However, the possibility that both AT₂ and AT₁ receptors mediate AII induced increases in i_{no} cannot be ruled out at this time.

321.4

FUNCTIONAL PROPERTIES OF TYPE 1 AND TYPE 2 ANGIOTENSIN II RECEPTORS IN NEUROBLASTOMA AND LIVER EPITHELIAL CELLS. R. Makl, A. Ades*, R. Mir*, S. Mah* and S.J. Fluharty. Dept. of Animal Biology and Institute of Neurological Sciences, Univ. of Pennsylvania, Phila., PA 19104.

The intracellular actions of angiotensin II (AngII) are mediated by two distinct receptors (Type 1 and Type 2). We examined the coupling of these receptor subtypes to phospholipase (PI) hydrolysis and adenylate cyclase (AC) in neuron-like (NG108-15 and N1E-115 cells) and non-neuronal (WB cells) cell lines. In all cells examined, AngII caused a dose-related rise in inositol trisphosphate (InsP₃) production, and promoted the translocation of protein kinase C (PKC) from cytosol to membrane. Moreover, the InsP₃ response was reduced by the Type 1 selective antagonist DUP 753 but not by the Type 2 antagonist CGP 42112A. In addition to stimulatory effects on PI hydrolysis, AngII (1 µM) inhibited AC activity by 12% and lowered cAMP levels by 57.3 ± 31.2 pmols/mg prot in WB cells. In the presence of DUP 753, however, the inhibition of AC was greater (33%) and cAMP levels were reduced by 201.1 ± 52.3 pmols/mg prot, suggesting that some action of AngII at Type 1 receptors might interfere with its inhibition of AC. In this regard, the catalytic activity of AC was rapidly increased when PKC was activated by the phorbol ester PMA. In contrast, AngII increased AC activity and cAMP levels when Type 2 receptors were blocked with CGP 42112A perhaps because potentiation of cyclase by Type 1-mediated activation of PKC was unopposed by Type 2-mediated inhibition of AC. Finally, while AngII potently stimulates PI hydrolysis in neuroblastoma cells, it did not inhibit AC or reduce cAMP levels. These results suggest that the intracellular actions of AngII may involve antagonistic interactions between Type 1 and Type 2 receptors, and that the function of the Type 2 subtype is not identical in neuronal and non-neuronal cells. Supported by NS23986 and MH43787.

321.5

THE APPARENT ASSOCIATION OF SOLUBILIZED ANGIOTENSIN II RECEPTORS WITH G-PROTEINS AND PHOSPHOLIPASE C α IN N1E-115 CELLS. I.R. Siemens, K. Addya*, S. Mah*, D.R. Manning* and S.J. Fluharty*. Departments of Animal Biology, Pharmacology, and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

The murine neuroblastoma N1E-115 cell line possess membrane associated Type 1 and Type 2 angiotensin II receptors (AngII-Rs). While both of these receptor subtypes can be solubilized in CHAPS, the Type 2 receptor appears more stable in this detergent. Size exclusion chromatography of the solubilized membranes revealed that substantial amounts of AngII binding activity was present in large molecular weight complexes ranging from 250-350 kDa. In order to further examine the composition of these complexes, solubilized N1E-115 membranes were subjected to Heparin-Sepharose (HS) chromatography. Three peaks of specific 125 I-AngII binding activity eluted from the Heparin Sepharose column, the third of which was strongly retained by the column and required 1.5M NaCl for complete elution. Each binding peak was assayed for the presence of Type 1 and Type 2 receptors by using DUP753 and CGP42112A, respectively. The first and second peak contains equal amounts of binding activity, while the third peak exhibited 3-5x greater activity. In all three cases, the binding was predominantly at Type 2 sites, however, DUP753 appeared to stimulate binding at Type 2 sites in peak 3. Finally, we used antisera selective for the α -subunits of G-proteins and for a particular isozyme of phosphoinositide specific phospholipase C (PLC- α) to determine if these proteins co-eluted with AngII-Rs on the HS column. The majority of immunoreactive G-protein and PLC- α was present in peaks 2 and 3. Collectively, these data suggest that Type 2 AngII-Rs can associate with a heterotrimeric G-protein and PLC- α in a neuron-like cell line. Supported by NS23983 and MH43787.

321.7

LOCALIZATION OF THE AT₂ ANGIOTENSIN RECEPTOR SUBTYPE IN THE BRAIN OF THE DEVELOPING RAT FETUS. V.I. Cook, K.L. Grove, K.M. McMenamin, J.W. Harding and R.C. Speth. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Angiotensin II (AII) receptor subtypes were examined by *in vitro* autoradiography in the brains of 15, 18, and 21-day gestation fetal and 2-day postnatal rats. Two nonpeptide AII antagonists were used: Dup 753 is type 1-specific (AT₁) and PD 123177 which is type 2-specific (AT₂). The AT₁ receptor subtype is known to mediate AII effects on cardiovascular regulation, while no physiological function has yet been established for the AT₂ receptor subtype. Our lab has recently shown that specific AII binding sites exist in the brain of rat fetus as early as the 13th day of gestation. We were therefore interested in the specific subtype of these early receptors. In the fetal rat brain, the AT₂ receptor subtype predominates throughout, even in areas that are mostly of the AT₁ receptor subtype in the adult rat, such as in the area nucleus tractus solitarius (NTS). It is possible that the AT₂ receptor subtype has a role in the development of fetal brain.

321.9

BINDING CHARACTERISTICS OF ANGIOTENSIN RECEPTOR SUBTYPES IN INDIVIDUAL RAT BRAIN NUCLEI. B.P. Rowe, R.C. Speth, and D.L. Saylor*. East Tennessee State Univ., Johnson City, TN 37614 0002, and Washington State Univ., Pullman, WA 99164 6520.

In vitro autoradiography studies of angiotensin II (AII) receptor (AIIR) subtype distributions in the brain routinely use a single subsaturating concentration of radioligand, assuming that it binds with equal affinity to all receptor subtypes. This prompted us to determine the affinity of brain AIIR subtypes for 125 I sar¹ile⁸ AII (125 I SIAII). Rat brain sections were incubated with 125 I SIAII (0.16-2.51 nM) to determine the K_d in 21 brain regions. The K_d at 10 nuclei previously characterized as having predominantly the AT₁ subtype was 0.66nM (range 0.5-0.9nM) while the anterior pituitary (also AT₁) K_d was 0.24nM. In contrast, the K_d at 7 nuclei having predominantly the AT₂ subtype was estimated to be 2.6nM (range 1.2-4.3nM). Estimates of K_d for AT₂ sites are subject to considerable error, but 125 I SIAII clearly shows selectivity (approx 4 fold) for the AT₁ subtype and previous competition studies therefore underestimate the proportion of AT₂ sites. Finally, these differences in affinity have not been observed in peripheral tissues, which might indicate differences between brain and peripheral AIIR subtypes.

CHARACTERIZATION AND DEVELOPMENTAL EXPRESSION OF AT₂ ANGIOTENSIN II RECEPTORS IN RAT CEREBRAL ARTERIES. K. Tsutsumi and J.M. Saavedra. Section on Pharmacology, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

We characterized Angiotensin II (AT) receptor subtypes in the cerebral arteries of young (2-weeks-old) and adult (8-weeks-old) rats by displacement with the specific AT₁ receptor antagonist Dup 753 and the AT₂ selective displacer CGP 42112A, using quantitative *in vitro* autoradiography. 125 I Sar¹-AT binding was located throughout the arterial wall. AT receptors in the chiasmatal segment of the anterior cerebral artery from young rats were completely displaced by CGP 42112A with an IC₅₀ of $6 \pm 1 \times 10^{-10}$ M, whereas Dup 753 did not compete in concentrations up to 10^{-4} M. Incubation in the presence of a single concentration of CGP 42112A (10^{-7} M), which totally eliminated AT binding from AT₂ receptors, resulted in complete displacement of AT binding in the orbital segment of the anterior cerebral artery, the sphenoid wing segment of the middle cerebral artery and the posterior communicating artery from both young and adult rats. A single concentration of Dup 753 (10^{-6} M) failed to displace AT binding from these arteries. Thus, larger cerebral arteries of the rats have AT₂ receptors. The apparent concentrations of AT binding in the cerebral arteries of young rats were several times higher than those of adult animals. These findings suggest that AT may exert its effects on cerebral circulation by stimulation of AT₂ receptors, and that these receptors may play a role during cerebrovascular development.

DIFFERENTIAL REGULATION OF TYPE 1 AND TYPE 2 ANGIOTENSIN II RECEPTORS IN MURINE NEUROBLASTOMA N1E-115 CELLS. A.M. Ades*, F. Slogoff* and S.J. Fluharty. Department of Animal Biology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

The murine neuroblastoma N1E-115 cell line contains a high density of membrane associated angiotensin II receptors (AngII-Rs). The heterogeneity of the binding of some AngII-related peptides suggested the possibility that these cells possess distinct subtypes of AngII-Rs, and this hypothesis has been confirmed using two newly developed antagonists, DUP 753 and CGP 42112A. When N1E-115 membranes were labelled with 125 I-AngII, DUP 753 exhibited high affinity binding at Type 1 receptors (K_d = 63 nM), while CGP 42112A primarily interacted with Type 2 receptors (K_d = 2.5 nM). Moreover, while most AngII-related peptides exhibited similar affinity at both AngII-R subtypes, AngIII and the N-terminally extended peptide Crintia-AngII had significantly higher affinity at Type 2 receptors, and sarcosine-substituted peptides displayed reduced affinity at these same sites. In addition to pharmacological distinctions between Type 1 and Type 2 subtypes, it also appears that these proteins are differentially regulated in N1E-115 cells. For instance, *in vitro* differentiation selectively increased the density of Type 2 receptors from 24.8 ± 2.1 to 143.2 ± 15.2 fmols/mg prot, without altering Type 1 receptors (65.6 ± 2.9 vs 61.9 ± 1.7 fmols/mg prot). On the other hand, the Type 1 subtype appeared to be more susceptible to downregulation induced by brief exposure of intact cells to AngII (10 nM; 5 min). Collectively, these data demonstrate that the density of Type 1 and Type 2 AngII-R subtypes can be selectively altered, and that N1E-115 cells are an ideal system in which to examine the expression of AngII-R subtypes. Supported by NS23986 and MH43787.

IDENTIFICATION OF A NEW ANGIOTENSIN RECEPTOR SUBTYPE IN GUINEA PIG BRAIN. J.W. Harding, J.M. Hanesworth*, J.N. Swanson*, V.I. Cook, A.V. Wing*, J.W. Stobb*, L.L. Jensen, M. Sardinia*, and J.W. Wright. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

Recent reports have demonstrated the existence of two distinct angiotensin receptor subtypes designated AT₁ and AT₂. Both receptor subtypes bind AII, AIII, and Sar¹-substituted angiotensins. We report here the discovery of a previously unrecognized angiotensin receptor subtype specific for the hexapeptide fragment, AI(3-8), which is different from AT₁ or AT₂. This receptor is highly localized in cardiovascular tissues including aorta, heart, kidney, adrenals, and brain. In addition, it can be found in almost all mammalian species examined including guinea pig, rabbit, cat, dog, pig, horse, and cow. The receptor has been solubilized and partially purified. Preliminary biochemical studies indicate that the receptor is very acidic, heat stable in the presence of divalent cations, and possesses a molecular weight in the range of 150,000 daltons. The receptor is extremely specific, saturable, and reversible. The N-terminal structure of the binding ligand is paramount in determining binding affinity. While the binding of AII(3-8) is very tight (K_d = 4 nM), the binding of Sar¹ Ile⁸-AII, Sar¹-AII, AII and AIII is all but nonexistent (K_d > 10^6 M). Small changes in the N-terminal valine dramatically reduce affinity, usually, 2,000 to 10,000 fold. These changes include substitution of L-val with D-val or Sar, removal of L-val to produce the pentapeptide and extension of the N-terminal with additional amino acids. The function of this receptor and its accompanying peptide system is unknown and presently under investigation.

INTERACTIONS BETWEEN ANGIOTENSIN II AND CORTICOSTEROID RECEPTORS IN NEUROBLASTOMA CELLS. S.Y. Chow, R.R. Sakai, L.P. Reagan, B.S. McEwen, and S.J. Fluharty. Depts. of Psychology, Animal Biology, and Inst. of Neurological Sciences, Univ. of Penna., Phila., PA 19104, and Lab. of Neuroendocrinology, Rockefeller Univ., New York, NY 10021.

The central actions of angiotensin II (AngII), particularly its ability to elicit sodium appetite, are potentiated by both mineralocorticoids and glucocorticoids in the rat. Moreover, it appears that this potentiation may result from an upregulation of AngII receptors (AngII-Rs). We have examined the interactions between AngII-R subtypes and the cytosolic mineralocorticoid (MR) and glucocorticoid (GR) receptors in cultured neuron-like cells. Murine neuroblastoma N1E-115 cells possess both Type 1 and Type 2 AngII-Rs. However, only the Type 2 receptor increases during *in vitro* differentiation. A similar pattern of receptor changes was noted in NG108-15 neuroblastoma x glioma hybrid cells. N1E-115 and NG108-15 cells also contain both MR and GR receptors. In undifferentiated neuroblastoma cells the density of GR receptors ($B_{max} = 100-250$ fmols/mg prot) was 10-20x greater than the level of MR binding, and unaffected by differentiation. However, in NG108-15, but not N1E-115 cells *in vitro* differentiation substantially increased MR receptors. Moreover, aldosterone, corticosterone and RU28362 upregulated AngII-Rs in NG108-15 cells, but only corticosterone and RU28362 produced this change in N1E-115 cells. The upregulation of AngII-Rs resulted from a small rise in Type 1 receptors and a 3-5x increase in Type 2 receptors. Finally, it is likely that the steroid induced upregulation of AngII-Rs results from genomic changes because they were blocked by actinomycin. Collectively, these results suggest that the gene(s) encoding for the multiple subtypes of AngII-Rs possess a steroid responsive element. Supported by NS23986 and MH43787.

PRELIMINARY CHARACTERIZATION OF 3H -DuP 753 BINDING IN THE RAT BRAIN AND LIVER: EVIDENCE FOR ANGIOTENSIN II AND NON-ANGIOTENSIN II DISPLACEABLE BINDING SITES. K.L. Grove and R.C. Speth. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Multiple subtypes of angiotensin II (AII) receptors (AII-R) have been identified in the rat brain and other tissues using highly selective non-peptidic AII-R antagonists and other agents. This study examines the possibility of using the selective AT₁ antagonist, DuP 753, which displays antihypertensive action, as a radioligand (3H -DuP 753) to selectively radiolabel the AT₁ subtype. Initial studies carried out in rat liver membranes revealed a high affinity binding site for 3H -DuP 753, with a dissociation constant (K_D) of approximately 20 nM. Competition by AII for 3H -DuP 753 binding accounted for only 15-20% of specific (10 μ M DuP 753 displaceable) binding in the liver. Specific binding of 3H -DuP 753 in the rat brain was of slightly lower affinity than in the liver, with a similar proportion of this binding inhibited by AII. To characterize the non-AII binding site of 3H -DuP 753 a number of transmitter receptor specific ligands, e.g., adrenergic, serotonergic, cholinergic, were tested and displayed little competition for 3H -DuP 753 binding sites. Several ion channel blockers, e.g., verapamil, quinidine, d-propranolol, lidocaine, caused moderate (25-50%) reductions in 3H -DuP 753 binding in the liver at high (100 μ M) concentrations that were additive with the competition by AII. However, the ion channel blockers were ineffective against 3H -DuP 753 binding in the brain. These observations suggest that DuP 753 may bind to sites other than the AT₁ receptor subtype in the brain and other tissues.

STRUCTURE-ACTIVITY STUDIES OF ENDOTHELIN ON A₀ SMOOTH MUSCLE CELLS. M. Knight, K. Takahashi, and P.M. Sweetnam. Peptide Technologies Corporation, 125 Michigan Ave. NE, Washington, DC 20017 and Nova Pharmaceutical Corporation, 6200 Freeport Centre, Baltimore, MD 21224

Structure-activity studies of the recently discovered cardiovascular peptide, endothelin, will establish the basis of its biological actions. Endothelin-1, (Ent-1) a 21 residue peptide, is released from endothelial cells and stimulates potent contraction of smooth muscle cells lining the vascular wall. An initial vasodilatory component has been described in intact vascular beds. Receptors for Ent-1 have been characterized in the cardiovascular system and, interestingly, in the nervous system. We have measured receptors in neuronal and non-neuronal cells and in thoracic A₀ cultured smooth muscle cells.

To develop a specific Ent-1 receptor inhibitor, single amino acid substitutions at positions, 12 through 14 of Ent-1 were applied systematically in the design of Ent-1 analogs. These along with fragments of Ent-1 and a peptide with the carboxyl hexapeptide region modified were measured for inhibition of ^{125}I -Ent-1 binding to the cultured smooth muscle cells. The results indicate that the 21-mer analogs displayed high affinities (values of $IC_{50} < 10^{-8}M$), whereas the Ent-1 [1-15] bicyclic portion and the Ent-1 [16-21] hexapeptide fragment both interacted with the receptors with low potencies, IC_{50} values $> 10^{-7}M$. The effect of changes in amino acid positions 12 to 14 of the Ent-1 molecule on its binding to receptors will be discussed.

Supported by NIH SBIR grants HL43483 to PTC and HL46098 to NPC.

ANGIOTENSIN RECEPTOR SUBTYPES IN THE ALBINO RABBIT EYE. P. Mallorga, M. Whitfield* and M. F. Sugrue*. Merck Sharp & Dohme Research Laboratories, West Point, PA 19486.

Receptors for Angiotensin II (AII) have been divided into the subtype I, which possesses a nM affinity for the nonpeptide antagonist DuP-753 and a μ M affinity for another antagonist WL-19, and the subtype II which displays the inverse profile, i.e., having a high affinity for WL-19 and a lower affinity for DuP-753. The two subtypes have been shown to be present in rat brain membranes. Only the subtype I was found in the rabbit cerebral cortex. In the rabbit eye AII binding sites are present in the ciliary process and the retina. *In vitro* experiments were undertaken to characterize the subtype(s) present in these tissues, as assessed by the abilities of DuP-753 and WL-19 to displace the antagonist ^{125}I -[Sar,Ile]-AII (SARILE) from its binding sites in these tissues. Scatchard plots of SARILE binding were linear in both tissues and K_D values of 152 μ M and 49 μ M were found for the ciliary process and the retina, respectively. The corresponding B_{max} values were 35 and 22 fmol/mg protein. In both tissues, Hill coefficients for the displacement curves by DuP-753 and WL-19 were greater than 0.9 indicating the presence of one population of binding sites. The K_i values of DuP-753 for the ciliary process and retina were 50 nM and 16 nM, respectively. In contrast, the corresponding K_i values for WL-19 in these tissues were 76 μ M and 74 μ M. Based on the relative selectivities of DuP-753 and WL-19 for AII receptor subtypes 1 and 2, these studies indicate that the great majority of AII receptors present in both the ciliary process and the retina of the rabbit are of the subtype 1 and in this respect resemble the cerebral cortex.

A TYPE I BUT NOT TYPE 2 ANGIOTENSIN II ANTAGONIST INHIBITS WATER AND 3% NaCl INTAKE INDUCED BY INTRACEREBROVENTRICULAR (pICV) RENIN OR SODIUM DEPLETION. C. Polidori, S.Y. Chow, S.J. Fluharty and A.N. Epstein. Departments of Biology, Psychology, Animal Biology, and the Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Central pulse injection of renin (pICV) or sodium depletion elicits water and salt intake that is mediated by angiotensin II (AngII) acting in the brain. Recently, the existence of two AngII receptor subtypes (Type 1 and Type 2 receptors) has been demonstrated in rat brain. We tested the effects of DUP 753 (a selective antagonist for the Type 1 receptors), and the CGP 42112A (selective for Type 2 receptors) on the drinking behaviors induced by pICV renin (50 ng/ μ l), and furosemide-induced sodium depletion (10 mg/rat/sc, furosemide). After pICV renin, DUP 753, at the doses of 25, 250 and 2,500 ng/5 μ l, reduced the water intake by 24, 64 and 100%, and the salt intake by 2, 20 and 90%, respectively. After sodium depletion, DUP 753 at 2,500 ng/5 μ l reduced the water and 3% NaCl intake by 50%. On the other hand, the same doses of CGP 42112A had no effect on renin-induced water and salt intake and at the higher dose showed signs of toxicity. To verify that DUP 753 and CGP 42112A were selective for AngII receptors we tested them on the dipsogenic effect of pICV carbachol (300 ng/ μ l). Both DUP 753 and CGP 42112A had no effect on carbachol-induced water intake. These results suggest that the Type 1 AngII receptor is involved in water and salt intake, and that the Type 2 receptor does not appear to be involved in these behaviors. Supported by NS23986 and MH43787.

ENDOTHELIN-MEDIATED STIMULATION OF PHOSPHOLIPASE C IS MEDIATED BY GUANINE NUCLEOTIDE BINDING PROTEIN(S). F. Gusovsky, LBC, NIDDK, NIH, Bethesda, MD 20892

In permeabilized NIH 3T3 fibroblasts and C6 glioma cells, the peptide endothelin 1 (ET-1) in combination with GTP γ S stimulates the formation of inositol phosphates. In the presence of 10 μ M GTP γ S, ET-1 induces the formation of IP₂ + IP₃ with an EC₅₀ value of 6 nM for NIH 3T3 cells and 2 nM for C6 glioma cells. The analogous peptide ET-3 is less potent than ET-1 in such action. ET-1-induced effects were unaffected by pretreatment of the cells with pertussis toxin (1 μ g/ml) in NIH 3T3 cells, but were partially reduced in C6 cells. In binding studies in whole NIH 3T3 cells and C6 cells, specific binding for [^{125}I]ET-1 was detected. Cross linking of [^{125}I]ET-1 in whole C6 cells revealed the presence of two binding proteins for ET-1 of 74 kD and 55 kD. ET-1 at 100 nM inhibited the labelling of both proteins by [^{125}I]ET-1. However, ET-3 inhibited the labelling of the 55 kD protein only. The results indicate that in NIH 3T3 cells and C6 glioma cells, receptors for endothelin are present, which are coupled to phospholipase C through guanine nucleotide binding (G) proteins. In C6 cells, endothelin-mediated phospholipase C activation is partially inhibited by pertussis toxin pretreatment, but in NIH 3T3 cells stimulation is not affected by pertussis toxin pretreatment. The endothelin receptor involved in phospholipase C stimulation in C6 cells seems to correspond to a 74 kD protein which binds ET-1 but not ET-3.

321.17

NALOXONE-REVERSIBLE INHIBITION OF CYCLIC AMP PRODUCTION BY TYR-MIF-1 IN SH-SY5Y HUMAN NEUROBLASTOMA CELLS. J.E. Zadina, S.L. Chang, L.J. Ge* and A.J. Kastin. VAMC, Dept. of Medicine and Neuroscience Program, Tulane U. Sch of Med., New Orleans, LA 70146 and *Dept. of Physiology, LSU School of Dentistry.

Tyr-MIF-1 (Tyr-Pro-Leu-Gly-NH₂) is a peptide isolated from brain that binds to mu opiate receptors (PB&B 25: 1305, 1986) and its own non-opiate sites (Life Sci 47: PL25, 1990). Tyr-MIF-1 has been shown to antagonize the effects of opiates in several tests (Life Sci 39:2153, 1986). In this study, we observed an opiate agonist-like effect of Tyr-MIF-1, inhibition of forskolin-stimulated cyclic AMP production, in a neuroblastoma cell line (SH-SY5Y) that expresses both mu opiate receptors and Tyr-MIF-1 binding sites (Excerpta Medica 914:151, 1990). In cells differentiated by retinoic acid for 5-6 days, Tyr-MIF-1 inhibited cAMP with an IC₅₀ of about 8 μM. Similar results were observed in undifferentiated cells. At high (100 μM) doses, Tyr-MIF-1 was able to induce inhibition (60-70%) comparable to that seen with high doses of morphine. The inhibition was reversible by naloxone. Thus, at concentrations consistent with occupation of the mu opiate receptor, Tyr-MIF-1 is capable of a full agonist response. Actions of Tyr-MIF-1 that are antagonistic to opiates may occur at sites other than the mu receptor, including its own non-opiate site.

FRAGMENTS OF HUMAN DIAZEPAM BINDING INHIBITOR (H-DBI) REVEAL HETEROGENEITY OF BENZODIAZEPINE RECEPTORS (BZ) IN HUMAN LYMPHOCYTES.

A. Berkovich, C. Ferrarese, M. Woodbridge, C. Pierpaoli, A. Guidotti, E. Costa, F.G.I.N., Georgetown Univ., Washington, D.C. 20007; *Neurological Clinic of the University of Milan.

In rat glial cells the binding of [³H]Ro5-4864 and [³H]PK11195 is displaced by DBI(1-86) and by DBI(17-51)-TTN, a processing product of DBI (Mol.Pharm.37:164, 1990). Since DBI and DBI derivatives are found in human CSF and plasma, we studied whether synthetic peptides, which may be processing products of human DBI, displace [³H]PK11195 and [³H]Ro5-4864 from human lymphocytes. In intact lymphocytes, DBI(37-70) and DBI(37-80) displaced both ligands with a K_i of 2-5 μM, whereas, using crude membranes the K_i was 10 times higher. However, protoporphyrin IX binding had a low K_i on membranes and practically failed to displace the labeled ligand bound to intact cells. Both protoporphyrin IX and DBI fragments do not readily cross the cell membrane, and the activity of both compounds does not change in several different ionic media tested. Therefore we hypothesize that the difference in behavior of the two classes of ligands may be due to a complex receptor structure involving at least two binding sites having different selectivity for protoporphyrin IX and H-DBI fragments.

POSTSYNAPTIC LOCALIZATION OF FUNCTIONAL OXYTOCIN RECEPTORS ON PREGANGLIONIC NEURONS IN THE RAT DORSAL MOTOR NUCLEUS OF THE VAGUS NERVE. M. Dubois-Dauphin*, M. Raggenbass*, E. Tribollet*, J.J. Dreifuss. Dept of Physiology, Univ. Med. Cent., 1211 Geneva 4, Switzerland.

The dorsal motor nucleus of the vagus nerve (DMN) of the rat receives oxytocin (OT) immunoreactive axons of hypothalamic origin. Vagal motoneurons send their axon to visceral ganglia through the ipsilateral vagus nerve. OT binding sites are detected in the DMN, whereas the neighbouring nucleus of the solitary tract (NST) is endowed with vasopressin (AVP) binding sites. To assess the pre- or postsynaptic location of the binding sites in DMN, we cut unilaterally the vagus nerve distally to the nodose ganglion. Two weeks after axotomy, the presence of binding sites was examined by film autoradiography using [³H]AVP and [¹²⁵I]OTA as ligands. In lesioned animals, as in controls, the same density of AVP binding was present bilaterally in the NST. In contrast, OT binding sites were fewer or absent altogether from the DMN ipsilateral to the cut vagus nerve. A strong axon reaction was revealed by choline acetyltransferase immunocytochemistry in the ipsilateral DMN. In parallel, the sensitivity to OT of antidromically identified vagal motoneurons was tested by intracellular recordings on brainstem slices. OT applied at 0.1-1.0 μM caused a reversible depolarization and generated, under voltage-clamp conditions, a transient inward current which was TTX-resistant and which was not synaptically mediated, since it persisted in a low-calcium, high-magnesium solution. Our observations favour the notion that OT of hypothalamic origin acts directly rather than indirectly on rat vagal motoneurons.

¹²⁵I-LHRH ANALOGUE DISPLACEMENT FROM HIPPOCAMPAL MEMBRANES, T.L. Thompson & R.L. Moss, Dept. of Physiol. Univ. Texas Southwestern Med. Cntr. Dallas, TX 75235

Autoradiographic evidence has shown that high affinity luteinizing hormone releasing hormone (LHRH) receptors are present in rat hippocampus. Pharmacologically these receptors appear very similar to those found in the pituitary. Evidence from our lab suggests that more than one binding site for LHRH may be present in rat brain. This is based on the inability of a potent LHRH antagonist to inhibit both Ac-LHRH⁵⁻¹⁰ fragment induced mating behavior and inositol phosphate accumulation while effectively inhibiting similar LHRH induced responses. To determine whether more than one binding site exists for neuronal LHRH, we have initiated a series of experiments examining the characteristics of [¹²⁵I]-[D-Ala⁶, N-Me-Leu⁷, Pro⁹, NET]-LHRH (a stable analogue of LHRH) binding to hippocampal membranes prepared from female rats. Competition curves were performed by adding increasing concentrations of native LHRH or Ac-LHRH⁵⁻¹⁰ fragment (2x10⁻⁷M-1x10⁻¹¹M). The LHRH competition curve is of "normal steepness" and bound [¹²⁵I]-LHRH analogue was completely displaced by the native peptide. Preliminary findings suggest that the Ac-LHRH⁵⁻¹⁰ fragment is unable to completely displace the radiolabeled LHRH (80%) and exhibited a very shallow competition curve. Logit-log analysis of the competition data reveal an IC₅₀ of 3.5nM for LHRH while the fragment has an IC₅₀ of .7nM. This suggests that the fragment has a 5 fold greater affinity for the hippocampal receptor than native LHRH. Whether or not this increased affinity alone can account for the inability of the LHRH antagonist to block the effect of Ac-LHRH⁵⁻¹⁰ fragment has yet to be determined. However, the shallowness of the competition curve suggests there may be more than one binding site for LHRH in rat hippocampus. A more complete kinetic analysis of LHRH receptor binding and competition by the fragment is being completed. This work is supported by NIH Grant MH47418.

QUINPIROLE INHIBITS THE REFILLING OF THE INTERNAL CALCIUM POOL MOBILIZED BY THYROTROPIN-RELEASING HORMONE IN BOVINE ANTERIOR PITUITARY CELLS S.L. Shorte* and J.G. Schofield* (SPON: Brain Research Association). Dept. of Biochemistry, University Walk, Bristol, BS8 1TD, U.K.

The cytosolic calcium concentration ([Ca²⁺]_i) was measured in single bovine anterior pituitary cells using fura-2 and fluorescence microscopy (Shorte et al., 1991). TRH-sensitive internal calcium pools were depleted by exposure to TRH (20 nM) in the presence of only 0.1 μM external calcium as previously described (Shorte et al., 1990). Under these conditions, a subsequent application of agonist did not result in a rise in [Ca²⁺]_i unless cells were exposed to millimolar external calcium. However, if the D₂-receptor agonist, quinpirole (1 μM), was present only during the transient re-exposure to 1 mM external calcium, the amount of calcium released during a subsequent exposure to TRH was significantly reduced. The effect was reversed when the concentration of K⁺ in the bathing medium was also transiently raised from 5 mM to 60 mM during the re-exposure to external calcium and quinpirole. Cells pre-treated with pertussis toxin (20 hrs; 100 ng/ml), which reverses the inhibitory action of dopamine on PRL secretion (Schofield et al., 1988), also displayed a reversal of the effect of quinpirole on pool refilling, and did not differ from control observations.

We interpret these data to indicate that activation of the D₂-receptor, present on the membranes of normal bovine anterior pituitary lactotropes, reduces the entry of calcium through voltage-activated calcium channels and that this precludes the refilling of TRH-depleted internal calcium stores.

AFFINITY LABELING OF BRAIN MU OPIOID RECEPTORS WITH [³H]14BETA-BROMOACETAMIDO-7,8-DIHYDROMORPHINE. J.M. Bidlack¹, R.A. Kaplan¹, R. Subramanian¹, A. Seved-Mozaffari² and S. Archer². ¹Dept. of Pharmacology, University of Rochester, Rochester, NY 14642 and ²Dept. of Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12181. [³H]14β-Bromoacetamido-7,8-dihydromorphine (H₂BAM) bound to rat and bovine striatal membranes with high affinity and selectivity for the μ opioid binding site. In the absence of a disulfide bond reducing reagent, [³H]H₂BAM did not bind covalently to the μ binding site. However, after treating membranes with dithiothreitol (DTT), followed by the addition of [³H]H₂BAM, the affinity ligand bound irreversibly to the μ binding site, as determined by solubilization and subsequent precipitation of brain membranes. The specificity of labeling was dependent on the DTT and [³H]H₂BAM concentrations, and the time and temperature of the incubation. Opioids, selective for the μ opioid receptor, blocked the specific alkylation of the binding site, while δ- and κ-selective ligands did not protect the site from alkylation with [³H]H₂BAM. In order to determine which protein(s) were specifically alkylated, [³H]H₂BAM-labeled brain membranes were separated by SDS-polyacrylamide gel electrophoresis, followed by either fluorography or gel slicing. A prominent protein with a molecular weight of 54,000 was specifically labeled in both rat and bovine brain membranes. The labeling of this protein was reduced by μ-selective opioids. These studies demonstrated that after reduction of a disulfide bond at the μ opioid binding site, [³H]H₂BAM specifically alkylated the μ opioid binding site, which is localized in a 54,000 dalton protein in both rat and bovine striatal membranes. (Supported by USPHS grants DA03742 and DA01674.)

322.3

Potential mu-opioid receptor subtype specificity of [¹²⁵I] labeled DAGO, [D-ala², NME-Phe⁴, Glyol] enkephalin. D.S. Roane¹ and J.W. Crim². ¹Div. Pharm/Tox, NE La. Univ., Monroe, La. 71209 and ²Dept. of Zoology, Univ. of Ga., Athens, Ga. 30309.

125I-DAGO, [D-ala², NME-Phe⁴, Glyol] enkephalin has been used in numerous studies as a valuable tool in the autoradiographic measurement of mu-opioid receptors. However, the binding properties of this ligand have not been thoroughly investigated as compared to the better characterized 3H-Dago. In a recent series of comparative saturation binding studies we have found substantial differences in the B_{max} and K_d of 125I- and 3H-Dago.

125I-Dago, prepared by the chloramine-T method, was purified to the mono-iodo fraction by HPLC. Binding studies for both 125I and 3H-Dago were completed over a 0.04-2.0 nM range of labeled ligand using membranes split from a single preparation. K_d and B_{max} values for 125I-Dago, respectively, were 1.65 nM and 3.82e-11 M, while the values for 3H-Dago were 0.39 nM and 6.09e-11 M. With the higher K_d and lower B_{max}, the data suggests the 125I-Dago binds the lower affinity mu subtype receptor. This is supported by an r² value of 0.97 on a linear regression of the Scatchard plot of the 125I-Dago and is consistent with a one-site fit.

322.5

COMPARATIVE QUANTITATIVE AUTORADIOGRAPHIC DISTRIBUTION OF μ OPIOID RECEPTORS IN THE BRAINS OF SUPEROXIDE DISMUTASE-TRANSGENIC (SOD-Tg) MICE AND OF THEIR NON-TRANSGENIC (Non-Tg) LITTERMATES: AGE EFFECTS. K. Kullral, V. Jackson-Lewis, S. Fahn, E. Carlson, C. J. Epstein and J. L. Cadet. Dept. of Neurology, Columbia Univ., New York, NY 10032.

Oxygen-based radicals are thought to be an important factor in the aging process. It is thus possible that some of the changes observed in the concentration of neurotransmitter receptors may be secondary to deleterious effects of these free radicals. In order to test that possibility, we used receptor autoradiographic techniques to compare the distribution of opioid μ receptors labeled with [³H]DAGO (Tyr-D-Ala-Gly-NMe-Phe-Gly-ol) in SOD-Tg and non-Tg mice at 6 weeks and 20 months of age. Saturation analysis revealed that the shell subdivision of the nucleus accumbens (NAc) of SOD-Tg mice contained higher maximal binding capacity (B_{max}) of μ receptors in comparison to that of non-Tg mice at both ages. With aging, only non-Tg mice showed significant decreases in B_{max}. These decreases in B_{max} were associated with an increase in receptor affinity. In contrast, there were no significant differences in B_{max} or in affinity in either the patches nor the matrices of the caudate-putamen of the two strains at any age. Interestingly, whereas several brain structures showed age-related decreases in μ receptors only in the non-Tg mice, both the substantia nigra pars compacta and the ventral tegmental area showed significant age-related decreases only in the SOD-Tg mice. These results suggest that increased SOD activity may affect expression of opioid receptors in a complex fashion.

322.2

IRREVERSIBLE MU-SELECTIVE OPIOID BINDING OF 14-BETA-THIOGLYCOLAMIDO-7,8-DIHYDROMORPHINONE. O. Jiang¹, A. Seved-Mozaffari², S. Archer², and J. M. Bidlack¹. ¹Dept. of Pharmacology, Univ. of Rochester, Rochester, NY 14642, and ²Dept. of Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12181.

Affinity labeling of opioid receptors has been studied in order to determine the pharmacological and molecular properties of these receptors. Previous studies have shown that after treating brain membranes with the disulfide-bond reducing reagent dithiothreitol, 14β-bromoacetamido derivatives of morphine and morphinone irreversibly inhibited μ opioid binding, suggesting the presence of a disulfide bond at or near the μ binding site. The present study was designed to characterize the affinity, selectivity, and irreversibility of the sulfhydryl-containing affinity ligand 14β-thioglycolamido-7,8-dihydromorphinone (TAMO). TAMO IC₅₀ values for inhibiting the binding of 0.25 nM [³H][D-Ala²,(Me)Phe⁴,Gly(ol)⁵]enkephalin (DAGO), a μ-selective peptide, 0.2 nM [³H][D-Pen²,pCl-Pen⁵]enkephalin (pCl-DPDPPE), a δ-selective peptide, and κ binding, as measured by either 0.2 nM [³H]bremazocine in the presence of μ and δ blockers, or 1 nM [³H]U69,593, were determined using bovine striatal membranes. The IC₅₀ values for TAMO were 1.58 ± 0.1 nM for 0.25 nM [³H]DAGO, 22.4 ± 2.1 nM for 0.2 nM [³H]pCl-DPDPPE, 35.6 ± 2.3 nM and 52.4 ± 7.4 nM for inhibition of 0.2 nM [³H]bremazocine and 1 nM [³H]U69,593 binding, respectively. Preincubation of membranes with TAMO, followed by extensive washing, revealed a concentration-dependent irreversible inhibition of [³H]DAGO binding. Therefore, these studies suggest that TAMO selectively binds to μ opioid binding sites and produces covalent binding by attacking the disulfide bond at the μ binding site to form a disulfide bond with the binding site. EFFECT OF CHRONIC MORPHINE EXPOSURE ON μ-OPIOID RECEPTOR REGULATED CYCLIC AMP PRODUCTION IN RAT STRIATAL NEURONS B.J. Van Vliet¹, H.J. Groenewegen¹, A.H. Mulder² and A.N.M. Schoffeleers¹. ¹Depts of Pharmacology and Anatomy¹, Free University, Medical Faculty van der Boeorchorststraat 7, 1081 BT Amsterdam, The Netherlands

Rat striatal neurons cultured in serum-free, hormone-supplemented medium, were exposed to 10 μM morphine for several hours or days before intracellular cyclic AMP production was measured. Dopamine D₁ receptor- and β-adrenoceptor-stimulated cyclic AMP production were profoundly increased upon morphine treatment (up to 150 % of control). In contrast, cyclic AMP production induced by direct activation of the catalytic unit of adenylate cyclase with forskolin remained unaffected. Interestingly, the relative inhibitory effect of the μ-opioid receptor agonist DAGO on dopamine D₁ receptor- and β-adrenoceptor-stimulated cyclic AMP production was unchanged after exposure to morphine. On the other hand, unlike μ-opioid receptors chronically exposed to morphine, β-adrenoceptors mediating activation of adenylate cyclase were rapidly desensitized upon prolonged exposure of the neurons to isoprenaline.

It is suggested that tolerance to morphine is not caused by desensitization of central μ receptors, but by the fact that morphine is acting against upregulated signal transduction mechanisms. The adaptive changes following morphine treatment may involve enhanced expression and / or biochemical modification of dopamine D₁ receptors, β-adrenoceptors or G proteins, independent of possible changes at the level of dopaminergic or noradrenergic nerve terminals, which are not present in primary cultures of rat striatum.

322.6

BINDING OF THE DERMORPHIN ANALOG TYR-(D-ARG)²-PHE-SAR-OH (TAPS) TO μ₁- AND μ₂-OPIOID RECEPTOR SUBTYPES. S. Vonnhof, P. Paakkari, G.Z. Feuerstein, and A.-L. Sirén. Dept. of Neurology, USUHS, Bethesda, MD 20814 and Dept. Cardiovasc. Pharmacol., SmithKline Beecham, King of Prussia, PA 19406, USA.

TAPS, a D-Arg²-dermorphin derived tetrapeptide was recently shown to exert an enhanced analgesic potency compared to morphine (Sasaki et al., BBRC 120: 214-218, 1984). Opposed to morphine, however, TAPS increased ventilatory minute volume at equianalgesic doses (Paakkari et al., Proc. of the INRC, 385-388, 1990). This effect was attenuated by the μ₁-opioid receptor antagonist naloxonazine, suggesting a μ₁-opioid related mechanism. Additionally, TAPS antagonized the respiratory depression induced by the selective μ-agonist dermorphin in naloxonazine pretreated animals, congruent with an antagonistic mode of action at the μ₂-opioid site. In order to determine the selectivity of TAPS at μ-opioid binding sites, μ₁- and μ₂-selective binding assays (Clark et al., Mol. Pharmacol. 34: 308-317, 1988) were performed in calf thalamus homogenates, using [³H]DADL (μ₁) and [³H]DAMGO (μ₂). The K_i-values for TAPS at μ₁- and μ₂-opioid binding sites were 0.4 and 1.3 nM respectively. Addition of 10 μM Gpp(NH)p in the presence of 100 mM NaCl reduced the affinity of TAPS 49-fold at the μ₁-site but significantly less (4-fold) at the μ₂-subtype. The results indicate that TAPS exerts moderate selectivity to the μ₁-opioid binding site with a strong agonistic property. The comparatively small reduction of affinity in the presence of guanosine nucleotides may indicate a partial agonistic/antagonistic activity at the μ₂-opioid binding site.

322.7

PHARMACOLOGICAL CHARACTERIZATION OF THE ANALGESIC EFFECTS OF LEVORPHANOL. L. Tive, K. Ginsberg, C.G. Pick and G.W. Pasternak. The Cotzias Lab. of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Depts. of Neurology and Pharmacology, Cornell U. Medical College, New York, NY 10021.

We have previously shown that there is unidirectional cross-tolerance between morphine and levorphanol in the rat, prompting us to study the receptor mechanisms of levorphanol analgesia in a mouse model. Levorphanol produced a dose-dependent analgesia in the mouse which was partially sensitive to the μ_1 antagonist naloxonazine. Although naloxonazine shifted the dose-response curve to the right, the shift was far smaller than that seen with traditional μ drugs. Furthermore, naloxonazine imposed a ceiling effect not seen in control animals. Levorphanol produced analgesia following either spinal or supraspinal injections. Isobolographic analysis of simultaneous i.c.v. and i.t. injections revealed synergistic interactions similar to those previously reported for morphine. There was no cross-tolerance between levorphanol and U50,488H, suggesting the lack of a significant κ_1 component in levorphanol analgesia. However, mice tolerant to the κ_3 agonist NalBzoH showed some cross tolerance to levorphanol, implying a role for κ_3 receptors. In conclusion, levorphanol analgesia appears to comprise a complex interaction of μ and κ_3 receptor mechanisms.

322.9

MU AND KAPPA RECEPTOR STIMULATION DIFFERENTIALLY AFFECT IN VIVO D2 RECEPTOR BINDING IN NEONATAL RATS. P. KEHOE, K.M. WARD* and C.B. BOYLAN*. Dept. of Psychology, Trinity Coll., Hartford, CT 06016.

Previous research has indicated that endogenous opioids modulate isolation vocalizations, analgesia and reward in neonatal rats. Activation of specific opioid receptor subtypes, however, produces differing effects on these behaviors. μ receptor stimulation with morphine promotes both a decreased rate of ultrasonic calling and positive associations. Conversely, the kappa receptor agonist, U50,488H, increases the rate of vocalizing and does not support preference behavior. Both systems produce neonatal analgesia. This differential functioning may be due to differences in opioid-dopamine interactions that may depend on the specific receptor subtype. To assess this interaction, in vivo striatal D2 receptor binding was done on 10-day-old rats treated with ip morphine (1.0 mg/kg), U50,488H (0.25 mg/kg) or saline and then injected icv with the D2 receptor antagonist, ^3H -Raclopride (0.2uCi/10ul). Following icv injection and a brief isolation, during which the pups' vocalizations were recorded, the pups were decapitated and their brains dissected for striatal and cerebellar tissue. Morphine-treated pups had the least striatal ^3H -Raclopride binding, while U50,488H had the most. These results suggest that U50,488H caused significantly less striatal D2 receptor occupation than controls, while morphine produced the highest, presumably through the release of dopamine at these terminals.

322.11

OPIOID MECHANISMS IN RATS BRED FOR LEARNED HELPLESSNESS E. Edwards, J. Munevirci*, P. Van Houten*, C. Michel* and F.A. Henn. SUNY at Stony Brook, NY 11794

We have examined various parameters of opioids mechanisms in rats bred for Learned Helplessness (LH; generation 21st rats used without any exposure to the learned helpless paradigm). Plasma β -endorphin levels of LH strain rats were decreased as compared to levels detected in NLH and naive control rats (17.5 ± 1.6 , LH vs 26.25 ± 2.6 , NLH & 25.5 ± 2.4 , NC; data expressed in pg/ml \pm S.E.M, n=17/group).

In LH strain rats, μ receptor densities measured with binding of ^3H -DAGO to brain homogenates, were significantly up-regulated in all limbic regions tested (CX, HPC, HT, Sep: 40-300%).

Tail-flick latencies were measured for both LH and NLH strain rats in response to exposure to a controlled heat source and were significantly lower in the LH strain rats as compared to NLH strain rats (LH: 4.6 ± 0.4 secs; NLH: 7.8 ± 0.6 secs, n=10/group).

LH strain rats also exhibited significantly reduced precipitated withdrawal symptoms after exposure to opiate agonists as compared to NLH strain rats (LH: 6 ± 0.4 ; NLH: 17 ± 1.5 escape attempts, n=10/group).

The dysregulation in opioid mechanisms in the LH strain rats supports the hypothesis of an involvement of endorphin systems in the pathophysiology of depression.

322.8

SODIUM POTENTIATES THE INHIBITION OF OPIOID AGONIST BINDING BUT ANTAGONIZES THE INHIBITION OF OPIOID ANTAGONIST BINDING BY A BENZODIAZEPINE IN THE RAT SPINAL CORD. Gopi A. Tejwani, Anil K. Rattan* and Anne-Marie Duchemin. Depts. of Pharmacology and Anesthesiology, College of Medicine, The Ohio State University, Columbus, OH 43210.

Midazolam, a benzodiazepine receptor agonist can either enhance or decrease the antinociception produced by intrathecal administration of morphine in the rat. Furthermore, midazolam at high doses can inhibit the binding of several opioid ligands to the spinal opioid receptors *in vitro* (Rattan et al. *Anesthesia & Analgesia*, *In press*). We now report that sodium ions can either antagonize or potentiate the inhibition of spinal opioid receptors by midazolam depending upon the agonistic/antagonistic nature of the opioid ligand used. The specific binding of radioactive opioid ligands to spinal membrane preparations was performed as described before (Tejwani and Hanissian *Neuropharmacology*, 29 445, 1990). Binding of opioid antagonist [^3H]-naloxone (0.5-10 nM) to the rat spinal opioid receptors was increased in presence of 100 mM NaCl alone. Midazolam (100 μM) decreased the binding of [^3H]-naloxone significantly at nine different concentrations. However, in the presence of 100 mM NaCl this inhibition by midazolam was not observed. The binding of μ receptor agonist [^3H]-DAGO (Tyr-D-Ala-Gly-Methyl-Phe-Glyol-enkephalin) (1-20 nM) was inhibited by 100 mM NaCl or 100 μM midazolam, independently. However, when NaCl and midazolam were used together they inhibited the binding of [^3H]-DAGO much more than that observed when NaCl or midazolam alone was used. These results suggest that sodium ions play an important role in the modulation of spinal opioid receptors by benzodiazepines.

322.10

2-CHLOROPROCAINE INTERACTIONS AT MU AND KAPPA OPIOID RECEPTORS. B. Coda*, S. Bausch*, M. Haas*, H. Hill*, C. Arnett, C. Chavkin. Depts. of Anesth., Pharm., and Psychiatry, Univ. of Wash. and Fred Hutchinson Cancer Research Ctr. Seattle, WA 98104.

Clinically, epidural 2-chloroprocaine (2CP), but not lidocaine, can decrease the analgesic effect of subsequently administered epidural fentanyl. In contrast, 2CP does not antagonize epidural butorphanol in humans. In the present study, we investigated possible opioid receptor interactions with these local anesthetics which may explain these observations.

The potencies of 2CP and lidocaine for displacing selective ligands were determined in two *in vitro* membrane binding assays using either [^3H]-DAGO or [^3H]-U69,593 to label μ or kappa-opioid receptors respectively. 2CP caused displacement of [^3H]-DAGO binding up to 100% at highest concentrations, with an EC_{50} of $810 \pm 290 \mu\text{M}$, while lidocaine reduced [^3H]-DAGO binding only partially even at 10 mM. Both were more potent at the kappa site: 2CP displaced [^3H]-U69,593 completely with an EC_{50} of $177 \pm 47 \mu\text{M}$, while the EC_{50} for lidocaine was $2.53 \pm 0.48 \text{ mM}$. Thus, 2CP was about 4.5 times more potent at kappa than μ sites, and 2CP was 14 times more potent than lidocaine at kappa sites. 2CP is likely to have significant occupancy at kappa as well as μ receptors at clinically relevant doses, whereas lidocaine is unlikely to reach a high enough concentration to bind either of these opioid receptors.

Using extracellular electrophysiologic recording in an *in vitro* hippocampal slice preparation, we found that chloroprocaine reduced opioid induced responses in CA1 region (μ) and dentate gyrus (kappa). However, these changes were not due to specific μ or kappa receptor actions, but were typical of local anesthetic effects.

322.12

THE ROLE OF OPIATE RECEPTOR SUBTYPES IN THE β -ENDORPHIN INDUCED PROLACTIN INCREASE IN LACTATING AND CYCLING FEMALE RATS. J. Janik and P. Callahan, Miami University, Oxford, OH 45056.

We have previously reported that the increase in prolactin following β -endorphin administration is potently antagonized by the specific κ antagonist, nor-Binaltorphimine (nor-BNI). However, it is the μ site which has been identified in morphine induced prolactin release. The purpose of this study was to determine the role of the μ site in the β -endorphin induced prolactin secretory response in female rats.

Post-partum, lactating or diestrous female Sprague-Dawley rats were used for all experiments. Animals were implanted with chronic intraventricular (ivt) cannulae into the lateral ventricle of the brain. Following a 5 - 7 day recovery period and one day prior to an experiment, each animal was implanted with a chronic jugular cannulae. Animals were administered saline or β -funtaltrexamine (β -FNA, 1 or 5 μg , ivt) 4 hours prior to saline or β -endorphin (0.025 μg , ivt) administration. Both these doses of β -FNA significantly antagonized the morphine induced prolactin increase.

The prolactin secretory response to β -endorphin was blocked by the 5 μg β -FNA dose only: the 1 μg dose was completely ineffective in blocking the action of β -endorphin. It seems that β -endorphin not only acts through a κ site to elicit a prolactin secretory response but also acts via the μ opiate receptor subtype in both lactating and diestrous female rats.

IMMUNOBLOTS WITH RHODOPSIN ANTISERA PROVIDE EVIDENCE THAT A MU OPIOID BINDING PROTEIN BELONGS TO THE G-PROTEIN-COUPLED RECEPTOR FAMILY. T.L. Gioannini^{1,2}, E.R. Weiss³, G.L. Johnson⁴, J.M. Hiller² and E.J. Simon². ¹Baruch College, NY, NY 10017; ²NYU Med. Ctr., NY, NY 10016; ³Univ. of North Carolina, Chapel Hill, NC 27599; ⁴Nat. Jewish Center for Immun. and Resp. Med., Denver, CO 80206.

A mu opioid binding protein (OBP) purified to homogeneity from bovine striatal membranes (Gioannini et al J. Biol. Chem. 260:15117, 1985) was investigated in immunoblots using antisera against bovine rhodopsin. One antibody was produced against membrane-bound rhodopsin while 5 others were made against defined regions in the rhodopsin molecule, the sequence of which is known. Three of the antibodies produced positive signals (2 strong, 1 weak), while three others did not recognize OBP. The pattern and degree of crossreactivity mimics strikingly the crossreactivity with the same antisera previously observed with the beta adrenergic receptor. These results indicate that mu-OBP contains regions that are antigenically similar to those in two G-protein coupled receptors. The findings strongly support the hypothesis that OBP is a member of the family of G-protein coupled receptors and, when sequenced, will be found to have the structure, including the 7 transmembrane domains, characteristic of such molecules.

322.15

N-SUBSTITUTED DERIVATIVES OF NORMETAZOCINE: DIFFERENTIATION OF SIGMA-1 AND SIGMA-2 RECEPTORS. L. Di Paolo¹, F.J. Carroll², P. Abraham², X. Bai², K. Parham², S.W. Mascarella², X. Zhang², P. Wallace¹, J.M. Walker¹, and W.D. Bowen¹. ¹Brown University, Providence, RI 02912 and ²Chemistry & Life Sci., Research Triangle Institute, Research Triangle Park, NC 27709

Sigma receptors can be divided into sigma-1 and sigma-2 subtypes. While these sites bind [³H]DTG with equal affinity, they can be differentiated by stereoselectivity for opiate benzomorphans: sigma-1, (+)-enantiomer > (-)-enantiomer; sigma-2, (-) > (+). Sigma-1 sites are enriched in guinea pig brain and are selectively labeled by 3 nM [³H](+)-pentazocine. Sigma-2 sites are enriched in rat brain, rat liver, PC12 cells, and some neuronal cell lines (*Brain Res.* 527:244-253, 1990; *Soc. Neurosci. Abstr.* 16:370, 1990; and abstr. this meeting) and are labeled using 5 nM [³H]DTG in the presence of 1 uM dextralorphan to mask sigma-1 sites. Here we further test this model by characterizing a novel series of enantiomeric benzomorphans. (+) or (-)-*cis*-Normetazocine was N-alkylated with various alkyl halides. Typical results for sigma-1 were, K_i (nM): N-benzyl, (+)=0.67/(-)=36.5; N-4'-phenylbutyl, (+)=3.2/(-)=85.2; N-5'-phenylpentyl, (+)=2.6/(-)=38.5. However, at sigma-2 sites (rat liver), reversed stereoselectivity was observed: N-benzyl, (+)=1379/(-)=217; N-4'-phenylbutyl, (+)=1204/(-)=202; N-5'-phenylpentyl, (+)=820/(-)=69.2. Similar results were obtained for other members of this series. These results are consistent with those obtained previously with the normetazocine derivatives pentazocine and SKF-10,047 and support the proposed classification scheme. The high affinity of these novel benzomorphans at sigma-1 sites suggests their utility in further studies of sigma receptors. (Supported by PHS Grant DA-05721)

IDENTIFICATION AND EXPLOITATION OF SIGMA LIGAND PHARMACOPHORES. J.B. Fischer¹, K. Burke Howie², A. C. Server¹, M. El-Ashmawy¹, A. Ismaiel¹, M. Yousif¹, S. Ablordepey¹ and R.A. Glennon²; ¹Cambridge Neuroscience, Inc. Cambridge, MA 02139 and Department of Medicinal Chemistry, MCV/VC; Richmond, VA 23298-0540.

Sigma receptors offer a new approach to the development of agents for the treatment of mental disorders. Haloperidol, 3-PPP, and sigma-opiates bind at, but lack selectivity for, sigma receptors. We have identified the primary pharmacophore of the sigma-opiates (such as NANM; K_i = 430 nM) as being an N-substituted 2-phenylaminoethane (*J. Med. Chem.* 1991, 34:1094), a pharmacophore that is common to 3-PPP-like agents. For example, N-(3-phenylpropyl)-1-phenyl-2-aminopropane (PPAP) binds at sigma receptors with increased affinity (K_i ca 20 nM). Further manipulation of structure results in analogs with even higher affinity. Unlike other sigma agents, these do not bind at PCP sites or dopamine receptors. Phenylpiperazine (K_i > 10,000 nM) can serve as a phenylaminoethane-mimic; incorporation of PPAP substituents increases sigma affinity by more than 10,000-fold and has allowed identification of a sigma-selective pharmacophore of haloperidol (K_i 0.8 nM relative to 10 nM for haloperidol) with reduced affinity for dopamine receptors. Thus, it is possible to account for the binding of these major classes of sigma ligands via structurally similar pharmacophores.

EFFECTS OF NALOXONE ON [11-C] BUPRENORPHINE BINDING IN BABOON BRAIN. I. Galynker¹, D. Schlyver², S.L. Dewey², J.S. Fowler², M.J. Holland³, J.D. Brodie³, E. Simon³, R.R. McGregor², R. Ferrier² and A.P. Wolf². ¹Mount Sinai Medical Center, New York, NY, ²Brookhaven National Laboratory, Upton, NY, and ³NYU Medical School, New York, NY

Buprenorphine is a partial opiate agonist used clinically as an analgesic, and is of interest in the treatment of some forms of psychosis and opiate and cocaine abuse. In the present study the effects of naloxone administration on O-[11-C]-buprenorphine (11-C BPN) in female baboons (*Paio anubis*, N=3) were examined using positron emission tomography (PET). 11-C BPN (specific activity of 1.0-2.0 Ci/μmol at EOB) was synthesized using a modified method of Lever et al (1990) and 2.5-5.0 mCi in doses of 0.001-0.002 mg/kg was administered to the baboons followed in 30-40 min by a bolus of 1.0 mg/kg of naloxone. In all cases naloxone reduced buprenorphine binding in thalamus, striatum, cingulate gyrus, and frontal cortex by 40-70% with minimal effects on occipital cortex and cerebellum. Patlak plots using a metabolite-corrected plasma integral or a nonspecific binding region gave similar results: analysis of buprenorphine binding in untreated baboons produced linear plots (slope 0.066 ± 0.0016 min⁻¹ for combined specific binding) up to the point of naloxone injection, at which time the slope decreased significantly and was similar to the one obtained with naloxone pretreatment (slope 0.031 ± 0.0008 min⁻¹, p<0.01). This change indicated a decrease in the number of available opiate receptors and possible 11-C BPN displacement by naloxone. These results indicate feasibility of displacement as well as pretreatment methodology for receptor studies with PET. They are of particular interest in view of reported partial reversibility of buprenorphine-induced respiratory depression with naloxone and lack of abstinence induction by naloxone in buprenorphine-using subjects (Jasinsky et al, 1978). USDOE, NS-15638.

322.16

CHARACTERIZATION OF N-SUBSTITUTED *cis*-N-[2-(3,4-DICHLOROPHENYL)ETHYL]-2-(1-PYRROLIDINYL)CYCLOHEXYLAMINES AND N-[2-(3,4-DICHLOROPHENYL)ETHYL]-2-(1-PYRROLIDINYL)ETHYLAMINES: NOVEL COMPOUNDS WITH HIGH SIGMA RECEPTOR AFFINITY AND SELECTIVITY. K. Hsu¹, B.R. de Costa², L. Radesca², L. Di Paolo¹, and W.D. Bowen¹. ¹Div. Biol. & Med., Brown Univ., Providence, RI 02912 and ²Lab. Med. Chem., NIDDK, Bethesda, MD 20892.

We have previously shown that 1*S*,2*R*(-)-*cis*-U50,488 exhibited a sigma K_i of 81 nM, and lacked affinity for kappa opioid receptors labeled by [³H]bremazocine (*J. Med. Chem.* 32:1996, 1989). Reduction of the carbonyl moiety produced BD737, with sigma K_i of 1.3 nM (*J. Med. Chem.* 33:3100, 1990). Here we investigate a related series of (-)-*cis*-N-[2-(3,4-dichlorophenyl)ethyl]-2-(1-pyrrolidinyl)cyclohexylamines by changing the N-alkyl substituent, and measuring ability to displace [³H](+)-3-PPP from guinea pig brain membranes. For the indicated N-substituent, the following affinities were observed (K_i, nM): H, 0.49; Me, 1.3; Et, 3.5; Pr, 55.7, CyPrMe, 38.1. Removal of the cyclohexane ring produced a series of N-[2-(3,4-dichlorophenyl)ethyl]-2-(1-pyrrolidinyl)ethylamines. N-Substituted derivatives in this series are, to date, some of the most potent sigma ligands known: H, 1.11; Me, 0.34; Et, 0.51; n-Pr, 1.35; allyl, 1.39; n-Bu, 11.7. Other modifications such as opening of the pyrrolidine ring and varying substitution at the remaining N-atom have also produced ligands with sub-nanomolar affinity at sigma receptors. Most of these ligands lack affinity for PCP, dopamine, and kappa opiate receptors. Selectivity studies and further SAR data will be discussed. Compounds in this series will prove useful in structural and functional studies of sigma receptors. (Supported by PHS Grants NS-26746 and DA-04988)

FURTHER STUDIES ON THE IDENTITY OF SIGMA RECEPTORS IN RODENT LIVER AND BRAIN. M.S. Sonders and E. Weber. Department of Pharmacology, UC Irvine, Irvine, CA 92717.

The most recognizable feature of the sigma receptor [haloperidol-sensitive, sigma-1, or DM/sigma] is its ability to bind with high affinity a limited number of drugs from several disparate structural and pharmacological categories. This broad ligand specificity and the high density of binding sites in rodent liver with a "sigma-like" pharmacological profile have led several groups to propose that the sigma receptor is a member of the cytochrome P-450 enzyme superfamily. Consistent with this hypothesis is the finding that cytochrome P-450 inhibitor SKF-525A can inhibit the binding of several different radioligands in sigma binding assays employing liver and brain tissue.

We have sought to characterize and purify the binding sites for the sigma ligand DTG (di-ortho-tolyl-guanidine) from guinea pig and rat livers. Subcellular fractionation studies have yielded data consistent with previously-reported results indicating that activity is predominantly associated with the microsomal and mitochondrial fractions. [³H]-DTG radioreceptor assays on rat microsomal fractions displayed a pharmacological profile quite similar to that seen in brain membrane assays though the affinity for haloperidol was somewhat lower. (+)Pentazocine and SKF-525A inhibition curves were markedly biphasic, suggesting that [³H]-DTG may bind to more than one site, though scatchard analyses detected only one.

Preliminary studies on the effects of phenobarbital administered to male Sprague-Dawley rats (15 mg i.p./rat/day X 5 days) showed no significant change in the level of [³H]-DTG binding sites in either liver or brain membranes when compared to vehicle-injected rats. Should a cytochrome P-450 comprise some of the [³H]-DTG binding sites, it is non-inducible by phenobarbital.

[³H]-DTG SELECTIVELY LABELS "SIGMA-1" SITES IN SOLUBILIZED RAT LIVER HOMOGENATES. G. K. Ehrlich, G. Lem*, G. Singh*, R. B. Murphy, D.J. Schuster. New York University, Dept. of Chemistry and Center for Neural Science, New York, NY 10003.

[³H]-DTG is known to bind to two distinct pharmacological sites in rat liver homogenates, which have been suggested to represent components of the sigma receptor/binding site (SRBS). These two components are differentiated by their enantiomeric selectivities for benzomorphans. While both subtypes exhibit high affinities toward [³H]-DTG, [³H]-haloperidol and [³H]-(+)-PPP, "SIGMA-1" sites bind (+)-benzomorphans with higher affinities than (-)-benzomorphans. In both CHAPS and sodium cholate solubilized rat liver preparations, we have demonstrated the selective labeling of a sigma subtype with [³H]-DTG which retains the pharmacological characteristics of the putative "SIGMA-1" site. This selective labeling with [³H]-DTG is also observed in solubilized bovine cerebellar homogenates. Moreover [³H]-haloperidol does not discriminate between subtypes of similar solubilized preparations. Hence, these results suggest that [³H]-DTG can be used as a selective label in the characterization of "SIGMA-1" sites in tissues which contain a heterogeneous population of sigma sites. This work was supported by NIDA grant 1 R01 DA 05728.

PREPARATION AND CHARACTERIZATION OF SUBSTITUTED 3'-[N-(4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE)] PROPIOPHENONES AS POTENT AND SELECTIVE SIGMA LIGANDS. G. Singh*, W. E. Frieze*, A. Khodabakhsh*, H. Zhao*, R. B. Murphy, D.J. Schuster. New York University, Dept. of Chemistry, New York, NY 10003.

We have prepared a series of substituted 3'-[N-(4-phenyl-1,2,3,6-tetrahydropyridine)] propiophenones, with very high affinities toward sigma receptor/binding sites from bovine cerebellar homogenates labelled with [³H]-haloperidol and [³H]-DTG, and with very low affinity toward D₂ receptors in rat striatal preparations. These compounds were synthesized through Mannich reactions of substituted 4-phenyl-1,2,3,6-tetrahydropyridines or 4-phenylpiperidines with acetophenones and other enolizable methyl ketones. The relationship of the structures of this series of compounds with their affinities toward sigma receptor/binding sites will be presented, along with their pharmacological profiles. The compound displaying the highest sigma activity in the series (IC₅₀ = 1 nM) is 3'-[N-(4-(*p*-chlorophenyl)-1,2,3,6-tetrahydropyridine)] propiophenone hydrochloride, shown below. These compounds are of potential interest as novel, selective ligands for the sigma site. This work was supported by NIDA grant 1 R01 DA 05728.

CATECHOLAMINE RECEPTORS: DOPAMINE III

323.1

SITE-DIRECTED MUTAGENESIS OF DOPAMINE D₂ RECEPTORS. K.A. Neve, B.A. Tester, R.A. Henningsen, G.C. Hughes, A. Spanovannis, and R.L. Neve. VAMC, Portland, OR; and Univ. of Calif., Irvine, CA.

We are characterizing three sets of mutations introduced into rat D₂ receptors, to determine amino acids that contribute to the binding of ligands to D₂ receptors or to the interaction of the receptors with G proteins to modulate second messengers. All mutants were stably expressed in C₆ glioma cells. One set of mutations involves potential alpha helical regions from the third cytoplasmic loop of D₂ receptors. Deletion of one such region, amino acids (AA) 231-255 of D₂₄₁₅, prevents inhibition of adenylyl cyclase by dopamine without substantially altering the affinity of antagonist ligands. Deletion of AA 271-283 of D₂₄₄₄ had very different consequences, since this mutant was capable of inhibiting adenylyl cyclase but had markedly lower affinity for several antagonist ligands. This difference is striking because 13 of the residues missing in del231-255 (242-254) are those deleted in del271-283 of D₂₄₄₄. The second set of mutations consists of three conserved aspartate residues: D80, D114, and D131. Perhaps the most interesting effects resulted from changing Asp-80 to Ala (D80A). D80A had slightly-to-moderately decreased affinity for many ligands, but a complete loss of sodium-sensitive binding of substituted benzamides and agonists. Also, D80A was unable to inhibit adenylyl cyclase. The third set of mutations consists of 4 conserved serine residues: S193, S194, S197, and S391. S193 contributed most and S194 least to the binding affinity of dopamine. (MH 45372, HD 18658, VA Merit Review Program)

323.2

FLAG-D₂₄₁₅ AND FLAG-D₂₄₄₄, UNIQUE MUTANTS OF DOPAMINE D₂ RECEPTORS D₂₄₁₅ AND D₂₄₄₄, OFFER A NOVEL APPROACH FOR RAPID PURIFICATION OF D₂ RECEPTORS. B.A. Tester, R.A. Henningsen, A. Spanovannis, R.L. Neve, and K.A. Neve. VA Medical Center, Portland, OR, 97201; UC Irvine, CA, 92707.

We have constructed cDNAs in which a short sequence (Flag) is attached to the amino terminus of each molecular form of dopamine (DA) D₂ receptors. A commercially available anti-Flag antibody can be used to purify proteins bearing the Flag sequence (MDYKDDDDKS) from solubilized membranes. D₂₄₁₅, D₂₄₄₄, Flag-D₂₄₁₅ and Flag-D₂₄₄₄, have been stably expressed in C₆ glioma cells. Binding studies on membrane preparations of the transfected cell lines demonstrate that the attached Flag sequence does not change agonist or antagonist binding. Flag-D₂₄₁₅ and Flag-D₂₄₄₄ receptors bind [¹²⁵I]epidepride and other antagonists with equal affinity, and these values are equivalent to those of wild-type D₂ receptors. Competition curves for inhibition of the binding of [¹²⁵I]epidepride by DA shift from two sites in the absence of GTP to one low affinity site in the presence of GTP, suggesting coupling of G proteins to the Flag-D₂₄₁₅ and Flag-D₂₄₄₄ receptors. These mutants will be useful tools for selective purification of D₂₄₁₅ and D₂₄₄₄ receptors. Potential applications include analysis of post-translational modifications of the receptors, as well as analysis by co-purification of selective coupling of Flag-D₂₄₁₅ and Flag-D₂₄₄₄ to G proteins. (MH45372, HD18658, VA Merit Review Program)

STRUCTURE:FUNCTION PREDICTIONS FOR G_i-PROTEIN COUPLING BY THE D₂ DOPAMINE RECEPTOR. S.D. HANDRAN and J.R. STARKEY*. Department of Microbiology, Montana State University, Bozeman, MT 59717.

Predictions for intracellular D₂ dopamine receptor sequences likely to interact with G_i-protein domains during receptor signal transduction were sought by comparing the published D₂ amino acid sequence with the sequences for numerous other G_i coupled membrane receptors. Using "Alima", a program which looks for structure: function homologies, the D₂ receptor was found to exhibit most overall homology with the α₂-adrenergic receptor and a lesser homology with the m₂-muscarinic receptor. The homology with the α₂-adrenergic receptor included a highly conserved region in the putative third cytoplasmic loop (D₂ receptor residues 291-356; α₂-adrenergic receptor residues 277-342), and this region of homology is suspected to mediate a major portion of the G-protein coupling interaction. Secondary structure predictions from the "Stroud" and "Mseq" programs were used with InsightII and Discover programs to model the third cytoplasmic loop of the D₂ receptor and the putative interacting domain of the G_{iα} subunit. These models are being used to guide docking and peptide mapping experiments to confirm the predictions for the protein:protein interacting sequences. Supported by the Montana Technology Development Trust and NSF grant # RII-8921978.

VARIABLE EXPRESSION OF THE D₂ DOPAMINE RECEPTOR (D_{2R}) IN GH₃C PITUITARY TUMOR CELLS: EFFECTS ON FUNCTIONAL RESPONSE. E. Meller, T. Puza*, J.C. Miller, W. Chan*, D. Filer*, A.J. Friedhoff, Y. Wang*, and M. Armour*. Dept. of Psychiatry, NYU Medical Center, New York, NY 10016.

We have recently shown that dopaminergic inhibition of prolactin (PRL) secretion in the rat anterior pituitary displays very efficient receptor/effector coupling, as evidenced by a large receptor reserve for full dopamine agonists both *in vivo* and *in vitro* (Meller et al., JPET 257:668-675, 1991). While the D_{2R} exists in both short and long forms due to alternative splicing, only the long form (D_{2R}) is expressed in the rat anterior pituitary (Dal Toso et al., EMBO J. 8:4025-4034, 1989; Giros et al., Nature 342:923-926, 1989). GH₃C pituitary tumor cells secrete PRL but are devoid of D₂ receptors. We have therefore transfected GH₃C cells with a cDNA encoding the D_{2R} isoform in order to examine the relationship between functional response and D_{2R} density.

The complete cDNA for the coding region of D_{2R} was amplified by the polymerase chain reaction and the insert was subcloned into the pRSV expression vector. DNA sequence analysis of the D_{2R} insert was found to be complete and correct. GH₃C cells were co-transfected with pRSV(D_{2R}) and another expression vector (pSVneo) containing the neomycin resistance gene. Single colonies expressing neomycin resistance were selected and subcultured. Cell membranes from individual clones were subjected to saturation analysis of radioligand binding with [³H]-spiperone. In transfectants, D_{2R} density varied over an approximately 8-fold range (70-570 fmol/mg protein), whereas untransfected cells displayed no detectable binding. Dopaminergic inhibition of basal as well as stimulated PRL secretion in these transfectants is currently being examined. The relationship between expressed D_{2R} density and functional responsiveness will be reported. Supported in part by BRSG S07-RR5399-29.

323.5

DETECTION OF RNA TRANSCRIPTS FOR BOTH ISOFORMS OF THE DOPAMINE D₂ RECEPTOR IN SEVERAL NEURAL CELL LINES
 Christina A. Harrington and Noel J. Buckley*, Department of Physical Biochemistry, National Institute for Medical Research, London NW7 1AA

A panel of neural cell lines has been screened for the presence of dopamine D₂ receptor RNA. Oligomer primers flanking the alternative exon between transmembrane regions V and VI were used in PCR amplification reactions with cell line RNA. Among the lines tested, IMR 32 cells, 132IN1 cells, and SH-5Y5Y cells contained RNA transcripts for the D₂ receptor. The detection of D₂ transcripts in the IMR 32 line is consistent with the report of Monsma et al. (Brain Research, 1989, 492:314-324) that significant levels of specific receptor binding by the D₂ antagonist [³H]methylspiperone are present in these cells. Transcripts for both isoforms of the D₂ receptor are detected in the lines expressing D₂ RNA. In general, the longer form of the D₂ receptor transcript, D₂(444), is present in higher abundance than the D₂(415) isoform transcript.

Neural cell lines expressing the dopamine D₂ receptor will provide useful assay systems for initial characterization of the promoter for the D₂ receptor gene. These lines may also be useful for studying other aspects of the regulation of dopamine receptor RNA. Experiments are currently in progress to determine whether D₂ transcript levels or isoform type can be varied with cell treatment.

323.7

6-OHDA LESION INCREASES RAT STRIATAL D₂ RECEPTOR mRNA LEVELS WHILE CHRONIC RECEPTOR BLOCKADE DOES NOT. S. Xu and Ian Creese. Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102.

Chronic receptor blockade by antagonists, denervation by 6-hydroxydopamine (6-OHDA) and depletion of dopamine by reserpine have been considered to be functionally equivalent, leading to an increase in striatal D₂ receptor B_{max}, as well as behavioral supersensitivity to dopaminergic agonists. cDNAs encoding two forms of the rat D₂ receptor (D_{2L} & S) derived from alternative splicing have been isolated and allow us to investigate directly the regulation of dopamine receptor gene transcription following chronic treatment with antagonists or denervation. Treatment of rats with haloperidol HCl (0.5 mg/kg/day, s.c., for 2 h, 7, 14, 21 days and 21 days+3 days withdrawal) had no effect on D_{2L} or D_{2total} mRNA levels, in spite of significant increases in striatal receptor density at the later time points. In contrast, 21 days following unilateral nigro-striatal pathway lesion with 6-OHDA HCl (8 µg), striatal D_{2L} and D_{2total} receptor mRNA levels were increased by 54.1 and 52.4%, respectively (p < 0.05, Dunnett t test), along with a significant increase of 38.2% in striatal D₂ receptors. These findings suggest that different molecular mechanisms can be responsible for D₂ receptor up-regulation and that denervation, but not chronic receptor blockade by antagonists, results in an increase in D₂ receptor gene transcription.

AGE-RELATED DECREASES IN DOPAMINE D₂ RECEPTOR mRNA EXPRESSION IN RAT NEOSTRIATUM. D.M. Dorsa, K.M. Merchant, D.J. Dobie and M.W. Hamblin. GRECC, Seattle VA Medical Center; Depts. of Medicine, Pharmacology and Psychiatry, Univ. of Washington, Seattle, WA 98195.

Expression of dopamine D₂ receptor mRNA in young (3 mo), middle aged (12 mo) and old (24 mo) male Fisher 344 rats was examined by *in situ* hybridization histochemistry. A ³⁵S-labeled antisense RNA probe derived from the 3'-untranslated region of the D₂ receptor cDNA was employed to detect the expression of both long and short transcripts of the D₂ gene. Film autoradiograms were generated by apposing the hybridized sections to Hyperfilm Bmax. Densitometric analysis of the four quadrants of the neostriatum of the young and middle aged rats showed that the expression of D₂ receptor transcripts was greater in the lateral quadrants compared to that in the medial regions. In the senescent rat, there was a significant reduction in D₂ receptor mRNA expression. Although the decreases were evident in all four quadrants of the neostriatum, they were maximal in the ventrolateral region thereby greatly attenuating the lateral-medial gradient observed in the young rats. These data are consistent with previously reported age-related decline in D₂ receptor binding. Potential differential decline in the expression D₂-short and D₂-long transcripts during aging is being investigated. (Supported by Washington Institute for Mental Illness; Research Service Department of Veterans Affairs; NS 20311).

323.6

STRIATAL DOPAMINE D₂ RECEPTOR-REGULATED GENE EXPRESSION IN MICE FOLLOWING TREATMENT WITH 6-HYDROXYDOPAMINE AND RELATED NEUROTOXINS. S. HOWARD, J. JOYNER*, D. BLANK*, and C.L. BLANK†. Department of Pharmacology, UCLA, Los Angeles, CA, 90024 and †Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK, USA, 73019.

6-Hydroxydopamine and related species exhibit neurotoxicity towards both noradrenergic and, usually, in higher doses, toward dopaminergic neurons. In the current study, the loss of endogenous dopamine and related metabolite levels in the striatum of the mouse was investigated at various times up to one week following intraventricular treatment with the neurotoxin. These level measurements were then correlated with the specific expression of messenger RNAs encoding the D₂ dopamine receptor. Results were found to be enhanced through the utilization of euthanasia by microwave irradiation, which decreased the post mortem enzymatic activities.

Levels of catecholamines, indoleamines, acetylcholine, and related metabolites were determined using multiple column, multiple detector liquid chromatography with electrochemical detection similar to that described for a single column approach in Lin et al., J. Liq. Chromatogr., 7, 509-538 (1984).

Measurement of the specific expression of messenger RNAs encoding for the D₂ receptor employed a Northern Blot procedure with quantitation by densitometry using random primed, radiolabelled oligonucleotide probes which were complementary to the mRNA similar to that described by Gerfen et al., Science, 250, 1429-1433 (1990). *In situ* hybridization approaches were also attempted to assess localization.

323.8

CHANGES OF THE mRNAs FOR TWO DOPAMINE D₂ RECEPTOR ISOFORMS IN RAT BRAIN BY HALOPERIDOL OR METHAMPHETAMINE TREATMENT. I. Sora, Y. Fujiwara, H. Tomita*, H. Ishizu*, K. Akiyama, S. Otsuki*, H. I. Yamamura. Dept. of Pharmacology, Univ. of Arizona, Tucson, AZ 85724

Dopamine D₂ receptors are the target for drugs used in the treatment of several neurological disorders. The cDNA of a rat D₂ receptor, D₂(415), has been cloned and that was followed by the finding that two D₂ receptor isoforms; D₂(444) and D₂(415). These isoforms are generated by alternative RNA splicing. To investigate changes of the two mRNAs encoding the D₂ receptor isoforms by haloperidol or methamphetamine treatment, we performed *in situ* hybridization histochemistry in the rat brain with the two oligonucleotide probes, an "insert probe" hybridizing to the longer D₂(444) mRNA, and a "spanning probe" hybridizing to the shorter D₂(415) mRNA. Both D₂(415) and D₂(444) mRNAs were found in the striatum, accumbens nucleus and substantia nigra in all rats treated with the drugs and these treatments did not change the distribution of mRNA for two D₂ isoforms. The changes of the two mRNAs were in broad agreement with descriptions of the receptor binding experiments and there were not any evidence that one of two D₂ receptor isoforms alone has relation with effects of these drugs.

323.10

IDENTIFICATION AND REGULATION OF DOPAMINE D₂ RECEPTORS (D₂R), G PROTEINS AND TIS mRNA'S IN MMQ CELLS; A PROLACTIN-SECRETING CELL LINE. H. Zawadzka*, X. He*, L. Li*, D. Tang*, D. Filer*, J.Y. Lew and M. Goldstein. Neurochem. Res. Lab, N.Y. Univ. Med. Ctr., N.Y., N.Y. 10016

To study the effects of DA agonists at the gene level we have characterized the D₂ R protein and examined the gene expression of D₂ R and of genes which might modulate these responses (G proteins and TIS [early response] genes) in MMQ cells. The D₂ R in the MMQ cells was identified by photoaffinity labeling with 125I-N-(p-azido m)[125I]iodophenethylspiperone of membrane preparations. The major labeled D₂ R binding protein has a M.W. of approx. 32-34 kDa. The analysis of D₂ mRNA shows that its size is similar in the MMQ cells as in the 7315a tumor from which these cells were derived, as well as in the striatum. In addition, Gi_{2α} and Gs_α and TIS (c-Fos and TIS1 and TIS8) genes are expressed in the MMQ cells. Exposure of the cells to the D₂ agonist quinpirole (10⁻⁶M) for 24 hrs results in a decreased D₂ R mRNA, suggesting an agonist-induced down-regulation. The effects of quinpirole on G proteins and TIS mRNA's levels are under investigation. Thus, these cells provide a useful model for investigating D₂ R regulation. Supported by NIMH 02727 and NINCDS 06801.

323.11

REGULATION OF D2 RECEPTOR mRNA BY ESTRADIOL IN THE RAT PITUITARY. Y. Shiffman*, M. Jakubowski*, M. Shiffman, J.L. Roberts, S.C. Sealton. Fishberg Research Center for Neurobiology and Dept. of Neurology. Mount Sinai Medical School. New York, NY 10029

17 β -estradiol (E2) increases the number of dopamine receptors (D2R) in the anterior pituitary (AP) of ovariectomized rats (Endo 119, 2484:1986). We investigated whether altered D2R mRNA levels contribute to this increase in receptor number. Two weeks following ovariectomy, rats received either E2 or empty silastic implants for 72 h. Cytoplasmic AP and neurointermediate lobe (NIL) RNAs from each group were assayed using a multiplex nuclease protection assay, enabling simultaneous measurement of D2R, prolactin, POMC and cyclophilin mRNAs. Data were expressed as fg mRNA/ μ g DNA. In the NIL, D2R, POMC and cyclophilin mRNAs increased slightly, but not significantly, with E2. In the AP, however, E2 increased D2R mRNA ~2-fold and prolactin mRNA ~6-fold; cyclophilin and POMC mRNA levels did not change significantly. The E2-induced rise in D2R mRNA levels in the AP suggests that the reported E2-stimulated increase in D2R number is due, at least in part, to increased biosynthesis. Supported by NIH grants K11 DK01854 and MH 45212.

323.13

EPIDERMAL GROWTH FACTOR INDUCES THE EXPRESSION OF D-2 DOPAMINE RECEPTORS IN THE GH-3 CELL LINE. C. Missale, L. Castelletti*, F. Boroni*, S. Sigala*, R. Dal Toso, P.F. Spano. Inst. of Pharmacol. Exp. Ther., Univ. of Brescia and Fidia Res. Lab., Abano Terme, Italy.

GH-3 is a prolactin (PRL) secreting cell clone which lacks receptors for dopamine. Exposure of GH-3 cells to epidermal growth factor (EGF) induced the expression of dopamine (DA) D-2 receptors. The polymerase chain reaction (PCR) was utilized to amplify D-2 related fragments from GH-3 cell cDNA; evaluation of the products suggested that both the D-2(415) and the D-2(444) isoforms were 7-fold increased by EGF. These changes were paralleled by the expression of the receptor protein as shown by the appearance of a saturable, high affinity binding for 3H-spiroperidol ($K_d = 0.8 \pm 0.2$ nM; $B_{max} = 116 \pm 10$ fmoles/ 5×10^5 cells) with a D-2-peculiar pharmacological profile. This receptor was functionally active in controlling PRL secretion; the selective D-2 agonist quinpirole, which was inactive in naive GH-3 cells, recovered indeed the property to inhibit PRL release in the cell cultures exposed to the neurotrophic factor.

323.15

SELECTIVE IMMUNOPRECIPITATION OF THE D-2 DOPAMINE RECEPTOR ISOFORMS: DETECTION OF PHOSPHORYLATED RECEPTOR PROTEIN. P.L. Olinger*, C.L. Chio*, I. Abraham, R.M. Huff*. Cell Biology, The Upjohn Co., Kalamazoo, MI 49001.

The recent cloning of dopamine receptor subtypes has enabled characterization of these proteins in a manner not previously possible. Two molecular forms of the D-2 receptor resulting from differential splicing of a single gene have been identified. These two proteins differ by 29 amino acids present (RD-2A) or absent (RD-2B) in an intracellular loop of the receptor known as IC3. We have developed antibodies that are specific for either D-2A or D-2B receptors. These antibodies have been used to selectively immunoprecipitate either receptor protein from CHO cells transfected with the D-2A or D-2B dopamine receptor cDNA. We have found that both receptor isoforms are phosphorylated following pretreatment of the cells with dopaminergic agonists or by activation of PKC but not by activation of PKA. Activation of the D-2 receptors in these cells does not lead to increased production of inositol phosphates so we do not think stimulation of PKC is part of the dopaminergic signalling pathway. The agonist- and/or the PKC-induced phosphorylation may be related to changes in receptor function such as desensitization.

323.12

SEX DIFFERENCES IN DOPAMINE D₂ RECEPTORS IN THE RAT PREOPTIC AREA. C.E. Roselli, T.A. Fasasi* and A. Janowsky. Dept. Physiol., Ore. Hlth. Sci. U., Portland, OR 97201.

The incertohypothalamic dopamine (DA) system (A13) is involved in the hormone-dependent regulation of both copulatory behavior and gonadotropin secretion. The preoptic area (POA) receives projections from A13 neurons involved in these functions. We used [¹²⁵I] epidepride to characterize DA D₂ receptors in the POA and investigate whether they are influenced by sex or androgen status. Scatchard analyses of epidepride binding to POA membranes derived from gonadally-intact male rats demonstrated a K_d of 70.9 ± 23.2 pM and a B_{max} of 18.5 ± 3.6 fmol/mg protein ($n=6$). Neither binding nor receptor affinity was altered 1 wk after males were gonadectomized (GX) ($B_{max} = 19.2$ fmol/mg protein; $K_d = 109.1 \pm 14.3$ pM; $n=5$). By contrast, D₂ receptor levels ($B_{max} = 45.2$ fmol/mg protein; $K_d = 120 \pm 27.2$ pM; $n=5$) in age-matched GX females were significantly greater than in males ($p < 0.01$). The pharmacological profile of binding in POA was similar to that in striatum (epidepride > spiperone > +butaclamol > sulpiride). Binding in POA was higher than in hypothalamus, amygdala, or frontal cortex. POA was the only area where a sex difference in binding was evident. These sex-related differences in POA D₂ receptor density could lead to the differential modulation of POA activity in males and females. Supported by HD23293.

323.14

CHARACTERIZATION OF THE LONG FORM OF THE DOPAMINE (DA) D₂ (D_{2L}) RECEPTOR IN MOUSE FIBROBLAST LTK⁻ CELLS. J.Y. Lew, G.T. Saez*, D. Filer*, A. Pellicer*, J. Grebb* and M. Goldstein. Departments of Psychiatry and Pathology, N.Y.U. Med. Ctr., N.Y., N.Y. 10016.

The D_{2L} receptor was stably expressed in mouse fibroblast LTK⁻ cells, and subsequently characterized using ¹²⁵I-N-(p-azido-m)[¹²⁵I]iodophenethyl spiperone (¹²⁵I-NAPS) for photoaffinity labeling and antipeptide antibodies for immunoblotting. In the membrane fraction from LTK⁻ cells that were transfected with the D_{2L} receptor, ¹²⁵I-NAPS labelled a single, major protein with an approx. M.W. of 48 KDa. ¹²⁵I-NAPS also labeled several minor, higher M.W. proteins, which may be partially glycosylated forms of the D_{2L} receptor. ¹²⁵I-NAPS did not label any of these proteins in non-transfected LTK⁻ cells. Proteins with the same MWs were detected, however, by immunoblotting of the membrane fraction of transfected LTK⁻ cells using an affinity-purified antibody that had been raised against a peptide containing the 18 amino terminal amino acids of DA D_{2L}.

The specificity of this antibody was also demonstrated by immunoblot analysis of solubilized rat brain membranes. The antibody recognized a protein with an approx. MW of 92-94 KDa in striatal but not cerebellar membranes. Thus, these data show that transfected LTK⁻ cells produce a DA D_{2L} receptor which can be identified by both photoaffinity labeling with ¹²⁵I-NAPS and immunoblotting with an antipeptide antibody. Supported by NIMH 02717 and NIMH 43230.

323.16

CHARACTERIZATION OF [³H]QUINPIROLE BINDING IN RAT STRIATUM. B. Levant, D.E. Grigoriadis, E.B. De Souza. Central Nervous System Diseases Research, The DuPont Merck Pharmaceutical Company, Wilmington, DE 19880-0400.

The putative D₂ dopamine receptor agonist quinpirole (LY 171,555) has been extensively employed in a variety of *in vivo* and *in vitro* studies of D₂ receptor mediated effects. In addition to possessing agonist activity at the D₂ receptor, quinpirole may have even higher affinity for the recently described D₃ dopamine receptor (Sokoloff et al., Nature, 347:146-151). The present study characterizes the *in vitro* binding properties of newly developed [³H]quinpirole in rat striatum. [³H]Quinpirole binding was assessed in homogenized striatal membrane preparations using a filtration assay. Nonspecific binding was defined in the presence of 1 μ M (+)butaclamol. Data were analyzed using Ligand (Munson and Rodbard, 1980). Specific [³H]quinpirole binding was saturable, membrane concentration dependent, temperature dependent, stereoselective ((+)-butaclamol >> (-)-butaclamol and (-)-sulpiride >> (+)-sulpiride), and of high affinity ($K_D=2-10$ nM). The affinity was confirmed by association-dissociation kinetics. The pharmacological profile of [³H]quinpirole binding in striatum was: (-)NPA \geq 6,7-ADTN \geq quinpirole > bromocriptine > dopamine > SKF 38393 >> 5-HT for agonists; spiperone > (+)butaclamol > (-)sulpiride > clozapine \geq SCH 23390 > cinanserin for antagonists. These data demonstrate that [³H]quinpirole exhibits dopaminergic pharmacology. Further investigation is required to determine the specific characteristics of the receptor binding site for [³H]quinpirole.

323.17

DIHYDREXIDINE, A SELECTIVE DOPAMINE RECEPTOR AGONIST THAT MAY DISCRIMINATE POSTSYNAPTIC D₂ RECEPTORS. D.M. Mottola¹, L.L. Cook¹, S.R. Jones¹, R.G. Booth¹, D.E. Nichols² and R.B. Mailman¹. ¹University of North Carolina¹, Chapel Hill, N.C. 27599. ²Purdue University², West Lafayette, IN. 47907

Dihyrexidine (DHX) is a member of a novel structural class of dopamine receptor ligands (trans-hexahydrobenzo[a]phenanthridines). As we previously reported (J. Med. Chem. 33:1756, 1990), DHX is a high potency (IC₅₀ = 10 nM), full efficacy D₁ receptor agonist with moderate potency (IC₅₀ = 120 nM) for D₂ receptors. The present study was designed to address: i) the overall selectivity of DHX for dopamine receptors and ii) the functional activity of DHX at D₂ receptors.

DHX was tested in 31 different radioreceptor binding assays, as well as eight other binding assays related to loci associated with cell signaling. This series of tests indicated that DHX, while active at dopamine receptors, was essentially inactive (IC₅₀ ≥ 10 μM) at all other tested binding sites, with the sole exception of the α₂ adrenergic receptor (IC₅₀ ≈ 1 μM). These data demonstrate that DHX possesses a high degree of selectivity for dopamine receptors. We also sought to resolve whether DHX was acting as an agonist or antagonist at D₂ receptors. Data from radioligand (³H-spiroperone) competition analysis resulted in a Hill coefficient (n_H) < 1, consistent with the behavior of other D₂ agonists in this preparation. In addition, *in vivo* behavioral testing of DHX (Darney et al. Neuropsychopharmacology 1991, in press) found that this agent, like the D₂ agonist quinpirole, induced locomotion; this effect was blocked by the D₂ antagonist remoxipride. This effect of DHX apparently is not due to its action as an indirect agonist since it is a weak competitor for the dopamine uptake site (IC₅₀ ≈ 50 μM). Furthermore, in preliminary experiments DHX did not alter dopamine release in striatal slices. In tyrosine hydroxylase (TH) assays, DHX inhibited TH, but these effects were not blocked by D₂ antagonists. These inhibitory effects of DHX on TH are probably due to direct actions on the enzyme, rather than being mediated via autoreceptors. Together, these data suggest that DHX does not act on D₂ autoreceptors which regulate release or synthesis but does affect postsynaptic receptors having D₂ pharmacological characteristics. Coupled with its potent D₁ activity, DHX should be an important tool to define the activity of dopamine receptors.

323.19

STIMULATION OF MITOGENESIS IN TRANSFECTED CHO CELLS BY ACTIVATION OF THE D₂ RECEPTOR. M.E. Lajiness¹, C.L. Chio¹, D.K. Hyslop², and R.M. Huff¹. ¹Cell Biology and ²CNS Research, The Upjohn Co., Kalamazoo, MI 49001.

The dopamine D₂ receptor is a member of the G protein coupled receptor family. Other receptors in this family have been shown to mediate growth by agonist activation of the receptor/G protein complex. We used CHO cells which express rat D₂ receptors to assess growth stimulation by activation of D₂ receptors. Treatment of these cells with D₂ agonists causes an increase in mitogenesis as measured by ³H-thymidine incorporation during a two hour labeling period. EC₅₀ values for D₂ selective agonists correlate with K_d values determined by binding analysis. The EC₅₀ values also correlate with the IC₅₀ values for inhibition of forskolin-stimulated cAMP accumulation. Agonist induced mitogenesis and inhibition of cAMP accumulation are both sensitive to pertussis toxin. Treatment of the cells with 8-(4-Chlorophenylthio) cAMP inhibits growth and prevents mitogenic effects of dopaminergic agonists. Similar dose response curves and pertussis toxin sensitivity indicate that the mitogenic response could be related to cAMP levels.

COMBINED EFFECTS OF CONTINUAL D₂ AGONISM AND PULSATILE D₁ ANTAGONISM IN A PARKINSONIAN ANIMAL MODEL. J. Hubble, T. Basham, A.R. Dick, and W. Koller. University of Kansas Medical Center, Kansas City, KS 66103.

The antiparkinson effect of dopamine agonists appears chiefly dependent on D₂ receptor activation with D₁ stimulation playing a lesser role. The precise means by which "ideal" receptor co-activation can be achieved in parkinsonism remains undetermined. In the 6-hydroxydopamine lesioned animal model, we have previously shown that continuous s.c. D₂ agonist therapy [(+)-4-propyl-9-hydroxynaphoxazine (PHNO)] produces antiparkinson effects (contralateral turning) in rats throughout a 7-day pump period; turning is maximal by day 3, then plateaus or decreases coincidental with the appearance of stereotypic behaviors. To clarify the role of D₁ receptor activity in this behavioral paradigm, we administered pulsatile D₁ antagonist (SCH 23390) therapy in rats receiving continual s.c. PHNO for 14 days. Initially (days 2,6) no difference was observed, by days 10 & 13 SCH 23390 (10 ug/kg i.p.) produced significantly greater turns in the 72-min time interval following injection compared to PHNO-only controls (12.3±2.2 vs 5.9±2.0 turns/min, p<.01 ANOVA/Newman-Keuls posthoc test). Smaller SCH 23390 doses (0.03,0.3,3.0 ug/kg i.p.) did not enhance turning; rather, 0.3 ug/kg appeared to suppress turning but did not reach statistical significance. In conclusion, our results suggest that D₁ antagonists could potentially serve an adjunctive role in the pharmacological management of parkinsonism.

EFFECTS OF DOPAMINE D₂ RECEPTOR ACTIVATION MEASURED BY A NOVEL TECHNIQUE: MICROPHYSIOMETRY. M.P. Rosser, M.R. Kozlowski, and K.A. Neve. Dept. of Screening and Biochemical Research, Bristol-Myers Squibb, Wallingford, CT 06492 and Research Service, VA Medical Center, Portland, OR 97207.

The dopamine (DA) D₂ receptor is involved in the pathology of a number of neurological and psychiatric disorders including Parkinsonism, schizophrenia and drug addiction. The effects of D₂ receptor stimulation may be mediated at least in part by a Na⁺/H⁺ exchanger. This possibility was examined by monitoring an indicant of proton export, the rate of acidification of the medium, in response to cellular D₂ receptor stimulation. These measurements were made with the aid of a device called a microphysiometer (Molecular Devices Corp., Menlo Park, CA). This device employs a light addressable potentiometric sensor (LAPS) to measure the acidity of the medium bathing the cells.

A glioma cell line (C6) transfected with the D₂ receptor (D2-415) was cultured in a flow chamber in contact with the LAPS. Drugs were introduced into the medium perfusing the chamber and the response was measured. Introduction of the D₂-selective agonist quinpirole resulted in a dose-dependent increase in the rate of acidification relative to non-drug-treated controls. The maximum effect was obtained with 100nM quinpirole. This effect was blocked by the dopamine antagonist spiperone (10μM). No effect of quinpirole was seen on the non-transfected parent cell line.

323.20

COMPARISON OF THE EFFECTS OF REMOXIPRIDE, RACLOPRIDE AND HALOPERIDOL ON THE ACTIVITY OF CENTRAL DOPAMINERGIC NEURONS AND HORMONESECRETION FROM THE PITUITARY. M.J. Eaton, Y. Tian, K.J. Lookingland and K.E. Moore. Dept. of Pharmacol. and Toxicol. Michigan State University East Lansing, MI 48824

Remoxipride (REM) and raclopride (RAC) are selective D₂ dopamine (DA) receptor antagonists currently being investigated for clinical use as antipsychotic drugs. The present study was designed to compare the time course and dose response of REM, RAC and haloperidol (HAL) on central DA neuronal activity, as well as their ability to alter plasma levels of prolactin (PRL) and α-melanocyte stimulating hormone (α-MSH) in male rats. DA neuronal activity was estimated by measuring the DOPAC/DA ratio in brain regions containing terminals of different DA neurons. RAC (1.0 mg/kg) and HAL (0.1 mg/kg) increased PRL, α-MSH and the activity of mesolimbic, nigrostriatal and incertohypothalamic DA neurons in a comparable manner. In contrast, REM (3.0 mg/kg) increased PRL and the activity of mesolimbic and nigrostriatal DA neurons, but did not alter α-MSH or the activity of incertohypothalamic DA neurons. These data suggest that there may be more than one D₂ receptor subtype functioning in the rat with REM selectively antagonizing the receptor type found on lactotrophs and mesotelencephalic DA neurons, but not those on melanotrophs and some hypothalamic DA neurons. RAC and HAL recognize D₂ receptors on all of these cell types. (Supported by NIH grants NS 15911 and NS 07279)

323.22

DIFFERENTIAL EFFECTS OF NEUROLEPTICS ON SLEEP-WAKING STATES IN THE RAT. M. Trampus, N. Ferri* and E. Ongini. Research Laboratories, Schering-Plough S.p.A., I-20060 Comazzo (Milan), Italy.

Sedation is a common side effect encountered during therapy with classic neuroleptic agents. We studied a series of neuroleptics, having different selectivity for dopamine D₁ and D₂ receptors, on the sleep-waking patterns in the rat. Haloperidol, a D₂ antagonist which also interacts with other receptors, markedly increased the time spent in non-rapid eye movement (non-REM) sleep (mean effect = +81% of control). Chlorpromazine, a mixed D₁/D₂ antagonist, and the atypical neuroleptic clozapine, tended to increase non-REM slightly. The selective D₂ blockers, raclopride and remoxipride, did not modify the duration of non-REM sleep. Regarding D₁ antagonists, SCH 23390 enhanced non-REM markedly (+81%), whereas SCH 39166 had no effect on this stage. Neuroleptics are reported either to not affect or reduce duration of REM. Accordingly, in our studies, haloperidol and raclopride did not modify this stage, whereas clozapine, remoxipride and chlorpromazine tended to reduce it. Conversely, both SCH 23390 and SCH 39166 enhanced REM (+123 and +58%, respectively).

From the data, D₂ selective neuroleptics appear to have little sedative potential, whereas D₁ selectivity seems to play a role in the regulation of important sleep stages, such as REM and non-REM.

323.23

CHRONIC HALOPERIDOL TREATMENT CAUSES CHANGES IN CHOLECYSTOKININ AND TYROSINE HYDROXYLASE mRNA LEVELS IN RAT BRAIN. V. McKibbin*, D.J.S. Sirinathsinghi and J. Hughes. Parke Davis Research Unit, Cambridge, England. CB2 2QB.

There is substantial evidence for the co-localization of cholecystokinin (CCK) within dopamine (DA) neurons in the ventral midbrain, suggesting a role for CCK in the modulation of forebrain (mesencephalic) DA neurotransmission. This report further investigates this interaction at the molecular level through the study of gene expression. Chronic neuroleptic treatment has been shown to alter the levels of both synthetic enzymes such as tyrosine hydroxylase (TH), and the DA D2 receptor complex. Here, the effects of haloperidol (administered via osmotic minipumps at 2.4 mg/Kg for 3 and 7 days) on mRNA levels for TH, DA D2 isoforms and DA D1 receptors and CCK was examined by *in situ* hybridization using oligonucleotide probes. Areas of the CNS containing mRNA were visualised by autoradiography and measured using a Quantimet densitometer. The experiments showed increases in mRNA for TH (70% $p < 0.05$), at the level of the substantia nigra and increases in mRNA for the DA D2 receptor isoforms. In addition to these expected changes in the DA system, there was a significant decrease in CCK mRNA in the prefrontal cortex (30% $p < 0.05$). Although difficult to interpret, these changes indicate a potential interaction between components of the DA system and CCK at the level of mRNA.

CATECHOLAMINE RECEPTORS: DOPAMINE IV

324.1

QUANTITATIVE AUTORADIOGRAPHY OF IODINATED DOPAMINE LIGANDS: POTENTIAL PITFALLS IN THE USE OF IODINATED BENZAMIDES. I.A. Wortman*, D.C. Rice*, R.D. Burwell, C.P. Lawler, V.J. Watts*, C.A. Mathis*, P. Morell, M.H. Lewis, R.B. Mailman. University of North Carolina, Chapel Hill, NC 27599; Health and Welfare Canada, Ottawa K1A 0L2; and Lawrence Berkeley Laboratory, University of California, Berkeley CA 94720.

[¹²⁵I]epidepride (EPI), a benzamide with high affinity and selectivity for the D₂-type of dopamine receptor, has been suggested as being especially suited for quantitative autoradiography. Consistent with recent reports, saturation analysis of [¹²⁵I]EPI indicated that 50 mM NaCl decreased the K_D (to 38 pM), and increased the B_{max} (to 220 fmol/mg protein). This large effect of sodium, coupled with some difference between the K_D of [¹²⁵I]EPI vs. the K_i of unlabeled epidepride in competing for [³H]spiperone binding sites, suggested the need to characterize carefully the binding of [¹²⁵I]EPI in quantitative autoradiographic assays. Thus, the association of three [¹²⁵I] labelled dopaminergic ligands was compared as a function of time and temperature in 15 μm sections of rat striatal tissue using three radioligands: the D₂ ligands [¹²⁵I]EPI and [¹²⁵I]iodosulpiride (IS); and the D₁ ligand [¹²⁵I]SCH23982 (SCH). Autoradiographic studies were done at 4°, 25°, and 37°C, and time-sampled at 0.25, 0.5, 1, 2, 9, and 18 h. At 22°, the binding of [¹²⁵I]SCH reached equilibrium at 2 h, remained stable until 9 h, and then rapidly declined by 18 h. At 4°, the binding of SCH did not reach equilibrium until 18 h. At 37°, SCH binding was maximal at 0.5 h, but reached a level only ca. 50% of that measured at the lower temperatures; binding then declined slowly through 18 h. The behavior of the D₂ ligands was particularly interesting. At 4° or 22°, the binding of [¹²⁵I]EPI increased throughout the time course of this experiment (18 h). There was a 35% increase between 9 and 18 h. At 37°, binding was maximal at 2 h (but lower than at 4° or 22°), and decreased significantly with time. A similar pattern was seen with [¹²⁵I]IS, although maximum binding at 22° was ca. 50% on the 4° maximum. These data indicate that the incubation times commonly used with these ligands may not reflect equilibrium, and that time-temperature conditions may differ markedly from other radioligands. Thus, while [¹²⁵I]EPI may be a radioligand of potential utility, its binding must be carefully characterized prior to use in quantitative autoradiography.

NOVEL F-18 LABELED ANALOGUES OF BENPERIDOL FOR PET STUDY OF DOPAMINERGIC D-2 RECEPTOR BINDING IN VIVO. S.M. Moerlein, J.S. Perlmutter and D. Parkinson. Mallinckrodt Institute of Radiology, Department of Neurology and Neurological Surgery, and Department of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO 63110

Benperidol is a butyrophenone ligand that binds to dopaminergic D-2 receptors with high affinity and high selectivity. With the goal of developing an F-18 (t_{1/2} = 110 min) labeled tracer with improved selectivity for binding to D-2 receptors *in vivo*, we have synthesized novel radiofluorinated analogues of benperidol for evaluation as PET tracers. In particular, synthetic pathways to F-18 labeled benperidol ([F-18]B), N-methyl benperidol ([F-18]MB), N-fluoroethyl benperidol ([F-18]FEB) were developed. [F-18]B and [F-18]MB have the radiolabel attached to an aromatic site, whereas [F-18]FEB has the radiolabel attached to an alkyl location. Differences in the metabolic behavior of these tracers is thus anticipated. *In vitro* binding assays using primate cerebral tissues indicate that these ligands have high affinity for binding to D-2 receptors (K_i = 0.3, 3.6, and 5.2 nM for B, MB, and FEB, respectively) and relatively poor affinity for S-2 receptors (K_i = 33, 89, and 31 nM for B, MB and FEB, respectively). No-carrier-added [F-18]B and [F-18]MB were prepared using a three-step procedure in 5-7% radiochemical yield and specific activity >1000 Ci/mmol within an overall preparation time (including HPLC purification) of 100 min. [F-18]FEB was produced at the no-carrier-added level via a two-step, one-pot synthetic sequence. Radiochemical yields of 25-30% and specific activities >1000 Ci/mmol were accomplished within an overall preparation time of 110 min. The results of *in vivo* experiments with these promising D-2 receptor binding PET tracers will be presented.

324.2

REGIONAL LIGHT AND ELECTRON MICROSCOPIC LOCALIZATION OF IMMUNOREACTIVITY FOR DOPAMINE D2 RECEPTOR PEPTIDE IN THE RAT BRAIN. S.R. Sesack, C.J. Aoki, and V.M. Pickel. Dept. Neurology & Neuroscience, Cornell Univ. Med. Coll. New York, NY 10021.

We examined the light (LM) and electron microscopic (EM) localization of immunoreactivity for a rat polyclonal antiserum raised against amino acids 273-287 of the dopamine D2 receptor protein. By immunoblot analysis, this antiserum was specific for the parent peptide and did not recognize fragments from adjacent positions on the D2 or β-adrenergic receptors. In acrolein fixed rat brain sections, specific peroxidase labeling for D2 peptide-like immunoreactivity (D2-LI) was detected upon incubation with immune serum, but not with preimmune serum or with immune serum preadsorbed with 100 μg/mL of D2 peptide. By LM, D2-LI was localized (1) to cell bodies and thick processes in regions of dopaminergic perikarya (the substantia nigra and ventral tegmental area), and (2) to diffuse punctate processes in dopaminergic target regions (the striatum and prefrontal cortex). These immunoreactive elements were identified by EM as, respectively (1) perikarya and dendrites, and (2) spines, dendrites and terminals. Within dendrites, D2-LI was most densely associated with the smooth endoplasmic reticulum, mitochondrial and plasma membranes and postsynaptic densities. Within terminals, labeling was additionally associated with some, but not all vesicles. Terminals containing D2-LI formed primarily symmetric junctions or failed to exhibit synapses in single sections. The distribution of D2-LI by LM and EM (1) suggests that the peptide antiserum is specific for dopamine D2 receptors and (2) indicates a number of cellular sites for dopamine action within midbrain and forebrain circuitry. (Support: NS08193, EY08055, MH40342 and NARSAD).

F-18 LABELED BENZAMIDE ANALOGS AS POTENTIAL LIGANDS FOR STUDYING THE DOPAMINE D2 RECEPTOR *IN VIVO* WITH POSITRON EMISSION TOMOGRAPHY (PET). RH Mach, *JG Scripko, *RL Ehrenkauser, *PA Nowak, *RR Luedtke, PB Molinoff, and M Reivich. Univ. of Pennsylvania, Philadelphia, PA.

Two fluorine-containing benzamide analogs were prepared as potential candidates for studying dopamine D2 receptors *in vivo* with PET. *In vitro* binding experiments indicate that both compounds, 2,3-dimethoxy-N-(p-fluorobenzyl)piperidin-4-yl benzamide (MBP) and 2,3-dimethoxy-N-(9-(p-fluorobenzyl)-9-azabicyclo[3.3.1]nonan-3β-yl benzamide (MABN), possess a sub-nanomolar affinity for D2 receptors (K_i for inhibition of [¹²⁵I]NCG 298 binding to rat striatal tissue = 0.4 nM for MBP and 0.03 nM for MABN). *In vivo* studies in rats indicate that both [F-18]MBP and [F-18]MABN have a high brain uptake and a regional distribution consistent with that of D2 receptors. The striatum:cerebellum ratio for [F-18]MBP and [F-18]MABN, 180 min post-*in vivo* injection, was 20 and 45, respectively. The striatal uptake of both analogs was blocked by co-injection of spiperone, a potent D2 antagonist. These data indicate that [F-18]MBP and [F-18]MABN are potential candidates for studies of dopamine D2 receptors *in vivo* with PET.

D₃ DOPAMINE RECEPTOR LOCALIZATION USING ANTI-PEPTIDE ANTISERA: COMPARISON TO OTHER CNS DOPAMINE RECEPTORS. M.A. Ariano, E.M. Smyk-Bandall¹, and D.R. Sibley¹. Anatomy and Neurobiology, UVM College of Medicine, Burlington, VT 05405; and ¹ Molecular Pharmacology Unit, ETB, NINDS, Bethesda, MD 20892.

We have developed antisera against synthetic peptides corresponding to sequences for the rat D₁, D₂, and D₃ dopamine receptor subtypes. These antisera are directed against both extracellular and intracellular portions of the receptor proteins, and were conjugated to thyroglobulin prior to immunization in rabbits. Their titers and specificities were determined by ELISA analysis of the sera and immunofluorescent detection of the recombinant receptor proteins expressed in stably transfected Chinese Hamster Ovary (CHO) cells.

Medium sized striatal cells were immunofluorescent for all three receptor subtypes, with D₁ > D₂ > D₃ staining. D₁ receptor subtype expression was also robust within the neuropil. Staining in the olfactory tubercle was most obvious for the D₃ receptor antisera, and showed an intense reaction at the cell membrane and initial processes in these neurons. The hippocampus exhibited D₃ and D₂ membrane staining in pyramidal neurons, while D₁ expression was less abundant. The substantia nigra stained for all three receptor proteins; D₃ and D₂ were especially robust in compacta neurons. The regional distribution of the receptor subtypes using these antibody reagents suggests that overlap of the different dopamine receptor subtypes occurs in the CNS areas examined. Further analyses will determine the potential cellular coincidence of the receptor subtypes.

This work was supported in part by USPHS NS 23079 to MAA.

324.7

LOCALIZATION OF ³H-QUINPIROLE BINDING TO D-2 AND D-3 RECEPTORS IN RAT BRAIN. D.R. Gehlert, S.L. Gackenheim, P. Seeman and J.M. Schaus. CNS Pharmacology, Lilly Research Laboratories, Indianapolis, IN 46285 and Departments of Pharmacology and Psychiatry, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

Until recently, receptors for dopamine were divided into biochemical subtypes based on their ability to modulate the activity of adenylate cyclase. Using molecular biological techniques, Sokoloff and coworkers (Nature 347: 146, 1990) have reported that a third, genetically distinct subtype of dopamine receptor gene exists with a unique distribution of mRNA in the brain. While mRNA encoding for D-1 and D-2 can be found in high density in the basal ganglia, D-3 mRNA was found principally in the islets of Calleja, nucleus accumbens and olfactory tubercle. When the gene was expressed in COS cells, the dopaminergic agonist, quinpirole, was found to be highly selective for D-3. In order to detect the D-3 receptor in the brain, we have synthesized a radiolabeled form of quinpirole for use in autoradiographic studies.

³H-quinpirole was synthesized by tritium gas hydrogenation of trans-(-)-4aR, 8aR)-4, 4a, 5, 6, 7, 8, 8a, 9-octahydro-5-allyl-1H-pyrazolo[3,4-g]quinoline hydrochloride [LY 275947] (Amersham and DuPont-NEN). Sections of rat forebrain were labeled with ³H-quinpirole using standard techniques. After a 60 day exposure to tritium sensitive film, the binding to sections was evaluated using quantitative image analysis. The binding of ³H-quinpirole to sections of rat forebrain had a K_d of 9.5 nM and a B_{max} of 230 fmoles/mg tissue dry weight. At a concentration of 10 nM, the autoradiographic distribution of ³H-quinpirole binding sites was similar to that reported for other D-2 selective ligands being highly localized to the caudate-putamen, nucleus accumbens and olfactory tubercle. The inclusion of 10 μM Gpp(NH)p in the incubation media markedly reduced binding to most regions of the brain; however, binding could be detected in the islets of Calleja and, to a much lesser extent, the nucleus accumbens.

These data indicate that ³H-quinpirole binds to the high affinity agonist conformation of the D-2 receptor as well as the D-3 receptor in rat brain.

324.9

PRODUCTION OF D2 RECEPTOR-UBIQUITIN FUSION PROTEINS FOR THE DEVELOPMENT OF POLYCLONAL ANTI-RECEPTOR ANTIBODIES. R.R. Luedtke, V.A. Boundy and P.B. Molinoff. Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

The sequence encoding the third intracellular loop (i3) of each of the isoforms of the D2 dopamine receptor (D2_L and D2_S) was subcloned into the Eco RI site of the pNMHUBpoly (pNM) vector. The plasmid pNM is an expression vector containing the heat-inducible λP_L promoter and the ubiquitin gene. Following induction, this vector will overexpress fusion proteins consisting of ubiquitin and the peptide corresponding to the introduced cDNA. The pNM-i3_L and pNM-i3_S ligation products were used to transform C1+ *E. coli*, and colonies with DNA inserts in the appropriate orientation were identified by restriction mapping. AR58 *E. coli* were transformed with the pNM-i3 clones. In AR58 *E. coli* transformed with the nonrecombinant plasmid, a 31.5 kDa protein was expressed. Proteins with molecular weights of 25.6 kDa and 22.3 kDa were expressed after transformation with pNM-i3_L and pNM-i3_S, respectively. Cell lysates were electrophoresed on preparative SDS-PAGE, and proteins were visualized with CuCl₂. Bands were excised and used for the monthly immunization of rabbits. A solid phase RIA using synthetic peptides corresponding to portions of the i3 loop was used to monitor the production of antibodies. Both fusion protein immunogens produced antisera which were reactive in the solid phase RIA at a dilution of 1:10⁴. An immunoprecipitation assay was used to determine if the antisera could recognize solubilized D2 receptors. Digitonin-solubilized extracts of rat caudate were incubated with anti-ubiquitin-i3 antisera and [¹²⁵I]-NCQ298, a high-affinity antagonist selective for D2 receptors. The antibody/receptor/¹²⁵I-NCQ298 complex was precipitated with Pansorbin. Both anti-ubiquitin-i3 antisera were shown to precipitate [¹²⁵I]-NCQ298 binding sites from preparations of receptor solubilized from rat caudate. (USPHS GM 34781 and NS 18591)

324.6

D2 DOPAMINE RECEPTOR LOCALIZATION USING ANTIPEPTIDE ANTISERUM: MORPHOLOGICAL DIVERSITY OF RECEPTOR-BEARING NEURONS IN RODENT NEOSTRIATUM DEMONSTRATED BY COMBINED IMMUNOHISTOCHEMISTRY/GOLGI-GOLD TONING. R.S. Fisher, D. Birt, M.A. Ariano, D.R. Sibley and M.S. Levine. MRRC & Brain Res. Inst., UCLA, Los Angeles, CA 90024, Dept. Anat. & Neurobiol., UVM Coll. Med., Burlington, VT 05405, Mol. Pharmacol. Unit, ETB, NINDS, Bethesda, MD 20892.

Receptor-binding and immunohistochemical studies suggest that the D2 dopamine receptor is located in the targets of dopamine innervation including medium and large neurons in rodent neostriatum as well as the dopamine neurons of the substantia nigra-compacta zone ("autoreceptors"). Others have implied that medium spiny neurons are the principal targets of dopamine inputs to neostriatum. We tested the hypothesis of preferential dopamine receptor localization in the medium spiny neostriatal targets of nigrostriatal dopamine inputs. Morphological methods were combined to label D2 dopamine receptor in the perikaryal cytoplasm of neurons (polyclonal antiserum directed against a 54-peptide sequence of D2 receptor, ABC immunohistochemistry) and somatodendritic parts of neurons (single-slice Golgi impregnation/gold-toning for transverse labeling) in the same aldehyde-fixed Vibratome sections of rodent neostriatum.

We observed specific and consistent double-labeling of three types of D2 receptor-bearing neurons distributed throughout the neostriatum. 1) Medium spiny neurons were frequent (>95% of doubly labeled cells, somatic diameters = 12-25 μm). Some of these cells also had somatic and proximal dendrite spines. 2) Medium sparsely spiny neurons were infrequent (2-3% of doubly labeled cells, somatic diameters = 12-22 μm). 3) Large sparsely spiny or aspiny neurons were infrequent (1-3% of doubly labeled cells, somatic diameters = 30-50 μm). We conclude that diverse morphological types of neostriatal neurons contain the D2 dopamine receptor. Thus, all major types of neostriatal neurons have the potential to be modulated via the D2 dopamine receptor. Supported by USPHS HD05958.

DEVELOPMENT OF ANTI-RAT D2 DOPAMINE RECEPTOR ANTIBODIES USING SEQUENCE-SPECIFIC PEPTIDES. V.A. Boundy, R.R. Luedtke and P.B. Molinoff. Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Peptides corresponding to portions of the third intracellular loop of the rat D2 dopamine receptor were synthesized and used to produce polyclonal anti-peptide antisera able to recognize the two D2 receptor isoforms. Peptides D2-244 (aa 244-270, unique to the D2_L isoform) and D2-284 (aa 284-311, common to both the D2_L and D2_S isoforms) were covalently coupled to keyhole limpet hemocyanin (KLH). Rabbits were immunized monthly with peptide-KLH conjugates. A solid phase RIA was used to verify the immunogenicity of the peptides. Both immunogens produced antisera that were effective at dilutions ranging from 1:10⁴ to 1:10⁵ in a solid phase RIA within 10 weeks of the initial immunization. Specificity of the antisera was demonstrated by lack of reactivity of preimmune antisera and by the absence of cross-reactivity to the other (non-immunization) peptide. An immunoprecipitation assay was used to determine if the anti-peptide antisera could recognize solubilized D2 receptors. Rat and canine caudate tissue was solubilized using 1% digitonin, and solubilized preparations were enriched chromatographically using a heparin-agarose column. Solubilized receptors were incubated with anti-peptide antisera and [¹²⁵I]-NCQ298, a high-affinity antagonist selective for D2 receptors. The antibody/receptor/¹²⁵I-NCQ298 complex was precipitated with Pansorbin. The anti-(D2-284) antisera were found to quantitatively precipitate [¹²⁵I]-NCQ298 binding sites from both rat and canine solubilized receptor preparations while the antisera against peptide D2-244 were found to immunoprecipitate the D2 receptor solubilized from rat but not from canine caudate. (USPHS GM 34781 and NS 18591)

324.10

PHARMACOLOGICAL CHARACTERIZATION OF "D₃" DOPAMINE RECEPTORS IN LIMBIC AND NON-LIMBIC AREAS OF THE RAT BRAIN BY QUANTITATIVE AUTORADIOGRAPHY. M.L. Coco and C.D. Kilts. Depts. of Psychiatry and Pharmacology, Duke Univ. Med. Ctr. Durham, NC 27710.

The recently cloned D₃ receptor has been shown to bind D₂ receptor ligands when expressed in CHO or COS-7 cells (Sokoloff et al., 1990), with particular compounds demonstrating preferential affinity for either the D₃ or D₂ site. In situ hybridization of D₃ receptor mRNA suggests a primarily limbic system localization in the rat, whereas D₁ and D₂ receptors are more widely expressed. We sought to examine the D₃-like properties of receptors located in limbic and non-limbic areas of the rat brain by using quinpirole (a D₂ agonist with a reported 113-fold greater affinity for D₃) and domperidone (a D₂ antagonist with a reported 32-fold greater affinity for D₂) to displace [¹²⁵I]iodosulpiride binding in 10 μm thick coronal brain sections. Initial results fail to demonstrate D₃-like properties of limbic-localized receptors compared to non-limbic [¹²⁵I]iodosulpiride-binding receptors when characterized by these pharmacological means. The K_i's obtained from autoradiographs of either quinpirole- or domperidone-generated competition curves did not significantly differ between various divisions of the caudate-putamen, nucleus accumbens, olfactory tubercle or central or intercalated nuclei of the amygdala. Quinpirole showed an approximate 7-fold greater affinity for [¹²⁵I]iodosulpiride binding sites in the lateral septal nucleus or bed nucleus of the stria terminalis compared to dorsal caudate.

324.11

DOPAMINE RE-UP TAKE SITES IN HUMAN BRAIN: AUTORADIOGRAPHY WITH ^3H -CFT. M.B. Knable, M.F. Casanova, J.E. Kleinman, and D.R. Weinberger. Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032.

The distribution of dopamine re-uptake sites in the human brain was examined using full hemisphere autoradiography with the ^3H -CFT ligand. Brains from four patients without brain pathology or neuropsychiatric history were studied. Tissue sections were incubated with $3\mu\text{M}$ ^3H -CFT. Nonspecific binding was determined using $30\mu\text{M}$ cocaine as a blocker. Computerized image densitometry was used to measure ^3H -CFT binding sites. Specific binding was observed in the caudate, putamen, anterior cingulate gyrus and entorhinal cortex. A regional gradient of dopamine re-uptake sites was found in the putamen with the highest concentration in its ventral portion. Detectable, but lower levels of binding were observed in the amygdala and dorsomedial thalamus. Binding was specific since it exhibited saturability or a cortical laminar preference. The mapping of ^3H -CFT sites in limbic areas provides a basis for the study of illnesses with postulated abnormalities of dopamine re-uptake.

324.12

Regulation of Binding to the Dopamine Uptake Complex by Metal Cations. E.K. Richfield. Departments of Neurology and Pharmacology, University of Rochester, Rochester, NY 14620

The dopamine uptake complex (DAUC) is responsible for the reuptake of dopamine (DA) after release by DAergic terminals. Cocaine binding to the DAUC is responsible for many behavioral effects of this drug. A quantitative autoradiographic assay using [^3H]GBR 12935 was used to study the effects of metal cations on the DAUC in rat and human brain.

Metal cations were found to have variable effects on binding to the DAUC. Cations known to be highly reactive to sulfhydryl groups (Hg^{2+} , Cu^{2+} , and Cd^{2+}) resulted in dramatic loss of binding of [^3H]GBR 12935 to the DAUC. These effects could be partially reversed by the use of the reducing agent dithiothreitol. Three metal cations (Mn^{2+} , Mg^{2+} , and Ca^{2+}) had no effect on the binding of [^3H]GBR 12935. Three transitional metal cations (Ni^{2+} , Zn^{2+} , and Co^{2+}) resulted in marked increases in binding to the DAUC. Of these 3 ions, zinc had the highest affinity for the DAUC and produced the greatest increase in binding.

The increased binding of [^3H]GBR 12935 to the DAUC was due to an increase in the affinity of the compound (K_d) and not to an increase in the density (B_{max}). Cocaine and WIN 35,428 both compete for binding at the DAUC with two affinities. Zinc increased the high affinity (K_H) for both compounds and increased the proportion of sites present in the high affinity state (R_H).

These findings suggest a sulfhydryl group may be important for binding of certain drugs at the DAUC. Zinc plays an important role in regulating binding to the DAUC. These findings will be important in designing drugs active at the DAUC.

CATECHOLAMINES: DOPAMINE I

325.1

EFFECTS OF APOMORPHINE ON REGIONAL GLUCOSE METABOLISM IN NORMAL AND 6-OH DOPAMINE LESIONED ANIMALS. C.A. Ray, S. Koch, N.F. Nichols, and M.F. Piercey, The Upjohn Co., Kalamazoo, MI 49001.

Dopaminergic (DA) neurons in the Substantia Nigra Pars Compacta (SNPC) and adjacent lateral Ventral Tegmental Area (VTA) were lesioned unilaterally with 6-OH DA injections. Animals which turned following 1 mg/kg apomorphine (APO) 1 wk after 6-OHDA injections were considered successfully lesioned. Lesioned animals had reduced glucose metabolism in the anterior caudate (Cd) and several regions of the anterior cerebral cortex. With the exception of some cortical regions, ipsilateral and contralateral sides of lesioned animals were not significantly different, indicating predominantly bilateral effects. In unlesioned animals, APO (1 mg/kg i.v.) stimulated metabolism most significantly in the anterior VTA and Substantia Nigra Pars Reticulata (SNPR) but also stimulated the Globus Pallidus (GP) Tuberculum Olfactorium (Tub Olf), and the lateral Cd. In lesioned animals, APO reversed most lesion effects and stimulated lateral Cd as well as both posterior and anterior VTA and SNPR, with the ipsilateral posterior SNPR being significantly more stimulated than observed either on the contralateral side or in control animals. It is concluded that unilateral DA lesions have bilateral effects and that turning may be due to supersensitive DA receptors in striatonigral pathways.

325.3

COMPARISON OF DOPAMINE RECEPTOR LIGAND BINDING AND mRNA EXPRESSION IN TWO DISTINCT MODELS OF 6-OHDA-INDUCED CENTRAL DENERVATION. C.P. Lawler, J. H. Gilmore, A.M. Eaton, S.B. Southerland, M.H. Lewis and R.B. Mailman. University of North Carolina, Chapel Hill, N.C. 27599.

The prototypical rodent model used to study denervation responses of central dopamine systems is the 6-OHDA-induced unilateral lesion of the substantia nigra. This lesion causes a behavioral supersensitivity to direct agonists (turning) accompanied by an increase in D_2 receptor density on the lesioned side. We have recently shown [Miles et al., Brain Research (in press)] that either bilateral or intracisternal 6-OHDA lesions cause supersensitive behavioral responses without causing changes in either D_1 or D_2 receptor density or affinity. The present studies used molecular biological techniques to characterize further these important differences in dopamine receptor adaptation produced by two distinct models of dopamine denervation. Rats were lesioned by unilateral injection of 6-OHDA (8 μg) into the right substantia nigra or by two successive injections of 6-OHDA (200 μl) into the cisterna magna. Rats were killed ca. 2-3 weeks post lesion. HPLC-EC analysis of tissue samples from both groups of lesioned rats confirmed that dopamine was depleted by greater than 90% in the lesioned striatum, compared to the appropriate sham-lesioned controls. *In situ* hybridization was performed on 15 μm coronal brain slices at a mid-caudate level, using a mixture of ^{35}S -labeled oligoprobes directed at unique regions of either D_1 or D_2 mRNA. Adjacent sections were used for receptor autoradiographic assays of D_1 and D_2 receptors, labeled with [^{125}I]SCH23982 and [^{125}I]iodosulpiride, respectively. Consistent with earlier findings from this laboratory, D_2 receptor density was increased significantly on the lesioned side in the unilateral subjects, while D_1 receptor density was unchanged. Neither D_1 nor D_2 receptor binding was altered in the intracisternally lesioned rats. Initial results from densitometric analysis of D_1 *in situ* labeling in dorsal lateral caudate nucleus indicated that the overall D_1 mRNA levels did not change in either unilaterally or intracisternally lesioned rats. A frequency distribution analysis of neurons expressing D_1 message indicated, however, a trend toward lesion-induced differences in D_1 message expression in subpopulations of labeled neurons for both groups of subjects, suggesting a possible heterogeneity of neural response to dopamine denervation.

AUGMENTED DOPAMINE RECEPTOR SENSITIVITY IN LATERAL, BUT NOT MEDIAL, CAUDATE FOLLOWING NEONATAL 6-HYDROXYDOPAMINE LESIONS. H.E. Criswell, P.E. Simson, and G.R. Breese. Department of Psychiatry, University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC 27599.

Extracellular single unit recording and microiontophoretic techniques were employed to determine the sensitivity of D_1 - and D_2 -dopamine (DA) receptors throughout the caudate putamen (CPu) of adult rats that had received 6-hydroxydopamine lesions as neonates or as adults. Only lesioned rats displaying behavioral supersensitivity to D_1 - and D_2 -dopamine agonists, as defined by increases in locomotion and other behaviors in response to peripheral administration of D_1 - and D_2 -dopamine agonists, were included in the present study. Electrophysiological testing revealed regionally specific increases within the CPu in sensitivity to microiontophoretically applied D_1 - and D_2 -agonists in rats lesioned as neonates, but not adults. In particular, current-response curves demonstrated an augmented inhibitory response, in neonatally-lesioned rats as compared to adult-lesioned and control rats, to both the selective D_1 agonist SKF-38393 and the selective D_2 agonist quinpirole in lateral, but not medial, portions of the CPu. At least 60% of neurons in both lateral and medial portions of CPu responded to both D_1 - and D_2 -agonists across all three groups. This is consistent with co-localization of D_1 - and D_2 -receptors. However, despite this extensive D_1/D_2 -receptor co-responsiveness, there was no evidence for a purported supra-additive D_1/D_2 interaction. Supported by HD23042; NS21345.

SPECIFIC DOPAMINERGIC NEUROTOXICITY OF MPP⁺ AND ANALOGS IN CULTURED MESENCEPHALON: ROLE OF THE DOPAMINE UPTAKE SYSTEM AND INHIBITION OF MITOCHONDRIAL RESPIRATION. M.S. Saporito, H.M. Geller, S.K. Youngster, W.J. Nicklas, A.N. Basma and R.E. Heikkila. UMDNJ-Robert Wood Johnson Medical School, Piscataway, N.J. 08854.

Analogues of MPP⁺ were synthesized and evaluated for their neurotoxic potential in cultured neurons from mouse mesencephalon. These same compounds were evaluated for their affinity for the dopamine (DA) uptake system and ability to inhibit complex I of the electron transport chain from isolated mitochondria. Simultaneous [^3H]DA and [^{14}C]GABA uptake, as well as immunocytochemical staining for tyrosine hydroxylase and GABA, were used to quantify DA and GABA neurons. MPP⁺, which possessed a high affinity for DA uptake system and is an inhibitor of complex I respiration, caused a time and concentration dependent loss of DA neurons with an LD_{50} of less than 1 μM . MPP⁺ did not affect GABAergic neurons up to a concentration of 30 μM . Analogues of MPP⁺ which had high affinity for the DA transporter and were similar to MPP⁺ in inhibiting mitochondrial respiration also caused a selective DA neurotoxicity. The pyrimidinium analogue of MPP⁺ which had a high affinity for the DA uptake system, but did not inhibit mitochondrial respiration, was not neurotoxic up to a concentration of 100 μM . The 4-alkylated analogues of MPP⁺, which were poor substrates for DA uptake system but potent inhibitors of mitochondrial respiration, caused neurotoxicity to both DA and GABA neurons. This study describes the neurotoxicity of a number of analogues of MPP⁺ and highlights the importance of the DA uptake system and the ability of MPP⁺ to inhibit mitochondrial respiration as critical processes in conferring selectivity and neurotoxicity, respectively, to MPP⁺ and analogues for DA neurons in culture.

THE EFFECTS OF NEUROSTEROIDS ON THE STRESS-INDUCED ACTIVATION OF DOPAMINE SYSTEMS IN THE PREFRONTAL CORTEX. A. Christina Grobin, Robert H. Roth, and Ariel Y. Deutch. Departments of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06510.

Neurosteroids can be formed endogenously in the brain, independent of adrenal release. These include allopregnanolone and the A-ring metabolite of deoxycorticosterone, $3\alpha,5\alpha$ -tetrahydrodeoxycorticosterone (THDOC). THDOC is a potent positive modulator of the GABA_A receptor. This is consistent with behavioral investigations which suggest that neurosteroids have anxiolytic properties. Moreover, brain and plasma levels of THDOC increase after swim stress. We have therefore examined the effects of intraventricular administration of THDOC on the stress-induced activation of the dopamine (DA) innervation of the prefrontal cortex (PFC). Animals with chronic indwelling cannulae in the lateral ventricle received THDOC (0.5-25.0 μ g) or vehicle, and were sacrificed 30 min later. THDOC selectively reduced DA metabolism in the PFC in a dose-dependent fashion; other mesotelencephalic DA regions were not affected. Stress increased DA metabolism in the PFC; this effect was partially reversed by 25 μ g THDOC. These data indicate that a neurosteroid selectively alters dopaminergic function in the PFC, and are consistent with the suggestion that THDOC is an anxiolytic agent. Supported by MH-45124, MH-14092, GM-07324, and the National Parkinson Foundation Center at Yale University.

EVIDENCE THAT 5HT₂ RECEPTORS MEDIATE THE INHIBITORY EFFECTS OF STRESS ON THE ACTIVITY OF TUBEROINFUNDIBULAR AND TUBEROHYPOPHYSIAL DOPAMINERGIC NEURONS IN FEMALE RATS. J.L. Goudreau, J. Manzanares, K.J. Lookingland and K.E. Moore. Dept of Pharmacology and Toxicology, Michigan State University, East Lansing, MI, 48824

The purpose of the present study was to examine the role of 5-hydroxytryptamine (5HT) neurons and their receptor subtypes in mediating the inhibitory effects of stress on the activity of tuberoinfundibular (TIDA) and tuberohypophysial dopaminergic (THDA) neurons in female rats. TIDA and THDA neuronal activity was estimated by measuring the concentrations of 3,4-dihydroxyphenylacetic acid (DOPAC) in the median eminence and intermediate lobe of the pituitary. Brief exposure to diethylether (2 min) followed by 30 min of supine restraint decreased the activity of TIDA and THDA neurons, and this effect was blocked by either neurotoxin-induced lesions of 5HT neurons (5,7-dihydroxytryptamine; 200 μ g/rat; i.c.v.; 7 days) or inhibition of 5HT neuronal activity following administration of the 5HT_{1A} receptor agonist, 8-hydroxy-2-(di-n-propylamino)-tetralin (8-OH-DPAT; 0.3 mg/kg; s.c.; 30 min). Taken together, these results indicate that 5HT neurons mediate the inhibitory effects of stress on TIDA and THDA neurons. Pretreatment of rats with the 5HT₂ receptor antagonist MDL-11,939 (1.0 mg/kg; i.p.; 30 min) blocked the inhibitory effects of stress on the activity of TIDA and THDA neurons, whereas the 5HT₃ receptor antagonist ondansetron (0.1 mg/kg; s.c.; 30 min) was without effect. These results indicate that the stress-induced decrease in the activity of TIDA and THDA neurons in female rats is mediated by postsynaptic 5HT₂ receptors. (Supported by NIH grant NS 15911)

CHRONIC MORPHINE INCREASES SYNAPTIC DOPAMINE IN THE NUCLEUS ACCUMBENS AND NALOXONE DECREASES IT UNLESS WITHDRAWAL IS BLOCKED WITH CLONIDINE. E. Pothos, P. Rada*, G.P. Mark & B.G. Hoebel. Dept. Psych., Princeton U., Princeton, NJ 08544

Microdialysis was used to measure extracellular DA in the NAC of freely moving rats before and after morphine dependence, as well as after naloxone-precipitated withdrawal with and without clonidine therapy. All subjects were given daily injections of morphine for 7 days and naloxone on day 8 (20 mg/kg i.p.). After naloxone administration, all subjects showed symptoms of opiate withdrawal (wet dog shakes, diarrhea, teeth-chattering). On day 1, morphine resulted in an average 50% increase in DA for 3 hours after injection (n=8, p<.05). On day 7, basal DA was still normal and morphine increased DA again by an average 50% in the contralateral NAC (p<.05). On day 8, naloxone decreased DA by 40% 1.5 hr. after injection (p<.05). By comparison, naloxone did not alter DA levels in non-dependent animals. Pretreatment of dependent subjects with clonidine (200 μ g/kg i.p.) blocked the naloxone-induced DA depression and attenuated the above withdrawal symptoms. These results demonstrate (a) similar increases in NAC DA before and after morphine dependence, (b) precipitated reduction in DA during withdrawal, and (c) blockade of the DA withdrawal effect by a noradrenergic agonist. Consequently, NAC DA may play a role in morphine withdrawal and therefore addiction. Supported by USPHS grant DA-03597

325.6

ONSET OF DOPAMINERGIC INNERVATION OF THE RAT PITUITARY INTERMEDIATE LOBE DECREASES MITOTIC RATE IN DEVELOPING MELANOTROPES. K.A. Gary and B.M. Chronwall, School of Basic Life Sciences, University of Missouri-Kansas City, Kansas City, MO 64108.

The intermediate lobe (IL) of the rat pituitary is innervated by axons of dopaminergic neurons located in the mediobasal hypothalamus. Immunohistochemical studies indicate that both tyrosine hydroxylase (TH) and dopamine (DA) are first detected on post-natal (PN) day 3 during development. *In vitro* and *in vivo* studies utilizing D₂ receptor agonists and antagonists have established that dopamine receptor activation decreases the mitotic rate of melanotropes in adult rat IL. In this study, we have examined the effects of DA innervation on melanotrope mitotic rate during ontogeny. Rat pups were injected at PN 2-14, with [³H]thymidine and sacrificed two hours later. Pituitaries were harvested, osmicated, dehydrated, embedded in plastic, sectioned, and processed for autoradiography. Analysis of labeled melanotropes indicates mitotic rate decreases 48% at PN 3, concomitant with the appearance of DA-immunoreactive (IR) axon terminals. To correlate DA expression and post-synaptic action with decreased mitotic rate, rat pups of ages indicated above were injected intracranially with 200 mg 6-OHDA in 25 μ l normal saline with 0.01% ascorbic acid. TH-IR was decreased within the IL and neural lobe of all injected pups at each time point. DA levels were assayed by reverse phase HPLC with electrochemical detection (detection limit 100 fg). DA levels were decreased to 48% of controls at PN 3, and to 20% at later stages. 6-OHDA blocked the reduction of mitotic rate normally occurring on PN 3; the mitotic rate remained similar to that observed in normal pups prior to onset of innervation. Thus, we have shown that the onset of DA expression occurring with innervation directly decreases mitotic rate of the melanotropes.

EFFECT OF ACUTE MORPHINE TREATMENT ON INCERTOHYPOTHALAMIC DOPAMINERGIC NEURONS: THE ROLE OF 5-HYDROXYTRYPTAMINERGIC NEURONS. Y. Tian, M.J. Eaton, K.J. Lookingland and K.E. Moore. Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI 48824

The purpose of the present study was to characterize the acute effect of morphine on incertohypothalamic dopaminergic (IHDA) neurons. DA neuronal activity was estimated by measuring concentrations of the DA metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) in medial zona incerta (MZI) and dorsomedial hypothalamic nucleus (DMN) which contain cell bodies and terminals of IHDA neurons. Morphine increased DOPAC concentration in MZI and DMN in a dose- and time-related fashion. No difference was observed in either basal activity or in response to acute morphine treatment of IHDA neurons between male and female rats. The stimulatory effect of morphine on IHDA neurons was blocked by pretreatment of animals with naltrexone. Morphine also increased 5-hydroxyindoleacetic acid (5HIAA) concentrations in MZI and DMN, which was blocked by pretreatment with naltrexone, indicating a stimulatory effect of morphine on 5-hydroxytryptamine (5HT) neurons. These data suggest that 5HT neurons may mediate the stimulatory effect of morphine on IHDA neurons. One week after an i.c.v. injection of the 5HT neurotoxin, 5,7-dihydroxytryptamine, 5HT concentrations in the MZI and DMN were undetectable. In these 5HT-depleted animals morphine still increased DOPAC concentration in the MZI and DMN. These results indicate that morphine stimulates IHDA neurons, but this stimulatory effect is not mediated through 5HT neurons. (Supported by NIH grant NS 15911.)

CHRONIC MORPHINE AND CHRONIC COCAINE DECREASE NEUROFILAMENT LEVELS IN THE RAT VENTRAL TEGMENTAL AREA. D. Reitner-Johnson, X. Guitart, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts. of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06508.

Dopaminergic neurons in the ventral tegmental area (VTA) are thought to mediate some of the reinforcing properties of opiates and cocaine. We have demonstrated previously that chronic morphine and cocaine exert common actions on tyrosine hydroxylase in the VTA and in one of its projection areas, the nucleus accumbens (*J Neurochem*, 57:344, 1991). We now report that neurofilament (NF) proteins of 200, 160, and 68 kD are also regulated in the same way by chronic morphine and chronic cocaine in the VTA. NF levels were studied by immunolabeling, protein staining, and back phosphorylation. Each method indicated that chronic morphine and cocaine decreased the total amounts of the various NFs by between 15-50% in the VTA, but not in some other regions of the central nervous system studied. NF levels were not altered by chronic haloperidol or imipramine, drugs without reinforcing properties, or by acute morphine or cocaine treatment.

In the course of these studies, we found by use of microdissection techniques that NF proteins are highly enriched in the VTA, and to a lesser extent in the substantia nigra and locus coeruleus (also catecholaminergic nuclei), compared to a large number of other brain regions examined. The possibility that NFs are highly expressed in VTA neurons suggests that these dopaminergic cells display some specialized function subserved by NF proteins. Decreased levels of NFs in the VTA elicited by chronic morphine and cocaine may contribute to drug-induced functional alterations in these neurons that are part of the molecular basis of morphine and cocaine addiction and craving.

325.11

DOPAMINERGIC BRAIN REWARD REGIONS OF LEWIS AND FISCHER 344 RATS CONTAIN DIFFERENT LEVELS OF TYROSINE HYDROXYLASE AND NEUROFILAMENTS. X. Guitart, D. Beitner-Johnson, and E.J. Nestler, Laboratory of Molecular Psychiatry, Depts. of Pharmacology and Psychiatry, Yale Univ. School of Medicine, New Haven, CT 06508.

The ventral tegmental area (VTA) and one of its projections, the nucleus accumbens (NAc), are considered brain reward regions that mediate some of the reinforcing actions of drugs of abuse. Lewis (LEW) and Fischer (F344) rats are genetically inbred strains that show different levels of self-administration of several types of abused substances. Since chronic morphine and cocaine treatments regulate tyrosine hydroxylase (TH) and neurofilaments (NFs) specifically in the VTA-NAc pathway (see Beitner-Johnson et al., this volume), we studied these phosphoproteins in LEW and F344 rats to better understand possible genetic factors involved in drug addiction.

Major differences were found in levels of these proteins in the VTA and NAc of LEW vs F344 rats. LEW rats (the drug-preferring strain), compared to F344, had 40% higher levels of TH immunoreactivity in the VTA, and 50% lower levels of TH in the NAc. LEW (vs. F344) rats also had about 40% lower levels of the NF subunit proteins of 200, 160, and 68 kD in the VTA, as measured by immunolabeling, protein staining, and back phosphorylation. Each of these strain differences are strikingly similar to the effects of chronic morphine and chronic cocaine on the levels of TH and NFs in these neurons. The strain differences in levels of TH and NFs exhibited regional specificity within the central nervous system.

These findings suggest that levels of TH and NF expression in the VTA-NAc pathway may reflect part of the biochemical basis of individual genetic vulnerability to drug addiction.

325.13

EFFECTS OF PRE- & POST-NATAL COCAINE EXPOSURE ON THE STRIATAL DOPAMINERGIC SYSTEM IN NEWBORN MICE. E. Yablonsky-Alter, Y. Belenky*, M.A. Nathan, I. Glezer, T.I. Lidsky and S.P. Banerjee, Inst. of Brain Research, Staten Island, N.Y. and CUNY Medical School, N.Y., N.Y. 10031

Cocaine (Coc) was injected (10mg/kg, i.p.) at an interval of 24 hrs to a group of pregnant mice at the beginning of gestation. A control group of mice received equal volumes of saline. Administration of saline and Coc was continued for another 21 days after the delivery, and the female mice were allowed to feed milk to their newborn pups. The pups were sacrificed at the ages of 3, 7, 11, and 21 days and striatal dopamine levels were measured with high pressure liquid chromatography. Administration of Coc to pregnant mice decreased the striatal content of dopamine as compared to control by 28%, 34%, 29% and 33% in 3, 7, 11, and 21 day old pups respectively. These results indicate that a third of striatal dopamine is lost due to prenatal Coc exposure. No further damage of the striatal dopaminergic system could be seen during the post-natal exposure to Coc. Thus, the Coc-induced insult to the striatal dopaminergic system appears to be much greater during prenatal period as compared to the postnatal stage.

325.15

THE PROGRESSIVE CHANGES OF NEURONAL ACTIVITIES OF THE NIGRAL DOPAMINERGIC NEURONS UPON WITHDRAWAL FROM CONTINUOUS INFUSION OF COCAINE. H. Zhang, T.H. Lee, and E.H. Ellinwood, Dept. of Psychiatry, Box 3870, Duke Univ. Med. Ctr., Durham, NC 27710.

We hypothesized that the residual withdrawal effects of continuously chronic cocaine infusion would increase the autoreceptor sensitivity of the dopaminergic neurons in the substantia nigra pars compacta (SNpc) to apomorphine upon cocaine withdrawal. Previously we found that after chronic amphetamine, apomorphine inhibition of SNpc neuron firing goes from subsensitivity on day 1 after withdrawal to supersensitivity on day 7 (Lee and Ellinwood, 1989). In the present study, rats (S-D, male) were pretreated with cocaine (40 mg/kg/day) or saline via subcutaneous osmotic minipumps for two weeks. One, 7 or 14 days after the removal of the minipumps, the spontaneous discharges of the dopaminergic neurons in the SNpc was recorded, and the effect of intravenous injection of apomorphine (expressed as percentage inhibition of the baseline firing rate) was examined. A hypersensitivity to apomorphine was observed on the first day of cocaine withdrawal (ID_{50} 16 ± 3 (5) vs. 11 ± 2 (10) μ g/kg, i.v. in control). A hypersensitivity was displayed on day 7 of cocaine withdrawal (ID_{50} 6 ± 3 (7) μ g/kg, i.v.). In addition, a significant increase of the baseline firing rate (6.0 ± 1.2 vs. 3.1 ± 1.2 spikes/sec in control animals) was also present among the neurons recorded 7 days after the cocaine withdrawal, while a slight increase (3.9 ± 1.5 spikes/sec) was seen among the rats tested on the first day of withdrawal. Both the baseline firing rate and the neuronal sensitivity returned to the control level on day 14 of cocaine withdrawal. We propose that an altered sensitivity of the dopamine autoreceptor (D_2) and the neural pathways to which the D_2 receptors are related are responsible for the changes of the neuronal activities induced by continuous cocaine treatment.

325.12

LEWIS AND FISCHER 344 RATS AND DRUG ADDICTION: BEHAVIORAL AND BIOCHEMICAL CORRELATES. R.Z. Terwilliger, C. Bradberry, X. Guitart, D. Beitner-Johnson, D. Marby, T.A. Kosten, R.H. Roth, and E.J. Nestler, Lab. of Molecular Psychiatry, Depts. of Pharmacology and Psychiatry, Yale Univ. School of Medicine, New Haven, CT 06508.

Lewis (LEW) and Fischer (F344) rats are inbred genetic strains that show different levels of self-administration of several types of drugs of abuse, and can therefore be used to study genetic factors that contribute to drug addiction. First, we confirmed this strain difference in drug preference by showing that LEW rats develop >2-fold more conditioned place preference to morphine and to cocaine compared to F344 rats. We then studied possible biochemical factors involved.

We have reported that chronic morphine and cocaine decrease levels of $G_{i\alpha}$, and increase levels of adenylate cyclase (AC) and cyclic AMP-dependent protein kinase (cA-K), in the nucleus accumbens (NAc) (*Brain Res*, 548:100, 1991), a brain region implicated in drug reward. In the current study, we found, analogous to the drug effects, that LEW compared to F344 rats exhibit 50% lower levels of $G_{i\alpha}$, and 30-40% higher levels of AC and cA-K, specifically in the NAc. We also studied extracellular levels of dopamine in the NAc of LEW and F344 rats by *in vivo* microdialysis. Acute administration of cocaine elicits dramatically smaller increases in extracellular dopamine in the NAc in LEW vs F344 rats. This could be related to strain differences in levels of tyrosine hydroxylase in the NAc (see Guitart et al., this volume).

Strain differences observed in G-proteins, the cyclic AMP pathway, TH and dopamine levels, and some other phosphoproteins (see Guitart et al.) could in part underlie the strain difference in drug preference. These studies will lead to the identification of molecular mechanisms involved in individual genetic vulnerability to drug addiction.

325.14

SYSTEMIC COCAINE CHALLENGE AFTER CHRONIC COCAINE TREATMENT YIELDS COCAINE SENSITIZATION OF EXTRACELLULAR DOPAMINE CONTENT IN NUCLEUS ACCUMBENS BUT DIRECT COCAINE PERFUSION INTO NUCLEUS ACCUMBENS DOES NOT - *IN VIVO* MICRODIALYSIS STUDIES. J. Chen, R. Marmor*, W. Paredes*, A. Pulles* and E.L. Gardner, Depts of Psychiatry and Neuroscience, Albert Einstein Col. of Med., New York, NY 10461

Chronic cocaine treatment produces enhanced response to subsequent cocaine challenge (e.g., Kilbey & Ellinwood, *Life Sci*. 20: 1063, 1977). Many hypotheses have been proposed to explain this cocaine "sensitization", including enhanced DA release, DA autoreceptor desensitization, and postsynaptic DA receptor alterations (e.g., Kalivas et al., *J. Pharm. Exp. Ther.* 245:485, 1988; Zahniser et al., *NIDA Res. Monogr. Ser.* 88:55, 1988). In the present study, rats were treated with cocaine (20 mg/kg/day, i.p.) for 16 days followed by 7 days wash-out. On the 24th day, rats were challenged with the same dose of cocaine and extracellular DA in nucleus accumbens (Acc) was measured by *in vivo* microdialysis. Rats challenged with systemic cocaine showed enhanced Acc extracellular DA content (compared to rats not receiving chronic cocaine), but those challenged with cocaine by perfusion of 10^{-5} M cocaine directly into the Acc did not. These data suggest that cocaine sensitization, as manifested by enhanced Acc DA content to acute cocaine challenge, does not involve neural mechanisms occurring locally within the Acc. Thus, cocaine sensitization may be due to changes at other neural loci or may be due to pharmacokinetic factors (see, e.g., Pettit et al., *J. Neurochem.* 55:798, 1990).

NIGRAL DOPAMINERGIC NEURONS: CRUS CEREBRI LESIONS ALTER SPONTANEOUS UNIT ACTIVITY AND RESPONSE TO AMPHETAMINE AFTER LONG-TERM TREATMENT. B.A. Heidenreich and G.V. Rebec, Prog. Neural Science, Dept. Psychol., Indiana Univ., Bloomington, IN 47405.

Two mechanisms mediate the inhibitory effect of amphetamine (AMPH) on the activity of dopamine (DA) neurons in the substantia nigra compacta (SNc): self-inhibition via autoreceptors and post-synaptic feedback from striatal targets. We assessed their relative contribution to the subsensitivity to AMPH previously observed after repeated treatment (Kamata and Rebec, *Neuropharmacol.*, 22:1377, 1983). Adult, male rats received electrolytic lesions in the crus cerebri or sham lesion surgery. After a week, rats received either 5.0 mg/kg d-AMPH or saline twice daily for 6 days. On the following day, single-unit activity of DA neurons was recorded in the SNc under urethane anesthesia. Mean spontaneous firing rate did not differ among the 4 treatment groups. Among both lesioned and sham-operated rats, higher doses of i.v. d-AMPH were necessary to inhibit unit activity after treatment with this drug, relative to saline treatment. In lesioned rats, mean spontaneous firing rate was highly correlated with the dose of d-AMPH necessary to inhibit unit activity ($r=.92$). This correlation was positive among lesioned rats after saline ($r=.42$) or d-AMPH ($r=.95$) treatment. No such relationship was present after sham lesions ($r=.07$). In fact, this correlation was in opposite directions among shams who received saline ($r=.39$) or d-AMPH ($r=-.49$) treatment. These results suggest that subsensitivity of SNc DA neurons to AMPH after long-term treatment represents both pre- and post-synaptic mechanisms of adaptation.

Supported by USPHS grant DA 02451.

THE EFFECTS OF PROLYL-LEUCYL-GLYCINAMIDE (PLG) ON IDENTIFIED MIDBRAIN DOPAMINE NEURONS. C. Rouillard¹, R.K. Mishra² and R.L. Johnson³. ¹Lab. of Neurobiology and Dep. Pharmacology, Laval University, Québec, Canada, G1J 1Z4, ²Department of Psychiatry, McMaster University, Hamilton, Canada and ³Department of Medicinal Chemistry, University of Minnesota, Minneapolis, USA.

The tripeptide PLG has a pharmacological profile which strongly suggests that it exerts a modulatory effect on dopaminergic systems and could have antiparkinsonian properties. PLG has been demonstrated to potentiate the behavioral effects of dopamine agonists, attenuate catalepsy induced by neuroleptics and cause an increase in the binding of dopamine agonists to striatal dopamine receptors. In this study, extracellular single-unit recording techniques were used to examine the effects of PLG on the electrophysiological activity of identified nigrostriatal (NSDA) and mesoaccumbens (MADA) dopamine neurons in anesthetized rats. Intravenous administration of PLG (0.1 µg/kg-10 mg/kg) produced a dose dependent increase in the firing rate of NSDA and MADA neurons. However, pretreatment (3 min) with PLG (0.1 mg/kg or 10 mg/kg) did not alter the sensitivity of NSDA neurons to apomorphine ($ED_{50}=7.5\pm 2.42$ µg/kg and 14.14 µg/kg respectively vs 9.18 µg/kg in control rats). These data indicate that PLG can modulate the activity of mesencephalic dopaminergic pathways. Additional studies are currently underway to determine the mechanism by which PLG can influence dopamine neuronal activity. (Supported by FRSQ [CR] and NIH [RKM and RLJ]).

ALPHA-ADRENERGIC MODULATION OF MIDBRAIN DOPAMINE CELL ACTIVITY. J. Grenhoff and T.H. Svensson. Dept. of Pharmacology, Karolinska Institute, S-104 01 Stockholm, Sweden.

Interactions between brain adrenergic and dopaminergic (DA) systems have been suggested in a number of studies. We have previously shown that stimulation of presynaptic alpha-2 adrenoceptors regularizes the firing of midbrain DA neurons.

Here we have utilized extracellular recording from single identified DA neurons in chloral hydrate-anaesthetized male rats to examine the effects of alpha-adrenergic substances on the firing rate and pattern of DA cells in the ventral tegmental area, the origin of the mesocorticolimbic DA pathway. The alpha-1 adrenoceptor antagonist prazosin (0.15-0.6 mg/kg IV) regularized the firing pattern and markedly decreased burst firing without affecting the firing rate of the neurons. In addition, the deregularizing action of the alpha-2 antagonist idazoxan was blocked by prazosin.

The present results indicate that adrenergic neurons exert a tonic modulatory influence on midbrain DA cell firing via alpha-1 receptors.

EVIDENCE FOR NMDA AND AMPA SUBTYPES OF THE GLUTAMATE RECEPTOR ON SUBSTANTIA NIGRA DOPAMINE (DA) NEURONS. C.L. Christofferson and L.T. Meltzer. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The present studies evaluated whether NMDA or AMPA subtypes of the glutamate receptor mediate the excitatory effects of glutamate on DA neurons. Extracellular single-unit activity was recorded from chloral hydrate anesthetized rats. Iontophoretic administration of both AMPA and NMDA increased neuronal firing and could induce depolarization inactivation. In contrast, glutamate increased neuronal firing but did not induce depolarization block. In preliminary studies the selective NMDA antagonist CPP reduced the excitatory effects of NMDA and glutamate but not AMPA, while the selective AMPA antagonist NBQX reduced the excitatory effects of AMPA and glutamate but not NMDA. NBQX produced a greater reduction of the glutamate effect than did CPP. These data provide evidence for both NMDA and AMPA receptors on DA neurons.

CATECHOLAMINES: BIOSYNTHESIS I

326.1

TYROSINE AND PHENYLALANINE AS SUBSTRATES FOR DOPAMINE SYNTHESIS IN PC12 CELLS. F.R. DePietro, R.P.S. Kwok and J.D. Fernstrom, Dept. Psychiatry, Univ. Pittsburgh, Pittsburgh PA 15213.

Phenylalanine (PHE) is reputed to be both a substrate for and an inhibitor of tyrosine hydroxylase (TH) and catecholamine (CAM) synthesis. It is difficult to study CAM synthesis from PHE *in vivo*, as PHE is rapidly converted to tyrosine [TYR] in the liver. To define the role of PHE in CAM synthesis more clearly, we are studying dopamine [DA] synthesis from PHE using PC-12 cell cultures. DA synthesis is estimated via ³H-DA formation from ³H-PHE (or ³H-TYR); TYR hydroxylation is also quantitated via DOPA accumulation following inhibition of aromatic-L-amino acid decarboxylase. Samples are analyzed for endogenous DA or DOPA by HPLC/electrochemical detection; ³H-DA is quantitated by counting HPLC fractions. Endogenous amino acids are measured fluorometrically using a Beckman 6300 amino acid analyzer. Labeling and DOPA results agreed well, yielding a K_m for TYR of 1-2 µM (extracellular [EC] concentration; the K_m = 60 µM using intracellular [IC] TYR concentrations) and a V_{max} = 19-25 pmol/min/mg protein. The K_m for PHE (EC concentration; IC measurements in progress) was 7.7 µM, and V_{max} = 9.9 pmol/min/mg protein using PHE as substrate. DOPA and DA synthesis rates declined when EC TYR was >10-30 µM; inhibition did not occur for PHE at EC levels ≤300 µM. TYR and PHE each inhibited DA synthesis from the other amino acid, though TYR was 10-times more potent than PHE. These results suggest that PHE shares many properties in common with TYR as a substrate for TH and CAM synthesis in the PC12 cell.

EXTRINSIC FLUORESCENCE STUDIES OF TYROSINE HYDROXYLASE L. G. Gahn and R. Roskoski, Jr. Department of Biochemistry and Molecular Biology LSU Medical Center New Orleans, Louisiana 70119

Tyrosine hydroxylase (TH) is the rate limiting enzyme in the biosynthesis of the catecholamines dopamine, norepinephrine and epinephrine. We have studied the effects of substrate and inhibitor binding on the conformation of purified rat TH (from PC12 cells), using the extrinsic fluorescence probe 8-anilino-1-naphthalene sulfonate (ANS). ANS non-covalently binds to proteins at hydrophobic sites and exhibits a characteristic fluorescence spectrum. A change in protein conformation may alter this spectrum. At pH 6.0, ANS interacting with TH resulted in a fluorescence spectrum with a maximum at 455 nm upon excitation at 380 nm. Tyrosine, a substrate, decreased the fluorescence slightly (10%) whereas 3-iodo-tyrosine, a competitive inhibitor with respect to tyrosine, increased fluorescence by 10%. In contrast to 3-iodo-tyrosine, the catecholamines are competitive inhibitors of TH with respect to the reducing cofactor tetrahydrobiopterin. All of the inhibitory catecholamines at a 100 µM concentration (dopamine, norepinephrine and isoproterenol) produced a 30% decrease in TH/ANS fluorescence. Metaproterenol, an isomer of isoproterenol which has no effect on TH activity, did not alter fluorescence. These results suggest that tyrosine and 3-iodo-tyrosine, which probably bind to TH at the same site, have only minor effects on TH conformation, while the catecholamine inhibitors all appear to significantly influence TH conformation. Supported by USPHS Grant NS-15994.

326.3

NGF- AND PHORBOL-STIMULATED PHOSPHORYLATION OF TYROSINE HYDROXYLASE AT SER³¹ IS MEDIATED BY ERK1/ERK2. J.W. Haycock¹, N.G. Ahn², M.H. Cobb^{3*}, & E.G. Krebs^{2*}. ¹Dept. Biochem., Louis. State U. Med. Ctr., New Orleans, LA 70119; ²Dept. Pharmacol., U. Wash., HHMI, Seattle, WA 98195; ³Dept. Pharmacol., U. Texas, Southwestern Med. Ctr., Dallas, TX 75235

Tyrosine hydroxylase (TH) is phosphorylated at four sites (Ser⁸, Ser¹⁹, Ser³¹ and Ser⁴⁰) *in situ* and *in vivo*. The protein kinases (PK) which mediate the phosphorylation of Ser⁸, Ser¹⁹ and Ser⁴⁰ appear to be proline-directed PK, Ca²⁺/calmodulin-dependent PK II and cAMP-dependent PK, respectively. However, the PK(s) responsible for phosphorylating Ser³¹, the NGF- and phorbol ester-sensitive phosphorylation site, has not previously been identified.

The amino acid sequence surrounding Ser³¹ (rat, -EAVTS³¹PRF-; human, -EAIMS³¹PRF-) did not suggest any candidate PKs, and a number of purified PKs failed to phosphorylate TH at Ser³¹ *in vitro*. However, two Ser³¹ kinase activities were identified in extracts of NGF-treated PC12 cells. Fractionation of the extracts on MonoQ columns produced two peaks of Ser³¹ kinase activity, which corresponded exactly with two peaks of myelin basic protein kinase activity. These kinase activities had been previously identified as ERK1 and ERK2—two related PKs of M_r ~45 kDa and ~42 kDa, respectively. To demonstrate that ERK activity was responsible for the Ser³¹ kinase activity, activated ERK1 was purified to homogeneity and shown to phosphorylate purified PC12 TH selectively at Ser³¹.

In intact PC12 cells, the phosphorylation of TH at Ser³¹ is increased by a number of agents in addition to NGF. Such treatments (e.g., phorbol dibutyrate, bradykinin, barium) also increased ERK1/ERK2 activity.

Taken together, these data identify ERK1 and/or ERK2 as the effectors of Ser³¹ phosphorylation *in situ* and, as such, identify the first physiological substrate for these protein kinases.

326.5

EFFECTS OF MPTP ON THE EXPRESSION OF TYROSINE HYDROXYLASE AND TETRAHYDROBIPTERIN (BH₄) BIOSYNTHETIC ENZYMES IN MOUSE BRAIN. P.Z. Anastasiadis, J.F. Solus^{2*}, S. Tait^{1*}, S.K. Demetriou¹ & R.A. Levine. Lab Mol. Neurobiol., Cellular & Clinical Neurobiol. Pgm, Wayne State Univ. (WSU) & Lafayette Clinic, Detroit, MI, and ²Center for Mol. Biol., WSU.

BH₄ is the essential cofactor for tyrosine hydroxylase (TH), the initial and rate-limiting enzyme in dopamine (DA) synthesis. The three major enzymes catalyzing successive reactions in BH₄ biosynthesis within DA neurons are GTP cyclohydrolase (GTP-CH), 6-pyruvoyl-tetrahydropterin (6-PPH₄), and sepiapterin reductase (SR). 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) causes a selective degeneration of nigrostriatal DA neurons. In male C57/B1 mice, MPTP (10 mg/kg i.p., once each day for 5 days; sacrifice on day 17) had the following effects in striata: 1) decreased *in vitro* TH activity by 50% and DA and metabolites by greater than 70%; 2) decreased BH₄ and GTP-CH activity by 50%, and 3) did not alter 6-PPH₄ synthase or SR *in vitro* activities. Radiolabelled cDNA probing of northern blots containing substantia nigral total RNA demonstrated a 33% reduction of TH mRNA following MPTP; preliminary experiments showed that nigral SR mRNA rose to 160% of control, indicating the potential for enhanced expression of SR in response to partial DA neuronal destruction. It is possible that striatal SR activity remains equal to control due to a compensatory enhancement of SR expression in surviving DA neurons. However, the lack of change in striatal SR and 6PPH₄ synthase activities following MPTP could also indicate that these enzymes are not predominantly localized to DA neurons and catalyze other reactions not involved in BH₄ biosynthesis, although other functions for these enzymes are unknown. Current experiments are examining the ability of MPTP to enhance the expression of the other BH₄ biosynthetic enzymes in nigrostriatal DA neurons.

326.7

INDUCTION OF ADRENAL GAD BY RESERPINE: RELATIONSHIP TO AGE-RELATED ALTERATIONS IN TH INDUCTION. C. Hale^{1*}, J.W. Haycock¹, V. Reddy^{2*}, B. Raghu^{2*}, M. Wessels-Reiker^{2*} and R. Strong^{2*}. The Dept. of Pharmacological and Physiological Science and the Dept. of Internal Medicine, St. Louis Univ. School of Med. and the Geriatric Research, Education and Clinical Center, St. Louis VAMC, St. Louis, MO 63125; and Biochemistry and Molecular Biology, LSUMC, New Orleans, LA 70119.

We previously reported age-related increases in adrenal tyrosine hydroxylase (TH) gene expression, but age-associated decreases in TH induction by reserpine. Since we also reported that activation of GABA receptors inhibits TH induction, we examined the effects of aging and reserpine on adrenal glutamate decarboxylase (GAD), the enzyme that synthesizes GABA. The effects of reserpine on GAD and TH were compared simultaneously in adrenals from rats aged 2, 12 and 27 months. Reserpine treatment was associated with an increase in GAD. This is the first report that reserpine induces adrenal GAD. Moreover, although there was no effect of age on GAD in vehicle treated groups, aging was associated with super-induction of GAD. Thus in reserpine-treated groups, GAD was increased to 300% of control at 2 months, 400% of control at 12 months and 700% of control at 27 months. By contrast, TH increased with age in vehicle treated groups, but reserpine was less effective in inducing TH in older animals. Thus, reserpine increased TH by 250% in the 2 month group, increased TH 200% at 12 months, but by 27 months of age reserpine had no significant effect on TH. Moreover, regression analysis revealed a highly significant negative correlation ($r = -0.7241$; $p < 0.002$) between the magnitude of TH induction and the extent of GAD induction. These data provide evidence that TH and GAD are coordinately regulated. Our previous studies showing that GABA receptors modulate reserpine induced increases in TH gene expression, together with the present findings, provide evidence that age-associated alterations in GAD expression may influence TH induction during aging.

EFFECTS OF ELECTROCONVULSIVE SHOCK ON *IN VIVO* HYDROXYLATION OF TYROSINE AND ON TETRAHYDROBIPTERIN LEVELS IN THE BRAIN OF 6-HYDROXYDOPAMINE LESION RATS. Mir Ahamed Hossain^{1*}, Joseph M. Masserano and Norman Weiner. Dept. of Pharmacology, C-236, Univ. of Colorado Health Sciences Center Denver, Co. 80262.

We have evaluated the effects of electroconvulsive shock (ECS) on the rate of *in vivo* hydroxylation of tyrosine and the status of tetrahydrobiopterin (BH₄) levels in the nigrostriatal system in 6-hydroxydopamine (6-OHDA) lesioned (right substantia nigra) rats. Electroconvulsive shock (300 mA, 0.2 sec) was administered to 6-OHDA lesioned rats 5 min after NSD-1015 (100mg/kg.i.p.) treatment and sacrificed 30 min later. Rats were sacrificed 5 min after ECS treatment for BH₄ assay. The rate of formation of DOPA was significantly decreased in the striatum (3%) and in substantia nigra (34%) of the non-shocked 6-OHDA lesioned rats as compared to the contralateral non-lesioned striatum and substantia nigra (100%). The application of ECS significantly increased the rate of formation of DOPA by 43% in the right striatum and by 40% in the right substantia nigra compared to that in the non-shocked rats. BH₄ levels in the right nigrostriatal system were significantly increased following ECS treatment. Our results indicate that in 6-OHDA lesioned rats the rate of *in vivo* hydroxylation of tyrosine and BH₄ levels are increased significantly after ECS treatment reflecting an enhancement of dopaminergic function in the nigrostriatal system of these rats. This result suggests that the nigrostriatal system following 6-OHDA treatment still maintains the potential for further up-regulation of dopaminergic function in response to ECS treatment. Supported by USPHS Grant NS09199.

CLONING, SEQUENCING, AND CHARACTERIZATION OF HUMAN BRAIN SEPIAPTERIN REDUCTASE (SR) cDNA. R.A. Levine^{1,2*}, J. Solus^{2*}, J.C. States^{2*}, S.K. Demetriou^{1*}, S. Tait^{1*}, B. Citron^{4*}, and S. Kaufman^{1*}. ¹Lab of Molecular Neurobiology, Lafayette Clinic & ²Dept of Psychiatry, Wayne State University (WSU), Detroit, MI; ³Center for Molecular Biology, WSU; and ⁴Laboratory of Neurochemistry, National Institutes of Mental Health, Bethesda, MD.

Sepiapterin reductase (SR) catalyzes the final reaction in the synthesis of tetrahydrobiopterin (BH₄), the essential cofactor for tyrosine and tryptophan hydroxylases in dopamine and serotonin synthesis, respectively. Cloning of human SR and other BH₄-related genes will allow the study of altered genetic expression of BH₄ biosynthetic enzymes in neuropsychiatric illnesses caused by altered biogenic amine metabolism. A previously cloned rat SR cDNA was used to screen a lambda ZAP human frontal cortex cDNA library. Following screening of 300,000 clones (40% formamide, 42°C), one positive clone was identified on duplicate filters and remained positive upon re-screening. Southern blot analysis of the SR cDNA revealed a full-length size of 1.67 kb, which was confirmed by sequencing. Restriction fragments of human SR cDNA were subcloned in pBS in preparation for sequencing. Subcloned fragments were amplified using symmetric polymerase chain reaction (PCR), followed by asymmetric PCR to prepare single stranded DNA templates for dideoxy sequencing. Comparison of rat and human SR cDNA sequences revealed greater than 60% homology at the nucleotide and translated amino acid levels with no forced gaps introduced in either sequence. Northern blot analysis of rat and human liver RNA demonstrated that there was weak cross-hybridization of rat and human SR cDNA with mRNA from the opposite species. Human SR mRNA was slightly larger than rat SR mRNA. Current studies are focused on measuring SR mRNA in human tissues and isolating the human SR gene from genomic DNA libraries.

REPEATED IMMOBILIZATION STRESS ELEVATES TYROSINE HYDROXYLASE AND DOPAMINE β -HYDROXYLASE mRNA LEVELS IN RAT ADRENALS. A. McMahon^{1*}, Kvetnansky^{2*}, K. Fukuhara^{2*}, I.J. Kopin^{2*}, A.B. Drakontides^{1*}, and E.L. Sabban^{1*}. ¹New York Med. Coll., Valhalla, NY 10595 and ²NIHDS, NIH, Bethesda, Md. 20892.

Repeated immobilization has been shown to increase the activity of adrenal catecholamine biosynthetic enzymes. The molecular mechanism of this activation is not known, although it is known to require trans-synaptic stimuli. We examined whether alterations in adrenal mRNA levels of tyrosine hydroxylase (TH) and dopamine β -hydroxylase (DBH) were involved in the response to immobilization stress. Immobilization for 30 min had no effect on TH or DBH mRNA levels, however, immediately following a single two hr immobilization, TH mRNA levels were elevated over 5-fold. Under the same conditions, DBH mRNA levels were unchanged. After 24 hr, TH mRNA levels had declined toward control values, and could be re-elevated by another 2 hr immobilization. The rise in TH mRNA was inhibited by actinomycin D, suggesting an increase in transcription. Repeated immobilization for 2 hr periods daily for seven consecutive days, elevated both TH and DBH mRNA levels about 4-fold.

Thus both adrenal TH and DBH mRNA levels are affected by immobilization stress, however the results indicate that the mechanism and/or timing of the regulation of TH and DBH are not identical.

326.9

PROCESSING AND GLYCOSYLATION OF RAT DOPAMINE β -HYDROXYLASE IN A CELL FREE SYSTEM. Z. Feng¹, R.H. Angeletti², and E.L. Sabban¹. ¹Dept. Biochem. & Mol. Biol. N.Y. Med. Coll. Valhalla, NY 10595 and ²Dept. Dev. Biol. & Cancer, Albert Einstein Sch. Med. Bronx, NY 10461.

Dopamine β -hydroxylase (DBH) is the enzyme which catalyzes the synthesis of norepinephrine. DBH is present in both membrane-bound and soluble forms in neurosecretory vesicles. Tetramers of the membrane-bound form contain both 77K and 73K monomers, while only the latter are in soluble DBH. Cloning of rat DBH (McMahon et al., 1990, J. Neurosci. Res. 25, 395-404), revealed a single open reading frame and an unusually long putative signal sequence. If conversion of the 77K to the 73K monomer entails proteolytic processing cleavage, it must occur at the C- or N- terminus. Antisera to a synthetic peptide to the deduced amino acid sequence at the C-terminus immunoprecipitated both the 73K and 77K forms of DBH from PC12 cells. To examine processing in the ER, full length rat DBH cDNA was generated. DBH mRNA was synthesized by T3 RNA polymerase in vitro, capped and expressed in a cell free system. The mRNA coded for a translation product of about 68K apparent Mr. Translation with pancreatic membranes added co-translationally, also synthesized a band of higher apparent Mr. This band was sensitive to endo H digestion, confirming the role of glycosylation in the modification of DBH. Experiments are being directed to determining if the signal sequence was removed in the *in vitro* product.

326.11

NEUROLEPTIC ACTIVATION OF STRIATAL AROMATIC L-AMINO ACID DECARBOXYLASE (AADC) ACTIVITY IS NOT DUE TO *DE NOVO* PROTEIN SYNTHESIS. M.Y. Zhu^{*}, A.V. Juorio, I. A. Paterson and A.A. Boulton, Neuropsychiatric Research Unit, University of Saskatchewan, Saskatoon, SK, Canada. S7N 0W0.

Decarboxylation of phenylalanine by AADC is the rate limiting step in the synthesis of 2-phenylethylamine (PE), which is stimulated by neuroleptics. Recent experiments have shown that blockade of D1 and D2 receptors by SCH 23390 or pimozide increase AADC activity in the rat striatum whereas D2 receptor blockade increased AADC in the mesolimbic system. The increases were observed within 30 minutes after treatment and lasted for at least 2-4 hours. Analysis of the enzyme kinetics indicated that Vmax increased with little change in the Km. The object of the present study was to test whether the changes in striatal AADC activity induced by DA antagonists is due to *de novo* synthesis of the enzyme. AADC activity was determined in rat striatum homogenates by measuring the amount of DA formed from L-DOPA with HPLC-ED. Using a 2-way ANOVA design, rats were given intraperitoneal injections of vehicle, cycloheximide (10 mg/kg), SCH 23390 (0.1 mg/kg) or pimozide (0.3 mg/kg), 30 minutes prior to death. SCH 23390 and pimozide significantly increased AADC activity in the striatum and increases were unchanged in rats treated with cycloheximide. These findings confirm further that AADC activity in the striatum is increased by D1 and D2 receptor blockers and show that these rapid changes in activity are not due to increases in protein synthesis. Supported by Saskatchewan Health and the Saskatchewan Health Research Board.

ANALYSIS OF PHENYLETHANOLAMINE N-METHYLTRANSFERASE GENE PRODUCTS IN THE ADULT RAT BRAIN AND ADRENAL GLAND. T.C. Wessel, H. Baker and T.H. Joh, Lab. of Molec. Neurobiol., Cornell Univ. Med. Coll., The Burke Medical Research Institute, White Plains, NY 10605.

The enzyme phenylethanolamine N-methyltransferase (PNMT) converts norepinephrine to epinephrine in the brain and adrenal gland. Some uncertainty exists as to the regional expression of the PNMT gene in the developing and adult brain: PNMT has been localized to the anterior olfactory nucleus, mesolimbic system as well as the hypothalamus, in addition to the less controversial sites in the brainstem. We have utilized two polyclonal rabbit antisera to purified bovine adrenal PNMT in conjunction with a 1.0 kb full-length rat PNMT cDNA probe to investigate the distribution of PNMT protein and mRNA in the adult rat brain. Cellular immunohistochemical staining and *in situ* hybridization (ISH) signal could only be detected in the ventrolateral medulla (C1 neurons) and the nucleus tractus solitarius (C2 neurons) in the brainstem; no further rostral structures could be identified. Intraventricular injection of colchicine (150 μ g in 10 μ l) produced more intense immunostaining of the C1 and C2 neurons, while reserpine (10 mg/kg SQ) had a less pronounced effect. These manipulations did not produce significant changes in mRNA levels as measured by grain counts. In contrast, reserpine caused increased PNMT transcription and protein synthesis in the epinephrine cells of the adrenal medulla as demonstrated by increased mRNA levels at 24 hours and enhanced immunoreactivity at 72 hours. Interestingly, reserpine injection elicited rapid c-fos and c-jun expression, within one hour, in the adrenal medulla that had a similar distribution to that of PNMT. In addition, the C1 and C2 neurons also exhibited an induction of these proto-oncogenes after reserpine which implicates a role for the Fos-Jun dimer in adrenergic cell function and possibly in PNMT gene regulation. Supported by MH44043 and MH24285.

EFFECTS OF cAMP AND GLUCOCORTICOID ON DOPAMINE BETA-HYDROXYLASE mRNA LEVEL AND CATECHOLAMINE CONTENT IN BOVINE CHROMAFFIN CELLS. O. Hwang, J.D. Lee^{*} and T.H. Joh. Univ. Ulsan Coll. Med., Seoul, 138-040, Korea and Lab of Mol. Neurobiol., Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605

Dopamine beta-hydroxylase (DBH) catalyzes the conversion of dopamine to norepinephrine in catecholamine neurons and adrenal medulla. Our recent studies on the structure of DBH gene indicates the presence of GRE and CRE in the 5' upstream. In order to investigate the possibility of whether these two cis-acting elements are functional, the effects of cAMP and glucocorticoid on DBH transcription in bovine primary chromaffin cells were examined at the mRNA level, and the contents of norepinephrine and epinephrine were measured.

Treatments with various doses of forskolin and dexamethasone resulted in a small increase of approximately 30 to 50% in DBH mRNA level. On the other hand, the same treatments resulted in dramatic increases (3-4X) in both tyrosine hydroxylase and phenylethanolamine N-methyltransferase mRNA levels, as we have previously reported. Norepinephrine and epinephrine contents increased by 30 to 70%. These results suggest that in the primary culture of bovine chromaffin cells, regulation of DBH gene transcription by cAMP or glucocorticoid is not as dramatic as the other catecholamine biosynthetic enzymes. The results are different from the similar experiments being carried out in PC12 cells, which may be due to cell type or species differences.

326.12

CYCLIC AMP INCREASES DOPA BUT DECREASES DOPAMINE AND DOPA DECARBOXYLASE OF PHEOCHROMOCYTOMA PC12h CELLS. N.Nakanishi, S.Onozawa^{*}, R.Asaumi^{*}, and S.Yamada^{*} Dept. of Biochem., Meikai Univ. Sch. Dent., Sakado, Saitama 350-02, Japan

We found that although NGF rose the levels of tetrahydrobiopterin (BH4; a cofactor of tyrosine hydroxylase), dopa (DO) and dopamine (DA) of PC-12 and PC12h cells, dibutyryl cAMP (dBcAMP), cholera toxin and forskolin increased BH4 and DO but decreased DA in the cells. We then examine the mechanism of cAMP effect on DA. Decrease in cellular DA was observed within 30 min of dBcAMP addition with the concomitant increase in DA in the medium, though dBcAMP did not stimulate the DA secretion from the cells washed with fresh culture medium or saline. *In vivo* and *in vitro* DA producing activities of the cells treated with dBcAMP for 12-24 h were lower than those of the control cells. dBcAMP gave only slight effect on DA degrading activity. These results suggest that cAMP lowers the DA level via two different ways: by increasing the leakage of cytosolic DA which is not yet transported into secretory granules; and by decreasing the dopa decarboxylase activity. (Supported in part by a Grant from the Ministry of Education, Culture and Science of Japan, No.01571027)

PRESENCE OF PNMT-LIKE IMMUNOREACTIVITY IN ASTROCYTES IN PRIMARY CULTURE. M.I.Masana and I.N.Mefford. Sec. Clin. Pharm., ETB, NIMH, Bethesda, MD 20982

The involvement of glia in transmitter-related functions is becoming increasingly well documented. Astrocytes are known to possess binding sites for several neurotransmitters, high affinity uptake systems for virtually all neurotransmitters and catecholamines as well as enzymes involved in the metabolism of neurotransmitters, such as monoamine oxidase, catechol-O-methyltransferase, phenolsulpho-transferase and other methyltransferases. Using astrocytes in primary culture derived from hypothalamus, brainstem and cortex of 2 days old rats, we demonstrated the presence of astrocytes doubled staining for phenylethanolamine N-methyltransferase (PNMT) and the glial fibrillar acidic protein (GFAP). The intensity of the fluorescence for PNMT was higher in hypothalamus-derived astrocytes than astrocytes derived from other regions. The enzymatic activity determined by a radiometric assay, using norepinephrine as substrate, was 17.1 ± 1.5 pmol/h/mg prot (n=6) in astrocytes derived from hypothalamus with no regional-specificity. Only 30% of this activity was blocked by the PNMT inhibitor DCMB (10 μ M) in cortex and brainstem-derived astrocytes and 40% in hypothalamus derived astrocytes. The enzyme seemed to be nonspecific because the activity using tryptamine as substrate was similar to that obtained with norepinephrine in most of the regions except for hypothalamus which was higher (29.9 ± 3.3 pmol/h/mg prot, n=6). These data suggest that astrocytes could be involved, perhaps in early stages of the development, in the methylation of different substrates, including norepinephrine, contributing to the formation of epinephrine in the central nervous system.

326.15

INSULIN STIMULATES ADRENAL PHENYL-ETHANOLAMINE-N-METHYL TRANSFERASE (PNMT) IN VITRO. F.N. Norflus* and J.K. Stewart. Dept. of Biology, Virginia Commonwealth University, Richmond, Virginia 23284-2012.

Previously we showed that insulin induced hypoglycemia rapidly stimulates PNMT activity in the rat adrenal, brain and spinal cord. In this study, adrenal glands from male Sprague Dawley rats were dissected free of fat, partially bisected and perfused for 2 hours in Locke solution continuously equilibrated with 95% O₂/5% CO₂. Half of the adrenals were perfused with solution containing insulin (1U/ml). PNMT activity (mean ± SE) in the 4 insulin treated adrenals was 4106 ± 701 DPM/60 min/adrenal compared to 2639 ± 80 in 5 controls (P ≤ 0.05). These findings show that 2 hours of perfusion with pharmacological levels of insulin increase adrenal PNMT activity and suggest that insulin or insulin-like factors directly stimulate adrenal PNMT. Supported by NIH grant NS26992.

NEURAL CONTROL OF IMMUNE FUNCTION

327.1

CRF mRNA IN THE SPLEEN. F. Aird*, M.B. Prystowsky* and E. Redei. Depts. of Psychiatry and Pathology, University of Pennsylvania, Philadelphia, PA 19104.

CRF is a primary mediator of the neuroendocrine stress response and has also been found to influence immune function directly. CRF receptors, similar to those found in the anterior pituitary and the brain, have been identified in resident macrophages of mouse spleen.

We have detected and identified CRF in the rat spleen by using gel filtration followed by specific RIA. Primary cultures of adherent cells derived from rat spleen secreted immuno- and bioactive CRF in resting state and in response to glucocorticoids. This CRF may be synthesized locally in the spleen, or alternatively, synthesized elsewhere and internalized by spleen cells. In order to distinguish between these two possibilities, we examined whether CRF mRNA is present in the spleen. Total RNA was isolated from adult mouse spleen, reverse transcribed into cDNA and amplified by the polymerase chain reaction using a set of CRF gene-specific oligonucleotide primers. A discrete band corresponding to the amplified CRF product was detected on ethidium bromide stained gels, indicating that CRF is synthesized in the spleen. We suggest that splenic CRF may function as an immunomodulator. Supported by ADAMHA grant AA07389.

327.2

THE DISTRIBUTION AND FUNCTION OF CALCITONIN GENE RELATED PEPTIDE IN THE MOUSE SPLEEN AND THYMUS. K. Bulloch, T. Radojicic*, R. Yu*, J. Hausman*, L. Lenhard* and S. Baird*. Dept. of Psych. and Path. UCSD, San Diego, CA 92093. CGRP nerve fibers and their corresponding receptors have been characterized within the mouse thymus and spleen. In this study, the function of these receptors on immunocytes was evaluated by two *in vitro* immunological assays. Previous anatomical studies demonstrated that two populations of cells and intrathymic nerves were positive for CGRP antibody. No CGRP nerves or cells were observed in the spleen. In contrast, both the spleen and thymus demonstrated binding sites for CGRP. *In vitro* studies show that CGRP significantly suppressed a Con A induced proliferation of both murine thymocytes (by 55%) and splenocytes (by 25%) at 10⁻⁶M. Furthermore, 10⁻⁶M CGRP inhibited proliferation of murine responder cells by 30% in a mixed lymphocyte reaction. These doses are within the physiological range of the Kd for the receptor in both the spleen and thymus (10⁻⁶M). The results of these experiments suggest that the immunological *in vivo* role of CGRP may be to control lymphocyte trafficking and the microenvironment in which these cells are permitted to respond to pathogens. Furthermore, in disorders such as diabetes, aberrant expression of the CGRP gene or its product may contribute to the immune abnormalities reported for this disease. Supported by ONR grant #N0014-89-J-1256 and the Kettering Foundation.

EXPRESSION AND HORMONAL REGULATION OF THE β_2 -ADRENERGIC RECEPTOR GENE IN THE RAT THYMUS. B. Marchetti, M.C. Morale, *P. Paradis, M. Bouvier. Dept. of Pharmacology, Catania Univ., Med. Sch., 95125 Catania, Italy, and Dept. of Biochemistry, Montréal Univ., Québec, Canada.

Sympathetic innervation of the thymus gland constitutes a morphological link in the communication between neuroendocrine and immune cells. The localization of a beta₂-adrenergic receptor (β_2 AR) population in the medulla of the rat thymus, coupled with the marked hormonal modulation of β_2 AR distribution, prompted us to pharmacologically characterize the β_2 AR signalling system of the rat thymus and to examine the hormonal regulation of the β_2 AR gene expression. We report here that the thymic β_2 AR is functionally coupled to the adenylyl cyclase signalling pathway. Northern blot analysis, using a human β_2 AR cDNA as a probe, revealed the presence of a mRNA of 2.3 Kb, consistent with the size of the β_2 AR mRNA found in other rat tissues. Ovariectomy induces a significant decrease in both receptor number and mRNA levels, while oestrogen replacement brings the β_2 AR mRNA levels even higher than those found in control animals, suggesting that the β_2 AR gene expression is under transcriptional control of oestrogens in the rat thymus.

CHANGES IN INTRACELLULAR CALCIUM CONCENTRATION AND MEMBRANE POTENTIAL IN RAT THYMOCYTES IN RESPONSE TO NEUROTRANSMITTERS AND LYMPHOKINES: EXAMINATION OF POSSIBLE MECHANISMS UNDERLYING NEURO-IMMUNE COMMUNICATION. Carolyn B. Lacey¹, Martin W. Wessendorf¹, Robert Elda¹ and Jeffrey L. Barker². ¹Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455 and ²Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

Several neurochemicals have been implicated in the communication between the nervous and immune systems. In the present study we have begun to examine the possible mechanisms by which putative neurotransmitters may function in cellular signal transduction in rat thymocytes. To study the effects of various neurotransmitters on calcium regulation and membrane potential, we utilized the calcium indicator dye, FLUO-3, and the voltage sensitive oxonol dye, DiBAC₄(3), respectively. Single cell suspensions were prepared from rat thymus (100-150g) by mechanical dissociation and resuspended in physiological buffer containing 10µg/ml aprotinin. Changes in fluorescence signals were monitored utilizing a fluorescence spectrophotometer. The addition of substance P and ACTH, in concentrations ranging from 10nM to 1µM, caused an increase in the intracellular Ca²⁺ concentration. Addition of the β -adrenergic agonist, isoproterenol (1µM to 10µM) and the lymphokine, interleukin-2 (IL-2), also independently caused decreases in the Ca²⁺ signal. In preliminary experiments using DiBAC₄(3), an increase in fluorescence with the addition of IL-2 (75-750U/ml) was observed, indicating relative depolarization of the cells. These results indicate possible mechanisms through which the nervous and immune systems interact. Supported by DA 06299, DA 05695, and DA 05466.

NEUTRAL ENDOPEPTIDASE 24.11 INVOLVEMENT IN IMMUNOCYTE ACTIVATION AND INHIBITION. ¹D. Duvaux-Miret*, ²E.M. Smith*, ³T.K. Hughes*, ⁴M.K. Leung, ⁵L. Mallozzi and ⁶G.B. Stefano. Pasteur Institute, 1, rue de la Prof. Calmatte, Lille, France; Depts. ²Psychiatry Behavioral Sci., and ³Microbiology. Univ. TX. Medical Branch at Galveston, TX 77550; ⁴Aging CTR, SUNY/Old Westbury, Old Westbury, NY 11568-0210.

Opioid peptides, a group of transmitter substances have a high degree of phylogenetic conservation, and diverse functions. For example, they have been shown to play a role in immunomodulation in both vertebrates and invertebrates. Furthermore, since we know that neutral endopeptidase 24.11 (enkephalinase; NEP) inhibition potentiates the stimulatory effect of enkephalins, it was of interest to determine if this would hold true for other "neuropeptides". We demonstrate that authentic alpha-MSH, in a dose response manner (peak effect 10^{-7} M), can "deactivate" molluscan hemocytes, that is return them to a round conformation following stimulation by tumor necrosis factor which results in an "active" amoeboid conformation. This was demonstrated using human, *Mytilus*, and *Biomphalaria* immunocytes in an *in vitro* computer assisted cellular assay (American Innovation Image Analysis). Addition of the NEP inhibitor, phosphoramidon (100 nM) potentiated the effect of alpha-MSH (peak 10^{-9} M). Other enzyme inhibitors e.g., captopril, were not as effective as phosphoramidon. Thus, NEP may play a critical role in modulating either signal molecule presentation to the receptor, degradation after receptor activation or both. Furthermore, it appears to be involved with both stimulation and inhibition of cellular conformational changes. Supported by ADAMHA-17138 & 47392

DECREASE IN 3H-DIHYDROALPRENOLOL BINDING SITES ON SPLENIC LYMPHOCYTES OF GENETICALLY EPILEPSY-PRONE (GEPR-9) RATS. J.A. Carr, K.A. Ortiz*, L.L. Paxton*, L.C. Saland, D.D. Savage. Department's of Anatomy and Pharmacology, University of New Mexico, School of Medicine, Albuquerque, New Mexico 87131.

Recent evidence indicates that the GEPR-9 rat exhibits a reduction in plaque-forming cell (PFC) responses after immunization *in vivo* with sheep erythrocytes (Rowland et al., 1991, Life Sci. 48:1821-1826). At present, the cellular events underlying this immunosuppression are not known. Since the neurotransmitter norepinephrine has been shown to act through β -adrenoreceptors to augment antibody responses, we examined β -adrenergic receptors on splenic lymphocyte membranes (SLM) obtained from 100-120 day old GEPR-9 and age-matched, non-epileptic Sprague-Dawley control rats. The antagonist dihydroalprenolol (3H-DHA) was used to label β -adrenergic receptors. Initial experiments in which SLM were incubated with 1 nM 3H-DHA in the presence or absence of 1 μ M l-propranolol revealed a 33% reduction in specific binding of 3H-DHA to SLM from GEPR-9 rats. Subsequent saturation studies of 3H-DHA binding revealed a significant decrease in the maximum number (B_{max}) of 3H-DHA binding sites on SLM from GEPR-9 rats. There was no difference in the mean apparent affinity constants obtained for 3H-DHA binding to SLM from GEPR-9 and control rats. Our results suggest that a deficiency in the expression of lymphocyte β -adrenoreceptors may be a contributing factor to the reduced PFC response seen in GEPR-9 rats. Neuromodulation of IgG secretion from plasma cells in avian lacrimal gland

P.R. Brink and B. Walcott Departments of Physiology and Biophysics and Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

IgG secretion in the avian lacrimal gland can be transiently increased by exposure to neurotransmitters like acetylcholine (carbachol). Gland fragments containing numerous plasma cells exposed to carbachol showed in a 5 fold increase of IgG output for 10-20 minutes. The binding of the muscarinic receptor ligand ANB to sectioned glands indicates that both the acinar cells and plasma cells contain muscarinic receptors. In an effort to determine the nature of the transduction pathway for neurotransmitter stimulated immunoglobulin secretion, the effects of various agents have been tested. Pretreatment of glands with atropine blocks carbachol's stimulatory effects. The presence of Cd²⁺ (1mM) significantly reduces carbachol stimulated IgG release. Forskolin (20 μ M) also inhibits carbachol stimulated IgG release. We have previously demonstrated that plasma cells isolated from avian lacrimal gland contain maxi-K channels (Brink et al., Pflugers Arch. 417). The inhibitory effect of forskolin on IgG secretion is likely to be related to its ability to increase maxi-K channel activity which hyperpolarizes the cells. Hyperpolarization could override a potential forskolin activation of Ca²⁺ channels which, if occurring, should cause an enhancement of secretion. Further we present indirect evidence which suggests that plasma cells have an inward Ca²⁺ current. Our data support the notion that the plasma cells contain receptors which enables them to respond directly to neurotransmitters. It appears that a Ca²⁺ inward current is involved in the transient transmitter stimulated IgG secretion of the plasma cells. These data clearly indicate that a major interaction is possible between the CNS and the immune system. Supported by NIH grant 31299.

EVIDENCE FOR KAPPA OPIOID BINDING SITES ON MURINE LYMPHOMA CELLS. D.M.P. Lawrence and J.M. Bidlack. Department of Pharmacology, University of Rochester Medical Center, Rochester, NY 14642.

The aim of this study was to determine if the murine lymphoma cell line R1.1 possessed opioid binding sites. Membranes prepared from R1.1 cells were resuspended in 50 mM Tris-HCl, pH 7.5. At 25°C, specific (-)[³H]bremazocine binding increased linearly with protein concentration and reached equilibrium by 30 min. Nonspecific binding, which was less than 20% of total binding, was measured by inclusion of 1 μ M naloxone. R1.1 cell membranes bound [³H]bremazocine with a K_d value of 10.6 \pm 0.2 pM and a B_{max} value of 22.5 \pm 1.4 fmol/mg protein. The δ -selective peptides, [D-Pen²,D-Pen⁵]enkephalin and [CI 174,864 at concentrations up to 10 μ M did not inhibit 12 pM [³H]bremazocine binding, while μ M concentrations of the μ -selective opioid [D-Ala²,(Me)Phe⁴,Gly(ol)⁵]enkephalin were needed to inhibit binding. In contrast, the κ -selective ligand U50,488H inhibited [³H]bremazocine binding with an IC₅₀ value in the low nM range. [³H]Bremazocine binding was stereoselectively inhibited by (-)pentazocine, which had an IC₅₀ value in the low nM range, while the (+) isomer was 20 times less effective. [³H]Bremazocine binding was inhibited in a concentration-dependent manner by NaCl at concentrations greater than 10 mM. Thus, R1.1 cells possess high affinity κ opioid binding sites that share many properties with brain κ opioid receptors. These cells will be very useful in the characterization of the molecular and functional properties of κ opioid receptors on lymphocytes. (Supported by USPHS grant DA04355 and DA07232.)

EFFECTS OF KAINIC ACID INDUCED LATERAL SEPTAL AREA AND HIPPOCAMPAL LESIONS ON CELL MEDIATED IMMUNITY IN FEMALE RATS. L. Wetmore J. G. Gartner*, J. Green-Johnson* and D. M. Nance. Depts. of Pathology /Physiology, Univ. of Manitoba, Winnipeg, MB, Canada, R3E 0W3.

Previously, we have shown that kainic acid (KA) lesions of the lateral septal area (LSA) and the hippocampus have inhibitory and facilitatory effects, respectively, on the humoral immune response of female rats. Presently, we report the effects of KA (2.0 μ g/ μ l, 0.25 μ l) induced LSA and hippocampal lesions on cell mediated immune responses of female rats. Animals received either bilateral KA infusions into the LSA or the hippocampus, whereas controls were infused with saline. Two weeks later spleen cells were analyzed for natural killer (NK) cell activity, T cell responsiveness to mitogen (CON A) or specific activation (using a mAb (R73) to the TCR $\alpha\beta$ chain). The results indicate that rats with KA lesions in the LSA have significantly higher NK cell activity, as compared to sham operated controls. There was a trend for T cell responsiveness to CON A to be lower in the LSA lesioned females, relative to controls, but LSA lesions had no effect on specific T cell activation. Lesions of the hippocampal region (CA3 and CA4 fields) did not affect NK cell activity nor T cell reactivity to nonspecific or specific *in vitro* stimulation. These results further demonstrate the importance of LSA-KA sensitive cells in neuro-immunoregulation and indicate that these immune alterations are specific to the class of immune cell being analyzed. Thus, different arms of the immune system are differentially modulated in LSA lesioned female rats. Although the hippocampus is involved in regulation of the humoral immune response, the absence of cell mediated immune alterations in KA hippocampal lesioned rats suggests that the hippocampus may not regulate NK cell activity or splenic T-cell responsiveness. Thus, the LSA is involved in the complex and differential regulation of immune function. Supported by MRC.

ADRENOCORTICOTROPIC HORMONE (ACTH) AND ACTH FRAGMENTS MODIFY PHYTOHEMAGGLUTININ-STIMULATED LYMPHOCYTE PROLIFERATION. T.L. Keadle*, D.W. Horohov* & P.A. Melrose. LSU School Vet. Med., Baton Rouge, LA 70803.

Published results have suggested that immune cell ACTH receptors are distinct from adrenocortical ACTH receptors. The present study tested for effects of ACTH and ACTH fragments on the phytohemagglutinin(PHA) proliferative response of equine lymphocytes in order to determine if carboxy and/or amine terminal fragments would mimic effects of native ACTH. Experiment 1 tested peptide effects on PHA-stimulated peripheral blood mononuclear cells (PBMC) from castrate male (G), experiment 2 tested effects on PHA-stimulated PBMC from intact female (F) and experiment 3 tested effects on PHA-stimulated T lymphocytes(TL) from G. In each experiment, 2 X 10⁶ PBMC or TL cells were incubated with vehicle, PHA, PHA + interleukin(IL)-2 or PHA + variable amounts of peptides. ACTH(A), ACTH₁₋₂₄(A1), ACTH₁₋₁₀(A4) or ACTH₁₋₃₉(A18) were tested at 10⁻⁵, 10⁻⁷, 10⁻⁹ and 10⁻¹¹ M concentrations. Cells were subsequently cultured for 3 days before quantifying incorporation of radiolabeled thymidine. Data were analyzed by ANOVA and means compared using LSD. In experiment 1, 10⁻⁶ M A and A18 both inhibited (P < .01) the PHA response whereas 10⁻⁹ M A stimulated (P < .01) proliferative response and remaining treatments were ineffective. For experiment 2, all A fragments reduced (P < .01) proliferative response at 10⁻⁵-10⁻⁷ M and A reduced (P < .05) proliferation at 10⁻⁹ M. Conversely, the proliferative response of TL was stimulated by 10⁻⁵-10⁻¹¹ M A4 (P < .01) and 10⁻⁷-10⁻¹¹ M A1 (P < .05) whereas 10⁻⁶ M A inhibited (P < .05) proliferation. Results from these experiments suggest that ACTH receptors on PBMC and TL may respond to both carboxy and/or N-terminal ACTH fragments that extend beyond the core tetradecapeptide sequence normally associated with proopiomelanocortin peptide effects on the adrenal cortex. Further work is needed in order to determine whether differences in activity may occur due to binding variations, cell-specific responsiveness and/or multiple receptor classes.

DIURNAL COMPARISON OF ADRENAL STEROID RECEPTOR ACTIVATION IN BRAIN, PITUITARY AND IMMUNE TISSUE. R.L. Spencer, A.H. Miller, S.S. Kang*, M. Stein and B.S. McEwen. Lab. of Neuroendocrinology, The Rockefeller Univ., New York, NY 10021.

We have previously found in the rat a heterogeneity between tissues in the proportion of mineralocorticoid (Type I) and glucocorticoid (Type II) adrenal steroid receptors that are occupied and activated (as estimated by cytosolic receptor binding) under basal and acute stress conditions (Miller et al, *Am J Phys* 259, E405, 1990). In general, we find a greater degree of receptor activation by morning basal and stress levels of glucocorticoids in brain tissue than in pituitary or immune tissue. Since basal levels of corticosterone in the rat are much higher during the evening than the morning, we have compared the in vivo activation of adrenal steroid receptors (basal vs acute stress) during both morning (AM) and evening (PM) conditions. For these studies, male Sprague-Dawley rats (270-330 g) were maintained on either a normal or reversed 12:12 h light-dark cycle with lights on or off at 7AM. Animals were sacrificed between 8 and 9 AM. Rats treated with acute stress were sacrificed immediately after 1 hr of restraint. Diurnal differences in adrenal steroid receptor activation were especially evident in the hippocampus in which the degree of both Type I and Type II receptor activation during PM basal conditions was equivalent to the degree of receptor activation after acute stress in the AM. Acute stress in the PM did not further increase hippocampal receptor activation. In immune tissue, diurnal differences in receptor activation were present in isolated peripheral blood mononuclear cells which exhibited evidence of Type II receptor activation only after acute stress in the PM. These data indicate that the relative level of adrenal steroid receptor activation by basal and stress levels of endogenous steroid may vary depending on the time of day and suggests that the relative contribution of endogenous glucocorticoids to HPA axis negative feedback regulation and immune function may vary accordingly. AUTHENTIC α -, γ -, AND β -ENDORPHIN ARE NOT PRESENT IN HUMAN PERIPHERAL BLOOD LEUKOCYTES.

A.D. van Woudenberg*, J.P.H. Burbach*, D. de Wied*, V.M. Wiegant. Rudolf Magnus Institute, Dept. of Pharmacology, University of Utrecht, Vondellaan 6 3521 GD Utrecht, The Netherlands.

Immunoreactivity (IR) for proopiomelanocortin (POMC) derived peptides has been found in cells of the immune system, in particular when cultured in the presence of stimulatory agents, such as corticotropin releasing factor (CRF) or Newcastle disease virus (NDV). The chemical identity of this IR material has not yet been established. In the present study, endorphin-like IR in extracts of human peripheral blood mononuclear cells (PBMC), freshly isolated or cultured in the presence or absence of Concanavalin A, was analyzed. Fractions of HPLC and gel filtration were analyzed in four region specific RIA systems. Using a RIA system recognizing the midportion of β -endorphin (β E) with each of the three extracts a similar HPLC-profile was observed in which a number of IR-peaks was found. Analysis of the same HPLC fractions in the other RIA systems recognizing the C-terminus of α E, γ E and β E respectively, showed that none of these substances were related to these endorphins. To further investigate the presence of a β E-related peptide, the extracts were digested with Cathepsin D, an enzyme that cleaves the Leu¹⁷-Phe¹⁸ bond in the β E sequence, thereby generating the C-terminus of γ E, which is detectable in the γ E RIA. In none of the HPLC fractions of Cathepsin D treated extracts, however, γ E-IR peaks were detectable, indicating that no β E-like sequence had been present in the extracts. Gel filtration of the extracts showed that the major amount of endorphin-IR, as detected with all four RIA systems, eluted as high molecular weight material. These data indicate that the endorphin-like IR found in human PBMC does not represent authentic α E, γ E or β E or other known forms of these peptides.

MORPHINE ATTENUATES THE ENHANCED METASTATIC EFFECTS OF SURGERY IN RATS G.G. PAGE, S. BEN-ELIYAHU, & J.C. LIEBESKIND Dept. of Psychology, UCLA, Los Angeles, CA 90024.

Pain and stress can inhibit immune function and enhance tumor growth in laboratory animals. We used the MADB106 tumor cell line in which the number of lung metastases is sensitive to natural killer (NK) cell control. Rats were divided into 3 groups, subjected to a standard abdominal surgery under halothane anesthesia, to anesthesia only, or to no treatment. In exp. 1, 5 hours after completion of surgery/anesthesia, all animals were injected with 3×10^5 MADB106 cells. Lungs were taken 21 days later and surface metastases counted. Animals undergoing surgery exhibited significantly more metastases compared to both the anesthesia only and control groups (which did not differ from each other). In exp. 2, blood and spleens were harvested for the in vitro NK cytotoxicity (^{51}Cr release) assay 24 h after surgery. There was significant suppression of NK cytotoxicity in the surgery group compared to the other two groups. We are now finding that analgesic doses of morphine (MS) attenuate the enhanced metastatic effect of surgery in a 2x2 design: surgery vs anesthesia only and MS vs vehicle. MS was administered pre- and postoperatively in saline and a sustained release suspension, respectively. The surgery/MS group has developed fewer metastases than the surgery/vehicle group. Supported by the Oncology Nursing Foundation/Purdue Frederick Research Grant, the UCLA Psychoneuroimmunology Program, and NIH grant NS 07628.

EFFECTS OF CONTINUOUSLY ADMINISTERED NICOTINE AND HALOPERIDOL ON CLASS II MHC, CD4, CD5, AND CD8 MARKERS IN RATS. L.L. Wing, M.A. Coggiano, D.G. Kirch, Y. Shien, R.J. Wyatt and H. Killaga.

Neuropsychiatry Branch, NIMH @ St. Elizabeths, Washington, D.C. 20032.

The incidence of smoking among schizophrenic outpatients was higher than among the general population (88%) (Hughes et al., 1986). Many of these patients are treated with the DA receptor blocker haloperidol decanoate (HAL). The present study examined the change in peripheral blood mononuclear cell populations obtained from rats treated repeatedly with either nicotine (NIC) or HAL, or both.

After 28 days of treatment, animals were sacrificed and trunk bloods collected. Cells were stained for Class II MHC (B-cells, macrophages and T-cells), CD4 (T-helper response), CD5 (T-cells and some B-cells) and CD8 (cytotoxic or suppressor cells). Cell counts were analyzed by flow cytometry (Becton Dickinson FACScan). Chronic NIC resulted in a general suppression of fluorescence of the primary population of Class II MHC and CD5 cells, of a medium population of CD8 cells, and skewed the distribution of CD4 cells. Chronic HAL resulted in an increase in number for the secondary population of CD4 cells, an increase in fluorescence of a secondary population of CD5 cells, but suppression of a medium population of CD8 cells. NIC/HAL resulted in a separation of 3 populations of CD4 cells and an decrease in CD8 cells of medium brightness. Thus, chronic stimulation with a cholinergic agonist or dopaminergic antagonist alters immune responsiveness.

327.14

MORPHINE-INDUCED IMMUNOSUPPRESSION IS NOT MEDIATED BY ACTIVATION OF THE HYPOTHALAMIC-PITUITARY ADRENAL AXIS. L.R. Flores*, K. Gale and B.M. Bayer*. Dept. of Pharmacology, Georgetown Univ. Medical School, Washington D.C., 20007.

These studies investigated the mechanism by which acute morphine administration inhibits peripheral blood lymphocyte proliferation in rats. We have previously reported that morphine (5-25 mg/kg) inhibits Concanavalin A stimulated lymphocyte proliferation in a dose-dependent manner. Maximal inhibition (80%) by morphine occurred with a dose of 10 mg/kg two hours after drug administration. Concurrent with this immunosuppressive effect was a dose-dependent increase in plasma corticosterone concentrations. Therefore, we examined the potential contribution of the hypothalamic-pituitary-adrenal (HPA) axis to the immunosuppressive effects of morphine. In order to assess the role of glucocorticoids, rats were pretreated with the steroid antagonist RU 486 (20 mg/kg) 30 min prior to morphine (10 mg/kg) and were sacrificed two hr later. In the presence or absence of RU 486, significant inhibition of lymphocyte activity occurred with morphine. Furthermore, adrenalectomy failed to attenuate the inhibitory actions of morphine. To examine the potential role of pituitary hormones in the immunosuppressive effect, morphine was administered to hypophysectomized animals. In sham or hypophysectomized animals, morphine (10 mg/kg) was found to maximally inhibit lymphocyte proliferation. These results suggest that neither intact pituitary nor adrenal glands are required for the inhibitory actions of morphine on peripheral blood lymphocytes. Supported by NIDA DA-04358.

327.16

STRESS-INDUCED SYMPATHETIC ACTIVATION SUPPRESSES BLOOD NATURAL KILLER CYTOTOXICITY AND INCREASES METASTATIC SPREAD IN RATS: MEDIATION BY ADRENAL EPINEPHRINE S. Ben-Ellyahu, R. Yirmiya, G. Page, H. Weiner, A. Tan, A. N. Taylor and J. C. Liebeskind Dept. of Psychology, UCLA, Los Angeles, CA 90024

Stress can suppress natural killer (NK) cell activity and increase tumor growth. We have recently provided evidence for a causal relationship between the NK-suppressive and tumorigenic effects of stress using a tumor model in which pulmonary metastases of a syngeneic mammary adenocarcinoma, MADB106, are controlled by NK cells. We now report the involvement of the sympathetic nervous system in mediating these effects. Fischer 344 rats subjected to intermittent forced swimming were compared to nonstressed rats. In both conditions rats were pretreated as follows: injected with the ganglionic blocker, chlorisondamine (3 mg/kg i.p.) or saline; adrenal demedullated (AD) or sham operated (SO); injected with the selective β -2 adrenergic antagonist, butoxamine (25 mg/kg i.p.) or saline. One hour after stress rats were injected i.v. with 3×10^5 MADB106 cells. Surface lung metastases were counted 21 days later. Stress significantly increased number of metastases only in control animals. This increase was markedly attenuated in chlorisondamine treated animals and completely blocked by adrenal demedullation and butoxamine. In a fourth experiment, a whole blood, 4-hour ^{51}Cr release assay against YAC-1 targets was conducted 1 hour after stress on AD and SO rats to assess cytotoxicity per unit volume of blood. Stress markedly suppressed whole blood NK cytotoxic activity in SO but not AD rats. These findings suggest that sympathetic activation, specifically adrenal epinephrine binding to β -2 adrenergic receptors, mediates the suppressive effects of stress on cytotoxic activity in blood and that such effects are reflected in increased metastatic spread. PHOTOPERIOD AFFECTS IMMUNE FUNCTION AND TUMORIGENESIS. Joan M.C. Blom* and Randy J. Nelson. Dept. of Psychology, Johns Hopkins University, Baltimore, MD 21218.

Many animals display seasonal cycles in physiology and behavior. Commonly, seasonal adjustments in energy-coping systems have been studied (e.g., reproduction, thermogenesis, etc). In addition to the energy constraints imposed by winter, the stress of food restriction, low temperatures, and lack of cover may compromise immune function in rodents. Although the direct causes remain obscure, rodents die more frequently during the winter than summer. Because of this strong seasonal selective pressure, we hypothesized that rodents should physiologically anticipate winter and bolster the immune system. We hypothesized that rodents use photoperiodic information to enhance immune function. Deer mice, *Peromyscus maniculatus*, housed for 8 weeks in short days (LD 8:16) have higher white blood counts and leucocyte numbers than mice maintained in long days (LD 16:8). We tested the functional significance of this photoperiodic effect by examining the efficacy of a chemical carcinogen, 9,10-dimethylbenzanthracene (DMBA), in causing mammary gland tumors. Adult female deer mice were injected s.c. either with DMBA dissolved in DMSO (50 mg/kg) or with the vehicle alone. None of the mice maintained in short days developed mammary tumors 8 weeks after treatment. In contrast, 85 % of the animals housed in long days, developed tumors within 3-4 weeks post injection. None of the mice in either daylength developed tumors after DMSO treatment. Injection of DMBA also irritated the skin, resulting in lesions. Short day animals exhibited fewer skin lesions (60 % vs 80 %) as well as accelerated healing of the lesions when compared to long-day animals (18 vs 42 days). The difference in healing rate suggests a photoperiodic effect on cytokine activity. Taken together, these results suggest that day length can influence immune function and that risk of developing mammary tumors in response to a carcinogen is reduced in short day lengths.

MORPHINE-INDUCED IMMUNE ALTERATIONS: DOSE DEPENDENCY AND COMPARTMENT SPECIFICITY. V. J. Watts*, L. A. Dykstra, and D. T. Lysle, Departments of Psychology and Pharmacology, University of North Carolina, Chapel Hill, N.C. 27599

Opioids have been shown to modulate a variety of immune responses in humans and in animals. Examples include altered immune function in heroin users and suppression of immune responses in mice following implantation of controlled release morphine pellets. Given the lack of information about the doses at which these effects occur, the purpose of the present study was to determine whether morphine suppressed immune function in a dose-dependent manner. Morphine was injected subcutaneously into Lewis rats (0.0, 5.0, 10.0, 15.0 and 25.0 mg/Kg). One hour later, the spleen, mesenteric lymph nodes and a sample of peripheral blood were collected. Immune function was assessed by a variety of *in vitro* assays. For splenic lymphocytes, morphine produced a dose-dependent suppression of lymphocyte function as measured by natural killer (NK) cell cytotoxicity, and interleukin 2 (IL-2) production. Additionally, morphine suppressed mitogen-induced proliferation of spleen and blood lymphocytes in a dose-dependent manner. In contrast, the doses of morphine examined here did not alter lymphocyte proliferation or IL-2 production in the mesenteric lymph nodes. Collectively, these results show that morphine's immunomodulatory effects are dose-dependent and compartment-specific. (Supported by UPS grants DA02749, MH46284 and BSRG 2 S07 RR07072.)

327.21

EVIDENCE THAT IMMUNE SUPPRESSION INDUCED BY A CONDITIONED AVERSIVE STIMULUS IS MEDIATED BY BETA-ADRENERGIC RECEPTORS. Linda J. Luecken & Donald T. Lysle. Department of Psychology, University of North Carolina, Chapel Hill, NC 27599-3270

The purpose of our study is to further characterize the immunomodulatory effects of exposure to a conditioned aversive stimulus, (CS). Our research with rats investigated the role of the beta-adrenergic system in this conditioned immunomodulatory effect by administering the non-selective beta-adrenergic antagonist propranolol and the peripherally-acting beta-1 receptor antagonist atenolol prior to exposure to the CS. Both antagonists were found to attenuate the CS-induced immune suppression as measured by the mitogenic response of splenic lymphocytes to ConA, PHA, LPS, and ionomycin/phorbol. Further tests with Atenolol also showed an attenuation of the CS-induced suppression of natural-killer cell activity. These results suggest that immune suppression induced by a CS is mediated by beta-adrenergic activity at peripheral beta-1 receptor sites. (Supported by MH46284)

BETA-ENDORPHIN LEVELS IN PERIPHERAL MONONUCLEAR CELLS OF PRIMARY HEADACHE PATIENTS. P. Sacerdote, B. Manfredi*, M. Leone*, G. Bussone* and A.E. Panerai. Dept. Pharmacology, School of Medicine, Un. of Milano, and Istituto Neurologico "C. Besta", Milano, Italy.

Beta-Endorphin (BE) is synthesized in human peripheral mononuclear cells (PMNC), and it is regulated by some neurotransmitters in a way similar to hypothalamic and pituitary BE. Since in migraine (M) and cluster (CH) headache, plasma and CSF levels of the opioid peptides are deranged, we studied whether also PMNC BE could be altered in this pathology. The levels of the peptide were significantly lower in all the migraine patients studied (60 M without aura, and 27 M with aura) and in the CH patients in remission (17 patients) in comparison to 30 healthy, age and sex matched, controls; no difference was present between controls and episodic tension-type headache (20 cases). In addition a significantly lowered BE lymphocytic levels characterized the CH patients in remission in comparison to M with and without aura patients. These results have been obtained in patients out of attack and free from any prophylaxis since two weeks, so that pain and pharmacological treatments do not account for the observed differences. Our data seem to confirm previous findings showing a central opiateergic dysfunction in migraine and cluster headache and confirm the hypothesis that the lymphocyte can be considered a peripheral window to the brain.

PAVLOVIAN CONDITIONING OF MORPHINE-INDUCED IMMUNE ALTERATIONS. Mary E. Coussons, Linda A. Dykstra, and Donald T. Lysle. Department of Psychology, University of North Carolina, Chapel Hill, NC 27599-3270

Previous work has demonstrated that immune responses are affected by administration of morphine, suggesting interactions between the opiate and immune systems. Additionally, it has been shown that stimuli associated with morphine administration can become conditioned and subsequently elicit opiate-like behavioral effects when presented alone. The purpose of the present investigation was to examine the role of Pavlovian conditioning in morphine-induced alterations in immune function. Lewis rats received pairings of morphine (15mg/Kg) with a distinctive environment. Subsequent exposure to the distinctive environment alone induced morphine-like alterations in immune function including decreased T-cell and B-cell responsiveness to mitogen stimulation, decreased natural killer cell activity, and a reduction in interleukin-2 production. Control procedures showed that these alterations were the result of a conditioning process. These findings provide evidence that conditioning can play a role in opiate-induced alterations of immune function. (Supported by PHS grants DA02749, DA07244, MH46284 and BSRG 2 S07 RR07072.)

327.22

MODULATION OF IMMUNE FUNCTION BY A CONDITIONED AVERSIVE STIMULUS: EVIDENCE FOR MEDIATION BY CENTRAL OPIOID RECEPTORS. Donald T. Lysle, Linda J. Luecken, & Kimberly Maslonekt. Department of Psychology, University of North Carolina, Chapel Hill, NC 27599-3270.

Our research program is designed to characterize the immunomodulatory effect of a conditioned aversive stimulus (CS) in rats. The present study investigated the effect of administration of the opiate-receptor antagonist, naltrexone, on CS-induced immune alterations. The results showed that naltrexone blocked the CS-induced suppression of the mitogenic response of splenic lymphocytes to ConA, PHA, LPS, and ionomycin/phorbol. Naltrexone also blocked the CS-induced suppression of natural-killer cell activity and interleukin-2 production. In contrast, systemic administration of the quaternary form of naltrexone, N-methylnaltrexone, did not block the immunomodulatory effects of the CS. These results indicate that CS-induced opiate activity does not directly affect lymphocytes, but modulates the sympathetic output responsible for the alterations in immune function. (Supported by MH 46284)

RECOMBINANT INTERFERON-ALPHA INHIBITS OPIOID LIGAND BINDING TO BRAIN MEMBRANES. R.A. Menzies, S.E. Rier*, N.R.S. Hall, M.P. O'Grady and J. Oliver*. Depts. of Psychiatry and Medical Microbiology, Univ. of South Florida College of Med., Tampa, FL 33613.

Interferon-alpha (IFN α) may be part of the communication network between the central nervous system (CNS) and the immune system. This cytokine modulates a number of CNS functions such as attenuation of naloxone-precipitated withdrawal symptoms in morphine-dependent rats, cognitive behavior in humans, analgesia, and electrical activity of temperature- and glucose-sensitive neurons. We are testing the hypothesis that IFN α interacts with the CNS via opioid receptors. The ability of recombinant human IFN α (rhIFN α) to alter the binding of various radiolabelled opioid ligands is being assessed in a rat brain membrane preparation. Nonspecific binding is determined in the presence of non-labelled ligands such as levorphanol, naloxone, morphine or [met⁵]enkephalin. Inhibition of ³H-naloxone binding by rhIFN α is dose-dependent from 500-5000 U/ml. K_Ds for naloxone increased from 3.37 nM for controls to 6.9 nM in the presence of 5000 U/ml of rhIFN α . Intermediate K_D values were observed for 1500 and 3000 U/ml. B_{MAX} values did not change. Thus, over this concentration range, rhIFN α behaves as a competitive inhibitor to naloxone. However, only a maximum of 60-70% inhibition was observed. When ³H-[D-al²-D-leu²]enkephalin binding was studied, maximum inhibition was 30% as compared to naloxone. These data support the hypothesis that certain biological properties of IFN α are mediated via opioid systems. This work is supported by ADAMHA (DA05723, DA07245), and USF Research/Creative Scholarship grant (6118-932-RO).

ALTERATIONS IN PERIPHERAL ANTERIOR PITUITARY HORMONES ASSOCIATED WITH IMMUNE FUNCTION AFTER SEVERING ANTERIOR HYPOTHALAMIC AREA (AHA) CONNECTIONS. C.P. Phelps, L.T. Chen*, R.A. Menzies, J. Oliver* and N.R.S. Hall. Dept., of Anat., Psychiatry and Behav. Med. Coll. Med. Univ. So. Fla., Tampa, FL, 33612

Hormonal communications between hypothalamic and immune systems were studied in males after surgical interruption of AHA neural connections. Virus free SD rats (Harlan, 380-400g) maintained under 12:12LD with jugular catheters were habituated to daily handling and sampling arenas. Pre-operative AM and PM blood samples (bs) were drawn for assay of corticosterone (Cort) and prolactin (Prl) by RIA. Groups of rats then received either 1) knife cuts severing anterior ($r=1.5$ mm) and lateral (2.0mm) AHA connections (LFC) 2) sham surgery (Sh) or 3) remained controls (C). Subsequent bs were taken at 3 and 4d intervals over 30d. Hematocrits, WBC counts and presence of bacterial pathogens were monitored. Spleens were removed for assay of 3d lymphocyte response to mitogens (PHA, con A and LPS) and natural killer (NK) activity using YAC-1 cells. Thymus, spleen and LFC locations in brain were examined histologically. LFC group AM Cort levels were significantly elevated vs. Sh at 7 and 14d, whereas PM Prl levels were lower only at 7d. Moreover, Cort and Prl directional changes during most days appeared synchronized, so that parallel changes occurred more frequently. All of the effects were also associated with a significant increase in core body temp ($1.0 \pm 0.17^\circ\text{C}$) during the first 7d. Although Sh was associated with a significant decline in NK activity and lymphocyte response to PHA vs. C, the effects of LFC were diminished compared to C. In conclusion, although LFC of the AHA produces neuroendocrine and immune changes similar to AHA destructive lesions (Phelps, et al., Endo Mtg., 1991), they are less severe in the long term. Supported by MH46808.

MONOAMINE LEVELS IN HYPOTHALAMUS OF 10 DAY OLD RATS WITH ACUTE CYTOMEGALOVIRUS (CMV) INFECTION. M.P. O'Grady, R.A. Menzies, K. Olejar*, S. Spector* and N.R. Hall. Div. of Psychoimmunology, Dept. of Psychiatry, and Dept. of Med. Microbiology & Immunol. #, Univ. of South Florida College of Medicine, Tampa, FL 33613.

During the course of an immune response to a viral or bacterial infection, activity in various neurons and endocrine glands has been demonstrated to be altered. Firing rates in hypothalamic neurons were increased after antigenic stimulation. Cerebral noradrenergic metabolism was stimulated in mice that had been inoculated with Newcastle Disease Virus. Most of the studies have been performed in adult animals. Neonatal mice had elevated corticosteroid levels during acute reovirus type 3 infection which were restored to normal by administration of a thymic extract. In the present experiment, we measured hypothalamic catecholamine and indolamine levels in CMV-infected rat pups.

On the day of birth (Day 0), pups were cross-fostered and redistributed on the basis of birth weight. Test litters were comprised of 5 males and 5 females. On day 1, one group was inoculated with 10⁵ units of CMV. Vehicle-injected and uninjected groups served as controls. On day 10, pups were sacrificed and hypothalami were removed. Norepinephrine, dopamine, epinephrine, serotonin and their catabolites were measured in hypothalamic homogenates by HPLC with electrochemical detection. Data are discussed in terms of brain-immune interaction and the "stress hyporesponsive period." Research was supported by NIDDK 41025.

MORPHINE IMPAIRS MEASURES OF THE IMMUNE SYSTEM IN SPINAL CORD-INJURED RATS. N.R.S. Hall, J.B. Gelderd*, J. Oliver*, R.A. Menzies, S.E. Rier* and M.P. O'Grady. Depts. of Psychiatry and Medical Microbiology, Univ. of South Florida College of Med., Tampa, FL 33613, and Dept. of Anatomy*, Texas A&M Univ., College Station, TX 77843-1114.

Morphine's effects upon the immune system of spinal cord transected rats were studied. Adult male Sprague Dawley rats were anesthetized and a dorsal midline incision was made in the mid-thoracic region. A laminectomy was performed at the T5-T6 vertebral level, and the spinal cord was transected with a scalpel. A 75 mg pellet of morphine was implanted sc at the time of surgery which results in sustained plasma levels in excess of 250 ng/ml. Sham-surgery and unhandled control rats were also included. Seventy-two hours following transection and morphine administration, a significant reduction in thymic weight was observed in the transected morphine-treated rats compared with all other groups ($p < .05$). Reductions in splenic lymphocyte responsiveness to Con-A and LPS were also observed. Spinal levels of IL-1 adjacent to the transection were significantly reduced, but whether this represented an effect of morphine upon glial or monocytic sources of IL-1 is currently being determined. A high incidence of cannibalism was also observed in the transected morphine-treated rats. In other studies in this laboratory using non-transected rats, morphine either enhanced or had no effect upon the immune system depending upon the measure. These combined results suggest that spinal injury creates a microenvironment within which morphine is able to suppress the immune system. These studies were supported in part by grants from ADAMHA (DA05723, DA072450).

EFFECT OF THE CEREBRAL INTERFERON TREATMENT ON THE GLIOMA PROGRESSION IN VIVO. M. Wiranowska**, A. Gonzalvo* #, K.C. Roetzheim**, M. Nolan, L.D. Prockop**. Depts. of Neurology+, Pathology#, Anatomy, Univ. of South FL College of Medicine, Tampa, FL 33612.

This work is based on earlier findings that osmotic blood-brain barrier (BBB) alteration allows cerebral interferon (IFN) entry. The in vivo model of intracerebral mouse glioma G-26, developed in this laboratory was used. G-26 of astrocytic origin is positive for glial fibrillary acidic protein (GFAP). G-26 cells at concentration $3-5 \times 10^7$ cells/ml in 1 μ l were implanted in the right cerebral cortex of C57BL/6 mice (23-25 gm). Histology was done at 4, 7, 14, 21 and 28 days after implant. On day 3 post implant animals were treated once via the right carotid artery with mouse interferon MuIFN α/β (8×10^4 units in 0.1 ml) following injection of 1.6 M Arabinose or infused subcutaneously (sc) for 3 days (osmotic pumps) with MuIFN α/β (8×10^4 units). Their median survival time was compared to nontreated controls. The osmotically altered, MuIFN α/β treated mice (n=11) showed 2.9 days longer survival than nontreated controls (n=14) $p=0.02$ (Student's t-test). Supported by NIH-NINDS grant R01 NS28989.

828.6

CHARACTERIZATION OF MAJOR HISTOCOMPATIBILITY (MHC) PROTEINS AND CELLULAR INFILTRATE IN EXPERIMENTAL AUTOIMMUNE PINEALITIS (EAP). J.D. Kelly*, L.M. Fox*, C.F. Lange*, C. Bouchard*, E.B. Pedersen*, and J.A. McNulty. Depts. of Cell Biology, Neurobiology & Anatomy, Microbiology & Immunology, and Ophthalmology, Loyola Univ. Stritch Sch. of Med., Maywood, IL 60153 and Institute of Neurobiol., Univ. of Aarhus, Denmark.

The pineal gland (PG) lacks a blood-brain barrier and is accessible to both humoral and cellular components of the immune system. Under normal physiological conditions, positive immunocytochemical (ICC) staining was observed for microglia/macrophages (OX42), MHC class II (OX6), MHC Class I (OX18), and lymphocytes (OX1, OX19). An enhanced immune response by EAP was induced in Lewis rats after immunization with Peptide M (an 18 a.a. pathogenic segment of S-Antigen). Rats were immunized with 50 μ g Peptide M in CFA and 20 μ g of pertussis toxin. Control rats were uninjected or injected with CFA and pertussis alone. The autoimmune response in the PG was analyzed by ICC for OX42, OX6, helper T-cells/microglia (W3/25), cytotoxic/suppressor T-cells (OX 8) and astrocytes (GFAP). Compared to controls, PG from immunized rats exhibited enhanced staining for OX42, OX6, W3/25 and OX8. The W3/25+ and OX8+ cells, which represent T-cell infiltrate, were co-localized in specific subcapsular sites within the PG. The OX42+ / OX6+ cells were localized in these same subcapsular sites. OX42+, OX6+ and W3/25+ cells were also distributed throughout the gland. Our findings suggest that MHC class II is expressed on a sub-population of resident microglia and that antigen presentation is an important mechanism of autoimmune processes of EAP. These findings are also consistent with the hypothesized role of the PG as a "gateway" for neuroimmunomodulation. Supported by NSF (BNS 88-01726).

CORTICAL RAT NEURONS SUPPRESS MHC CLASS II INDUCIBILITY IN ASTROCYTES. U. Tontsch*, A. Hermann and H. Wekerle*. Max-Planck-Institut f. Psychiatrie, D-8033 Martinsried.

The normal brain does not express significant levels of MHC antigens. In contrast, *in vivo* after degeneration of local neurons, and *in vitro*, by treatment with gamma-interferon (IFN- γ), glia cells can be readily induced to express MHC class II gene products. Thus, rat recombinant IFN- γ (50 U/ml) applied for 72 hr induced MHC class II in 85% of primary astrocytes as determined by MAB OX6 labeling and FACS analysis.

To investigate the question whether the absence of MHC class II expression is due to mere lack of induction or rather due to active suppressor mechanisms, possibly exerted by neuronal CNS elements, we established a coculture system for astrocytes and cortical neurons. Cortical neurons were isolated from Lewis rat embryos (E14). After 3 days in culture, syngeneic astrocytes (95% GFAP positive), grown on coverslips, were added to the neurons in such a way as to allow direct cell-cell contact (upside down) and were treated with IFN- γ . Highly significant cell-mediated suppression of MHC class II inducibility could be demonstrated. On the contrary there was no downregulatory effect of soluble factors alone (astrocytes added upside up). In addition, the cortical neurons also suppressed MHC class II inducibility in the presence of activated T cells, a physiological source of multiple upregulatory factors. Supported by FWF, Austria, J0464.

INFLUENZA VIRUS AND POLY I:C ENHANCE ANTIVIRAL ACTIVITY IN RABBIT SERA, BUT NOT IN RABBITS TOLERIZED TO THE VIRUS. M. Kimura-Takeuchi, J. A. Majde, L. A. Toth, and J. M. Krueger. Univ. of TN, Memphis, TN 38163, and Off. Naval Res., Arlington, VA 22217*.

We recently found that influenza virus induces non-rapid-eye-movement sleep and fever in a rabbit model. If the virus challenge was repeated 24 h later, animals neither slept more nor febrile. Pretreatment of animals with synthetic double-stranded (ds) RNA, poly I:C, also induced physiological tolerance to the virus. We hypothesized that virally-induced sleep and fever occurred in response to cytokines (probably an interferon, or IFN) induced by viral dsRNA, and that physiological tolerance resulted from the inability of animals to elaborate IFN in response to the second challenge. In this study, we analyzed the serum levels of IFN in virally-challenged rabbits. Male rabbits were injected IV with: 1) influenza virus (20,000 mouse LD₅₀ of A/PR/8/34) twice (at intervals of 24 h), or 2) poly I:C (2.5 ug/kg) followed by the virus 24 h later. Serum samples and colonic temperatures (T_{co}) were taken just before the injection (time 0), 4, and 24 h later. Serum IFN activity was determined in RK-13 cells challenged with vesicular stomatitis virus (Indiana strain). Baseline IFN activity was below detectable levels. Four hours after the first injections of the virus or poly I:C, IFN titers were 351 \pm 179 IU/ml and 2600 \pm 536 IU/ml, respectively, and there was an elevation of T_{co}. Twenty four hours after the injections, antiviral activities returned to baseline. However, a second injection of virus 24 h after either viral or poly I:C challenge failed to induce antiviral activity. In conclusion, poly I:C can simulate the tolerogenic action of whole virus, lending support to the hypothesis that constitutional symptoms such as excess sleep and fever in viral infections are mediated by cytokines with IFN activity triggered by virus-associated dsRNA.

INTRAVENOUS MORPHINE-INDUCED IMMUNOMODULATION & STEROID RELEASE. L.L. Lockwood, L.H. Silbert*, M. Fleshner, J.R. Watkins, M.L. Laudenslager, K.C. Rice, R.J. Weber, & S.E. Maier. Dept Psych,

U CO, Boulder, CO 80309 ¹Lab Med Chem, NIDDK, NIH, Bethesda, MD 20892

Morphine can alter immune function. Use of morphine is widespread and so an understanding of these effects is important. Acute and chronic doses of morphine suppress *in vitro* measures of immune function. However, how accurately *in vitro* immune measures reflect *in vivo* immunocompetence is unknown. Chronic morphine alters *in vivo* function. This is, however, difficult to interpret due to drug tolerance and toxicity. Since *i.v.* morphine is widely used we determined if acute *i.v.* morphine would be immunomodulatory on an *in vivo* immune measure. Sprague Dawley rats were injected *i.p.* with 100ug of antigen, keyhole limpet hemocyanin (KLH), followed immediately by *i.v.* saline or 5, 10, or 15mg/kg doses of morphine sulfate. Blood samples to measure corticosterone were taken 20, 40, 60, and 120 minutes post injection and blood samples to measure antibody (AB) were taken 7, 9, 14, and 21 days post injection. Serum levels of corticosterone were determined using radioimmunoassay (RIA) and serum levels of KLH AB were determined using ELISA. Morphine groups exhibited significant increases in corticosterone levels & significant decreases in anti-KLH AB production. The experiment was repeated in Fischer 344 rats in order to begin to assess generality. Again, morphine produced significant increases in corticosterone & significant decreases in AB production. These results indicate that acute morphine results in immunosuppression as measured by *in vivo* antibody production and that high levels of corticosterone are correlated with these immune system changes. Further studies examining receptor specificity, stereoselectivity, and peripheral vs. central sites of action are being performed. BNS-8088840.

BRAIN-REACTIVE MONOCLONAL AUTOANTIBODIES: PRODUCTION AND CHARACTERIZATION. Ni A. Khin* and S.A. Hoffman. Dept. of Microbiology, Arizona State University, Tempe, AZ 85287.

Brain-reactive autoantibodies (BRAA) have been proposed as a mechanism underlying neuropsychiatric manifestations of systemic lupus erythematosus (NP-SLE). Previous studies in our laboratory have shown a diversity of BRAA in murine models of SLE. In order to detect pathogenic BRAA, it would be useful to have a library of monoclonal BRAA. These autoantibodies could be used for characterization by determining their isotype, the epitope and the location of brain antigens with which they bind, and their functional effects. We recently developed B cell hybridomas secreting monoclonal BRAA. This was done by fusion of splenocytes from autoimmune strains of mice (BXSB, MRL/l) with non-secreting myeloma cells (Sp2/0, Ag14). Monoclonal BRAA in hybridoma supernatant have been detected by their reactivity against integral brain membrane protein (BMP) using the ELISA technique. Moreover, the monoclonal BRAA have been characterized by their binding to BMP that were separated via SDS-polyacrylamide gels and transferred to nitrocellulose. Currently, we have two monoclonal antibodies which react against BMP with apparent molecular weight of 14.7 and 21.3 kD. We are in the process of identifying where these antibodies bind in brain by immunohistochemical staining of brain sections using selected monoclonal BRAA. These studies are designed to identify a subset of pathogenically important BRAA.

RESPONSES OF NEURONES IN DORSAL VAGAL COMPLEX TO GASTROINTESTINAL ANAPHYLAXIS IN THE RAT. RJ HOLLAND*, WR EWART*. GI Science Research Unit, London Hospital Medical College, London. SPON: Brain Research Association

The aim of the present experiments was to develop a model of GI anaphylaxis in the rat, in order to study the effects of anaphylaxis and anaphylactic mediators on the interpretation of afferent activity by the dorsal vagal complex (DVC) *in vivo*. Male Hooded-Lister rats (150 g) were sensitized with an IP injection containing 10 μ g ovalbumin (OA) and 10 mg AIOH in sterile saline. Sham-treated controls were also prepared. Fourteen days later, 0.3 ml of plasma was obtained from all experimental rats and passive cutaneous anaphylaxis (PCA) performed to verify the degree of sensitization. Rats were anesthetized with Equithesin (0.30 ml/100 g IP). The fundus was cannulated and a 2 ml gastric distension was able to be applied. Close arterial injections were able to be given by a cannula placed adjacent to the stomach. Using stainless steel micro-electrodes, extracellular recordings were made from single units in the DVC. Units recorded were either spontaneously active or were evoked by gastric distension. Electrode placement was verified by examination of electrolytic lesion marks. Gastric distension (GD) changed the firing rate in 23 out of 35 units studied; 39% were excited and 61% inhibited. Of the GD sensitive units, both histamine (20 ng IA, n=5) and 5HT (20 ng IA, n=9) produced changes in firing rate. One unit responded to all stimuli tested, with OA (100 μ g intragastric) converted the regular frequency to a 'burst-type' configuration. Compound 48/80 (100 ng IG) modulated the activity in 1 of 3 units tested. Thus, some of the observed effects of anaphylaxis on the GI tract may be attributed to the perturbation of vago-vagal reflex activity in the brainstem.

(+)-PENTAZOCINE AUGMENTS ANTIGEN-SPECIFIC ANTIBODY PRODUCTION TO SHEEP RED BLOOD CELLS AND LIPOPOLYSACCHARIDE *IN VIVO*. D.J.J. Carr, B.R. DeCosta, J.E. Blalock, and K.C. Rice. Dept. Physiology & Biophysics, UAB, Birmingham, AL 35294 and Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

(+)-Pentazocine selective binding sites have recently been described on lymphocytes. (+)-pentazocine modulates lymphocyte proliferation *in vitro* in response to concanavalin A, pokeweed mitogen, and lipopolysaccharide (LPS). We investigated (+)-pentazocine for immunoregulatory characteristics following administration *in vivo*. Female C57Bl/6 mice (n=5) treated with (+)-pentazocine (10mg/kg *i.p.*) following *i.p.* injection of sheep red blood cells (SRBCs; 1x10⁷ cells) showed a significant increase in the production of total (60%) and SRBC-specific (135%) IgM antibody by splenic lymphocytes as determined by ELISA. Mice (n=5) treated with phencyclidine (10mg/kg) following *i.p.* injection of SRBCs showed no apparent change in total or SRBC-specific antibody production by splenic lymphocytes. Mice (n=5/group) treated with (+)-pentazocine (10mg/kg) or phencyclidine (10mg/kg) following *i.p.* injection with LPS (10ug) showed a significant increase in the production of LPS-specific IgG antibody by splenic lymphocytes as determined by ELISA. The data suggest phencyclidine and (+)-pentazocine operate through different pathways in the regulation of the immune system.

328.13

THE ROLES OF SPLENIC SYMPATHETIC NERVES IN THE SUPPRESSION OF CELLULAR IMMUNITY. T. Katafuchi, S. Take*, Y. Kaizuka* and T. Hori. Dept. of Physiology, Kyushu Univ., Fac. of Med., Fukuoka 812 Japan.

We have recently demonstrated that ICV injection of interferon α (IFN α) in rats resulted in a reduction of splenic natural killer (NK) cytotoxicity, which depends on central opioid receptors and intact splenic innervation. In the present study, we further examined the central and peripheral mechanisms of the immunosuppression mediated by the sympathetic nerves.

In urethane- α chloralose anesthetized rats, ICV injection of human recombinant IFN α (1.5×10^3 - 10^4 U/rat) produced a dose-dependent excitation of splenic sympathetic nerve activity, which was blocked by intravenous administration of naloxone. Electrical stimulation of the peripheral cut ends of splenic nerves (0.5mA, 0.5msec, 20Hz) resulted in the suppression of the cytotoxic activity of NK cells in the spleen, which was completely blocked by nadolol (β -antagonist), but not by prazosin (α -antagonist). The results suggest that IFN α -induced suppression of NK cell activity is brought about by the activation of splenic sympathetic nerves through a β -adrenergic receptor mediated process. Furthermore, bilateral stimulation of the preoptic/anterior hypothalamus (POA/AH) suppressed the activity of splenic nerves, while lesioning the POA/AH enhanced it.

These findings suggest that the neuronal network between the POA/AH and the splenic sympathetic nerves may play an important role in the suppression of splenic cellular immunity.

328.15

SPLENIC REDUCTION IN NOREPINEPHRINE IS FOUND IN MRL-LPR/LPR MICE WITH GENERAL ONSET OF LUPUS.

S.M. Breneman, L.A. Moynihan, L.I. Grota, S.Y. Felten. Depts Neurobiology & Anatomy and Psychiatry, Univ. Rochester Sch. Med., Rochester, NY 14642.

The MRL-*lpr/lpr* mouse has been used extensively as a murine model of systemic lupus erythematosus. These mice develop an autoimmune disease characterized by increased anti-DNA titers, arthritis, glomerulonephritis, marked lymphadenopathy and splenomegaly. The increased size in the lymphoid organs is due to an expansion of a subset of T-cells which are CD3+, CD4-, and CD8- (double negative, DN).

Sympathetic involvement in neural communication with the immune system has been examined by our lab in other autoimmune models (arthritis). Norepinephrine was measured in spleen in *lpr/lpr* mice along with their matched controls (congenic MRL +/+) at 3, 8, 12, 16, 20, and 24 weeks of age. At eight weeks the first sign of increasing spleen weight from the expansion of the DN T-cells is evident. At 3 wks of age the animals were not different in concentration (pMoles/g wet weight) or total amount of norepinephrine. At 8 wks, the +/- mice had a greater total amount of NE which increased with age. In contrast a lower total amount of NE was found in *lpr/lpr* mice which was maintained through 24 weeks.

Reduction appears to be specific to lymphoid tissue, as levels of NE in salivary gland were not different between the two strains, although thymus showed a significant reduction in NE after 16 wks. Supported by Grants NIMH R37 MH42076, NIH R01 NS25223.

328.17

ROLE OF THE SYMPATHETIC NERVOUS SYSTEM IN THE MURINE IMMUNE RESPONSE TO INFLUENZA VIRUS INFECTION G. Hermann and J.F. Sheridan. Depts. Med. Micro. Immunology and Oral Biology, Ohio State University, Columbus, Ohio 43210

The murine immune response to influenza virus infection has been well-characterized. It progresses from an inflammatory phase to the induction and recruitment of virus-specific effector cells to the site of infection, i.e., both cell-mediated as well as humoral immunity to the influenza virus. Repetitive restraint stress applied during the course of the infection resulted in a decreased inflammatory response as well as depression of virus-specific cell mediated immunity (Sheridan et al., JN1, 1991).

These experiments sought to examine the role of sympathetic innervation of draining lymph nodes in the development of the immune response to influenza virus infection. Surgical resection of the superior cervical ganglia interrupted sympathetic innervation of the superficial cervical and mediastinal lymph nodes as evidenced by a significant drop in catecholamine content in these tissues. The cell-mediated and humoral responses to the infection in sympathectomized animals were quite comparable to the responses in sham-operated animals. Sympathectomized animals survived beyond day 7 of the influenza infection (N = 27/29), while 6 of the 29 sham-operated animals died as a consequence of infection. Surgically sympathectomized animals appear to have a very efficient immune response to the influenza virus infection. The immunological response of sympathectomized animals subjected to restraint stress and infection are presently being examined.

MECHANISMS OF CENTRAL OPIOIDS-INDUCED SUPPRESSION OF RAT PERIPHERAL CELLULAR IMMUNITY. T. Hori, S. Take*, T. Mori*, Y. Kaizuka*, N. Shimizu* and T. Katafuchi. Dept. of Physiology, Kyushu Univ., Fac. of Med., Fukuoka 812, Japan.

Inescapable stress which produces opioid dependent analgesia is known to enhance the growth of implanted tumor cells and to reduce the cytotoxic activity of splenic natural killer (NK) cells in the rat (J. Immunol. 135, 834S, 1985). To see whether the stress-induced suppression of NK activity is mediated by central action of endogenous opioids, we observed the effects of intracerebroventricular (ICV) injection of β -endorphin and interferon α (IFN α), which is known to act on hypothalamic opioid receptors (Brain Res. 454, 361, 1988), on the splenic NK activity of the Wistar rat by the standard chromium release assay. ICV, but not systemic injection of β -endorphin (10-20 μ g) and recombinant human IFN α (1000-2000 U) produced a dose dependent suppression of splenic NK activity, which was completely blocked by naloxone. The suppression of NK activity was abolished by splenic denervation, but not by adrenalectomy. ICV injection of α -helical CRF reversed the central IFN α -induced suppression of NK activity. ICV injection of CRF (2 μ g/rat) increased the noradrenaline release in the spleen, which was measured by in vivo microdialysis technique. Furthermore, inescapable immobilization stress caused a rapid increase in the noradrenaline release in conjunction with the suppression of splenic NK activity. The results suggest that activation of brain opioid system by inescapable stress activates the CRF neurons, thereby suppressing the cytotoxic activity of NK cells predominantly through splenic sympathetic innervation.

DEVELOPMENT OF SYMPATHETIC INNERVATION OF XENOPUS SPLEEN. K.S. Kinney, S.Y. Felten, and N. Cohen* Univ. of Rochester Sch. of Med. & Dent., Rochester, NY 14642.

In rodent models, the observation of autonomic innervation of lymphoid organs has, in part, been responsible for an awareness of the fact that immune responses can be modulated by neural activity. Extending these observations to non-mammalian species allows us to begin to understand the phylogeny of neural immune interactions, as well as to take advantage of unusual life histories (e.g. metamorphosis) of different species and address questions about the development of such interactions. For these purposes, an anuran amphibian model has a number of advantages, and we have been using the frog *Xenopus laevis* as such a model. The spleen of *Xenopus* undergoes a dramatic change in both lymphoid and neural organization at the time of metamorphic climax. The larval spleen shows no compartmentation into red pulp and white pulp, and lymphoid innervation is absent. At metamorphosis, the spleen becomes compartmentalized, and innervation develops in the lymphopoietic white pulp areas. Blocking metamorphosis via administration of the goitrogen sodium perchlorate, strikingly delays the development of the adult pattern of both compartmentation and innervation, but with time, the adult pattern eventually appears in blocked animals. This suggests that both developmental stage and chronological age are involved in the signaling of change in splenic compartmentation and innervation. We are currently determining the age at which the adult pattern emerges in perchlorate-treated animals. We are also investigating whether there is a causal relationship between innervation and lymphoid compartmentation of the spleen.

THE DEMONSTRATION OF A POSSIBLE LINK FOR NEURAL-IMMUNE SYSTEM INTERACTION IN THE BELUGA WHALE. T.A. Romano, D.L. Felten, J.A. Olschowka and S.Y. Felten. Dept. of Neurobiology and Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642.

Bidirectional communication between the nervous and immune systems has been studied extensively in rodents and primates. Neural-immune interactions were studied in the beluga whale from an evolutionary standpoint, and to investigate the possibility of a nervous-immune system pathway whereby various neurotransmitters and/or neuropeptides released during periods of stress may effect immunocompetence and perhaps result in disease.

The spleen of the beluga was obtained approximately 1-2 hours postmortem, cut into 1 cm³ pieces and placed in 10 mls of 4% paraformaldehyde. Twenty-four hours later, the tissue was frozen, cut at 40 μ m and processed for tyrosine hydroxylase (TH) and neuropeptide-Y (NPY) immunocytochemistry.

Our preliminary results demonstrate both immune compartmentation and innervation of the beluga spleen. TH and NPY positive nerve fibers were found innervating the smooth muscle of the vasculature and trabeculae. Some nerve fibers were seen radiating out from central arteries and entering the periaortic lymphatic sheath, a T cell dependent zone. Furthermore, TH and NPY positive nerve fibers were present along the marginal zone where B lymphocytes and macrophages are abundant.

We have demonstrated an anatomical link between the nervous and immune systems in the beluga whale. This anatomical link provides a pathway whereby various physical and psychological stressors, may alter immune function of marine mammals in the wild or captivity. CATECHOLAMINE MODULATION OF LYMPHOCYTE-ENDOTHELIAL CELL INTERACTIONS. S.L. Carlson and J.P. McGillis, Depts. of Anatomy & Neurobiology and Microbiology & Immunology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084

Lymphocyte migration from the blood into tissues requires interactions between the lymphocytes and the endothelial cells (EC) lining the blood vessels. These interactions are mediated by specific adhesion molecules, eg. homing receptors and LFA-1 on lymphocytes binding to vascular addressins and ICAM-1 on ECs. These adhesion molecules are expressed on ECs in the lymphoid tissues and are induced at sites of inflammation. Catecholamine fibers from the sympathetic nervous system form plexuses around blood vessels and innervate lymphoid tissues. We have hypothesized that catecholamines may modulate the process of lymphocyte binding to ECs and migration into tissues, and thus have examined lymphocyte binding to rat heart-derived EC monolayers *in vitro*. To determine if catecholamines can modulate lymphocyte binding to ECs, the monolayers were incubated with the catecholamine agonist isoproterenol (10 μ M) for 4 hours. Peripheral lymph node derived lymphocytes were subsequently allowed to adhere for 1 hour. The number of adherent cells were counted microscopically after fixing and staining the cultures. Preliminary studies have shown that ECs bind fewer lymphocytes after exposure to isoproterenol compared to untreated ECs. We have confirmed that isoproterenol can signal the ECs by measuring increased cAMP levels in ECs after isoproterenol stimulation. Studies are being conducted to examine other time points and to determine if catecholamines will alter the ability of interleukin-1 to enhance lymphocyte binding to ECs. In addition, the effect of catecholamine pretreatment of the lymphocytes prior to the EC binding assay will be explored. [Supported by Univ. Kentucky Med. Ctr. Research Fund]

RESPONSE OF METABOTROPIC RECEPTORS IN DISCRETE AREAS OF THE BRAIN IN THE LEWIS RAT R. Bernardini, G. Mauceri*, V. D'Agata*, and F. Nicoletti. Institute of Pharmacology, University of Catania School of Medicine, 95125 Catania, Italy.

It has long been known that the hippocampus is as important target for the extrahypothalamic action of adrenal steroids. Hence, we have decided to study how glucocorticoids influence hippocampal neurotransmission.

As an initial step, we have measured the responsiveness of transmitter receptors coupled to polyphosphoinositide (PPI) hydrolysis in hippocampal slices prepared from inbred Lewis (Lew/N) rats, which exhibit a reduced activity in the hypothalamic-pituitary-adrenal (HPA) axis, due to a defect in the biosynthesis and secretion of corticotropin-releasing hormone (CRH).

Stimulation of [³H]-inositolmonophosphate (InsP) formation by norepinephrine (NE) in hippocampal slices was greater in Lewis rats than in histocompatible Fisher rats (F344/N). Stimulation by ibotenic acid (a glutamate receptor agonist) was slightly reduced, whereas stimulation by carbamylcholine (a muscarinic receptor agonist) did not change. The action of NE was also increased in hypothalamic slices from Lewis rats, albeit to a lesser extent. All transmitter receptor agonists stimulated [³H]-InsP formation to the same extent in cortical slices from Lewis or Fisher rats.

These results suggest that a chronic impairment of the HPA axis leads to an increased activity of α_1 -adrenergic receptors coupled to PPI hydrolysis in the hippocampus.

ALTERATIONS OF SPLENIC MACROPHAGE INTERLEUKIN-1 SECRETION AS WELL AS SYMPATHETIC AND NEUROENDOCRINE ACTIVITY FOLLOWING SYSTEMIC INTERLEUKIN-1 β ADMINISTRATION IN RATS. C.A.Y. Friend, L. Janz*, J. Zuo*, J. Green-Johnson*, S. Zalcman, D. Dyck* and A.H. Greenberg*. University of Manitoba, Winnipeg, Canada.

Interleukin-1 (IL-1) appears to activate the hypothalamic-pituitary-adrenal (HPA) axis and to suppress splenic macrophage secretion of IL-1 after intracerebroventricular injection which is dependent upon an intact splenic sympathetic nerve. There is some evidence that IL-1 induced systemically by antigen administration is transported into the brain or enters at the circumventricular organs. The present investigation assessed whether systemic administration of recombinant human interleukin-1 β (rIL-1 β) (100 or 200 ng) would influence (i) splenic sympathetic activity as well as the HPA axis and, (ii) splenic macrophage IL-1 secretion in Sprague-Dawley rats. Two hours following intraperitoneal rIL-1 β administration, marked reductions of splenic macrophage IL-1 secretion were evident at maximal LPS stimulation *in vitro*. Moreover, large decreases in splenic norepinephrine (NE) levels were observed 2 hours post-injection as well as elevated plasma ACTH and corticosterone levels. Taken together, these data suggest changes in splenic sympathetic activity coincidental with suppression of splenic macrophage secretion of IL-1.

KETAMINE ANESTHESIA MODIFIES AGONIST/ANTAGONISTS EFFECTS ON TC IN RATS. Simpson, C.W. and G.E. Resch: Sch. of Basic Life Sciences, Univ. of Missouri-Kansas City, Kansas City, MO 64108-2792

Unanesthetized and unrestrained rats responded to doses of PGE₂ that were 15 orders of magnitude below those of ketamine anesthetized rats (P < .001). These are the lowest doses ever reported for PGE₂ in MAHPOA heat gain sites. The Tc in unanesthetized rats increased (P < .02) following 10[-30] g, but not 10[-33] g or 10[-36] g (P > .48) of PGE₂. In ketamine anesthetized rats Tc values increased following 500X10[-15] g (P < .02), but not at 10[-15] g, 10[-18] g or 10[-21] g (P > .13) of PGE₂. Ketamine anesthetized and unanesthetized rats' Tc responses following PGE₂ were antagonized by the receptor blocker, SC19220 (P < .004). The blockade in unanesthetized rats persisted at 50 min (P < .001) and at 90 min (P < .004), but not at 120 min. Ketamine anesthetized rats showed no PGE₂ Tc responses in SC19220 treated rats vs PGE₂ alone at 50 min (P < .001), or at 90, 120, and 240 min (P < .0001). The lowest effective dose of SC19220 tested in ketamine anesthetized rats was 1X10⁻²⁴g. To test whether this anesthesia induced a similarly persistent blockade with other antagonists, hexamethonium, atropine, and methylergonovine were also tested. They exhibited the same blockade pattern as did SC19220 to their respective agonists. Therefore, the duration of blockade under ketamine appears to be a function of the anesthesia, rather than related to the characteristics of individual antagonists. Antagonists data in the present report suggest that the anesthetized rat may be much more sensitive to antagonist, which may become irreversible while anesthesia persists. These data suggest that the ketamine anesthetized rat might be an important model to investigate agonist/antagonist receptor binding changes at specific brain sites as well as a method to test anesthetic effects on membranes at functionally important brain sites. Supported by AFOSR #87-0297.

EXTRACELLULAR AND INTRACELLULAR RECORDINGS FROM THERMOSENSITIVE NEURONS IN THE RAT DORSAL MOTOR NUCLEUS OF THE VAGUS. H. Muratani*, T. Katafuchi, T. Hori¹ and T. Kosaka² Depts. of Physiology¹ & Anatomy², Kyushu Univ., Fac. of Med., Fukuoka 812 Japan.

Extracellular and intracellular recordings were made from neurons in the rat dorsal motor nucleus of the vagus (DMV) to investigate their thermosensitivity and membrane properties. Fifteen (21%) of 72 DMV neurons recorded extracellularly were warm-sensitive neurons which increase the firing rate to a rise in temperature with thermal coefficients > 0.6 impulses/sec and Q₁₀ > 2 and three (4%) were cold-sensitive neurons which responded with thermal coefficients < 0.5 and Q₁₀ < 0.5. Thermosensitivity was retained during perfusion with low Ca²⁺/high Mg²⁺ solution. Both the warm- and cold-sensitive neurons demonstrated linear and non-linear frequency-temperature response curves. Warm-sensitive neurons showed depolarization with Q₁₀ > 2 during warming, which was associated with a decrease in input resistance. The warming-induced depolarization was abolished in the presence of TTX (5x10⁻⁶M). Cold-sensitive neurons (Q₁₀ < 0.5) depolarized with an increase in input resistance during a fall in temperature. Two current-voltage curves of a warm-sensitive neuron in hyper- and hypothermic ranges crossed at about +20 mV of membrane potential. On the other hand, those of a cold-sensitive neuron did at about -82 mV. These results suggest that the depolarization of warm-sensitive neurons during warming is caused by opening the TTX sensitive Na⁺ channels, while that of cold-sensitive neurons during cooling is induced by closing the K⁺ channels.

329.3

THE HYPOTHERMIZING EFFECT OF INTRAPREOPTICALLY (iPO) MICRODIALYZED NOREPINEPHRINE (NE) IS MEDIATED VIA α_2 -ADRENOCEPTORS. N. Qvan, L. Xin, A.L. Ungar, and C.M. Blatteis, Department of Physiology & Biophysics, University of Tennessee, Memphis, TN 38163

Our previous findings suggested that the hypothermizing action of NE microdialyzed iPO may be mediated by α -adrenergic receptors. To identify the adrenoceptor subtype(s) involved, we microdialyzed into the PO of conscious guinea pigs one of the following adrenergic agonists or antagonists: the α_1 -agonist methoxamine, the α_1 -antagonist prazosin, the α_2 -antagonists yohimbine (YOH) or rauwolscine (RAW), the β_1 -agonist dobutamine, the β_1 -antagonists practolol or atenolol, the β_2 -agonist zintolol, the β_2 -antagonist butoxamine (all dissolved in pyrogen-free saline [PFS] to 1 μ g/ μ l), the α_2 -agonist clonidine (CLO, 0.5, 5 or 10 μ g/ μ l), or NE (10 μ g/ μ l). Other animals received one of the following combinations of drugs: 1 μ g/ μ l YOH+ 0.5 μ g/ μ l CLO, 1 μ g/ μ l RAW+ 0.5 μ g/ μ l CLO, 1 μ g/ μ l YOH+ 10 μ g/ μ l NE, or 1 μ g/ μ l RAW+ 10 μ g/ μ l NE. The core (T_{co}) and ear skin (T_{sk}) temperatures of the animals were monitored throughout the experiments. The α_1 -, β_1 -, and β_2 -agonists and antagonists did not induce significant T_{co} changes. The α_2 -agonist CLO produced dose-dependent T_{co} falls. The α_2 -antagonist YOH and RAW evoked no thermal effect *per se*, but they abolished the T_{co} fall induced by co-dialyzed CLO. The microdialysis of NE evoked, as before, a $-0.7 \pm 0.2^\circ\text{C}$ T_{co} fall which, too, was abolished by co-dialyzed YOH or RAW. No adrenoceptor agonist induced T_{sk} changes. These results indicate that the T_{co} fall induced by iPO microdialyzed NE is due to a reduction in metabolic heat production, mediated by α_2 -adrenoceptors. (Supported by NIH NS22716.)

THERMOSENSITIVE CHARACTERISTICS OF HYPOTHALAMIC NEURONS DETERMINED BY WHOLE-CELL RECORDING. J.D. Griffin* & J.A. Boulant, Physiology Dept., The Ohio State University, Columbus, OH 43210.

Neuronal thermosensitivity was studied by tight-seal, whole-cell recordings in horizontal tissue slices of the rat hypothalamus. Warm sensitive and temperature insensitive neurons were categorized by their firing rate responses to temperature changes. Compared to previous sharp-tip recordings, the whole-cell recorded neurons displayed very high input resistances (i.e., >200 megohms), and several neurons had pacemaker potentials that could be reset by brief injections of depolarizing current. In warm sensitive neurons, the rate of rise of the pacemaker potential was strongly temperature dependent, and these neurons had sharper after-hyperpolarizations compared to the temperature insensitive neurons. In addition, neuronal morphology was determined by intracellular filling with Lucifer Yellow. While temperature insensitive neurons displayed a variety of dendritic patterns with little branching, warm sensitive neurons displayed branching bipolar dendrites projecting laterally and medially. (Supported by NIH grant NS-14644.)

CONTRASTING TEMPERATURE RESPONSES ELICITED FROM BROWN ADIPOSE TISSUE FOLLOWING PREOPTIC STIMULATION. L. Kelly* and C. Bielajew, Dept. of Psychology, University of Ottawa, Ottawa, Canada K1N 6N5.

Cooling of the preoptic hypothalamic area (PO) has been shown to activate neurons in the ventromedial hypothalamus (VMH), and through the VMH, to cause an increase in the thermogenic activity of brown adipose tissue (BAT) (Imai-Matsumura, 1987). We reasoned that those VMH sites responsible for BAT thermogenesis should be synaptically linked to PO thermosensitive cells. As a first step in addressing this hypothesis, we examined the effect of PO stimulation alone on BAT temperature response. Moveable electrodes were implanted in seven male hooded rats, and lowered in 0.16mm increments. BAT temperature was monitored at each stimulated site, with core temperature maintained at 37°C throughout. Stimulation trains comprised 25x300 A square wave cathodal pulses of 100 s duration; trains were cycled in a 500ms on/500ms off pattern for 60s per site. One site in each of two mid-PO descents yielded BAT temperature increases, in contrast to the decrease in brown fat temperature observed with two other descents located in the paraventricular hypothalamic nucleus, and just lateral to that nucleus. Temperature drops ranged from 0.5 to 0.9°C , with a return to baseline in 30 to 120 minutes. Three descents showed no BAT effect; two were found in the medial corticohypothalamic tract and one in the dorsal hypothalamic area.

CHRONIC ADMINISTRATION OF 8-HYDROXY-2-(DI-N-PROPYLAMINO)-TETRALIN (8-OH-DPAT) ALTERS THE HYPERTHERMIC RESPONSE TO HEAT STRESS.

M.O. Thornton, D.A. Armstrong*, S.T. Ahlers, and J.R. Thomas, Naval Medical Research Institute, Bethesda, MD 20889.

A reduction of the hyperthermic response to heat stress is a hallmark of heat acclimation. Since 5-hydroxytryptamine (5HT) appears to be involved in thermoregulation, it is possible that plastic changes in specific serotonin sub-receptor types may mediate heat acclimation. Accordingly, the present study examined whether the development of tolerance to the hypothermic effects of the 5HT_{1A} agonist 8-OH-DPAT administered chronically would alter the response of rats to environmental heat stress. Ten rats were implanted with intra-abdominal telemetry thermistors and a baseline (PRE) hyperthermic response to a heat stress (38°C for 90 min) was obtained. Rats then received daily i.p. injections of 0.5 mg/kg 8-OH-DPAT or equivalent volume of 0.9% saline for 7 consecutive days. Rats were then re-exposed (POST) to the heat as before. Administration of 8-OH-DPAT produced a decrease of 2.0°C in core temperature on day 1 and a decrease of 0.48°C on day 7. In rats given interpolated saline injections, the difference in the magnitude of hyperthermic response between the PRE and POST heat exposures was $+0.1^\circ\text{C}$. In contrast, the group given chronic 8-OH-DPAT showed a slight attenuation of -0.38°C in the hyperthermic response during the second heat exposure which approached significance relative to the saline condition. These results suggest a possible modulatory role of the serotonin 5HT_{1A} sub-receptor in heat acclimation.

329.6

OSMOSENSITIVITY AND THERMOSENSITIVITY OF NEURONS IN RAT MEDIAN PREOPTIC NUCLEUS. K.A. Travis and A.K. Johnson, Depts. of Psychology and Pharmacology, Univ. of Iowa, Iowa City, Iowa, 52242.

The median preoptic MnPO nucleus has been shown to be important in the regulation of blood pressure and body fluids. This study evaluated the sensitivity of ventral MnPO neurons of male Sprague Dawley rats to changes in perfusate osmolality and temperature. *In-vitro* neuronal activity was recorded in midsagittal slices perfused with control (300 mOsm/kg), hyposmotic (280 mOsm/kg) and hyperosmotic (320 mOsm/kg) media.

Of the neurons tested, 28.6% (n=16) were temperature sensitive and 71.4% (n=40) were temperature insensitive. Fourteen of the temperature sensitive and 18 of the temperature insensitive neurons were treated with one or both of the experimental media. The majority of neurons tested in the hyperosmotic solution did not change their firing rate (16/21). The remaining 5 neurons decreased their activity. The majority of neurons tested in the hyposmotic solution were also unresponsive to the treatment (16/23). Five of the 7 neurons which responded to the treatment increased their activity. There was no difference in the proportions of temperature sensitive and temperature insensitive neurons which responded to the osmotic challenges.

INTRASCAPULAR BROWN ADIPOSE TISSUE (IBAT) RESPONSES OF ANESTHETIZED LONG EVANS OR SPRAGUE DAWLEY RATS FOLLOWING CNS ELECTRICAL STIMULATION OR NOREPINEPHRINE INFUSION. J. Thornhill, T. Huxie* and I. Halvorson*, Department of Physiology, University of Saskatchewan, Saskatoon, Saskatchewan Canada S7N 0W0

IBAT temperature, surface and colonic temperature responses were compared in weight-matched Long Evans and Sprague Dawley rats acclimated to 21°C following CNS electrical stimulation (0.5 ms pulses of 100 or 250 μA at 50 Hz for 30 sec) or following intravenous saline or noradrenaline infusion, 50 $\mu\text{g}/\text{kg}$ total dose infused at 100 μl per min for 10 min. These electrical or chemical stimuli were retested following propranolol HCl administration (2.5 mg/kg iv). Rises in IBAT temperature above core occurred in the Long Evans group following either noradrenaline infusion or electrical stimulation into the ventromedial hypothalamic area (VMH) or into a lateral preoptic area (LPA), increases subsequently reduced when retested after propranolol. The only significant increase in IBAT temperature in the Sprague Dawley group occurred following noradrenaline infusion. Taken with previous results these findings suggest further that a strain difference exists between lean Long Evans and Sprague Dawley rats acclimated to 21°C in their thermogenic capacity to evoke IBAT thermogenesis following CNS electrical stimulation.

AMBIENT TEMPERATURE AFFECTS MDP-INDUCED FEVER. W.Th. Perschel² and L. Amini-Sereshki. Department of Adult Health & Illness, School of Nursing and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA. 19104.

In the present preliminary experiments we have studied the effects of ambient temperature (T_a) on the characteristics of a fever induced by Muramyl dipeptide (MDP) in cat. Brain temperature (T_b), subcutaneous temperature (T_s), and electromyogram (EMG) were recorded in two cats at different T_a s of 10, 20 and 30°C. After MDP (25 μ g/kg, i.v.) was injected, T_b started to increase, shivering occurred, and the animal assumed a curled posture. In 13/18 cases the rise in T_b preceded the onset of shivering. After the T_b reached a maximum level ($T_b = 1.24-2.05^\circ\text{C}$), it started to decrease toward the normal level. The time between the injection and the rise in T_b , the onset of shivering, and the time during which T_b increased were affected by T_a , all being shorter at 10° and longer at 30°. There was no correlation between the ambient temperature and delta T_b or delta T_s in these experiments. The present study suggests that the ambient temperature may affect some characteristics of a fever reaction in cats.

SYSTEMIC ENDOTOXIN INDUCES C-FOS GENE EXPRESSION IN MULTIPLE BRAIN REGIONS. S.M. Sagar and K.J. Price*. Neurology Service, VA Medical Center, and Dept. of Neurology, Univ. of California, San Francisco, CA 94143.

To examine the functional neuroanatomy of the febrile response, endotoxin (lipopolysaccharide, LPS) 150 μ g/kg was administered through indwelling femoral vein catheters to adult, male Long Evans rats. Controls received saline vehicle. At varying time intervals, brains were examined for Fos immunostaining with a monoclonal antibody thought to be specific for authentic Fos. LPS induced Fos nuclear immunostaining in many brain regions, including circumventricular organs (organum vasculosum of the lamina terminalis, subfornical organ and area postrema), the anterior hypothalamic area (AV3V), magnocellular neurons of the paraventricular nu. (PVN) and supraoptic nu., arcuate nu., locus coeruleus, nu. tractus solitarius, and the A1 cell group of the ventrolateral medulla. Double label immunocytochemistry demonstrated that, within the magnocellular neurons of the hypothalamus, a greater proportion of oxytocin than vasopressin immunoreactive neurons expressed Fos in response to LPS. In addition, regions that respond non-specifically to stress, including cerebral cortex, central nu. of amygdala and parvocellular neurons of the PVN, also demonstrate Fos immunostaining in response to LPS. The Fos response was seen within 1 hr of LPS injection, peaked at about 3 hr and resolved by 24 hr. These results verify the known regional anatomy of the febrile response and permit the further investigation of that response at the cellular level.

Supported by NS27864 and the VA Medical Research Service.

INTERLEUKIN-1 β RECEPTOR ANTAGONIST BLOCKS THE EFFECTS OF INTERLEUKIN-1 β ON NEURONAL ACTIVITY IN GUINEA PIG PREOPTIC AREA SLICES. L. Xin and C. M. Blatteis. Department of Physiology & Biophysics, University of Tennessee, Memphis, Memphis, TN 38163

Interleukin-1 β (IL-1) is a cytokine that mediates many host defense responses against infection. One of these responses is fever production. The involvement of IL1 in this effect has been repeatedly substantiated by the rise in core temperature it provokes when it is injected systemically or centrally. Consequently, it has been suggested that IL-1 β may be an endogenous pyrogen. The development of fever is generally attended by a decrease in the firing rates (FR) of warm-sensitive (W) neurons and an increase in those of cold-sensitive (C) neurons, particularly in the preoptic area (POA); these neurons are presumed to be the ultimate targets of endogenous pyrogens and to modulate the febrile response. Recently, a human recombinant IL-1 β -receptor antagonist (hrIL-1 β ra) has been cloned and reported to block IL1 β -induced fever and sleep in rabbits. This study was undertaken to investigate whether hrIL-1 β ra may block the effects of hrIL-1 β on the FR of W and C neurons in guinea pig POA slices. hrIL-1 β (500 ng/ml) reduced the FR of 17 W neurons and increased those of 3 C neurons recorded; it had no effect on the FR of 8 thermally insensitive neurons. hrIL-1 β ra (0.5 mg/ml), which had no effect by itself on the FR of all the neurons, blocked the hrIL-1 β -induced FR changes of 16 of the 17 W and of all 3 C neurons when given before the cytokine. These results support the hypothesis, therefore, that IL-1 β may be an endogenous pyrogen acting on POA thermosensitive neurons to induce fever production. (Supported by NIH grant NS-22716.)

329.10

CHARACTERIZATION OF THE PGE1 FEVER RESPONSE IN THE URETHANE ANESTHETIZED RAT. T.J. Malkinson*, W.L. Veale, and K.E. Cooper. Faculty of Medicine University of Calgary, Calgary, Canada. T2N 4N1

In thermoregulatory physiology pharmacological agents are often administered by direct injection into a lateral cerebral ventricle (icv). We have shown that urethane anesthetized (1.5 gm/kg) adult male Wistar rats will respond in a similar manner to the conscious animal to icv PGE1. (Am. J. Physiol. 255:R73-R81, 1988). We thought it to be of interest to examine further this febrile response to icv PGE1.

Analysis of 275 fever responses to 300ng PGE1 showed that the maximum temperature reached fell on a normal distribution. If a second injection of PGE1 is given to the animal after the first fever is completed (180 min) there is no significant difference between the two sequential fevers in the same animal. (n=30 animals). We thought it to be of interest to examine if the rate of icv injection would influence the febrile response. Fifty animals each received two injections of 300 ng PGE1 at various rates ranging from instantaneous to 180 seconds. We found no correlation between the peak of the fever (r=0.03) or time until peak was reached (r=0.07) and the time taken to administer the PGE1 into the LCV.

329.12

BLOCKADE OF FEVER BY INTRAPREOPTICALLY ADMINISTERED SUBSTANCE P ANTAGONIST, BUT NOT INDOMETHACIN. C. M. Blatteis, L. Xin, A. L. Ungar and N. Quan, University of Tennessee, Memphis, TN 38163

Fever is thought to result from as yet not understood actions of pyrogens on thermosensitive neurons in the preoptic area (PO). Prostaglandin E₂ (PGE) is believed to modulate this effect. We showed previously that the integrity of the *organum vasculosum laminae terminalis* (OVL) is necessary for fever induction by blood-borne cytokines and suggested that they may interact with receptors in this site, evoking secondary signals that transduce their messages. These signals could be brain-synthesized cytokines (e.g., interleukin-1 (IL1)) or PGE, or their inducers. In this study, we microdialyzed the cyclooxygenase inhibitor, indomethacin (indo, 10 μ g/ μ l for 5 h at 2 μ l/min), into the PO (iPO) of conscious guinea pigs beginning 2 h before the i.v. injection of *S. enteritidis* lipopolysaccharide (LPS, 2 μ g/kg); or we microinjected iPO the substance P antagonist, [D-Pro², D-Phe⁷, D-Trp⁹]-substance P (antiSP, 20 μ g/ μ g), just before LPS i.v. SP stimulates both IL1 and PGE release from macrophages. Indo reduced the LPS-induced febrile rise (T_{co} \uparrow 1.5°C) by 0.5°C, without affecting its bimodal course; given i.m. (10 mg/kg), it blocked fever completely. AntiSP attenuated the febrile response by 1.3°C and abolished its bimodal pattern. SP (20 μ g/ μ l), microinjected iPO, caused a unimodal 1.5°C T_{co} rise; given i.v. (5 μ g/kg), it killed the animals. These data suggest that PGE probably is not a fever mediator within the PO, and that SP may be a pyrogenic neuromodulator in this site either by acting directly on thermosensitive neurons or by inducing IL1 locally. (Supported by NIH NS 22716.)

329.14

PROSTAGLANDIN E, INDUCED FEVER DURING ESTRUS CYCLE IN THE RAT. S.M. Martin, T.J. Malkinson*, W.L. Veale and Q.J. Pittman. Biology Department, Mt. St. Vincent University, Halifax, NS B3M 2J6 and Neuroscience Research Group, The University of Calgary, Calgary, AB T2N 4N1 Canada.

Fever height and duration in male rats have been shown to be influenced by the peptide arginine vasopressin (AVP) which acts on receptors in the ventral septal area (VSA). The source of this AVP is the bed nucleus of the stria terminalis (BST), a sexually dimorphic nucleus, in which the synthesis of AVP is dependent upon sex hormones. In light of differences in the levels of such hormones in males and females and throughout the various stages of the estrus cycle, we have examined the febrile response to PGE₁ in virgin, female rats.

Anesthetized, Sprague-Dawley rats were implanted with bilateral, intracerebroventricular cannulae for central injection of PGE₁ and abdominal transmitters for constant monitoring of body temperature by telemetry. After recovery from surgery, three doses of PGE₁ (2ng, 20ng, 100ng) were delivered during each of four phases of the estrus cycle, determined from inspection of vaginal smears. The peak fevers evoked for all animals in response to 2, 20, 100 ng PGE₁ were 0.73 \pm 0.08°C; 1.22 \pm 0.11°C; 1.87 \pm 0.12°C, respectively. The fevers were higher than those observed following similar doses of PGE₁ in male rats. Other than the resting body temperature, which was higher during estrus, there was no significant difference in the evoked fevers during the different phases of the estrus cycle. Supported by MRC of Canada and Mt. St. Vincent University.

THE EFFECTS OF IONTOPHORETICALLY APPLIED IL-1 β ON SINGLE UNIT ACTIVITY IN THE BED NUCLEUS OF THE STRIA TERMINALIS (BST).

M.F. Wilkinson*, W.B. Mathieson and O.J. Pittman. Neuroscience Research Group, Dept. Med. Physiology, Univ. of Calgary, Calgary, AB, CANADA, T2N 4N1.

IL-1 β is one of several endogenous pyrogens elaborated by immunologically stimulated phagocytes. IL-1 is also present within the CNS being expressed by neurons as well as glial cells. Nerve terminals containing IL-1 as well as IL-1 binding sites have been detected in the area of the BST. Because the BST has been implicated in the control of fever by virtue of its strong vasopressinergic projection to the ventral septal area (VSA), we sought to investigate the effects of local application of IL-1 β on BST neurons demonstrating electrical connectivity with the VSA. Single unit extracellular voltage recordings were made in the BST of urethane-anesthetized (1.5g/kg, ip) S-D rats. Iontophoresis was performed via a 7 barrel pipette glued to the recording electrode. Stimulation of the VSA, via a bipolar stimulating electrode, was used to elicit antidromic or orthodromic potentials in BST neurons. Of 39 such neurons (all of which were excited by glutamate), 18 units (46%) were excited, 3 (8%) were inhibited and 18 (46%) not affected by IL-1 β . BST neurons orthodromically excited or inhibited by VSA stimulation were most often excited by IL-1 β (67%). In contrast BST neurons antidromically invaded following VSA stimulation were seldom affected by IL-1 β (2/14, 18%). Typically IL-1 β evoked a slow onset (1-5 min) long lasting (> 5min) increase in firing rate. Administration of vehicle solution (PBS, pH 7.4) via a separate barrel of the electrode was without effect in each case. The effect of iontophoretic Na⁺ salicylate was also tested in 7 neurons excited by IL-1 β . In all cases salicylate partially or totally reversed the effects of IL-1 β without affecting basal firing rate on its own. These results indicate that IL-1 β , an endogenous pyrogen and neuroimmunomodulator, has potent excitatory effects on BST neurons, particularly those cells receiving orthodromic input from the VSA.

DESTRUCTION OF DIFFERENT FIBER TRACTS UNDERLIES DEVELOPMENT OF LATERAL HYPOTHALAMIC LESION-INDUCED HYPERTHERMIA AND LOSS OF BOMBESIN-INDUCED HYPOTHERMIA. M.W. Gunion, C.V. Grijalva, Y. Taché, and D. Novin. GRECC, Sepulveda VAMC, Sepulveda, CA 91343; Dept. Psychology and Medicine, U.C.L.A. Los Angeles, CA 90024.

Relative roles of fibers crossing the borders of the lateral hypothalamus (LH) were assessed for involvement in LH lesion-induced hyperthermia and bombesin-induced hypothermia. 24 h food-deprived anesthetized (methohexital, 50 mg/kg ip) male Sprague-Dawley rats (300-370 g) received control surgery or bilateral coronal knife cuts on the anterior or posterior border, or parasagittal knife cuts on the medial or lateral border, of the LH. Surgery was immediately followed by intracisternal injection of bombesin (500 ng/rat) or vehicle (saline, 10 μ l). Rectal temperature was measured just before anesthetization and 2 h after intracisternal injection. Cuts on the anterior border of the LH produced marked hyperthermia (+1.8°C, p < .03) which was attenuated by bombesin (-1.3°C, p < .05). Medial cuts caused marked but nonsignificant (+1.4°C, p = .12) hyperthermia which was also attenuated by bombesin (-2.5°C, p < .02). In contrast, lateral cuts did not produce hyperthermia (-0.2°C, ns) but completely prevented bombesin hypothermia (+0.3°C, ns). Posterior cuts showed moderate nonsignificant (+1.0°C, p = .15) hyperthermia which was moderately and nonsignificantly attenuated by bombesin (-0.6°C, p = .13). LH lesion-induced hyperthermia and bombesin-induced hypothermia primarily involve fibers crossing different borders of the LH, and therefore appear to involve separate thermoregulatory pathways. EFFECTS OF CHRONIC INFUSION OF A VASOPRESSIN ANTAGONIST INTO THE VSA OF THE RAT DURING FEVER INDUCED BY BACTERIAL INFECTION.

R. Cridland and N. Kasting, Dept. of Physiology, University of British Columbia, Vancouver, Canada, V6T 1Z3.

Physiological evidence suggests that arginine-vasopressin (AVP) may function as an endogenous antipyretic. Perfusion of AVP within the ventral septal area (VSA) of the brain reduces the fever induced by bacterial endotoxins or prostaglandin E. The present study examines the effects of chronic infusion of a V1 receptor antagonist into the VSA during fever induced by live bacterial infection. Telemetry was used for continuous measurement of body temperature in the unhandled rat. Saline (0.5 ul/hr) or a V1 antagonist (Manning Compound; 0.5 ug/hr) was infused continuously via osmotic minipumps for 5 days into cannulae implanted in the VSA. On day 2, rats were infected by i.p. injection of bacteria (E.coli). Febrile temperature was higher in rats infused with a V1 receptor antagonist (n=5) compared to those infused with saline (n=6) for 3 days after the bacteria injection, although these increases were only significant in the early evenings of day 3 and 4 (p < 0.05). These results suggest that infusion of a V1 receptor antagonist into the VSA may hinder the recovery of fever during bacterial infection, and they, therefore further support the hypothesis that AVP functions as an endogenous antipyretic.

ELECTRON MICROSCOPIC ANALYSIS OF SEPTAL AREA PROJECTIONS INVOLVED IN FEVER REGULATION. W.B. Mathieson. Dept. Anatomy, Dalhousie Univ., Halifax N.S. Canada.

Growing evidence suggests the ventral septal area (VSA) of the brain is involved in the regulation of febrile body temperature. The VSA contains axon terminals immunoreactive to the neuropeptide, arginine vasopressin as well as vasopressin receptors. Release of endogenous stores of vasopressin, or exogenous application of minute quantities of vasopressin within the VSA, but not the surrounding tissue, attenuate the magnitude of pyrogen-induced fever. Previous anatomical experiments using anterograde tracers placed within the vasopressin-sensitive area demonstrated septal efferent projections to CNS thermoregulatory centers. In the present study, WGA-HRP was pressure-injected (20nl, 2% solution) into the VSA of anesthetized rats. Electron microscopic analysis of labeled axons showed that VSA efferents form synaptic contacts in the lateral habenula, dorsomedial hypothalamus (DMH), arcuate nucleus of the hypothalamus (arc) and the ventral tegmental area (VTA) of the midbrain. HRP-labeled terminals with clear, rounded vesicles formed axo-dendritic, asymmetric synapses in each of the above target areas. In the lateral habenula, efferents with pleomorphic vesicles and symmetric synapses were also observed. Target nuclei for VSA efferents contain neurons that are believed to participate in the control of energy utilization, acute phase reactions and normal thermoregulatory processes. These data suggest neuroanatomical substrates for the central antipyretic actions of vasopressin. (Supported by Dalhousie Medical Research Committee Grant).

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONS: PHYSIOLOGY

330.1

SINGLE-TRIAL DETECTION OF SOMATIC EVOKED MAGNETIC FIELD FROM AN IN VIVO SWINE PREPARATION. Y. C. Okada, A. Lähnenmäki*, S. Kyuhou* & C. Xu*. Center for MEG, V A Medical Center, Albuquerque, NM 87108 and Depts. Neurology & Physiology, Univ. New Mexico Sch. Med., Albuquerque, NM 87131

A high-resolution magnetic field detector (Biomagnetic Technologies) was used to measure the magnetic field from the brain of 3 week-old farm swines (*Sus scrofa*) evoked by transcutaneous stimulation of the snout (10 mA, 0.3 ms). The juvenile swine was anesthetized initially with ketamine (20 mg/kg i.m.) and xylazine (1 mg/kg i.m.), the femoral vein was cannulated for infusion of anesthetics and the dorsal portion of the skull was removed bilaterally. Then, sodium pentobarbital was administered (25 mg/kg i.v.) prior to recording of the somatic evoked field (SEF). The anesthetized animal was placed in a head holder and positioned under the detector. The stimulation produced an SEF predominantly over the somatosensory area of the cortex contralateral to the side of stimulation. The responses over the measurement plane (3 mm above the vertex) were sufficiently strong (as much as 10-20 picotesla) for unaveraged analysis of the SEF (bandwidth = 0.3 to 1 kHz). The field mapping at 200 locations required less than 1.5 hrs. The polarity reversal of the SEF was observed across a distance of 1 cm indicating cortical activity underlying the SEF. The SEF showed activities over a wide area of the cortex extending over 2-3 cm along the anteroposterior and lateromedial directions. The temporal waveform varied across positions over the field plane, indicating the presence of sources activated asynchronously over time, and consisted predominantly of a triphasic waveform with a latency window of 15-50 ms. CURRENT SOURCE DENSITY ANALYSIS OF SOMATOSENSORY EVOKED POTENTIALS IN SENSORIMOTOR CORTEX OF THE MONKEY. N.S. Nicholson, S. Seto*, J.C. Arezzo. Albert Einstein College of Medicine, Bronx, New York, 10461.

The initial cortical components of the somatosensory evoked potential (SEP) provide an important index of the integrity of primary sensory and motor cortical regions. The precise anatomical and physiological generators of these components remain controversial. The present study examines the laminar distribution of SEPs in sensorimotor cortex, along with associated multiple unit activity (MUA) and current source density (CSD). Epidural and intracranial data were collected in awake *Macaca fascicularis*. Stimuli consisted of 100 μ sec square pulses delivered to the median nerve at the wrist. Intracortical recording utilized a multichannel (16) microelectrode with interchannel spacing of 150 μ m.

The earliest "near field" activity detected within somatosensory cortex (SI) consists of a brief current sink localized (based on physiological criteria) to lamina 4. This sink has an onset latency of approximately 6-7 msec which is coincident with the initial MUA burst in SI and subjacent thalamocortical radiations. The pattern of current flow in and around lamina 4 is consistent with early activation of additional localized neural elements. Centered approximately 150-300 μ m above and below this early sink are later and larger sinks. These findings suggest the initial component of the cortical SEP partially reflects the depolarization of thalamocortical terminals and the activation of lamina 4 interneurons, while the later principal cortical positivity (P1) represents the subsequent activation of laminae 3 and 5 pyramidal neurons. 330.3

THE FIRST (SI) AND SECOND (SII) SOMATOSENSORY CORTICES OF ONE HEMISPHERE DO NOT MEDIATE THE IPSILATERAL EVOKED POTENTIAL WITHIN THE SII OF THE OPPOSITE HEMISPHERE IN CAT. G.M. Murray*, H. Zhang*, M. Chan*, E. Low*, and M.J. Rowe*, School of Physiology and Pharmacology, Univ. of NSW, and *Dept. of Prosthetic Dentistry, Univ. of Sydney, Sydney, NSW, Australia.

The SII is said to contain a prominent representation of the ipsilateral body surface. The aim of this investigation was to determine whether the ipsilateral forepaw representation within the SII area depended on the integrity of the forepaw representations within the SI and SII of the opposite hemisphere. Twelve cats were anaesthetised with chloralose and the forepaw representations within the SI and SII of one side were mapped by recording surface potentials evoked by a mechanical step stimulus delivered to the contralateral forepaw; the ipsilateral focus within the SII of the same side as the mechanical stimulus was also mapped. A circular metal cooling block (7-mm diam.) equipped with a Peltier thermal cooling device was positioned over the contralateral forepaw focus within SI and another cooling block was positioned over the contralateral forepaw focus within SII. Cooling of one or other block from 38°C to 8-13°C abolished the evoked potential recorded underneath the cooled block and was evidence for inactivation of the underlying cortical region. Inactivation of either the contralateral SI or SII or both regions simultaneously did not change the latency or amplitude of the ipsilateral potential evoked within the SII on the side of the mechanical stimulus. These data suggest that the forepaw ipsilateral representation within the SII of one hemisphere does not depend on the integrity of the forepaw representations within the SI and SII of the opposite hemisphere. E. Low was supported by the Dental Alumni Society of the University of Sydney; M. Chan was supported by the Australian Dental Research Fund.

COMPARISON OF BARREL CORTEX NEURONAL RESPONSES TO WHISKER STIMULATION IN AWAKE-UNDRUGGED VS URETHANE-ANESTHETIZED RATS. D.J. Simons*, G.E. Carvell*, A.E. Hershey* and D.P. Bryant*, Depts. of Physiology and Physical Therapy, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Multi-unit SMI cortical responses to controlled deflections of individual vibrissae were recorded in hand-held, awake and undrugged rats. Subsequently, the same units were studied after the animal had been anaesthetized with urethane (1.5g/kg). Compared to the awake condition, urethane increased the magnitude of the response evoked both by principal (PW) and by adjacent (Adj) whisker stimulation. The time of the peak response (modal latency) was virtually identical for PW stimulation in awake and urethane conditions. By contrast, in the awake condition Adj modal latency occurred ~2 msec later than the PW response but on average 13 msec later under urethane anaesthesia. The response in the urethane condition may be mediated in part by the slowly depolarizing epsp that has been described *in vitro* following high intensity shocks to layer IV. The physiological conditions in which such circuitry is normally active remains to be determined. Supported by NS19950.

ORGANIZATION AND CONNECTIONS OF SOMATOSENSORY CORTEX IN MONOTREMES. L.A. Krubitzer*, P.R. Manger and J.D. Pettigrew, Vision, Touch and Hearing Research Centre, University of Queensland, Queensland, Australia 4072

The organization of somatosensory cortex was investigated in echidna (*Tachyglossus aculeatus*) using standard microelectrode mapping techniques. With as many as 532 recording sites in a single animal, the detailed somatotopy of cortical fields was readily obtained. In addition, recordings were made in visual and auditory cortex. We describe at least 3 topographically organized fields in the somatosensory cortex of the echidna. The primary somatosensory area, SI, was the largest field with the tail represented most medially, adjacent to visual cortex, and the hindlimb, forelimb and face represented progressively more laterally in the representation. Within SI, the rostral 1 cm of the bill occupied a large amount of cortical space and assumed approximately 1/3 to 1/2 of the entire representation. Rostral to SI, most neurons responded to deep stimulation such as joint manipulation or pressure to body parts. This deep region contained a complete representation of the body surface with a similar medial to lateral organization as SI. We interpret this region to be a separate representation from that of SI. Finally, caudal to SI, a smaller somatosensory field with large receptive fields has been defined. This field is in the approximate location of SII described in other mammals. Like SII, this field contains a complete representation of the contralateral body surface. Embedded within caudal somatosensory cortex was auditory cortex. Within the auditory cortex there were 2 topographically organized fields. Some portions of auditory cortex responded to auditory and somatosensory stimulation, auditory and visual stimulation, or auditory stimulation alone.

Injections of anatomical tracers in SI revealed connections with the ventral posterior nucleus of the thalamus. Major cortical connections were with other portions of SI, with cortex caudal to SI, in the caudal somatosensory field, and with cortex rostral to SI.

330.4

PROPERTIES OF NOCICEPTIVE NEURONS IN THE LATERAL THALAMUS OF THE SQUIRREL MONKEY. A.V. Apkarian*, T. Shi*, R.T. Stevens*, Kt.-D. Kniffki* and C.J. Lodge, Dept. Neurosurgery, SUNY Health Science Center, Syracuse, NY 13210. ¹ Physiol. Institut, Univ. Würzburg, D-8700 Würzburg, Germany.

Few studies have examined nociceptive neurons (NN) in the lateral thalamus of the monkey. The squirrel monkey is ideal for this type of study since it has a large, well defined VPI distinct from VPL and PO. Therefore, this study examines NN in the squirrel monkey lateral thalamus; their frequency and locations relative to spinothalamic terminations (STT) and to cytoarchitectural boundaries.

Five days prior to recordings, animals received unilateral injections of 2% WGA-HRP in the cervical enlargement, using sterile surgery. Recordings were done in anesthetized animals (chloralose and nembutal drip). Responses to adequate somatic stimuli were determined for all isolated units. Recording sites were marked and tissue reacted for HRP.

Nociceptive neurons were found in VPL, VPI and PO. The overall incidence of NN was 17% (46 of 275). This incidence was 30% in VPI and PO and, only 13% in VPL. Most NN in VPL were wide dynamic range type (90%; 18 of 20); while most high threshold type cells were in VPI (7 of 10). Most NN had thermal and mechanical responses, and a small number of these, located at the boundary between VPL and VPI, responded to innocuous cooling. Many NN were located within 200µm of STT terminals (68%, 19 of 28). The receptive fields of NN located in VPL were in continuity, both in size and body location, with surrounding low threshold units; NN with largest receptive fields were located in PO. The results indicate segregation of nociceptive cell types across VPL, VPI and PO, and correspondence between these cells and sites of STT terminations.

330.6

SOMATOSENSORY RECEPTIVE FIELD PROPERTIES OF CORPUS CALLOSUM FIBRES IN THE RACCOON. J.P. Guillemot*, L. Richer*, M. Pitois*, F. Lepore*, Dept. of Kinesiology, UQAM and Dept. of Psychology, Univ. of Montréal, Montréal, Canada.

Corpus Callosum (C.C.) is involved in the interhemispheric transfer of somatosensory information. Previous anatomical experiments in the raccoon have shown that neurons belonging to the cortical somatosensory areas (SI and SII) sent somesthetic information to the other hemisphere through axons crossing at the rostral portion of the C.C. In the present study callosal somesthetic receptive fields (R.F.) were identified and characterized in terms of localization and specific sensory modalities.

Acute recordings were carried out in curarized raccoon using micropipettes electrodes and N₂O:O₂ anaesthesia. The recording site in the rostral C.C. was identified visually using an operating microscope and fibre activity amplified in the conventional manner. R.F.'s were determined using von Frey calibrated hairs, puffs of air, light touch or pressure and passive movement of the limbs.

Results indicated that various functional sub-modalities were represented originating from cutaneous, deep and paciniform receptors. Some neurons also responded to hair and whisker displacements. Moreover, both slowly and rapidly adapting axonic responses were found. R.F.'s were situated in pelvic limb (4%), trunk (45%), head (33%) or thoracic limb (6%) regions. Of the latter 82% concerned the proximal limb areas whereas 18% represented the distal limb or forepaw. These neurons all represented unilateral body parts. In addition, bilateral R.F.'s were found in the face, trunk, thoracic or pelvic limbs.

These results suggest that callosal connections may be associated to different sensory functions such as midline fusion of the two halves of the body or processing of complex sensory discrimination.

330.8

COMPARISON OF RESPONSES ELICITED IN SI AND SII SOMATOSENSORY CORTICES BY MECHANICAL STIMULATION OF THE HAND IN MONKEYS. H. Hämäläinen*, A. Lähteemäki*, K. Reinikainen*, S. Carlson and A. Pertovaara, Depts. Psychol. and Physiol., Univ. Helsinki, Finland.

Recordings of multiple unit activity and electric fields, elicited by mechanical pulses and vibration delivered to the hand, were made from SI and SII cortices of two awake monkeys. In SI the multiple unit responses were quite uniform, well reflected the stimulus features, and were elicited by stimulation of the contralateral hand only. The onset latencies of the responses to mechanical pulses varied between 7-33 ms, and in 90% of the recordings a sustained response corresponding to the duration of the vibratory stimulus was measured.

The multiple unit responses elicited by similar stimuli in SII could be categorized into two groups according to the onset latency of the responses. In group A the onsets of the responses to contralaterally applied pulses varied between 7-28 ms, whereas in group B they varied between 28-113 ms. 66% of the cell groups studied had bilateral receptive areas. The response onsets varied between 47-157 ms to ipsilaterally applied pulses.

In group A the response duration corresponded to the duration of the vibratory stimulus in only 25% of the measurements. However, in group B there was no correspondence between the stimulus and response features.

330.9

SENSORY RESPONSES IN POM, BUT NOT IN VPM, DEPEND ON INPUT FROM THE SI BARREL FIELD CORTEX. M.E. Diamond, M.A. Armstrong-James, M.J. Budway* and F.F. Ebner, Center for Neural Science, Brown University, Providence, RI 02912.

We have shown that POM cells respond to whisker movement at a threefold greater latency than do VPM cells (18.7 ms vs 6.7 ms). The long latency of POM cells raised the question: Is the trigeminal complex providing the main sensory drive to this thalamic nucleus? We speculated that POM may receive its dominant sensory drive via descending projections from barrel field cortex. To test this idea, the response of cells in POM to whisker movement was measured before, during and after reversible suppression of only barrel field cortex in urethane-anesthetized rats. Cortical suppression was achieved by Mg SO₄ or cold ACSF. The criteria for "suppression" were: the ECG trace was nearly flat and all cortical single unit activity was silenced. All POM cells studied during cortical suppression lost their response to whisker stimulation (interquartile range of response suppression: 86-100%). Spontaneous activity was reduced as well. The POM cells recovered their response when cortex recovered from suppression, although this could take > 1 hour. The effect of cortical suppression was significantly ($p < .001$) less pronounced in VPM (interquartile range of response suppression: 15-50%). There was often a slight increase in response latency among VPM cells. We conclude that barrel field cortex provides the dominant sensory drive to POM, but only a modulatory input to VPM. POM participates in a cortico-thalamo-cortical loop whose properties are consistent with a role in enhancing communication between barrel-columns. (Supported by NS-25907)

330.11

DIFFERENTIAL EFFECTS OF GABA_A AND GABA_B RECEPTOR-MEDIATED INHIBITION ON VPM RESPONSES TO SOMATIC STIMULI. S.M. Lee, M.H. Friedberg and F.F. Ebner, Center for Neural Science and Section of Neurobiology, Brown University, Providence, RI 02912

We have shown previously that a kainic acid-induced lesion of the thalamic reticular nucleus in rats leads to an immediate increase in the number of whiskers which elicit responses in a thalamic ventral posteromedial (VPM) neuron from an average of 2.4 to 7.4 whiskers. Here we have assessed the basis for these changes by selectively blocking GABA-mediated inhibition with iontophoretic application of a GABA_A receptor antagonist, bicuculline methiodide (BIC) or GABA_B receptor antagonist, 2-hydroxy-saclofen (2-OH-S).

The effect of BIC (40-83 nA) on vibrissa-evoked responses in VPM was a preferential enhancement in the responses elicited by the vibrissa giving rise to the highest probability response (center RF whisker). The effect of 2-OH-S was nearly the opposite; significant increases in responsiveness to the less effective whiskers in the peripheral areas of the receptive field (surround RF whiskers) were seen with iontophoretic currents ranging between 40 and 80 nA. This enhancement of the SRF following the blockade of GABA_B-mediated inhibition resulted in a 2.3-fold increase in the average RF size of VPM neurons; no statistically significant increase in RF size was seen with BIC.

We conclude from these results that GABA_A receptor-mediated inhibition in VPM regulates the temporal response characteristics of thalamic relay neurons to sensory stimulation. In contrast, GABA_B receptor-mediated inhibition appears to control the effectiveness of late arriving inputs from the trigeminal complex, thereby regulating the efficacy of the sensory stimulus. (grants NS-25907 and NS-13031).

330.13

KINESTHETIC INPUT IN PRIMARY SOMATOSENSORY CORTEX (SI) DURING REACHING MOVEMENTS. M.J.L. Prud'Homme, J.F. Kalaska, Université de Montréal, Montréal, Québec, Canada, H3C 3J7

We studied SI proprioceptive cell activity in a two-dimensional reaching task in order to study the cortical mechanisms of kinesthesia. The task required monkeys to move a manipulandum from a central starting position to 8 peripheral target lights. One hundred and fifty proprioceptive cells were recorded in four monkeys. The majority (90%) of the cells showed continuously-graded changes in activity during arm movements in different directions, centered on a preferred movement direction, which varied from one cell to another. This broad directional tuning activity resembled that recorded in motor and parietal cortex in similar task conditions. Eighty percent (120/150) of the cells showed movement-related activity and 66% showed tonic posture-related activity while the monkey held his arm over peripheral targets. A smaller proportion of the cells (40%, 58/150) also showed directional changes of activity before movement onset, but very few preceded the onset of EMG. External loads applied to the arm in different directions produced continuously graded changes in activity for 50% (25/50) of the cells tested. These loads changed the level of muscle activity but did not alter the handpath or the joint angle changes of the arm during the movements. This indicates that information about both movement kinematics and movement dynamics are represented in an SI cell population implicated in kinesthetic sense. Supported by MRC Group Grant in Neurological Sciences (JFK) and FCAR (MP).

330.10

ANESTHETIC STAGE AS A DETERMINANT OF VPM RECEPTIVE FIELD PROPERTIES IN THE RAT.

Friedberg, M.H., Lee, S.M. and Ebner, F.F., Section of Neurobiology and Center for Neural Science, Providence, RI 02912

Changes in response properties of the thalamic ventral posteromedial (VPM) nucleus were assessed quantitatively at different anesthetic depths under halothane and urethane anesthesia. Fast Fourier transform analysis of electrocorticograms (ECoG) defined the stage of anesthesia while recording unitary responses extracellularly in VPM to controlled deflection of the contralateral vibrissae.

Predictable increases in the dominant ECoG frequency were seen from stage III-4 (1.2 Hz) through III-3 (3-4 Hz) to III-2 (5-7 Hz). Receptive field (RF) size and latency of VPM cells to whisker stimulation increased from stage III-4 to III-1. A sharp increase in RF size and latency occurred from stage III-3 (RF ~2 whiskers, latency ~7 ms) to stage III-2 (RF ~6 whiskers, latency ~11 ms).

Transecting the axons of Spinal Trigeminal Interpolaris neurons altered VPM RFs. RFs of >3 whiskers disappeared in all VPM neurons after disconnecting the interpolaris input. In addition, the changes in the response properties seen at different anesthetic depths were abolished after interpolaris pathway transection.

We conclude that the nucleus principalis projection mediates the one-to-one correspondence between a VPM cell and its center RF whisker. In contrast, the interpolaris input to VPM is responsible for transmitting a different component of sensory information; characterized by large RF, long response latency, and low response magnitude and probability which can be observed in VPM neurons under light anesthesia and probably in the awake animal. (grants NS-25907 and NS-13031)

330.12

INDUCTION OF HIGH FREQUENCY ACTIVITY IN THE SOMATOSENSORY THALAMUS OF RATS RESULTS IN LONG-TERM POTENTIATION OF RESPONSES IN SI CORTEX *IN VIVO*.

F.F. Ebner and S.M. Lee, Center for Neural Science, Brown University, Providence, RI 02912.

We have previously shown that high-frequency (HF) discharge occurs in rat thalamic (VPM) neurons when GABA-mediated inhibition is blocked using bicuculline methiodide (BIC). Here, we begin to characterize the ability of this HF thalamic activity to alter the responsiveness of barrel field cortical neurons to sensory stimulation.

Computer controlled whisker stimulus-single unit responses were measured simultaneously in VPM and in barrel field neurons. Highly cross-correlated responses of these functionally-linked units to 10 msec deflections of a vibrissa were measured using a PSTH to establish a baseline level of response. Baseline was followed by the induction of HF activity in VPM (conditioning stimulus) by two methods: i) direct electrical stimulation of the thalamus or ii) whisker stimulation during thalamic BIC disinhibition. Both methods produced a conditioning paradigm of 4-spikes "bursts" of high-frequency activity (50-100 Hz) with an interburst frequency of 7 Hz.

In 8 out of 9 cases following the CS, the response of cortical neurons to single vibrissa test stimuli increased by 37 - 62% over baseline values which persisted for as long as one hour. This enhancement of the cortical response was not accompanied by increased thalamic responses, suggesting that the potentiation was specific to the thalamocortical synapse. (NIH grants #NS13031 and NS25907)

330.14

RESPONSES TO GROOVE WIDTH, FORCE AND VELOCITY IN SOMATOSENSORY CORTICAL AREAS I (SI) & II (SII), & THALAMIC VPL NUCLEUS OF MONKEYS DURING ACTIVE TOUCH OF TEXTURED SURFACES. R. Sinclair and H. Burton, Department of Anatomy & Neurobiology, Washington University Sch. Med., St. Louis, MO 63110. (supported by NIDCD 00096)

Recordings were made from 164 SI, 150 SII, and 35 VPL neurons in 2 *M. mulatta* trained to stroke their fingertips over pairs of horizontal gratings. Downward applied force (F) and velocity (V) of stroke were measured. Groove width (Gw) varied from 500-2900 μm. Ridge width was constant at 250 μm. Responses proportional to Gw were previously reported in all 3 areas. Based on ANOVA and correlation analyses, all VPL cells responding to Gw were also affected by F and V, like peripheral afferent fibers. Independent responses to Gw or F were seen in SI and SII, and thus may result from cortical processing. Preliminary analysis indicates a larger proportion of SII than SI cells independently responded to Gw. Activity in one VPL neuron was proportional to F independent of Gw or V. F independent responses were previously reported as most frequent in SI area 1 SAs (slowly adapting). There were no obvious SA vs RA (rapidly adapting) distinctions in SII or VPL. Results suggest that an independent cortical representation of Gw may underlie perceptual constancy of grating roughness. Independent sensory representation of force applied during active touch may arise from subcortical processing.

330.15

PRIMARY SOMATOSENSORY CORTICAL (SI) UNITARY RESPONSES TO ACTIVE AND PASSIVE TOUCH. C.E. Chapman and S.A. Ageranioti-Bélanger. Centre de recherche en sciences neurologiques, Université de Montréal, Québec, Canada H3C 3J7.

Previous studies have shown that the transmission of cutaneous inputs to SI cortex is decreased, or gated, during movement, at least in situations in which the test signal has no relevance to the performance of the motor task. It is not known if behaviourally significant inputs are subject to the same controls. The present experiments were designed to test the latter hypothesis, comparing SI unitary responses to differently textured surfaces (smooth or smooth/rough) explored using either active touch (monkey actively moves digits, scanning the tips over the surface presented) or passive touch (monkey immobile, surface displaced passively under digit tips). The animal indicated the surface texture encountered in a trial by pushing or pulling a lever with the opposite arm. Of 76 units with cutaneous receptive fields on the digit tips contacting the surfaces (2 hemispheres in 1 monkey), 52 discharged differently over the rough and smooth surfaces. 44% of these showed a clear texture-related response with passive touch but *not* with active touch, suggesting that even when inputs are relevant to an animal they are subject to gating controls. Only 10% signalled texture during active, and not passive, touch. The remaining 46% signalled texture during both active and passive touch, but the texture-related response was often obscured during active touch. It is concluded that most cutaneous signals to SI cortex, relevant and irrelevant, are subject to gating controls during movement. Supported by the Canadian MRC and the FRSQ.

NEURAL CODING OF TACTILE ROUGHNESS: SUBJECTIVE ROUGHNESS IS RELATED TO SPATIAL VARIATION IN FIRING RATE. C.E. Connor, S.S. Hsiao, and K.O. Johnson. Bard Laboratories, Dept. Neuroscience, The Johns Hopkins University Sch. of Medicine, Baltimore, MD, 21205.

Plastic surfaces containing embossed dot patterns were used as texture stimuli in combined psychophysical and neurophysiological experiments. Psychophysical subjects scanned the distal pad of the index finger across the surfaces and reported the subjective magnitude of surface roughness. In neurophysiological experiments, the surfaces were scanned across the receptive fields of cutaneous mechanoreceptor afferents while recording spike activity. The two data sets were compared in an attempt to ascertain the neural code for tactile roughness.

Previous work had shown that the sensation of roughness may be related to temporal or spatial firing rate variation in slowly-adapting (SA) Merkel's and rapidly-adapting (RA) Meissner's afferents (C.E. Connor et al., J. Neurosci. 10: 3823-3836, 1990). In this study we measured temporal variation in neural responses by convolving neural records with 1-dimensional gabor filters. Spatial variation was measured by convolution with 2-dimensional gabor filters and 2-dimensional difference of gaussian (DOG) filters. Gabor filters effectively measure variation in one direction at a time while DOG filters measure variation in all directions simultaneously. The periods and sizes of the filters were varied as parameters in the analysis. Temporal variation in SA responses was correlated with subjective roughness for some but not all of the texture patterns studied. Spatial variation in SA responses was closely correlated with subjective roughness for all patterns studied. The correlation was particularly strong for spatial variation as measured by 2-dimensional gabor filters, and somewhat weaker for spatial variation measured by DOG filters. Spatial variation in RA responses was somewhat correlated with subjective roughness for all stimulus patterns. Supported by NIH grant NS18787.

APPROXIMATING THE PROCESSING FUNCTION OF SINGLE UNITS IN SI CORTEX USING NEURAL NETWORK MODELS. I.A. Twombly*, K.O. Johnson, S.S. Hsiao. Bard Laboratories, Dept. Neuroscience, Johns Hopkins Univ. Sch. Med., 725 N. Wolfe St., Baltimore MD 21205

Feedforward neural networks were used to model the response properties of neurons in SI cortex of macaca mulatta. The input layer of the networks was a 2-dimensional array analogous to an array of mechanoreceptive afferents on a distal phalanx. The output layer of the network was a single unit analogous to an area 3b neuron. Models were constructed utilizing both direct convergence from the input array to the output unit and convergence from the input array through a layer of intermediate units to the output unit.

Neurophysiological data from experiments using embossed letters as stimuli were used to adjust the connection weights. Impulse rates from peripheral afferents were fed into the input layer of a network, and the output was compared to the impulse rates recorded from single units in area 3b. A least squares fit to the neural responses evoked by the letters A-M was used to produce the optimal network weights. The network responses to the letters N-Z provided an indication of the ability of the network to reproduce responses that it was not trained to match.

Linear solutions were sought using a 2-layer network with a linear output function. These linear networks were unable to reproduce many of the key features of the neuronal responses. A simple nonlinear solution using a 2-layer network with a positive linear output function also failed to reproduce many of the key features of the neuronal response. A more complex nonlinear solution was sought using a three layer network with positive linear output functions at both the intermediate and output layers. This architecture proved capable of reproducing the cortical responses quite well, suggesting that many area 3b neurons are operating in their nonlinear ranges when processing complex stimuli such as scanned letters.

330.16

THE EFFECT OF ATTENTION ON THE RESPONSES OF NEURONS IN THE SECOND SOMATOSENSORY CORTEX. S.S. Hsiao, D.M. O'Shaughnessy*, K.O. Johnson. Bard Laboratories, Dept. Neuroscience, The Johns Hopkins University Sch. Medicine, Baltimore, MD, 21205.

The effects of attention on neurons in the secondary somatosensory cortex (SII) were studied in a Macaque monkey trained to perform both a tactile letter discrimination task and a visual detection task. The tactile letter discrimination task required the animal to match one of six embossed letters (ALXPHO) scanning across his fingertips (scanning velocity = 20 mm/sec) with a letter presented visually to him on a screen. The visual detection task required the animal to attend to 3 lights on a screen and to detect when one of the lights dimmed. During the recording sessions the embossed letters were continuously scanned across a neuron's receptive field while the monkey was required to switch back and forth between the visual and tactile tasks.

This study investigates the effects of attention while controlling for other behavioral effects. Since both tasks required the animal to maintain a constant state of arousal and both tasks used the same reward switch, any differences in neural responses can be attributed to differences in attentional focus required to perform the tasks.

The results showed that the task had a significant effect on the responses of neurons in area SII. Although the effect varied between neurons, the general result was that SII neurons were more responsive when the animal was required to identify the letters tactually. In addition there were significant differences in the spatiotemporal spread of the responses. These results suggest that the animals attentive state may play a role in determining the form of representation at the level of SII cortex.

330.18

SPATIAL STRUCTURE OF PRIMARY AFFERENT RECEPTIVE FIELDS IN THE SOMATOSENSORY SYSTEM. F. Vega Bermudez, K.O. Johnson. Dept. of Neuroscience, Johns Hopkins Sch. Med. Baltimore MD 21205.

A new tactile stimulator with multiple, independently controlled probes has been developed to study the spatiotemporal responses of somatosensory neurons. Responses to multi-probe stimuli are studied in peripheral afferents.

The tactile stimulator comprises seven linear motors that drive seven probes (0.5 mm diam) arranged in a hexagonal rosette (1.0 mm spacings), which is embedded within a large hexagonal array of static probes. The entire array is mounted on a three-axis translation stage allowing movement to different receptive field sites. Four stimulus sets were used to study the receptive fields: i) single probe stimuli were used to map receptive fields; ii) dual probe stimuli were used to study interactions between two probes; iii) multiple probe stimuli were used to study responses to stimuli of increasing complexity; iv) the effect of contact indentation between the array and the skin was studied by varying the baseline indentation.

The receptive fields of RA and SA1 afferents vary in shape but are generally round or oval with eccentric hot spots and field borders that are very sharp. RA field sizes are more sensitive to indentation magnitude than SA1 field sizes; at the larger intensities RA fields are larger than SA1 fields. Neither the response magnitudes nor the spatial structure of the receptive fields were affected by baseline indentation, which suggests that primary afferent responses depend on relative rather than absolute indentation magnitudes. In both afferent types, responses to two probes presented simultaneously evoked less impulses than the maximum response to either of the probes presented alone. Accordingly, the evoked response declines monotonically with increasing numbers of active probes. At the hot spot the numbers of action potentials evoked by seven probes are 27% (SA1's) and 47% (RA's) of the numbers evoked by a single probe.

The most probable mechanism for the peripheral "surround suppression" is based on skin mechanics as additional probes relieve the strain at the hot spot. These suppressive effects in primary afferent responses must be taken into account when assessing responses of cortical neurons to complex stimuli.

331.1

MECHANISMS OF COMPENSATORY PLASTICITY OF THE BRAIN AFTER CORTEX AND MIDBRAIN DAMAGE. M.S. Sinyava, Lab. Physiology of reception, Pavlov Institute of Physiology of the Acad. Sci. of the USSR, Leningrad, 199034, USSR.

The compensatory processes in S₁ area of the cortex were studied on the both operated and non-operated hemispheres after one-sided brain damage. We used electrical stimulation of visceral and somatic nerves. In cats after brain damage at the midbrain level on the operated side the decrease of responding cells could be observed 2-10 hours after the operation. This process resulted in the full blockade of neuronal activity. The neurons with bilateral sensitivity occur on the non-operated side 8-10 months after the operation. The amount of active neurons increases to 80% in the cortex of the non-operated side. Compensatory process in the cortex of the non-operated side becomes similar to that in cats with brain damage at the cortical level. Earlier we showed the bilateralization of neuronal sensitivity after the damage at the cortical level. We supposed that there was a general principle of compensatory reorganization in S₁ area after one-sided damage either at cortex or midbrain levels.

331.3

REVERSIBLE CHANGES OF THE RECEPTIVE FIELDS OF DCN, VPL THALAMIC AND SI CORTICAL NEURONS FOLLOWING PERIPHERAL APPLICATION OF LIDOCAINE H.-C. Shin, S.A. Raymond, G.R. Strichartz Anesthesia Research Labs, Brigham & Women's Hospital, Harvard Medical School, Boston, MA, 02115.

Because the outcome of local anesthesia (LA) in the periphery is contingent on the functional effects induced in the CNS by the block, it is important to characterize the changes in CNS responsiveness caused by peripheral LA. Single or multiple units from neurons in brainstem dorsal column nuclei (DCN, n=8), ventroposterolateral (VPL, n=15) thalamus, and primary somatosensory (SI, n=16) cortex were recorded to examine the response of the cutaneous dorsal column-lemniscal somatosensory pathway to LA application to the distal extremities of anesthetized rats (n=12, 300-400g, 50-60mg/kg Na pentobarbital, i.p.). After determining stable receptive fields (RFs) for 10-50 min, lidocaine (L: 1-5ul, 0.01-1.0M) was injected subcutaneously to either the original RF or the homotopical area on the opposite side and subsequent changes of the RF were monitored. Nine of 12 SI cortical units showed a reversible block of original RF with 0.1 & 1.0M L and expansion of RF to neighbouring area of the forepaw (FP, initial expansion: 1-15 min, maximum expansion: 8-27 min, recovery: 17-62 min). Two SI units showed only abolition of original RFs. One SI unit did not exhibit any change after injection of 0.01M L. Four other SI units showed temporary expansion of RFs after injection of L at ipsilateral (Ipsi.) homotopical FP without losing original RFs. Eight of 11 VPL units also showed loss of original RFs and expansion of RFs to neighbour after contralateral (Cont.) LA (0.1 & 1.0M L). Interestingly, 3 of 4 VPL units exhibited Cont. RF plasticity after LA to Ipsi. FP. Three of 6 DCN units exhibited temporary expansion around original Ipsi. RF, which itself was blocked by L. However, DCN units (2) did not show any change of RF after L injection at Cont. homotopical FP. Overall, this study demonstrates that changes of RF following lidocaine anesthesia of the RF occur at all three levels of DC-lemniscal pathways to the SI cortex. The results also suggest that interhemispheric transfer of plasticity involves interactions between thalamus and cortex. Supported by PHS grant NIH-GM35647.

CHANGES IN LOCAL CIRCUIT AXON DISTRIBUTION IN MOUSE BARREL CORTEX FOLLOWING NEONATAL DENERVATION. K.L. Bernardo, J.S. McCasland, K.L. Probst, and T.A. Woolsey, Dept. Neurosurg., Div. Exp. Neurol. & Neurosurg. and McDonnell Center for Studies of Higher Brain Function, Washington University School of Medicine, St. Louis, MO 63110.

Using a bulk-labeling HRP technique and automated image analysis, we analyzed patterns of intrinsic connections in mouse barrel cortex quantitatively. We compared normal cortices from adults with those for which the contralateral infraorbital nerve (ION) was sectioned at postnatal day 7 (PND7), a time at which the cortical representation of the whiskers has already appeared. After peripheral denervation cortical HRP-labeled fiber distribution differed significantly from controls. Control animals showed axons projecting primarily within the barrel row which was injected, as well as into the next anterior adjacent barrel row, as described previously (Bernardo et al., 1990). In animals sacrificed as adults following PND7 ION lesions we found a near-total absence of fibers projecting outside a vertical "column" defined by the HRP injection site. These results were highly significant statistically (p=0.0003). This is the first demonstration of dramatic alterations in intracortical connections in response to the loss of peripheral inputs after the barrel map has been established.

331.2

EFFECTS OF SENSORY DEPRIVATION ON ZINC HISTOCHEMISTRY IN THE RAT BARREL CORTEX. N.D. Akhtar and P.W. Land, Dept. of Neurobiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

Zinc is released at excitatory cortical synapses, and is thought to modulate neurotransmission at the NMDA type of glutamate receptors. Zinc storage granules in rat somatosensory barrel cortex (SI) show lamina-related differences in distribution that reflect cyto-architectonic and metabolic subdivisions of that region. Interestingly, histochemical staining for zinc is particularly light in lamina IV barrels compared with the surrounding, darkly stained septa.

Here we examined the effects of sensory deprivation produced by whisker trimming on histochemical staining for zinc in the barrel cortex. Rats had one or more rows of whiskers trimmed for 5-10 weeks beginning either at birth or at 2 months of age. Trimming whiskers of adult rats does not visibly alter the zinc staining pattern in the corresponding barrels. By contrast, in rats with whiskers trimmed from birth, zinc staining is markedly enhanced in deprived barrels when compared with adjacent non-deprived barrels in the same hemisphere or with barrels in untrimmed animals. These data suggest that neonatal sensory deprivation results in increased zinc storage by normal barrel afferents and/or ingrowth of novel, presumably excitatory inputs into deprived regions of cortex. Such changes may be related to the abnormal responsiveness of neurons in neonatally deprived barrels. (Supported by NIMH grant MH09773)

HISTOCHEMICAL COMPARTMENTS OF SQUIRREL MONKEY SOMATOSENSORY THALAMUS FOLLOWING NERVE INJURIES. L. Harrison and C.G. Cusick, Neurosci. Training Program and Anatomy Dept., Tulane Univ., New Orleans, LA 70119.

To investigate regulation of thalamic activity by somatosensory inputs, immunoreactivities for the calcium binding proteins calbindin-D 28k (CB-ir) and parvalbumin (PV-ir) were localized and compared to cytochrome oxidase staining (CO) ten weeks after injury to the median and ulnar nerves. Ipsilaterally, the non-deprived ventroposterior lateral nucleus (VPL) contains dense CO as well as CO-poor regions, many of which relate to discontinuities in the sensory representation. Dense CB-ir occupies the ventroposterior superior and inferior divisions (VPS and VPI) and anterior pulvinar (Pa). VPL proper contains little CB-ir, except for dense patches in CO-poor regions, and a population of small neurons interspersed through the nucleus. PV-ir is dense in CO-rich zones of VPL, and sparser in VPI and Pa. In the portion of VPL related to the hand, the intensity and pattern of staining for CB, PV, and CO are similar bilaterally, and similar numbers of calbindin positive cells are found. The results suggest that oxidative metabolism and expression of calcium binding proteins are maintained at nearly normal levels after nerve injuries, at a postinjury time when the deafferented zones of VPL have been completely reactivated by the radial nerve (Garraghty et al., Soc. Neurosci. Abstr., 16:831, 1990).

331.6

PLASTICITY OF SOMATOSENSORY CORTEX (SI) VENTRUM REPRESENTATION AND SIZE OF VENTRUM RECEPTIVE FIELDS DURING LACTATION IN RATS. J.M. Stern, C. Xerri*, and M.M. Merzenich, Psychology, Rutgers Univ., New Brunswick, NJ; Psychophysiol., Univ. of Provence, Marseilles, France; Coleman Labs., Physiology, UC-SF, San Francisco, CA.

Norway rats spend ~80% of their time nursing in the first days postpartum (PP); this measure gradually declines to ~25% by day 17 PP. We asked whether this intensive, natural stimulation of the ventrum, in particular the nipples, would alter the sensitivity of the ventrum, in terms of SI representation and receptive field sizes. To date, 4 primiparous lactating rats were studied at 6, 12, 16 and 19 days PP; 5 controls included 2 virgins and 3 primiparous nonlactating PP rats (1 newly parturient before onset of nursing and 2 at 16 and 18 days PP whose litters were removed on the day of birth). In lactating rats we found a 2.2-fold increase in SI ventrum representation between days 12-16 PP and a 1.2-fold increase on days 6 and 19 PP compared to controls. Ventrum receptive fields, many nipple-centered, are much smaller on average in lactating than in control rats (4.6 vs. 13.4 cm² and 7.9 vs. 27.3% of ventrum surface, a 2.9 and 3.4-fold differences, respectively).

Supported by MH-40459 (JMS) and NS-29343 (MMM).

331.7

CORTICAL SOMATOTOPY AND PERIPHERAL TERMINATIONS IN BRAIN STEM AND SPINAL CORD FOLLOWING REVERSIBLE DEAFFERENTATION OF THE GLABROUS HAND IN INFANT AND ADULT MACAQUES. M. Carlson, S.L. Florence, P.E. Garraghty, and J.H. Kaas. ¹Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115; ²Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

In the visual system, monocular deprivation early in life has a more devastating effect than in adulthood. To explore the behavioral, physiological and anatomical consequences of sensory deprivation in the somatosensory system, we have examined the effects of median and ulnar nerve crush performed in infant and adult macaques (M. mulatta). Following the crush of a peripheral nerve, the distal processes degenerate to be replaced eventually by the regenerating fibers. Thus, during the period of regeneration, central targets of the glabrous hand are deprived of normal driven activity following crush of the medial and ulnar nerves.

We examined the somatotopy of cortical area 3b and the pattern of central terminations of skin surfaces within the glabrous surface of the hand in adults experiencing deafferentation as infants or adults. We detected no abnormalities in either somatotopic organization in area 3b or in the pattern of afferent termination in the cuneate nucleus of the brain stem in either the early or late deprived animals. These observations are consistent with the normal behavioral capacities of macaques undergoing nerve crush as infants. On the other hand, relative to normal, afferent projections to the spinal cord from transient deafferented skin sites are expanded after both infant and adult nerve crush. The fundamental relevance of these expansions, if any, are unknown. (Supported by BNS 86-17085 and 88-46157 to M.C. and NS16446 to J.K.)

331.9

CONVERGENT SUBTHRESHOLD INPUT TO THE ULNAR NERVE REPRESENTATION IN CAT SI CORTEX MAY PLAY A ROLE IN IMMEDIATE CORTICAL REORGANIZATION: AN *IN-VIVO* INTRACELLULAR AND EXTRACELLULAR RECORDING STUDY. R.S. Waters, C.X. Li, A. Oladchin, C.A. McCandlish, E.F. Johnson. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, Col. of Medicine, Memphis, TN 38163.

The immediate reorganization of the primary somatosensory cortex (SI) after peripheral nerve injury suggests the existence of previously undetected inputs. As a first step in understanding reorganization, we mapped the forepaw representation using extracellular recordings methods and then examined subthreshold input onto SI cortical neurons serving the ulnar nerve using intracellular recording combined with natural and electrical peripheral stimulation.

In adult cats anesthetized with Nembutal (35mg/kg), SI was exposed, and a Lucite chamber was installed on the surrounding bone. The paw was placed in a customized holder and six stimulating electrodes were inserted into selected regions of the skin. Carbon fiber electrodes were used to map the distal forepaw representation. After mapping, an intracellular electrode (2M Potassium Acetate, 50-85 M Ω) attached to a Burleigh microdrive and mounted onto the recording chamber, was inserted into the ulnar nerve representation to record threshold and subthreshold input onto individual SI neurons. By these methods, two results are noteworthy:

1. The majority of cells in the ulnar representation in SI cortex (Layer IV) received convergent input from regions of skin served by more than one peripheral nerve.
2. In many cases, PSPs could be elicited in SI cortical cells from all six stimulating electrodes suggesting that SI cortical neurons receive a wealth of subthreshold input which may serve, in part, as the underlying substrate for cortical reorganization.

Supported by NSF Grant BNS 88-02766)

331.11

CHANGES IN NISSL-STAINED AND GABA(+) NEURONS IN THE VENTROPOSTERIOR NUCLEUS (VP) AFTER ABLATION OF SOMATOSENSORY CORTICAL AREAS IN RHESUS MONKEYS. J. Chmielowska and T.P. Pons. Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892.

Cell soma areas of Nissl-stained or GABA(+) neurons in the hand representation of VP were measured in both unoperated and operated hemispheres. The operated hemispheres received complete (areas 3a, 3b, 1 and 2) or partial ablations (e.g. 3b) of hand representations in postcentral cortex 8 weeks prior to sacrifice. In VP of unoperated hemispheres, areas of Nissl-stained cell bodies regions ranged from 20 μm^2 to 550 μm^2 with the majority of cells having an area of 130-150 μm^2 . GABA(+) cell body areas ranged from 20 μm^2 to 240 μm^2 , with most cells having an area of 80-100 μm^2 . In the affected regions of operated hemispheres there was almost a total loss of Nissl-stained neurons with areas > than 160 μm^2 . Most of these remaining cells had areas < 100 μm^2 . There was no increase in the number of cells/mm² for any given area, and the ratio of GABA(+) to small (< 160 μm^2) Nissl-stained cells remained constant, indicating a loss of neurons with relatively large areas (>180 μm^2) instead of shrinkage. These results indicate that large projection neurons in VP degenerate completely after ablation of postcentral cortex and are no longer available to serve as a source of activation to other cortical areas.

331.8

REORGANIZATION IN PRIMARY AND SECONDARY SOMATOSENSORY CORTEX (SII) AFTER COMPLETE DEAFFERENTATION OF THE HAND IN RHESUS MONKEYS. A.K. Ommaya and T.P. Pons. Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892.

Removal of all cortical hand representations in the postcentral strip (areas 3a, 3b, 1 and 2) results initially in the deactivation of the hand map in SII but eventually to reactivation of the hand map by the foot. To compare the effects of central versus peripheral deafferentation on the pattern of representation in SII, we cut and tied the three nerves normally innervating the hand and, 6-8 weeks later, recorded from both SII and the postcentral strip. We found that tissue normally devoted to the postcentral hand representations had become responsive to somatic stimulation of both the arm and face, although stimulation thresholds were abnormally high. By contrast, sites in the expected location of the SII hand representation were largely unresponsive to somatic stimulation. The few sites in this region that did respond had receptive fields and response thresholds that were virtually identical to those in the reorganized portion of the postcentral strip. The results indicate major differences in the way SII reorganizes after peripheral and central nervous system injury.

331.10

PLASTICITY OF RACCOON SOMATOSENSORY CORTEX: POTENTIATION IN A CORTICOCORTICAL PATH. P. Kirchberger, S. Witte, and P. Zarzecki. MRC Group in Sensory-Motor Physiology, Dept. of Physiology, Queen's University, Kingston, Ontario, Canada.

Plasticity of digit representations in raccoon SI cortex may depend on a corticocortical (C-C) path between two SI subregions. Normally, neurons in the glabrous zone (GZ) for each digit are activated from only that digit, while in the heterogeneous zone (HZ) convergent inputs from off-focus digits are common. We have reported that a C-C path from the HZ to the GZ is a probable route for the few off-focus inputs to the GZ. After digit removal, when reorganization of the cortical map has occurred, more neurons of the GZ respond like those of the HZ. This change occurs without an increase in incidence of C-C connections. Is there instead a strengthening of existing synapses in the C-C path that could account for the new receptive fields?

C-C epsps were recorded intracellularly in the digit 4 representation in two groups of anaesthetized raccoons; normal controls and an experimental group surviving 4 to 9 months after removal of digit 4. Short latency C-C responses to single shock ICMS of the HZ were not different in amplitude, half width, or integrated amplitude, but epsps from the experimental group had shorter latencies and faster rising phases.

In some neurons of both groups, epsps became more effective in generating action potentials during train stimulation. Epsps that generated action potentials were faster rising than immediately preceding epsps in the same train. Changes in the rising phase of C-C epsps may facilitate transfer of new somatosensory inputs to reorganized SI cortex.

331.12

MICROSTIMULATION OF RAT "BARREL" CORTEX RESULTS IN AN EXPANDED METABOLIC AND ELECTROPHYSIOLOGIC CORTICAL VIBRISSE REPRESENTATION D. Sirois and R. Hand. Dept. Animal Biology, Sch. Vet. Med. and Neurology, Sch. Med., Univ. of Pa., Phila., Pa. 19104

The cortical representation of rodent vibrissae is highly organized, with a primarily 1:1 correlation between a vibrissa and its cortical layer IV "barrel". Intra-cortical microstimulation (ICMS) of only a few hours duration has been shown to alter the cortical representation of the body surface (Recanzone and Merzenich, *Soc. Neurosci. Abstr.*, 1989). In this study, we examined the metabolic and electrophysiologic effects of ICMS in the first somatosensory (SI) barrel cortex of awake, adult rats using the 14C-2-deoxyglucose (2DG) and multiple site evoked potential recording techniques.

The SI barrel cortex was exposed under ketamine and xylazine anesthesia and the barrel field explored to identify 2 neighboring barrels with non-overlapping principle-whisker receptive fields (RF). Tungsten microelectrodes were placed at a depth of 700um and fixed to a connector attached to the skull. At 1-3 week post-operative intervals all whiskers were clipped bilaterally sparing only one whisker corresponding to one of the barrels containing an implanted electrode, as well as that whisker's contralateral homologue (control). Charge balanced 5uA monophasic pulses were delivered at 300pps for 40ms, 1 train every second, in the awake rat. ICMS continued for up to 6 hours and the RFs of the two barrels were examined at 1-hour intervals. After ICMS completion, the rat received an IP injection of 14C-2DG and the whiskers were then stimulated bilaterally for 45 minutes. The rat was euthanized using pentobarbital sodium and the brain was removed and prepared for 2DG autoradiography, cytochrome oxidase, and thionin staining.

Prior to ICMS the experimental whisker evoked a response in only its corresponding barrel. As ICMS continued, the whisker evoked responses in both its corresponding barrel and the neighboring, non-corresponding barrel. 2DG autoradiography revealed an expanded area of activity which included adjacent barrels, whereas activation of the contralateral "control" whisker resulted in signal restricted to its corresponding barrel.

These results demonstrate that the cortical metabolic and electrophysiologic representation of the vibrissae is dynamically maintained and that novel inputs (e.g., non-corresponding whiskers) can be selected over a short time period. Additional studies are in progress to determine if the observed plasticity is strictly a cortical phenomenon or a cortical-subcortical event.

331.13

RECOVERY OF RESPONSIVENESS IN AREA 1 AFTER CHRONIC ABLATIONS OF PORTIONS OF CORTICAL AREAS 3A AND 3B IN MONKEYS. P.E. Garraghty, S.L. Florence, and J.H. Kaas. Dept. Psychology, Vanderbilt Univ., Nashville, TN 37240.

We have previously reported that ablating physiologically identified parts of the somatotopic maps in cortical areas 3a and 3b in New World monkeys results in the immediate loss of responsiveness to peripheral stimulation of neurons in somatotopically matched regions of area 1. We can now add that this effect in area 1 is not due to a generalized deactivation of VPL, including those neurons projecting to area 1. We have recorded in VPL before and after ablation of areas 3a, 3b, and 1, and find no obvious immediate effect of the removal of cortex. Similar multiunit receptive fields were defined, and there was no apparent change in the strength of the evoked activity. Thus, these thalamic neurons could eventually gain or regain the capacity to drive initially silenced neurons in area 1. In monkeys which were allowed to recover for 2-6 months after ablations of physiologically defined portions of areas 3a and 3b, we found that the acutely silenced zone of cortex had indeed regained responsiveness. The map which had emerged, however, differed from the one defined in area 1 prior to the ablation in that activity was evoked by stimulation of skin surfaces with intact representations in areas 3a, 3b, and 1. These results provide strong support for the hypothesis that area 1 is activated by serial cortico-cortical inputs, with thalamic inputs perhaps playing a modulatory role. (Supported by N.I.H. NS16446.)

STIMULUS-LOCKED ~ 10 Hz OSCILLATIONS IN VISUAL AND SOMATOSENSORY CORTICES: EXPERIMENT AND DYNAMIC THEORY. G. Schöner, H.R. Dinse, F. Spengler, K. Kopecz. Inst. Neuroinformatik, Ruhr-Univ., 4630-Bochum, Germany.

Temporally structured neural responses to photic on/off stimuli have been observed in different areas of visual cortex of cats: Between 2 and 4 activity peaks in PSTHs at periodic intervals reflect stimulus-locked oscillations in the range of 5 to 20 Hz that lead to time-dependent receptive fields (RFs) and RF properties (Dinse et al., *Concepts of Neurosci.* 1, 199-238 (1990)). Recent experiments in fully awake animals (rabbit, visual cortex) have revealed similar stimulus-locked oscillations (Dinse & Krüger, unpublished). In a new series of experiments in somatosensory cortex of urethane anesthetized rats we ask how these long-lasting oscillations (up to several hundred milliseconds) affect response to new incoming stimuli by investigating temporal interference patterns between intrinsic neural dynamics and the timing of stimulating cutaneous RFs either periodically or with a double click at different interstimulus intervals. In ~ 50 % of the cells we observe stimulus-locked oscillations at frequencies of 9 to 15 Hz (between 4 and 9 peaks in the PSTH). Our results suggest that the neural response contains two components: a strictly stimulus-locked early response, that can be understood in terms of a classical transfer function model, and an oscillatory late response, that is stimulus-locked only if the system is excited from a resting initial state. We propose that these oscillations can be viewed as indicative of collective states of cortical networks and build a dynamic theory of cortical neural response on these basic functional units.

331.14

REORGANIZATION OF PRIMARY SOMATOSENSORY CORTEX AND FUNCTIONAL RECOVERY FROM STROKE IN THE ADULT OWL MONKEY. C. Xerri*, W. M. Jenkins, M. M. Merzenich, B. Peterson* and R. Beitel.* Coleman Laboratory, UCSF, San Francisco, CA 94143-0732, USA.

A previous study conducted in our Laboratory showed that focal lesions within the area 3b of the primary somatosensory cortex (S1) resulted in a drastic reorganization of the cortical map within the zone of cutaneous representation of hand digits. Cortical remodeling consisted in 1) the emergence of a new representation of the skin surfaces formerly represented within the infarcted zone, in the cortical territories surrounding the lesion; 2) abnormal topographies and receptive field sizes. The present experiment examines the hypothesis that causal association exists between representational reorganization and functional recovery of digit dexterity after a focal cortical infarct in area 3b. Owl monkeys were trained to retrieve small banana pellets from different size wells on a modified Kluver board. A map of the cortical representation of the hand used in this retrieval task (RT) was derived on the basis of multiunit recordings at the completion of testing. A vascular lesion restricted to the representation of the 2 digits primarily engaged in the RT was induced. Post-lesion functional deficits and subsequent recovery of digit dexterity were assessed by a quantitative evaluation of changes in the RT performance. Preliminary results indicate that: 1) a hand preference can develop as a result of training, depending on the degree of digital dexterity required in the RT; 2) acquisition of digital dexterity seems to selectively induce a significant enlargement of the representations of engaged digit surfaces; 3) the relatively large cortical lesion induces profound deficits in RT performance; 4) functional recovery occurs progressively. After recovery of the RT performance, remapping experiments suggest that 1) within area 3b some specific skin surface representations re-emerge in the cortical zones bordering the injury site; 2) re-emergent skin surfaces appear to be functionally related to the RT; 3) within area 3a a cutaneous representation of behaviorally engaged skin surfaces emerges; no such cutaneous representation was observed in area 3a ipsilateral to the hand used in the RT; 4) alteration of the representational features within area 1 may also be related to the functional recovery. RESPONSE PROPERTIES OF TWO DIFFERENT SETS OF NEURONS IN SMI CORTEX OF THE RACCOON. S.D. Stoney, Jr. and G.S. Doetsch. Dept. of Physiol. & Endocrinol. and Dept. of Surg. (Sect. of Neurosurg.), Med. Coll. Ga., Augusta, GA 30912.

Extracellular recordings were made from single neurons in glabrous skin (G) and "heterogeneous" hairy skin/claw (H) subdivisions of forepaw digit 3 somatosensory cortex in chloralose-anesthetized raccoons. Fifty G cells and 41 H cells, each receiving excitatory input from on-focus digit 3, were studied with electrical and mechanical stimulation of each digit. G and H neurons differed significantly in their input convergence--the percentage of neurons (%N) excited by stimulating off-focus digits and the number of digits from which neurons could be driven were much greater for H cells. Surprisingly, G and H neurons responsive to stimulating any one digit did not show significant differences in probability of firing (P), spikes per response (S/R), or spike latency (L). The pattern of convergent excitatory inputs from different digits to each set of neurons was symmetrical--%N and P decreased, while L increased, with distance of each off-focus digit from digit 3, indicating corresponding variations in synaptic accessibility and conduction time. S/R did not vary significantly across digits, suggesting that strength of synaptic drive is largely independent of accessibility. These findings indicate that strengthening of existing patterns of off-focus inputs to G and H neurons may contribute to the appearance of "novel" responses of digit 3 neurons following digit 3 denervation (Kelahan & Doetsch, 1984). Supported in part by NSF Grant BNS-8419035.

VISUAL CORTEX: ORGANIZATION AND CONNECTIONS

332.1

COMPARISON BETWEEN THE DISTRIBUTION OF THE INOSITOL TRISPHOSPHATE RECEPTOR AND CALCIUM-BINDING PROTEINS IN THE CENTRAL VISUAL SYSTEM. L.B. Nabors¹, B.R. Mize¹, N. Maeda², and K. Mikoshiba². Dept. Anatomy and Neurobiology, Univ. of Tennessee, Memphis, TN 38163¹ and Inst. for Protein Research, Osaka University, Osaka, Japan².

Many intracellular systems depend upon the maintenance of calcium homeostasis in brain cells. One is the phosphatidylinositol system, in which inositol trisphosphate (IP3) binds to its receptor causing the release of calcium. Other systems involve the calcium-binding proteins which are believed to mediate intramembrane Ca⁺⁺ transport and buffering. Immunocytochemical studies have shown that cerebellar Purkinje cells have high concentrations of both the IP3 receptor and the calcium-binding proteins calbindin (CaBP) and parvalbumin (PV). Selected neurons in the central visual system also are labeled by CaBP and/or PV antibodies. In this study, we asked whether these neurons are also labeled by antibodies to the IP3 receptor.

In agreement with previous studies, cerebellar Purkinje neurons were intensely labeled by antibodies to CaBP, PV, and the IP3 receptor. Within the visual cortex, the IP3 receptor was concentrated primarily in small and medium-sized neurons within layer IV. By contrast, CaBP was localized primarily in small neurons in layers II-III. PV was localized in selected neurons throughout layers II-VI. No neurons were found to be labeled by the IP3 receptor antibody in the lateral geniculate nucleus, pretectum, or superior colliculus, even when antibody exposure time was increased 2 fold and/or the concentration of the antibody was increased 10 fold. By contrast, PV and CaBP positive neurons were found in all three subcortical visual structures, as we have reported previously. We conclude that within the visual system of cat the inositol trisphosphate receptor and the calcium-binding proteins must be involved in different intracellular Ca⁺⁺ related events. Supported by NIH grant EY 02973.

332.2

LATERAL GENICULATE PROJECTIONS TO THE SUPERFICIAL LAYERS OF VISUAL CORTEX. W. Usrey, E. Muly, and D. Fitzpatrick. Dept. of Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

In recent studies of tree shrew striate cortex, we have focused on the organization of geniculate projections to layer IV and the projections from layer IV to layer III. While these pathways no doubt play a dominant role in determining the response properties of layer III neurons, there are additional pathways from the lateral geniculate nucleus that terminate directly in layer III. Previous studies using bulk injections of WGA-HRP demonstrated that the projections to layer III originate from layers 3 and 6 of the LGN and terminate in different parts of layer III. In the present study we used extracellular injections of biocytin to examine the cortical projection patterns of single neurons in LGN layers 3 and 6.

Consistent with earlier work, we found that LGN layer 3 terminates densely in layer IIIb with sparse terminations continuing to layer I, while LGN layer 6 projects heavily to lower IIIc. In addition, however, we found that both layers 3 and 6 send collaterals to other cortical layers: neurons in LGN layer 3 project sparsely to layers V and VI as well as to the middle of layer IV; neurons in LGN layer 6 project to the bottom of layer IVb and sparsely to layers I-IIIb.

Thus, both LGN layers 3 and 6 project to multiple layers of striate cortex, including layers III and IV. The patterns of projections to layers III and IV are significant in light of our studies of the connections from cortical layer IV to layer III. Individual neurons in LGN layers 3 and 6 send axonal branches to subdivisions of layers III and IV that are themselves interconnected. Therefore, LGN neurons that project to the superficial cortical layers have axons which respect the patterns of interlaminar connections established by layer IV neurons. Supported by EY06821.

332.3

THE MORPHOLOGICAL BASIS FOR BINOCULAR AND ON/OFF CONVERGENCE IN TREE SHREW STRIATE CORTEX. E. Muly and D. Fitzpatrick, Dept. Neurobiol., Duke Univ. Med. Ctr., Durham NC, 27710.

Based on the pattern of lateral geniculate terminations in layer IV, we have suggested that ON/OFF and binocular convergence in the tree shrew occurs in two stages: 1) the ON pathways from the two eyes are combined in layer IVa and the OFF pathways from the two eyes in layer IVb; 2) binocular ON and OFF pathways are brought together via the projections from layer IV to the superficial layers. We tested this idea using biocytin to examine the projections of layer IV neurons.

Consistent with our view, we found that neurons in IVa and IVb have overlapping terminal fields throughout layers II and III. These projections are organized in a highly stratified, mirror-symmetric fashion: neurons located at the edges of layer IV (upper IVa and lower IVb) project to the deepest part of layer IIIc; neurons in the middle of layer IV (lower IVa and upper IVb) project to layer IIIB and above; neurons in the middle of IVa and the middle of IVb have terminal fields that are intermediate between these extremes.

The stratified nature of the projection out of layer IV resembles the pattern of ipsilateral and contralateral eye inputs to layer IV: inputs from the ipsilateral eye are limited to upper IVa and lower IVb; those from the contralateral eye terminate throughout the depth of IVa and IVb. Thus cells near the edges of layer IV receive strong input from both eyes, while those in the middle of layer IV receive mostly contralateral input. We suggest that the projections from layer IV to layer III are organized to bring together the ON and OFF pathways while matching the ocular dominance gradients established in IVa and IVb. Supported by EY06821 and EY06661.

332.5

MORPHOLOGY OF NEURONS IN CAT LATERAL SUPRASYLVIAN SULCUS THAT PROJECT TO AREA 17 AND TO THE SUPERIOR COLLICULUS. G. Einstein and Y. Liu, Department of Neurobiology, Duke University, Durham N.C. 27710

The laminar organization of efferent neurons in the cat's visual association cortex is well established, but their dendritic morphology and its relation to afferent input has not been fully explored. Since it is this relationship that underlies neuronal receptive field properties, and hence the type of information neurons relay, we studied the dendritic morphology of two populations of neuron in the posterior medial lateral suprasylvian sulcus (PMLS); those that project to area 17 and those that project to the superior colliculus. We did this by combining retrograde tract tracing methods with intracellular injections of Lucifer Yellow in lightly fixed slices.

Both projection populations contained diverse morphologies of spinous neuron. Cortical-projecting neurons in layer 2/3 had medium sized somas, basilar dendrites that extended only to the top of layer 4, and apical dendrites that ascended to layer 1; in layers 4-6 they had small to medium somas of atypical pyramidal morphologies with dendrites that could be very short or could extend horizontally for long distances (up to 1 mm) remaining within the infragranular layers. In contrast, most collicular-projecting neurons had medium to large somas, basilar dendrites that extended into layer 6, and apical dendrites that ascended to layer 1. These results indicate that cortical- and collicular-projecting neurons sample input from the same afferent pool; however, because their dendritic morphologies differ, they sample it in different ways. Cortical-projecting neurons are distributed to layers 2-6 but have restricted dendritic fields; so a single neuron receives input from, at most, a few sources. Collicular-projecting neurons are restricted to layer 5 but have dendritic fields that stretch from layer 1 to layer 6; so a single neuron probably receives input from multiple sources. Thus, in association, as in primary visual cortex, the information these two populations send their respective targets is probably different. (Supported by NEI grant R29 EY07840)

332.7

RETINOTOPIC SCATTER WITHIN CELL COLUMNS IN THE LATERAL SUPRASYLVIAN CORTEX IS REMARKABLY SMALL. K. Mulligan and H. Sherk, Dept. of Biological Structure, U. of Washington, Seattle, WA 98195.

Many electrophysiological studies of the striate-recipient region of the cat's lateral suprasylvian cortex have described its retinotopic map as disorderly. This disorder has been generally attributed to a high degree of scatter among receptive fields within cell columns perpendicular to the cortical surface. However, only tangential electrode penetrations have been used in mapping studies, so the degree of scatter *within* cell columns remains unknown. We have recorded receptive fields in penetrations parallel to columns by angling the electrode about 45° from vertical, and entering the cortex from the medial side of the suprasylvian gyrus. The electrode traversed the suprasylvian gyrus from medial to lateral, passing through white matter and then through layers 6 to 2 of the lateral suprasylvian cortex. Histological reconstructions showed that 13 penetrations were nearly parallel to cell columns (on average 8.7° away).

Although the receptive fields were large within each penetration, they were surprisingly tightly clustered, with many fields almost completely superimposed. At any given eccentricity the scatter of receptive field centers was much less than the area of the largest field. We also measured the scatter in the receptive fields of afferents from area 17 and 18 after silencing suprasylvian cells with local kainic acid injections. Again, we found only modest scatter.

The scatter of the receptive field centers of cells in the lateral suprasylvian cortex relative to the area of the largest field within a cell column was comparable to that reported in area 17. It was much less than that reported in areas 18 and 19. This high degree of local order suggests that the global disorder cannot be attributed to scatter within cell columns.

332.4

ORGANIZATION OF VISUAL CORTEX IN THE CALIFORNIA GROUND SQUIRREL. M.J. Sereno, H.R. Rodman, and H.J. Karten, Departments of Cognitive Science and Neurosciences, U.C. San Diego, La Jolla, CA 92093.

Ground squirrels are especially suitable for studies of the mammalian visual system because of their well-developed visual pathways, color vision, diurnal habit and availability. We made extensive microelectrode maps of visual cortex in urethane-anesthetized California ground squirrels (*Spermophilus beecheyi*), and then stained the cortex with the Gallyas myelin stain after physically flattening it.

As in tree squirrels (Hall et al., 1971), these animals have an extensive representation of the lower visual field in dorsal V1. The horizontal meridian is approximately parallel to the coronal plane and the upper field representation begins near the occipital pole, curving underneath the dorsal surface. Receptive fields in V1 are as small as 2 deg. in diameter at the center of gaze and increase to about 15 deg. in the far periphery. As in rabbits, rats, and cats, the binocular visual field nearest the vertical meridian is represented bilaterally in V1. This bilaterally represented binocular zone (assayed by recordings from both hemispheres through one eye) is 5-7 deg. wide near the horizontal meridian. There are three distinct compartments in the myelin pattern within V1 that may correspond to the monocular, binocular, and bilateral binocular zones.

Progressing laterally beyond the border of V1, receptive fields move out 10-30 deg. and then reverse to approach the vertical meridian, suggesting that much of V1 is bordered by two successive areas akin to V2 and V3 in tree squirrels (Hall et al., 1971). We have no evidence for the existence of multiple visual areas *directly* adjoining dorsal V1 similar to those found in rats and other rodents. Beyond the third representation is a zone of variable responsiveness and patchy myelination containing an expanded representation of the horizontal meridian and at least two additional maps of the visual field. Lateral to this intermediate zone, responses are much more robust and at least two distinct areas are found: 1) area L has large fields and an orderly map of the contralateral hemifield, with lower fields located rostrally and upper fields caudally, and 2) ventral to L, within a heavily myelinated zone designated Tp by Hall et al., is an area with strongly responsive neurons and receptive fields covering as much as the whole contralateral lower hemifield.

332.6

A REASSESSMENT OF THE MAP IN LATERAL SUPRASYLVIAN VISUAL CORTEX: THE LOWER VISUAL FIELD. H. Sherk and K. Mulligan, Dept. of Biological Structure, U. of Washington, Seattle, WA 98195.

The visual field representation in the cat's lateral suprasylvian cortex has been studied by a number of groups. However, we have observed retinotopic peculiarities in this region not described in any published map. We therefore reinvestigated the lower field representation in the suprasylvian area that receives striate input, the Clare-Bishop area. (It coincides approximately with the lower field representation in Palmer, Rosenquist and Tusa's area PMLS). Both physiological and anatomical mapping (by the injection of tracers in area 17) were done. The entire suprasylvian cortex was flattened graphically by computer. In experiments with large numbers of recording sites, a complete map was generated by non-linear interpolation between sites.

The map was more orderly than reported by some groups, and its overall layout was simple. The most inferior visual field was located anteriorly, and central field was posterior, at the bend of the suprasylvian sulcus. As noted by others, there was often a progression from periphery towards the vertical meridian (VM) when the electrode moved down the medial bank of the suprasylvian sulcus. However, in detail the map was not simple. Some parts of the visual field, such as the area centralis, were duplicated. Curiously, the lower VM was split into two islands, and the gap between them represented more peripheral visual field. The posterior VM island was entirely embedded within the map instead of lying along a border.

Magnification factor could not be measured directly due to the map's complexity, but was deduced by comparisons with area 19. As in area MT in the macaque, the inferior VM (beyond about 15° down) was highly compressed, while the area centralis was expanded relative to area 19.

332.8

FEEDBACK CONNECTIONS IN VISUAL CORTEX CONTACT INHIBITORY NEURONS. R.R. Johnson and A. Burkhalter, Dept. of Neurosurgery, Washington Univ. Sch. Med., St. Louis, MO 63110.

Little is known about the role of feedback input from extrastriate cortex (area 18a) to primary visual cortex (area 17). To understand the circuitry we have examined whether inhibitory neurons are targets of feedback excitation. For this purpose we labeled feedback projections with the anterograde tracer Pha-L and examined their relationship to neurons in area 17 that were stained for glutamic acid decarboxylase (GAD) or parvalbumin.

Feedback projections from area 18a terminated in all layers of area 17 except layer 4. Boutons from feedback fibers were closely apposed to every GAD cell body within the projection zone, except in layer 1. Feedback boutons on parvalbumin labeled dendrites also indicated the presence of axodendritic contacts. Many feedback fibers appeared to terminate on unlabeled elements which may represent components of pyramidal cells. Such cells were always surrounded by a large number of GAD and parvalbumin labeled terminals.

These results suggest that inhibitory and excitatory neurons in layers 2/3, 5 and 6 of area 17 receive feedback excitation. By contrast feedback input to layer 1 appears to provide only for direct postsynaptic excitation of pyramidal cells via their apical dendrites. It seems likely that feedback input on inhibitory neurons results in the suppression of pyramidal cell activity. The results are also consistent with the possibility that feedback excitation results in both direct facilitation of pyramidal cells followed by indirect inhibition mediated through GABAergic interneurons.

332.9

SPECIALIZED VASCULARIZATION OF THE PRIMATE VISUAL CORTEX. D. Zheng, A. S. LaMantia and D. Purves Department of Neurobiology, Duke University Medical Center, Durham, NC 27710

We have analyzed the distribution of cerebral microvessels with respect to cortical modules, laminae, and cytoarchitectonic areas in the squirrel monkey visual cortex. In tangential sections of the primary visual cortex (area 17), the mean total length of microvessel profiles per unit area within blobs was 42% greater than within adjacent (interblob) areas. Similarly, microvessel length per unit area in another class of module, the stripes in the secondary visual cortex (area 18), was 27% greater than in interstripe regions. Microvessel distribution also varied systematically from layer to layer in the primary visual cortex, being greatest in lamina IVC. Finally, the overall microvessel length per unit area in sections of area 17 was 26% greater than that in area 18. These results indicate that the distribution of microvessels in the monkey visual cortex reflects the pattern of iterated cortical modules such as blobs and stripes, and major features of cortical organization such as laminae and areal boundaries. In principle, these vascular patterns should be discernible in living animals with appropriate techniques, and may facilitate non-invasive imaging of modular, laminar and areal architecture in the intact brain.

332.11

COMPARISON OF INPUTS FROM AREAS V1 AND V2 TO AREAS V4 AND TEO IN MACAQUES. H. Nakamura*, R. Gattass, R. Desimone, and L.G. Ungerleider. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

To investigate the differential inputs to areas V4 and TEO, we injected them with multiple retrograde tracers in 4 macaques and analyzed the distributions of labeled neurons in V1 and V2 using flattened preparations of the cortex. In V1, labeled neurons were seen after injections in V4 but not TEO. V4-projecting neurons were located in the foveal representation of V1, overlapping both the cytochrome oxidase-rich blob and interblob regions. In V2, labeled neurons arising from both V4 and TEO were seen. Although TEO-projecting neurons were far sparser, they were intermingled with V4-projecting neurons. Both V4- and TEO-projecting neurons were located in stripes running orthogonal to the V1/V2 border. V4-projecting neurons were in both cytochrome oxidase-rich thin stripes and interstripe regions, confirming prior reports, and also formed a continuous band along the V1/V2 border in the foveal representation that intersected the stripes in V2. TEO-projecting neurons were also found in the interstripe regions and probably the thin stripes as well. Because similar anatomical subregions of V2 project to V4 and TEO, they may receive similar visual information. This could explain the partial sparing of color and form vision that are seen after lesions of V4.

332.13

SUBCORTICAL CONNECTIONS OF INFERIOR TEMPORAL AND POSTERIOR PARIETAL CORTEX IN MACAQUES. J.S. Baizer, L.G. Ungerleider, and R. Desimone. Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892.

To investigate the subcortical connections of the object-vision and spatial-vision cortical processing pathways, we injected the inferior temporal (area TE) and posterior parietal (areas VIP and LIP) cortex of 6 rhesus monkeys with retrograde or anterograde tracers. Although several subcortical structures were found to project to both the temporal and parietal cortex, including medial and lateral pulvinar, claustrum, and n. basalis, the cells projecting to the two cortical regions were mainly located in nonoverlapping parts of those structures, except in n. basalis where they were intermingled. Likewise, the projections from temporal and parietal cortex to subcortical structures, including the caudate and putamen, were largely segregated. Finally, projections to the pons and superior colliculus arose from parietal but not temporal cortex, whereas the lateral basal and medial basal nuclei of the amygdala were found to be reciprocally connected with temporal but not parietal cortex. Additional, nonreciprocal, projections to the lateral nucleus of the amygdala arose from temporal cortex only. The results indicate that, like the cortical connections of the two visual pathways, the subcortical connections are remarkably segregated. (Supported by MH4213 and the Whitehall Fdn.)

332.10

A COMPARATIVE STUDY OF THE SUBCORTICAL CONNECTIONS OF THE DORSOLATERAL AREA (V4) IN PRIMATES. G. E. Steele, R. E. Weller and J. H. Kaas. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294 and Dept. of Psychology, Vanderbilt Univ., Nashville TN 37240.

In monkeys, the major cortical source of visual information to inferior temporal cortex is an area called the Dorsolateral Area (DL) or V4. Patterns of cortical connections suggest that DL (V4) possesses caudal and rostral subdivisions (Steele et al., '91, *J. Comp. Neurol.*, 306). The present study determined the subcortical connections of caudal DL/V4 in squirrel monkeys (*Saimiri sciureus*), owl monkeys (*Aotus trivirgatus*) and macaque monkeys (*Macaca fascicularis*) following sterile injections of WGA-HRP, tritiated amino acids and fluorescent dyes in anesthetized animals. The injections in caudal DL and V4 labeled similar structures, including the locus coeruleus, dorsal raphe, superior colliculus, pretectum, lateral and inferior pulvinar, lateral geniculate, intralaminar nuclei, lateral hypothalamus, basal ganglia and claustrum. These results support the hypothesis that at least caudal DL and V4 are homologous. Supported by EY07147 to REW and EY02686 to JHK.

332.12

SUBCORTICAL CONNECTIONS OF INFERIOR TEMPORAL AREAS TE AND TEO IN MACAQUES. M.J. Webster, L.G. Ungerleider, and J. Bachevalier. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

To investigate the subcortical connections of inferior temporal cortex, we injected areas TE and TEO of 6 rhesus monkeys with retrograde and anterograde tracers. TE and TEO receive nonreciprocal inputs from several thalamic nuclei, including paracentralis, ventralis anterior magnocellularis, centralis (mainly densocellularis), and limitans, and TE also receives input from reuniens. Additional nonreciprocal inputs to both areas arise from the hypothalamus, basal nucleus of Meynert, dorsal raphe, locus coeruleus and reticular formation. TE and TEO are reciprocally connected with the pulvinar and ventral portion of the claustrum. The main subcortical nonreciprocal output from TE and TEO is to the basal ganglia and from TEO to the superior colliculus. TE also sends a very limited projection to the n. medialis dorsalis magnocellularis of the thalamus. Although the connections of TE and TEO are overlapping in most subcortical structures, they are partially segregated in the pulvinar and basal ganglia. In the pulvinar, the connections of TE are located medial to those of TEO in the medial, lateral, and inferior nuclei. In the basal ganglia, the projections of TEO extend into more caudal portions of both the ventral putamen and tail of caudate than do those of TE.

332.14

CORTICOCORTICAL CONNECTIONS IN MACAQUE VISUAL CORTEX EXHIBIT DIFFERENTIAL PATTERNS OF NEUROFILAMENT PROTEIN DISTRIBUTION. S.B. Kupferschmid, P.R. Hof, J.H. Morrison. Fishberg Research Center for Neurobiology, Mt Sinai Sch Med, New York, NY 10029.

SMI32 is a monoclonal antibody that recognizes a nonphosphorylated epitope on neurofilament protein that, within the primate cerebral cortex, is localized largely in pyramidal neurons with a specific regional and laminar pattern. The distribution of SMI32-immunoreactive (ir) neurons in the cortex suggests that certain cortical efferents are preferentially SMI32-ir. After an injection of Fast Blue (FB) in V2 near the V1 border many of the FB-containing cells in layer 4B of V1 are double labelled with SMI32. The contralateral callosally projecting neurons in deep layer 3 are 100% double labelled. The V2 injection also shows a population of superficially placed pyramidal cells in V3 that are double labelled. While McGuire & Siegel (*Soc. Nsci. Abstr.*, 1990, p. 5) show that the neurons in layer 6 of V1 that project to V5 (MT) are SMI32-ir, we found that the projection from V5 back to V1 lacks an SMI32-ir component. Preliminary data suggest that double labelling with FB and SMI32 is asymmetric with respect to reciprocal connections in the hierarchical forward-feedback organization of visual areas. We are quantifying our results and examining other areas in the visual cortex to understand better the relationship of neurofilament immunoreactivity to cortical organization. Finally, after FB injection in V1 we observed that the geniculocortical projection is immunoreactive for the calcium binding protein parvalbumin. Supported by NIH grant AG06647, MSTP training grant GM07280-14 and AHAF.

332.15

COMPARATIVE IMMUNOCYTOCHEMISTRY OF CYTOSKELETAL PROTEINS IN VISUAL CORTEX OF CETACEANS AND PRIMATES.

I.I. Glezer, P.R. Hof, W. Janssen, J.H. Morrison, C. Leranthe and P.J. Morgane
CUNY Med. Sch., NY, NY 10031, Fishberg Res. Ctr., Mt. Sinai Sch. Med., NY, NY 10029, Yale Univ. Sch. of Med., New Haven, CT 06510, Worcester Found. Exp. Biol., Shrewsbury, MA 01545.

Light and electron microscopic immunocytochemistry combined with computerized image analysis were used to study the laminar distribution of nonphosphorylated neurofilament (SMI32-positive) and microtubule-associated (MAP2-positive) proteins. Primary (V1) and secondary (V2) visual areas in primates (*Homo sapiens* and *Macaca fascicularis*) and toothed whales (*Delphinapterus leucas* and *Globicephala melaena*) were studied. In cetacean V1 and V2 visual areas SMI32-positive pyramidal neurons are concentrated predominantly in layer V. In primate V1 and V2 visual areas SMI32-positive neurons are more uniformly distributed across all cortical layers, except layer I. There is no significant difference in overall numerical density of SMI32-positive neurons between primate and a cetacean visual cortices, although the laminar distribution is significantly different. MAP2-positive pyramidal cells in visual cortex of primates and cetaceans are present in significantly higher numbers than SMI32-positive neurons. The overall numerical density of MAP2 neurons is significantly higher in cetacean visual cortices than in primates. The ratio SMI32/MAP2 is significantly lower in cetacean visual cortex as compared to primates. The difference of this ratio between primates and cetaceans is especially prominent for upper layers (I-IV) of the visual cortex. The observed differences between primate and cetacean visual cortices in concentration and laminar distribution of cytoskeletal proteins may reflect the considerable disparity in cortical phylogenesis of these species. Supported by AHAF, NIH AG06647, and NSF grant BNS-87-42032.

VISUAL PSYCHOPHYSICS AND BEHAVIOR: BASIC PROCESSES

333.1

THE AFFERENT COMPONENT IN BLINK SUPPRESSION. W. H. Ridder III*, A. Tomlinson* and P. Simmons.

Southern California College of Optometry, Fullerton, CA. 92631.

Previous studies of blink suppression have suggested that the mechanism is independent of the afferent signal. If this theory is correct, manipulation of the afferent visual input should not affect the magnitude of suppression. We tested this hypothesis by presenting sine-wave gratings (16 msec duration, square-wave onset and offset) at several times after the blink (post-blink, onset times of 0, 25, 50, 100, 200 and 400 msec) to measure blink suppression. The afferent signal was manipulated by changing the spatial frequency of the grating (1.0, 4.0 and 10.5 c/deg) viewed by the two subjects. The stimulus was presented on a Tektronix 608 monitor (viewed at 1.5 meters) with an Innisfree Image Synthesizer. The task was one of detection. A minimum of 20 trials were run at each of 5 contrast levels centered around threshold for each post-blink, onset time. Psychometric functions were produced from the data for each post-blink, stimulus onset and a Weibull function was fit to the data to determine threshold. As in previous studies, the magnitude of suppression was the greatest immediately following the blink and gradually declined until no suppression was evident at 100 msec after the blink. Contrast sensitivity curves were produced for the 0 and 400 msec post-blink, stimulus onset times. The difference in contrast sensitivity between the post-blink, onset times (the sensitivity at 400 msec minus that at 0 msec) was greatest for the low spatial frequencies. This suggests that the afferent signal does influence the magnitude of blink suppression. In light of this data, models of blink suppression should be modified to include an afferent component.

333.3

Stabilized Retinal Perimetry with a Hemianopic Patient: Implications for Blindsight. C.M. Wessinger*, R. Fendrich and M.S. Gazzaniga. Program in Cognitive Neuroscience, Dartmouth Medical School, Hanover, N.H. 03756

Blindsight is the ability of cortically blind patients to describe certain attributes of stimuli they report no conscious awareness of seeing. Blindsight occurs in some patients but not others. One possible explanation for this discrepancy is that some patients have a small degree of cortical function remaining within their damaged visual cortex, which mediates the residual capacities in perimetrically blind regions.

We performed perimetry on a patient, CLT, rendered hemianopic by a right occipital stroke. A Purkinje image eyetracker and mirror stabilizer system were employed to eliminate eye motion artifacts. Using a two-alternative forced-choice paradigm, 40 locations in the central 15° of CLT's blind field were tested by flashing a 1° diameter black circle 3 times for 96 msec on a white CRT screen. The task was to identify during which of two consecutive 600 msec intervals the target was flashed. Stabilization insured the accurate retinal placement of the target despite the extended presentations.

Humphrey perimetry had previously shown a dense left field hemianopia with lower left quadrant macular sparing. Our stabilized perimetry revealed the scotoma had a complex structure, with a narrow zone of sparing along the vertical meridian in the blind upper left quadrant, a zone of blindness along the vertical meridian in the spared lower left macula, and a 1° island of residual vision embedded within the scotoma. The existence of this small isolated island of vision gives credence to the idea that some demonstrations of blindsight may be mediated by residual cortical function in the form of similar islands of sparing. Supported by NIH/NINDS P01 NS17778-09 and the McDonnell-Pew Foundation.

333.2

THE GREAT CIRCLE MODEL OF SPATIAL LOCALIZATION AND VISUAL PERCEPTION OF ELEVATION. L. Matin and W. Li*. Dept. of Psychology, Columbia Univ., New York NY 10027.

Changing the pitch* of a complexly-structured visual field produces linear changes in the elevation of a target perceived to lie at eye level (VPEL). A single 63.9° pitched-from-vertical line in darkness yields an influence 83% as large. The 1-line influence increases exponentially with line length (space constant = 15°). Most other discriminations (e.g. intensity discrimination threshold) manifest spatial summation over less than about 1°; but the influence on VPEL from two parallel 12° pitched-from-vertical lines separated horizontally by 50.3° manifests summation as great as the increase with line length.

The Great Circle Model (GCM) accounts for these results: Assume a spherical approximation to the stationary eye; two principles of GCM are: (1) The influence of a line on VPEL increases monotonically with the angular distance on the central vertical retinal meridian (CVRM) between the upper pole of the eye and the point of intersection with the great circle containing the line's image. (2) The influences on VPEL of all lines whose images lie on great circles which intersect the same point on the CVRM (e.g., all parallel pitched-from-vertical lines) summate along a common exponential function. (Supported by AFOSR-91-0146, NSF BNS-8615059, and USPHS EY05929).

* Pitch = rotation of a visual field around a horizontal axis in the frontal plane of the observer.

BANDWIDTH OF HUMAN ORIENTATION SENSORS MEASURED BY FILTERED NOISE STIMULI. M. Shadlen, K. Britten and W.T. Newsome. Dept. of Neurology and Neurobiology, Stanford University, Stanford, CA. 94305

We report a new stimulus paradigm for the study of visual mechanisms underlying the perception of orientation. Stimuli are random textures in which a desired orientation is made to appear more conspicuous by filtering out unwanted noise components at distant orientations. By varying the bandwidth properties of the filter, the relative visibility of one orientation may be affected preferentially, and the difficulty of discriminating between any two orientations may be varied smoothly. At extremely narrow bandwidths, the stimulus appears as one dimensional oriented noise and is easily discriminated from a similarly filtered pattern at a dissimilar orientation. At very broad bandwidths the pattern appears more like a random texture and the intended orientation can only be guessed. Between these extremes the pattern appears crinkled and even orthogonal orientations can be discriminated only imperfectly.

We have employed such stimuli to estimate the bandwidth of orientation channels in normal human observers using standard 2AFC psychophysical methods. Results are in agreement with prior estimates employing masking/detection methodology. We expect these stimuli to be valuable in the investigation of neural mechanisms underlying simple orientation discriminations.

SACCADIC LATENCIES TO STIMULI DEFINED ONLY BY LUMINANCE, CHROMINANCE, MOTION, AND DEPTH. R. M. McPeck*, M. A. Sommer*, and P. H. Schiller. Department of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

Bimodal saccadic reaction time distributions have been observed in visual detection tasks with targets defined by luminance information. The shorter-latency population of saccades has been called the "express saccade" population. We examined whether express saccades can be generated by a rhesus monkey to stimuli made visible only by luminance, chrominance, motion, and depth cues.

We found bimodal distributions of reaction times for luminance, chrominance, and motion detection tasks, suggesting that express saccades can be made to stimuli defined solely by these attributes. In contrast, we did not find an express saccade population of reaction times in the stereoscopic depth detection task.

These results suggest that express saccades are not generated exclusively by a pathway involving the striate cortex, area MT, and the parietal lobe, but can also be generated through other channels. This hypothesis is supported by lesion studies, in which express saccades have been observed in rhesus monkeys with MT lesions, V4 lesions, and paired MT-V4 lesions (Schiller et al, *Invest. Ophthalmol. Vis. Sci.*, **31**, 1967, 1990).

RELATIVE DEPTH FROM MOTION AND STEREO CUES.

George J. Carpan, Salk Institute VCL, San Diego, CA 92186.

A number of retinal cues provide information about the relative distance (depth) of surfaces in the visual environment from an observer. Here I describe how two of these cues, motion parallax and stereoscopic disparity, may be processed in similar fashion to yield a common representation of relative depth of surfaces useful for determination of the shape and trajectory of 3D objects.

When an observer moves while fixating at infinity, images of objects in the environment will have retinal velocities V_r which are inversely proportional to their depth H_i . But when an observer moves while tracking some nearby object, this relationship is broken by the additional component of retinal velocity V_e due to pursuit eye movement. However, this component of retinal motion is common to all images and constant across the retina at any given time. Thus by computing the relative velocity $V_{ri} = (V_r - V_e)$ we obtain measures of retinal motion which are independent of pursuit eye movements, and which are inversely proportional to the depth of objects. Furthermore, ratios of this relative velocity will be invariant over changes in eye or observer motion, providing part of a mechanism for relative depth constancy, and an explanation of motion contrast effects.

A similar inverse relationship exists between the retinal disparity D_i and object depth H_i for observers fixating at infinity. When observers fixate nearby objects, however, the nonzero eye convergence breaks this simple relationship by adding a global component of retinal disparity D_e . This component of disparity due to convergence can be removed by computing the relative disparity $D_{ri} = (D_i - D_e)$, providing measures which are inversely proportional to depth of objects. Furthermore, ratios of this relative disparity will be invariant over changes in convergence angle, providing another part of a mechanism for relative depth constancy, and an explanation of stereo contrast effects.

Due to the similarity of the proposed processing, both cues can be combined into a single representation constituting a map of relative depth in the visual field. The Middle Temporal (MT) area is the first representation of the primate visual pathway containing neurons selective for both retinal motion and retinal disparity, and which exhibit an antagonistic receptive field structure suitable for computing relative velocity. I will test this hypothesis by recording single MT neurons in awake, fixating macaques. I expect these neurons will exhibit supraclassical inhibitory surrounds for binocular disparity similar to those known for monocular motion. (Supported by NIH NRSA EY06179.)

TRANSPARENCY CONSTRAINS MOTION, FORM PERCEPTION, AND STEREOPSIS. Daniel J. Plummer and V.S. Ramachandran, UCSD, La Jolla, CA, 92093.

If two neutral density (ND) filters overlap partially the luminance of the overlapping region is given by a multiplicative relationship. We had two grey rectangles overlapping to form a "cross" and randomly varied the luminance of the intersection. Naive subjects' ratings of transparency showed a surprising consistency with the physics. A similar relationship is seen if two moving square wave gratings are superimposed. When the intersection luminances were close to the multiplicative case, component motion was seen. (Ramachandran, 1989; Stoner, Albright, and Ramachandran, *Nature*, 1990) We offer two interpretations. (a) the visual system has access to 'tacit knowledge' of transparency, shadows, and veiling luminances. (b) if you assume a log signal compression in the retinae, multiplying the grating luminances is equivalent to adding them, and hence there would be zero Fourier energy at the blobs. But if you simply add the gratings you would inadvertently introduce Fourier energy of the blobs and this would cause 'motion capture'. (Ramachandran and Inada, 1985) The critical experiment is, therefore, to vary the intersection luminances independently of the gratings. We find this nulls out the energy at the blobs to produce component motion. We regard (a) and (b) as being complementary rather than mutually exclusive accounts. We also show that transparency powerfully constrains 1) stereopsis. 2) 'Form Perception' in preattentive search or pop-out; alphabetical letters could be clearly discerned from background splotches if they were transparent, but were 'camouflaged' if luminances were incompatible. MOTION PERCEPTION AND OPTOKINESIS AT ISOLUMINANCE
A. Chaudhuri

The Salk Institute for Biological Studies, La Jolla, California

It is generally believed that motion perception is degraded at chromatic isoluminance and that moving objects appear to slow down. In this study, the oculomotor consequences at isoluminance are evaluated and the results are compared with perceived motion under similar conditions.

The stimulus was a lattice composed of 3x3 pixel tokens (3.6 min arc/pixel), randomly assigned to be red or green, and separated from neighbouring ones in all directions by 3 pixels. The background was either dark or an isoluminant gray. In all cases, pattern movement was to the right or left and restricted to an integral multiple of the period, usually 6 pixels. The luminance of the red components was fixed and the green varied. A 2-AFC direction discrimination paradigm was used for psychophysical assessment on three human subjects. Eye movements were obtained from two humans and two monkeys (*Macaca mulatta*) using magnetic search-coil oculography.

The results showed that optokinetic eye movements (OKN) were produced at all red/green ratios when a dark background was used, including the isoluminant condition. However, a significantly reduced OKN response was obtained with an isoluminant gray background. Perceived motion remained salient under both conditions. These results demonstrate that motion correlations based on chromatic differences alone can produce an optomotor response only if there is sufficient luminance contrast with the surround. The implications for neural processing of motion are discussed.

HUMAN HEADING PERCEPTION DURING COMBINED TRANSLATIONAL AND ROTATIONAL SELF-MOTION.

L. S. Stone and J. A. Perrone*. Life Science Div. & Vision Group, NASA Ames Research Ctr, Moffett Field, CA 94035.

Local differential motion (LDM) of nearby points at different depths is one method for extracting heading from optic flow. To test this idea, 3 subjects made judgments of horizontal heading in response to visually-simulated forward translation plus yaw rotation under two conditions: motion toward (A) two superimposed vertical planes of random dots at different depths or (B) two non-overlapping half-planes at different depths above and below fixation. A 5.7° strip along the horizontal meridian was blank and stationary frames of A & B were indistinguishable. A provides LDM, B does not. Therefore, poor performance and higher sensitivity to rotation is predicted for B. However, mean systematic errors in perceived heading were small for both A & B (0.1±0.7° and 1.3±0.6° respectively for 1.5°/s yaw). Precision was similar for A & B and only weakly related to yaw rate (1.2° and 2.3° at 1°/s vs 2.0° and 2.4° at 2°/s) with performance nearly asymptotic by 200ms. We conclude that self-motion processing, thought to occur in extrastriate cortex, does not rely on LDM.

ON FILLING THE BLIND SPOT AND OTHER MEDICAL MARVELS V. S. Ramachandran and W. H. Aiken, UCSD, La Jolla, CA 92093, USA

Does filling in the blind spot involve creating an actual neural representation of the surround? We designed several new stimuli to answer this question. 1) A line running through the blind spot appeared continuous. This interpolation occurred even if the line segments on the two sides of the blind spot were colored differently. 2) If the center of a "star" fell in the blind spot, the pattern appeared complete. 3) If part of a circle was placed in the blind spot it appeared "chopped off", i.e. it was not completed. 4) A vertical column of dots was placed on the blind spot. At low spatial frequencies a "missing dot" was noticeable, i.e. no completion occurred. 5) A red ring (annulus) placed on the blind spot with its inner margin overlapping the outer edge of the blind spot looked like a homogenous red disk. Yet if a set of thin concentric rings were added around the annulus the blind spot appeared filled in with rings instead of homogenous red! Thus what fills in is not merely what is in the immediate surround but also the pattern from the remote surround. 6) A ring was placed on the blindspot so that it looked like a disc. If several other rings were scattered in the visual field, the ring in the blind spot region "popped out" preattentively. 7) A vertical line passed through the blind spot. The "terminators" created by the blind spot, interrupting the line and could not be used for motion correspondence.

What causes the "filling in?" We suggest that the effect arises partly in VI itself and partly from the activity of extrastriate neurons whose large receptive fields may straddle the blind spot.

PHANTOM CONTOURS: STIMULI THAT SELECTIVELY ACTIVATE THE MAGNOCELLULAR PATHWAY. D. Rogers-Ramachandran and V. S. Ramachandran. UCSD, La Jolla, CA 92093.

Equiluminous contours mainly excite the parvo (P) pathway and provide only a weak input to motion (Ramachandran and Gregory, 1978). Here we report a novel technique for selectively stimulating the magnocellular (M) pathway. The stimulus (Frame 1) was a "texture border" between black and white spots on a grey field. This was followed by frame 2 in which all the black spots were replaced with white, and white with black. At 20 Hz, subjects could not discriminate between the spots but could nevertheless see a "phantom contour" separating the two indiscriminable regions. On occluding the phantom contour the difference between the spots could be discriminated only at about 7 Hz. Since the M pathway can follow high flicker rates but is insensitive to the sign of the border the phantom border is "seen" exclusively by the M system. The P system can report the sign of the border but only at low flicker rates. Phantom contours were enhanced by blur, tolerated low contrasts (<10%) and vanished if red/green equiluminous spots were used.

The use of phase-reversing edges to stimulate the M pathway was first suggested by Livingstone & Hubel (J. Neuroscience, 1987). Our stimulus differs from theirs in using a texture border which effectively eliminates any edge artifacts (e.g. Mach Bands) that might arise from "real" contours.

Phantom contours allows us to "lesion" the P pathway in man. We find that the tilt illusion, "barber pole" illusion, size aftereffect and McCollough effect can be conveyed by phantom contours but not binocular rivalry. Phantom contours also provide a clinical test for glaucoma.

VISUAL REVERSAL-LEARNING DEFICITS AFTER TELEENCEPHALIC VISUAL-SYSTEM LESIONS IN PIGEONS. L. Chaves* and W. Hodos. Dept. of Psychology, Univ. of Maryland, College Park, MD 20742.

Lesions of the telencephalic targets of the thalamofugal visual pathway (laminae IHA and HD of the visual wulst) in pigeons result in disrupted performance on a color reversal-learning task (Shimizu and Hodos, *Behav. Neurosci.*, 1989). A subsequent study (Chaves and Hodos, *Neurosci. Abstr.*, 1989) found that lesions of the OPT complex, the thalamic equivalent of the lateral geniculate, and source of afferents to the visual wulst, had no effect on this task. In contrast, lesions of nucleus rotundus, the thalamic component of the tectofugal visual pathway, resulted in greater reversal-learning impairments than did visual wulst lesions. We report here that lesions of ectostriatum, the telencephalic component of the tectofugal visual pathway and target of n. rotundus, produce deficits comparable to those observed after lesions of n. rotundus. This finding suggests that the deficits in reversal-learning after wulst lesions are not the result of interruption of the thalamofugal visual pathway, but rather that those effects are a consequence of the wulst's connections to the tectofugal pathway.

VERNIER ACUITY DEFICITS IN MENTALLY RETARDED ADULTS Stephen Gross III and Robert Fox. Department of Psychology, Vanderbilt University, Nashville, Tennessee 37240.

Our prior investigations, using random element stereograms (RDS) and kinematograms (RDK), have found that mildly mentally retarded adults appear to have fundamental deficits in depth and motion perception. Form discrimination and detection are impaired as element density, temporal correlation and number of frames are reduced. The deficits appear to be selective as visual acuity, contrast sensitivity, and color perception are not impaired. Moreover, control conditions indicate that the deficits cannot be attributed to failures of comprehension or peripheral visual anomalies.

These data have led us to investigate vernier acuity for both luminance-defined and motion-defined stimuli. Both mentally retarded and nonretarded adults were tested using conventional paradigms that utilize forced-choice methodologies. Although the mentally retarded subjects exhibited elevated thresholds for both stimulus classes, the thresholds for the motion defined stimuli were significantly higher and were further impaired by reductions in element density.

This pattern of results is similar to those obtained in our earlier studies and suggests that mildly mentally retarded adults have substantial perceptual deficits that arise early in the visual system. Consequently, these results invite reexamination of a prevailing view in the field of mental retardation that assumes most mildly mentally retarded adults have no patent neurological impairments. To that end, we discuss the results with respect to neural network models and research relating known neurological impairments to selective perceptual impairments in other populations. DOG AND CATS: THEY MAY LOOK DIFFERENT BUT THEY SEE THE SAME. M.S. Loop and M.M. Martin. Dept. of Physiological Optics, School of Optometry, University of Alabama at Birmingham, B'ham, AL 35294.

We have extensively examined the behavioral spatial contrast sensitivity and reaction time of a dog in a testing situation previously used with cats. To a flashed (70 cd/m², 500 msec, 10°, vertical, sine-wave) grating the dog was most sensitive around 1.0 cpd with a cut off sensitivity around 3.0 cpd. At equal physical contrasts the dog detected 0.25 cpd faster than he detected 2.5 cpd. At threshold equivalent contrasts 0.25 and 2.5 cpd were detected with the same latency around threshold but faster detection of the low spatial frequency emerged above threshold. These results were quite similar to those found with cats.

When grating duration was varied (100 or 1000 msec) at 0.25 cpd it had no effect upon sensitivity and no effect upon reaction times. However, at 2.0 cpd the dog was reliably more sensitive to the 1000 msec flash yet detected the 100 msec flash faster. Thus the dog behaved as if he (1) detected low spatial frequencies with a mechanism which responded relatively quickly and in a transient fashion; and (2) detected high spatial frequencies with a relatively slower mechanism which responded in a sustained fashion.

These data complement the reported similarities in ganglion cell morphologies between dogs and cats (Peichl, 1989, *Neuroscience Abstracts*, p. 1207). (Supported by EY05576; RR05807)

Visual and Auditory Cortex Ablations Following Cross-Modal Transfer and Recovery of Function in the Rat. R.A. Salazar*, R.B. Wallace and G.L. Baker-Salazar*, Depts. of Psychology, Univ. of New Mexico, Albuquerque, NM. 87131 & Univ. of Hartford, West, Hartford, Ct. 06110.

Twenty Long-Evans Hooded rats were trained either under visual-auditory (V-A) or auditory-visual (A-V) Cross-Modal Transfer. Prior to the second training session, 5 of the A-V animals received auditory ablations and 5 V-A animals received visual ablations. The other ten control animals received sham operations, whereby they went through the same surgical procedures as the experimental animals but no ablations were performed. All animals were given two weeks to recover. Testing revealed significance using a 2X2 ANOVA during the second training session for the CTL versus EXP groups, the CS Modality groups, and the interaction. Transfer had occurred even though the cortex that the animal used in the original training session was ablated. Information could have been received from the cortex used during the original training session by the cortex used in the second or retraining session, just prior to the operation. Visual Functions Associated with Rhesus Visual Pursuit Tracking. H. Zwick¹, D.O. Robbins², J. Calabrese¹, K.R. Bloom¹ and M. Cook¹. ¹ Letterman Army Institute of Research, San Francisco, CA 94129 and ² Ohio Wesleyan University, Delaware, OH 43015.

Degradation of visual performance following laser exposures has been extensively examined under a variety of different spatial and spectral viewing conditions. Much less work has been done relating the effects that suppression of foveal receptor mechanisms has on visually guided tasks such as pursuit tracking. Using various target resolution criteria we have evaluated the effects that subretinal damage threshold dosages have on visual pursuit tracking. Two rhesus monkeys were trained on a pursuit tracking task which required the animals to continuously track a horizontally moving annulus by maintaining a small spot from a HeNe laser pointer in the center of this annulus. By changing the wavelength of the annulus, intensity tracking performance functions for time on target could be obtained. Spectral sensitivity functions derived for high resolution requirements were more easily fitted with the 575 nm photopigment than were those requiring lower resolution. Laser flash effects measured for either on- or off-axis exposure revealed a significant parafoveal component related to resolution criteria. For high resolution criteria, both an on- and off-axis exposure effects were observed; for lower resolution criteria only the parafoveal function was affected. The neural motor processing of normal or degraded visual inputs may require both fine and gross neural processing mechanisms at and beyond the retinal level.

333.17

NEURAL NETWORK ANALYSIS OF VISUAL FIELD DEFECTS: WHAT IS THE NETWORK USING TO LEARN? M. Wall, M.E. Mulet, A.D. Nelson, Tulane University School of Medicine, Departments of Neurology and Ophthalmology, 1430 Tulane Avenue, New Orleans, LA 70112.

The visual field patterns used by neural networks to separate patterns of disease from a normal visual field is unknown. We trained a neural network (Brainmaker, California Scientific Software) on 393 visual fields to separate patients with visual loss due to pseudotumor cerebri from normal subjects. Conflicting facts were first purged from the data set. A training tolerance of 0.1 with a learning rate of 1 was used. We had 57 inputs (Humphrey program 24-2+). Test sets were made to see the influence of various nerve fiber bundle areas by equalizing test scores in various nerve fiber bundle areas. The testing tolerance was 0.20.

The network correctly categorized 85% of the subjects. With elimination of the area around the blind spot, the efficiency fell to 64%. The results for the inferior nasal area and cecentral area were 72% and 76% respectively. We conclude pattern recognition of abnormal visual fields has a significant contribution from the peripapillary area.

333.18

THE RELEVANCE OF EYE MOVEMENTS AND BLINK MEASURES TO OBJECTIVE AND SUBJECTIVE MEASURES OF WORKLOAD. R. S. Kennedy, J. G. May, W. P. Dunlap, and M. G. Smith*. Essex Corporation, Orlando, FL 32803.

New cockpit display systems being introduced into military aircraft make high demands on human information processing. A need exists to link cognitive and motor performance to objective measures of workload, perhaps by indexing neurophysiological events to task demands of the situation. Using a within-subjects design, bioelectric measures of various aspects of eye movements and blink (frequency, acceleration, displacement, etc.) were measured while visual and auditory (in the dark) tasks were performed. Oculomotor task demands and a workload metric were assessed independently and found to be related to the ocular measures. The general findings are that elements of eye activity (range of movement, number of blinks, and blink duration) correlated at a statistically meaningful level with either the visual task demands or with the workload. This study was the first step in the design of an automated task load analysis system using eye movements as biocybernetic applications to aid in designing new aircraft cockpit display systems.

BASAL GANGLIA AND THALAMUS: ELECTROPHYSIOLOGY

334.1

VOLTAGE-DEPENDENT 40-HZ OSCILLATIONS IN RETICULAR THALAMIC NEURONS. D. Pinault and M. Deschênes, Centre de Recherche en Neurobiologie, Laval Univ. Québec, Canada G1J 1Z4.

There is now growing evidence that focused arousal is associated with the occurrence of 40-Hz field potential oscillations in the brain. As most oscillatory neuronal activities in the central nervous system depend upon the intrinsic membrane properties of the cellular populations in which oscillations develop, and because the reticular thalamic (RT) nucleus occupies a pivotal position in thalamocortical networks, one may wonder if RT cells would not possess intrinsic membrane properties that could allow them to act as pacemakers of 40-Hz oscillations in the thalamus and cortex. Recordings performed in the rat RT nucleus under urethane anaesthesia revealed that, amidst spontaneously bursting units, many neurons discharged tonically, like clocks, at rates that were remarkably fixed within a frequency range of 25-60 Hz (i.e. 40 Hz). Control recordings performed in various thalamic nuclei and cortical regions did not disclose any field potential or unitary activity in the 40-Hz range. On the other hand, intracellular recordings showed that the clock-like behavior of RT cells was driven by a subthreshold membrane potential oscillation whose frequency was voltage-dependent; membrane depolarization increased the frequency while hyperpolarization decreased it and eventually stopped completely the oscillator. In thalamic relay cells, the 40-Hz firing of RT neurons was associated with the occurrence of inhibitory postsynaptic potentials in the 40-Hz range. Given the pivotal position of RT neurons in thalamocortical networks, the present results support the hypothesis that the RT nuclear complex might play a pacemaker function in the genesis of 40-Hz field potential oscillations in the thalamus and cortex during states of focused arousal. (Supported by the MRC of Canada)

334.2

CONTROL OF 40-HZ FIRING IN RETICULAR THALAMIC CELLS BY AMINES AND EXCITATORY AMINO ACIDS. M. Deschênes and D. Pinault, Centre de Recherche en Neurobiologie, Laval Univ., Québec, Canada G1J 1Z4.

In a companion abstract we reported a 40-Hz firing mode in reticular thalamic (RT) cells in rats under urethane anaesthesia. This tonic mode of discharges was shown to depend upon an intrinsic voltage-dependent pacemaker mechanism. Since this pacemaker activity was present at membrane potentials positive to -65 mV, we investigated which neurotransmitters might be involved in depolarizing RT neurons within the voltage range where the pacemaker activity is expressed. Experiments were conducted in urethane anaesthetized rats using extracellular recordings and local application of antagonists against neurotransmitters known to be involved in the modulation of RT cells' activity. All drugs were dissolved in a Ringer solution (pH: 7.4) and they were applied in small quantities (25-100 nL) by pressure through one barrel of a micropipette assembly (tip size: $\approx 10 \mu\text{m}$; distance between the tips: $\approx 70 \mu\text{m}$). The effect of each drug was tested on at least 10 RT cells that were firing spontaneously at 40 Hz. Forty-Hz firing was abolished by the $\alpha 1$ antagonist prazosin (10 μM) and by kynurenic acid (100 μM), a wide spectrum antagonist of glutamate and aspartate. Ketanserin, at a concentration of 20 μM , also blocked tonic firing but this effect could be due to the affinity of the drug for α noradrenergic receptors. Conversely, scopolamine (100 μM) exerted a permissive action on the expression of 40-Hz activities. Many spontaneously bursting units started firing at 40 Hz under the influence of this muscarinic antagonist. Given the mode of action of amines and acetylcholine on RT neurons, and the possibility of a metabotropic action of glutamate, the above results suggest that deactivation of (a) K conductance(s) is critically involved in the expression of a 40-Hz pacemaker activity in RT cells. (Supported by the MRC of Canada).

RESPONSES TO INJECTION OF RAMP CURRENTS IN NEOSTRIATAL NEURONS. Galarraga, E. and Bargas J. Depto. de Fisiología, Biofísica y Neurociencias. CINVESTAV IPN. Ap. Postal 14-740, México, D.F. 07000.

Intracellular recordings were obtained from brain slices of the rat brain. 1) Predominant ionic conductances in a given voltage range, 2) their thresholds, and 3) their actions on the firing pattern, were analyzed using membrane voltage responses after ramp currents (rate: 0.01 to 0.1 nA/ms). Quasi-steady-state I-V plots and I-F plots were performed. I-V plots were not linear and presented a hysteresis which was analyzed under the action of different blockers (TTX, Cd, Ni, 4-AP, TEA, etc.). Sudden alterations in the voltage rate of change signaled thresholds and decreases or increases in R_{slope} indicated outward or inward current predominance respectively. Examples: anomalous rectification (range ≤ -70 mV), inward and outward subthreshold conductances (range: -60 to -40 mV), calcium spikes after TTX (threshold: -25 to -15 mV), AHP-like Cd-sensitive hyperpolarizations present upon returning from depolarizing ramps even in the absence of "all-or-none" spikes, suggesting the presence of a lower threshold gCa albeit not able to trigger autorregenerative spikes. CONACYT grants P228CCOX891576 to E. G. and P228CCOX891559 to J. B.

334.4

THE ACTION OF APAMIN ON THE MEMBRANE PROPERTIES OF THE SUBSTANTIA NIGRA PARS COMPACTA NEURONES IN VITRO.

N. C. Harris* & S. A. Greenfield* (SPON: Brain Research Association.) Dept. of Pharmacology, Oxford University, Oxford OX1 3QT, U.K.

Electrophysiological studies have characterised the properties of the substantia nigra pars compacta (SNc) neurones. Intracellular recordings *in vitro* have shown action potentials with a characteristically wide action potential (approx 2 ms) and a long lasting after-hyperpolarisation (lasting approx 100 ms), which has been suggested to be in part due to a calcium dependent potassium conductance. Apamin is a polypeptide neurotoxin that selectively blocks small conductance calcium dependent potassium channels. The purpose of this study was to investigate the effects of apamin on SNc neurones *in vitro*.

Recordings were made from guinea pig brain slices by previously described methods (Harris et al. Neuroscience 31: 355, 1989). Seventy percent of the neurones recorded were spontaneously active 2.5 ± 0.4 spikes/s, displaying a very regular firing pattern. In response to hyperpolarising current pulses voltage sensitive inward and outward rectification was seen. Apamin reduced the large after-hyperpolarisation of spontaneous and evoked action potentials. Apamin was bath applied to a total of 14 neurones at concentrations ranging from 0.2 - 1 μM . Apamin had a variable effect on the firing rate of the neurones. The firing frequency of 60% of the cells were increased, but overall there was no statistically significant change in the firing rate. However, there was a significant increase on the variance of the interspike intervals following the application of apamin. These results show that a small conductance $\text{gK}(\text{Ca})$ is involved in the spike after-hyperpolarisation, but that blockage of this conductance does not alter the spontaneous discharge frequency of SNc neurones. Supported by the Parkinson's Disease Society (U.K.) and Bristol Myers Squibb Co.

SKF 38393 INCREASES THE EXCITABILITY OF STRIATAL NEURONS *IN VITRO* FOLLOWING CHRONIC DOPAMINERGIC DENERVATION. L. A. Thompson, J. R. Walters, and M. J. Twery, NINDS, Bethesda, MD, 20892.

Systemic administration of the D_1 receptor agonist SKF 38393 inhibits the activity of substantia nigra pars reticulata (SNR) neurons in rats with 6-hydroxydopamine (6-OHDA) lesions, but produces variable effects on SNR activity in normal rats. Since the striatum may be the site of action of systemic SKF 38393, we have investigated the effect of chronic unilateral dopaminergic denervation on the response of striatal neurons to SKF 38393 *in vitro*. Intracellular recordings both ipsilateral and contralateral to 6-OHDA lesions (6-10 wks) were obtained from coronal slices containing striatum. Since striatal neurons were silent at rest, neuronal excitability was evaluated by varying the amplitude of depolarizing current pulses and determining the number of spikes elicited. Superfusion of SKF 38393 (1-3 μ M) increased the excitability of neurons *ipsilateral* to the lesion (15/19 neurons), without inducing consistent changes in membrane potential (ΔV_m : 0.5 ± 0.8 mV) or membrane resistance (% Δ : $5.2 \pm 5.6\%$). Four (of 19) *ipsilateral* neurons were inhibited by SKF 38393. In contrast, among *contralateral* neurons, SKF 38393 predominantly decreased neuronal excitability (9/15). Only three *contralateral* neurons exhibited increased excitability in the presence of SKF 38393 and another three neurons were apparently unaffected. Regardless of hemisphere, decreases in excitability were typically associated with a small membrane depolarization (mean: 2.0 ± 0.47 mV, $n=13$). These results indicate that chronic dopaminergic denervation changes the predominant effect of D_1 stimulation in the striatum from inhibition to excitation. This change in the responsiveness of striatal neurons may contribute to the pronounced inhibitory actions of SKF 38393 observed in the SNR following dopaminergic lesions *in vivo*.

WHOLE-CELL PATCH-CLAMP ANALYSIS OF MEDIUM SPINY NEURONS IN THIN SLICES FROM RAT NEOSTRIATUM. A. Mori*, Y. Miyashita and H. Kasai, Department of Physiology, Faculty of Medicine, University of Tokyo, Hongo, Bunkyo-ku, Tokyo, 113 Japan.

In order to characterize the biophysical properties of the principal neurons of the basal ganglia, the whole-cell patch-clamp method was applied to thin (130 μ m thickness) slices of caudate nucleus from 8 to 14 day old rats. Medium sized (10-18 μ m) neurons were selected under Nomarski optics and subjected to whole-cell clamp measurements. Injection of Lucifer Yellow revealed extensive dendritic trees stubbed with spines in most of these cells. Resting membrane potentials ranged between -55 and -70 mV and input resistances between 200 and 500 M Ω . Membrane depolarization activated Na and K currents. In addition, non-inactivating Ca currents were recorded at potentials larger than -40 mV, when intracellular K was replaced by Cs. Focal stimulation of slices by current pulses through a second glass pipette evoked synaptic currents as well as antidromic Na spikes. The synaptic currents were mediated by AMPA-, NMDA- and GABA $_A$ -receptors. A quickly decaying component of synaptic current had a reversal potential of about 0 mV and was abolished by CNQX (10 μ M) in the presence of picrotoxin (100 μ M). A slowly decaying component appeared at potentials larger than -60 mV, had a reversal potential of about 0 mV and was blocked by APV (500 μ M). In the presence of CNQX and APV, synaptic currents reversed at around -60 mV and were blocked by picrotoxin. Polysynaptic inputs were also eliminated by picrotoxin, suggesting the presence of collateral inputs from the axons of other medium spiny neurons. Thus, the thin-slice patch-clamp method offers a way to study the structural and biophysical properties of the principal neurons and to characterize the local circuits in the basal ganglia.

GABA $_B$ RECEPTORS REDUCE BOTH GLUTAMATERGIC EXCITATION AND GABA $_A$ INHIBITION OF RAT STRIATAL NEURONS THROUGH PRESYNAPTIC MECHANISMS. E.S. Nisenbaum, T.W. Berger, and A.A. Grace, Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Recent evidence has indicated that GABA $_B$ receptors can mediate presynaptic inhibition of neurotransmitter release in several brain systems. The present experiments investigated the potential regulation by GABA $_B$ receptors of cortically-evoked glutamatergic excitation and GABA-mediated paired impulse inhibition of striatal neurons using intracellular recording techniques in an *in vitro* corticostriatal slice preparation.

In response to single stimulation of cortical afferents, a monosynaptic EPSP was recorded in striatal cells which could be completely blocked by the glutamatergic kainate/quisqualate receptor antagonist, CNQX (10 μ M; $n=5$). In addition, when the allosteric GABA $_A$ receptor agonist, pregnanolone (5.0-7.5 μ M; $n=17$), was used to enhance GABAergic input, paired impulse stimulation of cortical fibers selectively decreased EPSP amplitude and probability of spike discharge in response to the second impulse of ISIs of 10-30 ms. Application of the GABA $_B$ receptor agonist, baclofen (0.5-2 μ M; $n=23$), markedly inhibited the glutamate-mediated EPSP evoked by single stimulation of cortical afferents. Similarly, in pregnanolone-treated slices, administration of baclofen produced an increase in stimulation threshold for spike discharge, and reversed the paired impulse inhibition of striatal cell responses. Baclofen did not alter either the resting membrane potential or the input resistance of striatal neurons. The baclofen-induced inhibition of glutamatergic and GABAergic responses could be blocked by the GABA $_B$ receptor antagonist, 2-OH-saclofen (100-500 μ M; $n=10$). These results suggest that the release of glutamate and GABA in response to stimulation of cortical afferents can be regulated by presynaptic GABA $_B$ receptors. IN VITRO ELECTROPHYSIOLOGICAL CHARACTERIZATION OF STRIATAL NEURONS FOLLOWING CHRONIC UNILATERAL 6-HYDROXYDOPAMINE LESIONS OF DOPAMINE CELLS. M. J. Twery, L. A. Thompson and J. R. Walters, NINDS, NIH, Bethesda, MD 20892.

Lesions of midbrain dopamine cells produce profound changes in the neurotransmitter content and the apparent responsiveness of striatal neurons to dopaminergic stimulation. The present study investigated whether chronic (6-10 wk) unilateral dopamine cell lesions altered the passive membrane properties or excitability of striatal neurons by comparing responses in tissue slices obtained ipsilateral and contralateral to the lesion site. Intracellular recordings from striatal neurons located ipsilateral to the lesion site revealed no spontaneous activity ($V_m = -77.8 \pm 1$ mV, $n=32$). Depolarizing current pulses (0.8-2.2 nA, 0.3-3 sec) elicited predominantly repetitive firing (20/32 neurons) characterized by a spike latency dependent on pulse amplitude. Less frequently, pulses elicited an initial spike followed by a rapidly accommodating burst of spikes (6/32) or an initial single spike alone (6/32). Striatal neurons contralateral to the lesion were also silent ($V_m = -77.1 \pm 1.5$ mV, $n=29$) and exhibited a generally similar response pattern with repetitive (23/29) and initial single spike (5/29) firing. Rapid accommodation of burst firing, however, was infrequently observed (1/29). I-V relations obtained from neurons ipsilateral and contralateral to the lesion revealed no differences in slope resistance near rest (39 ± 2 M Ω , $n=61$) associated with evoked firing patterns. This study indicates that the chronic loss of dopaminergic input to striatum does not lead to widespread changes in neuronal excitability or passive membrane properties. Postulated changes in striatal function following chronic denervation may reflect alterations in the responsiveness of neurons to neurotransmitters.

DYE-COUPLING IN TYPE I AND TYPE II STRIATAL NEURONS: ALTERATION BY APOMORPHINE AND LOCALIZATION TO THE PATCH/MATRIX. S-P. Omm, T.W. Berger and A.A. Grace, Depts. of Behavioral Neuroscience & Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260

Despite numerous studies examining the effects of dopamine (DA) on single neurons in the brain, only recently have studies begun to address DA on the assemblies of functional networks of neurons such as those mediated by electrical coupling. This study examined the effects of apomorphine, a DA agonist, on the extent of dye-coupling (as an index of electrical coupling) among Type I and Type II striatal neurons in adult anesthetized rats. Type I and Type II neurons were defined on the basis of their paired impulse response to stimulation of excitatory cortical afferents. All cells were recorded intracellularly *in vivo* using Lucifer yellow-filled microelectrodes. After recording and staining, the cells were also localized with respect to the patch/matrix architecture of the striatum by immunocytochemical labeling of calbindin 28 Kd, a known marker for matrix (antiserum kindly provided by Dr. M.R. Celio). In control rats, dye-coupling was found exclusively between pairs of neurons (8/43; 18%) and in all cases neurons were localized in the matrix. In each case, coupling was observed between medium spiny neurons that shared Type II response patterns (Type I: 0/15 vs Type II: 8/28). However, intravenous apomorphine (0.1mg/kg) increased the incidence of dye coupling (7/10; 70%) and the numbers of cells stained by each injection, with up to six cells being labeled after a single injection (4/7 cases showing labelling of 5-7 cells; 1 for Type I and 3 for Type II cells). Thus, in addition to its action on single cells, DA appears to play a role in regulating the intercellular communication within the striatum. (Supported by Huntington's Disease of America Grant & NS08288 to S-P.O. and NS19608, MH42217 & MH00343 to T.W.B and A.A.G.).

334.10

STRUCTURE-FUNCTION RELATION OF THE GLOBUS PALLIDUS NEURONS: AN *IN VITRO* STUDY IN GUINEA PIG BRAIN SLICES.

A. Nambu and R. Llinás, Dept. of Physiology and Biophysics, New York Univ. Med. Ctr., New York, NY 10016

Intracellular recordings obtained from globus pallidus neurons revealed the existence of at least two classes of neurons on the basis of membrane properties. Type I neurons were characterized by a low threshold calcium spike, fast transient K^+ -current (A-current) and a prominent spike accommodation. Continuous depolarization of type I neurons produced Ca^{2+} -dependent slow membrane oscillation (around 2 Hz), which triggered Na^+ -spikes. Type II neurons were characterized by a low threshold calcium spike and capability of high frequency firings (up to 150 Hz) by intracellular depolarizing pulse. Continuous depolarization of type II neurons produced Na^+ -dependent membrane oscillation (10 - 100 Hz), which triggered Na^+ -spikes. Morphology of these neurons was studied by intracellular injection of biocytin and ABC method. Some size of type I neurons (30-50 μ m long and 15-30 μ m wide) was larger than that of the type II neurons (20-40 μ m long and 10-25 μ m wide). Both types of neurons had 2-6 primary dendrites. Most dendrites had few spines and exhibited varicosities especially in their terminal branches. Axons originated from soma or dendrite. All axons were prominently beaded. Usually axons had collaterals, and in some cases, one axonal branch was followed caudally and another one was followed rostrally into the striatum. These axonal patterns suggest the inhibitory effect of the pallidal neurons on the striatal neurons as well as on the other pallidal neurons. (This work was supported by NIH grants NS13742. A.N. was also supported by the Naito Foundation.)

EXCITATORY POSTSYNAPTIC CURRENTS OF IDENTIFIED LARGE ASPINY CELLS IN THE MATRIX OF THE NEOSTRIATUM *IN VITRO*. Y. Kawaguchi, Lab. for Neural Systems, Frontier Research Program, RIKEN, Wako 351-01, Japan

Most large neurons in the neostriatum are considered as interneurons that are cholinergic. It has been suggested that they are different from medium sized spiny projection cells in firing pattern, excitatory inputs and vulnerability to excitatory amino acids. The large neurons are candidates for connecting the patch and matrix compartments of the striatum. These are studied in rat slice preparation by whole cell recording. Large neurons were identified by soma diameter larger than 20 μm and confirmed by biocytin staining. Compartment identification was made by calbindin immunohistochemistry. All large neurons stained had aspiny and sparsely spiny dendrites and were in the matrix or on the border of this compartment. Axons close to the boundaries avoided invading patches by curving or running along the border. Some dendrites close to the boundaries avoided crossing by curving but a few entered the patch and made numerous fine branches with spine-like appendages. The cells had action potentials with large AHP and inward rectification occurred only with potentials hyperpolarized by -20 mV. EPSCs had two components. A later component had depolarizing rectification which was eliminated in Mg-free solution and blocked by 50 μM DL-APV. An early component was blocked by 10 μM CNQX. A few large cells with varicose dendrites had virtually no NMDA components in their EPSCs. These results show that most large neostriatal cells have NMDA and non-NMDA component EPSCs, that the axons observe the compartment organization and only specialized dendrites cross the boundary. (Supported by HFSP)

INWARD RECTIFICATION AND SYNAPTIC RESPONSES OF NEURONS IN THE INTACT TURTLE STRIATUM *IN VITRO*. D.J. Rossi, P.D. Morrison, and N.T. Slater, Department of Physiology, Northwestern University Medical School, Chicago, IL 60611 U.S.A.

Despite the wealth of information obtained using intracellular recording methods in mammalian striatal neurons *in vitro* and *in vivo*, no studies to date have examined the striatum of lower vertebrates. We have employed an intact preparation of turtle striatum *in vitro* to study the membrane properties and synaptic responses to stimulation of afferent sites within the telencephalon of striatal neurons.

Intracellular recordings of the passive electrical properties and synaptic responses in striatal neurons were obtained in the intact turtle (*Chrysemys picta*) striatum *in vitro* using both conventional 'sharp' microelectrodes and 'blunt' patch electrodes for current- and voltage-clamp recording. Penetrations were confined to the rostral pole of the striatum, where medium-sized spiny cells predominate. Turtle striatal neurons displayed prominent fast inward (anomalous) rectification which was blocked by external cesium and barium, but not by TTX. Under voltage clamp, the activation of the inward rectifier current was too fast to observe inward current relaxations to hyperpolarizing voltage commands, despite coating of patch electrodes to reduce capacitive transients. Little spike adaptation or post-burst AHPs were observed following depolarizing current injection. Electrical stimulation of the dorsal (visual) cortex and the dorsal ventricular ridge (DVR) evoked both monophasic EPSPs and compound EPSP-IPSPs. Stimulation of the lateral forebrain bundle evoked primarily compound IPSPs. Both EPSPs and IPSPs could be blocked by excitatory amino acid antagonists; fast EPSPs and IPSPs were blocked by CNQX (5 μM), and a slow component of the corticostriatal EPSP was blocked by D,L-AP5 (100 μM). *I-V* curves for the EPSCs recorded with patch electrodes displayed either linear or bell-shaped curves in individual cells over the range -40 to -120 mV.

The results demonstrate the utility of the turtle preparation for the study of striatal function, and illustrate that turtle striatal neurons have similar electrical and synaptic properties to those of mammals. Supported by NS 17489 and NS 25682.

DOPAMINERGIC MODULATION OF SODIUM CURRENTS IN RETROGRADELY IDENTIFIED RAT STRIATONIGRAL NEURONS.

D.J. Surmeier, C.J. Wilson, A. Stefani and S.T. Kitai, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

The role of dopamine in controlling the excitability of neostriatal neurons remains controversial. One source of experimental difficulty is the existence of multiple receptor subtypes. Recent work has suggested that particular subtypes may be restricted to striatopallidal or striatonigral neurons. We have tested this hypothesis in the striatonigral population by using the dopaminergic modulation of the sodium current as an assay.

Neurons from the neostriatum of adult rats (> 4wks postnatal) with rhodamine bead injections into the substantia nigra were dissociated using techniques previously reported by our group. Briefly, the striata were dissected from 500 μm coronal slices. Tissue fragments were incubated in oxygenated saline containing pronase E (1.5mg/ml) at 35 degrees C. After a 30 minute digestion, tissue was washed and mechanically dissociated. Electrophysiological recordings used conventional techniques at room temperature. Striatonigral neurons were visualized with epi-fluorescence.

Our results indicate that in a significant percentage of striatonigral neurons, sodium currents are modulated by both D1 and D2/3 class receptors. In most neurons, D1 and D2/3 agonists both produced a shift in the voltage dependence of steady-state inactivation toward more negative membrane potentials. In some neurons, D1 and D2/3 agonist effects were antagonistic. This work was supported by USPHS grants NS 20702, NS 28889 and NS 26473.

QUANTITATIVE *IN VITRO* AUTORADIOGRAPHY OF EXCITATORY AMINO ACID BINDING IN THE PRIMATE BASAL GANGLIA. A. S. Clark and P. S. Goldman-Rakic, Dept. of Psychology, Dartmouth College, Hanover, NH 03755 and Sect. of Neurobiology, Yale Univ. Sch. Med., New Haven CT 06510.

The corticostriatal pathway has been implicated in numerous neurological and psychiatric disorders including schizophrenia. To understand the functions of neurotransmitter systems within the corticostriatal-thalamo-cortical loop in the nonhuman primate, we examined glutamate binding in the basal ganglia (BG) and related structures.

Adult rhesus monkeys were anesthetized and perfused transcardially with PBS followed by 0.1% paraformaldehyde containing increasing concentrations of sucrose. The brain was removed and a block containing the BG dissected from both hemispheres and frozen in isopentane. Quantitative autoradiography of glutamate receptor subtypes was conducted on cryostat sections through the extent of the BG. Binding to NMDA and kainate sites was present at nearly equal levels in the rostral and caudal aspects of the caudate nucleus (800 fm/mg protein). Similar levels were observed in the putamen. Binding for both ligands was significantly lower in the globus pallidus (< 200 fm/mg). MK-801 binding was also observed in the caudate/putamen with highest levels in the ventral aspect of the putamen (1400 fm/mg). Finally, NMDA binding appeared higher than kainate binding in the amygdala (1200 vs. 700 fm/mg). Identifying the distribution and kinetics of glutamate receptor subtypes in the primate BG and their relationship to other neurotransmitter systems may provide insight into the neurochemical dysfunctions underlying psychiatric disorders.

DEVELOPMENTAL FEATURES OF SODIUM CURRENTS IN RAT NEOSTRIATAL NEURONS. A. Howe and D.J. Surmeier, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

In the course of postnatal development, a number of changes take place in the integrative properties of neostriatal neurons that may be attributable to alterations in the properties of Na currents. To characterize these changes, Na currents were studied in neurons taken from embryonic and postnatal animals through the fourth week of life.

Voltage-clamp techniques were used to study Na currents in cultured and acutely dissociated neurons. Cultures were derived from embryonic striata (E17) using techniques previously published. Acutely-dissociated cells were obtained by dissecting striata from 500 μm slices, enzymatically digesting with pronase E (1.5 mg/ml at 35 C), and then mechanically dissociating. Whole-cell and excised patch recordings used conventional techniques. Most recordings were made at room temperature; some experiments, including those studying deactivation tail currents, were done at 10 C using a temperature controlled bath.

Sodium currents changed in several respects over the late embryonic and early postnatal period. The most obvious change was an increase in current density. Another change was in the characteristics of inactivation. In embryonic and early postnatal cells, inactivation at depolarized potentials was well-fit with a single exponential; at later times, a slow component of inactivation was seen in addition to the faster component seen in younger animals. In contrast, the recovery from inactivation was well-fit only with a sum of exponentials at all ages studied. This work was supported by USPHS grant NS 28889.

THE DEVELOPMENT OF POTASSIUM CURRENTS IN NEOSTRIATAL GRAFTS. Z.C. Xu, C.J. Wilson, D.J. Surmeier, A. Stefani, and S.T. Kitai

Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN, 38163

Previous studies have shown that a slowly inactivating transient potassium current develops in neostriatal neurons over the first 2-4 weeks of life, while a similar but much more rapidly inactivating current is present at birth and continues to be seen in adults. This offers the opportunity to examine a developmentally regulated ionic conductance in neostriatal grafts, which are usually considered to be immature in their physiological properties.

A cell suspension prepared from fetal striatal primordia was implanted into the kainic acid-lesioned neostriata of adult rats. Two to six months after implantation, we employed intracellular recording in tissue slices and whole cell voltage clamp recording on acutely dissociated cells to compare transient potassium currents present in spiny neurons of the neostriatal graft with those in normal adult and neonatal cells of the same type.

Voltage-clamp recordings from graft neurons revealed both slowly and rapidly inactivating potassium currents, as seen in adult neurons. No significant differences in the voltage-dependence or kinetics of these currents were found. Responses of spiny neurons to current injection in slices confirmed the presence of the late developing current in graft neurons. Thus, while graft neurons are developmentally arrested in some respects, they do express normally the full complement of transient potassium conductances activated by depolarization. Supported by NIH grant NS26473.

ROLE OF D₁ AND D₂ DOPAMINE RECEPTORS IN MODULATION OF SYNAPTIC RESPONSES OF NEOSTRIATAL NEURONS. M. Bertolucci, C. Cepeda, N.A. Buchwald and M.S. Levine. Mental Retardation Research Center, UCLA, Los Angeles, CA 90024.

Dopamine (DA), that is released from axon terminals of neurons originating in the substantia nigra, has an important role in regulating responsiveness of neostriatal neurons. We previously showed that DA application decreased the amplitude of locally-evoked synaptic responses in neostriatal neurons in a dose-dependent reversible manner. The present experiments assessed whether the modulatory effects of DA were mediated by activation of D₁ or D₂ receptor subtypes. Intracellular recordings were made from neostriatal neurons in slices obtained from rats. Local extracellular stimulation elicited short-duration excitatory postsynaptic potentials (EPSPs). When domperidone (20 μM), a D₂ antagonist, was added to the bath, the decrease in EPSP amplitude produced by DA was blocked (n=8), suggesting that the D₂ receptor may be involved in the mediation of this effect. Furthermore, bath application of a specific D₂-agonist, quinpirole hydrochloride (10 μM, 20 μM, 50 μM) also induced a significant dose-dependent reduction in the amplitude of the EPSP (n=5). When the effects of the specific D₁ antagonist, SCH23390 (50 μM), were assessed, only 1 cell (n=5) displayed a total blockade of the DA-induced decrease in the EPSP. Two cells showed a partial blockade and the remaining cells showed no effect. These data suggest that the D₂-receptor mediates DA-induced modulation of synaptic responsiveness in neostriatal neurons. Supported by USPHS AG 07462 and HD05958.

CONTRASTING EFFECTS OF DOPAMINE ON EXCITATORY RESPONSES EVOKED BY NMDA AND GLUTAMATE IN NEOSTRIATAL NEURONS. N.A. Buchwald, C. Cepeda, Z. Radosavljevic and M.S. Levine. Ment. Ret. Res. Ctr., UCLA, Los Angeles, CA 90024.

These experiments assessed the effects of dopamine (DA) on responses evoked by excitatory amino acid receptor agonists in the neostriatum (NS). NS neurons were recorded intracellularly in a slice preparation. Slices (400 μm) were obtained from adult rats or cats and maintained according to standard procedures. The following substances were applied iontophoretically in the vicinity of the recorded neuron; DA (0.1 M, pH 4.5), glutamate (GLU) (0.2 M, pH 8), N-methyl-D-aspartate (NMDA) (0.1 M, pH 8) and saline for current control. In some cases, bicuculline was bath applied to enhance the response evoked by the excitatory amino acids. Data were obtained from 17 cells (9 from cats and 8 from rats). Average values were: resting membrane potential -77 mV, spike amplitude 72 mV and input resistance 19 MΩ. In all NS cells, responses evoked by GLU consisted of a fast rising membrane depolarization, repetitive firing but no consistent changes in input conductance. The cell recovered rapidly after discontinuation of GLU. Excitation evoked by NMDA consisted of a slow rising membrane depolarization accompanied by a decrease in input conductance, followed by membrane oscillations and bursts of action potentials. Recovery after NMDA was slow and action potentials persisted for several seconds. Concomitant iontophoretic application of DA produced contrasting effects on the excitation induced by amino acids. Repetitive firing induced by GLU was inhibited by DA. This inhibition was accompanied by a membrane hyperpolarization without noticeable changes in input conductance. Membrane oscillations and bursts induced by NMDA were enhanced when DA was applied. Bicuculline (20 μM) in the bath potentiated excitatory responses evoked by GLU. Iontophoretically applied DA was less effective at inhibiting firing induced by GLU; higher currents were required to alter spike frequency. This contrasting effect of DA may have an important role in modulating the actions mediated by different excitatory amino acid receptor subtypes. (Supported by USPHS 05958).

334.18

EFFECTS OF GABA ON RESPONSES EVOKED BY EXCITATORY AMINO ACID RECEPTOR AGONISTS IN INTRACELLULARLY RECORDED NEOSTRIATAL NEURONS. C. Cepeda, N.A. Buchwald and M.S. Levine. Ment. Retard. Res. Ctr., UCLA, Los Angeles, CA 90024.

GABA is the major inhibitory amino acid neurotransmitter in the neostriatum (NS) and is contained in the medium-sized spiny neurons. These neurons have both extrinsic and intrinsic projections. The present experiment was designed to assess the effects of GABA on responses evoked by glutamate and NMDA. Intracellular recordings were made from NS neurons in an *in vitro* slice preparation. Slices (400 μm) obtained from rats or cats were maintained following standard procedures. Compounds were applied iontophoretically in the vicinity of recorded cells; GABA (0.1 M, pH 5.5), glutamate (0.2 M, pH 8), NMDA (0.1 M, pH 8) and saline (as a current control). The average resting membrane potential of NS neurons was -71 mV (n=9 in rats, n=8 in cats). When GABA was applied the membrane displayed a fast depolarization which reached a plateau at the Cl equilibrium potential (-60 mV). If the membrane was first depolarized by intracellular injection of positive current, the response to GABA was a hyperpolarization. Changes in membrane potential were accompanied by increases in input conductance. Excitatory postsynaptic potentials evoked by local extracellular stimulation, believed to be mediated by non-NMDA receptors, decreased markedly in amplitude and duration when GABA was applied. Excitatory responses induced by glutamate (membrane depolarization and repetitive firing) were also inhibited by GABA. Excitatory responses induced by NMDA (oscillatory depolarizations and bursts of action potentials) were less affected by GABA. In some cases GABA modified the pattern of excitation induced by NMDA, blocking bursting activity and increasing input conductance, but leaving the membrane depolarization unaffected. These findings suggest that, even though GABA exerts inhibitory effects, its efficacy in altering excitatory responses induced by excitatory amino acid receptor agonists, may depend on the receptor subtype activated. (Supported by USPHS 05958).

LONG-TERM POTENTIATION (LTP) OF EXCITATORY SYNAPTIC INPUT TO MEDIUM SPINY NEURONS OF THE RAT STRIATUM. J.P. Walsh, J. Division of Neurogerontology, Andrus Gerontology Center, Los Angeles, CA 90089

Excitatory synaptic input to medium spiny neurons comes largely from pyramidal neurons of the cortex. To activate this synapse, extracellular stimulating electrodes were placed at the junction of the dorsal striatum and the corpus callosum in an *in vitro* slice preparation. Synaptic responses were monitored using intracellular recording techniques (electrodes were filled with 2% biocytin). Control synaptic responses (> 10 mV) were obtained, followed by the delivery of a robust tetanizing stimulus (four tetani each of 1-sec duration at 100 Hz at 10-sec intervals, adapted from Zalutsky and Nicoll, 1990). In normal artificial cerebral spinal fluid (ACSF), post-tetanic potentiation (PTP) was observed to last 2-3 min following the tetanizing stimulus. Thereafter, the EPSP amplitude returned to its pre-tetanic control level. Similar results were also obtained when GABA_A mediated inhibition was removed by bathing the slice in ACSF + 30 μM bicuculline methiodide. Medium spiny neurons exhibit negative resting membrane potentials (> -75 mV) and possess significant voltage-dependent K⁺ conductances both of which oppose the activation of voltage dependent inward currents participating in the generation of LTP (i.e. NMDA, Ca²⁺). Slices were therefore bathed in Mg²⁺-free ACSF to remove the voltage dependent block of NMDA receptor coupled channels. In the Mg²⁺-free ACSF, the tetanizing stimulus elicited bursts of action potentials. The EPSP demonstrated PTP that lasted the first few minutes and LTP (an increase in the amplitude of the EPSP of greater than 30%) that lasted 60 minutes. In a second set of experiments, slices were bathed in ACSF + 30 mM tetraethyl ammonium (TEA). Similar to the Mg²⁺-free ACSF experiment, tetanizing stimuli in the TEA treated slices elicited PTP and LTP following the same criteria of a 30% enhancement of EPSP amplitude. The present experiments illustrate that, under appropriate experimental conditions, LTP of excitatory synaptic input can be produced in the striatum.

BASAL GANGLIA AND THALAMUS: MOLECULAR

335.1

TONIC INHIBITORY ROLE OF D2 RECEPTORS IN THE REGULATION OF GAD mRNA EXPRESSION. M.J. Besson*, J. Caboche*, M. Rogard*, B. Zaic, J. Mallet*, P. Vernier* and J.-F. Julien*. Lab. de Neurochimie-Anatomie, IDN-UPMC, 75005 Paris, and Lab. de Neurobiol. Cell. Mol. & Clinique, INSERM-U134, 75013 Paris, and Lab. de Neurobiol. Cell. & Mol., CNRS, 91198 Gif-sur-Yvette.

In order to further investigate the role of DA in the regulation of striatal neurons we measured the levels of mRNA encoding glutamic acid decarboxylase (GAD), the rate-limiting enzyme in the production of GABA) and preproenkephalin (PPE, the precursor of Enkephalin) after chronic injections of typical (haloperidol: a D1 and D2 receptor antagonist) and atypical (sulpiride: a selective D2 receptor antagonist) neuroleptics. Rats were injected (s.c., twice a day, 14 d.) with haloperidol (1 mg/kg), sulpiride (80 mg/kg) or saline. After *in situ* hybridization with specific ³⁵S-cDNAs, densitometric measurements were performed in the whole rostro-caudal extension of the caudate-putamen (CPU), the nucleus accumbens (NAc) and the olfactory tubercles (OT). In the dorsal CPU, both GAD and PPE mRNA levels were increased after haloperidol (+30%) and sulpiride (+20%) treatments. In the NAc, GAD and PPE mRNA are distributed according to a rostro-caudal gradient. Haloperidol treatment increased GAD mRNA levels in the anterior part (+17%) and PPE mRNA levels in the posterior part (+34%) of the NAc. No changes of GAD and PPE mRNA were found after sulpiride treatment. None of these treatments produced a modulation of GAD and PPE mRNA levels in the OT.

The co-regulation of GAD and PPE mRNA expression observed in the CPU after these treatments indicates a tonic inhibitory role of DA mediated by D2 receptors and likely reflects a regulation in striato-pallidal neurons. The different regulation of GAD and PPE mRNA expression in the anterior and posterior part of the NAc could be related to the differential CCK-DA innervation of the nucleus.

Supported by CNRS and INSERM grant n°90.0601.

SUBCELLULAR LOCALIZATION OF THE GTP-BINDING PROTEIN, G_i, IN THE BASAL GANGLIA REVEALS ITS POTENTIAL ROLE IN BOTH SIGNAL TRANSDUCTION AND VESICLE TRAFFICKING. N. Aronin and M. DiFiglia. Dept. of Medicine, Univ. of Mass. Med. Sch., Worcester, MA 01655, and Dept. of Neurology, Mass. General Hosp., Boston, MA 02114

The G-protein, G_i, is known to mediate signal transduction in cells by inhibiting adenylyl cyclase and by affecting ion channel functions. The immunohistochemical localization of G_i was examined in the basal ganglia using an antiserum directed against the alpha subunit of G_i-1 (gift of E.J. Neer). Immunoreactive G_i was present in medium-sized spiny and aspiny neurons in the neostriatum and in numerous axon terminals in the neostriatum, globus pallidus (GP) and substantia nigra (SN). Labeled axon terminals in the GP and SN formed symmetric synapses characteristic of neostriatal spiny projection neurons. G_i immunoreactivity in neostriatal somata and dendrites was present in rough and smooth endoplasmic reticulum, microtubules and vesicles in transport and along the inner aspect of plasma membranes. In axon terminals in all regions, G_i was evident at different sites along the inner face of the plasma membrane and heavily labeled the membranes of synaptic vesicles, but was not present in the axoplasm or in mitochondria. Western blot analysis with the same anti-G_i antiserum demonstrated a predominant 41 kDa protein in both neostriatal and pallidal synaptosomes, confirming the presence of G_i alpha in the axon terminals. **Conclusions:** G_i is localized to neostriatal projection pathways, where it may function in membrane-bound signal transduction, both pre- and post-synaptically. G_i localization in vesicle membranes points to a potential role for this G-protein in vesicle trafficking such as that recently shown for smaller molecular mass proteins. Supported by NSF BNS-8819989 and NIH NINDS 16367.

DOPAMINERGIC AND NON-DOPAMINERGIC REGULATION OF STRIATAL NEUROTENSIN mRNA EXPRESSION. K.B. Serogy, K.H. Lundgren* and C.M. Gall. Departments of Anatomy & Neurobiology, University of Kentucky, Lexington, KY 40536 and University of California, Irvine, CA 92717.

Manipulation of the dopaminergic mesencephalic system can profoundly modulate levels of neuropeptides and their mRNAs within striatal neurons. To determine if aberrant striatal peptide expression is strictly due to dopaminergic influence or whether other non-dopaminergic mechanisms or circuitries may be involved, adult rats were treated according to either of two paradigms: 1) acute haloperidol administration or 2) induction of limbic seizures by unilateral electrolytic lesion of the hippocampal dentate hilar region. *In situ* hybridization using an ³⁵S-labeled synthetic oligonucleotide probe complementary to neurotensin mRNA was used to examine possible changes in forebrain expression of this peptide, which is infrequently present within striatal neurons in the normal rat. Acute (1 hr or 3 hr) treatment with haloperidol (2 mg/kg, i.p.) resulted in a dramatic increase in the number of neurons expressing neurotensin mRNA in dorsolateral aspects of the caudate-putamen. By 24 hr post-hilus lesion, a significant increase in hybridization for neurotensin mRNA was also observed in the dorsolateral caudate-putamen and in ventral striatal regions (including medial nucleus accumbens) as well as in the septum and bed nucleus of the stria terminalis. In contrast, hybridization to the peptide mRNA appeared to be decreased in the subiculum and hippocampus following hilus lesion. These data demonstrate that dopaminergic mechanisms are not the sole factors regulating striatal peptide expression and that physiological activity radiating from other brain areas exerts a regulatory influence over striatal peptides as well.

NGFI-A mRNA EXPRESSION IS INDUCED IN THE RAT STRIATUM BY INDIRECT DOPAMINE AGONISTS

R. Moratalla, H.A. Robertson, and A.M. Graybiel. Dept. of Brain and Cognitive Science, M.I.T., Cambridge, MA.

In neurons, immediate early genes (IEGs) encode transcription factors that may be involved in the control of genomic events following neuronal stimulation. We have previously shown that cocaine and amphetamine induce *c-fos* and *jun-B* but very little *c-jun* mRNA in the striatum. Moreover, at rostral levels, amphetamine induces Fos-like immunoreactivity (Fos) preferentially in the striosomal compartment of the caudoputamen, whereas cocaine induces Fos about equally in striosomes and matrix. We now show that treatments with amphetamine and cocaine result in similar drug-specific patterns of NGFI-A (*zif/268*, *erg-1*, *Krox-24*) induction. NGFI-A mRNA was detected by *in situ* hybridization with oligonucleotide probes, and striosomes were identified by ³H-naloxone binding in adjacent sections.

NGFI-A mRNA induction by each drug was dose dependent, being scarcely detectable at 5mg/kg and progressively stronger at 10 and 15 mg/kg (amphetamine) or 25 and 50 mg/kg (cocaine). In the rostral caudoputamen, induction by amphetamine was striosome-selective but cocaine induced NGFI-A mRNA in both striosomes and matrix. Induction in the nucleus accumbens was greater in the core than in the shell except after 50 mg/kg cocaine. Pretreatment with the D1-selective antagonist SCH 23390 (0.5 mg/kg) inhibited NGFI-A mRNA induction by either drug. We conclude that IEGs of at least two gene families can be induced in the striatum in drug-specific and striosome-matrix selective patterns.

MOLECULAR CHARACTERISTICS OF STRIATAL NEURONS THAT EXPRESS FOS ON STIMULATION BY INDIRECT DOPAMINE AGONISTS.

S. Berretta*, R. Christie*, H.A. Robertson, and A.M. Graybiel. Dept. of Brain & Cognitive Sci., M.I.T., Cambridge, MA 02139.

Dopamine (DA) regulates neurotransmitter expression in striatal neurons, and increasing evidence suggests that induction and/or repression of immediate-early genes such as *c-fos* could participate in this regulation. To characterize striatal neurons in which DA can activate *c-fos*, we acutely treated rats (n=14) with the indirect DA agonists cocaine (10,25,50 mg/kg) and amphetamine (5,10,15 mg/kg) and tested for neurochemical specializations of the medium-sized striatal cells in which nuclear Fos-like immunoreactivity (Fos) was induced. Sections from treated rat brains were doubly stained, with immunogold and DAB as distinguishable chromogens, for Fos and for enkephalin-like (ENK) or dopamine and cAMP-regulated phosphoprotein-like (DARPP-32) immunoreactivity. ENK-immunoreactive neurons have been shown to express D2 dopamine receptors, whereas DARPP-32 is thought to be a third messenger characteristic of neurons with D1 (and perhaps D5) receptors.

Fos induced by cocaine and amphetamine was nearly always colocalized with DARPP-32 but was almost never colocalized with ENK. This selective pattern of Fos induction may be related to the different patterns of DA regulation of striatal ENK, substance P and dynorphin. As ENK is the major known neuropeptide in the striato-GPe-subthalamic loop pathway, our results further suggest that indirect DA agonists may produce a signalling imbalance in the direct and indirect output pathways of the basal ganglia.

COMPARATIVE DISTRIBUTION OF mRNAs ENCODING TWO GAD ISOFORMS IN OUTPUT NUCLEI OF THE BASAL GANGLIA IN RATS. M. Mercugliano¹, H. Nguyen*, S. Feldblum², M. Erlander², A.J. Tobin² and M-F. Chesselet¹. Dept. of Pharmacol., Univ. of Pennsylvania, PA19104 ¹, and Dept. of Biol., UCLA, Los Angeles, CA90024 ².

Glutamic acid decarboxylase (GAD) is the rate-limiting enzyme in the synthesis of GABA, the neurotransmitter of basal ganglia efferent pathways. Two genes encode isoforms of GAD (M_rs 67,000, GAD67, and M_rs 65,000, GAD65) which differ in their co-factor requirement (Erlander et al. Neuron, in press). We performed *in situ* hybridization histochemistry with ³⁵S-radiolabelled probes complementary to mRNAs encoding each GAD isoform in globus pallidus (GP), entopeduncular nucleus (EP) and substantia nigra pars reticulata (SNR) of adult rats. Quantification of autoradiographic signal in emulsion-coated slides was performed at the single cell level with a Morphon Image Analysis system. Average labelling per rat was calculated for each region in sections processed in parallel. Both mRNAs were expressed in projection neurons of the three regions examined. In the pallidum, however, the mean ratio of EP/GP labelling in individual rats was 0.71+1 for GAD67 mRNA and 1.95+1.17 for GAD65 mRNA (N=4), revealing marked differences in the relative expression of mRNAs encoding the two GAD isoforms in some output neurons of the basal ganglia. Supp. by MH 44894 (MFC), NS 22256 (AJT) and MH 14654.

THE INFLUENCE OF TH-CONTAINING AFFERENTS ON THE DEVELOPMENT OF MODULAR ORGANIZATION IN EMBRYONIC STRIATAL GRAFTS. E.-C. Liu¹, S.B. Dunnett² and A.M. Graybiel¹. ¹Dept. Brain and Cognitive Sciences, MIT, Cambridge, MA 02139, USA, and ²Dept. Experimental Psychology, Univ. of Cambridge, Cambridge, CB2 3EB, UK.

The most prominent feature of embryonic striatal grafts is that they develop a modular organization in which patches enriched in neurochemical substances (P regions) are embedded in surrounds (NP regions). Of particular interest is that patches of TH-positive fibers correspond spatially to the AChE-rich P regions in which many striatal markers are concentrated. This spatial alignment suggests that the TH-containing fibers, predominantly derived from the host's substantia nigra, may be capable of regulating the development of cells in the P regions of the grafts. In the present study we sought to determine whether the ingrowing TH-positive fibers from the host striatum are important for inducing or maintaining a subpopulation of grafted cells to form P regions. Unilateral 6-OHDA lesions were performed on host rats to destroy the nigrostriatal bundle 29-32 days before grafting. The hosts further received ibotenate lesions of the denervated striatum a week prior to grafting. Cell suspensions derived from E15 striatal primordia were then injected into the degenerated striatum. Survival times for the grafted rats were 3.6-6 months. Our results indicate that the destruction of TH-containing dopaminergic afferents does not disrupt the formation of modular organization in the grafts, as patches containing AChE activity, medium-sized calbindin-positive, enkephalin-positive, DARPP-32-positive and calcineurin-positive neurons are still present in the grafts. Given that the modular organization may reflect an admixture of striatal tissue (P regions) and non-striatal tissue (NP regions), our results suggest that the ingrowing TH-positive fibers from the host striatum are probably not obligatorily involved in sorting out of striatal from non-striatal cells to form P regions in embryonic striatal grafts. PRIMING OF A D1-LIKE DOPAMINE RECEPTOR AND INTRA-STRIATAL ACTIVATION OF IMMEDIATE-EARLY GENES.

M.L. Paul¹, A.M. Graybiel², M.R. Peterson¹ and H.A. Robertson¹. ¹Dept. of Pharmacology, Dalhousie University, Halifax, N.S. Canada B3H 4H7 and ²Dept. of Brain & Cognitive Sci., MIT, Cambridge, MA 02139, U.S.A.

Repeated administration of D1 or D2 dopamine agonists can lead to a long-lasting increase in the responsiveness of a D1-like receptor, a phenomenon known as PRIMING (*J.Pharm.Exp.Ther.* 234:447, 1985). We have speculated that this priming response may involve activation of immediate-early genes, as these have been implicated in other long-term changes in the brain.

In rats with unilateral 6-OHDA lesions of the medial forebrain bundle, the contralateral turning response elicited by the D1-selective dopamine agonist SKF38393 (2 mg/kg,i.p.) was significantly enhanced by a single prior exposure (48 hr prior to SKF38393) to either apomorphine (0.5 mg/kg,i.p.) or the D2-selective agonist LY171555 (0.25 mg/kg,i.p.). Immunohistochemical detection of Fos-like protein demonstrated that apomorphine (but not saline) produced activation of *c-fos* throughout the denervated striatum. MK801 (0.1 mg/kg,i.p.) given 30 min prior to apomorphine, blocked the apomorphine-induced priming response, but had little effect on *c-fos* activation. Both priming and induction of *c-fos* by apomorphine were blocked by a higher (0.5 mg/kg,i.p.) dose of MK801. LY171555 was a good primer of SKF38393 behaviour, but induced little if any *c-fos* activation in the striatum. SKF38393 produced robust activation of *c-fos* both in unprimed animals and in animals exhibiting behavioural priming. These findings demonstrate that priming of the dopamine receptor, as determined by turning responses, can be dissociated from activation of *c-fos* in the striatum. Preliminary evidence from Northern blotting is consistent with the immunohistochemical results and further suggests a dissociation for at least two other immediate-early genes, *jun B* and *NGFI-A*. NEURONAL LOCALIZATION OF RC3 PROTEIN IN RODENT NEOSTRIATUM. J.B. Watson and R.S. Fisher, Mental Retardation Research Center, Department of Psychiatry, UCLA School of Medicine, Los Angeles, CA 90024.

RC3 is a 78-amino acid neuron-specific rat protein first identified by subtractive cDNA cloning. The RC3 sequence is nearly identical to bovine proteins termed neurogranin or BICKS which were isolated by properties of protein kinase C (PKC) phosphorylation and calmodulin-binding. RC3 resembles GAP-43 protein (neuromodulin, B-50) in a highly conserved sequence containing a PKC phosphorylated serine and a calmodulin-binding domain. The localization and functional roles of RC3 are largely uncharted. Our aims were to determine if neostriatal neurons express the RC3 protein and to demonstrate its cellular sites of accumulation.

Specific and equivalent immunolabeling patterns of the neostriatum of rats were obtained with two polyclonal antisera directed against synthetic peptides of different regions of RC3. Light microscopy revealed fine labeling in the neuropil. Practically all medium and large neuronal cell bodies located in immunoreactive section faces contained RC3. Immunohistochemistry/Golgi-gold toning showed RC3 expression in medium spiny, medium sparsely spiny and large sparsely spiny neurons. Correlative light/electron microscopy demonstrated subcellular sites of RC3 in nucleoplasm, perikaryal cytoplasm, and dendritic cytoplasm. Dendritic spines were the most frequently labeled profiles while labeled axons were seen sporadically.

We conclude that most, if not all, of the neostriatal neurons express the RC3 protein. RC3-positive cells of distinct morphological types always had at least a few dendritic spines. RC3 may act as a "third messenger" principally in dendritic spines of neostriatal neurons and other forebrain neurons. Supported by NICHD HD 25831.

335.11

THE PHOSPHOINOSITIDE SECOND MESSENGER SYSTEM IS ENRICHED IN STRIOSOMES OF THE PRIMATE STRIATUM.

M. Fotuhi, T.M. Dawson, A.H. Sharp, L.J. Martin, A.M. Graybiel, and S.H. Snyder, Dept. of Neurosci., The Johns Hopkins Sch. Med., Baltimore, MD, 21205 and Dept. of Brain and Cognitive Sci (AMG), M.I.T., Camb, MA, 02139.

A large number of neuropeptides and neurotransmitter markers are preferentially distributed in either striosome or matrix compartments of the striatum. In the present study, we examined the distribution of selected components of the phosphoinositide (PI) second messenger system using immunocytochemical staining with antibodies against inositol triphosphate receptor, phospholipase C beta, and phospholipase C gamma in the striatum and in other regions of the primate basal ganglia.

The immunoreactivity for these markers appeared in distinct regions of the basal ganglia and in specific patterns. In the substantia nigra pars compacta, only a subset of neurons showed positive immunoreactivity for these epitopes. In the substantia nigra pars reticulata, as in both segments of the globus pallidus, only fibers and terminal-like punctate staining were present. In the striatum, both striosomes and matrix contained positive perikarya and neuropil staining. Striatal zones with heightened PI-IR were identified as striosomes by reference to calbindin-IR in adjacent sections.

These findings suggest that the PI second messenger system is differentially represented in basal ganglia pathways. The striosomal pattern of the PI system indicates that the striatum is compartmentalized with respect to second messengers.

SUBSTANCE P RECEPTOR mRNA EXPRESSED SELECTIVELY IN CHOLINERGIC NEURONS IN THE STRIATUM AND BASAL FOREBRAIN.

C. Gerfen, Lab of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892

In the striatum, substance P (neurokinin-1) receptor mRNA is selectively localized in large neurons that also express mRNA encoding choline acetyl transferase (CHAT) by *in situ* hybridization histochemistry. Substance P receptor mRNA is also localized in ChAT mRNA containing neurons in the medial septum and basal forebrain cell groups. Thus, in the rat forebrain the substance P receptor appears to be expressed selectively by cholinergic neurons. Striatal neurons that contain substance P also utilize gamma-aminobutyric acid (GABA) as a transmitter. These neurons make synaptic contact with striatal cholinergic neurons (Bolam, et al., 1986, *Brain Research*, 397: 279-289), which are shown here to express the substance P receptor, and with other GABAergic neurons in the striatum and substantia nigra, which express GABA receptors but not substance P receptors. This suggests that individual striatal neurons may differentially affect target neurons dependent on the receptors expressed by those target neurons.

DOPAMINERGIC REGULATION OF GLUTAMIC ACID DECARBOXYLASE mRNA IN PALLIDAL PROJECTION NEURONS. A.E. Kincaid, R.L. Albin, S.W. Newman, J.B. Penney and A.B. Young, Depts. of Anatomy and Cell Biology and Neurology, University of Michigan, Ann Arbor, MI 48109.

Fluoro-gold (FG) tract tracing and *in situ* hybridization were combined to study the dopaminergic regulation of GAD mRNA levels in globus pallidus (GP) projection neurons. FG was injected into the entopeduncular nucleus or substantia nigra (SN) of adult rats. After 8 days animals received an injection of 6-hydroxydopamine in the SN ipsilateral to the FG injection. Animals were perfused with 4% paraformaldehyde and sections were cut through the forebrain (12 um) and midbrain (40 um). Tyrosine hydroxylase immunocytochemistry identified complete lesions of SN. An ³⁵S-labeled 30 base oligonucleotide probe was used to identify cells containing GAD₆₇ mRNA. More GP projection neurons, identified by FG labeling, contained GAD mRNA in the lesioned animals (88% vs 53% of control), and these neurons contained more mRNA than neurons from control animals. Supported by NIH NS20629 to SWN and NIH NS19613 to ABY and JBP.

335.12

DIFFERENTIAL ACTIVATION OF THE c-FOS PROTO-ONCOGENE IN SUBSETS OF STRIATAL NEURONS BY DOPAMINERGIC DRUGS.

H. Steiner and C. R. Gerfen, Lab. of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892.

Subsets of striatal neurons can be differentiated by the targets of their projection, the expression of neuropeptides, as well as by the expression of dopamine receptor subtypes. Dopamine plays a crucial role in the function of the striatum; it appears to modulate the activity of striatal neurons, the lack of which results in imbalanced basal ganglia output and, thus, in movement disorders. Long term activation of dopamine receptor subtypes has been shown to lead to specific alterations in gene expression in striatal neurons. Dopamine agonists also affect the activity of immediately early genes such as *c-fos*, and such genes, therefore, provide a mechanism to study short term changes in gene expression under the influence of dopaminergic activity. In a series of studies, we examined *c-fos* expression induced by dopaminergic drugs in different subsets of striatal neurons. Expression of this gene was analyzed with *in situ* hybridization after application of amphetamine, cocaine and specific D1 and D2 dopamine receptor agonists, alone and in combination, in normal rats and after 6-HDA lesions of the dopaminergic nigrostriatal projection. Colocalization was used to determine the neuronal subtype. These dopaminergic drugs led to specific regional patterns of *c-fos* activation, as well as to differential activation in neuronal subsets of the striatum.

335.14

INTRODUCTION OF THE *E. COLI* LACZ GENE INTO RAT NEOSTRIATAL NEURONS USING HERPES SIMPLEX VIRUS MUTANTS. Q. Huang¹, J.P. Vonatell¹, P.A. Schaffer², R.L. Martuza², X.O. Breakefield¹ and M. DiFiglia¹, Depts. of Neurology and Neurosurgery¹, Massachusetts General Hosp., and Dana Farber Cancer Inst.², and Harvard Medical School^{1,2,3}, Boston, MA 02114.

Introducing genes into adult neurons *in vivo* may be a useful tool for understanding and modulating neuronal function. Two herpes simplex virus type 1 (HSV 1) mutants, 7134 and RH105, which have deletions of viral genes ICPO and TK, respectively, were used to determine if adult rat neostriatal neurons can express the substituted foreign gene, *E. coli*, *lacZ* introduced by viral infection. After intra-striatal injection of the mutants, rats survived for 1-70 days with no apparent adverse effects except significant shrinkage of the injected hemisphere at longer postinoculation intervals. At the injection site, both mutants produced a marked focal necrosis and gliosis. Expression of the *lacZ* gene product, β-galactosidase (βgal) was maximal at three days postinoculation in all types of striatal neurons and was present in many more cells with mutant 7134 which has some capacity to replicate than with RH105 which is replication defective. βgal expression was also present in a higher than normal proportion of large neurons and in some glia. At the EM level neurons infected with mutant 7134 ranged from severely pathologic to remarkably healthy and were contacted by degenerating axon terminals. Results show that foreign genes can be delivered to neostriatal neurons by HSV 1 infection. Further minimizing the cytotoxicity of HSV 1 mutants will be important in determining their success as vectors for gene delivery. Supported by NIH grants NS16367 to MD and NS24279 to XOB and RLM.

Increased expression of fos-like immunoreactivity, preproenkephalin A and proneurotensin mRNAs in rat striatum following pertussis toxin administration.

Sarah J. Augood*, Simon M. Luckman* and Piers C. Emson.
MRC Group, #Dept. of Neuroendocrinology, AFRC, I.A.P. & G.R., Babraham, Cambridge, CB2 4AT. U.K.

The effects of a unilateral intrastriatal microinjection of pertussis toxin (PT) on the expression of proneurotensin (NT) and preproenkephalin A (PPE A) mRNAs was investigated in the rat striatum using non radioactive *in situ* hybridisation. Sham injected rats received vehicle alone. Rats were allowed to recover for 22 hours following stereotaxic surgery. A single microinjection of PT resulted in a significant increase in the expression of both NT and PPE A mRNAs in the ipsilateral striatum when compared to sham injected rats. Further, cryostat sections stained to visualise fos-like immunoreactivity (-LI) demonstrated an abundance of weakly stained fos-LI cells in both the ipsilateral and contralateral sham injected striata and lateral septal nuclei. Following PT treatment, an increase in the expression of fos-LI was detected in some cells in the ipsilateral striatum. However, not all striatal cells displayed this increased expression at this time point. Co-expression studies, combining non radioactive *in situ* hybridisation and immunocytochemistry, are in progress to determine the neurochemical identity of the cells expressing an increase in fos-LI.

BASAL GANGLIA AND THALAMUS III

336.1

THE EFFECT OF POST-IMPLANTATION INTERVAL AND HALOTHANE ANESTHESIA ON DIALYSATE DOPAMINE AND AMINO ACID LEVELS IN THE DORSOLATERAL STRIATUM OF THE RAT. K.G. Kramlinger, W.T. O'Connor*, S. Lillrank*, and U. Ungerstedt*. Department of Pharmacology, Karolinska Institute, Stockholm, Sweden.

In the present *in vivo* microdialysis study, post-implantation interval and halothane anesthesia were investigated for their effects on extracellular striatal dopamine (DA), DOPAC, HVA, 5-HIAA, GABA, glutamate (GLU), and aspartate (ASP) levels, which were measured from the same perfusate sample. Three groups of male Sprague-Dawley rats (350-400gms) were compared: A) halothane anesthetized rats 3 hours following probe implantation (n=9); B) halothane anesthetized rats 48 hours following probe implantation (n=7); and C) awake, freely moving rats 48 hours following probe implantation (n=7).

There are large differences in the dialysate concentrations of these substances: DA & GABA (2-12nM); ASP & 5-HIAA (60-200nM); DOPAC & HVA (300-700 nM); and GLU (600-4000nM). DA and GABA levels are similar in all 3 preparations. However, acute probe implantation (A vs B) is associated with elevated DOPAC (143%) and HVA (149%), but reduced GLU (21%) and ASP (32%) levels. In contrast, 5-HIAA levels are not affected by post-implantation interval, but are elevated (121%) by halothane anesthesia (B vs C).

These data suggest that use of different microdialysis preparations may systematically affect results obtained in otherwise comparable study designs and thus limit comparisons across studies.

ELECTROPHYSIOLOGY OF THE GLOBUS PALLIDUS (GP) IN CATS SYMPTOMATIC FOR AND RECOVERED FROM MPTP-INDUCED PARKINSONISM. D.S. Rothblat and J.S. Schneider, Depts. of Neurology and Physiology and Biophysics, Hahnemann Univ., Philadelphia, PA 19102

Recent research has shown significant changes in the electrophysiology of the caudate nucleus (CD) in cats with MPTP-induced parkinsonism and severe striatal dopamine depletion. Changes observed were decreased responses to peripheral sensory stimuli and increased responsiveness to electrical stimulation of monosynaptic afferent inputs. The present study examined changes in globus pallidus (GP) neurons in cats while normal, while exhibiting parkinsonian symptoms of akinesia, rigidity and diminished response to environmental stimuli due to MPTP exposure, and while recovered from these deficits. Spontaneous firing rates of GP neurons in symptomatic cats decreased by 77% as compared to the normal condition. The spontaneous firing rates of GP neurons in recovered cats was decreased by 48% as compared to normals. Changes were also observed in the percentage of units responding to electrical stimulation of the CD. In the normal condition 54% of GP units tested responded to CD stimulation. When cats were symptomatic for MPTP-induced parkinsonism, only 40% of GP units tested responded to CD stimulation. In recovered cats, the percentage of units responding to CD stimulation returned to normal (57%). The stimulus threshold for activation of a GP unit from CD stimulation was not significantly different between the three test conditions. This differed from results from CD recording studies in symptomatic animals in which there was increased responsiveness to and decreased threshold for stimulation of monosynaptic afferents. The potential significance of these findings for understanding the consequences of dopamine loss on striatal and pallidal response properties will be discussed. Additionally, the responses of GP neurons to peripheral sensory stimulation across conditions will be compared to data from CD recording studies and possible mechanism(s) for the modulation of motor function and for the mediation of dopamine-dependent sensorimotor deficits will be discussed. Supported by NIH grant NS23980

336.2

THE DOPAMINERGIC INNERVATION OF THE DORSAL STRIATUM IN CATS RECOVERED FROM MPTP-INDUCED PARKINSONISM: A TH-IMMUNOHISTOCHEMICAL AND RETROGRADE TRANSPORT STUDY. J.S. Schneider, D.S. Rothblat and M.G. Smith*, Depts. of Neurology and Physiology and Biophysics, Hahnemann Univ., Philadelphia, PA 19102

Administration of MPTP to cats results in a parkinsonian syndrome characterized by akinesia, rigidity, and diminished responsiveness to external stimuli. Neuropathologically, there is severe loss of substantia nigra pars compacta (SNc) dopamine (DA) neurons and less loss of DA neurons in adjacent regions such as the ventral tegmental area (VTA), retrorubral area (RR), and substantia nigra pars lateralis (SNl). MPTP also causes extensive DA depletion in the striatum, with the dorsal lateral caudate (DL CD) and dorsal putamen most severely affected. Interestingly, cats spontaneously recover motor function in 4-6 wks. without significant increase in dorsal striatal DA levels or recovery of SNc neurons. TH-immunohistochemistry in symptomatic MPTP-treated cats showed extensive loss of immunoreactivity throughout the striatum with slightly less loss ventrally, medially and caudally. In cats recovered from MPTP-induced parkinsonism, there were still only scattered TH-positive fibers visible in the dorsal striatum and a continued reduction in terminal field-like staining but increased TH-positive staining in ventral caudate regions, nucleus accumbens, and ventral putamen. Retrograde transport studies with WGA-HRP injected into dorsal medial and DL CD in recovered cats showed no labeled neurons in the SNc but some scattered labeled neurons in the RR and SNl. The patterns of retrograde neuronal labeling in recovered animals were similar to those seen in normal animals, though few neurons overall were labeled in the recovered cats. These data suggest that motor recovery in the MPTP-treated cat is not accompanied by an endogenous sprouting response in the dorsal striatum originating from residual ventral mesencephalic neurons which innervate other striatal regions. Supported by NIH grant NS23980.

336.4

MOTOR RECOVERY IN MPTP-TREATED CATS IS ACCOMPANIED BY PARTIAL RECOVERY OF EXTRACELLULAR DOPAMINE LEVELS IN DORSAL LATERAL CAUDATE NUCLEUS. L. DiStefano and J.S. Schneider, Dept. of Neurology, Hahnemann Univ., Phila., PA. 19102.

Cats made parkinsonian by administration of the dopaminergic toxin MPTP tend to spontaneously recover gross motor function by 4-6 wks. after the last MPTP injection. Symptomatic and recovered cats do not have significantly different levels of dopamine (DA) (98% vs. 94% depletion, respectively) in the dorsal lateral caudate (DL CD) as measured in post mortem tissue samples. The present study was conducted to examine whether there might be more extracellular DA available in the DL CD in recovered animals than would be predicted based on post mortem measures of tissue DA levels and whether this would correspond with motor recovery. Cats were implanted with indwelling cannulae above the DL CD through which microdialysis probes could be inserted. For dialysate sampling, the cats were placed in a canvas restraint bag in which they had been previously adapted to sit quietly. Probe recovery was estimated *in vitro* at 37°C and the probe was equilibrated *in vivo* for 60 min. prior to data collection. Baseline measurements of DA, DOPAC and HVA levels were obtained prior to administration of MPTP. After MPTP administration and while cats were symptomatic, DL CD extracellular fluid (ECF) levels of DA, DOPAC, and HVA were reduced 97%, 99% and 96%, respectively, corresponding with the tissue loss of these substances. When cats first recovered from motor impairments, ECF levels of DA, DOPAC, and HVA were depleted 54%, 94% and 82%, respectively while post-mortem tissue levels of these substances were depleted 94%, 92% and 50%, respectively. This data suggests that motor recovery in the MPTP-lesioned cat might at least in part be due to significant recovery of ECF DA levels available for use in the DL CD, the cat's sensorimotor striatum. This DA may arise from an up-regulation of DA synthesis and release from the few spared DAergic elements innervating the DL CD. Alternatively, the increased amount of ECF DA in the DL CD may originate in other, less denervated striatal regions and may reach the DL CD via enhanced diffusion due to loss of DA reuptake sites. Supported by NIH grant NS23980.

PRE AND POST-SYNAPTIC ALTERNATIONS IN STRIATUM OF CATS SYMPTOMATIC FOR AND RECOVERED FROM MPTP-INDUCED PARKINSONISM. P.A. Frohna, D.S. Rothblat, J.S. Schneider and J.N. Joyce. Depts. Psychiat. and Pharmacol., Univ. of Pennsylvania School of Medicine and Dept of Neurology, Hahnemann Univ., Phila., PA.

Cats treated with MPTP develop parkinsonism, >95% striatal dopamine (DA) depletions and spontaneously recover motor function with no recovery of tissue DA levels in dorsal striatum but significant recovery of DA levels in ventral caudate and nucleus accumbens (NAS). The present study examined autoradiographically the regional integrity of pre-synaptic DA systems (by measuring [³H]mazindol binding) and the numbers and regional distribution of D2 and D1 receptors in the striatum in cats sacrificed while symptomatic for parkinsonism and after recovery of motor function. Symptomatic and recovered cats were sacrificed 1 and 6 wks, respectively, after the last MPTP injection. One hemisphere was used for measurement of tissue DA and metabolites, and the other for autoradiographic studies. In both symptomatic and recovered cats, [³H]mazindol binding was greatly reduced in the dorsal striatum (DS) (>94%) and substantia nigra (90%) and less diminished in NAS and ventral caudate. In normal cats, [¹²⁵I] Epidepride binding to D2 receptors was most dense in the DS where it was approximately double the density of binding in NAS and substantia nigra pars compacta (SNc). D2 binding was significantly decreased in the SNc in symptomatic and recovered cats. Ventral striatal D2 binding was decreased in symptomatic cats and further decreased in recovered cats but unchanged in DS in both conditions. In normal cats, D1 receptors labeled with [¹²⁵I] SCH 23982 were denser in the NAS and ventral caudate than in DS. D1 binding was increased in symptomatic and decreased in recovered cats in DS. These results suggest a continued loss of direct DAergic input to DS in recovered cats. Reduced receptor binding in recovered animals could reflect enhanced DA turnover and release in ventral striatum and increased availability of DA to DS due to loss of DA uptake sites and enhanced DA diffusion. SELECTIVE SPARING OF GABA-ERGIC INTERNEURONS IN THE GERBIL STRIATUM AFTER TRANSIENT ISCHEMIA. C. Gonzales¹, B. C-S Lin² and M-F Chesselet¹, Dept of Pharmacol. Univ. of Pennsylvania, Phila., PA 19104 ¹, and Dept of Physiol. and Bioph., Hahneman U., Phila., PA 19102 ²

In addition to efferent GABA-ergic neurons, the striatum contains GABA-ergic interneurons, distinct from interneurons containing somatostatin, and expressing high levels of one isoform of glutamic acid decarboxylase (Mrs 67,000: GAD67) and of the calcium-binding protein parvalbumin. We have previously shown that cholinergic and somatostatinergic interneurons are spared after transient ischemia in the gerbil striatum, despite loss of efferent neurons, suggesting that striatal interneurons are less vulnerable to ischemic damage than projection neurons. In this study, Mongolian gerbils were sacrificed 4,7 and 10 days after occlusion (5min) of the common carotid. Striatal sections were processed for immunohistochemistry with a monospecific antibody for GAD67 (A. Tobin, UCLA) and a monoclonal antibody for parvalbumin (M. Celio, Fribourg). Staining for GAD was decreased within an area of profound cell loss in Nissl stain. However, the number of neurons intensely stained for GAD67 and of parvalbumin-positive neurons, was similar in controls and in the lesioned area, indicating a relative sparing of GABA-ergic interneurons in the ischemic striatum. Supported by MH 44894 and NS 29230 (MFC), and S07-RR07-241 (RCSL).

EXPRESSION OF GAD mRNA IN THE FELINE MOTOR THALAMUS AND EFFECT OF SUBSTANTIA NIGRA LESIONS. K. Kultas-Ilinsky¹, M. Merugliano², M-F Chesselet² and I.A. Ilinsky¹, ¹Dept. of Anatomy, Univ. of Iowa Coll. Med., Iowa City, IA 52242, ²Dept. of Pharmacology, Univ. of Pennsylvania, Philadelphia, PA 19104.

Previous studies (Kultas-Ilinsky et al., Brain Res., 1990, 511:197) suggest that deafferentation of the thalamus from substantia nigra (SN) induces short- and long-term changes in local thalamic GABAergic mechanisms. Glutamic acid decarboxylase (GAD)-containing local circuit neurons (LCN) represent one of the systems that may react to deafferentation. In this study we used cDNA for GAD from A. Tobin, UCLA; (Kaufman et al., Science 1986; 232:1138) to produce [³⁵S]-labeled mRNA probes to label LCN in frontal and sagittal serial sections through the cat thalamus. Intensity of labeling and distribution pattern of cells expressing GAD mRNA were analyzed both qualitatively and quantitatively in thalamic nuclei receiving basal ganglia afferents. In control unoperated animals GAD mRNA content was higher in lateral regions of the motor thalamus than in medial, which is consistent with earlier immunocytochemical studies (Kultas-Ilinsky et al., J. Neurosci., 1985; 5:1346). One year after kainic acid lesioning of pars reticularis of SN, this gradient was not detectable due to an increase in GAD mRNA in medial regions of the basal ganglia afferent territory, i.e., in the nigrothalamic projection zone. The data suggest that nigral lesions result in long-term alterations of GAD gene expression in GABAergic interneurons in thalamic regions normally receiving nigral inputs. Supported by RO1NS19280 (KKI), MH44894 (MFC) and training grant MH14654 (MM).

SOMATOSTATIN (SOM) AND GLUTAMIC ACID DECARBOXYLASE (GAD) mRNAs IN QUINOLINIC ACID-LESIONED STRIATUM OF ADULT RATS. Y. Qin, J-J Soghomonian and M-F Chesselet Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA, 19104.

Rat striata were lesioned by local injections of quinolinic acid (QA), an agonist of NMDA receptors which produces a pattern of cell loss similar to that observed in the striatum of patients with Huntington's disease. The level of expression of mRNAs encoding SOM and two isoforms of GAD (Mrs 65,000, GAD65 and 67,000, GAD67) was examined by quantitative in situ hybridization histochemistry. After 2 weeks survival, Nissl stains showed profound loss of neurons in the injected striata. With 120 nmol of QA, the lesioned area was completely devoid of SOM mRNA-positive neurons but cells expressing NADPH-diaphorase (a marker of SOM neurons in striatum) were still detectable in the same area. After 60 nmol of QA, the number of neurons expressing SOM mRNA in the lesioned area was not different from controls and their level of labelling was increased. In this group, some GAD67 mRNA-labeled interneurons were still observed in the lesioned area whereas no GAD65 mRNA labeled cells were detected. The results show that QA induces dose-dependent alterations in the expression of striatal SOM mRNA and reveal a relative sparing of GABA-ergic neurons in the QA-lesioned rat striatum. Supp. by MH 44894 and by the PMAF (JJS).

NIGROSTRIATAL LESIONS DIFFERENTIALLY AFFECT mRNAs ENCODING GLUTAMATE-DECARBOXYLASES (GADs) IN SUBPOPULATIONS OF STRIATAL NEURONS. J-J Soghomonian, C. Gonzales and M-F Chesselet. Dept. of Pharmacology, U. Pennsylvania, Philadelphia, PA, 19104.

We examined the effect of lesions of dopamine (DA) afferents to the striatum on the level of expression of mRNAs encoding two isoforms of GAD. Rats had an injection of 6-hydroxyDA in one substantia nigra and were sacrificed 2-3 weeks later. Sections of the striatum were processed for in situ hybridization histochemistry with radiolabeled RNA probes. Autoradiographic signals were quantified at the single-cell level with computer-assisted image analysis. Labeling for mRNA encoding GAD (Mrs 67,000) increased in medium-sized striatal neurons normally expressing low levels of this mRNA. This effect occurred in both the striosomes and the extrastriosomal matrix, and was accompanied by increased immunostaining for the corresponding protein with a monospecific antibody (Kaufman et al., J. Neurochem. '91). In contrast, labeling was decreased in neurons normally expressing high levels of mRNA encoding GAD (Mrs 67,000) (GABAergic interneurons). Labeling for mRNA encoding GAD (Mrs 65,000) (Erlander et al., Neuron '91) was not modified in the DA-depleted striatum. Results show that DA depletion differentially affects gene expression for different isoforms of GAD in subpopulations of striatal neurons. Supp. by MH 44894 and the PMAF (J-J S.).

STRESS-INDUCED ALTERATIONS IN FOS EXPRESSION IN NEURONS INNERVATING THE VENTRAL TEGMENTAL AREA: AN APPROACH TO THE DETERMINATION OF THE STRESS CIRCUIT. Martha Gillham¹, Michael Iadarola², and Ariel Y. Deutch¹. ¹Department of Psychiatry, Yale Univ. Sch. of Medicine, New Haven, CT 06510 and ²Neurobiology and Anesthesia Branch, NIDR, Bethesda, MD 20892.

We have previously reported that restraint stress increases Fos protein expression in dopamine (DA) neurons innervating the prefrontal cortex (PFC). The increase in Fos expression is dependent upon the time interval between stress and sacrifice. We have therefore examined stress-elicited alterations in Fos expression in neurons retrogradely labelled from the ventral tegmental area (VTA). In these studies rats were sacrificed at a time point earlier than that required to increase Fos expression in the VTA. Neurons in a variety of telencephalic sites (e.g., PFC, ventral striatum, ventral pallidum, lateral hypothalamus, and amygdala) were retrogradely labelled from the VTA. Similarly, neurons in a number of brainstem sites (e.g., dorsal raphe, pedunculopontine tegmental nucleus, mesencephalic locomotor region, ventrolateral medulla) were also retrogradely labelled from the VTA. Initial examination indicates that certain of these neurons, prominently including neurons in the pons, express Fos protein at a time point prior to the expression of Fos in DA neurons projecting the PFC. This approach may lead to identification of components of the pathways through which stress gains access to the midbrain DA neurons. Supported by MH-45124 and the National Parkinson Foundation Center at Yale University.

THE EFFECTS OF ATYPICAL ANTIPSYCHOTIC DRUG ON STRIATAL FOS EXPRESSION. Maggie Lee¹, Michael J. Iadarola², and Ariel Y. Deutch¹. ¹Yale University School of Medicine, New Haven, CT 06510 and ²Neurobiol. Anesth. Branch, NIDR, Bethesda, MD 20892.

Double-blind trials indicate that both clozapine and remoxipride are atypical antipsychotic drugs (as defined on the basis of clinical efficacy and very low EPS liability). The former has been most extensively studied, and interacts with dopamine (DA) D₁ and 5-HT₂ as well as D₂ receptors; remoxipride has relatively high affinities for the D₂ and sigma receptor sites. We have compared the effects of remoxipride and clozapine with those of the typical antipsychotic drug haloperidol on striatal Fos protein expression. Haloperidol, as has been previously reported, dramatically increased Fos expression throughout the dorsal striatum. In contrast, an increased number of striatal neurons which express Fos after both clozapine and remoxipride was observed in the medial striatum, i.e., the region of the dorsal striatum receiving projections from A10 DA neurons and the medial prefrontal cortex. Moreover, the effects of remoxipride on striatal Fos expression were predominantly observed in the areas of the medial striatum which stain poorly for calbindin, i.e., the striatal patch compartment. These data suggest that atypical antipsychotic drugs may differ from the prototypical neuroleptic haloperidol by virtue of prominent effects on the striatal sector associated with A10 DA neurons and association rather than sensorimotor cortex. Supported by MH-45124 and the National Parkinson Foundation at Yale Univ.

BASIC FIBROBLAST GROWTH FACTOR MARKEDLY ENHANCES THE GROWTH OF NEOSTRIATAL GABAergic NEURONS IN VITRO. Dan Zhou¹ and Marian DiFiglia, Massachusetts General Hospital, Boston, MA 02114.

Basic FGF (bFGF) promotes the survival of some CNS neurons including neostriatal neurons in vitro (Wallicke, 1988). We examined the effects of bFGF on the growth of GABAergic neurons taken from the newborn caudate-putamen and cultured for 12 to 18 days. Control cultures showed three types of immunoreactive GABAergic neurons based on somatic size (small: >10 μm, medium: 10-20 μm; and large: >20 μm) and distinct dendrite-like and axon-like processes in all cell types. In the presence of bFGF (6 pM), small and medium-sized GABAergic neurons showed significant increases (p < .0005) in five parameters of neuritic growth (number of primary dendrites, dendritic-field radius, dendritic branch order, length and arborization of axons) compared to untreated neurons. Large GABAergic neurons were unaffected by treatment with bFGF. Striatal GABA neurons exposed to nerve growth factor were not different from untreated controls. The potent effects of bFGF on the neuritic outgrowth of striatal GABAergic neurons suggests a major role for bFGF in striatal cell development and regeneration. L-DOPA INDUCES STRIATAL FOS IN RAT WITH PARTIAL DOPAMINERGIC DENERVATION. D.Cole, J.Growdon, M.DiFiglia, Department of Neurology, Massachusetts General Hospital, Boston, MA 02114.

L-DOPA induces the immediate early gene product Fos in striatum in a rat model of Parkinson disease (PD) when there is dopamine (DA) receptor supersensitivity. To establish if L-DOPA also induces Fos with partial striatal DA denervation we made graded unilateral stereotaxic nigral 6-hydroxydopamine lesions in adult rats, determining extent of denervation by counting rotations after intraperitoneal (ip) apomorphine (1mg/kg) and amphetamine (5mg/kg). Two hours after ip caridopa/L-DOPA (2.5/25 mg/kg), rats were perfused. Brains were examined immunohistochemically. Rats with >90% denervation (rotation to apomorphine) had Fos-like immunoreactive (FosLI) neurons throughout the striatum, rats with 50-90% denervation (rotation to amphetamine but not apomorphine) had FosLI neurons only in the lateral and rostro-ventral striatum, and rats with <50% denervation (no rotation) had no FosLI neurons. Accumbens and pallidum never had FosLI neurons. Nissl counterstaining revealed that only medium-sized neurons were FosLI. L-DOPA induces Fos in this model with partial DA denervation. This effect suggests that early use of L-DOPA in PD may induce striatal cellular adaptation.

TOPOGRAPHY OF CONNECTIONS BETWEEN CORTICAL VISUOMOTOR AREAS IN MACAQUE. J.D. Schall, A. Morel, D.J. King, C. Whalley². Department of Psychology, Vanderbilt University, Nashville, TN 37240

The frontal eye fields (FEF) systematically represent small to large saccades in a ventrolateral-dorsomedial progression. We determined that lateral and medial portions of FEF have coarse topographic connections with visuomotor areas in frontal and parietal cortex by placing injections of 2 or 3 tracers (fluorescent dyes and/or WGA-HRP) in regions of FEF representing smaller (sFEF) and larger (lFEF) saccades determined through intracortical microstimulation in *Macaca mulatta*.

sFEF and lFEF connections with SEF overlapped substantially. Even so, sFEF afferents extended further caudally, and connections with lFEF, further rostrally and laterally. This rough topography is consistent with the relative amplitudes of saccades evoked by stimulation of rostral and caudal SEF (Tehovnik & Lee, 1990, *Soc. Neurosci. Abstr.* 16:900).

sFEF and lFEF connections in the intraparietal sulcus overlapped and interdigitated, occupying both the densely myelinated LIP/VIP⁺ and the lighter, dorsal LIP. sFEF connections extended further rostrally and lFEF, more caudally. The patchy inputs to sFEF and lFEF from the intraparietal sulcus may be related to the mapping of the upper and lower visual fields from LIP into the FEF.

These results indicate that saccade amplitude is represented topographically in SEF and LIP although with less precision than in FEF. This pattern of organization would seem to be a necessary correlate of the fact that saccade-related activity in LIP and SEF, unlike that in FEF, varies with orbital position.

CHARACTERISTICS OF "ANTI"- AND "NORMAL" SACCADES IN MAN. Heike Weber¹ and Burkhard Fischer. Abt. Neurologie und Neurophysiologie, Universität Freiburg, Hansastr. 9a, 7800 Freiburg

Saccades with extremely short latencies (express saccades) can be elicited by the onset of a stimulus which at the same time is the saccade target. We instructed 4 adult human subjects to execute saccades in the opposite direction to the side where a visual stimulus appeared (anti-task). The gap (fixation point offset precedes stimulus onset by 200ms) and the overlap (fixation point remains on) paradigm were used. As control served the normal task with target-directed saccades. All subjects had been trained to produce express saccades in the normal gap task. Stimuli were computer generated on a color monitor and eye movements were recorded using infrared light reflexion. Reaction time (SRT), velocity, amplitude and duration of the saccades were analysed and compared. Distributions of SRTs in the normal gap consisted of a small group of anticipatory saccades (SRT < 80ms), followed by a large peak between 80 and 120ms (express saccades) and by another group ranging up to 180ms (regular saccades). In the anti gap anticipatory saccades and saccades with SRTs longer than 100ms were obtained. Express saccades were missing. Distributions of SRTs in the normal and anti overlap were unimodal with mean values of 216ms (normal) versus 231ms (anti). The velocity of anti saccades was slightly (10%) but significantly slower. Control experiments show that the absence of express saccades in the anti task is not due to an interhemispheric transfer time. We conclude that to program a saccade to a position where no target appears, using the onset of the visual stimulus only as a temporal trigger cannot be executed within the latency of an express saccade. These data provide further evidence for a reflex-like pathway from the retina to the oculomotor nuclei mediating express saccades.

337.3

EXPRESS AND ANTISACCADES IN SCHIZOPHRENIC, AFFECTIVE DISORDER, AND NORMAL CONTROL SUBJECTS. A.B. Sereno and P.S. Holzman*. Dept. of Psychology, Harvard Univ., Cambridge, MA 02138.

Previous work (Guitton et al, 1985; Fukushima et al, 1990) suggests that both frontal lobe lesioned patients and schizophrenic patients have difficulties in an antisaccade paradigm (where subjects must look opposite to where the target appears). All subjects performed 4 tasks. Three of the tasks examined saccadic eye movement performance: a prosaccade task (as a measure of baseline performance), an antisaccade task, and an express saccade task (i.e., a gap paradigm, where the central fixation point is removed before presentation of the target; in this study, gap duration=150 ms). The order of the saccadic eye movement tasks was counterbalanced within each subject group. Each subject also performed a smooth pursuit tracking task.

Schizophrenic subjects showed a greater increase in both saccadic response time and error rate than did normal controls in the antisaccade task. In addition, schizophrenic subjects showed a greater decrease in saccadic response time than did normal controls in the gap task. Although affective disorder subjects also showed a greater response time and error rate increase than normal controls in the antisaccade task, they did not show a greater benefit in saccadic response time than normal controls in the gap task. The relation between performance on the antisaccade and gap paradigms will be discussed and its relevance to a prefrontal deficit hypothesis of schizophrenia. In addition, the relationship between the quality of smooth pursuit and performance on these tasks will be discussed.

337.5

ADAPTATION TO DISCONJUGATE RETINAL SLIP FOLLOWING VERTICAL SACCADES. Z. Kapoula. Lab. de Physiologie Neurosensorielle, CNRS-UPR2, Paris, France.

This study tests the ability of normal subjects to create post-saccadic eye drift (PSD) in opposite directions in the two eyes. The question is whether this can be achieved by readjusting the pulse-step saccadic signals differently in each eye.

Two slides of the same image containing fusable contours were projected. The images (32x32 deg) were polarized 90 deg apart; subjects used polarized lenses. At first, subjects saw a single, stationary image. They were asked to saccade between two points of the image. At the end of each vertical saccade, the L eye image drifted on-wards (in the same direction as the saccade), while the R eye image drifted backwards. Motion of the images was exponential (to 50 ms) and its amplitude was 3,6 or 10% of the vertical saccade size. Three subjects were trained for 1.5 hr. During training, eye movements were monitored by EOG. Pre and post-training binocular recordings were made with the search-coil method.

At first, subjects followed the images only 45% of the time with an early backward component, more prominent in the R eye, and a later, onward, vergence component seen only in the L eye. The mean delay (from the saccade offset) was 79 ms in the R eye; that of the L eye onward motion was 174 ms. After training, responses in the direction of drifting images rose to 70%. The delays decreased particularly, in the dominant eye. The mean R eye delay dropped to 15 ms and that of the L eye to 111 ms. These decreases could be produced by adaptive changes in the timing of vergence and/or changes in PSD. To evaluate the latter we examined spontaneous saccades in the dark. Training led to an increased but conjugate backward drift. These preliminary results show no evidence for disconjugate PSD by the saccadic system.

337.7

ENDOGENOUSLY GENERATED AND VISUALLY GUIDED SACCADES AFTER LESIONS OF THE HUMAN FRONTAL EYE FIELDS. A. Henik*, R. Rafal and D. Rhodes, UC Davis, VAMC Martinez, CA 94553.

Latencies for endogenously generated and visually guided saccades were measured in 9 patients with unilateral lesions involving the frontal eye fields (FEF), in 7 control patients with lesions of dorsolateral prefrontal cortex not involving FEF, and in 12 normal control subjects. Visually guided saccades had shorter latencies than endogenously generated saccades in the control subjects. In the FEF lesion patients, but not in patient controls, endogenously generated saccades had longer latencies to targets in the contralesional field; whereas visually guided saccades had shorter latencies toward the contralesional field. In a control experiment in which key press responses rather than saccades were made, reaction time to contralesional targets was slower in FEF lesioned patients. Visually guided saccades did not have shorter latencies than endogenously generated saccades toward the field ipsilesional to FEF lesions. The FEF functions in generating endogenous saccades and also inhibits reflexive visually guided saccades. FEF lesions appear to disinhibit the ipsilesional superior colliculus; and this disinhibited colliculus may also inhibit the opposite colliculus to slow visually guided saccades toward the ipsilesional field.

337.4

GRAVITY AFFECTS THE POSITION OF THE PARALYSED CAT'S EYE. L. R. Harris, M. J. Steinbach and H. C. Goltz*, Dept. Psychology, York University, Toronto, Canada M3J 1P3

To see whether gravity might potentially disturb fixation in the cat, we measured the position of the paralysed cat's eye. Cats were anaesthetized with sodium thiamylal (5 mg/kg/hr i.v.) and paralyzed with gallamine triethiodide (10 mg/kg/hr i.v.). EKG and CO₂ were monitored. Animals were tilted in 45 deg steps around the pitch and roll axes and eye positions were subsequently measured from photographs. A laser beam reflected from a mirror held on one eye by gum tragacanth, provided an additional, translation-insensitive measure of eye rotation.

The occurrence of eye rotation was consistent with the front of the eye being heavier (to the left when tilted left ear down, towards the top of the orbit when upside down, etc...). The response to tilts in the pitch plane revealed which orientations the eye regarded as upside down and right way up. They did not correspond to the plane of the horizontal semicircular canals. These findings suggest that cat's eyes are different from human's in having the centre of mass closer and anterior to the centre of rotation (cf. Steinbach et al. IOVS Suppl. 31:533 1990). Interspecies differences may correlate with the differential occurrence of eye-muscle proprioceptors. The arrangement in both species poses a continuous challenge to fixation that depends on the direction and magnitude of the prevailing gravito-inertial forces.

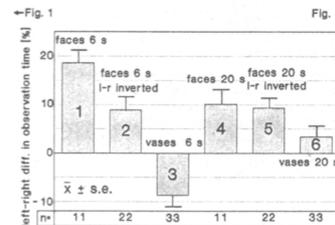

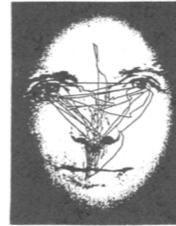

337.6

INSPECTION OF FACES AND OBJECTS IN A VISUAL MEMORY TASK.

I. Mertens*, H. Siegmund* and O.-J. Grüsser. (SPON: European Brain and Behavior Society) Inst. Physiol. Humboldt-Universität, Dept. Physiol. Freie Univ. Berlin, Germany.

The relation of face and non-face perception to parameters of eye movements was studied in a learning paradigm. 33 right-handed subjects (21-47 years) were asked to inspect a set of slides (20 faces, features only; 20 vases), each projected onto a tangent screen (7.5°x10°) for 6 s and 20 s. In the control series all pictures were left-right inverted. Eye position was recorded by an infrared system with a precision of about 0.1° (fig. 1). Fig. 2 indicates that with faces (1,2,4,5) the center of gaze remained longer in the left visual field (right half of the face), regardless of presentation time. 4 faces evoked the opposite results during inverted presentation, indicating a stimulus factor in addition to the left/right bias. Vases did not evoke the left/right bias (3,6).

CAFFEINE INCREASES THE MAXIMUM VELOCITY OF SACCADEIC EYE MOVEMENTS. B. Schielke*, T. Mager* and T. Duka* (SPON: European Neuroscience Association). Schering Research Laboratories, Müllerstr. 170-178, 1000 Berlin 65, FRG.

There has been a longstanding discussion on the occurrence of an increase in the maximum velocity of saccadic eye movements of a given amplitude, i.e. the occurrence of a steeper rise of the main sequence in young healthy people. This was reflected by publications on faster saccades during vestibular stimulation, unchanged saccadic velocities during smooth pursuit and conflicting findings for different stimulant drugs.

Using the infrared reflection technique the amplitude, maximum velocity, duration and reaction time of saccades were measured in sixteen healthy young (18-45 years old) male volunteers after oral administration of placebo, 5 mg baclofen (GABA-B-receptor-agonist), 5 mg diazepam (GABA-A-receptor-agonist) and 250 mg caffeine in a four-fold cross-over double-blind study under standardized conditions in terms of diet, sleep and withdrawal of stimulants (nicotine, caffeine and other xanthine derivatives) and sedatives (urine drug screen). Saccades elicited before administration of the substances did not reveal any differences between the groups. 2 hours after application there was a significant difference between the caffeine and the placebo group as well as between the diazepam and the placebo group ($p < 0.05$). 6 hours after oral administration we could still find a significant difference between the caffeine and the diazepam group ($p < 0.05$) but not between any drug and placebo. The parameters of the baclofen group failed reaching the level of significance compared with placebo. So there is evidence that the saccadic system is not working at its optimum point even in young healthy people. However the observed differences could well be an effect of caffeine withdrawal in a population ingesting the stimulant drugs of daily living, although no difference was found comparing the subpopulations of coffee-drinkers (11) and non-coffee-drinkers (5).

337.9

THE RESPONSE OF GAZE VELOCITY PURKINJE (GVP) CELLS TO IMMEDIATELY VELOCITY (1-2 s) DOES NOT PREDICT THEIR RESPONSE IMMEDIATELY AFTER A RAPID HEAD ACCELERATION. L.H. Snyder and W.M. King. Department of Physiology, University of Rochester, Rochester, NY 14642.

GVP cells modulate their discharge with eye position and velocity and with head velocity when tested with sinusoidal stimuli. These data have been obtained over a limited frequency range and the transient responses of GVP cells to rapid changes of eye and head velocity have not been well characterized.

Monkeys were trained to fixate and track LED or laser targets and eye movements were monitored using search coils. GVP cells were identified by recording their discharge during the constant velocity phase (~2 s) of matched trapezoidal smooth pursuit or trapezoidal whole body rotations. During the latter paradigm, the monkeys canceled the vestibulo-ocular reflex by viewing a head fixed target. GVP head or eye velocity responses obtained with these stimuli were comparable to sinusoidal steady state responses published in the literature. To obtain transient responses of GVP cells, we applied brief pulses (~120 ms) of whole-body rotation (500 d/s/s up to 25 d/s) to the monkey immediately after extinguishing an LED target.

The majority of GVP cell responses to transient head accelerations could not be predicted by linear combinations of the head and eye velocity responses obtained with the trapezoidal stimuli. For example, in most cells, the responses measured 100 ms after the onset of head acceleration were dependent on initial eye position and in ~50% of the cells, firing rate increased regardless of the direction of rotation.

TORSIONAL CHARACTERISTICS OF THE HUMAN OCULAR MOTOR PLANT S.H. Seidman, R.L. Tomsak*, M.P. Grant and R.J. Leigh. Depts of Biomedical Eng. and Neurol., Dept. of V.A. Med Center and Case Western Reserve Univ, Cleveland OH 44106.

To determine the properties of the ocular motor plant (OMP), we are studying the time course of the return of the eye after it has been released from a horizontal or torsional displacement. Using the magnetic search coil technique, we measured torsional, horizontal, and vertical eye movements in two humans. One eye viewed a stationary target, while the anesthetized, non-viewing eye was abducted, intorted, or extorted using ophthalmic forceps. Using techniques of non-linear parameter estimation, the return of the eye following release from forced duction was fit to a two time-constant model of the OMP as described by Robinson (1964). The shorter time-constant of this model proves difficult to estimate with accuracy, but estimation of the longer time-constant is comparatively simple. We find that the eye returns more rapidly from extorsional duction ($\tau=163\text{ms}, 98\text{ms}$) than from abduction ($\tau=205\text{ms}, 146\text{ms}$) in each subject. Returns from an intorsional starting point, however, follow a time course similar to or longer than that of abduction ($\tau=331\text{ms}, 132\text{ms}$). Data from three subjects will be presented.

THE PRIMATE INTERSTITIAL NUCLEUS OF CAJAL AND THE NUCLEUS OF DARKSCHEWITSCH. X. J. Hu*, J. Czech*, J.A. Rafols, W.J. Crossland. Dept. Anatomy and Cell Biol., Wayne State U. Sch. Med., Detroit, MI 48201.

The neuronal organizations of the interstitial nucleus of Cajal (iC) and the nucleus of Darkschewitsch (nD) were studied in Golgi impregnated brains of adult monkeys (*Macaca mulatta*). The four (I-IV) neuron types distinguished in iC are similar to types I-IV in the rostral interstitial nucleus of the MLF (riMLF-see accompanying abstract). However, the spine densities of types I and II in iC are higher than those of the corresponding types in riMLF. Additionally the dendrites of types I and II in iC appear to be confined strictly to its boundaries. Except for type IV, a local interneuron, all the other types in riMLF and iC may have long projecting axons. The sole type in nD has a medium polygonal cell body which gives rise to 4-6 thick dendrites. The dendrites seldom branch, taper to 2-4um in diameter and extend linearly 450-600um from the soma. Most dendrites in nD radiate dorsolaterally and ventromedially. However, some radiate medially into the periaqueductal gray. Moderate spine densities are found along the entire dendritic length. The axon does not impregnate beyond the initial segment and may project extrinsically. This study shows that most cell types in riMLF are found in iC. It also shows that the cells of nD are morphologically homogeneous and distinct from the cells in iC and riMLF. (Supported by grants EY04068, GM08167, and the Michigan Eye Bank).

COMPUTER SIMULATION OF PURSUIT EYE MOVEMENTS DURING DORSAL LATERAL PONTINE NUCLEUS STIMULATION. K.D. Pfann* and E.L. Keller. UCSF/UCB Grad. Group in Bioeng., Dept. of Elect. Eng., Univ. of Cal., Berkeley CA and Smith-Kettlewell Eye Res. Inst., San Francisco CA.

Pursuit eye movements may be altered by electrical microstimulation of pursuit-related cortical and brainstem areas. Two classes of models have been proposed to explain normal pursuit. Both produce realistic simulated pursuit movements, but they have radically different neural architectures. One emphasizes generation of a target velocity signal using efference copy, while the other emphasizes visual processing via parallel pathways. We modeled the effects of stimulation applied to these two systems and compared the results to actual pursuit perturbations produced in monkeys by stimulation of dorsal lateral pontine nucleus during "steady state" pursuit. We model the effects of stimulation with several variations, 1) substituting the stimulation signal for a model pathway, 2) perturbing a portion of an otherwise intact pathway or 3) altering a model state by changing the gain of an intact pathway.

Sites were found in each model that generate stimulation perturbed responses similar to the actual responses produced by pontine stimulation during open loop (OL) or closed loop (CL) tracking. However, no manipulation in either model generated both the constant acceleration (OL) and the reversal of acceleration (CL) observed with pontine stimulation. Although perturbation of part of an intact pathway in the models is an appealing way to explain the different effects during OL and CL, the resulting visual feedback error cannot completely overcome the disturbance and, therefore, cannot generate the amount of reversal seen in CL pontine stimulation. We believe the current models will require revision in order to account for the observed effects of pontine stimulation. (Supported by EY06860 and T32 GM07379)

THE PRIMATE ROSTRAL INTERSTITIAL NUCLEUS OF THE MEDIAL LONGITUDINAL FASCICULUS. J.A. Rafols, X-J. Hu*, and W.J. Crossland. Dept. Anatomy and Cell Biology, Wayne State Univ. Sch. Med., Detroit, MI 48201.

Our morphological investigation of the rostral interstitial nucleus of the medial longitudinal fasciculus (riMLF) in 50 Golgi impregnated adult (*Macaca mulatta*) brains revealed five (I-V) neuron types. Type I has a large polygonal cell body issuing 3-7 primary dendrites which extend up to 680um from the soma. The large, bulbous cell body of type II neurons, the only type with many spines, issues 2-4 dendrites which radiate 120-280um from the soma. Type III has a medium size fusiform soma and its dendrites become varicose as they extend 340-520um from the soma. Type IV cells have small cell bodies issuing 3-4 dendrites which extend 200-250um, possess bulbous appendages, and frequently end in axon-like arborizations. Type V has a giant fusiform cell body from which two thick dendrites arise and extend 700-800um from the soma. Three dimensional rotation of digitized representative examples of each cell type demonstrated that the dendritic spread of the type I, III, and V cells is discoid and confined mainly to the frontal plane, well situated to intercept MLF fibers. Type II and IV cells appear to radiate their dendrites in a spherical compartment and may sample more topographically localized input (type II) or carry out inhibitory interactions (type IV). FINE STRUCTURE OF THE MACAQUE ZONA INCERTA. T.P. Ma, G.A. Hoskins*, J.C. Johnson*, G.A. Mihailoff, and P.J. May. Depts. of Anatomy and Ophthalmology, University of Mississippi Medical Center, Jackson, MS 39216.

We have studied the fine structure of the zona incerta (ZI) in macaque monkeys to determine whether ZI contains the anatomical substrate necessary for its hypothesized role in orienting movements. Two cell types, similar to those observed in light microscopic preparations, could be distinguished. Putative interneurons ($n=2$) exhibited a highly indented nucleus, a thin rim of cytoplasm containing few organelles or Nissl bodies, and a sparse Golgi apparatus. Principal cells ($n=15$) had large, highly indented nuclei, and cytoplasm that contained the full range of organelles. Few synaptic contacts were found on the soma of either type. We examined 504 synaptic profiles in which clear pre- and postsynaptic membranes were present and distinguished at least three classes of synaptic profiles. Type A synapses (35%) form symmetrical contacts and exhibit considerable variability in vesicle packing density. Some Type A profiles contain large synaptic vesicles, dense-cored vesicles, and/or presynaptic grids. It is not clear whether these differences constitute distinct subtypes or simply represent normal variation. Type B synapses (6%) form asymmetrical contacts, are relatively large, and contain moderate numbers of pleiomorphic vesicles, coated vesicles, and mitochondria. Type C synapses (54%) form distinct asymmetrical contacts and may exhibit postjunctional bodies. These profiles contain vesicles of varying sizes as well as dense-cored vesicles and multivesicular bodies. The remaining 5% could not be classed. All synaptic types contact cell bodies and dendrites and may contact multiple postsynaptic structures. Only Type C boutons contact spines or other vesicle-containing profiles. In sum, two cell types and three synaptic classes were identified in the primate zona incerta. The complexity observed here is consistent with the multiple inputs known to terminate in the zona incerta and forms the substrate necessary for the control of orienting movements. EYE MOVEMENT DEFICITS REVEALED BY STEP RAMP TRACKING ERRORS IN MONKEYS WITH MAGNO AND PARVOCELLULAR LGN LESIONS. W.K. Page*, W.M. King, W.H. Merigan, and J.H.R. Maunsell, University of Rochester Medical Center & Center for Visual Science, Rochester, NY 14642.

Cortical processing of retinal information utilizes two parallel pathways. These pathways are anatomically separated in the parvocellular and magnocellular layers of the primate lateral geniculate nucleus (LGN). Cortical areas MT and MST, which receive most of their retinal input via the magnocellular pathway, are likely involved in processing retinal image motion and provide inputs to the oculomotor system for ocular tracking. To test the contribution of the magnocellular pathway to ocular tracking of moving targets, we made selective unilateral ibotenic acid lesions of magnocellular layer 1 of the LGN in two macaque monkeys trained to pursue small target spots. Later, a selective lesion was made in parvocellular layers 4 and 6 of the opposite LGN. By only testing the contralateral eye, lesions specific to layers 4 and 6 or layer 1 could be studied. Ocular tracking was tested several months after the lesions using step ramp target trajectories. Both animals detected, and made accurate saccades to, stationary targets stepped into either visual field, even when the target spot was extremely dim. The animals accurately pursued targets stepped onto the fovea and ramped temporally or nasally at speeds up to 20 deg/s. In contrast, smooth pursuit eye velocity had an increased latency and showed deficient tracking gain when targets were stepped into either the parvocellular or magnocellular lesioned fields, although initial pursuit acceleration appeared normal.

HUMAN OCULOMOTOR SYSTEM USES BOTH EXO- AND EGOCENTRIC CUES IN THE LOCALIZATION OF SUCCESSIVE TARGETS. P. Dassonville, J. Schlag, and M. Schlag-Rey, UCLA, BRI and Dept. of Anatomy, Los Angeles, CA 90024.

Although it is well understood that, under certain conditions, egocentric cues are inadequate to allow the human perceptual system to accurately localize a visual target (Matin 1976), it has been assumed that these cues are sufficient to allow for accurate oculomotor localization (Hallett and Lightstone 1976). Recent studies have called this distinction into question: when a brief flash is presented during an initial saccade, the target is mislocalized, in the direction of the initial saccade, by the oculomotor system (Dassonville et al. 1990). The patterns of mislocalization are identical to those of the perceptual system (Honda 1990), and have led to the conclusion that the perceptual and oculomotor systems use a damped internal representation of eye position in an attempt to achieve direction constancy.

Can the oculomotor system utilize exocentric cues to improve its accuracy, as the perceptual system does? This question has only recently been investigated (Hayhoe et al. 1990). In the present study, five human subjects, in complete darkness, were required to make a saccade to the location of a 2 ms flash (S2) occurring near the time of an initial saccade directed to a previous flash (S1, 20° right of fixation point). A monocular magnetic search coil was used to measure eye position. In the first condition, S1 was of a short duration (5 ms) and was, therefore, extinguished well before the onset of S2. In the second condition, S1 had a longer, variable duration so that it remained on until replaced by S2. In four of five subjects, accuracy of the movement to S2 significantly improved in the latter condition ($p < 0.02$), where S1 and S2 were in close temporal proximity. Accuracy was also dependent on the distance between S1 and S2: errors were smallest when the two flashes were in close spatial proximity, a result similar to those of Mateeff & Hohnsbein (1989) with perceptual localization. These results suggest that the exocentric relationship of successive flashes can be used by the oculomotor system to reduce the errors of egocentric localization - a possibility that should be considered when interpreting the results of studies utilizing double-step stimuli. HEAD AND EYE MOVEMENTS IN THE MACAQUE: CONTRIBUTIONS OF THE PONS AND SUPERIOR COLLICULUS. R. J. Cowie and D. L. Robinson, Department of Anatomy, Howard University, Washington, D. C. and Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

The coordination of head and eye movements is essential for normal vision and many subcortical structures participate in the generation and integration of these motor activities. We have electrically stimulated the medial pontine reticular formation as well as the intermediate and deep layers of the superior colliculus in monkeys free to move their head and eyes. Excitation of the pons leads to brisk, saccadic-like movements of the head in a contralateral direction. Comparable head movements are evoked while the monkey performs a fixation task and during spontaneous behavior in total darkness. These evoked movements cause no significant gaze shift; the vestibulo-ocular reflex compensates for these head movements. If the head is restrained, stimulation does not evoke an eye movement. In contrast, when the superior colliculus is stimulated, large shifts in gaze occur. If the head is restrained, then contralateral saccadic eye movements result from stimulation. In the head-free condition, the majority of the gaze shift is accomplished with a saccadic eye movement; on a few trials there is a slight head movement which accompanies the saccade. At deeper collicular sites there is a significant head movement evoked which moves the head in the same direction as the eyes. Such head movements can be evoked with the head and eyes in their primary positions.

These data demonstrate that in the macaque both the superior colliculus and pontine reticular formation participate in the coordination of head and eye movements although they perform different functions. The collicular contribution is in the form of a gaze shift, most often with saccadic eye movements but head and eye movements are generated. The pons contributes in terms of movement of the head; this evoked movement does not create any gaze shift.

ADRENAL AUTOTRANSPLANT EFFECTS ON EYE MOVEMENTS IN PARKINSON'S DISEASE. D. Impelman and B. Brooks-Eidleberg, Dept. of Physiol. UTHSC, S.A. TX 78284

The effects of an adrenal medullary autotransplant on saccadic and smooth pursuit eye movements were followed in a longitudinal study of a 57 year old Parkinson(PD) patient for one year postoperatively. Presurgical motor deficits were bilateral and the right caudate was implanted. Computer generated 5°, 10°, and 20° saccadic target movements and 10° sinusoidal tracking routines were used in oculomotor measurements. The initial findings show a main effect on hypometria contralaterally. MANOVAS of bilateral frequency and interval effects show a significant decrease in the frequency of hypometric intervals less than 150 ms in PD saccades. Frequency analysis shows the number of normative saccades initiated during self-paced trials is significantly increased. Saccadic tracking is improved by a decrease in latency variability and a trend towards decreased lag times. Postsurgical smooth pursuit gain and phase lag effects are correlated with transplant effects on PD hypometria. In summary, there appears to be a decrease in saccadic inhibition shown by 1)the decrease in PD hypometria and 2)the increase of normative saccades. These implant effects are consistent with a reduction of the net GABAergic inhibition in the striatal-nigro-collicular pathway in PD eye movements.

THREE DIMENSIONAL INTERSEGMENTAL INTEGRATOR OF EYE MOVEMENTS J.Droulez*, J.Laczko, A. Berthoz, C.N.R.S. Lab. de Physiologie Neurosensorielle, Paris 75006 France

The question of how orienting movements are generated by neural networks led us to build a model of oculomotor integration. This model is an extension of the dynamic memory model proposed by Droulez and Berthoz (P.N.A.S., in Press and in The Oculomotor System ed.Shimazu & Shinoda.) in which the instantaneous target position is stored as the distributed activity of a retinotopic map and is continuously shifted according to the eye velocity signal. The input of the extended model are the gaze- and head velocity signals. The model solves some problems of other oculomotor integrators.

Graphical computer programs have been developed to simulate how a desired velocity can be transformed into relative position between two body segments (eye and head). The computer simulation obeys known features of eye-head coordination: 1. It considers the properties of the three dimensional rotational group. During the integration no cumulative error occurs in contrast with such models in which each dimension was integrated separately. 2. The output of the integrator is the position of the eye coded in intrinsic muscular coordinate system. This allows transformation between different frames of reference: the same model can be applied to the cephalomotor integrator to provide the adequate command for neck muscles. 3. The use of musculotopic coordinates makes it possible to formulate and maintain the rigidity of the muscular system. Rigidity is formulated by expressing each eye and head centered vectors as a linear combination of the vectorial products of the others and maintained by keeping the coefficients constant. This method offers a fast algorithm to maintain rigidity of the quasi-orthogonally organized eye muscles and it can be applied for arbitrary muscular systems with any number of muscles as well. 4. The model is compatible with Listing's law: it generates saccadic eye movements without torsional rotation component.

This computerized model is very useful to investigate properties and coding of orienting eye movements in different muscular and neural reference frames.

HUMAN HEAD SACCADIC GAIN. James H. Fuller
Dept. Oral Anatomy, Univ. of Illinois, Chicago IL 60612

Visually evoked gaze shifts were studied in nine young adults to define and examine head movement gain (head/target amplitude). Subjects (S) stepped their gaze with a free head between four randomly presented step sequences, beginning from: a, 0; b, 20; and c, 40 deg; and ending on the opposite side at: a, 40; b, 20; b' and c, 40 deg. Thus the a step is centric-eccentric, b is symmetrical; the b' and c steps start progressively eccentric. There were two tasks: the non-aligned (NA) task required: 1) gaze fixation and 2) a reaction-time, accurate, gaze step to the target; the head-aligned (HA) task required: 3) head alignment within 3 deg of fixation before the step sequence began. Gain = 0.27 NA, 0.67 HA.

It was found that S's were divided by: 1) the b step best characterized head-movers in the NA task; 2) the b step, HA task, best identified non-movers; 3) the a, b', c series in the HA task characterized the non-movers by a relatively linear increase in gain, but not head-movers. Three effects account for these results: 1) a midline-attraction effect increasing movement towards the center in head movers, and decreasing movement away from the midline in non-movers; 2) a momentum effect tending to carry the head across the midline in the b, b', and c steps; 3) an awareness/arousal effect due to the intrinsic nature of the alignment procedure.

OCULOMOTOR DYSFUNCTIONS IN SCHIZOPHRENIA. J.A. Sweeney, G.L. Haas*, J.R. Carl*, M. Keshavan*. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Pursuit eye movement dysfunctions are common in schizophrenic patients and their family members. We have observed significantly reduced pursuit gain in schizophrenia, bipolar disorder, psychotic and nonpsychotic unipolar depression and obsessive compulsive disorder, indicating limited specificity of this abnormality for schizophrenia. Memory-guided-saccade and anti-saccades, thought to be mediated by prefrontal cortex, were abnormal in twenty unmedicated schizophrenic patients. Latency, gain of first saccade and error of final resting position of memory guided saccades were all abnormal in schizophrenia. Saccades to target were more common and anti-saccades less accurate in schizophrenia. Neuroleptic treatment reversed right visual field advantages on some tasks. Preliminary analysis suggests that deficits on oculomotor tasks of frontal function are more specific to schizophrenia than pursuit impairments.

338.5

SMOOTH PURSUIT EYE MOVEMENTS IN PATIENTS WITH MAJOR DEPRESSION

A.Mackert*, N.Hierholzer*, K.-M.Flechner*, K.Frick*, and J.Kasper
Dept. Psychiatry, Free University of Berlin, D-1000 Berlin 19

Eye tracking dysfunctions (ETD) are believed to be a psychophysiological marker of schizophrenia. Although ETD is thought to be specific for schizophrenics, it has not clearly been established that patients with major depression have similar disturbances.

We analyzed smooth pursuit tracking in 17 patients with a major depressive disorder. No patient had psychopharmacological treatment at the time of the examination.

As controls, we tested 10 age- and sex-matched volunteers. Eye tracking was recorded with DC-EOG. The target was driven sinusoidally at a frequency of 0.4 Hz and an amplitude of 30° of visual arc. Beside a qualitative rating (5-point scale), a Fast Fourier Transformation (FFT) was computed and the power between 0.8 and 12.4 Hz calculated, which reflects the accuracy of tracking performance.

The mean qualitative ratings and the mean quantitative scores (FFT) of eye-tracking showed no significant difference between depressed patients and controls. This finding supports the hypothesis that ETD in psychiatric populations might be specific for schizophrenia.

338.2

SMOOTH PURSUIT ABNORMALITIES IN AMYOTROPHIC LATERAL SCLEROSIS (ALS). L.A. Abel, I.M. Williams*, K. Gibson* and L. Levi*. Dep't of Ophthal., Indiana Univ., Indianapolis and Neuro-Ophthalmol. Lab, Monash Univ. Dep't of Med., Melbourne, Australia.

Once held to be the only motor function spared in ALS, several studies have reported ocular motor defects, including reduced pursuit gain. To better define this latter defect, we examined ALS patients with moderate and severe clinical impairments and age-matched controls, using constant velocity and sinusoidal targets. In the former study, 17 patients and 17 controls followed 10 and 20°/s targets. Patients', but not controls', gain decreased with target speed. The severe group also showed a significant gain asymmetry at 20°/s. In another study, sinusoidal stimuli of ±5 and 10° from 0.25 to 2 Hz were presented to 9 patients and 11 controls. Targets were such that for all but one peak velocity there were two peak accelerations, allowing their separate assessment. Gain was reduced for the severes at all velocities; initially, moderates performed like controls, but at a peak velocity of 31.4°/s, went from being grouped with the normals to clustering with the severes when acceleration went from 98.6 to 197.2°/s². Thus, early in the disease process, an acceleration limit is present, to be joined later by a velocity limit. Pursuit impairment in ALS involves more than a simple, global gain reduction.

338.4

PURSUIT PROLONGS, WHILE FIXATION GAPS SHORTEN SACCADIC REACTION TIMES (SRT). D. Braun, D. Boman, J. Hotson. Calif. Inst. Med. Res., San Jose, CA & Stanford Univ. Sch. Med., Stanford, CA.

Changing the condition of attentive visual fixation on a stationary target alters SRT. SRT decrease when the fixation point is extinguished prior to saccade target onset and increase when the fixation point remains on after saccade target onset. The present experiments examine the affects of fixation conditions on SRT during smooth pursuit.

We compared vertical SRT during stationary fixation and during horizontal smooth pursuit using three fixation conditions: 1) Gap - fixation point offset occurred 200 msec prior to target onset, 2) Simultaneous - fixation point offset coincided with target onset, and 3) Overlap - fixation point offset occurred 200 msec after target onset. With both stationary and smooth pursuit fixation, SRT were shortest in the Gap condition and longest in the Overlap condition indicating that similar mechanisms may be involved in the disengagement of fixation from moving and stationary targets. Also, average SRT with stationary fixation were 10-40 msec shorter than during smooth pursuit under each condition. The disengagement of pursuit or the computation of its spatial displacement may slow saccade initiation.

COLOURED TARGETS AND LATENCIES OF EYE SACCADES. P.E. Hallett & Christian Perron, Institute of Biomedical Engineering & Department of Physiology, University of Toronto, Ontario, Canada M5S 1A8.

The task was to track a disk target as it stepped randomly between 7 equally spaced positions on a white screen. Tracking was frequent because the target stepped shortly after each successful foveation. Disk subtense was typically 2.3° and the step 5°. Colour was randomly switched between light/dark, yellow/blue, red/green or orange/cyan during different runs.

Analyses of mean latencies and multiple linear regressions showed that latency inflating factors were low tritanopic purity difference (i.e. blue or yellow colour), low achromatic or chromatic contrast, small size, and edge blur. Screen position and retinal meridian were very weak factors. Isoluminous chromatic targets were often well tracked, especially at high chromatic contrast. Severe blur was also fairly well tolerated.

A possible model is that saccadic latency is partly, if not largely, determined by the magno pathway.

338.7

Small lesions in the frontal eye field impair predictive pursuit but preserve the memory for movements past. E.G. Keating. Dept. of Anatomy & Cell Biology, SUNY-HSC, Syracuse, N.Y. 13210

Smooth pursuit is driven by current signals (visual, oculomotor) and prior experience (predictive strategies). Previously, large ablations of the frontal eye field (FEF) have impaired visually guided and predictive pursuit. This study searched for the subset of FEF critical for the impairment, and further explored the predictive pursuit deficit.

Three monkeys tracked visual targets designed to evoke predictive pursuit. For example, if a sinusoidal target suddenly disappeared, the monkeys' tracking continued to approximate sinusoidal pursuit for several reaction times.

Small unilateral FEF ablations, approximately confined to "low-threshold" FEF, impaired visually guided and predictive epochs of smooth pursuit. The decrement in peak velocity of the predictive sine epochs was worse than for visually guided epochs.

However, the impairment was not an amnesia for prior experience. After surgery, predictive sine pursuit, albeit impaired, still varied as a function of the prior visual target's frequency. When ramp targets had the same velocity on successive trials, the monkeys still occasionally evoked anticipatory pursuit, i.e., began pursuit prior to target motion. Variance in the latency of pursuit was related to the target velocity of prior trials.

The FEF deficit seems not a loss in predictive strategies directly, but impairment of some other control signal, perhaps eye velocity, on which predictive eye movements heavily depend. NSF BNS 8603915

338.9

THE STABILITY OF THE OCULOMOTOR SYSTEM TO TIME DELAYS
D.M. WOLPERT*, G.K. KERR, R.C. MIALL* & J.F. STEIN*

University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, UK

The oculomotor system has intrinsic delays (totalling about 200 msec) which represent the time taken by neuronal processing and eye dynamics. The ability of the eye to track and fixate objects accurately implies that the control system is well adapted to these intrinsic delays. We have therefore investigated the stability of the oculomotor system when additional time delays are imposed during fixation or pursuit.

We examined head restrained, human monocular tracking of a spot target using infra-red reflectometry. In order to incorporate an extra time delay of D msec into the oculomotor feedback loop, the spot was iteratively displaced from the target waveform by the angle through which the eye (sampled at 500 Hz) had moved during the previous D msec. Thus, the difference between the current and past eye positions was used to modify the target location.

Three subjects were examined whilst they performed two tasks. In the first the subject attempted to fixate a stationary target for 15 seconds during which delays of between 0 and 520 msec were added. In the second he tracked pseudorandom waveforms for 15 seconds. Delays of 0 to 280 msec were added.

The standard deviation of eye position during fixation trials increased greatly when the delay was made greater than approximately 200 msec. During pursuit the mean squared error increased greatly as delays rose above 150 msec.

These results suggest that added delays of less than 150 msec have little effect on the subjects' ability to fixate or pursue targets. This is surprising given that the system has intrinsic delays of a similar magnitude.

338.11

AUDITORY FACILITATION OF VISUALLY-GUIDED SACCADES
C.Lee, S.Chung*, J.Kim*, and J.Park*. Dept. of Psychology, Seoul National Univ., Seoul, Korea.

It has been shown that the latency of saccades toward a visual target is reduced when an auditory stimulus is simultaneously presented. In order to test whether this facilitation is spatially selective, we examined the effect of spatial congruence of visual and auditory stimuli on the saccade latency. Two human subjects, wearing a golden eye-ring fitted on the globe (Bour et al, IEEE BME31, 1984) with heads restrained, were instructed to fixate on a front LED and look to eccentric LEDs mounted on the center of speakers. The eye position signals were obtained with the circuit described by Rempel (1984), and sampled every 4 msec. The visually-guided saccade latency was reduced by approximately 20 msec when a tone was simultaneously presented at the same location as the lit LED, confirming previous reports. A tone delivered at the opposite side to impending saccades, however, had neither positive nor negative effects on saccade latency. These results indicate that the auditory facilitation is not due to general alerting caused by an auditory signal, but to spatially-selective intermodal interaction. (Supported by Korea Science and Engineering Foundation Grant 901-0408-007-2).

338.8

TRACKING EYE MOVEMENTS FOLLOWING LOOMING VISUAL STIMULATION U. Schwarz. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Tracking eye movements following brief periods of unidirectional, looming motion in the central visual field were studied in monkeys. The goal was to determine to what extent motion processing structures (MT/MST) in the brain utilize pure speed information in a subsequent tracking task, which might involve modules used in object recognition (V4). Monkeys were seated 200 mm in front of a video display with their head fixed. Eye position was recorded with the search coil technique. The target was a filled square subtending a visual angle of 1.6°. First, it was positioned in the center of the screen. The animals were trained to fixate the center of this square and were never reinforced for responses to target movements. After successful fixation for at least 1s the square was radially expanded at 12, 18, or 24°/s as annulus (same thickness as target) subtending an angle of 360, 270, 180, or 90° during 50, 100, 150, or 200ms. After this expansion period the annulus was reduced back to the square which continued the movement horizontally at either the same or changed speed for a total of 750ms. Controls consisted in ramp movements of the fixation target only. The eye responses were robust and showed these characteristics: no movements occurred during the expansion period (eyes locked in position). Latencies were similar in all conditions, but the time from the onset of the response to the onset of the saccade was shorter for longer expansion times, and eye acceleration was slightly higher when compared to the simple ramp task. Fractioned annuli produced an angle dependent change in eye acceleration prior to the onset of the actual pursuit response. Steady-state pursuit was always close to 100% in all conditions. These findings suggest that tracking performance is not tuned by speed information that by itself does not yet need to elicit eye movements (diverging optic flow during forward movements).

338.10

RAPID AND SLOW MECHANISMS FOR THE CONTROL OF OCULAR TORSION DURING VOLUNTARY GAZE SHIFTS.

J.A.M. Van Gisbergen and A.W.H. Minken*. Dept. Med. Phys. & Biophys., P.O. Box 9101, 6500 HB Nijmegen, The Netherlands.

It is known that Listing's law holds reasonably well during fixation and saccades when the eyes are not converged. Tweed and Vilis have demonstrated, for fixed-axis saccades, that implementing the law dynamically requires tilting of the angular velocity axis out of Listing's plane. We have investigated whether a dynamic implementation mechanism can also be shown in strongly curved (non-fixed axis) saccades. In addition, we explored the time course of Listing's law violations in near vision.

Eye movements were recorded in human subjects with the 3D scleral coil technique. Curved saccades were elicited in five subjects across a screen at 95 cm distance by two-dimensional double-steps. In the near-vision experiments, three subjects alternated fixation between various targets at 15 and 95 cm distance.

The results show that strongly curved saccades, corrected in midflight, obey Listing's law just as well as normal fixed-axis saccades. Thus, fixed-axis rotations are not a necessary condition for the dynamic implementation of Listing's law during saccades. Our curved-saccade results can be interpreted in terms of the 3D internal feedback model proposed by Tweed and Vilis (1987). The near-vision experiments show that violations of Listing's law during refixations in depth, manifest in torsion changes, were often very slow and sometimes had a different latency than the saccadic component of the gaze shift. These results seem nicely in line with the suggestion that near-vision violations of Listing's law may be due to a system linked to the control of convergence (Allen, 1954), but binocular 3D recordings are required to investigate this possibility further.

338.12

PREDICTIVE SACCADES IN HEMIPARKINSONS DISEASE (HPD).
J. Ventre, D. S. Zee, H. Papageorgiou, and S. Reich. The Johns Hopkins University, School of Medicine, Baltimore, MD 21205 and INSERM, Bron, France.

We recorded eye movements (EOG) in 9 patients with mild HPD and in 16 controls. Five patients were affected predominantly on the right side (RHP), and 4 on the left side (LHP). Reflexive saccades were elicited in response to the random appearance (timing and location) of a light-emitting diode (LED). Predictive saccades were elicited by alternately illuminating LEDs (R10-L10deg), at fixed frequencies of 0.25-1.0 Hz.

In the reflexive task there were no differences in saccade latency or amplitude between patients and controls. During predictive tracking, while mean saccade latency was not significantly different between patients and controls, two abnormalities were noted in timing. First, in LHP, there was a directional asymmetry in latency (L > R, eg. at 0.25 Hz, mean difference of 90ms). Secondly, in LHP, and especially in RHP, there was less consistent prediction as reflected in more variability of the mean value of saccade latency (for each group of subjects), at each point in time throughout a trial. Saccade amplitudes were also abnormal. Mean values were decreased in RHP but especially in LHP (eg. at 0.25 Hz, rightward saccades, 19 deg (1.6 sd) in controls, 14 deg (2.7 sd) in LHP, 15.7 deg (2.3 sd) in RHP).

In sum, HPD patients showed abnormalities in timing and in amplitude during predictive saccadic tracking, while more reflexive saccades were normal. The defects were most evident at low frequencies. While the defects were largely bilateral, our results suggest that the left and the right cerebral hemispheres make slightly different contributions to both the temporal (timing) and the spatial (accuracy) aspects of predictive saccadic tracking.

THE EFFECTS OF COMBINED SUPERIOR TEMPORAL POLYSENSORY AREA AND FRONTAL EYE FIELDS LESIONS ON EYE MOVEMENTS IN THE MACAQUE. J.P. Skelly, T.D. Albright, H.R. Rodman, and C.G. Gross. Dept. of Psychology, Princeton University, Princeton, NJ, 08544.

We previously found (Skelly, et. al., Soc. Neurosci. Abstr. 15:475.1) that lesions of the superior temporal polysensory area (STP) cause temporary deficits in the production of saccadic eye movements. In order to define regions participating in recovery, we examined the effects of adding lesions of the frontal eye fields (FEF) in 3 macaques who had regained preoperative performance on a saccade task after bilateral STP lesions and in 1 animal with a bilateral control lesion of inferior temporal (IT) cortex. Prior to initial surgery the animals were trained to saccade to targets appearing 8, 15, and 22 deg. to either side of and 8 deg. above and below a central fixation point (FP), and to make smooth pursuit eye movements to targets moving 5, 13, and 22 deg./sec.

After adding a unilateral FEF lesion to STP damage in one animal and a laterally asymmetric bilateral FEF lesion in another, the animals showed larger increases in saccade latency than are seen after either FEF (Lynch and Allison, Soc. Neurosci. Abstr. 11:144.9) or STP lesions. Animals often failed to make a saccade to peripheral targets within the second that they were given to respond. No effect on saccadic eye movements was found from adding a laterally symmetric FEF lesion to the third animal with bilateral STP damage or from adding a unilateral FEF lesion to the IT control. Addition of FEF lesions to STP or IT damage produced variable effects on pursuit, similar to those seen after FEF damage alone. After all of the FEF lesions there was a large initial deficit in fixating the FP, which was greatly ameliorated by turning on a dim light in the testing room. All of the deficits showed considerable recovery over time, especially within the first two weeks of testing.

The results are consistent with a contribution of the FEF to the recovery after STP damage alone.

Relation of Purkinje cell activity in the ventral paraflocculus of alert monkey to ocular following response. M. Shidara* and K. Kawano. Neuroscience Sect., Electrotechnical Lab., Umezono, Tsukuba-shi, Ibaraki 305, JAPAN.

Previous studies, using alert monkeys, showed that neurons both in the medial superior temporal area (MST) of the cortex and dorsolateral pontine nucleus (DLPN) are activated by movements of the entire visual field, eliciting ocular following response. In order to know the efferent limb of the DLPN neurons, the simple-spike activities of Purkinje cells (P-cells) were recorded in the ventral paraflocculus (VPFL; = folia V ~ XII of flocculus as defined by Madigan & Carpenter, 1971) of two monkeys.

The animal faced a tangent screen onto which a random dot pattern was projected and moved, and its eye movements were recorded with the magnetic search coil technique. P-cells in the VPFL were activated by the movements of the entire visual scene. One group of P-cells preferred downward motion, and the other preferred motion toward the side of recording. The latency of the simple-spike response of 70% of the P-cells to the movement of the large-field visual scene was ~8 msec shorter than the latency of ocular following. At the site of each recording, electrical stimulation of single negative pulse, 5 ~ 30 μ A, 0.2 ms in width was applied. 66% (19/29) of them elicited eye movements toward the preferred direction of the P-cell with a latency of 8 ~ 10 ms. These data suggest that P-cells in the VPFL participate in initiating the ocular following response.

338.14

A POPULATION CODING MODEL OF TWO DIMENSIONAL SACCADE GENERATION. M. Fujita, Neural Computation Section, Communications Research Laboratory, Koganei-shi, Tokyo 184.

Saccadic eye movement shows a nonlinear characteristics in its peak velocity vs. amplitude relationship which makes saccadic duration lengthened as the amplitude increases. Saccade system must have some mechanism to stretch a weaker (horizontal or vertical) component duration of eye movement in oblique saccades so as to keep its trajectory straight.

Our model is based on the idea of population coding in the brainstem neural circuits. We assume four ensembles of an element circuit, corresponding to the four burst neuron pools supposed to be active in a saccade to one of four directions (up, down, left or right). Each element circuit consists of a pair of long-lead burst neuron and medium-lead burst neuron with local feedback system, an equivalent circuit as the one proposed by Scudder (Soc. Neurosci. Abstr., 1984). A signal from the superior colliculus (SC) traverses two of the four ensembles with a variable trajectory since its output location from the SC varies according to the SC motor map and so the number of element circuits which the signal intersects and makes synaptic contacts with changes. In our model, this number becomes proportional to the direction factor which the ensemble encodes. Since the strength of an input signal to an element circuit represents the saccadic amplitude, activity duration of the circuit or the whole ensemble depends only on the amplitude, not on the direction, thus realizing naturally the stretching phenomena. Since the total output effect of one ensemble is proportional to the product of an element circuit output and a number of active elements in the ensemble, saccade trajectory becomes straight.

Population coding idea applied in the brainstem not only leads to plausible two-dimensional saccade generation, but also bears following features: it mimics neuronal signals in the brainstem, proposes neural mechanisms to realize a trigonometric function, does not need precise timing in the activity of pause neurons, explains the horizontally-dominated curvature of normal saccades and has ability to issue microsaccades with minor modification of the model.

BRAIN METABOLISM AND BLOOD FLOW IV

SYMPATHETIC EFFECTS ON RESISTANCE VESSELS OF THE BRAIN. J. A. DeMaro*, W. Finnegan*, J. Y. Wang*, and J. D. Fenstermacher. Department of Neurological Surgery, SUNY Stony Brook, Stony Brook, N.Y. 11794.

In the cerebral arteries of spontaneously hypertensive rats (SHR), luminal diameter is decreased and wall thickness and area are increased. These changes are thought to be driven by the sympathetic nervous system. To test this hypothesis, the superior cervical ganglion was unilaterally removed in one-month-old SHR and Wistar-Kyoto (WKY) rats (WKY are the normotensive control for SHR). Six months later, a set of 9 cerebral arteries were sampled and analyzed by light and electron microscopic morphometry. A similar set of arteries were also taken from age-matched intact (control) SHR and WKY. Differences, which were sizable and significant in a number of cases, were found between control SHR and WKY. In accordance with published data, luminal diameter was less and wall area and thickness were greater in SHR compared to WKY. Unilateral ganglionectomy (uGX) slightly decreased luminal diameter (D) in SHR and increased the differences in D between SHR and WKY. uGX had small and variable effects on wall area in both SHR and WKY. There were no differences in arterial wall structure between ipsilateral and contralateral sides in either uGX-SHR or uGX-WKY. In support of the hypothesis, alteration of the sympathetic nervous system at one-month of age affects cerebral arterial wall structure in adult SHR.

339.2

EFFECTS OF HYPOGLYCEMIA (H) ON AUTOREGULATORY ADJUSTMENTS OF NEWBORN PIAL ARTERIOLES (PA). T.S. Park, E.R. Gonzales*, A.R. Shah*, and J.M. Gidday. Department of Neurosurgery, Washington University, St. Louis, MO 63110

We investigated the effects of (H) on the progressive vasodilatory responses we previously observed in newborn pig PA in response to graded hypotension (GH). Two groups of newborn pigs were equipped with closed cranial windows for the observation of PA (50-100 μ m dia) by videomicroscopy. In the normoglycemic controls (C), PA diameters were measured during normotension, and during GH (MABP = 50, 40 and 30 mmHg) induced by hemorrhage. A similar protocol was followed in the H group, with H induced by insulin after normotensive normoglycemia.

MABP (mmHg)	Glu (mg/dl)	C Group (μ m)	MABP (mmHg)	Glu (mg/dl)	H Group (μ m)
74	105	67±3	67	100	76±5
68	-	79±4	62	18	99±6 * #
50	-	85±5 *	50	16	97±7 *
40	-	88±5 *	40	19	103±8 * #
30	159	97±5 * **	30	15	107±8 *

* and ** = p<0.05 compared to initial and second normotensive diameters, respectively, within each group. # = p<0.05 compared to corresponding C group diameter. Thus, H caused dilation of PA during normotension, but, in contrast with C animals, no further increase in PA diameters was observed with GH to 30 mmHg, indicating an impairment in autoregulation under conditions of H.

339.3

CHANGES IN MITOCHONDRIA AND CAPILLARIES ASSOCIATED WITH SYNAPTOGENESIS AND EYE-OPENING IN RAT VISUAL CORTEX. J.E. Black & W.T. Greenough. College Medicine, Neuroscience Prog, Depts of Psych and Cell & Structural Biol, University of Illinois, Urbana, IL 61820.

Capillaries and mitochondria in visual cortex undergo substantial growth during the postnatal period. The earliest stages of capillary and mitochondrial proliferation are probably controlled by a rigid developmental program. On the other hand, growth of both these components can be elicited of healthy, mature animals by manipulating neuropil volume and metabolic demand (e.g., Black, et al. *Neurosci Lett*, 1987; Black, et al. *PNAS*, 1990). This study examines capillaries and mitochondria in Layer IV of visual cortex during eye-opening, an interval with a sharp increase in metabolism about day 14.

Eight littermates were sacrificed in pairs on postnatal day P13, P15, P20, and P25. After perfusion and aldehyde fixation, tissue blocks from Area 17 were prepared for TEM. Montages at 32,500X were prepared from serial sections. Each set of serial montages contained a long segment of an apical dendrite from which 3-dimensional reconstructions of spines have been described (Hwang & Greenough, *Soc Neurosci*, 1985). Two montages from each animal were used to obtain estimates of mitochondrial volume fraction. Mean PSD length was estimated from a sampling of synapses nearby. Synapse density was estimated as $N_v = N_a / (D+t)$, where t is section thickness. Capillary density and mean capillary diameter were estimated from 1- μ m toluidine-blue stained sections. The Disector method will be used to estimate N_v mitochondria.

age	N_v syn (#/100 μ m ³)	PSD length(μ m)	mitochon(%)	cap dens(#/mm ²)
P13	47	.27	11.5	259
P15	81	.20	14.8	254

FATTY ACID UPTAKE AND ESTERIFICATION BY THE IN SITU PERFUSED RAT BRAIN. K. Washizaki, D. Purdon*, J. DeGeorge*, P.J. Robinson, S.I. Rapoport, and O.R. Smith. Laboratory of Neurosciences, NIA, NIH, Bethesda, MD 20892.

Radiolabeled fatty acids have been used following intravenous injection to examine cerebral lipid synthesis and turnover in awake animals. To evaluate the time course of brain precursor specific activity and the influence of plasma fatty acid concentration on brain fatty acid uptake and incorporation, pentobarbital-anesthetized rats were perfused in situ with artificial or whole rat blood containing [³H]arachidonate or [¹⁴C]palmitate, following the procedure of Takasato et al. (1984). At the end of perfusion (0-15 min), brains were microwaved and processed to quantitate tracer in brain phospholipid, triglyceride, diglyceride, phosphatidic acid, acyl-CoA and unesterified fatty acid pools using combined TLC, HPLC and GC. Fatty acid incorporation into brain phospholipid increased linearly with time and was shown to be measurable even with perfusion times of less than 1 min. Calculated transfer coefficients for incorporation (blood-to-brain phospholipid) equaled $1.71 \pm 0.37 \times 10^{-4}$ and $0.68 \pm 0.19 \times 10^{-4}$ ml/s/g for [³H]arachidonate and [¹⁴C]palmitate, respectively, and agreed well with reported in vivo values. Incorporation of [³H]arachidonate decreased with increasing perfusate unlabeled arachidonate concentration, as expected for competition. Preliminary estimates indicate that the half-time of free fatty acid in brain is ≤ 1 min. In summary, the in situ brain perfusion technique can be used to examine the dynamics of cerebral lipid metabolism in vivo. The results demonstrate that the incorporation of fatty acid label into brain phospholipid pools depends on the level of fatty acid in the perfusate and is very rapid.

INDUCTION OF C-FOS WITHIN DISCRETE BRAIN AREAS FOLLOWING INTRACEREBROVENTRICULAR INJECTION OF PROPIDIUM IODIDE IN THE RAT. Sheng Chen, Marina Bentivoglio (SPON: European Brain and Behaviour Society)

Institute of Anatomy, University of Verona, Italy.

It has been reported that intracerebroventricular (icv) injection of the fluorochrome propidium iodide (PI) results immediately in behavioral abnormalities, such as nystagmus, ataxia and truncal tremor. We aimed here at the identification of the structural substrate of the movement disorders induced by PI icv administration. Previous observations indicated that after icv injection PI labels selectively the Purkinje cells of the cerebellum and the dopaminergic neurons of the substantia nigra. In the present study, a prominent induction of c-fos protein, as revealed by immunohistochemistry, was observed bilaterally in the deep cerebellar nuclei, inferior olivary complex and pontine nuclei after icv injection of PI (0.2%, 3-10 μ l). Such induction was absent in control cases with icv injection of saline. The present results indicate that the PI selective uptake activates discrete brain circuits, thus resulting in the behavioral abnormality. These data may contribute to the understanding of the mechanisms of action of molecules circulating in the cerebrospinal fluid. Further investigations on these mechanisms are in progress.

339.4

METABOLIC MAP OF THE NORMAL RAT BRAIN AS REVEALED BY CYTOCHROME OXIDASE HISTOCHEMISTRY AND BIOCHEMISTRY. S. Liu, R. Hevner and M. Wong-Riley. Dept. Cellular Biology & Anatomy, Med. Coll. Wis., Milwaukee, WI 53226.

The rat has served as a useful experimental model, and a number of studies in the past have focused on its enzymatic distributions in isolated regions of the brain. The present study was undertaken to systematically establish a metabolic map of the rat brain based on cytochrome oxidase (C.O.) histochemistry (of sections cut in three different planes) and supplemented with biochemical assays of C.O. activity in selected brain regions. Previously, Darriet et al. ('86) have found a strong correlation between the two techniques. Our analysis indicates that the distribution of C.O. activity in the rat brain is quite heterogeneous at the regional, laminar, and cellular levels. The gray matter has a much higher level of C.O. activity than the white matter (about 4-10 fold). Quantitative analyses of both histochemical and biochemical data show that there are significant differences in C.O. activity among different structures in the gray matter ($p < 0.05$ to $p < 0.01$) as well as among regions of the white matter ($p < 0.01$). Visual cortex, caudate nucleus, and superior colliculus, for example, are more C.O. reactive than other brain regions, such as the thalamus ($p < 0.01$). Optic nerves have a higher level of C.O. activity than trigeminal nerves and the corpus callosum ($p < 0.01$). In conclusion, both histochemical and biochemical analyses reveal a distinct heterogeneous pattern of C.O. activity in the normal rat brain. These findings will serve as a reference for our future experimental studies. (Supported by NIH grant NS 18122 to MWR and an MCW MSTP Fellowship to RFH).

339.6

BRAIN N-ACETYL-L-ASPARTATE IS A MAJOR SOURCE OF ACETYL GROUPS FOR LIPID SYNTHESIS

R. Burri, N. Herschkowitz. University of Berne, Department of Pediatrics, CH-3010 Berne, Switzerland.

To investigate the possible function of N-acetyl-L-aspartate as a lipid precursor in the CNS, N-[¹⁴C]-acetyl-L-aspartate (NAA) was injected intracerebrally into 8, 15, 22 and 79-day-old rats. Four hours after the injections 5-20% of the injected NAA was recovered in the brain tissue. These amounts were taken as 100% in Table 1.

Table 1: Incorporation from NAA	% recovered radioact. in the lipid fraction	% recovered radioact. in the protein fraction
8 days	42.88 \pm 9.80 (4)	7.20 \pm 0.91 (4)
15 days	57.95 \pm 10.38 (4)	8.73 \pm 0.93 (4)
22 days	65.66 \pm 5.96 (4)	9.38 \pm 2.41 (4)
79 days	47.29 \pm 7.87 (9)	17.29 \pm 3.53 (9)
ANOVA (one-way)	$p < 0.01$	$p < 0.001$

NAA was a more efficient lipid precursor than a protein precursor. Incorporation into both fractions was age-dependent. The recovered radioactivity in the brain lipid fraction of rats injected with NAA was the same (8, 15, 22 days) or significantly higher (79 days) than in rats injected with [¹⁴C]-acetate (ACA). However, ACA was a better precursor for protein and cholesterol synthesis than NAA.

NAA is an efficient precursor for lipid synthesis in the brain of developing and adult rats. The comparison of NAA and ACA as lipid precursors suggests that lipid synthesis from NAA may occur without an intermediate product of free acetate.

339.8

SYNTHESIS OF IRON REGULATORY PROTEINS IN THE HUMAN CHOROID PLEXUS. C.V. FLAHERTY*, S.L. MENZIES* AND J.R. CONNOR. Dept. of Neuroscience & Anatomy, M.S. Hershey Medical Center, Hershey, PA 17033

The choroid plexus is responsible for the synthesis, secretion, and filtration of many of the constituents of the cerebrospinal fluid (CSF). Transferrin (Tf), the iron mobilization protein, is found in high abundance in the CSF and the plasma. The source of the high levels of Tf in the CSF has been in question, although recently the mRNA for Tf was demonstrated in the rat choroid plexus. In this investigation, we use immunohistochemistry, *in situ* hybridization and Northern blot analysis to demonstrate the presence of Tf, ferritin, the Tf receptor, and ceruloplasmin (ferroxidase) in the adult human choroid plexus. Human choroid plexus was obtained at autopsy and prepared for either immunohistochemistry or frozen on liquid nitrogen for RNA analysis. Immunohistochemical analysis revealed the presence of Tf, ferritin, the Tf receptor, and ceruloplasmin. While immunohistochemistry does not indicate whether these proteins were synthesized locally or transported via the plasma, Northern blot analysis for all the transcripts strongly implies local synthesis. These results suggest that the choroid plexus may be sensitive to alterations in iron plasma levels and may play a role in regulating iron in the nervous system. Supported by research grant AG09063.

INHALATIONAL ANESTHETIC AGENTS DECREASE SUSCEPTIBILITY TO CORTICAL SPREADING DEPRESSION IN THE CAT. R. D. Piper, G. A. Lambert* and J. Michalick*. Inst. of Neurological Sciences, Prince Henry Hospital and University of N.S.W, Sydney, Australia 2036.

Cortical spreading depression (CSD) has not been demonstrated in the human neocortex intraoperatively during human neurosurgery. In this study we examine the effect of halothane and isoflurane, two anesthetic agents used during human neurosurgery, on the incidence of CSD after cortical pinprick with a 26 gauge needle (depth 1-2mm) in the anesthetized cat. The presence of CSD was detected by laser Doppler, DC potential or single cell recordings, and confirmed by demonstrating abolition of the cortical dilator response to arterial hypercapnia. CSD was seen in 100% of cats anesthetized with α -chloralose (N=15). CSD was induced in 3 of 7 (42%) animals anesthetized with isoflurane alone ($p < 0.005, \chi^2$ with Yates correction) and 0% (n=6) with halothane alone ($p < 0.005, \chi^2$ with Yates correction). In all animals anesthetized with either halothane or isoflurane it was possible to initiate CSD after administering α -chloralose intravenously and ceasing the inhalational anesthetic. In animals anesthetized with α -chloralose, CSD was blocked by the addition of an inhalational anesthetic on 83% of occasions (isoflurane n=3, halothane n=3). These findings suggest that inhalational anesthetic agents decrease the threshold for the initiation of CSD. This observation may be one reason why CSD has not been reported during human neurosurgery.

339.11

CORTICAL HYPOPERFUSION ASSOCIATED WITH SPREADING DEPRESSION PERSISTS IN AWAKE RATS AFTER TREATMENT WITH TIRILAZAD MESYLATE (U-74006F). R.B. Duckrow and D.C. Beard*. Department of Medicine, Division of Neurology, The Pennsylvania State University, Hershey, PA 17033.

The 21-aminosteroid antioxidant tirilazad mesylate (U-74006F) has been reported to block the delayed hypoperfusion associated with spreading cortical depression (SCD) in anesthetized rats. This suggests that oxygen radical-induced lipid peroxidation may mediate this hypoperfusion. Because the resting vascular tone is one factor which determines the cerebral blood flow (CBF) response to SCD, the effect of this drug was reassessed in awake rats. Vascular catheters were placed using halothane/nitrous oxide anesthesia. Wounds were infiltrated with procaine and swabbed with xylocaine ointment. The hip girdle was immobilized using a plaster cast and anesthesia was withdrawn. After at least one hour, SCD was induced by passing direct current through a bipolar electrode previously implanted in the left lateral frontal cortex. CBF was measured using [14 C]isopropylodiamphetamine and quantitative autoradiography. Tirilazad mesylate (1mg/kg, i.v.) was given 5 minutes before induction of SCD and CBF was measured 90 seconds later. Drug was also given 10 minutes after induction of SCD and CBF was measured 8 minutes later. In both cases, a 30% reduction in cortical CBF was measured in the wake of SCD. Oxygen radical-induced lipid peroxidation may not mediate cerebral hypoperfusion after SCD induced by focal electrical stimulation in awake rats. (Supported by PHS NS24109)

EVIDENCE FOR AN AMILORIDE-SENSITIVE COMPARTMENT IN HIPPOCAMPAL BRAIN SLICES. T.S. Whittingham^{1,2}, C.W. Lin² and J.C. LaManna^{1,2}. Depts. of Neurosurgery, Biomedical Engineering, Neurology, Neuroscience, Physiology/Biophysics, Case Western Reserve Univ. Sch. of Med., Cleveland, OH 44106.

We have previously reported the apparent alkalization of rat hippocampal slices in control artificial cerebrospinal fluid (ACSF) using Neutral Red (NR) ratio microspectrophotometry (resting pH_i = 7.52, n=50). We have extended these observations using an improved data processing mechanism to record the responses of the NR pH compartment to an acid load in the presence of amiloride analogs.

Hippocampal slices were pre-loaded with 50 μ M NR and incubated in HEPES ACSF in an interface chamber. Each slice was trans-illuminated and the absorption spectrum calculated using stored reference spectra and a Gaussian spectral dispersion program to optimize amplitude determinations at 468 and 528 nm wavelengths. The previously determined calibration curve was verified by exposing slices to nigericin and high potassium while altering ACSF pH by known increments.

The alkaline resting pH in slices may result from activation of amiloride-sensitive Na/H antiport. Consequently, slices were acid loaded by exposing them to NH₄Cl, and the time required to recover to resting pH was monitored. The presence of 0.1 mM amiloride or 10 μ M 5-Hexamethylene amiloride (Hexa) decreased the recovery slope from 0.12 to 0.8 pH unit/min, while 50 μ M Hexa completely blocked pH recovery. These results suggest that amiloride-sensitive Na/H exchange is involved in pH_i regulation in the NR-detected compartment of brain slices.

BIPHASIC CEREBROVASCULAR RESPONSE TO CORTICAL SPREADING DEPRESSION IN RABBITS. M. Shibata, C.W. Leffer* and D.W. Busija*. Dept. Physiol. and Biophys., Univ. Tennessee, Memphis, TN 38163.

Cerebrovascular response to single cortical spreading depression (CSD) was examined using a closed cranial window and intravital microscopy. CSD was induced by KCl microinjection and its propagation was monitored electrophysiologically. Prostanoid levels in cortical periarachnoid cerebrospinal fluid (CSF) were determined by radioimmunoassay. Pial arteriolar diameter increased from 76 \pm 6 to a maximum of 119 \pm 5 μ m (57%) for 1.6 \pm 0.1 min when CSD reached the cortex just beneath the vessel. Shortly after CSD expiration from the cortex, pial arteriolar diameter decreased to a minimum of 67 \pm 5 μ m (12%) for 19.5 \pm 2.1 min. CSD was elicited again in the same animal while the cortical surface under the window was continuously superfused with artificial CSF. Pial arteriolar dilation was observed again during CSD. However, no constriction of the vessel was seen after CSD expiration. Indomethacin (INDO) enhanced the CSD-induced vasodilation from the pre-INDO levels of 59 \pm 9% to the post-INDO levels of 82 \pm 13%. In contrast, the post-CSD vasoconstriction observed before INDO (11 \pm 2% for 16.6 \pm 2 min) was completely ablated after INDO. CSF levels of prostaglandin (PG) E₂, 6-keto-PGF_{1 α} and PGF_{2 α} increased during the CSD-induced vasodilation by 102%, 34% and 93%, respectively. These prostanoid levels increased further during the post-CSD vasoconstriction: PGE₂ (213%), 6-keto-PGF_{1 α} (99%), PGF_{2 α} (236%). INDO decreased the resting levels of all the prostanoids and blocked their increases during the CSD-induced vasodilation and during the post-CSD period. These results suggest that pial arteriolar dilation observed during CSD is caused by neurogenic factors, and that the post-CSD constriction of the vessel is induced by prostanoids. Intraparenchymally synthesized and diffused into CSF. (NIH Grant HL 30260 and HL 34059)

BRAIN SLICE GLUCOSE UTILIZATION (SGU) MADE SIMPLE. G. C. Newman, C. S. Pataik, F. E. Hospod and H. Qi. Depts. of Neurology and Neurological Surgery, SUNY at Stony Brook, Stony Brook, NY 11794 and Northport VAMC.

Our goal is to increase the general usefulness of the *in vitro* glucose utilization method for brain slices (SGU) by simplifying calculations and permitting flexible incubation conditions. To achieve this, we use a form of the rate equation which requires only measurement of total radioactivity in the slice and buffer after incubation of slices in tracer amounts of ¹⁴C-2-deoxyglucose (2DG). We have also generated a table of coefficients which directly yield glucose utilization values when multiplied by the ratio of radioactivity in slice to bath. The table provides coefficients for incubation times of 15 to 60 minutes, rinse times of 5 seconds to 30 minutes and buffer glucose concentrations (C_b) of 4 to 10 mM.

The table of coefficients was generated using our 8 parameter kinetic model of 2DG metabolism. Rate constants for k₄ to k₈ were derived from our published values. To obtain values of K₁, k₂ and k₃ for all C_b between 4 and 10 mM, we measured values for V_d and k₃ at C_b of 4, 7 and 10 mM for hippocampal or hypothalamic slices and analyzed the results assuming Michaelis-Menton kinetics.

To test this approach we compared apparent SGU with the experimental values and determined the error introduced by the use of the theoretical 'universal slice' constants. For both hippocampal and hypothalamic slices, the error in SGU is about 2% at 4 mM glucose and almost 10% at 10 mM glucose although aberrations in hypothalamic slices at 4 mM suggest that glucose may be limiting.

Using this method it is now possible to measure glucose utilization of brain slices from any brain region under a wide variety of incubation conditions.

INFLUENCE OF LACTATE ON K⁺ TRANSPORT IN RAT HIPPOCAMPAL SLICES. E.L. Roberts, Jr. Department of Neurology, University of Miami School of Medicine, Miami, FL 33101

In this study, the contribution of glycolysis to K⁺ transport in hippocampal slices following the elevation of extracellular K⁺ (K_o) by electrical stimulation was examined. It was hypothesized that K⁺ transport would be faster if cellular ATP demands were met by both oxidative phosphorylation and glycolysis rather than by oxidative phosphorylation alone. This hypothesis was tested in hippocampal slices from male Fischer 344 rats of age six months. Slices were first exposed for 45-60 min. to an ACSF containing 10 mM glucose. K_o was then recorded in stratum pyramidale of hippocampal subfield CA1 before, during, and after transsynaptic activation of pyramidal cells in the stratum by 40 Hz stimulus trains lasting two seconds. Intensity of stimulation was varied so that a range of values for maximum K_o during a stimulus train was obtained. The slices were next exposed for 45-60 min. to glucose-containing ACSF, or to an ACSF containing 20 mM sodium lactate and no glucose. 20 mM sodium lactate was used because it potentially provided as much substrate as 10 mM glucose for oxidative phosphorylation. Slices were again stimulated at 40 Hz, and K_o changes recorded. K_o was essentially unchanged between glucose- and lactate-containing ACSF. Decay of K_o to its original baseline following its elevation by high frequency stimulation was unaffected by time of exposure to 10 mM glucose ACSF. However, the half-life for decay of K_o to baseline in lactate-containing ACSF was approximately 60% longer than in glucose-containing ACSF. These results imply that energy demands for K⁺ transport can be met by oxidative phosphorylation during resting (unstimulated) conditions, but are best met by a combination of glycolysis and oxidative phosphorylation following high frequency stimulation. (Supported in part by NIA grant AG08710)

TEMPORAL RELATIONSHIP BETWEEN 2-DEOXY-D-[1-³H]GLUCOSE UPTAKE AND GLYCOGEN HYDROLYSIS EVOKED BY NORADRENALINE IN PRIMARY CULTURES OF MOUSE ASTROCYTES. *N. Yu**, *J.-L. Marin* and *P. J. Magistretti*. Institut de Physiologie, Faculté de Médecine, Université de Lausanne, CH-1005 Lausanne, Switzerland.

Noradrenaline (NA), like other neurotransmitters such as Vasoactive Intestinal Peptide and adenosine, promotes the hydrolysis of glycogen in cultured astroglia. Recently we have observed that NA also promotes the uptake of 2-deoxy-D-[1-³H]glucose (2-DG) in the same cell type. In the experimental conditions used (namely absence of serum and 5 mM glucose in the medium) basal 2-DG uptake by astrocytes corresponds to 3.5 ± 0.3 nmol/mg prot/min of glucose; NA increases in a concentration-dependent manner 2-DG uptake, with an EC₅₀ of 0.5 μ M and a maximal effect of 2-fold increase over basal level at 10 μ M. As a comparison, NA-stimulated glycogen hydrolysis occurs at an initial rate of 5 nmol/mg prot/min. The effect of NA is mimicked by isoproterenol and inhibited by atenolol, indicating that, like for its glycogenolytic action, NA acts on β -adrenergic receptors to promote 2-DG uptake into astrocytes. However, a time lag of \approx 5 min between NA application and stimulation of 2-DG uptake is observed; the maximal effect of NA is reached within 20 min. This is in striking contrast to the rapid glycogenolytic action of NA which reaches 50 % of its maximal value within 5 min. Furthermore, this time lag is influenced by the glycogen content of the cultures; thus, high (> 200 nmol/mg prot; normal 10-40 nmol/mg prot) glycogen further delays the effect of NA on 2-DG uptake. These results suggest that NA-induced glycogenolysis is an early event and that 2-DG uptake stimulation is revealed once glycogen stores have been depleted.

OVERINDUCTION OF GLYCOGEN RESYNTHESIS FOLLOWING GLYCOGENOLYSIS EVOKED BY VASOACTIVE INTESTINAL PEPTIDE (VIP) IN CULTURED ASTROCYTES. *O. Sorg** and *P. J. Magistretti*. Institut de Physiologie, Faculté de Médecine, Université de Lausanne, CH-1005 Lausanne, Switzerland.

We have previously shown that VIP, noradrenaline (NA) and adenosine (Ado) promote a time- and concentration-dependent hydrolysis of glycogen in primary cultures of mouse cortical astrocytes, with EC₅₀ of 3, 20 and 800 nM, respectively. The effect of VIP is mimicked by two related peptides, PHI and secretin, while that of NA is mediated by β -adrenergic receptors, since it is mimicked by isoproterenol and it is antagonized by pindolol; the effect of Ado is inhibited by theophylline. Dibutyryl cyclic AMP, forskolin, and phorbol dibutyryl ester are also glycogenolytic.

Glycogen synthesis can also be induced by appropriate treatments. Thus, the acute exposure of the cultures to insulin 1 μ M for 2 hours increases glycogen levels by 2.5-fold. Furthermore, overinduction of glycogen resynthesis is observed after exposure to glycogenolytic agents. For example, when VIP (1 μ M) is applied for 2 minutes and then removed from the medium, two time-dependent phenomena are observed: during the first 30 minutes the well-documented glycogen hydrolysis occurs; this phase is followed by a time-dependent induction of glycogen resynthesis which results, after 9 hours, in glycogen levels that are 10 times higher than those observed before VIP application.

These results are consistent with at least two possible mechanisms: (1) a "rebound" effect following exposure to a glycogenolytic agent or (2) the induction by VIP of glycogen synthase in a population of astrocytes still at an early stage of differentiation.

HUMAN COGNITION: HEMISPHERIC LATERALIZATION, GENDER DIFFERENCES

340.1

METABOLIC SUBSTRATE OF HUMAN INTEGRATIVE BEHAVIOR: EVIDENCE FROM QUANTITATIVE STEREOTACTIC PET AND MRI FOLLOWING CORPUS CALLOSOTOMY. *M.E. Lévesque*, *L. Lebas**, *E. J. Behnke**, *J. X. Zhang**, *R. Lufkin**. Division of Neurosurgery and Brain Research Institute, UCLA School of Medicine, Los Angeles, California, USA, 90024.

This study was aimed to investigate the relative contribution of subcortical structures to integrative behavior following callosotomy. Stereotactic 18-fluoro-deoxyglucose Positron Emission Tomography (PET) and Magnetic Resonance Imaging (MRI) studies were obtained before and two weeks after callosotomy in two epileptic patients. A standard battery of neuropsychological tests were also obtained followed by tachistoscopic studies. Anatomical regions of interests (ROI) were drawn based on MRI and directly transposed to the identical functional PET image using a multi-modal stereotactic image analysis system (Lévesque, M, J Neurosurg, 1990). Average metabolic activity was measured for 40 ROIs per hemisphere including 6 subcortical structures (15 ROIs) for each study. Statistical differences were found between subcortical and neocortical ROIs that could support their relative role to integrative behavior.

DEVELOPMENTAL ASPECTS OF INTERHEMISPHERIC TRANSFER OF MOTOR LEARNING. *A. J. Chicoine*^{1*}, *L. Proteau*^{2*} and *M. Lassonde*¹. ¹Lab. de Neuropsychologie Expérimentale, ²Dép. d'éducation physique, Université de Montréal, Canada, H3C 3J7.

Studies addressing the issue of ontogeny of interhemispheric communication have established a parallel between the progressive morphological maturation of the corpus callosum and the concomitant increase in functional communication between the two hemispheres. There is a general consensus that the ability to effect intermanual transfer of tactual-motor information improves gradually until the age of 11 years, at which time the myelination of the callosal commissure is presumably completed. The present work was undertaken to extend the study of the development of interhemispheric transfer to tasks involving unilateral motor learning. Three groups of right-handed subjects (6-7, 11-12 and 20-30 years of age) were required to make aiming movements from a starting position towards either the middle or the side target ipsilaterally to the hand used, while maintaining central fixation. Prior to the learning phase, a pre-test was administered to determine the baseline performance of all subjects. Once the training was completed the test was repeated. In each group, half the subjects performed the pre- and post-tests with the right hand and the intermediate acquisition phase with the left and the others followed the opposite hand sequence. The results on the acquisition phase indicated that all subjects learned the aiming task as demonstrated by a reduction in spatial errors with an increasing amount of practice trials. Comparisons between performance on pre- and post-tests indicated a significant improvement of performance with learning attributable to an increase in interhemispheric transfer. This effect, however, was observed only in the 11-12 and adult groups, the 6-7 year old children showing no improvement in aiming accuracy on the post-test. The findings of the present study concur with previous works on the development of interhemispheric transfer in normal children and extend the range of information that are gradually transferred between the hemispheres to tasks involving motor learning.

340.2

EVIDENCE FOR SOMESTHETIC MIDLINE FUSION IN AGENESIS OF THE CORPUS CALLOSUM. *A. Schiavetto**, *M. Lassonde* and *F. Lepore*. Groupe de Recherche en Neuropsychologie Expérimentale, Univ. de Montréal, Qué., Canada.

The aim of this study was to investigate the role of the corpus callosum in midline fusion, in subjects with callosal agenesis. Three agenic subjects and nine control subjects were tested using a two-point discrimination task. Thresholds were established for both index fingers, the palms, the arms, the forehead and the back. Threshold was defined as the smallest separation at which an accuracy level of at least 80% was achieved. Results showed that the acallosal subjects did not have thresholds that were significantly different from normals in any of the distal or paraxial modalities and in the head area. However, all measures in the back (axial) were significantly larger than normals whether in midline or lateral positions, in both the vertical and horizontal axes. It is suggested that although the acallosal subjects can compensate in the distal and paraxial regions of the body and the forehead, they are unable to do so on the trunk. These results can be explained by electrophysiological data obtained in cats and monkeys which show that midline receptive fields of fibers crossing the corpus callosum are quite large. The acallosals' performance reflects the disruption that results from an abnormal callosal organization. Therefore we conclude that the corpus callosum is necessary for midline fusion in somesthesia.

ELECTROPHYSIOLOGICAL MEASURES OF INTERHEMISPHERIC TRANSFER OF VISUAL INFORMATION: STUDIES IN SPLIT-BRAIN PATIENTS. *G.R. Mangun*, *S.J. Luck*, *M.S. Gazzaniga* & *S.A. Hilliard*. Dartmouth Medical School, Hanover, NH 03756 & Univ. of California, San Diego, La Jolla, CA 92193

Event-related potential (ERP) studies in healthy human subjects have identified a series of components that reflect the processing of visual information in the visual cortices. The well studied P1 and N1 components elicited by unilateral flash stimuli can be recorded from occipital electrodes located over both the contralateral and ipsilateral hemispheres. Previous research by Rugg et al. (1985) has shown that in callosal agenesis patients, the ipsilateral N1 component was absent, supporting the hypothesis that this response was mediated by callosal activation of the ipsilateral hemisphere. The present study uses a similar logic in split-brain patients to investigate the neural source(s) of the P1 and N1 components recorded from over the ipsilateral hemisphere.

Visual ERPs were recorded from 30 scalp locations in four patients that had undergone complete section of the corpus callosum for the treatment of intractable epilepsy. Stimuli consisted of small bars flashed one at a time to the four quadrants of the visual field. Brain responses to the different stimuli were plotted as CSD topographic maps in order to localize the responses to the activated hemisphere.

The lateralized flash stimuli elicited P1 and N1 peaks over the contralateral occipital cortex in the patients. In contrast to normal controls, no activity could be observed over the hemisphere ipsilateral to the stimulated visual field in the split-brain patients. These data support the idea that these early ERP components over the ipsilateral hemisphere of normal subjects reflect the callosally mediated activation of the ipsilateral hemisphere following the initial registration of the visual information in the contralateral occipital cortex. Moreover, they provide functional measures of interhemispheric transfer of visual information in the split-brain patients that can be related to MR verification of callosotomy. Supported by NINDS 2P01 NS17778-09 and NIMH 1 K21 MH00939-01.

EFFECTS OF VIOLATIONS OF A FACE SCHEMA IN THE LEFT AND RIGHT HEMISPHERES OF SPLIT-BRAIN PATIENTS AND NORMAL SUBJECTS. Dahlia W. Zaidel. Dept. of Psychology, UCLA, Los Angeles, CA 90024.

Face perception is not a unitary function. The human face is perceived or remembered by either the left or the right hemispheres of the brain, and given hemispheric specialization this suggests that the rules that make a face, a face, are different in each hemisphere. Here we studied the role that three structural parameters of the face play in face perception in each hemisphere of complete commissurotomy patients and normal subjects. These parameters are, contour frame, individual features (e.g., lips, nose), and spatial juxtaposition of these features. The hemi-field technique was used to lateralize the stimuli to the left or right visual half-field. They consisted of line-drawings of normal faces as well as of face-like arrays with systematic violations of the parameters. The task was to match an isolated facial feature (e.g., lips) with its equivalent positioned within a face or face like array. The data showed both functional symmetries and asymmetries depending on the nature of the violation or its absence, with the number of violations that could be tolerated being smaller in the right hemisphere than in the left.

340.7

TIMBRE PERCEPTION AFTER UNILATERAL TEMPORAL LOBECTOMY IN HUMAN. S. Samson & R.J. Zatorre. Montreal Neurological Inst., McGill Univ. Canada H3A 2B4.

Timbre is a psychological quality associated with spectral shape as well as onset and offset characteristics of sounds. Based on prior research, we hypothesized that the right temporal lobe should be predominantly involved in discriminating spectral cues but little is known regarding the processing of temporal cues. The ability to discriminate different timbres was tested in patients with anterior right (RT) and left (LT) temporal lobectomy as well as in normal control (NC) subjects. The timbre discrimination task was composed of pairs of complex tones in which spectral and temporal information was manipulated independently. The digitized stimuli differed either by the number of harmonics (which alters the spectral cue) or by the duration of the attack (affecting temporal cue). The results showed that RT patients were impaired as compared to LT and NC subjects in discriminating both types of information, suggesting the importance of RT auditory cortex in perceiving timbre. Possible differences in processing spectral vs temporal information will be discussed.

INTRASUBJECT CORRELATIONS OF OCCIPITAL ASYMMETRY MEASUREMENTS BASED ON CT AND MRI. C.C. Chu, H. Damasio, & D. Tranel. Division of Cognitive Neuroscience, University of Iowa College of Medicine, Iowa City, IA 52242.

In vivo occipital asymmetry (OA) measurements have been used to infer functional asymmetries (e.g., cerebral dominance), but their intrasubject reliability has not been documented. We studied correlations between CT:CT, MR:CT, and MR:MR, using OA measurements derived by the same rater from different scans of the same subject. In MR, the effect of incidence was also studied. OA was calculated by summing Z-scores of occipital width, occipital petalia, and straight sinus deviation, after we found the three measures to be relatively independent. MR:CT correlations were calculated in subjects with either 0° (n=50) or negative (minus 10 to minus 15°; n=20) MR incidence; CT:CT correlations were calculated for 25 of these subjects; and MR:MR correlations were calculated for 20 additional subjects. The highest intrasubject correlation was for MR:MR (r=.79). The CT:CT value was similar (r=.76). CT:MR correlated nearly at the same level (r=.71), but only for the zero-incidence group; the correlation was small (r=.27) for the negative-incidence group. The findings indicate that the reliability of occipital asymmetry measurements is modest at best, setting a fairly low ceiling on the extent to which this variable can be used validly to infer other indices. OA measures based on zero-incidence MR have the best reliability.

340.6

LATERALITY EFFECTS IN THE PROCESSING OF HIGH AND LOW FREQUENCY AUDITORY STIMULI. P.C. Leiby, R.B. Ivry, L.C. Robertson and A.P. Shimamura*. Department of Psychology, University of California, Berkeley, CA. 94720.

The present study investigated laterality effects in the processing of auditory stimuli. In visual perception experiments, a right hemisphere advantage has been found for processing low spatial frequencies and a left hemisphere advantage for high frequencies. The present study examined whether a similar asymmetry exists in the perception of auditory stimuli. Subjects were presented monaurally with duplex tones consisting of a high and low frequency component. On different blocks, the frequency of one of the two components was adjusted lower or higher. Subjects judged whether the target component was higher or lower in frequency. Stimuli presented to the left ear/right hemisphere were judged more accurately when the target tone was lower in frequency. In contrast, stimuli presented to the right ear/left hemisphere were judged more accurately when the target tone was higher in frequency. Additional studies using patients with right or left temporal-parietal lobe damage are being conducted.

340.8

LATERALIZATION OF FRONTAL LOBE FUNCTIONS IN HUMAN MALES. K.Podell*, E.Goldberg*, R.Harner and S.Riggio*. Med. Coll. of PA, Phila, PA 19129

Prefrontal systems (PF) are critical in guiding behavior by internal representations (set maintenance-SM), and in flexible responses to environmental contingencies (set shifting-SS). We propose that SM is lateralized to the left and SS to the right PF. We developed a novel task to measure cognitive bias along the SM-SS continuum. A geometric form is presented as a target and a choice of one out of two other forms is made. Cognitive distances between targets and choices are quantified and summed across trials. Low total score means that choices are determined by target representations (SM); high score that they are determined by external multiple choice properties (SS). The task was given to right-handed males with left (N=5) and right (N=6) PF lesions (LPFL and RPFL), and 22 matched healthy controls (H). LPFL had high, RPFL low, and H intermediate scores, confirming the hypothesis. Difference between LPFL and RPFL scores was significant (t=25, p<.001). Variances were small in LPFL (F=26.7, p=.006) and RPFL (F=49, p<.001) relative to H, indicating strong lesion effects.

340.10

CEREBRAL DOMINANCE AND GENDER EFFECTS ON NEUROPSYCHOLOGICAL TEST PERFORMANCE AFTER BRAIN INJURY. Elaine MacNiven and M. Alan J. Finlayson*. Chedoke-McMaster Hospitals, Hamilton, Ontario, Canada. L8N 3Z5

Differences in cognitive functioning associated with sex and hand preference are now well known (Springer & Deutsch, 1981). These differences are consistent from early in development (Witelson, 1987) and may relate to neuroanatomical asymmetries in the corpus callosum (de Lacoste-Utamsing & Holloway, 1982; Witelson, 1989). The corpus callosum is known to be macroscopically damaged by the acceleration-deceleration forces characteristic of Closed Head Injury (CHI), with little imbalance in focal tissue damage in either hemisphere (Adams, Mitchell, Graham & Doyle, 1977; Strich, 1956). Thus, it is reasonable to inquire whether gender and hand preference have an influence on cognitive performance and recovery following brain injury.

We studied a sample of 59 CHI patients who had received an initial post-injury assessment and who had been followed after one year. Neuropsychological tests of verbal, spatial, mathematical and reasoning ability and emotional functioning revealed a number of significant differences between sexes and hand preference groups. Furthermore, there were differences in the extent of recovery attained on follow-up. Of particular interest, there was no difference between the performance of right and left-handers on a reasoning test given shortly post-injury. However, on follow-up, the left-handed patients made significantly fewer errors, suggesting that their problem solving ability had recovered to a greater degree. These results suggest that CHI results in differential levels of deficit contingent on neuroanatomical and neurophysiological disparities related to gender and cerebral dominance.

340.11

SEX DIFFERENCES IN SPATIAL NEGLECT. B. Laeng* and C.M. Butter. Dept. of Psychology, Univ. of Michigan, Ann Arbor, MI 48108.

The greater dependence of spatially-directed attention on the right as opposed to the left cerebral hemisphere may be more characteristic of the male than the female brain. This hypothesis is suggested by Kimura's findings that the left parietal lobe of women, compared to that of men, is less committed to language and praxis. To investigate this hypothesis, we tested 22 women and 21 men with infarcts involving the right parietal lobe in a line cancellation task sensitive to unilateral spatial neglect. As predicted, left neglect was less severe in the women than in the men; this effect was not due to group differences in age, extent of lesion or other factors known to affect neglect. A smaller group of patients with unilateral lesions in either parietal lobe was tested with the Weintraub & Mesulam search test. Again, among patients with right-sided lesions, the women tended to be less impaired than the men, whereas the reverse trend - also predicted by our hypothesis - appeared in the left hemisphere patients.

340.13

SEX DIFFERENCES IN COGNITIVE FUNCTION VARY WITH THE SEASON. D. Kimura and C. Toussaint*. Dept. Psychology, Univ. Western Ont., London, Canada

In young adults there appears to be a non-linear relation between androgen levels and spatial ability, with an optimum androgen level somewhere above the female average and below the male average. Testosterone levels are also known to be higher in human males in autumn than in spring. Since cognitive patterns vary with monthly hormone fluctuations in women, this study investigated the possibility of seasonal fluctuations in men, with spatial skills expected to be better in spring.

Three types of cognitive tests were given in either the fall or the spring to groups of male and female undergraduates, well matched for age and study program: neutral tests, tests favoring females, & tests favoring males (spatial). Typical overall sex differences were found on non-neutral tests. In addition, there was a sex X season X test-type interaction, such that on the spatial composite, men in spring performed better than in fall; and men and women did not differ significantly in fall. Female-favoring tests tended to show the reverse pattern, but there was no effect on neutral tests. Cognitive pattern appears to be biologically dynamic.

340.12

TESTOSTERONE ADMINISTRATION ENHANCES SPATIAL COGNITION IN OLDER MEN. J.S. Janowsky, S.K. Oviatt, J.S. Carpenter, E.S. Orwoll. Dept. of Psychology, Univ. of Oregon, Eugene, OR 97403 and Dept. of Endocrinology, Oregon Health Sciences Univ., Portland, OR 97201.

Recent studies have shown that spatial cognition and motor speed change across the menstrual cycle in relation to changes in estrogen (Hampson and Kimura 1988). The role of testosterone (T) in higher order cognition is not clear. Therefore, in a double blind study we assessed cognition in 40 men (mean age 68.4 years) before T administration and again after three months during which half the subjects wore T and half placebo scrotal patches. Peak T levels increased by a mean of 150% of baseline in those men who wore T patches. Whereas, T administration did not effect verbal or visual memory, cognitive flexibility, or motor speed, a significant enhancement of spatial cognition was found on the Block Design subtest of the WAIS-R. These results support the possibility that spatial cognition is enhanced by hormonal masculinization of the brain and suggests that T may play a role in maintaining sexually dimorphic cognitive specializations.

340.14

TACTILE SPATIAL TASK UNMASKS PERFORMANCE DIFFERENCES DUE TO SEX AND LEARNING DISABILITIES. J. Thomas, R. Pariser*, S. Turco*, and N. Gaudin*. Dept. of Psychology, Univ. of New Orleans, New Orleans, LA 70148.

The ability of a tactile task to detect differences in spatial performance related to sex, development, or possible brain dysfunction, were studied in students classified as learning impaired (LI) or unimpaired (UI). The task used required subjects to trace a nonsense shape that was hidden from their view and then to identify a picture of the shape from an array of three pictures. The results revealed that UI males made fewer errors than UI females, while LI males made more errors than both the UI males and the UI females. The error scores of the LI males and females, however, were similar to error scores of UI females. The identification of performance differences on this task among groups of males and females with and without LI suggests that this tactile spatial task may be useful for studying how different liabilities for learning disorders develop in males and females.

LEARNING AND MEMORY—ANATOMY V

341.1

DOES A NINE SECOND INTERTRIAL INTERVAL SUPPORT LEARNING IN THE INTACT RABBIT? A.F. Nordholm, D.G. Lavond, and R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

Recently Kelly et al. (1990) reported conditioning in the decerebrate/decerebellate rabbit using a 9 sec intertrial interval (ITI) and a single training session. The purpose of the present study was to determine if conditioning using this short ITI occurs in the intact animal. Group 1 rabbits were trained according to the standard convention (i.e., no pretraining exposure to conditioning stimuli and a 30 second ITI). Group 2 received training similar to that described in the Kelly paper (i.e., 100 pretraining trials of unpaired stimuli followed by conditioning with a 9 sec ITI and a 500 Hz tone CS). Group 3 was treated identically to group 2 except that a 1000 Hz tone served as the CS. Group 4 was identical to group 3 but was given no unpaired stimulus pretraining. Our results indicated that only group 1 exhibited learning across trials ($F=4.71, p<.01$). Groups 2-4, in fact, showed no signs of conditioning. This indicated that conditioning using a nine second ITI in a single session does not occur in the intact animal.

KAINIC ACID LESIONS OF N. INTERPOSITUS ABOLISH RETENTION OF CLASSICAL CONDITIONING IN RABBITS WHEN HVI STIMULATION IS THE US. R.A. Swain, P.G. Shinkman, & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

Previous experiments have shown that cerebellar HVI stimulation elicits a variety of behavioral responses which can be reliably classically conditioned to a tone CS (Brogden & Gantt, 1937, 1942; Shinkman, Swain, & Thompson, 1989). Such responses often include eyeblink, head movement or lip extension. The present experiment was designed to study the role of n. interpositus (IP) in this effect. New Zealand White rabbits (*Oryctolagus cuniculus*) were chronically implanted with bipolar stimulating electrodes in the white matter immediately underlying left lobule HVI. Cannulae were implanted approximately 1 mm above IP in each hemisphere. Following 1 week of recovery, the animals were trained using paired tone and HVI stimulation. One session past criterion performance, the rabbits received either left IP or bilateral IP injections of kainic acid (5 nmoles) depending on the nature of the response. These lesions produced abolition of both the CR and UR that persisted for the 5 days of postlesion training. These results provide additional evidence for the critical role of IP in classical conditioning of discrete motor movements. (Supported by NSF BNS8718300, ONR N0001488K0112, & McKnight to R.F. Thompson, and by Brain and Development Res. Ctr., University of North Carolina.)

341.3

LESIONS OF CEREBELLAR CORTEX IMPAIR DISCRIMINATION DURING PAVLOVIAN CONDITIONED INHIBITION OF THE RABBIT NICTITATING MEMBRANE RESPONSE. C. G. Logan & R. F. Thompson, Neurosciences Program, USC, Los Angeles, CA 90089-2520.

The role of cerebellar cortex vs. the deep cerebellar nuclei in eyeblink conditioning has been controversial. While some (Yeo et al., 1985) have reported that lesions of lobule HVI abolish a previously conditioned response, others (Lavond et al., 1987; Lavond & Steinmetz, 1989) have found that such lesions result in partial relearning of the response and severely impair, but do not prevent, acquisition in naive animals. The present study was designed to determine whether cerebellar cortex is essential for inhibitory conditioning by using a Pavlovian conditioned inhibition paradigm.

Rabbits were first trained to a light CS, then lesioned in crus I, crus II, and HVI and retrained to the light CS. While a control group relearned the CR almost immediately, the lesioned group required as long to relearn as for initial learning. These data support the idea that cerebellar cortex is involved but not essential for simple excitatory conditioning.

Following reacquisition to light, Pavlovian conditioned inhibition training consisting of differential conditioning with light as the CS* and a tone-light compound as the CS followed. The control group showed a significant effect of CS type over the 20 days of training in contrast to the lesioned group which responded at the same levels to both CSs throughout. Difference scores and relative inhibition ratios, both averaged over the last 5 days of conditioning, showed a significant difference between groups. Three other rabbits with similar lesions were given discrimination training with light as the CS* and tone as the CS. All were able to discriminate between the 2 CSs, indicating that the failure at conditioned inhibition was not merely due to an inability to discriminate between the tone and light stimuli. Rather, a role for cerebellar cortex in inhibitory conditioning is suggested. Supported by the McKnight Foundation, ONR N00014-88-K0112 and NSF BNS-8718300 to R.F.T.

341.5

ACCESSORY ABDUCENS LESIONS PRODUCE PERFORMANCE DEFICITS WITHOUT PERMANENTLY AFFECTING CONDITIONED RESPONSES. D. Ivkovich, C.G. Logan, & R.F. Thompson, Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

Rabbits were classically conditioned with a 3 psi unconditioned stimulus (US) to the cornea, lesioned in the accessory abducens nucleus, and subsequently retrained. Reflexive eyeblinks to 4 different US intensity levels (1, 2, 3, & 4 psi) were measured over the course of training.

Lesions severely impaired all eyeblink responses initially. Conditioned responses recovered to pre-lesion levels within 3-20 days following the lesion. Extent of the lesion determined recovery time. Extensive lesions prevented full recovery of the UR up to 30 days following the lesion. These findings indicate that performance of the CR is less sensitive to direct impairment of performance than is the UR itself and, therefore, argue against the notion that cerebellar lesions selectively abolish the CR because of hypothetical effects on "performance."

341.7

Associative Eyeblink Conditioning, but not Unpaired Conditioning, Causes Morphological Changes in Purkinje Spiny Branchlets. B. Anderson, K. Relucio, C. Mohr, C. Logan, B. Knowlton, F. Davis, A. Hawkins, J. Thompson, J. Steinmetz, R. Thompson, & W. Greenough. Dept. of Psych., Univ. of Ill., Urbana, IL, *Neur. Inform. Behav. Sci., Univ. South. Calif., Los Angeles, CA, *Dept. of Psych., Indiana Univ., Bloomington, IN.

Purkinje cells exhibit nearly simultaneous CR-related physiological activity with the interpositus nucleus during eyeblink conditioning (McCormick & Thompson, 1984; Berthier & Moore, 1986). Rabbits with lesions of lobule HVI have impairments in CR rate and amplitude (Lavond & Steinmetz, 1989). Although lobule HVI may not be essential for eyeblink conditioning, the physiological activity is indicative of a memory trace.

Previous studies have shown morphological change in the cerebellar Purkinje cells following environmental enrichment and motor learning (Floeter & Greenough, 1979; Black, et al., 1990). The eyeblink paradigm is ideal to test whether morphological changes are related to learning or to neuronal activation arising from CS and US exposure. Conditioned rabbits were trained unilaterally using pontine stimulation (350 ms) as CS paired with a coterminating corneal air puff (100 ms) as US. Unpaired rabbits received the same number of stimulation and airpuff presentations, but at random intervals varying from 1 to 32 sec. The contralateral hemispheres served as the controls for both groups. The branching pattern of spiny branchlets, sites of parallel fiber input, of lobule HVI Purkinje cells were analyzed. Significantly fewer branches were seen at order 5 & 6 in the hemisphere receiving paired conditioning trials than in the contralateral untrained hemisphere. Overall, the paired hemisphere had 15% fewer spiny branches ($p < .05$). There were no differences in branch numbers between hemispheres in the unpaired animals. These results suggest that morphological plasticity in the cerebellum is strictly related to conditions that cause learning.

Effects of Cerebellar Cortical Lesions on Extinction and Reacquisition of NM Conditioning in Rabbits. C. Weiss, C.G. Logan and R. F. Thompson, Program in Neuroscience, University of Southern California, Los Angeles, CA. 90089.

Lesions of the cerebellar cortex significantly retard acquisition of nictitating membrane (NM) conditioning. The present study examines the effects of such lesions on extinction and reacquisition of conditioned responses (CRs).

Rabbits with aspiration lesions aimed at HVI (n=5) and nonlesioned, but operated, controls (n=6) were run. Following one week of recovery, daily tone-airpuff conditioning sessions (108 trials/day) were given followed by tone alone extinction and then reacquisition. Criterion for acquisition and reacquisition was set as the 2nd day of $\geq 70\%$ CRs (≥ 0.5 mm NM extension); criterion for extinction was set as the 2nd day of tone alone trials with $\leq 30\%$ CRs.

Our results confirm that the lesion retards acquisition. They also indicate that there is no effect of the lesion on sessions to criterion for extinction or reacquisition. During initial acquisition the lesioned group exhibited an initial period of low %CRs, but then learned almost as fast as controls. On reacquisition the lesioned rabbits had fewer CRs, but reached criterion in a similar number of sessions. The latency of CRs (when they occurred) was similar between groups on acquisition and reacquisition, but during extinction, the lesioned animals had longer latencies. The amplitude of the CRs was greater in the control rabbits during most of the experiment, but especially during the initial days of extinction. On reacquisition the amplitude returned to preextinction levels for the lesioned group and increased further for the control group.

These results suggest that once the CR pattern is established it can be normally extinguished and reacquired without the cerebellar cortex. Thus, extinction and reacquisition are likely to result from modification of the existing motor program rather than creation of a new motor program. These data also suggest that the delay in initial acquisition may be due to an increase in the time for phase 1 learning. Support: BNS-8718300, ONR N0001488K0112, & McKnight to R.F.T.

EFFECTS OF REVERSIBLE LESION OF RETICULAR OR FACIAL NEURONS DURING EYEBLINK CONDITIONING. A.A. Zhang & D.G. Lavond. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

The cerebellum is the most likely site for neural plasticity associated with classical eyeblink conditioning.

Alternatively, the reticular formation (Rf) neurons adjacent to the caudal portion of the pars oralis of the trigeminal sensory complex or facial motor nucleus (FMN) may be essential sites for eyeblink conditioning.

Rabbits were implanted with a probe near the Rf or FMN. The probe can be cooled at the tip by injecting Freon and heating the shaft. After 1 week recovery from surgery we cooled the probe while training 5 days for classical conditioning (108 trials per day; tone conditioned stimulus; airpuff unconditioned stimulus) and recorded eyelid EMG activity for behavioral measurement.

The animals with Rf cooling showed conditioned responses (CRs) on the second day of acquisition training. This suggests that the Rf is not an essential locus for eyeblink conditioning.

However, in the FMN group, the animals did not show any CRs during training with cooling. However, with subsequent normal training without cooling, the animals showed CRs immediately. This suggests that the FMN can not be the site of the engraving, but could be essential output for eyeblink conditioning.

A MODEL OF EYELID CONDITIONING BASED ON THE CEREBELLUM. M.D. Mauk and N.H. Donegan. Dept. of Neurobiology and Anat., Univ. of Texas Med. Sch., Houston, TX 77225 and Dept. of Psych., Yale Univ., New Haven CT 06510.

We present a model of Pavlovian conditioned motor responses (CRs) that is inspired by the extensive characterization of the synaptic organization and physiology of the cerebellum. At the brain system level the model consists of a cerebellar and brain-stem network thought to be responsible for the development and expression of CRs. At a cellular level the model specifies sites of plasticity and the rules for inducing plasticity that allow the larger network to generate a diverse range of important phenomena of Pavlovian conditioning.

Synaptic plasticity is assumed to occur in both the cerebellar cortex (granule to Purkinje synapses) and in the cerebellar nuclei (mossy fiber synapses). Plasticity in the cortex is assumed to take the form of heterosynaptic long-term depression (LTD) induced by coactivation of granule cell and climbing fiber inputs. In the nuclei plasticity is assumed to be Hebbian, with a heterosynaptic modulatory influence from Purkinje cell inhibition. Importantly, the induction and maintenance of the cortical plasticity is assumed to be influenced by the inhibition of climbing fiber inputs by cerebellar output. This feature is critical for explaining sustained asymptotic performance, extinction, blocking, and conditioned inhibition.

This model particularly emphasizes the cerebellar mechanisms that might account for inter-stimulus-interval (ISI) functions and for the timing of CRs. The proposed timing mechanism is an elaboration of previous suggestions that stimuli are discriminated on the basis of the different subsets of granule cells they activate and that Golgi cell inhibition of granule cells improves this discrimination (e.g. Marr, *J. Physiol.* 202, 1969). We extend this thinking by assuming that such mechanisms allow discrimination among temporal components of a single stimulus. Since Golgi cells are excited by mossy fibers and by granule cells, we propose Golgi feedback inhibition permits the activation of different subsets of granule cells at different times during a tonic stimulus. Thus, the subset of granule cells that is active may encode not only a particular stimulus but also a specific time during that stimulus. This, combined with the LTD-like plasticity, can provide an appropriately timed disinhibition of nuclei cells. These assumptions, plus those regarding the influence of noise on granule cell activation, allow an account for ISI functions and for the timing of conditioned responses.

NEURAL NETWORK BASED ON THE CIRCUITRY OF THE CEREBELLUM SIMULATES THE TIMING OF MOTOR RESPONSES. D.V. Buonomano and M.D. Mauk, Dept. of Neurobiology and Anat., Univ. of Texas Med. School, Houston, TX 77225.

An important aspect of motor output is its timing in relation to sensory stimuli or in relation to other components of a movement. A simple example is the learned, adaptive timing displayed by conditioned eyelid responses. An effective US can follow CS onset by 80-2000 ms, within this interval the CR will peak near US onset.

We present a neural network based on the synaptic organization of the cerebellum that generates properly timed responses after the onset of a stimulus. Contrary to previous models addressing this issue, there are no delay lines, elements with a spectrum of time constants, or periodically oscillating elements. This neural network is based on a conceptual model (see previous abstract) in which different times during a stimulus are encoded as population vectors of active granule cells.

The network consists of 10000 granule units (GrU), 900 Golgi units (GoU) and 500 mossy fiber units (MFU). Each GrU is simulated as an integrate and fire element with excitatory (from MFU) and inhibitory (from GoU) synaptic conductances, as well as a leak conductance. GoU are similarly modeled except they receive excitatory synaptic inputs from the GrUs and MFUs. A stimulus is represented by activity in a subset of the MFUs. This activity is constant and thus contains no temporal information. At the onset of a stimulus a particular subset of GrUs becomes active depending on the convergence of excitatory input from MFUs and on the activity of the population of GoUs. Since the active GrUs influence subsequent GoU activity the negative feedback between the GoU and GrU results in a dynamic population vector of active GrUs. Thus, temporal discrimination occurs because different subsets of GrUs are active at different times during a stimulus. Due to local differences in connectivity the feedback between GoUs and GrUs varies throughout the network. This provides symmetry breaking and prevents the network from oscillating. All GrUs connect to a Purkinje unit (PU), initially with identical synaptic weights. By decreasing weights of the synapses active during a US, subsequent PU activity decreases to the extent that ongoing GrU subsets are similar to the reinforced GrU subsets. This decrease in PU activity peaks at, and anticipates the target time thus mimicking the timing of a conditioned eyelid response. This model demonstrates that a network based on cerebellar circuitry can generate time specific responses by encoding time as a population vector of active GrUs.

DEEP CEREBELLAR LESIONS DO NOT AFFECT THE DEVELOPMENT OF CLASSICALLY CONDITIONED JAW MOVEMENT RESPONSES IN RABBITS. C.M. Gibbs, K.L. Watson*, A.W. Gibbs* & B.M. Hester*, VA Med. Center & Univ. of South Carolina, Columbia, SC 29201.

Repeated pairings of tone (CS) with an intraoral pulse of water (US) lead to the development of learned masticatory responses (JM CRs) in rabbits. In light of current models of somatomotor learning, we sought to assess the effects of deep cerebellar lesions upon JM conditioning.

The studies included 6 New Zealand albino rabbits with extensive bilateral lesions of either the anterolateral interpositus n. or the brachium conjunctivum; another 7 animals served as sham-operated controls. Following post-operative recovery and the imposition of a 1h/day water-access regimen, animals received appetitive conditioning (1216-Hz CS; 2-s CS/US interval), followed by extinction training. Both lesion and control animals showed rapid acquisition of robust JM CRs, as well as their extinction; data from 5 additional control animals receiving unpaired CS/US presentations confirmed the associative character of the JM CRs. In contrast, lesion animals failed to acquire eyeblink CRs during subsequent aversive conditioning (304-Hz CS; eye-shock US; 0.5-s CS/US interval). Thus, the present data suggest that the lateral cerebellum is not an essential substrate for the development/expression of JM CRs associated with deglutition, a response constellation that transcends simple reflex mechanisms. ASSOCIATIVE EYEBLINK CONDITIONING IN THE INFANT RAT. J.H. Freeman¹, M.E. Stanton^{1,2}, and R.W. Skelton³.

¹Psych. Dept., UNC-Chapel Hill, NC 27514; ²Neurotox. Div., US EPA, RTP, NC, 27711; ³Psych. Dept., Univ. of Victoria, Victoria, BC, Canada V8W 2Y2.

The eyeblink conditioning paradigm may be well suited for studying the neurobiological bases of learning during development. Here we report associative learning of the eyeblink response in developing rat pups.

Pups were trained on delay conditioning or given unpaired training at either 17 or 24 days of age. Each animal received three sessions of 100 trials that consisted of a 280 msec tone CS and a 100 msec, 2 mA periorbital shock, delivered through subcutaneous electrodes. Responses were recorded from EMG electrodes implanted in the eyelid muscles (see Skelton, 1988, *Behav Neurosci*, 102, 586-590 for details). The results showed stronger conditioning at 24 days than 17 days but, at asymptote, both ages differed from their unpaired controls.

A second experiment showed that when 17- and 24-day-old rats received 0 mA, 1 mA, 2 mA, or 3 mA US-alone trials, UR amplitudes increased with US intensity but were the same for both ages at each US intensity.

These findings suggest that auditory conditioning of the eyeblink response develops around the time of weaning in the rat and that age differences in US-processing do not account for this effect. Further work examining sensory and parametric factors is in progress.

341.10

CEREBELLAR CORTEX ABLATION DISRUPTS EXTINCTION OF CONDITIONED EYELID RESPONSES. S.P. Perrett, B.P. Ruiz*, and M.D. Mauk, Department of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77225.

An inherent difficulty in examining the role of the cerebellar cortex in classical conditioning of motor responses arises from the degeneration of climbing fibers that results from cerebellar cortex lesions. Since climbing fibers are necessary for acquisition of conditioned responses (CRs) it is difficult to determine the contribution of the cortex to acquisition once a lesion has been made. Because extinction of CRs occurs in the absence of climbing fiber input, it is possible to investigate the role of the cerebellar cortex in extinction using cortical lesions. We report that cerebellar cortex ablation disrupts extinction of the classically conditioned eyelid response in rabbits.

Following 10 daily training sessions (109 trials each) using standard eyelid conditioning procedures, rabbits receive aspiration lesions of the ipsilateral cerebellar cortex (paramedian and ansiform lobules and the anterior lobe). Animals are then subjected to 2 additional sessions employing pre-lesion training parameters to assess the effect of the lesion on CRs. Based on previous findings (Perrett et al, *Neurosci Abstr.* 115.1 1990) we define a lesion as effective when the CRs display extremely short latencies to onset and to peak. Rabbits retaining pre-lesion timing are considered controls. Rabbits are then subjected to 10 sessions of extinction training in which they receive only the conditioned stimulus. We find that effective lesions produce profound deficits in CR extinction compared to controls. While CRs are virtually extinguished by the third session in control animals, with effective lesions we observe an 80% response rate with little diminution in CR amplitude during this session. Rabbits with effective lesions retain a 50% response rate during the tenth day of extinction, though with some reduction in amplitude.

These data provide evidence that the cerebellar cortex is required for extinction of CRs and support the hypothesis that it contributes to motor learning. These data further support the notion that acquisition and extinction of CRs involve synaptic plasticity in both the cerebellar cortex and deep nuclei, and suggest that the plasticity in the nuclei requires input from and possibly plasticity in the cerebellar cortex. We hypothesize that extinction is mediated by a decrease in strength of mossy fiber/deep nuclei synapses which is driven by Purkinje cell activity resulting from an increase in strength of granule cell/Purkinje cell synapses.

341.12

CORTICAL INHIBITION IN PAVLOVIAN CONDITIONING. L. Steele Russell, Anatomy, Texas A&M University, College Station, TX 77843.

The present experiment re-examined the role of the cerebral cortex in Pavlovian conditioning. Normal rabbits were tested for visual interocular transfer (IOT) using NM conditioning to a light stimulus (CS). They were first trained monocularly to criterion. Following this they were trained with the other eye. No signs of IOT were seen in any animal. All animals had to reacquire CRs from zero. This suggests that the normal rabbit can be used as a "functionalsplit-brain" animal. Accordingly, a small group of unilateral visual cortex lesioned animals had the visual input, via the crossed optic fibres into the intact hemisphere; and the other half had the input into the damaged hemisphere. In rabbit, the visual control of the NM response is solely via the crossed fibre system. The ipsilateral projections are incapable of supporting this response due to the lack of connections with the NOT and other oculomotor control centres (Russell et al, *Exp. Brain Res.*, 1987). The results showed that learning was retarded using the eye that projected into the intact hemisphere. In contrast, the learning was superior when using the eye that projected into the damaged hemisphere. There acquisition was significantly faster either with respect to the other eye or to monocular learning in normal control animals. This finding of faster NM conditioning in the decorticate hemisphere indicates the possibility of cortical inhibitory control over brainstem oculomotor systems. This is strong evidence for an important inhibitory role for the cerebral cortex in Pavlovian conditioning. The view that the cerebral cortex plays no role in simple associative learning can be no longer sustained. The contribution of the cerebral cortex was missed because earlier experiments were looking for deficits. The possibility of any improvement due to removal of cortical inhibition was never considered.

RED NUCLEUS PROJECTIONS TO CEREBELLAR CORTEX (HVI) IN RABBIT EXAMINED WITH WGA-HRP.

M.E. Rosenfield* and J.W. Moore. Dept of Psychol, Univ of Mass, Amherst, MA 01003.

Cerebellar cortex (Larsell's HVI) has been implicated in the generation of the classically conditioned eye blink/nictitating membrane response. The motor program for the conditioned response is presumably learned by the cerebellum and relayed to motoneurons via the red nucleus (e.g., Rosenfield, M. & Moore, J., *Behav Brain Res.*, 10:393, 1983). Cat red nucleus reportedly contains neurons that project to cerebellar cortex (Dietrichs, E. & Walberg, F., *Exp Brain Res.*, 50:353, 1983). Projections from the red nucleus to HVI could be important for brain stem and cerebellar processes involved in classical conditioning (e.g., Moore, J. et al, *Biol Cyber.*, 62:17, 1989).

We implanted WGA-HRP (Sigma L3892) unilaterally into HVI in 4 albino rabbits (Mori, J., et al, *Brain Res Bull.*, 6:19, 1981). The pipette remained *in situ* for 48 hours before sacrifice. Animals were perfused transcardially (descending aorta clamped) with approximately 2 L of .9% saline followed by .5 L of 10% formalin and then 3 L of 12% sucrose solution at 4 degrees C. Brains were blocked immediately on extraction (saving only the brain stem and cerebellum), placed in 30% sucrose in .1 M phosphate buffer (pH = 7.2), and stored at 4 degrees C for 24 h. Brain stem and cerebellum were embedded in gelatin; frozen sections were cut transversely at 60 μ , mounted on subbed slides, and reacted with tetramethylbenzidine. All HVI cases (defined by histological verification of the implantation locus and the presence of retrogradely labeled cells in the pontine nuclei, spinal trigeminal nucleus par oralis, and the dorsal accessory olivary nucleus) showed sparse retrogradely labeled cells in the more caudal (3rd nerve level) portions of the red nucleus, consistent with Dietrich and Walberg's cat study. (Supported by AFOSR grant 89-0391)

341.15

DIFFERENTIAL PROJECTIONS OF PONTINE NUCLEI TO INTERPOSITUS NUCLEUS AND LOBULE HVI. J.K.**Thompson, W.J. Spangler and R.F. Thompson.** Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

In earlier work using both retrograde and anterograde labelling we reported that projections to the interpositus nucleus from the pontine nuclei were primarily from the ventrolateral region of the pontine nuclei. In the present study, we extended these observations and compared pontine projections to the interpositus nucleus and region HVI of cerebellar cortex. Fluoro-gold, Fast Blue or WGA-HRP were injected into the anterior interpositus nucleus or into cortical tissue of HVI overlying the interpositus. Interpositus injections resulted in heavy retrograde labelling in the ventrolateral region of both contra- and ipsilateral pontine nuclei. In contrast, retrograde labelling from HVI injections was more prominent in the dorsolateral regions of the pontine nuclei.

LEARNING AND MEMORY—PHARMACOLOGY: OTHER I

342.1

COCAINE ENHANCES RETENTION OF A ONE-WAY AVOIDANCE RESPONSE IN MICE. S.B. Weinberger, C.A. Riedel*, P.H. Janak, and J.L. Martinez, Jr. Department of Psychology, University of California, Berkeley, CA 94720.

Post-training administration of cocaine both facilitates acquisition of an automated shelf-jump avoidance response (Janak and Martinez, this volume) and enhances retention of a trough avoidance response (Janak et al., *Psychopharm.*, in press) in rats. In the present study we found that cocaine (10 or 30 mg/kg IP) administered to mice immediately following completion of two training trials on Day One significantly enhances performance on Day Two of a one-way trough avoidance response. Neither cocaine methiodide nor lidocaine, when administered in doses equimolar to the effective cocaine doses, altered performance on Day Two. These data indicate that cocaine's enhancement of avoidance response retention most likely is neither peripherally mediated nor attributable to its local anesthetic properties.

342.2

POSTTRAINING COCAINE OR AMPHETAMINE ENHANCES JUMP-UP ACTIVE AVOIDANCE CONDITIONING IN RATS P.H. Janak and J.L. Martinez, Jr., Dept. of Psych., Univ. of Calif., Berkeley CA 94720

The effects of cocaine (COC) and amphetamine (AMPH) on jump-up avoidance response acquisition were examined in two experiments. For 2 days rats received 1 avoidance trial, and on the third day, received 8 avoidance trials, using a 310 μ A footshock. Rats escaped or avoided shock delivery by jumping onto a raised shelf. Immediately after each training trial in the 1st experiment, rats received an IP injection of either COC or saline. COC (2.75 mg/kg) facilitated acquisition of the jump-up response as compared to saline-treated rats as indicated by a difference between the slope of the acquisition functions at test on day 3 [$p < .025$]. In a 2nd experiment, AMPH (0.3 & 1.0 mg/kg) facilitated jump-up response acquisition as indicated by an effect of treatment for each dose as compared to saline-treated rats [0.3 mg/kg: $p < .02$; 1.0 mg/kg: $p < .04$]. Thus both stimulants enhance jump-up response acquisition, although the nature of the memory effects of COC and AMPH are different. (Supported by DA06192 to JLM & DA05375 to PHJ.)

342.3

D-PEN²-[D-PEN⁶]ENKEPHALIN IMPAIRS ACQUISITION AND ENHANCES RETENTION OF A ONE-WAY AVOIDANCE RESPONSE IN RATS J.L. Martinez, Jr., R.V. Hernandez*, and S.B. Weinberger. Department of Psychology, University of California, Berkeley, CA 94720.

D-Pen²-[D-Pen⁶]enkephalin (DPDPE), a delta opioid receptor selective analog of [Leu]enkephalin, impairs acquisition of an automated shelf-jump avoidance response in rats (*Reg. Pep.* 26:323, 1989) and acquisition of a one-way active avoidance response in mice (*Behav. Neurosci.* 102:678, 1988). In the present study we found that DPDPE (1.16 μ g/kg IP) administered prior to presentation of two training trials on Day One also impairs acquisition of a one-way active avoidance response in rats tested 24 hrs later. On the other hand, DPDPE (0.332 μ g/kg IP) administered following two training trials on Day One significantly enhances performance on Day Two. These results indicate that activation of delta opioid receptors has a modulatory effect on acquisition and retention of aversively motivated learning.

(Supported by NIDA #DA04195.)

342.4

[LEU]ENKEPHALIN (LE) AND ITS METABOLITE, TYR-GLY-GLY (TGG), IMPAIR RETENTION OF AN ACTIVE AVOIDANCE RESPONSE IN MICE. G. Schulteis & J.L. Martinez, Jr. Dept. of Psychology, University of California, Berkeley, CA, 94720.

In the present study we sought to determine whether LE and TGG affect retention of an active avoidance response. Male Swiss Webster mice were given 2 training trials in which footshock (140 μ A) was delivered 10 s after placement in the dark chamber of a two-compartment avoidance apparatus; mice could terminate the footshock by escape into the lighted safe chamber. The next day, mice were given 10 additional trials in which they had 10 s to enter the safe compartment; failure to avoid within 10 s resulted in administration of footshock. In Experiment I, saline-treated mice that received 2 training trials on Day 1 made significantly more avoidances ($\bar{X}=3.85 \pm 0.44$) the following day than mice that received 0 ($\bar{X}=2.00 \pm 0.43$) or 1 ($\bar{X}=2.00 \pm 0.48$) training trial. This indicated that significant retention of the training experience had occurred in the mice receiving 2 training trials, and that pharmacological treatments could potentially modulate the degree of retention. In Experiment II, LE given just after training produced a U-shaped effect on retention; while 30 and 100 μ g/kg LE impaired retention, 10 and 300 μ g/kg were without effect. TGG likewise affected retention in a U-shaped manner, with 16 and 53 μ g/kg (but not 160 μ g/kg) impairing retention. The mechanisms of action of TGG and LE most likely differ, because TGG exhibits little opioid activity. Supported by DA04195 & DA05334.

342.5

CHARACTERIZATION OF THE EFFECTS OF DYNORPHIN A(1-13) ON PASSIVE AVOIDANCE RESPONSE IN MICE. M. Ukai, X. Shan-Wu* and T. Kameyama. Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, Meijo University, Nagoya 468, Japan.

The effects of dynorphin A(1-13), a kappa-selective opioid peptide, on the cycloheximide (CXM)- and scopolamine (SCOP) induced amnesia were investigated using step-down-type passive avoidance task. Male ddY mice weighing between 30 and 35 g were employed in the study. CXM (30.0 mg/kg, s.c.) and SCOP (1.0 mg/kg, i.p.) administered 30 min before training produced amnesia in a retention test (24 hr later) as shown by short latency to step down from the platform on grid floor. Dynorphin A(1-13) (3.0 and 10.0 mg/kg, i.p.) given 15 min before either training or retention markedly prolonged step-down latency (SDL) in mice treated with CXM, demonstrating improvements of the amnesia. The above effects of dynorphin A(1-13) were reproducible, when administered the peptide (1.0 and 3.0 μ g) intracerebroventricularly. U-50,488H (1.0 and 3.0 mg/kg, i.p.) also produced an anti-amnesic effect in mice treated with CXM. Dynorphin A(1-13) (1.0 and 3.0 μ g, i.c.v.) produced a marked prolongation of SDL in mice treated with SCOP. These results suggest that the ligands selective for kappa opioid populations possess anti-amnesic effects.

342.7

CONDITIONED EMOTIONAL RESPONSE TO MORPHINE AS A CONDITIONED STIMULUS.

N. M. Bormann* and D. A. Overton. Department of Psychology, Temple University, Philadelphia, PA 19122.

Three expts. were conducted to determine whether morphine (4 or 6 mg/kg, i.p.) can act as a conditioned stimulus (CS) when paired with a shock unconditioned stimulus (US), to produce a conditioned suppression of drinking (CR) in water deprived rats. All expts. consisted of baseline, conditioning and extinction phases. In baseline, rats were injected, with morphine or saline 15 or 25 min before a drinking test to determine baseline water consumption. Conditioning in Exps. 1 and 2 consisted of drug-shock and saline-no shock pairings with drinking tube absent. In the conditioning phase of Exp. 3, three groups of 4 rats were given a 4 min drinking test 15 min after drug injection and 0-10 minutes before shock (or no shock). One group received drug-tube-shock sessions every day, one group every third day with saline-tube-no shock on other days, and the third group every third day with drug-shock on other days. Extinction consisted of drug or saline 15 min prior to 4 min drinking tests. In Exp. 1, rats conditioned with morphine (4 mg/kg), did not suppress drinking when tested as compared with baseline. In Exp. 2, twelve rats, conditioned with morphine (6 mg/kg), drank significantly less water during testing as compared with an unconditioned control group. In Exp. 3, contrary to our hypothesis, there was no difference between groups of rats, although there was a significant difference in water consumed during baseline and extinction phases. The conditioned fear CR found in Exp. 3 was to morphine + presence of drinking tube or to drinking tube alone as CS. The CR in Exp. 2 was to the morphine CS. Supported by NIDA grant DA-02405.

VIP INDUCES THETA-LIKE CELLULAR RHYTHMS IN HIPPOCAMPAL CA1 NEURONS. Oscar Prospero-Garcia, Scott Steffensen* and Steven J. Henriksen. Dept. Neuropharmacology, Scripps Research Institute, La Jolla, CA 92037.

We have previously shown that the Vasoactive Intestinal Polypeptide (VIP) induces REM sleep and memory retention in the otherwise insomniac (PCPA pre-treated) rat. In order to more precisely evaluate VIP's cellular site of action we have iontophoretically applied VIP onto hippocampal neurons and have measured variations in spontaneous and in evoked activity of neurons located in this mnemonic structure. Studies were performed on halothane anesthetized rats. Bipolar electrodes were implanted into the perforant pathway to electrically stimulate ipsilateral dentate gyrus (DG) and a second into CA3 commissural collaterals to stimulate contralateral CA1. Multi-barrel recording/injecting electrodes were employed, with the recording pipette protruding 25 μ m further than the drug barrels. Pyramidal neurons, granule cells and putative interneurons were electrophysiologically identified. Microiontophoretic application of VIP (100-200 nA for 10 min) doubled the spontaneous rate of isolated CA1 pyramidal cells and induced a regular pattern of discharge of approximately 4 Hz, determined from peri-stimulus interval spike histograms. Evoked activity of CA1 interneurons was also enhanced by VIP iontophoresis. In the DG, granule cell spontaneous activity also slightly increased following VIP administration. On the other hand, DG putative interneuron activity was reduced by this peptide. Our data suggest that VIP may favor the appearance of a regular, theta-like rhythm in CA1 by enhancing both pyramidal and interneuron activity. Conversely, theta-like activity was not induced by VIP in the DG where VIP differentially inhibited putative interneurons.

COMBINED EFFECTS OF VAGOTOMY AND ATROPINE METHYL BROMIDE ON LEU-ENKEPHALIN-INDUCED IMPAIRMENTS IN MEMORY STORAGE PROCESSES. C. L. Williams and R. A. Jensen. Dept. of Psychology, Southern Illinois University, Carbondale, IL 62901.

These experiments investigated the role played by the vagus nerve in integrating the effects of substances which do not enter the CNS, but which alter brain functioning when administered peripherally. Four experiments were conducted to examine whether the vagus represents one pathway by which peripheral substances modulate brain mnemonic processes.

Experiment 1 determined which doses of leu-enkephalin (LE) are effective in influencing memory processes. Posttraining administration of 100.0 μ g/kg of LE impaired retention performance relative to saline-treated animals or those receiving lower doses of this peptide. In Experiment 2, atropine methyl bromide (AMB), a peripherally acting anticholinergic, was administered posttraining in an inhibitory avoidance task. These results demonstrated that AMB produces bidirectional effects on memory processes. An intermediate dose of AMB improved performance relative to rats given a higher dose that produced amnesia.

Experiment 3 determined whether blockade of vagal efferents with AMB attenuates the effects of LE. The impairment in retention produced by 100 μ g/kg of LE in Experiment 1 was not observed when this peptide was injected with either a low or a high dose of AMB. The final experiment examined whether vagotomy attenuates LE's effects on retention and assessed the combined effects of vagotomy and AMB administration on LE-induced memory impairments. Unoperated and sham-operated animals given 100.0 μ g/kg LE after training had significantly lower retention latencies than their respective controls that received saline. The retention performance of vagotomized animals receiving 100.0 μ g/kg of LE was lower but not significantly different from vagotomized rats given saline. Administration of AMB in conjunction with LE to vagotomized rats also did not result in impaired retention performance. These results suggest that vagotomy or the combination of vagotomy and AMB attenuates, but does not completely abolish the memory-impairing effects of LE.

342.8

REINFORCEMENT OF HIPPOCAMPAL CA1 BURSTING BY CANNABINOID RECEPTOR ACTIVATION. B. G. Xue* and L. Stein. Department of Pharmacology, UCI School of Medicine, Irvine, CA 92717.

Involvement of cannabinoid receptors in behavioral reinforcement has been demonstrated by self-administration of Δ^9 -tetrahydrocannabinol (THC) and THC-induced reduction of self-stimulation reward thresholds. Cannabinoid receptors are found in high density in rat hippocampus (Michelle, et al. J. Neurochem. 55, 21-26, 1990). Using a hippocampal-slice operant conditioning preparation, reinforcement of CA1 or CA3 bursting activity by extracellular applications of dopamine and opioid receptor agonists, respectively, has been described (Stein & Belluzzi, J.D. Neurosci. & Biobehav. Rev. 13, 69-80, 1989). Here we report highly reliable CA1 cellular operant conditioning with the high affinity cannabinoid agonist CP-55940 used as reinforcement. A single-barrelled glass micropipette for simultaneous recording and pressure injection was filled with CP-55940 (2.5-100 μ M in 165 mM Saline) and aimed at spontaneously active pyramidal cells in the CA1 layer. In reinforcement periods, the pressure injector was activated for 10 ms at 15 P.S.I. to deliver an approximately 10 μ -diameter droplet of drug. More than 55% of the tested neurons were successfully reinforced by burst-contingent applications of CP-55940 (at concentrations of 5 and 10 μ M, but not at 2.5 and 100 μ M). The same microinjections, administered independently of firing, did not increase bursting rate and therefore provided a control for direct pharmacological stimulation or facilitation. The results indicate that cannabinoid receptor activation can reinforce hippocampal CA1 bursting activity. Cannabinoid receptors, like dopamine and opioid receptors, may play important roles both in behavioral and cellular operant conditioning.

SEQUENCE-SPECIFIC EFFECTS OF THE NEUROTACHYKININ SUBSTANCE P ON MEMORY, REINFORCEMENT, AND NEURAL TRANSMISSION. J.P. Huston, R.U. Hasenöhrl*, P. Gerhardt*, F. Boix*, J. Fornaguera*, F. Adams*, & R.K.W. Schwarting. Inst. Physiol. Psychol., Univ. Düsseldorf, 4000 Düsseldorf, Germany.

There is now considerable evidence that substance P (SP) can have nootropic and neurotrophic effects. Thus, the study of its mechanisms may provide new insights with regard to learning, memory, and neurodegenerative disorders, such as Alzheimer's and Parkinson's disease. Our work shows that SP, when given peripherally, is memory-promoting (inhibitory avoidance) and reinforcing (place preference). In both paradigms, a dose of 50 μ g/kg has repeatedly shown to be effective. The two effects seem to be mediated by different SP sequences, as an equimolar dose of SP1-7 enhanced memory, whereas SP5-11 was reinforcing. These differential behavioral effects were paralleled by selective and site-specific changes in dopamine (DA) release, as SP or its C-terminal increased DA release in the nucleus accumbens, but not the neostriatum. The neurochemical changes lasted at least 4 hours after injection. Direct injection of SP (1ng) into the NBM was also memory-promoting and reinforcing, and again, these effects were distinctively mediated by SP1-7 and SP5-11. Furthermore, such injections differentially affected biogenic amines in the nucleus accumbens, but not the neostriatum or frontal cortex. These results are discussed with regard to the role of SP in memory and reinforcement, and its interaction with brain DA.

NONPEPTIDE ANGIOTENSIN II RECEPTOR ANTAGONIST AND ANGIOTENSIN CONVERTING ENZYME INHIBITOR: EFFECT ON A RENIN-INDUCED DEFICIT OF A PASSIVE AVOIDANCE RESPONSE IN RATS. K. F. DeNoble, V. I. DeNoble, K. R. Spencer*, A. T. Chiu*, P. C. Wong*, and P. B.M.W.M. Timmermans*. The Du Pont Merck Pharmaceutical Company, P.O. Box 80400, Wilmington, DE 19880-0400.

Nonpeptide receptor ligands with differential affinity for the angiotensin II-1 (AII-1) receptor (EXP3312, EXP3880) or the AII-2 receptor (PD123177) and an angiotensin converting enzyme (ACE) inhibitor captopril were evaluated for the ability to protect against a renin-induced performance deficit in a passive avoidance (PA) task in rats. The ability to retain a PA response was shown to decrease as the dose of intracerebroventricularly (i.c.v.) administered renin increased with maximal retention deficits occurring at 1.0 µg/5 µl i.c.v. EXP3312 (1 - 100 µg/5 µl i.c.v.) and EXP3880 (1 - 100 µg/5 µl i.c.v.) produced dose dependent increases in retention latencies when co-administered with renin. The peak effect dose (PED) for EXP3312 and EXP3880 was 3 µg and 30 µg i.c.v., respectively. In contrast, PD123177 was not effective in preventing the renin-induced decrease in retention across a broad range of doses (0.1 - 100 µg/5 µl i.c.v.). Captopril (1 - 100 µg/5 µl i.c.v.) also prevented the renin-induced performance deficit with a PED of 30 µg/5 µl i.c.v. These results suggest that renin given i.c.v. produces a deficit in performance of a PA response in rats and that this effect can be attenuated by an ACE inhibitor, AII-1 receptor ligands, but not AII-2 receptor blockers.

EFFECT OF A PURINE ANALOGUE ON MEMORY IN MICE
R.F.Ritzmann, A.Kling, A.Glasky, VAMC/UCLA Sepulveda CA 91343 Advanced Immunotherapeutics Irvine CA 92714

An animal model has been proposed for human memory loss which occurs during aging. This model is based on the observation that in a T-maze once a rat or mouse enters a goal box and consumes all the food, on the next trial it will enter the other goal box. By increasing the time between trial it can be determined if the S can remember which side of the maze it entered on the previous trial. Male Swiss Webster mice, food deprived to 80% of their free feeding weight, were tested in this model. At delays of 30 or 60 seconds a correct response occurred 75% of the time. When the delay was increased to 90 seconds the correct response rate fell to chance (46%). Since there is a considerable amount of interest in comparing immune and brain function we tested a purine analogue with immunomodulatory activity, AIT0082, in this model. AIT0082 (0.5 mg/kg) improved performance at the 90 second delay to 65% correct. At higher doses (20-60 mg/kg) AIT0082 improved performance to 80% correct. The effect of the 60mg/kg dose was observed for 7 days following a single injection. The daily injection of the drug for 18 days indicated that tolerance did not develop. The injection of atropine (0.5 mg/kg) 30 min. prior to testing blocked the memory enhancing effects. Supported by VAMC Research Service & a grant from AIT.

PHENCYCLIDINE DISRUPTS LEARNING OF SPATIAL INFORMATION WITHIN A CONTINUOUS RECOGNITION AND A "CHEESE" BOARD TASK. R. P. Kesner, M. Dakis, B. L. Bolland, Dept. of Psychology, Univ. of Utah, Salt Lake City, UT 84112.

Rats with saline, 1, 2 or 4 mg/kg PCP injections (i.p.) were trained either on a 12 arm maze using a continuous recognition memory procedure or on a "cheese" board (dry-land version of water maze). For the 12 arm maze task the rats for each daily session were allowed sequential access to 12 arms of the maze from the center platform. Of the 12 presentations, three or four of the arms were repeated, but did not contain reinforcement. Repeated arms were presented with lags ranging from 0 to 6 (from 0 to 6 different arm presentations between the first and the repeated presentation). All animals received 16 sessions. Results indicated that compared to rats with saline and 1 or 2 mg/kg PCP injections, the rats with 4 mg/kg PCP injections could not learn the task even at 0 lag. For the "cheese" board task rats were given 8 trials a day for 3 consecutive days to learn the correct location of food, starting at different spatial locations relative to the correct food location. Results indicated that rats with 4 mg/kg PCP injections were similar to rats with saline or 1 and 2 mg/kg PCP injections by displaying improved learning within a day, but different by displaying forgetting between days.

342.12

LEARNING FACILITATED BY ANGIOTENSIN CONVERTING ENZYME INHIBITOR HOE 065 INJECTED SYSTEMICALLY OR INTO THE BASAL FOREBRAIN. P. Gerhardt*, F.J. Hock ², R.U. Hasenöhrl* and J.P. Huston. Inst. Physiol. Psychology, University of Düsseldorf, 4000 Düsseldorf 1, Germany. Hoechst AG, Dept. Pharmacology, 6000 Frankfurt a.M., Germany ².

Angiotensin converting enzyme (ACE)-inhibitors can facilitate learning in rats and improve symptoms of dementia in humans. We investigated the ACE-inhibitor HOE 065, a novel compound with low antihypertensive potency, for its effects on learning after i.p.-application and injection into the NBM area in rats. Effects on habituation learning were measured in an open field by recording the number of rearings during free exploration. Like Substance P (50 µg/kg) i.p. post trial administered HOE 065 (1 and 10 mg/kg) reduced the number of rearings during the next trial compared to controls, indicative of enhanced habituation learning. Effects of injection of HOE 065 or SP into the NBM were investigated on inhibitory avoidance learning, which involves punishment of a high-probability turning response on a tilted platform. Immediately after the learning trial, i.e. after a shock administered upon performing the response, the given substance was injected. Rats treated with HOE 065 (50 and 500 ng) or SP (1 ng) had longer uphill latencies during retest than controls, indicative of superior learning. Thus, HOE 065 improved learning after peripheral and central injection.

N6-CYCLOPENTYLADEOSINE IMPAIRS INHIBITORY AVOIDANCE RETENTION BY SELECTIVE ACTION AT A1 RECEPTORS.

H.J. Normile¹, N. Jadallah*, G. Johnson* and R.A. Barraco. Departments of Psychiatry¹ and Physiology, Wayne State Univ. Sch. of Med., Detroit, MI 48207.

The effects of N6-cyclopentyladenosine (CPA), a highly selective agonist for adenosine A1 receptors, on retention of a one-trial inhibitory avoidance response was examined in mice. Water-deprived mice were trained to avoid drinking by pairing foot-shock with licks from a water spout. Retention was measured as the suppression of drinking (latency to drink) 48 hr following training. Administration of CPA (0.15-2.25 µmols/kg) 30 min before training produced a dose-dependent impairment in retention of the original avoidance response. The CPA-elicited deficits in retention performance were blocked by pretreatment with 8-cyclopentyl-1,3-dipropylxanthine (DPCPX), a selective A1 receptor antagonist; DPCPX (15 µmols/kg) administration alone had no effect on retention. These findings suggest that selective activation of a presumably central population of A1 receptors may impair retention performance and influence information processing. 342.16

EFFECT OF THE ANESTHETIC AGENT DIPRIVAN (PROPOFOL) ON MEMORY PROCESSING IN MICE.

E. Rosman, R. Pang, D. Quartermain & H. Turndorf Anesthesiology & Neurology NYU Medical Center

Amnesic effects of the i.v. hypnotic agent Diprivan were studied in a single trial passive avoidance task. Mice were injected with propofol (PROP 50 & 100 mg/kg i.p.) 10 min before, or immediately after the training trial. Memory was impaired when the drug was administered before learning but not when injected after training. In a second experiment a dose response curve was demonstrated (PROP 5, 25, 50 & 75 mg/kg) with progressive impairment of retention as the concentration increased, and significant anterograde amnesia at 50 mg/kg. To determine if the anterograde amnesia resulted from state dependency, 2 groups of mice n=24 were injected with vehicle or 50 mg/kg PROP before training. Before testing each group was further divided n=12 and reinjected with either PROP or vehicle. Result showed that both the PROP-vehicle as well the PROP-PROP groups demonstrated robust memory impairment indicating that amnesia was not due to state dependent learning.

Kynurenic Acid Attenuates Cognitive and Memory Impairments Induced By An Environmental Neuroexcitotoxin. B.F. Petrie (1), C. Pinsky (2), N. Standish (1), R. Bose (2), and G. Glavin (2). (1) Department of Psychology, Red Deer College Red Deer, Alberta, Canada, T4N 5H5; (2) Department of Pharmacology, University of Manitoba, Winnipeg, Manitoba, Canada, R3E 0W3.

The present study is the first to examine the effect of parenteral injection of the neuroexcitotoxin domoic acid and the broad-spectrum neuroexcitotoxin antagonist kynurenic acid, on a memory task in mice. Domoic acid impaired performance on a previously learned place task in the Morris water maze, while kynurenic acid, administered subsequent to domoic acid, prevented an initial decline in performance. The results have implications for the mammalian neuroanatomic correlates of this spatial memory behavior, and suggest that the domoic acid-treated mouse is an appropriate animal model with which to study the functional deficits associated with neurodegenerative disorders, including senile dementia of the Alzheimer's type.

THE EFFECTS OF ALTERING BRAIN PROTEIN KINASE C ON PERFORMANCE IN THE MORRIS WATER TASK (MWT). R.Paylor, S.K. Morrison, J.W. Rudy, L. Waltrip, and J.M. Wehner. Institute for Behavioral Genetics, and Department of Psychology, University of Colorado, Boulder, 80309.

Protein Kinase C (PKC) has been implicated in learning and memory processes in *Aplysia*, *Hermisenda*, and rodents. More specifically, evidence has led researchers to speculate that hippocampal PKC contributes to spatial learning and memory. This project used two approaches to test the hypothesis that brain PKC contributes to performance in a spatial learning and memory task.

If PKC is involved, then manipulations of its activity should affect performance in a spatial-learning-dependent task. Phorbol esters are known to activate PKC. Therefore, in the first study the effects of the phorbol ester, PDBu, was tested on spatial learning in adult Long-Evans rats using the hidden-platform version of the MWT. Fifteen min after an ICV injection (10ng), PDBu-treated rats were better than controls at learning the position of the platform as measured by latency to escape scores. Twenty-four hours after the last trial PDBu-treated rats showed signs of having remembered the location of the platform better than controls as measured by heading error, latency to cross the place where the platform had been located, and platform-crossing score.

In the second study, rats were reared in either a complex environment or a normal lab environment for either 6 or 12 days starting when they were 15 days old. PKC was measured in cytosolic and particulate fractions. Rearing in the complex environment for 6 days had no effect on hippocampal PKC, however, after 12 days there was an increase in hippocampal cytosolic PKC. Preliminary results suggest that the performance in the MWT was improved in rats reared in the complex environment.

These results support the notion that brain PKC is involved in performance in the Morris water task. (Supported by NSF-BNS 8820076 to J.M.W.)

CALCIUM AND CALMODULIN ANTAGONISTS DISRUPT INTERMEDIATE-TERM MEMORY FORMATION (ITM) IN THE 2-DAY OLD CHICK. P.A. Serrano, D.R. Smith*, E.L. Bennett and M.R. Rosenzweig. Department of Psychology, Univ. of California, Berkeley, CA 94720

The one-trial peck-avoidance paradigm for the 2-day old chick has been extensively used to investigate neural mechanisms of memory formation (Gibbs & Ng, 1977; Patterson et al., 1986; Ali et al., 1988; Serrano, 1990).

Protein kinase C activity has been suggested as an important neural mechanism for long-term memory (Burchuladze et al., 1990; Lovinger et al., 1987; Serrano et al., 1990). We have investigated other protein kinase (PK) inhibitors for their role in memory formation: three calmodulin inhibitors, N-(6-aminohexyl)-5-chloro-2-naphthalenesulfonamide (NACN), W-7 and W-13, an intracellular calcium inhibitor, HA-1004, and two non-specific PK inhibitors, A-3 and ML-9. HA-1004, NACN, A-3 and ML-9 produced significant amnesia at a 24 hr test ($p < .01$). HA-1004 and NACN produced significant amnesia by 30 min post-training and at subsequent test times ($p < .01$). The time courses for A-3 and ML-9 are being determined. These time courses show ITM is disrupted, further implicating calcium and calmodulin as neural mechanisms for ITM formation. (NSF grant BNS-88-10528).

CLASSICAL CONDITIONING AND PROTEIN KINASE C IN YOUNG AND OLD RABBITS TREATED WITH BMY 21502. M.H. Kreps¹, D.K. Sasse¹, J.M. Coffin¹, S.L. Moon², & D.S. Woodruff-Pak¹. Department of Psychology¹, Temple University, Philadelphia, PA 19122 and CNS Neuropharmacology², Bristol-Myers Squibb Co., Wallingford, CT 06492.

BMY 21502, a substituted pyrrolidinone, was injected in young (Y) and older (O) rabbits to see if eyeblink classical conditioning could be facilitated. A 750 msec CS-US interval in the delay paradigm was used (850 msec, 1 KHz, 85 dB tone CS followed 750 msec after its onset by a 100 msec, 3 psi, corneal airpuff US) in 10 daily acquisition sessions with 90 paired or 180 unpaired trials. Fifty-four male and female rabbits were used (30 3-month; 24 30 to 48-month retired breeders). There were 4 conditions for both age groups of rabbits: Paired tone and airpuff presentations with (1) vehicle only; (2) BMY 21502, 5 mg/kg; (3) BMY 21502, 10 mg/kg; (4) unpaired tone and airpuff presentations with BMY 21502, 5 mg/kg. BMY 21502 enhanced conditioning at both dosage levels in O but not Y rabbits. There were large age differences in conditioning in vehicle-treated animals, but O rabbits with BMY 21502 learned as well as Y rabbits. Preliminary analyses indicate that ³H-PDBU binding redistributes within the layers of the hippocampus with age. In O animals the densest ³H-PDBU binding in hippocampus is in the pyramidal layer.

EDUCATION RELATED CHANGES AND INDIVIDUAL VARIABILITY IN WERNICKE'S AREA: A QUANTITATIVE DENDRITIC ANALYSIS. B. Jacobs and A. B. Scheibel. Brain Res. Inst., UCLA, Los Angeles, CA 90024.

This investigation, which is part of a more comprehensive multivariate project, examined the relationship between the basilar dendrites of supragranular pyramidal cells in Wernicke's area of both hemispheres and environmental variables, specifically education and general personal factors. Tissue was obtained from 10 male ($M_{age} = 52.2$; $range = 18-78$; $SD = 17.42$) and 10 female ($M_{age} = 47.8$ years; $range = 20-79$; $SD = 20.47$) subjects. All subjects were determined to be neurologically normal right-handers. Using a modified rapid Golgi technique, 10 pyramidal cells were sampled from each hemisphere (total cells = 400 cells; total segments = 16,697). The dendritic systems were evaluated according to total dendritic length (TDL), mean dendritic length (MDL), and dendritic segment count (DSC). A distinction was also made between proximal (1st, 2nd, and 3rd order) and the ontogenetically later developing distal (4th order and above) dendritic branches.

Considerable interindividual variation in dendritic systems appeared to reflect general sociocultural and/or personal experiences. Females characterized as being more active socially or occupationally tended to have greater TDL values. Males with jobs requiring manual labor tended to have TDL values below average. Education had a consistent and substantial effect such that dendritic measures tended to increase as one ascended the educational scale. Individuals with a university education typically had the highest dendritic values (TDL = 55,057 μm); those with a high school education were characterized by somewhat lower values (TDL = 51,695 μm); and individuals with less than a high school education had the lowest dendritic values (TDL = 43,397 μm). These neurohistological consequences were registered primarily in distal order segments, supporting their reported epigenetic sensitivity (Carughi et al., *J. of Nutrition*, 119: 2005-2016, 1989).

343.2

INCREASE IN THE NUMBER OF AXOSPINOUS SYNAPSES WITH SEGMENTED POSTSYNAPTIC DENSITIES AFTER THE INDUCTION OF LONG-TERM POTENTIATION (LTP). Y. Geinisman, L. deToledo-Morrell and E. Morrell. Dept. of CMS Biol., Northwestern Univ. Med. Sch. and Depts. of Neurol. Sci. and Psychol., Rush Med. Coll., Chicago, IL 60611.

Sustained enhancement of synaptic efficacy, which is characteristic of LTP, may be supported by an increase in synaptic numbers. Although no such change was detected in our previous study of synaptic contacts on dendritic shafts and spines, the ratio of perforated (with a discontinuous postsynaptic density, PSD) to nonperforated (with a continuous PSD) axospinous synapses was found to increase after LTP induction (Geinisman et al., *Soc. Neurosci. Abstr.*, 1990, 16: 979). The aim of the present study was to determine if this structural alteration reflects an increment in a certain subtype of perforated synapses. Young adult rats were implanted with stimulating electrodes in the medial perforant path and recording electrodes in the hilus of the ipsilateral dentate gyrus. Potentiated animals ($n = 7$) were stimulated (with fifteen 20 ms bursts of 400 Hz delivered at 0.2 Hz) on each of 4 consecutive days and sacrificed 1 h after the fourth stimulation. Unpotentiated but stimulated and unstimulated but implanted rats served as controls ($n = 7$ in each). Synapses were examined in the middle (MML) and inner (IML) molecular layer of the dentate gyrus. Using the disector technique, estimates of the number of synapses per neuron were differentially obtained for perforated axospinous junctions distinguished by a fenestrated, horseshoe-shaped or segmented PSD. The results showed that the number of synapses with segmented PSDs was markedly and significantly increased in the MML, but not in the IML, of potentiated rats relative to controls. This highly selective modification of connectivity, which involves only one particular subtype of synapses in the potentiated synaptic field, may represent a structural substrate of the enduring augmentation of synaptic efficacy typical of LTP.

Supported by Grants AG 08794 from NIA and BNS-8819902 from NSF.

343.3

KINDLING-INDUCED INCREASE IN THE NUMBER OF AXOSPINOUS SYNAPSES WITH SEGMENTED POSTSYNAPTIC DENSITIES. E. Morrell, Y. Geinisman and L. de Toledo-Morrell. Depts. of Neurol. Sci. and Psychol., Rush Med. Coll. and Dept. of CMS Biol., Northwestern Univ. Med. Sch., Chicago, IL 60612.

Kindling, which is evoked by repeated, low-level electrical stimulation of a focal brain area, is characterized by a virtually permanent augmentation of synaptic responsiveness in the stimulated circuit. Although this enduring synaptic plasticity may be due to an increase in synaptic contacts, our previous work failed to demonstrate such a change in the absolute number of axodendritic, axospinous perforated (with a discontinuous postsynaptic density, PSD) or nonperforated (with a continuous PSD) synapses; however, the relative proportion of perforated synaptic junctions was increased (Geinisman et al., *Brain Res.*, 1990, 507: 325). Perforated synapses can be further subdivided into those having a fenestrated, horseshoe-shaped and segmented PSD. These synaptic subtypes were differentially quantified in the present study. Rats were kindled via medial perforant path stimulation (1 msec pulses at 60 Hz for 2 sec at a current level that initially induced an afterdischarge of 10 sec or less) and examined morphologically 4 weeks after reaching a criterion of 5 generalized seizures. The number of synapses per neuron was estimated both in the middle (MML) and inner molecular layer of the dentate gyrus with the disector technique. Results indicate that kindling is indeed associated with an increase in synaptic numbers relative to controls. This change is highly selective: it involves only those perforated axospinous synapses which exhibit a segmented PSD and it is restricted to the directly stimulated synaptic field (MML). Since synapses distinguished by a segmented PSD may represent specialized contacts of an unusually high efficacy, a selective increase in their numbers may provide a structural substrate of synaptic plasticity associated with kindling.

Supported by Grants AG 08794 from NIA and BNS-8819902 from NSF.

343.5

ANATOMICAL BASIS OF RECOVERY OF SPATIAL LEARNING AFTER NEONATAL PREFRONTAL LESIONS IN RATS. B. Kolb, R. Gibb* and D. Muirhead*. Dept. of Psychology, Univ. of Lethbridge, Lethbridge, Canada, T1K 3M4.

Rats given medial prefrontal lesions on postnatal day 1 (FR1) or 10 (FR10) were trained on the Morris water task on postnatal days 19-21 or days 56-58. The animals then were sacrificed and stained with Golgi-Cox. Analysis of dendritic arborization and spine density was carried out in parietal layer II/III pyramidal cells. The results showed that the operated groups were equally impaired at the water task at 19-21 days but that the FR10 rats had recovered by 56 days. Dendritic results showed no group differences at day 22 but significant differences at day 60. The FR1 animals had less dendritic branching than the control rats whereas the FR10 rats had more than both other groups. Furthermore, there was a marked left/right asymmetry in dendritic branching, favouring the left, at Day 22 but not at Day 60. The results show (1) behavioural and anatomical outcome varies with precise age after early lesions, (2) that there is recovery rather than sparing of spatial learning after prefrontal lesions at 10 days, and (3) that the anatomical basis of the behavioural differences may be increased dendritic arbor, which develops between 22 and 60 days of age.

343.7

TACTILE COMPENSATION OF THE EFFECTS OF VISUAL DEPRIVATION IN THE CAT. P. Henning and J.P. Rauschecker. NIH Animal Center, NIMH, Poolesville, MD 20837, U.S.A. and Max Planck Institute for Biological Cybernetics, Tübingen, Germany.

Visual deprivation from birth leads to a remarkable improvement of auditory capacities in cats, which can be demonstrated on the physiological, anatomical, and behavioral level. We have also observed an excessive growth of the facial vibrissae in visually deprived cats. The present study tried to address the question whether these longer whiskers actually have any behavioral advantage and whether somatosensory compensation of early blindness can indeed be demonstrated.

Cats lid sutured from birth for several years were trained to find their way through a longitudinal maze. Normal adult cats acted as controls and were tested in the light and in darkness with the aid of an infrared camera system. The maze consisted of 10 small gates in 5 different, variable positions. Electrical contacts signalled when the animals passed through each gate, so running times could be measured very precisely. After an initial training period, cats were given at least 8 test blocks (3 trials each) to determine their performance in the maze task. In the light, the normal control group naturally performed somewhat faster than the blind animals, which had to "feel" their way through the maze, but the difference was not very large. In total darkness the normal cats lost their advantage completely, and the blind animals actually outperformed the normal ones.

It can be stated with certainty, therefore, that cats without visual experience can acquire knowledge about spatial relationships and can be trained to solve a spatial learning task. While vision obviously helps to solve such a task, the blind animals, when put in a comparable situation with sighted ones, perform at least as well if not better in such a spatial task. Since auditory cues cannot play a major role for this and odor cues were ruled out, we conclude that the somatosensory system, and in particular the vibrissae system, helps these blind animals to build a spatial representation, which is used for spatial orientation. Fundamental mechanisms of neural plasticity are assumed to form the basis for these behavioral adaptations.

343.4

INCREASE IN DENTATE GRANULE CELL SOMATIC SYNAPSES FOLLOWING RECURRENT LIMBIC SEIZURES IN RATS. M.C. Bundman and C.M. Gall. Depts. of Pharmacology and Anatomy & Neurobiology, Univ. of Calif., Irvine, CA 92717.

We have previously shown that hilus lesion-induced, recurrent limbic seizure activity leads to a robust elaboration of somatic spines on hippocampal dentate granule cells. The spines are evident 3 hrs following the start of seizure activity and persist in significant numbers for at least one month. Many of the spines receive fully developed synapses consisting of vesicle filled terminals, asymmetric membrane specializations and PSDs. The aim of the present study was to determine whether somatic spines form at the site of pre-existing synapses or whether the somatic spine synapses represent new synapses. Seven rats received hilus lesions (HL) and were sacrificed 5 hrs postlesion along with 7 anesthetic controls (CON). Hippocampal dentate gyrus, contralateral to the lesion, was prepared for electron microscopy and high power (27,000x print magnification) montages of 9 granule cells from each animal were analyzed. There was a 6-fold increase in somatic spines with HL and approximately 30% of the spines contained synapses in the single plane of section examined. The number of synapses directly on the soma did not differ in the HL and the CON rats; however, there was a 31% increase in the total number of granule cell somatic synapses (spine synapses-synapses directly on the soma) in the HL rats. These data suggest that the newly elaborated spines do not form at sites of pre-existing synapses but, rather, that the somatic spine synapses are new synapses and thus, represent a dramatic demonstration of activity dependant synaptogenesis. The increased somatic synapses may contribute to a change in the state of granule cell excitability following heightened physiological activity. Work is now in progress to determine the source of the afferents to the newly elaborated spine synapses. This work was supported by NIMH fellowship MH09868 to MCB and NINCDS grant NS26748 to CMG.

343.6

PLASTICITY IN AUDITORY CORTEX. P. Maldonado*, G. Gerstein and J. Altman*, Dept. of Physiology, Univ. of Pennsylvania, Philadelphia PA 19104

Changes in cortical somatosensory map structure have been observed after weak, pulsatile electrical stimulation of supragranular layers (Recanzone et al. *Soc. Neurosci. Abs.* 14:223, 1988). We report a similar experiment with rat auditory cortex using separable multi-neuron recording technology and analyses. Rats were anesthetized with Ketamine-Xylazine. Glued arrays of standard Tungsten electrodes (Microprobe, Parylene, 1.5Mohm) were inserted into auditory cortex. Stimuli were free field 50ms tone bursts over the range of 4-40kHz, intensity 40 dB above threshold, presented through one of two loudspeakers at +/- 60 degrees, in random sequence of frequency and direction. For frequency scans tone bursts occurred every 200ms; for study of "afterdischarges" they came every 2 sec. After auditory characterization of the neurons was completed, electrical stimuli (13 0.5ms pulses of 5ua, spaced 5ms, train repeated every 0.5sec) was given for one hour through one of the microelectrodes; characterization partly repeated; another hour of electrical stimulation given; and a final series of full auditory characterizations alternating with periods of spontaneous activity. PST histograms arranged into response planes; response areas were obtained by integrating these over a selected time window. Autocorrelations quantified periodicities in afterdischarges; cross-correlations and Joint PSTH characterized neuronal interactions and their temporal modulations.

About one half the neurons showed changes in response area after electrical stimulation. In some cases the peak moved to the frequency preferred at the stimulating electrode, in direct analogy to the somatosensory remapping reports. In other cases response area of neurons at stimulated and unstimulated electrodes moved to some intermediate frequency. After electrical stimulation most neurons that were studied for afterdischarge showed changes of its strength and/or of silent period following the direct tone burst response. Changes of correlation in the afterburst (JPST) were observed. These data examine changing neuronal organization underlying a rapidly changing cortical map. NIH MH46428.

COMPENSATORY CHANGES IN THE MOUSE VIBRISSE/BARREL SYSTEM AFTER EARLY BINOCULAR ENUCLEATION. LP. Rauschecker, B. Tian and M. Korte*. (SPON: European Brain and Behaviour Society). NIH Animal Center, NIMH, Poolesville, MD 20837, U.S.A. and Max Planck Institute for Biological Cybernetics, Tübingen, Germany.

Visual deprivation from birth in cats leads to compensatory changes in other sensory modalities. This can be demonstrated on the physiological, anatomical and behavioral level. Besides pronounced compensatory plasticity in the auditory system, we have also shown that visually deprived cats have on average longer whiskers than normal cats. With a switch in species, we were also able to demonstrate that the anatomically distinct barrels representing the mystacial vibrissae in the somatosensory cortex are enlarged in mice enucleated after birth as compared to normal littermates (Rauschecker, Krüger & Tian, 1990).

This finding, which we originally described with the cytochromoxidase technique, was followed up with Nissl staining and with GAD immunohistochemistry. We found that those barrels which correspond to the longest whiskers are the ones which expand most after visual deprivation. This fits in well with the finding that the longest whiskers are the ones which grow most in visually deprived cats.

In order to establish the missing link between the two species, we also measured whisker lengths and diameters in our binocularly enucleated mice. It turned out that both lengths and diameters are enlarged as compared to normal littermates, and this enlargement is very highly significant ($p < 0.0001$). What is more, the most significant relative growth occurred again in the positions with the longest vibrissae.

THE CORTICAL METABOLIC AND BEHAVIORAL EFFECTS OF TRAINING A SPARED RAT VIBRISSE. C.L. Hand, D. Noaker, R.L. Craik, K.M. Gallo, and W.J. Carr, Idaho State U., Pocatello, ID 83209; Beaver College, Glenside, PA 19038; and U. of Pennsylvania, Phila., PA 19104.

The first somatosensory (SI) cortical metabolic effects and behavioral consequences of associatively-paired (AP) and disassociatively-paired (DAP) training of a spared vibrissa was examined in 28 rats. Subtotal vibrissa deafferentation involved bilateral sparing of C3 vibrissa (SC3) before postnatal day 3. AP (classically pairing vibrissa stroking with 10% sugar water administration) or DAP (unpaired vibrissa stroking and 10% sugar water administration) training of left or right SC3 was continued at 5 min/day for 60 days; controls were handled an equivalent time. Behavioral testing involving 5 days of 4 minute trials in a darkened environment and using a raised, circular maze indicated that AP rats preferred to use the AP/SC3-trained vibrissa. In contrast, no preference was noted in the DAP/SC3-trained or control rats. Subsequently, the quantitative (14C)-2DG technique revealed, in the same rats and as compared to controls, a significant increase ($35 \pm 14\%$) and decrease ($37 \pm 11\%$) in the AP/SC3 and DAP/SC3 SI cortical representations, respectively. In conclusion, these results suggest that: (1) training a peripheral receptor organ affected somatosensory related locomotor behavior in the rat and (2) "meaningful" intervention alters the extent of a peripheral lesion-induced functional cortical reorganization that has predictable behavioral consequences. RECOVERY PROCESS OF HINDLIMB LOCOMOTION FOLLOWING BILATERAL DOUBLE HEMISECTION OF THE SPINAL CORD IN THE RAT. J. H. Kim, W. H. Lee*, A. Chen*, The Miami Project To Cure Paralysis, Dept. of Neurol. Surg., Univ. of Miami, Miami, FL 33136

Adult cats with serial double-hemisectioned spinal cords recovered the ability to stand and walk without any special training if the lesions were temporally separated by more than 8 days. In this preparation, neurons in the lumbosacral spinal cord receive no direct descending input from supraspinal motor centers. Therefore, it appears that the injured spinal cord is being reorganized to compensate for the lost descending input after the initial hemisection, and that the altered cord maintains the ability to generate locomotion following the second hemisection. The goals of the present study were: (1) to investigate recovery of locomotion in adult rats following double hemisection of the spinal cord, (2) to characterize the restored locomotion, and (3) to find the specific descending input required for reorganization of the injured spinal cord. Adult Sprague-Dawley female rats (225-250 g) were used in this study. Under sterile conditions, double hemisection of spinal cord was made at C4 and T6 using a No. 11 blade. The two hemisections were separated by 2-3 weeks. Following the hemisections, animals were tested for return of normal muscle tone, response to painful stimuli, and treadmill locomotion. After the first hemisection at C4 the animals lost temporarily ipsilateral muscle tone and withdrawal reflex. These animals regained reflex activity, and finally within two weeks recovered the ability to locomote. Following the second hemisection (T6 level), muscle tone of the hindlimb was restored within a few hours and spontaneous locomotion was observed within 48 hours. Recovery was gradual but within 2-3 weeks the prelesion speed of locomotion was obtained. Coordination between fore- and hindlimbs was permanently disturbed. NEW FORMS OF NEUROMUSCULAR PLASTICITY IN ADULT AND OLD MICE REVEALED BY EM SERIAL SECTIONING.

S. Nakashiro and N. Robbins, Dept. of Neurosciences, Case Western Reserve Univ., Cleveland, OH 44118.

In adult and especially in old mice, motor nerve terminals show ongoing outgrowth, retraction, constriction and expansion, but at any moment these events involve only a few percent of the nerve terminal area (*J. Neurocytol* 20:165, 1991; *Neurosci. Abstr.* 20:1162, 1990). Therefore, semiserial sectioning and correlated fluorescence microscopy were used in order to select and characterize the ultrastructural cellular events at these focal sites of neuromuscular plasticity. Three new findings emerged from this work: (1) Especially in old mouse neuromuscular junction (NMJ), nerve terminals showed frequent focal transitions from synaptic to axonal structure. The axonal regions were characterized by infrequent synaptic vesicles and absence of active zones, but there was no Schwann cell engulfment, and only occasional secondary folds. (2) At focal nerve terminal constrictions, the terminal was encircled by the Schwann cell and isolated from underlying secondary folds, probably indicating a prior state of synaptic differentiation before Schwann cell engulfment. Findings (1) and (2) together with previous *in vivo* data indicate that nerve terminals undergo constant and focal synaptic differentiation and dedifferentiation, affecting post-synaptic structure as well as the relation of nerve terminal to Schwann cell. (3) Satellite cells at NMJs were associated with myelin figures (in one case, clearly derived from muscle membrane) indicating that these cells may play a role in remodelling of post-synaptic membrane. Supported by NIA grants AG08886 and AG06641.

IMMEDIATE REORGANIZATION IN SI FOLLOWING SPINAL CORD HEMISECTION AT T12 IN SIX WEEK OLD KITTENS. M. B. Calford, L. A. Krubitzer, R. Tweedale, T. C. T. Yin* Vision, Touch and Hearing Research Centre, University of Queensland, Queensland, Australia 4072, *Univ. Wisconsin, Madison

Changes in the cortical organization of the primary somatosensory area, SI, were investigated in kittens, six weeks of age, after hemisection of the contralateral spinal cord at T12. Microelectrodes designed to record from single units and neural clusters, were used to examine responses in SI. Seventy eight to ninety four recording sites, approximately 250-500 μ m apart, were made in SI in each kitten, before and after hemisection, to obtain dense maps of the hindlimb, trunk and forelimb representations. In addition, selected portions of the representations were restudied in the intact animal to confirm that the degree of error in remapping was small. Immediately after to 4 hours after the hemisection, SI was remapped in detail. During the remapping, we endeavoured to place the electrode in the same location as electrode tracks made before the transection. Our results showed that neurons, previously responsive to stimulation of the hindlimb, either became unresponsive to somatic stimulation of any body part, or became responsive to stimulation of the trunk, or sometimes the forelimb. Thus, there was expansion of the trunk representation into cortex that was previously occupied by the hindlimb representation. In addition, there was a lateral shift in the boundary of the trunk representation into regions that previously were responsive only to proximal forelimb stimulation. When neurons in the representation of the forepaw were remapped, receptive fields were nearly identical to those defined before the hemisection. Within the expanded trunk representation there was a rough topography with middle portions of the trunk, adjacent to the deafferented lower trunk, being represented most medially, and the upper trunk was represented laterally, adjacent to the representation of the forelimb. There was a large expansion of the middle trunk representation.

EVIDENCE OF ALTERED RAT NEUROMUSCULAR JUNCTION AFTER CHRONIC CORTICOSTERONE TREATMENT. Mohamed A. Fahim, Faculty of Medicine, UAE University, Al Ain, United Arab Emirates.

Chronic exposure to glucocorticoids affects both structure and function of vertebrate skeletal muscles. As less is known about the effects of such steroids on the neuromuscular junctions (NMJs) of different muscle fiber types, the influence of chronic corticosterone (CORT) administration on the ultrastructure of NMJs of soleus and extensor digitorum longus (EDL) was studied. Five intact Fischer 344 male rats were injected daily with 5-10mg CORT for 3 mo and were sacrificed at 5 mo of age. Soleus and EDL muscles were bathed *in situ* for 10 min with 4% glutaraldehyde in 0.1M Phosphate buffer (PH 7.2). Fibers within 100 μ m of the surface were removed and placed in buffered glutaraldehyde at 4 C for 2 hrs, washed in buffer and post-fixed for 1hr in 2% buffered osmium tetroxide. Specimens were then dehydrated, embedded in Spurr, and thin sectioned (80nm). Sections were stained and examined by electron microscopy at 50,000X. Morphometric analysis of NMJs in CORT-treated rats, revealed significant decrease in fiber diameter, nerve terminal area and synaptic vesicle density, but a significant increase in synaptic cleft. The NMJs underwent partial denervation and reinnervation processes; as demonstrated by large areas of the presynaptic nerve terminal occupied by microtubules and electron dense granular material. Proliferation of muscle and nerve mitochondria was also observed. Subsarcolemmal electron dense vesicles of variable diameters were present near the NMJ. Treated animals exhibited prominent lysosome deposition, as well as increased nerve sprouting. These steroid-induced stress changes are similar to those observed in aging and disuse studies of NMJ. Thus, glucocorticoids hormones may play an etiological role in the homeostasis of the NMJ in response to various stimuli.

NATURALLY OCCURRING PROJECTION NEURON LOSS IN THE SONG CONTROL SYSTEM OF THE ADULT CANARY. J.R. Kim & F. Nottebohm, The Rockefeller University Field Research Center, Millbrook, NY 12545.

The motor pathway controlling learned vocalizations in songbirds consists in part of projection neurons linking the High Vocal Center (HVC) to the robust nucleus of the archistriatum (RA). In adult canaries, the total number of RA-projecting HVC neurons remains constant, although new cells of this type are continuously produced (Kim et al., 1991). Thus, addition of new projection neurons must be matched by loss. We now report that between spring and fall, a period encompassing the yearly transition from stable song to song plasticity in the canary, there is a massive loss and replacement of RA-projecting HVC neurons. Adult males received injections of fluorescent latex microspheres in RA in early April, thereby producing long term retrograde labelling of RA-projecting HVC neurons. RA in these birds was then re-injected with the retrograde tracer fluorogold 4 days prior to killing either in late April (n=4) or mid-October (n=5). The number of HVC neurons labelled with fluorogold remained constant, but that of double labelled cells was reduced by 50% between April and October (t-test; p<.005). The lateral magnocellular nucleus of the anterior neostriatum (LMAN) also projects to RA but does not recruit new neurons in adulthood. The number of double labelled RA-projecting LMAN cells did not change between April and October (p>.05). Thus, neuron loss was specific to RA-projecting HVC neurons. The canary appears to undergo a natural process whereby the entire HVC-to-RA circuit could be replaced within a year.

EVALUATION OF PARAMETERS IN APHASICS: A CLINICAL CONTRIBUTION TO NEURAL PLASTICITY. Ferreira, R.R. Dept. of Physiology and Biophysics, Institute of Biology, University of Campinas, SP, BRAZIL.

The prevalent paradigm in the studies of Neuropsychology referring to language express a reductionist approach due to historical and epistemological reasons. Usually the classical batteries of pattern-tests are employed for single evaluations or for several evaluations through short periods. The results thereby obtained are related to clinical and topographical syndromes. In the present work five aphasic adult subjects were evaluated, from weekly interviews ranging from 13 to 53 months as to their individual difficulties, and orientated in the linguistic process recovery. Aiming at this process a paradigm was worked out according to recent acquisitions which are not yet properly incorporated by Aphasiology. Concomitantly, they were submitted to a set of tests similar to those most frequently applied in aphasiological research. These observations allowed a diagnosis of a vascular disease in the left hemisphere at distinct areas as well as a set of clinical and neuropsychological symptoms regarding to the damaged area. In this methodology where diagnosis were not dissociated from therapy a significative improvement of the contextualized linguistic activities were reached by all aphasic subjects. The results are relevant not only concerning the rehabilitation but also because they offer a favorable support for a discussion beyond the present experimental conditions. In fact, these data point to the importance of the theoretical debate in the context of Vygotsky and Luria concepts in order to broad the neural plasticity knowledge.

HIGH RESOLUTION MAGNETIC RESONANCE IMAGING OF THE HAMSTER BRAIN. D.N. Kennedy* and D.O. Frost, Dept. of Neurology, Massachusetts General Hospital, Charlestown, MA 02129.

We are investigating the use of magnetic resonance imaging (MRI) for high resolution visualization of rodent brain structure *in situ*. Previous work in humans has demonstrated the value of this technique for determining the locus and extent of cerebral lesions, tumors, etc. in large brains.

Syrian hamsters were placed in a GE CSI Omega 4.7 Tesla imaging system equipped with Accustar self-shielded gradients and a 3 cm slotted resonator rodent head coil. An inversion recovery MRI sequence (TR=3 sec; TE=33 msec; TI=400 msec; slice thickness = 1mm; matrix = 256X128; 2 averages) was used. These parameters provided an in plane resolution of 156X312 μ m. A regularly spaced series of images in the coronal plane were obtained.

In T1 weighted images using these parameters, grey matter appears bright and white matter appears dark. Major axon tracts such as the corpus callosum, subcortical white matter, internal capsule, cerebral peduncle, fornix, optic tract, and external medullary lamina are readily visible; prominent tangential fiber laminae in the neocortex can be distinguished in some regions, although contrast is not sufficient for architectonic parcellation.

We are currently using these techniques for the *in situ* evaluation, in mature hamsters, of brain lesions induced at neonatal stages. This procedure permits the identification of cases in which the outcome of the neonatal surgery is most likely to have been appropriate for the behavioral testing of novel, surgically induced neural circuits.

We anticipate that refinement of the parameters of our MRI sequence will permit slice thicknesses as low as 750 μ m, improved in-plane resolution and faster imaging times.

343.16

LEFT HANDEDNESS AS RELATED TO SIDE OF FOCAL TEMPORAL-LOBE EPILEPSY (G. Leonard, A. Sapin*, B. Milner, T. Rasmussen* and W. Feindel*). Montreal Neurol. Inst., McGill Univ., Montreal, Canada H3A 2B4.

We report on a series of 276 consecutively studied patients, each of whom underwent an anterior temporal lobectomy (145 in the left hemisphere, and 131 in the right) to control pharmacologically intractable seizures. No patients showed evidence of extratemporal damage or more widespread epileptiform activity, and subjects who had motor or sensory deficits were excluded. The majority had onset of seizures before the age of five.

The total group comprised 223 strongly right-handed subjects, and 53 predominantly left-handed ones. Hand preference was assessed by means of a modified version of the questionnaire developed by CROVITZ and ZENER [Milner, 1965]. Of the left-handers, only 13 were in the right temporal-lobe group, whereas 40 had left temporal-lobe lesions (Chi-Square = 12.72, $p < .0004$). To account for the observed difference in proportion we suggest that interference in the left cerebral hemisphere, originating in the temporal lobe, can have an effect on hand preference.

MOTIVATION AND EMOTION II

344.1

THE CORTICOMEDIAL AMYGDALA AND HAMSTER AGONISTIC BEHAVIOR. M. Potegal, C. Ferris and L. Skaredoff* New York State Psych. Institute, NY and University of Mass. Medical Center, MA.

Field observations of many animal species have revealed short term increases in aggressive arousal occurring during the initial stages of agonistic encounters. We have developed a laboratory model of this phenomenon: "Priming" a female hamster by allowing it a single attack on an intruder increases its aggressive arousal, i.e., reduces the latency of attack over the next 30 minutes. We now report immunocytochemical evidence for an increased number of neurons expressing *c-fos* in the corticomedial amygdala (CMA) and pre-optic area of primed animals. Other limbic and hypothalamic nuclei show no such changes. Pursuit and biting of an inanimate object, exposure to a noxious olfactory stimulus, or engaging in sexual behavior, all highly arousing as indicated by activity measures, do not induce CMA *c-fos* expression of the same magnitude. Radiofrequency lesions of the CMA reduced aggression demonstrating the functional significance of this region. The greatest increases in attack latency and reductions in priming were significantly correlated with larger, more anterior lesions. Other behaviors, including a locomotor practice effect in a running wheel, were unaffected by CMA lesions. Control lesions of cortex and medial septum did not affect priming. These observations suggest that CMA *c-fos* expression marks a process coupled to aggressive arousal and support the hypothesis that the CMA is part of the neural circuitry mediating this phenomenon.

344.2

SEX DIFFERENCES IN ANTIPREDATOR DEFENSIVE REACTIONS AND THE EFFECTS OF ANXIOLYTIC DRUGS. D.C. Blanchard, J.K. Shepherd*, R.J. Rodgers, R. Agullana*, T. Flores* and R.J. Blanchard Bekesy Laboratory of Neurobiology and Department of Psychology, Univ. of Hawaii, Honolulu, HI 96822

Antipredator defensive reactions in rats comprise a pattern of behaviors (flight/avoidance, freezing, defensive threat/attack, risk assessment, inhibition of nondefensive behaviors) which vary with relevant situational features, intensity of threat, and immediacy and salience of the threat stimulus. Detailed characterization of these patterns in both males and females indicates fundamental sex differences in the organization of antipredator defense. When freezing is the prepotent response to predatory stimuli, it is more evident in females, and risk assessment is delayed, compared with males. Similarly, females show more defensive ultrasound, and inhibition of certain behaviors (e.g. eating) in situations associated with a predator. Sex differences are not seen in flight or defensive threat/attack, suggesting that enhanced female defensiveness is particularly associated with anticipatory defensive responses.

Sex differences are also observed in anxiolytic drug (diazepam, ethanol) effects on defensive responding. Preliminary studies with the serotonergic 5-HT_{1A} agonist, 8-OH-DPAT and the 5-HT₂ antagonist, ritanserin, indicate greater sensitivity in females, while males seem more sensitive to 5-HT₃ antagonists, MDL72222 and Ondansetron. While some of these effects can be explained in terms of baseline behavior, others seem to reflect true sex differences in drug sensitivity.

344.3

ANTIPREDATOR ULTRASOUNDS: SEX DIFFERENCES AND DRUG EFFECTS. R.J. Blanchard, S. Weiss*, R. Agullana*, T. Flores*, & D.C. Blanchard. Bekey Laboratory of Neurobiology, and Department of Psychology, Univ. of Hawaii, Honolulu HI 96822

Brief exposure to a predator for rats living in groups in a burrow system affording concealment elicits 18-27 kHz ultrasounds which may persist for up to an hour following such exposure. When each animal in 12, 1M, 1F groups was tested individually with the cat, with ultrasonic cries recorded on a RACAL instrumentation recorder and analyzed with a Kay 5500 digital sonograph, a pattern of sex differences emerged. Males made reliably fewer ultrasonic pulses. However, the mean durations of these were reliably longer, and the base frequency lower than for females. About 70% of male pulses, but less than 25% of female pulses, were of a negatively accelerated, descending pulse form with a generally ascending base frequency.

Effects of alcohol and morphine on these ultrasonic cries have been assessed. Morphine strikingly reduces such ultrasonic vocalizations, while alcohol effects involve dose x time interactions, with reduced persistence at higher doses. The consistent differences between the effects of these compounds on ultrasonic vocalizations, as opposed to their effects on other antipredator defensive responses suggest that such vocalizations may be physiologically as well as functionally different from other antipredator defensive behaviors.

344.5

EFFECTS OF 8-OH-DPAT ON ROUGH-AND-TUMBLE PLAY AND FEEDING IN JUVENILE RATS. S.M. Sivy and L.A. Kerrigan. Dept. of Psychology, Gettysburg College, Gettysburg, PA 17325.

Serotonin 1A (5HT_{1A}) receptors are thought to be involved in a variety of behaviors. To further study the behavioral function of 5HT_{1A} receptors in juvenile rats, the effects of the specific 5HT_{1A} agonist 8-OH-DPAT (DPAT) on rough-and-tumble play were assessed. Rats (30-45 days old) were housed individually and given a daily 5 minute opportunity to play. Male and female rats were injected with either saline or one of three doses of DPAT (0.125, 0.25, 0.5 mg/kg) 60 minutes prior to a play session. Frequency of pinning was used to assess levels of play. At 0.5 mg/kg, DPAT significantly reduced pinning by 13%. A higher dose (1.0 mg/kg) reduced pinning by 83%. Given that this dose also resulted in a marked "SHT syndrome", the behavioral specificity of this reduction is questionable. The effects of DPAT on feeding were also assessed in satiated juvenile and adult male rats. DPAT (0.1-0.5 mg/kg) had no effect on feeding in juveniles while increasing intake in adults. Since DPAT-induced feeding is thought to be mediated through pre-synaptic autoreceptors, juvenile rats may be differentially sensitive to the presynaptic effects of DPAT. Whether this will be a factor in understanding the extent to which 5HT_{1A} receptors are involved in the expression of mammalian playfulness remains to be determined.

344.7

MELATONIN MODULATION OF SEPARATION DISTRESS, SOCIAL PLAY AND AFFECT. Eric Nelson*, Jaak Panksepp, and Satoshi Ikemoto, Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403

Melatonin has been implicated in the control of a large number of behavioral processes as well as in the genesis of psychiatric disorders ranging from autism to depression. In the following work we analyzed the effects of melatonin on isolation-induced distress vocalizations (DVs) of domestic chicks, rough and tumble social play of juvenile rats and place-preference conditioning in adult long-Evans rats.

DVs were reduced in a dose dependently by 0.1, 0.5 and 1.0 mg/kg of melatonin. The effects lasted about an hour and were accompanied by drowsiness. Central melatonin (1, 5 & 10 ug, icv) exhibited similar, albeit more modest and shorter-lasting effects. Tolerance to repeated melatonin injections and cross tolerance to morphine was not evident. Naltrexone pre-treatment did not block the effects of melatonin, but chronic naltrexone facilitated melatonin effects. Pinealectomy reduced DVs, but did not change sensitivity to melatonin or effects of darkness.

Melatonin doses up to 1.0 mg/kg had no clear effects on play in rats, and pairing of 0.1 and 1.0 mg/kg of melatonin with distinct environments did not yield either place preferences or place aversions. The data suggest that melatonin reduces separation distress without effecting several other affective behaviors.

344.4

THE PRESENCE OF A SOCIAL COMPANION ALTERS ISOLATION RESPONSES OF 3-DAY OLD RAT PUPS. S.E. Carden & M.A. Hofer. Columbia Univ. & N.Y.S. Psychiatric Inst., NY, NY 10032

Three-day old rat pups, isolated in a novel environment, emit ultrasonic calls thought to be predominantly under thermal control (Allin & Banks, Dev.Psychobio., 1971). In 10- and 14-day old pups, the presence of a single anesthetized littermate reduces the rate of ultrasonic vocalization (Carden & Hofer, Behav.Neurosci., 1990; Hofer & Shair, Dev.Psychobio., 1978). We now find that the crying of 3-day old pups is also decreased by the presence of an anesthetized littermate. To determine if this quieting is a function of the body heat of the companion, in a second study, the companion's axillary temperature was lowered to 22°C. The presence of this cool companion also reduced the number of ultrasonic vocalizations. A third study showed that isolation calls were not diminished by the presence of a room temperature, plastic surrogate. Studies on opioid mediation of the companion effect are currently being conducted.

344.6

BUSPIRONE EFFECTS ON SOCIAL EMOTIONS IN RATS AND CHICKS. L. Normansell, M. Euken*, M. Porter*, M. Nemanitis* and D. Pippel*. Dept. of Psychology, Muskingum College, New Concord, OH 43762.

Buspirone (BUS), a 5HT_{1A} agonist, has emotional effects in chicks, including increasing separation-induced distress vocalization (DV) and reducing the latency to jump from an elevated platform to rejoin the flock [Soc Neurosci Abstr 16: 599, 1990]. Following bilateral lesions of the archistriatum which reduced DVs by over 50%, the vocalization-enhancing effect of BUS remained intact. BUS did not change the tendency of control chicks to attempt to escape from the testing arena but dramatically reduced (by almost 70%) that tendency in lesioned chicks.

Chicks were also tested for vocalization in the presence of a large model owl. While controls continued to DV in the presence of this stimulus, BUS-treated chicks attenuated their calling.

Play in juvenile rats was observed following BUS administration. Play was reduced when testing occurred in white lighting rather than red, but this suppression was not attenuated by BUS. Rather, at the highest dose tested (2mg/kg), the number of pins and dorsal contacts were suppressed in the red light condition, perhaps indicating non-specific sedative effects rather than anxiolytic ones. Following chronic administration (5mg/kg, twice/day for 7 days) no anxiolytic effects were noted when animals were tested on an elevated plus maze.

In summary, BUS appears to have more robust emotional effects in chicks than it does in rats. Whether these effects reflect true anxiolytic activity will require more subtle analysis of brain emotional systems.

344.8

BEHAVIORAL CHARACTERISTICS AND NATURAL KILLER CELL ACTIVITY IN TRANSGENIC TGF α MICE. L.A. Hlaktvi-Clarke, P.K. Arora*, M. Burgess*, R. Clarke*, R.B. Dickson* and M.E. Lippman*. Lombardi Cancer Research Center, Georgetown Univ., Washington, DC 20007, and Lab. Neuroscience, NIDDK, Bethesda, MD 20892

Psychosocial factors have been widely implicated in tumorigenesis. Specifically, the ability to cope with stress and certain behavioral characteristics may contribute to an increased risk of developing a cancer. We examined the behavioral patterns associated with stress in apparently healthy 2-3 month-old male transgenic mice overexpressing the gene encoding human transforming growth factor α (TGF α) (Jhappan et al., Cell 61:1137-1146, 1990). These animals show a high incidence of liver carcinomas at the age of 10-15 months. It was found that the TGF α mice spent a significantly longer time immobile (Mann-Whitney U test; U=15, n=10+10, p<.02) in Porsolt's swim test, a model of depressive behavior, and an elevated time showing aggressive behavior (U=19, n=10+10, p<.02) in the resident-intruder test of aggression, as compared with control CD1 mice. The transgenic mice did not differ from the controls in the plusmaze test of anxiety or in respect to voluntary alcohol intake. To investigate the possible biological mechanisms mediating these behavioral changes, we measured the natural killer (NK) cell activity in the spleen. This data showed that TGF α mice exhibited 25% lower NK cell activity than the controls (two-way ANOVA; F(1,23)=8.26, p<.01). We are in the process of assessing the levels of steroid hormones from the blood in these animals.

The preliminary data indicate that transgenic male mice overexpressing TGF α exhibit behaviors characteristic of an impaired ability to cope with stress and increased aggressivity. These changes may be associated with reduced NK cell activity.

344.9

EFFECTS OF MEDIAL HYPOTHALAMIC STIMULATION UPON MASSETER EMG ACTIVITY IN THE CAT. S. Weiner*, S.N.V. Rao*, S. Dunn*, L. Laemle and A. Siegel. Dept. of Prosthodontics, NJ Dental School and Dept. of Neuroscience, NJ Medical School, Newark, NJ 07103.

Little is presently known concerning the neural substrates for jaw muscle hyperactivity. Therefore, we utilized the mean power frequency (MPF) of the masseter muscle following electrical stimulation of the medial hypothalamus (MH) as a model of centrally mediated muscle hyperactivity in the cat. EMG recordings were made from the masseter muscle with bipolar surface electrodes prior to, during, and immediately after electrical stimulation (0.2-0.6mA) of MH at which affective defense behavior could be elicited. Recordings were also made at rest and during forceful biting activity unrelated to MH stimulation. EMG data were collected in 1 sec intervals with a sampling rate of 2048 Hz and then converted into digital form. Fast Fourier Transforms were calculated and the MPF were determined. During MH stimulation, MPF were significantly higher than MPF observed at rest ($p < .01$). Immediately after stimulation, MPF were significantly lower than at rest ($p < .01$). Since MH stimulation and forceful biting both produced equally elevated levels of MPF, it is argued that MH stimulation can serve as a useful model for the study of centrally mediated jaw muscle hyperactivity.

EFFECTS OF AMPHETAMINE AND SULPIRIDE ON EXPLORATORY BEHAVIORS IN RATS WITH FORNIX KNIFE-CUTS. T.L. Steele and M. Williams*, Dept. of Psych., Univ. of Wis. Oshkosh, WI 54901.

Rats with lesions of the hippocampus often display deficits in learning and memory. These rats are also frequently stereotypic, hyperactive, and inattentive (1), behaviors which oppose exploration and learning. Similar behaviors are noted in rats given d-amphetamine (AMPH, 2), suggesting a role for dopamine (DA) in the modulation of exploratory behaviors. It was therefore predicted that enhancement of DA activity would potentiate exploration deficits whereas blockade of DA would attenuate these deficits in rats with fornix knife-cuts.

In Study 1, rats with sham (S) or fornix knife-cuts (F) were given 0, 1.5, or 3.0 mg/kg AMPH and placed in a large arena comprised of multiple familiar and novel features. In Study 2, food-deprived S and F rats were given 0, 30, or 60 mg/kg sulpiride and placed in a modified arena which also consisted of familiar and novel features. Rats were observed for 10 min per day for 10 days in each study.

Relative to F rats, S rats displayed more dispersed exploration, devoted more time to novel aspects of the arena, and exhibited different patterns of exploration. AMPH significantly reduced exploration. Both knife-cuts and AMPH produced responses reminiscent of behavioral traps. Although sulpiride altered certain aspects of exploration, the overall effects were not robust.

These results demonstrate that the hippocampus (via the fornix) influences exploration, potentially through modulation of mesolimbic DA activity. The role of sulpiride in reducing exploration deficits, however, remains speculative.

BIOLOGICAL RHYTHMS AND SLEEP VII

345.1

CHRONIC RO 15-1788 TREATMENT INCREASES REM SLEEP IN RATS. S.D. O'Connor, M. Urbancic, T.J. Marczyński and M. Radulovacki. Dept. of Pharmacology, University of Illinois, Chicago, IL 60612

Ro 15-1788, a benzodiazepine (BDZ) receptor antagonist, was shown to have BDZ agonist properties which manifested in increased sleep when the drug was administered to dogs and humans. In the present study, we examined the effect of chronic administration of Ro 15-1788 on sleep in rats. Ro 15-1788 (3.6 mg/kg/day in drinking water for 14 days) increased rapid eye movement (REM) and total sleep during a standard six hour EEG recording, with the increases in total sleep time due entirely to increases in REM. EEG recordings were obtained on days 0, 1, 3, 7, 10, 14, as well as 24 and 72 hours following drug withdrawal. Enhanced REM sleep reached significance on day 7 of continuous drug treatment and remained significantly increased on days 10 and 14, as well as at 24 and 72 hours following drug withdrawal. Ro 15-1788 may exert its hypnotic effect either through the adenosinergic system involving inhibition of adenosine re-uptake, as was suggested for the mechanism of hypnotic action of BDZ's, or through the ability of BDZs to increase REM sleep via the disinhibition of the cholinergic system.

THE ROLE OF THE M1 MUSCARINIC RECEPTOR SUBTYPE IN REM SLEEP. R.K. Zolatoski, M.D. Shalauta*, and J.C. Gillin. Dept. of Psychiatry, San Diego VAMC and University of CA, San Diego, La Jolla, CA 92093.

Microinjections of carbachol (carb) into the peri-a-locus coeruleus (α -LC) of cats induce rapid eye movement (REM) sleep. This response is blocked by pretreatment with atropine; however, the specific cholinergic receptors mediating the carb induced effects are not fully known. To study this, cats were surgically implanted with sleep recording electrodes and bilateral cannulas targeted for the α -LC region. Pirenzepine (a specific antagonist of the M1 receptor) (pir, 5 μ g) or saline (sal, 0.1 μ l) was administered bilaterally 15 minutes prior to the administration of either carb (0.4 μ g) or sal (0.1 μ l) in a randomized, repeated measures fashion. REM sleep was defined as presence of low frequency EEG, theta, PGO spikes, and atonia. Administration of sal and carb decreased latency to a dissociated REM state, characterized by all components of REM sleep, except theta waves; it also decreased slow wave sleep. Pir blocked this carb-induced effect, with the exception of the decreased latency of PGO spikes. Pir alone did not change the states measured. We hypothesize that the action of carb is mediated in part by the M1 muscarinic subtype. More studies involving different doses as well as other drugs are necessary to understand which cholinergic receptors (M1, M2, nicotinic) mediate REM sleep.

REM SLEEP SUPPRESSION INDUCED BY SEROTONIN UPTAKE BLOCKADE: EVIDENCE FOR A TYPE 2 RECEPTOR MECHANISM. R.J. Ross, S.J. Peymer*, L.D. Sanford*, W.A. Ball and A.R. Morrison. V.A.M.C. and Depts. of Psychiatry and Animal Biology, Univ. of Penna. Schools of Med. and Vet. Med., Phila., PA 19104.

Acute serotonin (5HT) uptake blockade by sertraline (SER) suppresses REM sleep (REMS) in the cat. To investigate the underlying serotonergic receptor mechanism(s), the effect of the relatively specific 5HT-2 antagonist ketanserin (KET) was investigated. Five cats were implanted with EEG, EOG, EMG, and lateral geniculate electrodes. Cats underwent 6-hr. polysomnographic testing under the following 5 conditions: 1) placebo capsule plus 3 cc saline, i.p.; 2) SER (1.0 mg/kg, p.o.) plus 3 cc saline, i.p.; 3-4) SER (1.0 mg/kg, p.o.) plus KET (either 1.0 mg/kg or 3.0 mg/kg, i.p.); and 5) placebo capsule plus KET (3.0 mg/kg, i.p.). Study condition order was counter-balanced, and all trials were separated by 1 week. KET co-administration reduced the inhibitory effect of SER on REMS% (REMS time/total sleep time), which increased from 4.0 (cond. 2) to 10.7 (cond. 3) and then 14.1 (cond. 4); yet REMS% remained lower than the placebo level (25.0). KET alone (cond. 5) increased REMS% to 31.5. Putative level of 5HT-2 receptor activation (cond. 2 > 3 > 4 > 1 > 5) correlated with REMS% ($r = -0.94$; $p < 0.01$). Thus, a 5HT-2 mechanism may partially explain SER's REMS suppressant effect. That 5HT-2 receptors are located primarily in the cortex suggests that some serotonergic modulation of REMS may occur rostral to the pons, where REMS control otherwise is thought to reside. EVOCATION OF POSTURAL ATONIA AND RESPIRATORY DEPRESSION BY PONTINE CARBACHOL IN DECEREBRATE RATS. O. Taguchi*, L. Kubin, S. Manaker, and A.I. Pack*. Center for Sleep and Respiratory Neurobiology and Department of Animal Biology, University of Pennsylvania, Philadelphia, PA 19104

Pontine microinjections of carbachol in decerebrate cats produce a prolonged postural atonia similar to that occurring during rapid eye movement (REM) sleep (Morales, *J Neurophysiol* 57:1118, 1987) and respiratory depression (Kimura, *J Appl Physiol* 60:2280, 1990). This novel, acute preparation may be very useful for electrophysiological studies of the neural mechanisms activated in REM sleep and narcolepsy. However, for neurochemical and *in vitro* studies, development of a corresponding acute rat model would be attractive. To verify the viability of such studies in rats, carbachol (25-50 nl; 10 mM) was microinjected unilaterally into the pons of Sprague-Dawley rats decerebrated at a precollicular level. The EMG of dorsal neck and intercostal muscles was recorded. Eleven injections performed in 8 rats resulted, within 3 min, in a profound depression of neck and intercostal muscle tonic activity and a slowing of the respiratory rate (to ~74% of control). The episodes lasted 8-28 min (mean: 15 min) and terminated abruptly with the return of all parameters to pre-injection levels. The injection sites were localized within the dorsal regions of oral and caudal pontine reticular nuclei. Thus, as in cats, pontine carbachol in decerebrate rats produces postural atonia and respiratory depression. In cats, however, the episodes last over 1 h and terminate gradually. Still, the episodes in rats are substantially longer than individual periods of natural REM sleep. Their abrupt termination suggests that mechanisms beyond the injection site determine the duration of the atonia. (SCOR HL-42236)

REM AND SLOW WAVE SLEEP-LIKE STATES IN THE WHOLE GUINEA PIG BRAIN MAINTAINED IN VITRO. M. Moga, D. Paré, M. deCurtis and R. Llinás. Dept. Physiology and Biophysics, New York Univ. Med. Ctr., NY, NY 10016.

As a prelude to studies of cellular mechanisms underlying different sleep states, we examined whether REM and slow wave sleep-like states can be pharmacologically induced in the adult whole guinea pig brain maintained in vitro (31-33°C). Bipolar electrodes were positioned in specific thalamic nuclei and their respective cortical projection fields under physiological control, i.e., by stimulation of their specific prethalamic afferents. In addition, a suction electrode was placed on cranial nerve III. Focal ECG recordings revealed the presence of spontaneous (6-10Hz) spindles occurring every 4-6sec throughout the neocortex in synchrony with spindles recorded from the corresponding thalamic nucleus. Muscimol injections (2-8µg) into the lateral hypothalamus produced cortical slow wave activity (1-4Hz) of high amplitude (1 mV). Microinjections of carbachol (4-8µg) into the pontine tegmentum produced two types of PGO waves in the lateral geniculate nucleus and occipital cortex: isolated PGO waves (100-200msec) and bursts of 3-6 waves per 1-2sec. Following carbachol injections, cortical spindles decreased in amplitude and were replaced by ECG desynchronization. Animals pretreated with p-chlorophenylalanine (PCPA, a serotonin synthesis inhibitor, 35mg/150mg for 3 days) showed spontaneous PGO wave activity in the dorsolateral pons, occipital cortex and lateral geniculate nucleus, and bursting in the oculomotor nerve. In PCPA-muscimol treated animals, both PGO waves and cortical slow waves were present simultaneously, suggesting some state dissociation.

ELECTROLYTIC LESION OF LOCUS COERULEUS (LC) AUGMENTS PARADOXICAL SLEEP (PS) IN FEMALE RATS, BUT NOT MALES. J. Fang, S. W. Yang and W. Fishbein. Dept. of Psychology, The City College & Graduate School, CUNY, New York 10031

In previous NS meetings we reported that (1) male rats have more PS than females and (2) this sexual dimorphism is influenced by neonatal manipulation of sex steroids. The present experiment is the first to examine the brain mechanism(s) involved in this phenomena. Since the LC is larger and embodies more neurons in females than males, we examined whether the inhibitory influence of the LC on PS may be different between the sexes.

Under anaesthesia we bilaterally lesioned the LC in both male (ME, n=7) and female (FE, n=8) adult (105-130 days) Sprague-Dawley rats by passing 1.0 mA direct current through stereotaxically placed electrodes. In all respects the control males (MC, n=9) and females (FC, n=8) were identically treated, with the exception that they were not lesioned. After 11 days recovery from lesion and sleep electrode implantation, sleep/wakefulness cycles were continuously recorded for 4 days. Verification of the lesions was determined by tyrosine hydroxylase stained brain sections using the immunohistochemistry technique.

Results: (1) Total sleep time and SWS are indistinguishable in all groups; (2) MC animals spend 4.08 min/hr in PS, FC 2.82 min/hr, reconfirming (p<0.02) our previous findings; (3) LC lesions increase PS significantly in females (4.45 min/hr; FE vs FC, p<0.001) but not males (ME, 4.27 min/hr). Partialled analyses shows that the PS increase is mostly found in the day time.

The results strongly suggest that the sex difference of PS in rats is mediated by the LC and its neuron projections.

PGO-WAVE SUPPRESSION DURING REM-SLEEP IN MONOCULARLY DEPRIVED KITTENS INCREASES LGN RELAY CELL PLASTICITY. J.P. Shaffery, G.A. Marks, S.G. Speciale and H.P. Roffwarg. U.T. Southwestern Medical School, Dallas, Texas 75235.

An ontogenetic function for REM-sleep has been advanced proposing that the large amounts of endogenous CNS activation, which characterizes this state, is a necessary component of normal CNS development and maturation. Monocular deprivation (MD) studies have demonstrated that visual experience during a "critical period" of development strongly influences cellular plasticity in LGN. We have previously observed that restricting REM-sleep during this "critical period" in MD kittens exaggerates the effects of MD alone on cell sizes in LGN. In addition to tonic activation of the EEG, a cardinal feature of REM-sleep is the periodic appearance of PGO-waves. Prior to the "critical period", bilateral pontomesencephalic lesions of ascending pathways, which carry brainstem-generated PGO-waves, have been shown to affect both cellular growth and number in LGN. In our study, these lesions, which spare the tonic aspects of REM-sleep, were performed during the "critical period" on kittens that had been monocularly deprived for one week and allowed a post-lesion survival of an additional week. To date, three MD kittens have received bilateral lesions removing PGO-waves. In one animal, PGO-waves could not be recorded, so no lesion was made. In a preliminary analysis, LGN cell size data from the three lesioned kittens were compared to data from the non-lesioned kitten pooled with data from four other MD-only controls from another study. In the LGN ipsilateral to the occluded eye, interlamina cell size differences in lesioned kittens were significantly larger (p<0.05) than in controls. This new evidence supports our ontogenetic hypothesis of REM-sleep function during CNS development.

AUDITORY STIMULATION ENHANCES REM SLEEP IN YOUNG AND OLD FISCHER 344 RATS. G. Arankowsky*, W.S. Stone and P.E. Gold. Department of Psychology, U. Virginia, Charlottesville, VA, 22903.

As in other mammals, aged rats exhibit profound deficits in sleep patterns, particularly including deficits in rapid eye movement (REM) sleep. Auditory stimulation (AS) applied during (REM) sleep enhances the duration of REM sleep in cats (Drucker - Colin et al, Br. Res 278 : 308 - 312, 1983). The present experiment investigated whether AS would enhance REM sleep in young (6 month - old) and aged (22 month - old) rats. Two 4-hr baseline sleep records were obtained for each rat prior to AS tests. In young rats, sleep stages were monitored during the AS test sessions (4 hrs) to allow administration of AS (2 KHz, 75 dB, 100 msec each 20 sec throughout each REM sleep bout) during REM sleep. Because the duration of REM sleep bouts is quite short in aged rats, AS could not be administered during these bouts. Therefore, old rats received AS on a fixed schedule - 10 min of AS (as above) alternating with 15 min of quiet. In young rats, AS enhanced REM sleep bout duration (101 ± 6 vs. 179 ± 10 sec, P < 0.001) and enhanced total REM sleep time (23 ± 2 vs. 27 ± 2 min) but reduced the number of REM sleep periods (14 ± 0.8 vs. 10 ± 0.6). Baseline REM sleep measures were substantially depressed in old rats. In the old rats, AS enhanced total REM sleep time (14 ± 3 vs 21 ± 6 min, P < 0.05) and enhanced the number of REM sleep periods (13 ± 3 vs. 16 ± 2, P < 0.05), but did not significantly increase the duration of REM sleep bouts (70 ± 7 vs. 74 ± 3 sec). Thus, AS is an effective manipulation with which to augment REM sleep in young rats. AS also augments REM sleep measures in aged rats, but does not restore them to levels seen in young rats. REM-SLEEP DEPRIVATION DIMINISHES NEUROTRANSMITTER LEVELS IN THE HYPOTHALAMUS AND FRONTAL CORTEX OF RATS: T. Porkka-Heiskanen, D. Stenberg and T. Taira*. Department of Physiology, University of Helsinki, Siltavuorenpenger 20 J, 00170 Helsinki, Finland.

Adult male rats were deprived of REM-sleep for 72 hours. The deprivation group was kept on small platforms (diameter 6.5 cm) in a water bath, and the control group on large platforms (11 cm). In addition one group was kept in a cage that was not filled with water. The deprivations ended in the morning and the rats were decapitated either directly or having been allowed to sleep for 5 hours. Frontal cortex and hypothalamus were rapidly dissected, frozen and stored in -80 C until the assays. Monoamines were measured by HPLC with EC-detection. In the anterior part of the hypothalamus the serotonin and noradrenaline concentrations of the REMs deprived rats were lower than those of the control groups. The dopamine concentrations of the deprived rats were lower in the posterior part of the hypothalamus. In the frontal cortex serotonin concentrations of deprived rats were lower than those of the controls. There was no recovery of the monoamine concentrations during the rebound sleep.

RELATIVE AMPLITUDE OF ELICITED PGO WAVES IS CORRELATED WITH BEHAVIORAL ORIENTING A.R. Morrison, L.D. Sanford*, W.A. Bail and R.J. Ross. Depts. of Anim. Biol. and Psychiatry, Univ. of Penna. and VAMC, Phila, PA 19104

During REM sleep the brain exhibits electrophysiological signs (low voltage, high frequency EEG; hippocampal theta) indicative of alerting in waking (W), and cats with lesions in the dorsolateral pons that eliminate atonia during REM (REM-A) may exhibit orienting-like behaviors in REM-A. Pontogeniculo-occipital waves (PGO) occur spontaneously in REM, and PGO-like waves may be elicited (PGO_e) in the lateral geniculate body by auditory stimuli (S) during W, non-REM (NREM), and REM. To determine the relationship between PGO_e and overt behavioral orienting (OR), we presented S to 12 cats in W, NREM and REM on two separate days one week apart. On each test day a minimum of five blocks of 40 (or more) S (tones or white noise, 90 msec, 90-100 dB, 1 or 4 kHz, 2 sec ISI, 20 min between blocks) were presented in W. Then, S were presented throughout a REM or NREM episode and in a final block in W. OR did not occur in REM or NREM. OR was seen most often during the initial trials in each W block on each test day. Mean PGO_e amplitude (AMP) was higher in REM than in NREM (p < .006) and W (p < .001). PGO_e of smaller amplitude persisted after OR had habituated. However, the largest PGO_e AMP occurred on the first one or two trials of each block in W, and they were comparable to PGO_e AMP in REM. That high-AMP PGO_e in W are closely associated with OR in W suggests that the relative AMP of PGO signals more than the mere sensory registration of S. With as little as a 20 min pause between S, renewal of S presentations appears to reintegrate OR and large AMP PGO_e. Because high-AMP PGO occur spontaneously in REM and PGO_e of similar AMP occur during OR in W, the spontaneous PGO of REM may mark the endogenous activation of mechanisms underlying OR that are typically triggered by S in W. Renewal of large amplitude PGO_e may hinge on the recruitment of activity of a larger number of neurons, the activity of which precedes spontaneous PGO at varying latencies in REM. ELICITED AND SPONTANEOUS WAVEFORM ACTIVITY IN LATERAL GENICULATE BODY AND THALAMIC CENTRAL LATERAL NUCLEUS ACROSS BEHAVIORAL STATES. L.D. Sanford, A.R. Morrison, W.A. Ball, R.J. Ross and G.M. Mann. Depts. of Anim. Biol. and Psychiatry, Univ. of Penna. and VAMC, Phila., PA 19104

Ponto-geniculo-occipital waves (PGO) in the lateral geniculate body (LGB) and PGO-like waves in the thalamic central lateral nucleus (CL) occur spontaneously during rapid eye movement sleep (REM). Loud auditory stimuli elicit PGO-like waves in LGB (PGO_L) and CL (CL_L) in waking (W). Both may reflect activity in mechanisms involved in alerting. To determine whether changes in behavioral state would affect patterns of responses in PGO_L and CL_L, we presented long series of tones to cats in W, REM and non-REM (NREM). We also recorded spontaneous activity in CL and LGB in all states. Seven cats were presented with four blocks of 40 tones (100 dB, 2 sec ISI, 4 KHz) in W, followed by tones presented throughout REM or NREM, and a final 40 tones in W. REM and NREM were tested on separate days one week apart in a counterbalanced order. PGO_L magnitude (MAG; combined measure of amplitude and occurrence) was higher in REM than in W ($p < .014$), yet was not significantly greater in NREM than in W. CL_L MAG was not significantly greater in REM or NREM than in W. Each REM and NREM period was divided into quartiles. PGO_L MAG decreased linearly across quartiles in REM ($p < .024$) with a similar, but non-significant pattern of decline in NREM. CL_L MAG did not decrease across quartiles in either sleep state. Just as CL_L did not mimic the pattern of PGO_L, neither did spontaneous CL waves mimic the characteristic pattern of PGO in sleep. Spontaneous waves during REM in CL occurred less frequently and generally appeared as single waves rather than bursts. The dissimilarity between patterns of spontaneous PGO and CL waves and the difference in responsiveness of elicited waves to tones in REM suggest that mechanisms producing each may have a different, perhaps functionally related, role in alerting. Supported by MH42903, MH18825 and the VA Med. Res. Serv.

EXCITATION OF BASAL FOREBRAIN NEURONS BY PEDUNCULOPONTINE STIMULATION. R. Szymusiak, S. Morairty and D. McGinty. VAMC Sepulveda, Depts. Anat. & Cell Biol., Neurosci., and Psychology, UCLA.

A prominent group of cholinergic neurons is located in the pedunculopontine tegmentum (PPT). PPT neurons project to several thalamic nuclei, exert excitatory effects on thalamic relay neurons, and are thought to contribute tonic arousal influences during EEG activated states such as waking and REM sleep. PPT neurons also project to the magnocellular basal forebrain (BF), an extrathalamic area implicated in the control of cortical activation, and, therefore, might be expected to exert excitatory effects on some BF cell types.

Adult cats were implanted with PPT stimulating electrodes and microwires for chronic BF unit recordings. Approximately 35% of BF units exhibiting spontaneous waking discharge responded to PPT stimulation with evoked excitation. Latency to onset averaged 4.9 ± 0.4 ms and mean latency to peak response was 7.3 ± 1.1 ms ($n=14$). Each PPT pulse evoked an average of 1.4 ± 0.2 action potentials and the mean duration of excitatory responses was 8.7 ± 1.3 ms. Latency and duration values suggest that evoked responses were predominantly multisynaptic. PPT stimulation also enhanced responses evoked in some BF neurons by stimulation of other brain sites (e.g., medial thalamus). This increase in synaptic responsiveness persisted for about 10 ms after single PPT pulses, and for as long as 25 ms following brief high frequency trains (300 Hz, 3 pulses). BF cells exhibiting PPT-evoked responses had high spontaneous discharge rates in waking (17.1 ± 2.6 Hz) and REM sleep (14.6 ± 3.2 Hz) compared to slow-wave sleep (6.7 ± 1.5 Hz).

APPLIED HEAT LOADS EVOKE DELAYED ENHANCEMENT OF SLOW WAVE SLEEP IN RATS. S. Morairty, R. Szymusiak and D. McGinty. VAMC Sepulveda, Depts. of Neurosci., Anat. & Cell Biol., and Psychol., UCLA.

There are strong positive correlations between slow wave sleep (SWS) and brain or body cooling. Further, increasing brain or body temperature has powerful sleep-promoting effects. In humans, late afternoon heat loads give rise to a delayed increase in SWS during the subsequent nocturnal sleep period. These data have suggested the hypotheses that SWS is a homeostatic process involved in brain and body cooling and is controlled by thermoregulatory mechanisms. However, there are no previous studies examining the delayed effects of heat loads on subsequent SWS in experimental animals.

Male Sprague-Dawley rats were implanted with thermocouples into the medial preoptic hypothalamus and with standard cortical EEG and neck EMG electrodes. During the last 4 hours of the light period, ambient temperature was increased to keep brain temperature (T_{br}) between 39.5 - 40.5 °C. Under the control condition, rats were limited to the hourly sleep averages recorded during the corresponding heating period.

During the first 4 hours of the dark period following heating, SWS was increased and T_{br} was reduced compared to both baseline and control conditions. Paradoxical sleep was also enhanced but less consistently and to a lesser extent. These results support the hypothesis of a mechanism that can store information about heat loads during wakefulness. Such a 'memory' could induce delayed compensation for heat loads through sleep-related cooling.

PHARMACOLOGICAL STUDY OF BASAL FOREBRAIN NEURONS IN GUINEA PIG BRAIN SLICES. A. Khatib, M. Serafin, B.E. Jones, A. Alonso and M. Mühlethaler. Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and *Montreal Neurological Institute, McGill University, Canada H3A 2B4

Providing a major innervation to the cerebral cortex, cholinergic neurons lie within the basal forebrain (BF) in amongst other cells, including GABAergic neurons. Collectively these cells sit in the path of ascending fiber systems originating in part within the brainstem and including noradrenergic, serotonergic, and also cholinergic fibers. Extending from preliminary results that revealed a class of BFn that exhibit oscillatory properties with low threshold calcium spikes, the potential influence of the chemically specific afferent input upon this class of cells and its properties were further investigated in the guinea pig slice by pharmacological means. Cells were recorded within the region of the horizontal limb of the diagonal band and substantia innominata, where choline acetyl transferase (ChAT)-immunoreactive neurons have been localized, and filled with biocytin in order to study their morphological and histochemical identity. The cells were strongly depolarized and excited by noradrenaline. In contrast, they were consistently hyperpolarized and inhibited by serotonin. The responses of these neurons to cholinergic agonists demonstrated that they are depolarized and excited by nicotine but hyperpolarized by muscarine. These results indicate that certain BFn may be strongly influenced by brainstem afferents, notably excited by noradrenergic input from the locus coeruleus yet inhibited by serotonergic input from the midbrain raphe. Although extrinsic cholinergic input may excite BFn via a nicotinic receptor, it or intrinsic cholinergic processes may inhibit these cells, which if cholinergic may involve a muscarinic autoreceptor. INVESTIGATING THE MECHANISMS OF AUDITORY PONTO-GENICULO-OCCIPITAL (PGO) WAVES IN THE CAT. G.A. Marks, J.P. Shaffery and H.P. Roffwarg. Department of Psychiatry, U.T. Southwestern Medical School, Dallas, Texas 75235.

PGO waves are gross field potentials that occur in association with REM sleep. Loci from which PGO waves can be recorded span diverse neurophysiological systems. Of interest to us has been the REM sleep-related phasic activity uncovered in the auditory system, specifically the cochlear nucleus (CN).

After the procedures of Hu et al ¹, we have chosen to study "PGO-like" waves recorded in the acute reserpinized cat under urethane anesthesia. Reserpine was administered (5mg/kg, p.o.) and followed 18 hours later by urethane (1.0g/kg, IP). The cerebellum was partially aspirated to uncover the dorsal medullary surface, which thereafter was continuously bathed in warmed artificial cerebrospinal fluid. Electrode placement into the CN was achieved under direct visual guidance.

Preliminary data reveal that reserpine PGO waves can be recorded from the dorsal CN (DCN) with a bipolar electrode (200u). Reserpine's action, during most of the procedure, results in the continuous rhythmic appearance of waves at a rate of about 40/min. Examined simultaneously, waves in the lateral geniculate nucleus had the same pattern as in the DCN. Several single units were recorded in the anterior ventral CN (AVCN). Cells are identified by their response to tone burst. To date, we have found only a weak association between a few AVCN units' discharges and occurrence of PGO waves.

We plan to study unit activity in the DCN, which may give rise to the field potential activity and to study the transmitter-receptor interactions underlying PGO phenomena. 1. Brain Research 1988, 473:394-397.

CEREBRAL METABOLISM AND PROTEIN SYNTHESIS DURING SLEEP IN THE RAT. P. Ramm. Dept. of Psychology, Brock Univ., St. Catharines, Ontario, Canada, L2S 3A1

Slow wave sleep (SWS) has been shown to conserve cerebral energy expenditure, and this conservation may favor or reflect alterations in any number of fundamental biochemical processes. Most prevalent are suggestions that sleep states favor the synthesis of cerebral proteins. We use quantitative autoradiography to measure regional cerebral metabolism and protein synthesis during sleep and wakefulness. We have previously reported that, in sleep-deprived animals (48-72 hr platform deprivation), SWS is linked to lower rates of cerebral metabolism (1) and higher rates of cerebral protein synthesis (2). We now report that, following very short deprivation, we continue to observe lower rates of metabolism, but fail to observe higher rates of protein synthesis during SWS.

Four days after surgery and following 3 hr of manual sleep deprivation, polygraphic and power spectral recording were initiated. Standard procedures for quantitative 14C-2-deoxyglucose or L-[1-14C]leucine autoradiography were performed during a 45 min incubation period, while the freely moving rats engaged in sleep/wake behavior. Autoradiographs were then prepared and showed that animals exhibiting more SWS also exhibited significantly lower rates of cerebral metabolism and of cerebral protein synthesis ($r_{xy} = -0.63, p < 0.05$).

These data converge with reports of cerebral energy conservation during SWS. However, they contrast with our previous observation of higher rates of protein synthesis associated with SWS in sleep-deprived rats. The present animals did not show the very deep SWS patterns seen following more extensive deprivation. A difference in sleep need may underlie the contradiction between synthesis rates observed in deprived and non-deprived animals during SWS.

SOMNOGENIC AND PYROGENIC ACTIVITY OF TUMOR NECROSIS FACTOR-ALPHA (TNF α), -BETA (TNF β) AND FRAGMENTS OF TNF α . L. Kapas¹, A.B. Cady¹, M.R. Opp¹, A.E. Postlethwaite², J.M. Sevey³, J.M. Krueger¹. Departments of Physiology and Biophysics¹, Medicine², and Biochemistry³, University of Tennessee, Memphis, TN 38163.

It is hypothesized that fever and increased sleep during acute infections are caused by cytokines. In fact, exogenous administration of IL-1, IFN α 2 and TNF α elicits fever and enhances non-rapid-eye-movement sleep (NREMS). We investigated the effects of TNF α , TNF β and nine TNF α fragments on sleep and brain temperature using a rabbit model previously described¹. TNF α and TNF β elicited dose-dependent increases in NREMS and biphasic fevers. Four TNF α fragments with overlapping sequences (TNF α ₁₀₋₃₆, TNF α ₁₀₋₆₉, TNF α ₃₁₋₄₅ and TNF α ₃₁₋₆₈) were somnogenic with a threshold dose of 25 μ g, two of them (TNF α ₁₀₋₃₆ and TNF α ₃₁₋₆₈) also elicited a monophasic fever. Two fragments (TNF α ₄₆₋₆₅ and TNF α ₆₉₋₁₀₀) induced monophasic fevers but not sleep. Three other peptides (TNF α ₄₄₋₆₈, TNF α ₁₀₁₋₁₃₅ and TNF α ₁₄₀₋₁₅₇) lack both hypnogenic and pyrogenic activities. These results indicate that the TNF α molecule has multiple active centers. Hypnogenic peptides contained amino acid residues 31-36, which is an exposed loop region in the three-dimensional structure of TNF α known to be important for biologic activity. Similar results were previously obtained using IL-1 β fragments¹. Such findings suggest the possibility that posttranslational and/or postreceptor hydrolysis of cytokines could provide a degree of tissue-response specificity.

MONOAMINE AND METABOLITE LEVELS IN CEREBROSPINAL FLUID OF HIBERNATING AND EUTHERMIC YELLOW-BELLIED MARMOTS. M.S.Reid¹, F.L.Watson², L.M.Romero¹, T.S.Kilduff¹, E.Mignot¹, H.C.Heller¹, W.C.Dement¹. Sleep Disorders Res. Ctr., Stanford Univ., Stanford, CA 94305.

The levels of monoamines and their metabolites in the cerebrospinal fluid (CSF) of yellow-bellied marmots, *Marmota flaviventris*, during euthermic and hibernating states were investigated. The concentrations of dopamine, dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), norepinephrine and serotonin in CSF samples were assayed by HPLC-EC. General population studies showed that dopamine levels were decreased ($p < 0.05$), while DOPAC ($p < 0.001$) and HVA ($p < 0.001$) levels were greatly increased in hibernating marmots. Norepinephrine ($p < 0.05$) and serotonin ($p < 0.01$) levels were also increased during hibernation. In paired population studies using a group of three marmots sampled during both euthermic and hibernating states the results were similar. These findings are consistent with previous studies showing a modulation of dopamine, DOPAC, HVA and 5HT levels in discrete brain regions of the hibernating ground squirrel, suggesting a role of monoaminergic neurotransmission in the regulation of hibernation. METABOLIC FUEL UTILIZATION DURING HIBERNATION AND AROUSAL. J. Dark and N.F. Ruby, Dept. of Psychology, UC-Berkeley, Berkeley CA 94720

The golden-mantled ground squirrel survives winter by hibernating; metabolic needs are reduced by decreasing body temperatures (T_b) to $\sim 2-3^\circ\text{C}$. Hibernation consists of a series of individual torpor bouts 2-14 days long, punctuated by periodic arousals of < 24 h. Energy during hibernation is derived from adipose tissue stores. This experiment evaluated the relative contribution of glucose and fatty acids during torpor and arousal using 2-deoxy-D-glucose (2DG) and mercaptoacetate (MA).

T_b was monitored telemetrically. β -oxidation of fatty acids and glycolysis were disrupted by MA and 2DG, respectively, during hibernation and forced arousals. Animals received MA, 2DG, and saline in a randomized order. MA induced arousals, but 2DG did not. Animals treated with 2DG did not differ from those injected with saline. Treatment with either 2DG or MA during an arousal did not affect latency to rewarm. Concurrent treatment with 2DG and MA, however, significantly retarded the rearming process.

These data suggest several conclusions: Torpor depends upon a specific metabolic fuel; fatty acids are necessary and glucose is neither necessary nor sufficient to sustain torpor. Mechanisms sensitive to fatty acid availability appear to function at the low T_b 's of hibernation. Fatty acid availability may influence torpor duration. Rewarming depends upon the general availability of metabolic fuels, rather than a specific fuel.

EFFECTS ON SLEEP AND BRAIN TEMPERATURE OF BILATERAL ETHANOL MICROINJECTION TO THE PREOPTIC AREA OF RATS. S. R. Ticho, G. Lekovic^{*}, M. Stojanovic^{*}, and M. Radulovacki. Dept. of Pharmacology, University of Illinois College of Medicine, Chicago, IL 60612.

We have examined the effects on sleep and brain temperature of bilateral intracerebral administration of 0.55%, 2.75%, and 5.5% ethanol to the preoptic area of rats. 2.75% and 5.5% ethanol significantly increased total sleep by 18% and 24%, respectively, during the 6 hr polygraphic recording period. Analysis of the various sleep states revealed that the enhancement of total sleep was due primarily to an increase in deep slow-wave sleep but the 2.75% dose also significantly increased REM sleep by 89%. Recording of brain temperature for 3 hrs after ethanol microinjection at all three doses showed no significant differences from saline microinjection. These observations support the hypothesis that the preoptic area may be the site of action for the sedative effects of ethanol in rats.

BIOLOGICAL RHYTHMS AND SLEEP VIII

346.1

ELECTROENCEPHALOGRAPHIC CORRELATES OF AROUSAL IN THE PERSISTENT VEGETATIVE STATE. S.P. Raps¹, N.R. Feikin¹, D.R. Labar¹ and F. Plum. Department of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021.

Although behavioral evidence of sleep-wake cycles are a part of the diagnostic criteria for the persistent vegetative state (PVS), no prior studies have detailed the electrographic correlates of cyclic arousal or the sleep architecture for patients in this condition. Continuously acquired 24h video electroencephalography (EEG) was performed in a 35-year old man in PVS for four years after severe head trauma. Subsequent post-mortem studies documented extensive white matter shearing, marked atrophy of the tegmentum and basis pontis, mild axonal loss from the pontine reticular formation, but nearly complete preservation of cerebral cortex. Periods of relative EEG synchronization and desynchronization were scored and correlated well with four behaviorally-determined states of arousal. These included unusual alternation between two states of wakefulness, one with stereotyped posturing and another with paucity of movement. Behavioral and electrographic cycling between these states occurred with a strikingly regular periodicity. An abnormal sleep architecture was present. Slow wave sleep (SWS) stages 1-3 progressed appropriately with regard to depth but cycled rapidly and were of shortened duration compared with normal sleep. REM sleep was absent. These findings suggest that: (1) EEG is reflective of state of arousal in this patient with focal subcortical injury, (2) the selective presence of SWS without REM sleep is consistent with experimental studies which indicate that there are multiple generators for SWS in forebrain and brainstem, while REM sleep may be more dependent on lower brain stem mechanisms.

346.2

EFFECTS OF SLEEP DEPRIVATION ON PLASMA CRH LEVELS IN MAJOR DEPRESSION. C. Reist, E. DeMet, C.C. Chen^{*}, A. Chhou^{*}, A. Chicx-DeMet, Depts. Psychiatry, Long Beach VA Medical Center, Long Beach, CA 90822 and Univ. California Irvine, Irvine CA 92717

Corticotropin releasing hormone (CRH) has been the focus of much interest since early studies reported elevation of CSF CRH in patients with major depression. A number of observations suggest that CRH may be involved in coordinating endocrine and behavioral aspects associated with depression. To further understand this relationship plasma CRH levels were studied in 13 inpatient depressed subjects and 10 normal controls. The depressed subjects were treated with one night of total sleep deprivation (SD), an intervention that results in transient improvement in many depressed subjects. Baseline (8:30am) plasma CRH levels did not differ between groups while ACTH and cortisol were significantly elevated in the depressed group. Sleep deprivation resulted in significant reduction of Hamilton Depression (HAM-D) scores. Paired comparisons of pre vs post SD values revealed robust positive correlations between CRH vs ACTH, and CRH vs HAM-D as well as an inverse relationship between CRH and GH. The results confirm that SD is an effective temporary therapeutic treatment for depressive symptoms. This treatment also resulted in concomitant neuroendocrine responses although these changes were not tightly coupled to the clinical response. A notable exception to this observation was CRH levels which paralleled changes in depression ratings after SD ($r = 0.82; p = 0.025$). This finding suggests that plasma CRH may, within individuals, be related to mood state.

346.3

ABNORMAL SLEEP-WAKING RHYTHMS IN PROFOUNDLY RETARDED INDIVIDUALS

Ch. E. Olmstead, R. H. Chaney¹ and C. Givens¹.
Olmstead Assocs, Playa del Rey, CA 90296, UCLA/MRRG
Gp, Lanterman Developmental Ctr, Pomona, CA 91769.

Disruptions of circadian rhythms are frequently seen in individuals with severe brain damage. 22.5% of 1082 residents of a state residential facility for the developmentally disabled showed disturbances of the sleep-waking cycle. We have carried out 24 hr behavioral observations in 41 individuals (Ages 21 to 64 years) to further characterize the rhythm disturbances.

Sleep-waking cycle disturbances ranged from mild to severe with total sleep times that ranged from 25 min to 10.25 hours distributed in from 2 to 18 bouts. Only 7 of the subjects showed normal periods of uninterrupted sleep during the night. The type of insomnia included sleep phase delay in 10 patients and paroxysmal arousals in seven. Extensive daytime sleep, up to 10 episodes, was seen in 7 patients. In general, those individuals whose probable hypothalamic damage was attributable to post-natal causes such as trauma or infection were the most likely to show near normal circadian variations, while those with prenatal etiologies were the most severely disrupted.

346.5

MECHANISMS OF POST-ASYSTOLE CORONARY BLOOD FLOW INCREASE DURING SLEEP. L.W. Dickerson, R.L. Verrier, Department of Pharmacology, Georgetown University School of Medicine, Washington DC 20007.

Spontaneous asystoles have been observed during sleep in normal humans and canines. We have recently shown in sleeping dogs that episodes of asystole of 1.1-8.0 sec are followed by surges in coronary blood flow (CBF) averaging 31% but ranging up to 84%. This study examined whether the post-asystole increase in CBF was due to (a) primary neurogenic coronary vasodilation, or (b) reactive hyperemia in response to the CBF decline during asystole. Five chloralose-anesthetized dogs were instrumented to record lead II ECG, femoral artery blood pressure (BP), and left circumflex (LCX) coronary artery Doppler flow. The cervical vagi were sectioned and the distal end of the left vagus was stimulated at 10 Hz to produce asystoles of approximately 2 sec duration. Then, the pericorony nerves of the LCX were damaged both mechanically and by formalin application. After a 20 min rest period, the vagus nerve was restimulated and the results were compared (means \pm SEM).

% Change from Pre-Asystole Baseline

	HR x BP	CBF
Normal	-30 \pm 2	27 \pm 6
Coronary denervation	-25 \pm 2	-1 \pm 4 (p<0.01)

Conclusions: (1) Vagus nerve excitation simulates the post-asystole increase in CBF observed during sleep, and (2) it appears to be due predominantly to primary vasodilation and not cardiac metabolic factors since damaging the pericorony nerves eliminates the CBF surge.

346.4

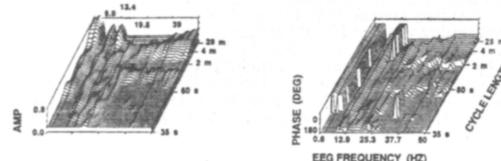

DELTA AMPLITUDE SHIFTS FOLLOWING 48 HOURS OF SLEEP DEPRIVATION IN HUMANS. H. Sing*, M. Thomas*, G. Belenky, N. Shepanek*, D. Thorne*, S. Balwinski*, Y. Shaham*, D. Penetar*, U. McCann, & D. Redmond*. Dept. of Behavioral Biology, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

Spectral analysis has been used to delineate EEG frequency changes during sleep stages and to characterize changes in the awake EEG of subjects (Ss) deprived of 24 hours of sleep. We instrumented 6 Ss for EEG, EOG, and EMG to document wakefulness during a PET study of brain glucose metabolism after prolonged sleep loss and while performing a cognitive task. All Ss were awake in both the rested and sleep deprived conditions, with few microsleeps in either condition. Spectral analysis of the delta frequency band (.75-3.75 Hz) in .5 Hz intervals revealed a shift in relative delta amplitude in both the C3 and Oz leads. Relative amplitude was greater in the sleep deprived condition than rested for the first third of the delta band (.75-1.75 Hz). This finding was reversed for the last third of the band (2.5-3.5 Hz). The increase in relative amplitude in the lowest delta frequencies suggests that neurons may be firing more synchronously, similar to slow wave sleep, and that this may underlie the slowing in mental performance resulting from sleep loss and/or a need to sleep. As a physiological marker of sleepiness, the changes in the delta frequencies may be used to distinguish alert Ss from sleepy Ss.

346.6

COHERENCE OF EEG SPECTRAL CHANGES AND VIGILANCE S. Makiej, M. Inlow and R. Galambos, Naval Health Research Center, San Diego, CA.

Ten male subjects participated in a total of 13 half-hour yes closed auditory vigilance tasks simulating passive sonar target detection. Targets were brief noisebursts peaking 6 dB above continuous background noise presented at a mean rate of 10 per minute. Button press responses to target bursts were recorded and fluctuations in vigilance estimated by fraction of targets responded to within a 32 s moving window. EEG was collected continuously from 13 scalp sites. The power spectrum of the local error rate measure was dominated by cycle lengths of 3-4 minutes and longer. Coherence between local error rate and EEG power in 81 frequency bins from 0.6-50 Hz was computed for each site and significance of coherence was determined by a Monte Carlo procedure. The figure plots coherence amplitude (square root coherence) at site Cz. 1) The EEG band structure is more marked in the coherence plane than in the mean EEG power spectrum. 2) A distinct band of significant coherence at high EEG frequencies for cycle lengths near 90 s per cycle is present at each scalp location. 3) At all scalp sites and for all cycle lengths, the coherence phase plane contains a sharp phase reversal near 6 Hz. 4) For almost all frequencies, EEG spectral changes neither lead nor lag performance changes.

INGESTIVE BEHAVIOR: SALT AND WATER

347.1

LICK RATE ANALYSIS OF SODIUM TASTE-DRIVE INTERACTIONS.

P.A. Breslin, C.M. Zambito¹, J.M. Kaplan, J.A.C. Spector, and H.F. Grill.
Psych. Dept., Univ. of Penn., Phila., PA 19104 and ¹Dept. of Psych., Univ. of Florida, Gainesville, FL 32611.

The physiological mechanisms responsible for sodium drive and sodium taste have received much attention. However, little is known about how these two factors combine to control sodium ingestive behavior. To measure this interaction we examined initial lick rates for different NaCl solutions in sodium replete and sodium deplete rats. In Experiment 1, the lick rates of six groups of rats, each consuming one of 6 NaCl solutions, were recorded at the beginning (first 3 min) of a NaCl meal (40 min), when post-ingestive influences of the test stimulus would be minimal. All six groups were offered the solutions while in the replete and deplete states in counter-balanced order. Depletion was accomplished by a 10 mg injection (ip) of the diuretic furosemide. All rats also received free access to water and Na⁺ deficient chow in the home cage. Replete rats' initial lick rates increased nonmonotonically with concentration peaking at isotonicity, thus resembling NaCl ingestion concentration functions. The concentration lick rate function for the deplete rats were uniformly elevated, but retained the same shape as that of the replete rats. In Experiment 2 eight naive rats received access to all 6 NaCl solutions within a single session (40 min) in either the replete or deplete states. The solutions were repeatedly presented to the rats in a random order for brief 10 sec exposures with at least a 5 sec ITI. The replete and deplete lick rate functions strongly resembled those obtained in Experiment 1. When the deplete rats' lick rate functions were broken into the three drive states coinciding with the beginning, middle and end of the sessions, three lick rate concentration functions were derived. The functions shifted down over the session, but retained their shape. Overall, drive state dramatically affected the absolute lick rates, but the relative affective quality of the solutions, as revealed by the shape of lick rate concentration functions, was unaffected. This research was supported by NIMH program project #43787.

347.2

NaCl INTAKE INCREASES DOPAC/DA IN ACCUMBENS AND OLFACTORY TUBERCLE AND 5HT/5-HT IN AMYGDALA IN SODIUM DEPLETED RATS. S.P. Frankmann, L. Broder*, J.H. DoKko*, D.V. Veltung* and G.P. Smith. Bourne Lab, NY Hosp.- Cornell Med. Ctr., White Plains, NY 10605.

Food intake following food deprivation increases central DA and 5-HT activity. To ask whether NaCl intake following sodium (Na⁺) depletion also increases central DA and 5-HT activity, male, Sprague-Dawley rats were given Na⁺ deficient diet overnight and brain regions were sampled at 24h after one of three treatments (n=16/ treat.): 1) vehicle injection, 2) Lasix (furosemide) injection (10 mg, sc) or 3) Lasix injection and 0.3M NaCl intake (for 9 min). DA, DOPAC, HVA, 5HT and 5HIAA were measured by HPLC-EC for amygdala (Amyg), caudate, dorsal hindbrain, hypothalamus, nucleus accumbens (Acc.) and olfactory tubercle (OT).

Sodium depletion alone significantly increased 5HIAA/5-HT activity in the Acc. Ingestion of NaCl ($\bar{x} \pm$ SEM = 8.0 \pm 0.8 ml) after Na⁺ depletion produced increases of 5HIAA/5-HT in the Amyg, and DOPAC/DA in the Acc.

		Vehicle	Lasix	Lasix & 0.3M NaCl
DOPAC/DA:	OT	0.17 \pm 0.01	0.18 \pm 0.09	0.20 \pm 0.01*
	Acc.	0.25 \pm 0.02	0.28 \pm 0.02	0.33 \pm 0.03*
5HIAA/5-HT:	Acc.	0.76 \pm 0.03	0.88 \pm 0.03*	0.91 \pm 0.05*
	Amyg.	0.77 \pm 0.03	0.84 \pm 0.04	0.94 \pm 0.04*

* = p < .05 vs Vehicle.

The increases in 5-HT and DA metabolism suggest that Na⁺ depletion stimulates 5-HT terminals in the Acc. and that intake of NaCl during Na⁺ depletion stimulates 5-HT terminals in the Amyg, and DA terminals in the Acc. and OT. We hypothesize that 5-HT and DA activity associated with NaCl intake are involved in the sensory and/or hedonic processing of the effects of NaCl intake in the Na⁺ depleted rat.

347.3

BED NUCLEUS OF THE STRIA TERMINALIS LESIONS: REDUCTION OF YOHIMBINE- AND FUROSEMIDE-INDUCED SALT INGESTION. A.M. Zardetto-Smith, T.G. Beltz and A.K. Johnson, Depts. of Psychology and Pharmacology, University of Iowa, Iowa City, IA 52242.

Subcutaneous (sc) injection of the alpha-2 antagonist yohimbine (YOH) rapidly produces salt ingestion in sodium replete rats. Previously, we demonstrated that rats with bilateral lesions of the central nucleus of the amygdala (CeA) show a significant reduction in their intake of 2% NaCl in response to sc injection of YOH. Rats with CeA-lesions also demonstrated a significant decrease in their intake of 2% NaCl after furosemide depletion (Zardetto-Smith et al., *Fed. Proc.* 5:A1145, 1991). The bed nucleus of the stria terminalis (BST), particularly its lateral subdivision, is similar to the CeA in many aspects of its cyto- and chemoarchitecture, connections, and function. In this study, cumulative 3-hr intakes of 2% NaCl after sc injections of YOH (3 mg/kg) or ip furosemide-depletion (FD) were measured in male, Sprague-Dawley rats both before and after bilateral electrolytic lesions of the BST (n = 6) and compared to a group receiving sham lesions (n = 6). Prior to surgery, the groups drank equivalent amounts of 2% NaCl in response to YOH and FD treatments. After surgery, sham-lesion rats showed a slight increase in their intake of 2% NaCl following sc YOH. However, intake of 2% NaCl in response to YOH was significantly decreased post-BST lesion when compared to both pre-surgery intake of the group and post-surgery intake of the sham group. BST-lesioned rats also showed a significant decrease in their intake of 2% NaCl after FD, while intake of the sham group remained unchanged. Before and after surgery, the groups drank equivalent amounts of water in response to 5% hypertonic saline. The results suggest the BST, like the CeA, may be an important integrative site for one or more afferent signals which mediate salt appetite. (Supported by NIH Grants HL44565 and HL14338).

347.5

CHORDA TYMPANI TRANSECTION ELIMINATES AMILORIDE-SENSITIVITY OF THE INGESTIVE RESPONSE TO NaCl IN THE RAT. S.I. Sollars*, E.M. Taylor* and J.L. Bernstein, Department of Psychology, University of Washington, Seattle, WA. 98195.

Fungiform papillae on the anterior tongue are the site of gustatory receptors which are maximally responsive to NaCl stimulation. In the rat, this receptor population is innervated by the chorda tympani nerve (CT) which contains fibers displaying a relatively specific responsiveness to NaCl and which are blocked by the Na transport blocker amiloride. Although electrophysiological studies support a specific role for the CT in NaCl responsiveness, behavioral studies indicate that rats with bilateral transection of the CT are, at the most, only marginally affected in their NaCl consumption. To further characterize the role of the CT in responsiveness to NaCl, the present study examined whether behavioral expression of amiloride sensitivity is dependent upon the CT.

Wistar rats received bilateral CT transection (N=8) or sham surgery (N=8). After surgery they were adapted to a 23-hr water deprivation schedule and trained to drink from a lickometer which provided brief presentations of taste solutions. Individual licks were detected by a photocell and recorded by microcomputer. To assess amiloride-sensitivity animals licked for a 3% NaCl solution for 3 minutes after either water or 100µM amiloride hydrochloride exposure. In intact rats, licking for 3% NaCl was significantly increased by preexposure to amiloride (p<.01). In contrast, after bilateral CT transection, amiloride preexposure did not significantly affect licking for 3% NaCl. This suggests that, in the rat, the CT is the primary gustatory pathway conveying amiloride-sensitive NaCl signals.

347.7

A ROLE FOR THE SALIVARY GLANDS IN THIRST AND SODIUM APPETITE IN RATS. T.M. Nicholson, M.J. Fregly* and N.E. Rowland, Depts Psychology & Physiology, Univ of Florida, Gainesville, FL 32611-2065

Male Sprague-Dawley rats were either completely salivarectomized (SX) or were sham operated (SHM). Completeness of SX was verified at the end of the studies by a test of prandial drinking. Starting 1 mo postoperatively (mean body weights were similar), tests of water and NaCl intake were administered.

The SX rats drank comparable amounts of water to SHM after SC injection of angiotensin (ANG) II, but drank 50-80% less than SHM following SC injections of either ANG III, isoproterenol, serotonin, polyethylene glycol, or ramipril (an ANG converting enzyme inhibitor). Stimulated plasma renin activities were similar in both groups.

Studies on salt appetite also suggested reduced ANG responsiveness in SX. The spontaneous preference/aversion function for NaCl intake was unaffected by long term SX, but the expression of NaCl appetite by chronic treatment with ramipril was completely absent in SX rats. In contrast, the appetite to either acute depletion of sodium or chronic administration of DOCA (mineralocorticoid) was virtually normal in SX rats.

[Supported by NSF BNS89-09439 and ONR N00014-88-J-1221].

347.4

ARTERIAL HYPOTENSION INCREASES THIRST, BUT NOT SALT APPETITE, TO ICV ANGIOTENSIN. R.L. Thunhorst and A.K. Johnson, Depts. of Psychology and Pharmacology, Univ. of Iowa, Iowa City, Iowa, 52242.

Drinking elicited by iv infusion of angiotensin II (AII) is enhanced when the concurrent pressor response is reduced. We tested if reduced blood pressure likewise would enhance drinking and salt ingestion elicited by icv infusion of AII. Rats received iv minoxidil (25 µg/kg/min) plus captopril (0.33 mg/min) to lower blood pressure and prevent endogenous AII formation. The resulting hypotension doubled water intakes compared with iv vehicle infusions (main effect) during 90 min of icv AII at 4 (3.8 vs 1.8 ml) and 16 (12.0 vs 6.2 ml) ng/hr. The increased intakes were maximal in the first 30 min of icv AII. Rats with access to both water and 0.3 M NaCl during 180 min of icv AII (16 ng/hr) responded to hypotension with increased water intakes in the first 30 min of icv AII (7.7 vs 4.4 ml), but not overall (14.4 vs 12.5 ml; interaction effect) compared to intakes during iv vehicle. Hypotension did not increase salt intakes (2.6 vs 3.2 ml). Overall, hypotension greatly reduced urine volumes, resulting in considerable fluid retention. The results indicate that AII and baroreceptor mechanisms interact in hypotensive states, enabling icv AII to elicit greater water intakes, but not greater salt intakes, in the face of fluid retention.

Supported by NIH grants HL44565 and HL14338.

347.6

DIFFERENTIAL EFFECTS OF PROLONGED SODIUM DEPRIVATION ON SALT APPETITE IN PREPUBESCENT AND SEXUALLY MATURE RAT PUPS. M.G. Scheidler, E.M. Stricker, J.G. Verbalis, Departments of Behavioral Neuroscience and Medicine, University of Pittsburgh, Pittsburgh, PA 15260.

Adult male rats deprived of dietary sodium for 8 days express a robust salt appetite, as do ovariectomized but not intact female rats (see table). These and other results suggested that estrogen in some way suppresses the salt appetite in rats induced by extended sodium deprivation. To test this hypothesis in a physiologically intact model, 30-day-old prepubescent male and female rats were placed on 4 and 8 days of sodium deprivation. After 4 days of deprivation, the juvenile pups, like the intact adults, showed a modest saline intake that was comparable in the males and females. After 8 days of sodium deprivation, juvenile male and female pups both showed equivalently enhanced salt appetites, which on an intake-to-weight basis was similar to that of intact male rats. However, when 40-day-old sexually mature male and female rats, were tested under conditions of sodium deprivation, they behaved like their adult counterparts in that only males expressed robust saline intakes (see table).

Sex	WATER	0.5 M NaCl	Sex	WATER	0.5 M NaCl
Adult	19.6 ± 2.6	19.4 ± 1.9	Adult	10.9 ± 1.4	7.5 ± 1.2
Gonad-x	11.9 ± 1.4	19.7 ± 1.5	Ovar-x	8.3 ± 1.8	18.2 ± 1.9
30 day	10.7 ± 0.7	6.5 ± 1.4	30 day	9.6 ± 0.7	6.6 ± 2.8
40 day	14.7 ± 3.2	20.8 ± 2.7	40 day	9.4 ± 2.4	13.7 ± 1.5

These studies in prepubescent and sexually mature juvenile rats therefore provide additional evidence in support of an inhibitory role of estrogen on salt appetite under conditions in which salt appetite is especially pronounced.

347.8

GENDER EFFECTS ON NaCl PREFERENCE AND TASTE REACTIVITY Q. Galaverna, J. Schalkin*, F.W. Flynn, M. Havens, J. Nardoizzi*, P. Wilson* and R.R. Moore*, University of Pennsylvania, and University of Wyoming.

Previous studies have demonstrated that sexually mature Sprague-Dawley female virgin rats ingest greater amounts of hypertonic NaCl than age matched males when sodium replete; they also ingest greater amounts of the salt when sodium hungry. In the following study we inquired whether the female's response to NaCl is different across a range of concentrations of NaCl in both taste reactivity tests using oral-facial profile, and in intake tests. For the taste reactivity test, rats were fitted with chronic cannulae and infused in ascending order with either .03, .15, .3 or 1 molar NaCl. We also tested their ingestion of the NaCl in home cage intake tests where the NaCl was given along with water and food. In the taste reactivity test, we found that the females expressed greater oral-facial ingestive responses to the .15 and the .3 molar NaCl than the males did. And in the intake tests we found that the females ingested greater amounts of the NaCl at .15, .3 and at 1 molar concentrations. These results when taken together provide evidence that the basic taste reactivity to NaCl is different in females than males, and provides further evidence that the female's ingestion of NaCl is also greater. The enhanced avidity for NaCl, in the female over that of the male, may lie in the demands that she faces for sodium and other salts during pregnancy and lactation.

347.9

EFFECTS OF HYDRATIONAL STATUS AND LEARNING ON THE DRINKING ELICITED BY INJECTIONS OF MUSCIMOL INTO THE MEDIAN RAPHE NUCLEUS. M.R. Pitzer, T.R. Stratford & D. Wirtshafter. Dept. Psych., Univ. Ill. at Chicago, Box 4348, Chicago, Ill.

We have shown that microinjections of the GABA-A agonist muscimol into the median raphe nucleus (MR) lead to large increases in water intake by nondeprived rats. In the present study we examined whether this drinking behavior could be inhibited by overhydrating the subjects. Preloading naive animals with 40 ml/kg of water attenuated muscimol-induced drinking. In contrast, similar preloads were ineffective in animals experienced with drinking under muscimol. These findings suggest that while the initial occurrence of muscimol induced drinking is dependent on the hydrational status of the animals, the drinking response may become conditioned to the muscimol state and thus independent of hydrational factors.

Further support for a role of learned factors in muscimol-induced drinking is provided by another study in which we demonstrated that animals experienced with drinking under muscimol showed larger water intakes when tested with food and water present than did rats experienced only with feeding under muscimol.

347.11

INTRAGASTRIC HYPERTONIC NaCl ELICITS DRINKING WITHOUT SYSTEMIC DEHYDRATION IN RATS. F.S. Kraly and Y.M. Kim. Dept. of Psychology, Colgate Univ., Hamilton, NY 13346.

Intragastric infusion of hypertonic NaCl increases plasma vasopressin without changing plasma osmolality in rats (Kwon et al., *Am. J. Physiol.* 259: E19, 1990). We examined whether such infusions elicit drinking without systemic dehydration. Adult Sprague-Dawley male rats were surgically prepared with a chronic gastric catheter. A test was initiated by a 2 ml (in 1 min) infusion of 300, 600 or 1200 mOsm NaCl. For rats (n=8) not deprived of food or water, 1200 mOsm NaCl decreased (p<.01) the latency to initiate drinking and increased (p<.05) 60-min water intake from 0.3 ± 0.2 ml on baseline (300 mOsm NaCl) to 2.3 ± 0.6 ml. For rats (n=5) food-deprived for 24 hr, 600 mOsm NaCl decreased (p<.05) the latency to initiate drinking without significant change in 60-min water intake; 1200 mOsm NaCl increased (p<.05) 60-min water intake from 0.4 ± 0.2 (300 mOsm baseline) to 6.6 ± 1.9 ml. Plasma osmolality and hematocrit (taken at the time drinking was initiated) were not affected by 600 or 1200 mOsm NaCl when compared to baseline (300 mOsm). Thus, intragastric hypertonic NaCl can elicit drinking in the absence of or prior to a change in systemic osmolality. These results are consistent with the hypothesis of an osmosensitive gastrointestinal and/or hepatic-portal mechanism for eliciting drinking in advance of systemic dehydration in the rat.

347.13

DIFFERENTIAL EFFECT OF DuP 753 ON VARIOUS TYPES OF EXPERIMENTALLY-STIMULATED WATER INTAKE IN RATS. N.E. Rowland and M.J. Fregly*. Depts Psychology & Physiology, Univ Florida, Gainesville, FL 32611

When administered SC, DuP 753, an angiotensin (ANG) type 1 receptor (AT-1) antagonist inhibits water intake evoked by SC ANG II in rats. We now extend this finding to intake after SC ANG III, suggesting either that both of these ANG peptides engage one receptor or that DuP blocks two sites. In contrast, DuP 753 (up to 20 mg/kg SC) did not inhibit water intake after SC isoproterenol (ISO), serotonin, or polyethylene glycol. The dipsogenic action of these agents thus may not depend upon the stimulation of AT-1 receptors accessed by SC-administered DuP 753. Alternatively, in the case of ISO, the plasma renin activity already enhanced by either ISO (10x basal) or DuP (24x basal), was further elevated (44x basal) by their combination, and the ANG II formed may overcome AT-1 blockade.

DuP 753 (SC) inhibited water intake after cerebroventricularly-administered (ICV) ANGII, suggesting that DuP 753 crosses the blood-brain barrier. DuP 753 (ICV) potentially reduced water intake after ICV ANG II (10 ng): the 50% inhibitory dose was 10-100 ng. In contrast, DuP 753 (100 ug, ICV) did not inhibit ISO (25ug/kg, SC)-induced drinking. Grant support: NSF BNS 89-09439, ONR N00014-889-1221.

EFFECTS OF DEPRIVATION AND PALATABILITY ON THE DRINKING BEHAVIOR INDUCED BY INJECTIONS OF MUSCIMOL INTO THE MEDIAN RAPHE NUCLEUS. I. Shim, T.R. Stratford & D. Wirtshafter. Dept. Psychol. Univ. Ill. at Chicago, Box 4348, Chicago, Ill.

In previous experiments we have demonstrated that robust feeding and drinking can be produced in nondeprived animals by injections of the GABA-A agonist muscimol into the median raphe nucleus (MR). In the current study we examined the extent to which muscimol induced drinking can be altered by fluid deprivation or by changes in palatability of the fluids presented.

Nondeprived rats were trained to drink either a dilute or a concentrated sucrose solution and baseline intakes of the concentrated solution were higher than those of the dilute solution. Intra-MR injections of muscimol produced a significantly larger increase in the intakes of the concentrated than of the dilute solution, relative to baseline intakes. In an analogous experiment, muscimol produced equivalent increases, relative to baseline, in deprived and nondeprived rats. These results indicate that intra-MR muscimol interacts differently with different palatability and deprivation induced drinking.

IBOTENIC ACID LESIONS OF THE DIAGONAL BAND OF BROCA RESULT IN EXAGGERATED POLYETHYLENE GLYCOL-INDUCED DRINKING BEHAVIOR. M.J. Sullivan, J.T. Cunningham, R. Nissen, A.M. Allen, E. Coderre and L.P. Renaud. Neuroscience Unit, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9

Drinking behavior induced by peripheral angiotensin appears to be influenced by blood pressure. Robinson and Evered (1987) have demonstrated that normalization of blood pressure during angiotensin infusions results in increased water intake. Electrophysiological data from this laboratory has demonstrated that the diagonal band of Broca (DBB) mediates baroreflex suppression of spontaneous activity of the vasopressinergic magnocellular neurons of the supraoptic nucleus. In this study, we examined the possibility that the DBB might also be involved in the regulation of water intake.

Ibotenic acid lesions of the vertical limb of the DBB were made in male Long Evans rats. Rats were injected with 0.5 µl of 5µg/µl ibotenic acid in phosphate buffered saline. A second group received control injections of 0.5µl the vehicle. Following a week of recovery, animals were tested for drinking responses to 0.9%, 4% and 6% saline (1ml/100 gm sc) and 40% polyethylene glycol (1ml/100 gm sc). Tests were carried out in home cages and were spaced a minimum of 48 h apart.

DBB lesioned rats drank significantly more than control rats in response to polyethylene glycol. The animals began drinking earlier and drank more in total volume over the course of five hours following the injection. No differences were seen in drinking responses to two doses of hypertonic saline.

The results suggest that the DBB plays a role in modulating drinking in response to hypovolemia.

EFFECTS OF AREA POSTREMA LESIONS ON SCHEDULE-INDUCED POLYDIPSIA IN RATS. K.-P. Ossenkopp and L. A. Eckel. Dept. Psychology, Univ. of Western Ontario, London, Ontario, CANADA N6A 5C2.

Food deprived rats develop excessive drinking when exposed to an intermittent schedule of food pellet delivery (schedule-induced polydipsia, SIP). In the present study acquisition of SIP was measured in male adult rats with area postrema lesions (APX) or sham lesions (APS). Following surgery the animals were given a 2 week rest period. Subsequently all rats were reduced to 85% of free-feeding body weight. During daily 1 hr conditioning sessions the rats were put in standard operant chambers and exposed to a fixed-time food presentation schedule of one 45 mg food pellet every 60 s. Water was freely available during the conditioning session and fluid intake levels were recorded every 15 min. Analysis of the results indicated that the APX rats showed significantly lower rates of SIP acquisition (p<0.01) than the control animals. When a 0.08 M NaCl solution was substituted for the water in the operant chamber, the APX rats drank more fluid than the APS animals. Substitution of a 0.08 M LiCl solution resulted in a large and rapid reduction in fluid intake in both groups, but the rats with area postrema lesions drank significantly (p<0.05) more of the LiCl solution than the sham lesioned rats.

347.15

A DIPSOGENIC EFFECT OF EXOGENOUS ANGIOTENSIN-II IN ICR MICE IS PARTIALLY MASKED BY ITS PRESSOR ACTION. D.A. Czech.

Dept. of Psychology, Marquette Univ., Milwaukee, WI 53233. Several small animals, including mice, are reported to be relatively insensitive dipsogenically to peripheral Angiotensin-II (AII). This might be partly attributable to AII's pressor action interfering with a drinking system/response.

An initial dose of AII (200 or 600 µg/kg) or 0.15 M NaCl vehicle (VEH), plus 35 mg/kg captopril (CAP) was given sc; followed 15 min later by an injection of d,l-isoproterenol HCl (ISOP) (100 or 200 µg/kg) or VEH. Three additional groups first received a VEH injection, followed by ISOP (100 or 200 µg/kg) or VEH, as a control series for ISOP-induced drinking. Following the second injection, mice were given access to deionized water (no food present) and intake was monitored for up to 3 hr during the light phase of the L/D cycle. Cumulative intakes were evaluated with ANOVA and t-test procedures. Alpha was set at p<0.05.

Both AII and ISOP stimulated modest, but significant, drinking. For both agents, both latency to drink and amount consumed were quite variable. Further, mean intake in response to 600 µg/kg AII was significantly higher when mice were also given 100 µg/kg ISOP; 200 µg/kg ISOP did not significantly facilitate AII-induced drinking. ISOP did not significantly affect drinking to 200 µg/kg AII. These data suggest greater dipsogenic sensitivity to peripherally administered AII in the mouse than was previously reported, and also indicate that a dipsogenic effect of AII is partially masked by AII's pressor action.

DRUGS OF ABUSE—COCAINE: ANTAGONISTS AND SEROTONIN

348.1

THE EFFECTS OF SELECTIVE D1 AND D2 RECEPTOR ANTAGONISTS ON KETAMINE SELF-ADMINISTRATION IN RATS. C.B. Hubner and J.E. Moreton. University of Maryland School of Pharmacy, Baltimore, MD 21201

A role for dopamine in mediating the reinforcing effects of psychomotor stimulant drugs has been suggested from studies which find that dopamine antagonists increase rates of responding maintained by cocaine and amphetamine under fixed-ratio (FR) schedules of reinforcement. The purpose of the present study was to investigate whether dopamine plays a similar role in mediating the reinforcing effects of ketamine. The effects of the D1 antagonist, SCH 23390, and the D2 antagonist, spiperone, on rates of responding maintained by ketamine were examined. Sprague-Dawley rats, trained to self-administer intravenous ketamine (2.0 mg/kg/injection) on a FR 5 schedule, were pretreated 30 minutes prior to the session with s.c. 2.0 - 20.0 µg/kg SCH 23390 (n=6) or 2.0 - 40.0 µg/kg spiperone (n=6). At low to intermediate doses of either antagonist, there was no effect on response rate. Decreases in rates of responding were obtained at the highest doses tested. We have previously demonstrated that SCH 23390 and spiperone produce increased rates of responding maintained by cocaine under a FR 5 schedule, suggesting a reduction in the reinforcing effects of cocaine. Taken together, these data suggest that D1 and D2 receptors are not critical for mediating the reinforcing effects of ketamine. [Supported in part by DA05292 (CBH), BRS grant 2S07RR05770-10 (CBH, JEM) and DA03173 (JEM).]

FOURPHIT INHIBITS COCAINE-INDUCED HYPERACTIVITY IN RATS. M.M. Schweri, B.R. de Costa* and K.C. Rice*. Mercer Univ. Sch. Med., Macon, GA 31207 and NIDDK, Bethesda, MD 20892.

Fourphit (4-isothiocyanato-1-[1-phenylcyclohexyl]piperidine; FPH), a phenylcyclidine derivative, irreversibly inhibits binding *in vitro* to the stimulant recognition site on the dopamine transporter, where cocaine (COC) is thought to exert its stimulant and reinforcing actions. The aim of this work was to determine whether FPH would inhibit the locomotor effect of COC in male Sprague-Dawley rats. Rats were acclimated overnight in individual cages in the activity monitors. After recording baseline activity for thirty min., rats were injected i.v. with 20 mg/kg of FPH (controls received vehicle [VEH]), and activity was monitored for 30 min. longer. Twenty-four hrs. later, both VEH and FPH-treated animals were challenged with 15 mg/kg COC·HCl (i.p.) and activity was recorded for 60 min. FPH significantly attenuated COC-induced hyperactivity (total, ambulatory, and nonambulatory) for the first 40 min. after injection of the stimulant, but not during the last 20 min. Surprisingly, no significant difference was found in binding to the stimulant recognition sites in striatal tissue of VEH and FPH-treated rats (measured using the [³H]methylphenidate radioreceptor assay), whether determined one hr. after injection of FPH or at the conclusion of the experiment. These results suggest that FPH antagonizes COC-induced hyperactivity, probably at a site other than the dopamine uptake complex. (Supported by grants from NIDA [ROI#DA06305] and NINDS [R15#NS28584].)

348.2

ATTENUATION OF COCAINE SELF-ADMINISTRATION BY THE SELECTIVE D1 DOPAMINE RECEPTOR AGONIST A68930.

J.E.G. Williams, P. Curzon, and D.B. Britton. Neuroscience Research, Dept. 47U, Abbott Laboratories, Abbott Park, IL 60064.

There is evidence that the reinforcing properties of cocaine are mediated in part by the actions of endogenous dopamine acting on D1 and D2 dopamine receptors. Acute blockade of D1 (or D2) receptors leads to a compensatory increase in the rate of cocaine self-administration (S/A) (Koob, et al., 1987). To more clearly assess the functional role of the D1 receptor in the maintenance of cocaine S/A, we tested the hypothesis that supplemental activation of the D1 receptor by pre-treatment with a potent D1 agonist (A68930 [1 α , 3 β] 1-aminomethyl-5,6-dihydroxyphenylisochroman HCL) would decrease the rate of cocaine S/A. Rats implanted with chronic intravenous catheters were trained to bar-press for cocaine (0.75 mg/kg/infusion) administered on an FR-5 schedule. Animals pre-treated with saline showed an average of from 17.2 to 20.2 infusions per 2 hour session. Pre-treatment with A68930 (0.32, 1.0, 1.8, and 2.5 µmol/kg, sc) resulted in decreases in S/A by 7.0, 43.0, 32.0, and 65.0% respectively. While the sensitivity of individual animals to the effects of the agonist varied, all rats showed a consistent, significant decrease in S/A within this dose range. These data are not in themselves conclusive, but are consistent with the hypothesis that rats regulate levels of cocaine self-administration to achieve an optimal level of activation of the D1 receptors.

348.4

ROLE OF GLUTAMATERGIC TRANSMISSION IN MEDIATING THE LOCOMOTOR STIMULATION PRODUCED BY COCAINE AND DOPAMINE RECEPTOR AGONISTS. F.G. Kaddis*, N.J. Uretsky, L.J. Wallace. College of Pharmacy, The Ohio State University, Columbus, OH 43210.

The injection of DNQX, an antagonist of AMPA/kainate (A/K) receptors, into the nucleus accumbens (NA) has been shown to antagonize the locomotor stimulant actions of amphetamine. To study the role of A/K receptors in the locomotor stimulation induced by drugs that enhance DA transmission, the effect of DNQX was studied on the locomotor stimulant responses to cocaine and DA receptor agonists. Cocaine (20 mg/kg, i.p.) produced a 5 fold stimulation of locomotion, which was almost completely antagonized by DNQX (1 µg) in the NA. Similarly DNQX antagonized the stimulation produced by the co-administration of a D-1 and D-2 agonist. In a microdialysis study, cocaine (20 mg/kg, i.p.) did not significantly increase the extracellular levels of glutamate in urethane-anesthetized rats. However, infusion with high potassium CSF (80 mM) produced a 3.6 fold increase over basal levels. Thus, the activation of A/K receptors is necessary for the stimulant response to DA agonists, but is not associated with an increase in extracellular glutamate in anesthetized animals.

348.5

D-SERINE MODULATION OF PHENCYCLIDINE- AND DIZOCILPINE-INDUCED CHANGES IN ACTIVITY AND MOVEMENT PATTERNS IN RATS. V.D. Lehmann-Masten, M.P. Paulus and M.A. Geyer. UCSD Dept of Psychiatry, Lab of Biol Dynamics and Theoret Med, La Jolla, CA, 92093

The behavioral effects of d-serine on animals treated with either phencyclidine (PCP 5.0 mg/kg) or dizocilpine (DIZ 0.5 mg/kg) were assessed in the Behavioral Pattern Monitor (BPM). The BPM provides quantitative assessments of the animals' horizontal movements (crossovers) and investigatory responses, and also provides information about the geometrical patterns of movements. These patterns can be quantified by the spatial scaling exponent, *d*, describing the relationship between path length and measurement resolution. The contributions to the overall behavior of different geometrical patterns, such as long straight paths versus local circumscribed movements, were assessed by the spectrum of geometrical scaling exponents, *f(d)*. 36 male Sprague-Dawley rats were injected with d-serine (0, 100 or 300 mg/kg, i.p.), a strychnine-insensitive glycine agonist, and tested in the BPM. In addition, the effect of d-serine (100 or 300 mg/kg) on DIZ (0.5 mg/kg, i.p.) or PCP (5.0 mg/kg, s.c.) induced behavioral changes were assessed in the BPM. DIZ and PCP increased the number of crossovers, as previously reported, and changed the overall geometrical movement patterns. The overall geometrical path structure was characterized by increased local or circumscribed movements (increased *d*). The *f(d)* function revealed that this dramatic increase in highly local movements was also accompanied by a strong decrease in long distance-covering movements. Although d-serine pretreatment potentiated the PCP-induced increase in crossovers, it did not affect the DIZ-induced hyperactivity. D-serine pretreatment attenuated both the PCP- and DIZ-induced increase in the spatial scaling exponent, *d*. The *f(d)* function revealed that this attenuation was due to an effect on the highly local as well as on straight path patterns. These findings indicate that changes in patterns of activity induced by PCP and DIZ may be modulated by the glycine receptor associated with the NMDA channel complex.

348.7

ANTAGONISM OF THE STIMULANT ACTIONS OF COCAINE IN MICE BY A BENZODIAZEPINE (TRIAZOLAM), A 5-HT₃ ANTAGONIST (ICS 205-930) AND AN NMDA ANTAGONIST (MK-801). S. Williams, G. P. Vincent and J. Sepinwall. Neurobiology & Obesity Research, Hoffmann-La Roche Inc., Nutley, NJ 07110.

The ability of three different types of compounds to block stimulation of locomotor activity induced by cocaine (30 mg/kg i.p.) in mice was evaluated in the Digiscan apparatus. Test compounds were administered 25 min and cocaine 15 min, respectively, before the start of a 1 h test session. Triazolam (0.03 and 1.0 mg/kg p.o.), selected as an agent which depressed activity when given alone, blocked cocaine-induced stimulation on the four key parameters (horizontal activity, total distance, vertical activity, stereotypy counts). This antagonism may have been a consequence of the depressant effects of triazolam alone. ICS 205-930 (0.1 mg/kg i.p.), a selective 5-HT₃ antagonist, did not alter activity when given alone but did produce small, statistically significant decreases in the response to cocaine at some time intervals on three key variables. Interestingly, ICS 205-930 failed to antagonize the effect of cocaine on vertical activity. MK-801 (0.065 mg/kg i.p.), an NMDA antagonist, slightly increased locomotor activity when given alone; it antagonized cocaine on only one parameter, vertical activity. (Additional doses of MK-801 are currently being studied.) This methodology enables qualitative distinctions to be seen among compounds that can antagonize cocaine and should be useful in the search for a novel cocaine antagonist.

348.9

THE ROLE OF SEROTONIN IN MODULATING BASAL AND COCAINE-INDUCED INCREASES IN DOPAMINE OVERFLOW IN THE NUCLEUS ACCUMBENS. A. Pert and C.B. Hubner. NIMH/BPB, Bethesda, MD 20892.

Several studies have suggested that serotonin may influence the behavioral effects of psychomotor stimulants. Since many of these effects are thought to be mediated by dopaminergic systems, the present experiments were designed to investigate the role of serotonin and a serotonin antagonist in modulating extracellular dopamine levels and cocaine-induced increases in extracellular dopamine in the rat using the *in vivo* microdialysis procedure. When compared with vehicle, infusion of serotonin (5×10^{-6} , 10^{-5} and 5×10^{-5} M) through the dialysis probe produced a dose-dependent increase in extracellular dopamine concentrations in the nucleus accumbens. The largest effect (approximately 500% of control) was obtained at the highest concentration examined. The effect of serotonin produced by the intermediate concentration (10^{-5} M) was antagonized by pretreatment with the 5-HT₃ receptor antagonist MDL 72222 (1.0 mg/kg, i.p.). Systemically administered cocaine (25 mg/kg, i.p.) also increased the levels of extracellular dopamine in the nucleus accumbens and in other experiments, stimulated locomotor activity. Ongoing studies are assessing whether MDL 72222 can antagonize these biochemical, as well as behavioral, effects of cocaine.

348.6

THE CALCIUM ANTAGONIST ISRADIPINE INHIBITS COCAINE AND MORPHINE REINFORCING PROPERTIES IN RATS. W.Fratta, A. Kuzmin *, M.C. Martellotta* and G.L. Gessa*. "B.B. Brodie" Dept. of Neuroscience, Univ. of Cagliari, Cagliari, Italy 09124.

Considerable evidence indicates that dopamine is involved in the rewarding action of cocaine and morphine. It has been also shown that both drugs increase dopamine release via calcium dependent mechanism. The effect of the DHP calcium antagonist Isradipine on cocaine and morphine reinforcing properties was investigated by means of place preference and intravenous self-administration (SA) in rats. Isradipine inhibited both cocaine-and-morphine induced place preference at the dose of 1 to 2.5 mg/kg s.c. Pretreatment of the rats with Isradipine (1 to 5 mg/kg s.c.) before morphine or cocaine SA sessions, induced dose-dependent increase in the number of infusions of these drugs. This response pattern was very similar to the one observed when morphine or cocaine were substituted by saline in trained rats not pretreated with Isradipine. These data suggest that Isradipine suppresses the reinforcing properties of morphine and cocaine and may represent an effective pharmacotherapy for treatment of cocaine and heroin abuse.

348.8

PHARMACOGENETIC ASSESSMENT OF THE USE OF CARBAMAZEPINE (CBZ) FOR THE TREATMENT OF COCAINE ADDICTION AND TOXICITY. R. J. Marley & S. R. Goldberg. NIDA-Addiction Res. Ctr., Box 5180, Baltimore, MD 21224.

CBZ is currently being tested in humans as a treatment for cocaine addiction and may be useful in the treatment of some aspects of cocaine-induced toxicity. We have previously shown that there are genetic differences among mouse strains in the development of increased susceptibility to the convulsant effects of cocaine following its repeated administration (cocaine kindling). The present studies evaluated genetic differences in the modulation of the convulsant and epileptogenic effects of cocaine by CBZ in BALB, C57 and SJL mice. The dietary administration of CBZ attenuated the development of cocaine kindling and suppressed the initial susceptibility to cocaine-induced seizures in all 3 strains, however, there were substantial differences among the strains in the degree to which CBZ inhibited cocaine-kindled seizures. Genetic differences in susceptibility to an acute, convulsant dose of cocaine were also observed following chronic CBZ alone, or in conjunction with cocaine kindling. The concurrent administration of CBZ and cocaine also had genotype-specific lethal effects. While little or no lethality was observed among C57 mice when administered either CBZ or cocaine alone, the concurrent administration of the two drugs resulted in 100% of the animals dying by the seventh day. No lethality was observed among BALB and SJL mice that received both drugs simultaneously. The pattern of genetic differences observed in these studies suggests that these strains may provide useful animal models for investigating the mechanisms underlying cocaine kindling and CBZ/cocaine interactions.

348.10

REGIONAL EFFECTS OF COCAINE ON SEROTONIN OVERFLOW FOLLOWING FOCAL APPLICATIONS. A. Zocchi, D.J. Fontana, and A. Pert. BPB, NIMH, Bethesda, MD 20892.

Cocaine prevents the neuronal reuptake of both serotonin (5-HT) and catecholamines. Alterations in dopaminergic (DA) functions by cocaine have been studied extensively and presumably underlie the major behavioral effects of this psychomotor stimulant. Less, however, is known about the actions of cocaine on 5-HT. The purpose of this study was to characterize the effects of focally applied cocaine on 5-HT overflow in rat forebrain structures with microdialysis procedures. A microbore reverse-phase HPLC-EC system was used in order to optimize detection of the relatively low levels of 5-HT in the extracellular space. Microdialysis probes were introduced into either the striatum, n. accumbens, or frontal cortex of chloral hydrate-anesthetized rats. Following stabilization of basal 5-HT levels (approximately 2 — 3 hours), various concentrations of cocaine (0.01, 0.1 and 1.0 mM) were introduced into the targetted brain structure in the perfusate. Focal applications of cocaine produced a concentration-dependent increase in serotonin in all three structures. The striatum, where the three concentrations of cocaine produced 5-HT levels of 226%, 553%, and 1042% of baseline, respectively, appeared to be the most sensitive to cocaine. Basal levels of 5-HT also differed among the three structures. Dialysate levels from the n. accumbens were approximately double those from the striatum, and frontal cortex levels were about half those in the striatum.

The effects of cocaine on 5-HT overflow in the striatum and n. accumbens are somewhat more modest than those found for DA in previous studies. Furthermore, cocaine appeared to have relatively little effect on DA in the frontal cortex, but in this study its effects on 5-HT were considerably more uniform across structures. This would suggest that 5-HT uptake mechanisms are more homogeneous throughout the brain.

COCAINE AND SEROTONIN: EFFECTS OF GEPIRONE ON BEHAVIORAL AND ELECTROPHYSIOLOGICAL PROPERTIES OF ACUTE AND CHRONIC COCAINE. *J.M. Paris, N.E. Goeders¹ and K.A. Cunningham.* Dept Pharmacol Toxicol, Univ Texas Med Branch, Galveston, TX 77550; ¹Dept Pharmacol Therapeut, Louisiana State Univ Med Cent, Shreveport, LA 71330.

Cocaine (COC) is known to interact with the serotonin (5-HT) systems in the brain. Serotonergic drugs which may modify the effects of COC are actively being explored as potential treatments for the cocaine abuser. We examined the effects of the partial 5-HT_{1A} agonist and novel anxiolytic gepirone (GEP) on the behavioral and electrophysiological effects of COC. Male Sprague-Dawley rats (n=8/grp) were treated in automated test enclosures with saline (SAL) or GEP (7.5 mg/kg, ip) followed 15 min later by SAL or COC (10 mg/kg, ip) twice daily for 7 days (Days 1-7). On Day 8, the locomotor activity of rats was monitored after challenge with SAL or COC (10 mg/kg). Comparison of the activity between Day 1 and Day 7 indicated that SAL+COC rats developed behavioral sensitization. Interestingly, the activity of GEP+SAL animals was not different than that of SAL+SAL rats on Days 1 or 7 while prolonged locomotor activity was displayed in GEP+COC vs SAL+COC rats on Day 7. On Day 8, diminished activity in response to COC was observed in GEP+COC vs SAL+COC rats suggesting that GEP pretreatment reduced the expression of COC sensitization. Furthermore, GEP+SAL rats demonstrated significantly lower activity when challenged with COC (10 mg/kg) as compared to SAL+SAL rats suggesting that pretreatment with GEP reduced the expression of the acute effects of COC. Additional rats treated with SAL or GEP (7.5 mg/kg, 2x/day, 7 days) were prepared for single-unit recordings of dorsal raphe 5-HT neurons. The inhibitory response of 5-HT cells to COC appeared to be unchanged in GEP vs. SAL-treated rats. Thus, GEP reduces the behavioral effects of COC in a manner possibly unrelated to GEP-induced changes in 5-HT autoreceptor sensitivity. SPECIFIC 5-HT₂ and 5-HT₃ RECEPTOR ANTAGONISTS FAIL TO ALTER BREAKING POINTS ON A PROGRESSIVE RATIO SCHEDULE REINFORCED BY INTRAVENOUS COCAINE IN THE RAT. *S. Lacosta and D.C.S. Roberts.* Dept. of Psychology, Carleton Univ., Ottawa, Canada, K1S 5B6.

An important role for serotonin in cocaine reinforcement is suggested by the findings that rats, on a Progressive Ratio (PR) schedule, will respond to higher breaking points following lesions of 5-HT systems and lower breaking points following pretreatment with the 5-HT re-uptake inhibitor, fluoxetine.

In an attempt to determine which serotonin receptors are involved, we investigated the effects of pretreatment with ketanserin and MDL 72222 (a specific 5HT₂ & 5HT₃ antagonist, respectively) on cocaine self-administration.

Neither ketanserin (0.4 - 6.4 mg/kg, IP) nor MDL 72222 (7.5 - 120 ug/kg, IP) significantly altered breaking point values. These data suggest that neither 5HT₂ nor 5HT₃ specific receptors play a role in cocaine reinforcement and the specific receptors involved remain to be determined. (Supported by NIDA contract no. 271-90-7401).

348.15

SEROTONIN MEDIATION OF CUE-INDUCED COCAINE CRAVING. *S.L. Satel*, P.L. Delgado* and D.S. Charney.* West Haven VAMC, Yale Univ Sch. of Med., New Haven, CT 06519

The aim of this study was to determine whether alteration in central serotonin, through the technique of tryptophan depletion, reliably influences cue-induced craving for cocaine. Twelve cocaine dependent males (DSM III-R) without other Axis I diagnoses underwent two test days during their hospitalization on rehabilitation unit. All subjects had positive tox screens for cocaine at the time of admission and negative urines 24 hours prior to testing. Test days, one week apart, took place between weeks 3 and 4 of hospitalization. The design entailed a double-blind counterbalanced placebo-controlled administration of control or active tryptophan-depleting amino acid drink. Assessment of plasma TRP and subjective measures of mood, arousal and craving were administered baseline (0), +340 mins, +400 mins and +420 mins. Previous research has determined that the depleting drink results in a 60-80% decrease in plasma tryptophan at about 6 hours after ingestion and this correlates with a 60% decline in central 5HT levels. Thus, six hours after a drink ingestion subjects were exposed to 15 minutes of cocaine cues (film of users, paraphernalia and guided imagery). Reported desire for cocaine assessed before and after cue-exposure represented the critical comparison. Mean subjective increase in reported cocaine craving following cue exposure was 20 mm on the depletion day and 55 on the control day (p<.056). Change in mood (at 400 mins. minus baseline) did not differ between test days. Data suggest that tryptophan depletion attenuates cue-induced desire for cocaine.

348.12

FLUOXETINE PRETREATMENT REDUCES BREAKING POINTS ON A PROGRESSIVE RATIO SCHEDULE REINFORCED BY INTRAVENOUS COCAINE IN THE RAT. *N.R. Richardson and D.C.S. Roberts,* Dept. of Psychology, Carleton University, Ottawa, Canada, K1S 5B6.

Previous studies have reported reductions in rate of stimulant self-administration following pretreatment with the specific serotonin re-uptake inhibitor fluoxetine. Since changes in rate are difficult to interpret, we re-evaluated the effects of fluoxetine on cocaine self-administration using a Progressive Ratio (PR) schedule.

Male Wistar rats were implanted with intravenous cannulae and trained to respond on a PR schedule for cocaine (0.6 mg/inj). Pretreatment with fluoxetine (2.5, 5.0, 10.0 and 20.0 mg/kg IP) significantly decreased breaking points at the 5.0 and 20.0 mg/kg doses.

These results, together with data suggesting that rats will respond to higher breaking points for cocaine following lesions of ascending serotonergic fiber systems, support the hypothesis that serotonin plays an aversive role in stimulant reinforcement. (Supported by NIDA contract no. 271-90-7401).

348.14

COMPARISON OF EFFECTS OF COCAINE AND COCAETHYLENE ON DOPAMINE AND SEROTONIN IN VIVO, USING MICRODIALYSIS. *C.W. Bradberry*, E. Murphy, J. Nobilette, P. Jatlow, and R.H. Roth** Depts. of Pharmacology, Psychiatry, and Laboratory Medicine, Yale Univ. Sch. Med., New Haven CT 06510.

Cocaethylene (CE) is an active metabolite of cocaine (COC), shown to be similar in potency to cocaine at inhibiting uptake of dopamine (DA) in vitro, and enhancing motor activity and extracellular DA in vivo. Initial reports suggested CE to be less effective at displacing 3H-paroxetine, (which binds to the 5-HT reuptake carrier) than cocaine. We performed in vivo measurements of extracellular 5-HT and DA to determine if CE differs from COC in its actions on 5-HT. Administration of 1 mg/kg i.v. COC and CE caused an indistinguishable increase in extracellular DA in the nucleus accumbens to 350-400% of basal levels. The actions on 5-HT were studied in the striatum using 5 mm microdialysis probes. Basal 5-HT values were approx. 2 fmol/ul (corrected for probe recovery). At 1 mg/kg i.v., COC caused a significant increase to 200% of basal levels, while CE caused no significant increase. To determine if larger doses of EC would be able to significantly increase 5-HT levels, 15 mg/kg i.p. was employed. With this dose, COC increased 5-HT levels to 350% of baseline, while EC caused a significant increase to 200% of basal levels. A portion of the microdialysates were used for determination of extracellular striatal levels of COC and EC following 15 mg/kg i.p. Supported in part by the State of CT, MH 14092, DA 04060, and DA 05119.

ON THE MECHANISMS BY WHICH 5-HT₃ RECEPTOR ANTAGONISTS INHIBIT COCAINE-INDUCED HYPERACTIVITY. *A.L. Svingos, R.E. Strecker, C.S. McNeish and R. Hitzemann.* Departments of Psychiatry and Psychology, SUNY at Stony Brook, Stony Brook, NY 11794-8101 and Psychiatry Service, VAMC, Northport, NY 11768.

In mice the 5-HT₃ receptor antagonists, zacopride and ICS 205-930, block the hyperactivity induced by an acute cocaine injection (Reith, 1990). We now report similar results in rats pretreated with (+)zacopride (0.03 mg/kg, i.p.), ICS 205-930 (0.1 mg/kg, i.p.), or MDL 72222 (1.0 mg/kg, i.p.) fifteen minutes before the challenge with (+)cocaine (10 mg/kg, i.p.). (+)Zacopride significantly inhibited (approximately 50%) the effects of cocaine at a dose of 10 µg/kg. 5-HT₃ antagonists may attenuate cocaine-induced behaviors through effects on dopamine transport or release (see e.g. Carboni et al. 1989). We investigated whether or not 5-HT₃ antagonists block the cocaine binding site on the DA transporter and/or effect the ability of DA to regulate this binding site. In well washed striatal membranes, neither zacopride nor ICS 205-930 (10⁻⁹ to 10⁻⁶M) inhibited ³H WIN 35,428 (3 x 10⁻⁹M) binding. Furthermore, neither of these compounds affected the ability of DA to block WIN 35,428 binding. To determine if 5-HT₃ is required for the 5-HT₃ antagonist effect, we are currently examining the interaction between cocaine and zacopride in rats pretreated with p-chlorophenylalanine (PCPA). We have also investigated, using *in vivo* microdialysis, the effect of zacopride on cocaine-induced release of DA from the nucleus accumbens. At both 30 and 100 µg/kg, zacopride did not block the 3-fold cocaine-increase of extracellular DA.

LONG-TERM FUNCTIONAL ALTERATIONS IN SEROTONERGIC SYSTEMS FOLLOWING IN UTERO EXPOSURE TO METHAMPHETAMINE G. Battaglia, T.M. Cabrera, F. Tung, A.D. Levy, P.A. Rittenhouse, Q. Li, J. Yracheta, K. Kunimoto, R.J. Handa, L.D. Van de Kar Department of Pharmacology & Dept. of Cell Biology and Anatomy, Loyola University Chicago, Maywood, IL 60153

In adult rats, methamphetamine (METH) produces biochemical alterations and degeneration of brain serotonin (5-HT) neurons. We hypothesized that since 5-HT is critical to the development of 5-HT neurons and target tissues during gestation, *in utero* METH would produce long-term changes in postnatal 5-HT systems. Pregnant Sprague-Dawley rats, administered either saline or METH (5 mg/kg s.c. b.i.d.) from gestational day 13 through 20, comprised 3 treatment groups (sal-inj./ad lib-fed; sal-inj./pair-fed; & METH-injected). All progeny were fostered to untreated lactating dams. Functional alterations were determined by measuring plasma hormone levels following 5-HT release induced by a single injection of 8 mg/kg PCA (p-chloroamphetamine). Marked attenuations in PCA-mediated increases in plasma renin activity (PRA; -68%) and plasma renin concentration (PRC; -54%) were observed in male progeny of METH-treated mothers on postnatal day (PD) 70. METH produced comparable reductions in PRC in PD28 female progeny. This METH treatment produced no neurodegeneration in the mothers as assessed by the lack of reduction in cortical 5-HT uptake sites. In contrast to the *in utero* data, no changes in PCA-mediated increases in either PRA or PRC were observed in adult rats 2 weeks post-treatment with neurotoxic doses of METH (20 mg/kg s.c., b.i.d for 4 days). These studies demonstrate the unique ability of *in utero* METH to produce long-term functional changes in progeny 5-HT systems. Additional studies should elucidate whether the functional deficits produced by *in utero* METH are due to (1) alterations within 5-HT neurons, (2) changes in 5-HT receptors or (3) changes in post-receptor components.

CHRONIC COCAINE INHIBITS THE SEROTONERGIC STIMULATION OF ACTH AND CORTICOSTERONE SECRETION. A.D. Levy, L.D. Van de Kar, A.M. Bonadonna, P.A. Rittenhouse, J.E. Kerr, L. Iyer, G.B. Herbert, M.C. Alvarez Sanz, S.J. Lent, M. Carnes, Dept. Pharmacology, Loyola Univ. Chicago, Maywood IL 60153 and Dept. Medicine, Univ. Wisconsin, Madison WI 53705.

To examine cocaine-induced changes in serotonergic function, the endocrine responses to the serotonin (5-HT) releaser p-chloroamphetamine (PCA), and 5-HT agonists RU 24969 and m-CPP were examined following repeated exposure to cocaine. In the initial experiments, the dose and duration of cocaine exposure were studied. Male Sprague-Dawley rats received cocaine (2x/day) in doses of 1-15 mg/kg for 30 days, or 15 mg/kg for 1-30 days, and were then administered PCA (8 mg/kg) 42 hr after the final cocaine dose. Rats were decapitated 1 hr following PCA and the blood was collected for radioimmunoassay of ACTH and corticosterone. In subsequent studies, rats received cocaine (15 mg/kg, 2x/day) for 7 days, and were challenged with RU 24969 (0.2-5 mg/kg) and m-CPP (1-20 mg/kg) 42 hr after chronic cocaine treatments. Blood was collected 30 min after 5-HT agonist challenges.

PCA markedly enhanced secretion of ACTH and corticosterone. The 15 mg/kg dose of cocaine for 30 days reduced the PCA-induced increase in corticosterone. Additionally, PCA-induced elevation of corticosterone was reduced by 1, 7, or 30 days of cocaine exposure (15 mg/kg), while PCA-induced enhancement of ACTH was inhibited only by 7 or 30 days of cocaine (15 mg/kg) pretreatments. Furthermore, the magnitude of the inhibitory effect of cocaine on PCA-induced ACTH release was more marked than for corticosterone. The 5-HT agonists RU 24969 and m-CPP also increase ACTH and corticosterone secretion. However, these increases were not reduced by 7 days of cocaine pretreatments. The data suggest that repeated cocaine alters function of 5-HT nerve terminals, but not postsynaptic 5-HT receptors. (Supported by DA04865 and MH45812).

CHRONIC COCAINE MODULATION OF PREFRONTAL CORTEX CELLULAR ELECTROPHYSIOLOGIC RESPONSES. J.M. Lakoski and H.J. Moday*, Dept. of Pharmacol., Univ. Texas Medical Branch., Galveston, TX 77550.

Acute administration of cocaine inhibits neuronal responses mediated by monoaminergic systems, including serotonin (5-HT). Repeated cocaine administration has been demonstrated to decrease sensitivity to a subsequent cocaine challenge as recorded at the dorsal raphe nucleus (DRN) 5-HT autoreceptor. In these present studies, we have investigated the effects of chronic cocaine exposure on a terminal projection region of the DRN, the prefrontal cortex (PFC).

Adult male Sprague-Dawley rats received: (1) acute cocaine (15 mg/kg, i.p.) or saline (2) chronic cocaine (15 mg/kg, 2X daily, i.p.) or saline for 30 days. At 24 hr following the last injection, pyramidal cell responses were recorded *in vivo* (chloral hydrate) and iontophoretic responses to cocaine, 5-HT and GABA evaluated. No significant differences in sensitivity (IT_{50} values) were evident between acute cocaine, acute saline and chronic saline treated groups. Chronic cocaine significantly decreased responsiveness to cocaine and 5-HT (2-3X increase). Desensitization may underlie the cellular basis of cocaine's numerous behavioral effects mediated in the PFC.

COCAINE-INDUCED ELEVATION OF PLASMA ACTH AND CORTICOSTERONE (CORT) IS MEDIATED BY SEROTONERGIC NEURONS. T.M. Cabrera, A.D. Levy, Q. Li, J.E. Kerr, P.A. Rittenhouse, G. Milonas, G. Battaglia & L.D. Van de Kar, Dept. of Pharmacology, Loyola Univ. of Chicago, Maywood IL 60153.

The role of serotonin (5-HT) neurons in the mediation of cocaine-induced enhancement of ACTH and CORT was examined. Male Sprague-Dawley rats were pretreated with either (1) p-chlorophenylalanine (PCPA), a 5-HT depleting agent, (2) 5,7-dihydroxytryptamine (5,7-DHT), a 5-HT neurotoxin, (3) BMY 7378, a 5-HT_{1A} antagonist, (4) ritanserin, a 5-HT_{2/1C} antagonist, or (5) their respective vehicles. The rats were then challenged with varying doses of cocaine (0-15 mg/kg, i.p.); 15 min later, the rats were decapitated, and trunk blood was collected for radioimmunoassay of plasma ACTH and CORT. Cocaine dose-dependently increased ACTH and CORT levels. These increases were prevented by PCPA, 5,7-DHT, and ritanserin but not by BMY 7378. These data suggest 5-HT_{2/1C} mediation of the cocaine-induced elevations in ACTH and CORT.

To determine whether cocaine's effect on the hypothalamic-pituitary-adrenal axis is peripherally or centrally mediated, cocaine (0-1000 µg/kg) was administered into the lateral cerebral ventricles through chronically indwelling cannulae. Trunk blood was again collected 15 min post-cocaine injection and assayed for CORT and ACTH. ICV administration of cocaine significantly increased ACTH and CORT levels at doses 300 times less than the i.p. dose necessary to produce the same effects, suggesting that these actions are centrally mediated. In conclusion, our data strongly support the hypothesis that cocaine-induced stimulation of ACTH and CORT secretions are mediated largely by 5-HT neurons in brain, and furthermore that 5-HT₂ or 5-HT_{1C} receptors are responsible for these effects. (Supported by NIDA DA04865)

348.20

THE EFFECTS OF SEROTONERGIC MANIPULATIONS ON COCAINE SELF-ADMINISTRATION IN RATS. R. Paltier and S. Schenk, Texas A&M Univ., Dept. Psychol., College Station, TX, 77843.

Recently, serotonin has been implicated as mediating the reinforcing properties of cocaine in that indirect agonists or specific neurotoxic lesions have been found to alter the rate of cocaine self-administration. The present experiment was an attempt to identify the specific serotonin receptor subtype that may be critical for this effect. Rats were trained to self-administer cocaine (0.5 mg/kg/infusion) and were then pretreated with the 5-HT_{1A} agonist, 8-OHDPAT (0.125, 0.25 or 0.5 mg/kg, SC) or the 5-HT₂ antagonist, ritanserin (0.01, 0.1 or 1.0 mg/kg, SC). Ritanserin had no effect on cocaine self-administration, while 8-OHDPAT produced a decrease in reinforced response rates. The effect of 8-OHDPAT (0.5 mg/kg) on the dose/response curve for cocaine self-administration was then assessed. A reduction of response rates was found for all doses of cocaine, although the effect was most pronounced when lower cocaine doses served as the reinforcer. Fluoxetine (10 mg/kg, IV) also reduced reinforced response rates for a low dose infusion of cocaine when the schedule was FR1. When an FR10 schedule of reinforcement was imposed, reinforced response rates for higher doses of cocaine were also reduced. Thus, under conditions that produce high rates of responding (low dose infusions or high ratio requirements/infusion) fluoxetine reduced responding. This effect may be due to effects at the 5-HT_{1A} receptor, since 8-OHDPAT produced a similar dose/dependent effect on cocaine self-administration. However, given the dose and task dependency of the effects of these 5-HT agonists, it is likely that the suppression of responding reflects an effect that is not specific to the reinforcing impact of cocaine.

COCAETHYLENE FORMATION FOLLOWING SEQUENTIAL ADMINISTRATION OF COCAINE AND ETHANOL TO HUMANS: PHARMACOLOGICAL, PHYSIOLOGICAL, AND BEHAVIORAL STUDIES. E.F. McCance-Katz, L.H. Price, C.J. McDougle, G.J. Marek, T.R. Kosten and P. Jallow. Yale University Depts. of Psychiatry and Laboratory Medicine, New Haven, CT 06519.

At least 50% of cocaine abusers in the U.S. are also concurrent ethanol abusers and simultaneous consumption is common. Coccaethylene (EC), the ethyl ester of benzoylcocaine, has been detected in urine and high concentrations have been measured in blood of individuals in association with concurrent cocaine and ethanol use. EC is equipotent to cocaine as an inhibitor of dopamine uptake and as a reinforcer in self-administration studies in primates. This study was undertaken to prospectively evaluate the interaction of cocaine and ethanol in humans. METHOD: Four cocaine-ethanol challenges were administered in a double-blind randomized sequence to each subject (n=4) over 8 days. The four test days included the following drug combinations: cocaine (2mg/kg)/ethanol (1g/kg), cocaine (2mg/kg)/ethanol placebo, cocaine placebo/ethanol (1g/kg), cocaine placebo/ethanol placebo. Cocaine hydrochloride powder was administered intranasally followed by ethanol administered orally. Physiological and subjective (visual analog scales, "High scale") measures and plasma cocaine, EC, and ethanol levels were assessed. RESULTS: EC formation following sequential administration of cocaine and ethanol was demonstrated. Peak concentrations of EC after single doses of cocaine and ethanol occurred at 90-120 minutes and were about one-sixth of the cocaine peak. Plasma concentrations of EC declined more slowly than cocaine, and by 8 hours concentrations of parent and metabolite were about equal. The plasma level of cocaine during combined cocaine/ethanol administration was significantly greater than that during cocaine/placebo administration ($p < .04$), but elimination constants for cocaine under the two conditions were approximately equal. Cocaine/ethanol and cocaine/placebo administration resulted in significant increases in heart rate as compared to ethanol and placebo administration. The combined use of cocaine and ethanol was associated with more intense subjective effects, which were prolonged over those of cocaine or ethanol consumption alone. CONCLUSION: This study confirms that EC is formed in humans following coadministration of cocaine and ethanol and may contribute to physiological and behavioral effects. During repeated self administration of cocaine and ethanol, as occurs during a binge, EC would accumulate. Higher cocaine levels detected during combined cocaine/ethanol administration may be the result of enhanced bioavailability of cocaine in the presence of ethanol.

WITHDRAWAL FROM CHRONIC COCAINE ADMINISTRATION: EFFECTS ON BEHAVIOR AND BETA ADRENERGIC AND SEROTONERGIC BRAIN RECEPTORS IN RAT. E.A. Johnson, I.J. Goodman, Y.H. Shahan* and A.J. Azzaro. Dept. of Behavioral Med./Psychiatry, Psychology, and Neurology, West Virginia Univ. Sch. of Med., Morgantown, WV 26506

The effects of withdrawal from chronic cocaine (COC) administration on behavior and on β adrenergic and 5-HT₂ receptors in frontal cortex and hippocampus were studied. Male Sprague-Dawley rats were administered cocaine (10 mg/kg, i.p.) daily for 15 days, then withdrawn from the drug. COC treated rats displayed a slower rate of adaptation to a novel open field at 24, 48, and 72 hours withdrawal, measured by exploratory behavior, compared to saline injected controls ($p < 0.05$). No difference between COC and saline controls was detected in the modified Porsolt swim test at any time. COC treated rats exhibited small, time dependent, differences in frontal cortex β ([³H]CGP12177) and 5-HT₂ ([³H]Ketanserin) receptor number compared to controls. No differences were detected in hippocampus. Cocaine withdrawal appears to be anxiogenic in rats. Supported by WVU Med. Corp. and NIH Biomed. Res. Grant No. 2S07RR05433

HEMODYNAMIC EFFECTS OF ACUTE COCAINE EXPOSURE IN CONSCIOUS LAMBS. F.M. Scalzo, J. Valentine* and B. Taylor. Department of Pediatrics, University of Arkansas for Medical Sciences & Arkansas Children's Hospital, Little Rock, AR 72205.

Cocaine is known to have potent cardiovascular effects which include hypertension and tachycardia in adults. However, the adverse effects of cocaine exposure on cardiovascular function in newborns are not well understood. To identify potential adverse effects of cocaine exposure in newborns, we examined the hemodynamic effects of acute cocaine exposure in unanesthetized one month old lambs that were instrumented for measurement of aortic pressure (AP), left atrial and ventricular pressures, left circumflex coronary artery flow (CF) and heart rate (HR). Lambs were studied for 1 hour following saline or cocaine-HCl (3.0 or 6.0 mg/kg, i.v.) injection. At the 6.0 mg/kg dose the maximum increases for AP, CF and HR were 170%, 148%, and 160%, respectively, of baseline. The lamb thus appears to be a good model to study the cardiovascular effects of acute cocaine exposure in newborns and the results suggest that exposure to cocaine causes adverse hemodynamic effects in this animal model (supported in part by DA-06319 and HL-01822).

EFFECTS OF INTRACEREBRAL COCAINE INFUSIONS ON I.V. COCAINE SELF-ADMINISTRATION. G.H. Jones, S.E. Hemby, D.B. Neill & J.B. Justice, Jr. Depts. of Chemistry and Psychology, Emory University, Atlanta, GA 30322.

The mesolimbic dopamine pathway, in particular, the ventral tegmental area, nucleus accumbens (NACC) and medial prefrontal cortex, have been strongly implicated in mediating the reinforcing effects of cocaine. This experiment was designed to assess the effects of infusing cocaine directly into discrete regions of this dopaminergic pathway on i.v. cocaine intake and the regularity of responding in the self-administration paradigm.

Rats were trained to self-administer cocaine i.v. in daily 3 hr FR-1 sessions. Each lever press delivered 0.25 mg cocaine HCl (in 0.1 ml saline) over a 4 sec period via a jugular catheter. Once stable responding had been achieved (a minimum of 10 days training) subjects were bilaterally infused with either 0.0, 12.5, 25, 50, or 100 μ g/ μ l cocaine on separate test days. For these intracerebral infusions cocaine was prepared in artificial CSF and infusions (2 x 1 μ l) were carried out over a 1 min period with 1 min allowed for diffusion. A Latin-square design was used to determine the sequence of infusions. On each test day the subjects were allowed to self-administer cocaine for a minimum of 1 hr prior to infusion to achieve stable baseline responding. Following intracerebral infusions responding was monitored for at least 90 min.

There were clear dose-dependent effects of cocaine infusions into the NACC (n = 10) on delaying the next lever press after infusion and on increasing the variability in the time interval between lever presses. In addition, all the NACC cocaine infusions significantly reduced i.v. cocaine intake in the 20 min period following infusion by about 50% (compared with the 20 min pre-infusion intake). This reduction in cocaine intake lasted for approximately 30 mins. CSF infusions into the NACC did not significantly reduce cocaine intake.

These effects of these NACC infusions will be compared with those following cocaine infusions into other regions of the mesolimbic dopamine pathway.

EFFECTS OF CHRONIC COCAINE AND WITHDRAWAL ON REGIONAL CEREBRAL BLOOD FLOW IN THE RAT. E.A. Stein and S.A. Fuller* Dept. of Psychiatry, Medical College of Wisconsin, Milwaukee, WI

Chronic opiates have long been recognized to produce a behavioral and pharmacologic tolerance together with the development of physical dependence and a marked withdrawal syndrome. In contrast, the syndrome following chronic cocaine is less well understood. Withdrawal in man is characterized by a 'psychosis-like' paranoia. Sensitization has been reported in animals, manifest as an increase in locomotion and increased susceptibility to cocaine-induced seizures. Chronic cocaine also increases both cocaine and dopamine in the nucleus accumbens. The present study addresses the question of which neuroanatomic structures respond to and perhaps mediate the behavioral sensitization following chronic cocaine administration and which become activated during withdrawal. Rats were injected with either 0, 1.0 or 10.0 mg/kg cocaine IP twice a day for 14 d. On the day of rCBF determination, each treatment group received a challenge injection of either saline or 1.0 mg/kg cocaine 6-8 hrs after their last chronic dose. rCBF was determined using [¹⁴C]iodoantipyrine according to the method of Sakurada et al. Analysis of variance indicated no differences between the two chronic 1 mg/kg groups and the saline group. Additionally, the chronic 10 mg/kg group receiving the acute drug challenge also did not generally differ from saline. In contrast, increases in rCBF were seen in 18/63 areas in the 10 mg/kg group receiving acute saline compared to low dose and saline groups. Those areas activated by or during withdrawal include the nucleus accumbens, olfactory tubercle, bed nucleus, diagonal band, medial prefrontal cortex, septum and habenula. It thus appears that withdrawal from high but not low cocaine doses results in selective neuronal activation, with acute cocaine returning many regions to their baseline levels (Supported by grant DA 05012).

349.6

ZIF/268 EXPRESSION IN THE RAT BRAIN DURING COCAINE WITHDRAWAL. D.J. Ennular, S.M. Babb*, S.E. Hyman and B.M. Cohen. Laboratory for Psychiatric Research, McLean Hospital and Harvard Medical School, 115 Mill Street, Belmont, MA 02178.

Changes in the expression of immediate early genes (IEGs) in response to drugs and other stimuli are generally characterized by rapid and transient kinetics. The present study describes long-term changes in the expression of the IEG zif/268 during cocaine withdrawal. Either 6 mg/kg cocaine or 0.9% saline (vehicle) was administered to male, Sprague Dawley rats (300-340g) by IV injection, via an implanted jugular cannula, 1 time daily (acute) or 3 times daily for 1 day, 2 days or 5 days (chronic). The chronically treated rats were allowed to withdraw from cocaine for 4 days, 3 days or 60 min, respectively. At the appropriate times three animals per group were sacrificed and the brains were rapidly removed and dissected into major regions of interest, based on changes in zif/268 expression during acute cocaine treatment, particularly amygdala (AM), frontal cortex (FC), and striatum (ST). Total RNA was extracted from the dissected brain regions and subjected to Northern analysis by hybridization with ³²P labeled probes for zif/268 and cyclophilin, as an internal reference. Following high stringency washes, the levels of cyclophilin and zif/268 were quantified by digitization of the resulting autoradiograms. After normalization to the amount of cyclophilin, the relative level of zif/268 was determined for the cocaine treated animals by comparison with the vehicle control. Acute cocaine treatment causes a rapid increase in the expression of zif/268 in the FC, ST and to a lesser extent in the AM. In this preliminary study, chronic treatment with cocaine resulted in a desensitization of the cocaine-induced increase in zif/268 expression. Also, withdrawal from continued cocaine treatment resulted in an apparent reduction in the expression of zif/268 below that found in vehicle controls. This observation may have implications in understanding the molecular and cellular changes that are associated with cocaine withdrawal.

ALTERATIONS IN DRUG METABOLISM RESULTING FROM PRIOR ADMINISTRATION OF DRUGS OF ABUSE. W.L. Backes, C.S. Eyer, G. Cawley, and J.M. Moerschbaecher. Department of Pharmacology, Louisiana State University Medical Center, New Orleans, LA 70112.

The purpose of this study was to determine if prior administration of different drugs of abuse could alter hepatic microsomal drug metabolism. Male Holtzman rats were pretreated with 3 daily i.p. injections of the following drugs: diazepam (1.8 mg/kg body weight), heroin (1 mg/kg), cocaine (18 mg/kg), and phencyclidine (PCP; 18 mg/kg). Rats were killed 24 hours after the final injection and liver microsomes were prepared. Drug-induced changes in the overall levels of cytochrome P-450, associated electron transport components, and a number of P-450-dependent reactions were examined to characterize the inductive response. PCP pretreatment produced a 30% increase in cytochrome b₅ levels, and a 55% increase in p-nitroanisole (pNA) demethylation. Heroin administration appeared to produce about a 30% decrease in 7-ethoxycoumarin-O-deethylation. Diazepam and cocaine were without effect in these initial experiments. Since cocaine has such a short biological half life, the effect of cocaine was reexamined using a different administration schedule. Cocaine was administered at time zero at a dose of 18 mg/kg body weight followed by injections at 12, 18, and 24 hrs. Microsomes were prepared at 36 hrs. Cocaine pretreatment resulted in a 45% increase in pNA demethylation, and a 35% increase in N,N-dimethylnitrosamine demethylation. These results clearly demonstrate that a number of drugs of abuse, particularly PCP and cocaine, can induce P-450-dependent activities. Such metabolic changes may have significant implications concerning the chronic abuse of these drugs. (Supported by NIEHS 04344 and DA03573).

EFFECTS OF MDMA ON ALCOHOL CONSUMPTION IN THE FAWN-HOODED RATS

A. H. Rezvani, C. J. Gordon*, D. B. Miller*, J. O'Callaghan*, P. L. Garges* and D. S. Janowsky. Skipper Boweels Center for Alcohol Studies, Chapel Hill, NC 27599 and The US EPA, Research Triangle Park, NC 27711

The Fawn-Hooded (FH) rats exhibit a genetically-controlled subsensitivity to serotonin (5-HT) stimulation. In addition, they show a significant preference for alcohol. It has been speculated that their alcohol preference is associated with their central 5-HT impairment. To further investigate the involvement of the serotonergic system in alcohol preference the following experiment was carried out. FH rats were given free access to water and 10% ethanol for at least 3 weeks. After establishing the baseline, rats were administered (sc) with either saline or 5 mg/kg of 3,4-methylenedioxymethamphetamine (MDMA), which promotes 5-HT release. Food, water and ethanol intake as well as body temperature were monitored during the course of the experiment. Our results show that MDMA, but not saline, significantly attenuated alcohol intake, increased water intake and body temperature without changing the food intake. The water and alcohol intake returned to the baseline the day after the treatment. These findings support the implication of a 5-HT deficiency hypothesis in alcohol-seeking behavior in a novel strain of alcohol preferring rats. (Supported in part by NCARA Grant# 9103 to AHR).

CAFFEINE EXAGGERATES EXCESSIVE FORWARD LOCOMOTION IN NRTTP-DAMAGED RATS. M.C. Fratzke, B.E. Digiann & R.M. Chesire, Univ. Hawaii-Manoa, Honolulu, HI 96822.

Damage of the nucleus reticularis tegmenti pontis (NRTTP) can produce uninhibited increases in forward locomotion that resemble Parkinsonian festination (1-4). Some of the major cataleptogenic or sedative hypnotic agents do not abolish such locomotion (4-6). However, amphetamine can decrease NRTTP damage-induced locomotion after its initial excitatory effects, by instating the stereotypical motor behaviors often elicited by such stimulants in otherwise normal rats (7,8). In this report, we describe additional locomotor stimulation produced by 20 mg/kg, i.p. caffeine in already excessively kinetic NRTTP-damaged rats. The results suggest that caffeine stimulates locomotion via effects on neural systems that do not depend on the NRTTP inhibitory system needed for the expression of some motor effects of cataleptogens. Coupled with the finding that caffeine normalizes some aspects of movement in NRTTP-damaged rats (9,10), the results imply that caffeine, a widely used and abused substance, may be of automedicative value (7-10) in some cases of pontine dysregulation.

RESPIRATORY PATTERNING FOLLOWING INTRAVENTRICULAR COCAINE ADMINISTRATION. C.A. Richard, R.K. Harper, H. Ni and R.M. Harper. Brain Research Institute and Dept. of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

Respiratory rate accelerates markedly in response to acute cocaine intoxication, a phenomenon which may contribute to respiratory failure associated with cocaine use in humans. This tachypnea develops almost immediately upon intravenous (IV) injection and can persist for 3-4 hours. We have quantified the diaphragmatic EMG response to IV cocaine by measuring total cycle time (TTot) as well as the inspiratory and expiratory phase durations (TI, TE, respectively; Richard et al. Pharmacol., Biochem., Behav., in press). To differentiate central and peripheral effects of cocaine, we unilaterally injected cocaine HCl into a lateral cerebral ventricle of adult cats. Animals were anesthetized and instrumented with EMG leads in the costal diaphragm. After 1-2 weeks of recovery baseline recordings were performed for 30-60 minutes in unanesthetized unrestrained animals. This was followed by an injection of 2.5 mg cocaine through a cannula placed in a lateral ventricle. TTot decreased by 45% at 10 min post-cocaine and the largest fall occurred at 60 min with a 59% reduction; however at 2 hr, TTot had increased to levels slightly higher than control (+3.56%). These changes were equally represented in the inspiratory and expiratory phase durations. TI/TE ratios tended to increase at 10 min but there were no significant differences from baseline over the duration of the intoxication. The TI/TTot ratio was significantly higher, however, at 10 min post-cocaine administration. The effects of ventricular administration are similar to those for IV injections except that recovery is much faster and a slight rebound in timing parameters occurs with intraventricular administrations. These results suggest that the primary respiratory effects of cocaine intoxication result from central actions on respiratory control systems rather than peripheral (e.g. diaphragmatic) actions. Supported by R01-DA04913.

349.10

PARTIAL NORMALIZING OF MOVEMENT BY CAFFEINE IN NRTTP-DAMAGED RATS. R.M. Chesire, M.C. Fratzke, & B.E. Digiann Univ. Hawaii-Manoa, Honolulu, HI 96822.

Nucleus reticularis tegmenti pontis (NRTTP) damage-induced increases in locomotion are not blocked by large doses of morphine, haloperidol or ethanol (1-4). Thus, these drugs exert their inhibitory effects partially via the intact NRTTP (1-4). Recently, we have shown that amphetamine (5,6) or caffeine (7) can increase the locomotion of NRTTP-damaged rats, and that amphetamine produces some normalizing of movement (6). Amphetamine-treated NRTTP-damaged rats first slow their locomotion, then increase it, then become trapped in the same stereotypies displayed by amphetamine-treated unoperated rats (6). In effect, amphetamine reintegrates the NRTTP-damaged animals' response to the drug. In this study, we report that 20 mg/kg i.p., caffeine normalized some postural/locomotor reactions of such rats. Caffeine produced a change from predominantly ventroflexed to predominantly lateral (normal) righting, and reduced excessive thigmotaxis in the open field. The results suggest that caffeine, like amphetamine (6) can exert reintegrative effects on locomotion/movement following NRTTP damage, via their effects on intact compensatory neural systems.

COCAINE EFFECTS ON CNS NEUROTENSIN CONCENTRATIONS.

S.T. Cain, D. Griff*, C.M. Joyner*, E.H. Ellinwood and C.B. Nemeroff. Depts. of Psychiatry and Pharmacology, Duke Univ. Med. Ctr. Durham, NC 27710

Neurotensin (NT) is an endogenous brain tridecapeptide which exhibits a variety of selective behavioral, neurochemical and physiological interactions with brain dopamine (DA) systems. (TIPS, 6, 1985, 201-205). In view, therefore, of the purported involvement of DA systems in cocaine-induced behavioral changes, we have initiated an investigation of the possibility that cocaine disrupts NT/DA homeostasis in the central nervous system (CNS). Adult male rats were used in all experiments. Using a sensitive and specific radioimmunoassay (RIA), the concentration of neurotensin-like immunoreactivity (NT-LI) was measured in the frontal cortex, nucleus accumbens, caudate nucleus, substantia nigra (SN), and ventral tegmental area 24 hours and 8 days following the conclusion of a 14 day regimen of 40 mg/kg cocaine/day administered as either 1 subcutaneous (sc) injection or continuously infused using minipumps. NT-LI was also measured 24 hours following one sc. injection of 40 mg/kg cocaine. Dopamine concentrations were measured using HPLC with electrochemical detection in nucleus accumbens and caudate nucleus 8 days following 14 days of chronic cocaine exposure.

Twenty-four hours following either an acute or 14 days of exposure to cocaine, NT-LI was significantly increased in the SN. Twenty-four hours following 14 days of once-daily, but not continuous exposure to cocaine, NT-LI was significantly increased in the frontal cortex. Acute, but not chronic exposure to cocaine, resulted in increased nucleus accumbens NT-LI. Eight days following chronic exposure to cocaine, no changes in NT-LI or DA concentration were observed in any brain region examined. These results provide evidence consistent with the early, but not residual involvement of NT systems in the behavioral and/or addictive properties of cocaine as previously suggested by Hanson et al. (Eur. J. Pharmacol. 160, 1989 23-30). Supported by NIDA DA-05303.

EFFECTS OF THE COCAINE METABOLITE BENZOYLECGONINE ON GLYCOSPHINGOLIPID SYNTHESIS BY NEUROBLASTOMA AND GLIOMA CELLS. Y. Lin, S. Hickerson* and K.C. Leskawa. Dept. Anatomical Sciences & Neurobiology, University of Louisville, Louisville, KY 40292

We have previously reported that following gestational exposure to cocaine total neutral glycosphingolipid (GSL) and ganglioside content of whole newborn rat brain approximately doubled (Jackson et al., Soc. Neurosci., 1989). To further pursue this, we have recently examined the effect of the major cocaine metabolite benzoylecgonine (BE) on GSL synthesis by neuroblastoma and glioma cells in culture using NG108-15 and C6 cells, respectively, as models. BE was added to complete growth media at varying concentrations (0 to 200 μ M), cells exposed for 48 hr and GSL synthesis examined by adding 14 C-serine to the media during the last 8 hr. BE at very low concentrations (10 and 20 μ M) significantly elevated the synthesis of both neutral GSLs and gangliosides by C6 cells. This stimulation was diminished, however, at BE concentrations higher than 50 μ M. No elevation of either neutral GSL or ganglioside synthesis was observed with NG108-15 cells exposed to BE, and above 20 μ M ganglioside synthesis was significantly reduced. Further examination demonstrated that the reductions observed at higher BE concentrations were not due to effects on glycolipid synthesis *per se*, but were due to cytotoxic effects. Diminished incorporation of 3 H-thymidine into DNA and loss of cells from the substratum was observed following exposure of cells to BE at 50 μ M and higher.

These results suggest that the elevated neutral GSL and ganglioside content observed in whole newborn brain may be due to the cocaine metabolite benzoylecgonine affecting synthesis by glial cells, and also demonstrate a cytotoxic effect of this compound at low levels.

COCAINE ATTENUATES PHORBOL ESTER STIMULATED GnRH RELEASE FROM THE RAT HYPOTHALAMUS IN VITRO: ROLE OF Na⁺ INFLUX. Thomas S. King, Inn Soo Kang*, Martin A. Javors and Robert S. Schenken*, Departments of CSB, OB-GYN and Psychiatry, University of Texas Health Science Center, San Antonio, TX 78284.

Phorbol esters, presumably acting to stimulate the activity of protein kinase C, have been shown to increase gonadotropin releasing hormone (GnRH) release from rat hypothalamus *in vitro* (*Brain Res. Bull.* 15: 657 - 659, 1985). Hypothalamic release of GnRH is dependent, in part, on fast Na⁺ channel activation and Na⁺ influx (*Neuroendocrinology* 32: 155 - 162, 1981). We therefore sought to determine whether Na⁺ influx influences phorbol ester stimulated hypothalamic GnRH release *in vitro*. Hypothalami were collected from ovariectomized rats injected s.c. with 50 μ g/kg of 17 β -estradiol benzoate the two previous mornings. Sagittal sections of this block of CNS tissue comprising the preoptic area/anterior hypothalamus and mediobasal hypothalamus/median eminence were perfused at a rate of 6.18 ml/min with a modified Krebs-Ringer buffer (pH 7.4) using a programmable perfusion system. Perfusion results are as follows: 10 min pulses of phorbol 12-myristate 13-acetate (PMA) or phorbol 12,13-dibutyrate (PDBu) increased GnRH release in dose-response fashion (0.01 - 1 μ M). In contrast, the biologically inactive α -phorbol was without effect on GnRH release. PDBu-stimulated GnRH release was blocked by both tetrodotoxin and cocaine, known inhibitors of Na⁺ influx. Cocaine attenuation of PMA-stimulated GnRH release could be partially restored by addition of monensin, a Na⁺ ionophore. These results suggest that the effects of phorbol esters to stimulate hypothalamic GnRH release are, at least in part, mediated through Na⁺ influx and that cocaine may directly affect hypothalamic GnRH release by blocking influx of this cation. (Supported by NIDA grant DA-06039 and by NIH grant HD-10102 [Neuroendocrine Core]).

GENETIC MODELS OF BEHAVIOR

350.1

HYPERACTIVITY INDUCED BY A SNAP-25 INCLUSIVE DELETION MUTATION IN COLOBOMA (Cm/+) MOUSE MUTANTS. E.J. Hess, H.A. Jinnah, and M.C. Wilson, Dept. of Neuropharm., Research Institute of Scripps Clinic, La Jolla, CA 92037 and U.C. San Diego Sch Med, La Jolla, CA 92093.

SNAP-25 is a neuron-specific synaptosomal associated protein which contributes to synapse formation. In characterizing SNAP-25 expression and function, we have identified the mouse mutant Coloboma (Cm/+) as carrying a chromosome 2 deletion mutation which includes the *Snap-25* gene. Coloboma mice are neurological mutants whose phenotype includes ocular deformation and stereotypic head shaking. We have also observed that these mice were extremely hyperactive. To quantitate the hyperactivity exhibited by Coloboma mice, the spontaneous locomotor activity of control and Coloboma mice was recorded in photocell cages over twenty-four hours. Both mutant and control mice habituated within the first 150 min of the testing session and Coloboma mice appeared to have a normal circadian rhythm which paralleled control mouse activity. However, Coloboma mice were significantly more active than their control littermates ($p < 0.005$) with nocturnal activity counts exceeding three times those of controls. Coloboma mice exhibited enhanced locomotor activity with no difference observed between control and mutants in time spent quiescent, so these mutants are hyperactive while maintaining normal sleep/wake patterns. Although it is clear that the Coloboma deletion mutation includes *Snap-25*, the size of this deletion is unknown. To define exactly the gene(s) responsible for the hyperactivity, the extent of the deletion was assessed. We have determined that *Bmp-2a* and *Pax-1*, genes which reside near *Snap-25* on mouse chromosome 2, do not appear to be deleted in the Coloboma mutation. These data suggest that a deletion of less than 5cM (the distance between *Bmp-2a* and *Pax-1*) which includes *Snap-25* results in the extreme hyperactivity exhibited by Coloboma mice. GENETIC ANALYSIS OF CHROMOSOME 11 LOCI USING RFLPS IN INDIANA FAMILIES WITH BIPOLAR AFFECTIVE DISORDERS. D.K. Lahiri, S. Bye*, T. Foroud*, C. York*, P.M. Conneally and J.I. Nurnberger, Jr. Laboratory of Molecular Genetics, Institute of Psychiatric Research, Indiana University School of Medicine, 791 Union Drive, Indianapolis, IN 46202

The affective disorders are a common and heterogeneous group of illnesses that are characterized by abnormalities of mood, cognition and neurovegetative functions such as sleep, appetite and libido. Genetic factors appear to contribute to the development of both bipolar and unipolar depression. The mapping of genetic loci for these disorders has been difficult due to apparent genetic heterogeneity and nongenetic forms of the disorder. A suggestive linkage has been reported to 11p15, though extension of the family weakened the initial lod score significantly (Kelsoe et al., 1989); a translocation at 11q 22-23 has been reported in another family (Potkin et al., 1989).

We have used a molecular genetic approach to localize the gene for affective disorder in two clinically well characterized families from Indiana with over 60 members. Our linkage analysis involves the use of RFLP markers within a specific genomic area and then typing affected families with the polymorphic probe/enzyme combinations by Southern hybridization. The results are tested using the LOD score method to determine if a specific RFLP locus is closely linked to a disease gene locus that may transmit with the disease phenotype in several generations. We have chosen DNA probes (cDNA or genomic DNA) or synthetic oligomers with a PIC value of at least 0.34, distributed throughout chromosome 11 (11p 15.5 - 11q 23 q24). Our preliminary results have excluded linkage of a disease gene with the following loci: *MUSC* (*SacI*), *SS6* (*TaqI*); we are testing linkage of *HRSAS* (*SacI*), *TH* (*PstI*), *pMCT128.1* (*MspI*), *IGF2* (*Bam HI*), *PTH* and *STMY* (*TaqI*) loci. Results of RFLP analyses and lod scores using multiple polymorphic probes and restriction enzyme pairs will be presented. Help from Dr. M.Hodes, Ms. D.Lawrence and C.Springer is gratefully acknowledged. Supported by the Indiana Department of Mental Health.

CENTRAL AUDITORY PROCESSING IN A PATIENT WITH SSADH DEFICIENCY. D.M. Daly, A. Hodson*, and K.M. Gibson*, Box 210855, Dallas, TX 75211, Univ Florida Jacksonville, FL 32225, and BRF, Dallas, TX 75246

SSADH deficiency, an inborn error of GABA metabolism, forces SSA reduction in CNS through hydroxybutyric acid (HB). Reported cases have been hypotonic, and retarded with marked delays in speaking and in acquiring language. We tested central auditory processing [1] in one family.

A 9 yr old girl, referred at 4 yrs for complex partial seizures and profound delay in speech and language, was hypotonic, clumsy in fine movements, and unresponsive to painful stimuli. Audiometrics and AER were within normal limits; IQ(WISC)-50. Seizures were controlled with carbamazepine; methylphenidate (MPD) was added to offset increased daytime somnolence. Seizures remitted and she has been 2 yrs without medication. She has also endured episodes of prolonged sleep (>20h/da) associated with increased 4-HB in urine and CSF. An afflicted brother sleeps 10h/da; an unaffected half brother may sleep 18h/da if permitted.

During testing she spoke and pointed to respond. Classifications were occasionally well-defined, but in aggregate performance approached chance levels with no obvious consistency between pointed and spoken responses. Performance improved significantly ($p < 0.0001$) following <5mg dose MPD sublingually; within 8 min she consistently distinguished each sound; within 10 min she spoke and pointed consistently; over next 30 min she returned to chance (confirmed with 2 observers and repeated with a second dose). While alert coordination improved; she spoke clearly and appeared free of gross auditory defect.

Whatever the relations between 4-HB and sleep, variations in vigilance can arise and be modified separately. Unlike controls with fluctuating vigilance, her initial unmedicated chance levels of performance seemed to arise from uniform responses to randomized stimuli.

FIFTH MONTH FETAL-SIZE MARKERS IN SCHIZOPHRENIA: A DISCORDANT MZ TWIN STUDY. H. S. Bracha, M.D., E. F. Torrey, M.D., L. B. Bigelow, M.D., K. Dykman, M.D., J. Mayfield, B.A.*; Clinical Brain Development Research Lab, Departments of Psychiatry and Neurology, University of Arkansas for Medical Sciences, and VAMC 116A1/NLR, North Little Rock, Arkansas 72114-1706

Fingertip dermal cells migrate to form ridges during the second prenatal trimester, which is also a critical period of neural cell migration to the cortex. Since prenatal insults rarely affect both MZ twins to the same extent, we hypothesized that intrapair discrepancies between two MZ twins in the dermal ridge count may be markers of factors that might affect one fetus differentially during the second trimester. We examined discordant MZ twins to estimate the differences in the prenatal environmental interference disrupting fetal development in the second trimester. We measured the absolute differences in fingertip ridge count in 30 pairs of MZ twins recruited over a seven-year period [23 pairs discordant for schizophrenia and 7 normal pairs]. MZ twins discordant for schizophrenia had significantly higher intrapair discrepancy in ridge count than normal MZ twins; i.e. their fingerprints were significantly less "twin-like". This study suggests that second trimester prenatal disturbances in epigenesis in one twin in pairs discordant for schizophrenia may be related to the fact that only one of the two twins expresses his/her genetic predisposition toward schizophrenia. This study provides support for a "two-strike" etiology in schizophrenia - a genetic diathesis plus an unknown prenatal environmental stressor.

INTERSTRAIN AGGRESSION IN WISTAR-KYOTO INBRED STRAINS: SHR, WKY, WKHA AND WKHT RATS. E.D. Hendley, W.G. Ohlsson* and R.E. Musty. Univ. Vermont, Burlington, VT 05405.

SHR and WKY rats have been selectively inbred for blood pressure: hypertension (HT) in SHR and normotension in WKY. These homozygous strains have also inadvertently been fixed with behavioral differences, including hyperactivity (HA) in SHR when compared with WKY. We developed WKHA and WKHT strains from a cross of SHR x WKY, and now WKHA express the HA trait and not HT, and WKHT express HT and not HA. These four strains were used in interstrain aggression studies to test whether aggression, reported in SHR, had cosegregated with the HA trait (if seen in SHR and WKHA and not in WKY and WKHT) or with the HT trait (if seen in WKHT and SHR and not in WKY and WKHA). We paired rats of different strains, but same age and sex, in an arena for 15 min, and counted aggressive acts according to Miczek (*Psychopharmacologia* 39:275, 1974). The most prevalent act observed was allogrooming (lick opponent's neck), and this was significantly higher in the strains with HT. In other dominance behaviors (attacks+upright postures+mounts) female WKHA and SHRs (HA trait) scored higher than all other groups. From this finding and others we concluded that the heritability of interstrain aggression is heterogeneously regulated in the rat genome, and that it is not a necessary cosegregant of either HT or HA. Supported by NIH R01-NS26390.

HAD AND LAD RATS RESPOND DIFFERENTIALLY TO THE STIMULATING EFFECT BUT NOT THE DISCRIMINATIVE EFFECTS OF ETHANOL. E. C. Krimmer. Dept. of Pharmacology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

The drug discrimination paradigm (DD) was used to evaluate behavioral differences of rats selectively bred for differential ethanol drinking preferences. Seventh generation high alcohol drinking (HAD) and low alcohol drinking (LAD) rats were trained to discriminate between ethanol (0.5 g/kg, IP) and saline vehicle, following a 2 min pre-session interval (PI), using an FR-10 schedule of reinforcement. The HAD strain was more responsive than the LAD strain to the stimulating effects of ethanol as measured by total response rates. ED₅₀ values of 0.239 and 0.244 g/kg for the HAD and LAD strains respectively do not reflect any difference in the discriminative effects of ethanol.

Response rates during DD indicated a dissociation of rate increasing effects and discriminative performance following ethanol. In addition to differential drinking preference these data suggest that selective breeding for the HAD and LAD animals also involves the stimulant action of ethanol but not on the discriminative effects. ACTIVITY RESPONSES TO NOVELTY IN WISTAR RANDBRED AND WISTAR-KYOTO INBRED STRAINS. R.E. Musty and E.D. Hendley.

Univ. Vermont, Burlington, VT 05405.

Hyperactivity and poor habituation to novel stimuli are behavioral characteristics which cosegregated with hypertension in the Spontaneously Hypertensive Rat (SHR), derived from the Wistar-Kyoto (WKY) strain of rat. Recombinant breeding of WKY and SHR followed by selective inbreeding to produce WKHA (hyperactive) and WKHT (hypertensive) strains has allowed us to study these characteristics of SHR separately. Randombred Wistar (WIS) and the aforementioned four strains were tested in an infra-red detector open field over three sessions: 1) with two identical objects in the field, 2) and 3) with one novel object replacing an object in 1). SHR and WKHA were more active than the other strains in session 1). Impaired habituation to stimulus change in 2) and 3) followed a similar pattern of strain differences. These data support the view that hyperactivity and attenuated response to novelty are cosegregated characteristics of WKHA. Supported by NIH R01-NS26390.

SPATIAL LEARNING IN INBRED MOUSE STRAINS. C-A Gutekunst, AT Hartney*, HD Rees and RC Green. Departments of Neurology and Psychology, Emory University School of Medicine, Atlanta, Georgia.

Strain-related differences in place learning ability were studied with a modified Morris water maze in the following strains: DBA/2, C3H/He, C57Bl/6J, El and ddY. DBA/2 mice are susceptible to audiogenic seizures after 2-3 weeks of age and El mice have generalized seizures in response to handling after 3 months of age.

At 7-9 weeks of age, males and females from the five strains underwent 32 training trials. DBA/2 and El mice without prior seizures, along with the non-epileptic ddY and C57Bl/6J mice all exhibited learning at rates that did not differ from one another (repeated measures ANOVA, $p=0.14$). The non-epileptic C3H/He mice were unable to learn the water maze task in the trials permitted (simple linear regression for latency across trials, $p=0.38$). In the C57Bl/6J strain only, female mice learned the task significantly faster than males (repeated measures ANOVA, $p=0.02$).

There was no difference in the learning rate between the El strain and its parent ddY strain prior to the development of seizures. These findings suggest that prior to the appearance of seizures in mice, genetic predisposition to epilepsy does not affect spatial learning ability. C3H mice are known to have poor visual acuity which may have contributed to their poor performance in this task. Sex differences in learning rates in the C57Bl/6J strain may be an example of sexually dimorphic learning behavior.

FIBRILLARY TANGLES IN HEMIMEGALENCEPHALY AND ALZHEIMER'S DISEASE SHARE A COMMON ANTIGENIC DETERMINANT. T. Duong, M. DeRosa*, H.V. Vinters*, W. Peacock* and R.S. Fisher. UCLA Mental Retardation Research Center, Pathology Dept. and Neurosurgery Dept., Los Angeles, CA 90024.

Hemimegalencephaly is a rare congenital disorder characterized by unilateral hypertrophy of a cerebral hemisphere, errors of cortical gyration and lamination, and presence of meganeurons. The latter accumulate abnormal amounts of the medium (NF-M) and heavy (NF-H) neurofilaments, resulting in intracytoplasmic tangle-like formations (Duong et al., *The Anatomical Record* 229 no. 4, p. 24A, 1991). In this study, neocortical surgical samples were obtained from 3 hemimegalencephalic patients (3-, 15-, and 30-month) who had undergone hemispherectomy for the treatment of intractable seizures. Surgical samples from pediatric patients with intractable epilepsy but without hemimegalencephaly, and age-matched pediatric autopsy samples were also collected. Sections (40µm-thick) were processed free-floating for immunohistochemistry. The primary antibody used was SMI34, purchased from Sternberger Monoclonals, Inc., Baltimore, MD. SMI34 is specific for the phosphorylated forms of both NF-M and NF-H, and labels intracellular neurofibrillary tangles in Alzheimer's disease. We report that neurofilamentous tangles in the meganeurons typical of hemimegalencephaly are also immunoreactive to SMI34. The pattern of immunoreactivity differed between the 3 month-old and the older megalecephalic patients. In the 3 month-old, the immunoreactive meganeurons were usually surrounded by a non-immunoreactive zone. The intracytoplasmic labeling revealed tangle-like formations within the perikaryon extending into the proximal dendrites. In older patients, meganeurons were also strongly labeled but did not display the non-immunoreactive zone surrounding the cell body. Intracytoplasmic filamentous tangles usually displaced the nucleus and also extended into dendrites. Thus, neurofilamentous tangles in hemimegalencephaly share a common antigenic determinant with Alzheimer's disease intracellular neurofibrillary tangles.

HISTOLOGICAL OBSERVATIONS ON THE CENTRAL NERVOUS SYSTEM OF ATRANSFERRINEMIC MICE. J.R. Connor, S.L. Menzies*, and W.P. Bartlett. Dept. of Neuroscience & Anatomy, Penn State University, M.S. Hershey Medical Center, Hershey, PA 17033.

The role of transferrin in transporting iron and the importance of iron in neural development is well established. Tf is synthesized in the brain by oligodendrocytes and the choroid plexus. A strain of mice (ATf) which have an autosomal recessive defect in the Tf gene (Huggenvik et al., *Blood* 74:482-486, 1989) resulting in plasma levels of transferrin which are <1% of normal are investigated. The animals are maintained into adulthood by weekly injections of mouse serum. The adult mice (provided by Dr. Jerry Kaplan) were either immersed fixed in 10% buffered formalin or perfused through the ascending aorta with a mixture of 2% paraformaldehyde and 2% glutaraldehyde. A series of standard histological stains were performed on the brain and spinal cords. Grossly, the brain of ATf mice appears normal, but the spinal cord is smaller consistent with less myelin staining in the lateral columns. Histologically, in ATf mice the cerebral cortex and habenular nucleus have an increased cell density. In addition to a noticeable decrease in myelin in the spinal cord, larger than normal neurons are present in both the dorsal and ventral gray matter. These observations suggest locally synthesized Tf in the brain is important for normal neuronal and glial development.

351.3

EFFECT OF *IN UTERO* ALCOHOL EXPOSURE ON IRON REGULATION IN THE RAT BRAIN. A.J. Roskams, M.W. Miller, J.R. Connor. Dept. of Neuroscience and Anatomy, Penn State College of Medicine, Hershey, PA, 17033, and Dept. of Anatomy, UMDNJ, Rutgers University, NJ, 08854.

Iron (Fe) and iron binding proteins Transferrin (Tf) and Ferritin (Ft) and the Tf receptor (TfR) have been identified in the rat brain, and are associated with growth and differentiation. A rat model of Fetal Alcohol Syndrome (FAS) is used to examine alcohol's effects on iron regulation in the developing brain. Some CNS effects of *in utero* alcohol exposure are decreased brain weight, delayed myelination and neuronal development patterns. A developmental study of Tf, TfR, Ft is described in the cerebral cortex, the cerebellum/pons and the midbrain. Three groups are studied-offspring of mothers who are chow-fed, fed an isocaloric liquid diet or ethanol diet. Animals are taken at PND 1-3, 6-8, 11/12, 17/18, 23/24, and 60. Iron levels in ETOH cortex are severely depressed at all time points. Cortex Tf levels are equivalent in all three groups at birth. By PND 11/12, the ethanol group has higher Tf levels. At PND 11/12, TfR levels in the ethanol exposed groups are 2.5 times higher than in the control groups, but normalize by 18d. Ft in ETOH exposed group is higher than normals beginning PND 7/8. Similar effects are observed in the cerebellum & the Midbrain. We conclude that CNS iron regulatory systems are effected by *in utero* alcohol exposure.

MORPHOLOGICAL BRAIN ASYMMETRIES IN MICE BORN ACALLOSAL AFTER GAMMA IRRADIATION EXPOSURE. E. M. Caparelli-Dáquer* and S. L. Schmidt, Instituto de Biología, UERJ and Instituto de Biofísica, UFRJ.

In a strain of mice (BALB/cCF), in which about 20% of the animals are born with a very small corpus callosum (c.c.), we have suggested a relationship between the development of the c.c. and the direction of cerebral asymmetries. Here we report a study on morphological brain asymmetries in another model of early callosal damage (prenatal gamma irradiation). At E16 (E1, day of conception) 19 Swiss male mice were exposed to a ⁶⁰Co gamma source receiving a total dose of 2 Gy (the dose rate varied between 56 and 59 rads/min). At adulthood they were intracardially perfused with saline followed by formaline. Then the brains were photographed in the dorsal view, split through the sagittal fissure, photographed in the lateral and medial view and weighed. The sagittal areas of the c.c. measured in the medial view photographs allowed us to define a subgroup with a little callosal remnant (n=9; areas ranging from 0.22mm² to 0.58mm²) and another with no measurable c.c. (n=10; acallosal subgroup). For each brain, an asymmetry score (A.S. = (R-L)/(R+L)) were calculated from 3 hemispheric measurement: 1-weight; 2-dorsal area and 3-lateral area. The means of the A.S. and of their absolute values (A.S.I) evaluated respectively the directional asymmetries and non-directional asymmetries. Neither the total irradiated group nor the acallosal subgroup presented directional asymmetries. The callosal remnant subgroup displayed a tendency toward directional asymmetry. In the total group and in the 2 subgroups there was a significant non-directional asymmetry. The presence of non-directional asymmetries and the absence of directional asymmetries in this model of early callosal damage had been already observed in the BALB/cCF model. Taken together these data suggest that the absence of directional cerebral asymmetries may be assigned to callosal development and not to a feature pertaining to any of the 2 models.

INCREASED ³H-FLUNITRAZEPAM BINDING IN VISUAL STRUCTURES OF ADULT CEREBRAL HEMISPHERECTOMIZED COMPARED TO NEONATALLY HEMISPHERECTOMIZED CATS. Youram Nassir*, Keith I Tatsukawa*, David Brown*, Ali Ebrahim*, Steven Chen*, David A Hovda, Jaime R Villablanca*, Harry T.Chugani. Depts. Neurology, MRRC, Neurosurgery, Pediatrics, UCLA School of Medicine, Los Angeles, CA. 90024.

We have previously reported [Hovda & Villablanca Behav Brain Res 1990;37:119-32] that there is relative sparing of visual field perception in neonatal but not adult cerebral hemispherectomized cats. Since GABA-mediated inhibition has been demonstrated to play a role in plasticity within the visual system, we measured ³H-flunitrazepam binding in visual structures of adult cats which had undergone left hemispherectomy either as kittens (NHEMI; N-2) or as adults (AHEMI; N-2) and compared values to controls (N-2). Following incubation of brain sections in 170 mM Tris-HCl buffer (pH 7.4) containing 2 nM ³H-flunitrazepam in the absence or presence of 1 μM clonazepam (nonspecific binding), sections were exposed for three weeks. Autoradiograms were analyzed using a JAVA system. Results showed increased ³H-flunitrazepam binding in the right lateral geniculate (600%), right visual cortex (370%), and right (281%) as well as left (257%) superior colliculus of AHEMI compared to NHEMI. Values for NHEMI were not different from controls. These results indicated that ³H-flunitrazepam binding is affected differentially by the age at lesion and may reflect the degree of neural plasticity, or lack thereof in the lesioned animals. (USPHS 5R01-MH 37916)

THE INFLUENCE OF CHRONIC ETHANOL EXPOSURE IN THE CHICK EMBRYO ON THE EXPRESSION OF NEUROTROPHIC FACTORS AND CHOLINERGIC ACTIVITY. D.J.Swanson*, M. Paiva*, D.W. Walker and M.B. Heaton. University of Florida College of Medicine and V.A. Medical Center Gainesville, FL, 32610.

We have begun to develop an avian model for chronic prenatal ethanol exposure and its influence on neural development. Previously, our laboratory showed that chronic adult ethanol exposure in rats produces a reduction in neurotrophic activity in hippocampal extracts as determined in a cultured chick dorsal root ganglion (DRG) neuron bioassay (Walker et al., Soc. Neurosci. Abst. 16:823, 1990). In the present study chick embryos were exposed to either ethanol (approximately 30mg/day) or saline from embryonic day 4 (E4) until sacrifice and brain tissues were assayed for the relative abundance of neurotrophic activity or choline acetyltransferase (ChAT) activity. While ethanol exposure reduced brain tissue wet weight and ChAT activity of optic tectum and forebrain at E19, this treatment did not markedly influence overall development of these embryos compared to saline controls, as determined by morphometric measurements. Chronic alcohol treatment *in ovo* produced a significant reduction in neurotrophic activity in E16 forebrain extract (following exposure from E4-E13), as measured in our DRG bioassay. These results suggest that the production of neurotrophic factors and cholinergic enzymes may be appreciably altered following chronic prenatal ethanol exposure. Such alteration could underlie certain CNS anomalies seen in the fetal alcohol syndrome. Supported MH15737, NS20387, AA00200, and the Dept. of Veterans Affairs.

351.6

LACK OF ASYMMETRY IN CEREBRAL GLUCOSE METABOLISM IN NEONATAL AS COMPARED TO ADULT CEREBRAL HEMISPHERECTOMIZED CATS. D.A.Hovda, H.T.Chugani and J.R.Villablanca. Div. Neurosurg., Nuc. Med., Dept. Neurology, Psychiatry, and the Ment. Retard. Res. Cent. UCLA Sch. Med., Los Angeles, CA 90024

Following neonatal cerebral hemispherectomy (NH) adult cats exhibit greater behavioral recovery, more reinnervation from the remaining cerebral cortex and less degeneration compared to animals sustaining this lesion as adults (AH). The current study was designed to determine if these anatomical-behavioral differences are reflected metabolically in cerebral glucose utilization rates. Three neonatal (5-15 days of age) and 4 adult cats received a left cerebral hemispherectomy and cerebral glucose metabolism was studied using [¹⁴C]-2-deoxy-D-glucose autoradiography as adults. Local cerebral metabolic rates for glucose (ICMRglu; μg/min/100gm) were measured in 48 regions bilaterally. Results indicated that on the intact side of the brain AH exhibited ICMRglu which were generally higher than either NH or intact controls (e.g., range of ICMRglu in the right cerebral cortex; AH=90.3-129.7; NH=71.5-101.2; Intacts=66.7-112.0). On the lesioned side ICMRglu values in regions not directly affected by degeneration or reinnervation were within the same range in all three groups (e.g. hypothalamus; 39.0-56.0). However, in AHs, nuclei ipsilateral to the lesion which, according to previous data, show more atrophy and less reinnervation compared to NH and controls exhibited ICMRglu which were much lower than the contralateral (intact) side (e.g. ventral posterior lateral thalamic n.; AH, ipsilateral = 76.8 contralateral = 107.0). Thus, overall, there was more left-right asymmetry in AH with ICMRglu being generally higher compared to both NH and intact controls with ICMRglu of NH being within the normal intact control range for most regions. (DOE, DE-AC03-SF, USPHS 5R01-MH37916, 2P01-NS15654).

GREATER NEUROLOGICAL IMPAIRMENTS IN PRENATAL VERSUS NEONATAL CORTICALLY-LESIONED KITTENS. J.R. Villablanca, J.B. Harrison, G.F. Jackson*, D.A. Hovda and C. Infante*, Mental Retardation Research Center, UCLA, Los Angeles, CA 90024

Our previous work showed fewer impairments in cats hemispherectomized as neonates than as adults; therefore, we expected even greater recovery after a prenatal lesion (see also Brain Res., 152:451, 1978). Kittens (N=8) received a unilateral (left) frontal cortical lesion prenatally (E 48.4 days mean age) and were tested as young adults (>7 months). Comparisons were with neonatally frontal-lesioned (N=4; P 5.5 days) and intact littermates. Comprehensive quantitative testing in prenatal-lesioned cats showed: left turning preference, mild right limb and eyelid paresis, decreased right face and right limbs tactile sensibility, defective right paw placing reactions, marked preference to use the left paw (food retrieval task), abnormal right paw attitude, and poor stereopsis (visual cliff test). Neonatal-lesioned cats either did not show some of the impairments or these were milder. Therefore, and since neurological impairments following this restricted lesion were more like those after neonatal hemispherectomy, we conclude that a unilateral brain lesion produces more impairments in the fetal versus the neonatal cat. This agrees with our anatomical results (Loopuij et al., this meeting; Soc. Neurosci. Abst., 13:1116, 1987). Grants US PHS R01 NS-25780; P01HD-05958.

351.9

EFFECTS FROM EXPERIMENTALLY INDUCED HYDROCEPHALUS ON HIPPOCAMPUS: AN ULTRASTRUCTURAL STUDY. R.M. Kriebel, D.M. Cavanaugh, S.A. Cosmi and J.P. McAllister II. Depts. Anatomy, Phila Col Osteopath Med, Temple Univ Sch Med, Phila PA 19131.

The neurological deficits found in infantile hydrocephalus have most often been explained by pathological changes in cerebral neocortex. It has been the primary goal of our studies to provide a cellular basis for the residual neurological deficits observed even though surgical intervention may have relieved the effects of ventriculomegaly on the cerebrum. Previous studies have shown significant structural changes in subcortical nuclei, specifically in septal nuclei of the basal forebrain. The present studies were done to examine the ultrastructural of the hippocampal cortex, a primary target of septal projections. Kaolin injection induced hydrocephalus; aldehyde fixed brains were sectioned for electron microscopy. Preliminary cell counts show 70% of hippocampal pyramidal neurons in varying stages of degeneration from densification of cytoplasm to fully pyknotic. The plexiform laminae showed hydropic cellular degeneration and the number of synaptic contacts was decreased. The thickness of the hippocampus was not decreased and microscopically there was no indication of edematous extracellular space. In addition, the ependymal lining contiguous with the hippocampus was structurally intact, including surface cilia, intracellular junctions, and cell shape. The apparent structural integrity of the hippocampus led to the suggestion that the neuronal degeneration seen in the hippocampus may have resulted from the deficiency in basal forebrain innervation.

QUANTITATIVE ANALYSIS OF TRANSMITTER-IDENTIFIED SYSTEMS IN THE MONKEY PARAVENTRICULAR NUCLEUS: EFFECTS OF DIFFERENTIAL REARING CONDITIONS. S.D. Ginsberg¹, P.R. Hof^{1,2}, W.G. Young³, G.W. Kraemer^{4*}, W.T. McKinney⁴, and J.H. Morrison^{1,2}. ¹Fishberg Res Ctr for Neurobiology and ²Dept of Geriatrics, Mt. Sinai Sch Med, New York, NY 10029, ³Dept of Neuropharmacology, Scripps Clinic, La Jolla, CA 92037, ⁴Dept of Psychiatry, Univ of Wisconsin Sch Med, Madison, WI 53792.

A robust monoaminergic input to the hypothalamus from brainstem nuclei has been reported in several species. The present study was undertaken to quantify putative noradrenergic (NA) terminals in the paraventricular nucleus (PVN) of socially deprived (SD) or socially reared (SR) rhesus monkeys. The subjects are sacrificed in pairs at 1-2 years of age. Presently, magnocellular (MC) and parvocellular (PC) subdivisions of the PVN in two SD and two SR have been quantified through serial sections on a laser scanning microscope (LSM) for dopamine- β -hydroxylase (DBH) immunohistochemistry, using adjacent Nissl sections for cellular landmarks. At the time of submission, we are blind to the rearing condition of each subject. However, preliminary analysis has shown differences across the two groups in DBH stained boutons in both MC and PC divisions: mean group I MC, 5641 \pm 1076; mean group II MC, 8151 \pm 791; mean group I PC, 8161 \pm 6; mean group II PC, 10469 \pm 1779. The implication is that maternal and peer deprivation may permanently affect NA afferents to the hypothalamus. Additionally, discrete populations of cells in the PVN immunoreact with tyrosine hydroxylase (TH) and corticotropin-releasing factor (CRF) antisera. Preliminary cell counts have revealed no difference between rearing conditions, yet an interesting trend in rostrocaudal cell density has been identified. In all cases examined, a gaussian type distribution of both TH positive and CRF positive cell bodies has been noted. Cell density is greatest at intermediate levels, and systematically decreases in both the rostral and caudal poles. Early social deprivation may cause permanent alterations in brain structure which account for the pronounced behavioral aberrations observed in these subjects. Supported by the MacArthur Foundation, and NIH AG06647.

EFFECTS OF MATERNAL DEPRIVATION ON NEURONAL POPULATIONS IN THE PRIMATE HIPPOCAMPUS. S.J. Siegel¹, P.R. Hof^{1,2}, W.G. Young³, G.W. Kraemer^{4*}, W.T. McKinney⁴, and J.H. Morrison^{1,2}. ¹Fishberg Research Center for Neurobiology and ²Dept. of Geriatrics, Mt. Sinai Sch. Med., New York, NY 10029, ³Dept of Neuropharmacology, Scripps Clinic, La Jolla, CA 92037, ⁴Dept. of Psychiatry, Univ. of Wisconsin Sch Med, Madison, WI 53792.

It has long been known that environmental manipulations during development have profound effects on the behavior of primates. However, many of the underlying brain regions involved in these behavioral abnormalities and the specific effects on these structures have yet to be elucidated. The long term effects of maternal deprivation on newborn monkeys include hypersexuality, inability to interact normally with peers and inappropriate responses to stress. Additionally the effects of hormones released during stress, glucocorticoids (GC), on neuronal populations in the hippocampal formation have been described. Increased GC have been shown to produce neuropathology in CA3 while sparing CA1 and dentate granule cells (Sapolsky, et al, *J.Neurosci.*, 1990:10). Conversely, adrenalectomy, leading to low levels of the hormone, produces a deficit in granule cells while sparing CA1 and CA3 (Sloviter et al, *Science*, 1989:243). We have examined the brains of 1.5-2 year old maternally deprived and matched control rhesus monkeys. Our hypothesis has been that maternal deprivation leads to chronic elevation of GC resulting in various forms of aberrant brain development. Preliminary data (n=6) suggests that there is a difference between groups in granule cell expression of a nonphosphorylated epitope of neurofilament protein recognized by the monoclonal antibody SM132. Also there is a possible alteration of CA3 dendritic pattern. Neuronal morphology (ie. spine counts of basal & apical dendrites within CA1, CA3 and granule cells) will be examined using a confocal laser scanning microscope and computer assisted morphometric analysis following intracellular injection of Lucifer Yellow. Supported by the MacArthur Foundation & NIH AG06647.

SYMPOSIUM. MOLECULAR BIOLOGY OF THE DOPAMINE SYSTEM: HETEROGENEITY OF THE DOPAMINE RECEPTORS. Q. Civelli, Oregon Health Sciences University (Chairperson); M. Caron, Duke University; D. Sibley, NIH-NINCDS; J.C. Schwartz, INSERM-Paul Broca; H. Van Tol, University of Toronto; S. Watson, University of Michigan

The dopamine system is a predominant neuronal system which is the target of clinical treatment of psychomotor or affective disorders such as Parkinson's disease or schizophrenia. Classically, this system was thought to rely on the interaction of the neurotransmitter dopamine with two receptors the D₁ and D₂ dopamine receptors. The recent cloning of dopamine receptors has revealed that this family of receptors is more heterogenous than expected. It is now clear that several dopamine receptors exist that were not detected in previous pharmacological assays. In addition, the availability of dopamine receptor clones has led to a new way at studying the dopamine system. This symposium will unite leaders in the molecular biology of the dopamine receptors to discuss the present state of our knowledge of complexity of the dopamine receptors and of the regulation of their genes.

354

SYMPOSIUM. HOW CELLS KEEP TIME: THE MOLECULAR AND CELLULAR BASIS OF CIRCADIAN RHYTHMS. D.R. Liskowsky & L.L. Hall, OTA, U.S. Congress (Chairpersons); J.C. Hall, Brandeis U.; J.S. Takahashi, Northwestern U.; B. Rusak, McMaster U.; M. Menaker, U. of Virginia; F.W. Turek, Northwestern U.

In the last ten years, molecular biology, genetics, neural transplantation and neuropsychology have begun to unravel the mystery of how circadian rhythms are generated. The symposium will provide a forum for discussion of these exciting developments. Dr. Jeffrey Hall will discuss how specific genetic mutations alter the circadian pacemaker and influence other biological rhythms. Dr. Joseph Takahashi will review a vertebrate model system of the circadian pacemaker, the avian pineal. He will discuss data concerning the cellular regulation of circadian rhythms by light, second messengers, and macromolecular synthesis. Dr. Benjamin Rusak will discuss photic effects on gene expression and neural activity in the rodent suprachiasmatic nucleus (SCN). The effects of light exposure on the expression of several immediate-early genes will be presented. Dr. Michael Menaker will discuss transplantation of SCN tissue in hamsters and the production of temporal chimeras. Their behavior and neuroanatomy will be discussed. Dr. Fred Turek will present data from recent studies demonstrating that photic and non-photoc stimuli can induce pronounced phase shifts in the rodent circadian clock. His presentation will focus on physiological mechanisms that mediate the phase shifting effects of these stimuli.

356.1

GABA_A INHIBITION OF EXCITATORY AMINO ACID-INDUCED [3H]DOPAMINE RELEASE FROM CULTURED MESENCEPHALIC CELLS. I. Chaudieu, H. Allaoua, R. Quirion and P. Boksa. Douglas Hosp. Res. Ctr., Dept Psychiatry, McGill Univ., Montreal, Quebec, Canada H4H 1R3.

The substantia nigra is known to contain the highest levels of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) in the mammalian brain. It has been shown that intranigral injections of GABA and GABAergic drugs decrease striatal dopamine (DA) release as measured by microdialysis. On the other hand, previous studies in our laboratory using cell cultures of fetal rat mesencephalon have established that NMDA, quisqualate (quis) and kainate stimulate [3H]DA release from DA neurons. In an attempt to evaluate the relationship between the GABAergic and glutamatergic systems in the mesencephalon, we investigated the effect of GABAergic drugs on [3H]DA release stimulated by excitatory amino acids (EAAs) from cultured mesencephalic cells. Muscimol (mus), a GABA_A agonist, inhibited [3H]DA release evoked by NMDA (IC₅₀ for mus = 0.2 μM; 100% inhibition at 1 μM mus) and quis (65% inhibition at 100 μM quis) but not the response evoked by kainate. Baclofen (100 μM), a GABA_B agonist, modified EAA responses only slightly. Muscimol inhibition of the NMDA response was reversed by bicuculline and picrotoxin and potentiated by 1 μM flunitrazepam. In the absence of Mg²⁺, muscimol inhibited the NMDA response less effectively, suggesting that hyperpolarization leading to inactivation of a voltage-dependent Mg²⁺ blockade may account for part of the muscimol effect. These results indicate that GABA modulates [3H]DA release stimulated by NMDA and quis, but not kainate, via GABA_A receptors. Supported by FRSQ.

356.3

THE CONTRIBUTION OF NMDA RECEPTORS TO EPSPS EVOKED BY SENSORY STIMULI IN THE VENTROBASAL THALAMUS (VB) IN VIVO. T.E. Salt and S.A. Eaton. Institute of Ophthalmology, Judd Street, London WC1H 9QS, England.

In order to study the contribution of NMDA excitatory amino acid receptors to epsps evoked by somatosensory stimuli under physiological conditions, intracellular recordings were made from VB neurons in urethane-anaesthetised rats, and amino acid agonists and antagonists were applied by iontophoresis.

Stimulation of hair or vibrissa follicle afferents with a 10ms-duration air jet at 0.5Hz typically evoked an epsp which invariably gave rise to one or two action potentials. This sequence appeared to be curtailed by one or more ipsp. Application of the NMDA-receptor antagonist CPP, with iontophoretic currents adequate to antagonise NMA, selectively caused a reduction of the late component of the epsp in 14 of 15 neurons. Stimulation of 1000ms duration evoked a sequence of epsps and ipsp leading to trains of action potentials. This excitatory response was also CPP-sensitive. Application of the GABA_A-receptor antagonist SR95531 greatly reduced the stimulus-evoked ipsp and consequently revealed an enhanced sensory epsp. These previously occluded epsp components were very sensitive to antagonism by CPP.

These results indicate that NMDA receptors are involved in both low and high frequency sensory synaptic transmission to VB, and that this input is curtailed by stimulus-evoked GABA-ergic ipsp.

356.5

CONFOCAL MICROSCOPIC IMAGING OF SUBCELLULAR CALCIUM CHANGES EVOKED IN CULTURED HIPPOCAMPAL CELLS BY NMDA. M. Segal and D. MANOR. Center for Neuroscience, The Weizmann Institute, Rehovot, Israel.

Changes in free intracellular calcium concentration ([Ca]_i) in response to NMDA were measured in cultured rat hippocampal neurons loaded with the calcium dye Fluo-3 and exposed to argon-ion laser light in a Wild-Leitz confocal microscope. NMDA caused a glycine dependent, Mg²⁺ and 2-APV blocked rise of [Ca]_i. A similar, but 2-APV, Mg²⁺ and glycine insensitive rise in [Ca]_i could be evoked by kainate and quisqualate. The effects of NMDA were seen in the absence of [Na]_o, but the recovery to normal [Ca]_i following NMDA was slower than normal, indicating the involvement of the Na-Ca exchanger in the removal of excess [Ca]_i. The rise in [Ca]_i was first detected near the plasma membrane, and a wave of elevated [Ca]_i could be seen, moving towards the center at a rate of 0.1 mm/sec. The level of [Ca]_i was normally lower in the nucleus than in the cytoplasm, but following exposure to NMDA, nuclear [Ca]_i was highest among all other cell compartments. Normal [Ca]_o was necessary for the rise of [Ca]_i following NMDA exposure, but the release of calcium from intracellular stores also contributed to this rise, as it was markedly reduced by dantrolene. It is suggested that activation of an NMDA receptor causes a rise in [Ca]_i by a combined influx of calcium and its release from internal stores.

356.2

EXCITATORY AMINO ACIDS CONTROL HIPPOCAMPAL FIELD POTENTIAL OSCILLATIONS. Schneiderman JH. Univ. of Toronto, Toronto, Ont., Can. M4Y 1J3.

Oscillating spontaneous field potentials (SFPs) in hippocampal slices become larger and slower in the presence of low doses of GABA blockers. These slow SFPs are due to synchronous synaptic potentials but the transmitters are unknown. We studied the role of excitatory amino acid (EAA) receptors in the production of SFPs since EAAs are important putative hippocampal transmitters.

The non-NMDA antagonist, CNQX (2-10 μM), completely blocked spontaneous activity in both ACSF and low concentrations of penicillin (50-300 IU/ml) as well as evoked responses in ACSF. The NMDA antagonist, APV (50-100 μM), partially suppressed SFPs in penicillin but had no effect on SFPs or evoked responses in ACSF. The late components of the evoked responses in penicillin were reduced, however, the early components were unaffected.

Non-NMDA receptors are critical for the production of SFPs. NMDA receptors participate only in the long-latency components of the SFPs and evoked responses in the presence of GABA antagonists. These delayed events are likely due to recurrent EPSPs.

356.4

A STUDY OF THE CONTRIBUTION OF EXCITATORY AMINO ACIDS TO SYNAPTIC POTENTIALS IN THE CAT PREFRONTAL CORTEX IN VIVO.

P.L. Henning and T.E. Salt. Sandoz Research Institute, CH-3000 Berne, Switzerland and Institute of Ophthalmology, Judd Street, London WC1H 9QS, U.K.

Agonists and antagonists of eaa receptors were applied by iontophoresis to 21 intracellularly recorded neurons in the prefrontal cortex of 13 halothane-anaesthetised cats during electrical stimulation of either the ipsilateral ventro-lateral thalamus (VL) or ipsilateral cerebral peduncle (PED). PED stimulation resulted in antidromic action potentials in 9 cells which were followed by a later latency depolarisation (local circuit epsp) in 5 cases. VL stimulation resulted in epsps or epsp-ipsps sequences in 18 cells. The selective AMPA receptor antagonist CNQX reversibly inhibited VL-evoked epsps in 6/6 cases. In several of these cells, AMPA-induced excitations were abolished by CNQX while NMDA-excitations were unaffected. The selective NMDA receptor antagonists D-AP7 or CPP partly reduced such epsps in 7/10 cells, predominantly affecting late epsp components. The NMDA antagonists produced larger reductions (60-80%) of PED-evoked epsps in 3/4 cells and also reduced ongoing activity in 6 neurons. Such effects occurred partly in parallel with the antagonism of iontophoretically applied NMDA. These results suggest a role for NMDA receptors in the generation of ongoing synaptic activity, local circuit epsps, and later components of thalamically-evoked epsps. AMPA receptors may be responsible for a major component of the early part of VL-evoked epsps.

356.6

DIAZOXIDE REVERSIBLY BLOCKS GLUTAMATE DESENSITIZATION AND PROLONGS EXCITATORY POSTSYNAPTIC CURRENTS. K.A. Yamada & S.M. Rothman. Departments of Pediatrics, Neurology, and Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Diazoxide (DZ) is an opener of ATP-sensitive potassium channels in pancreatic β-cells and smooth muscle cells. Ben-Ari and colleagues have suggested that ATP-sensitive potassium channels might also be present on the presynaptic terminals of hippocampal neurons (*Brain Res.*, 486: 159-164). We recorded evoked synaptic currents between monosynaptically connected pairs of hippocampal neurons in dissociated cell culture, anticipating that DZ would reduce excitatory and inhibitory synaptic currents (epsc's and ipsc's) by a presynaptic mechanism. However, DZ reversibly enhanced the peak (200±71% of control, n=8) and prolonged the decay of epsc's (276±145% of control), while reducing the peak and prolonging the decay of ipsc's.

L-glutamate or quisqualate were exogenously applied by a rapid, whole-cell technique. Steady-state currents measured 700ms into a 750ms long application were reversibly increased to 380±170% (n=5) and 520±83% (n=5) of control respectively. DZ had no effect on currents from identical applications of NMDA, kainate, or GABA. DZ had no effect upon the glutamate reversal potential or upon passive or active membrane properties. Agonists and antagonists of ATP-sensitive potassium channels did not mimic or block DZ's effects.

We conclude that DZ reversibly inhibits rapid glutamate receptor desensitization, resulting in enhancement of the peak and prolongation of the decay of the epsc.

GLUTAMATE-IMMUNOREACTIVITY IS ABOLISHED BY 6-DIAZO-5-OXO-L-NORLEUCINE. F. Conti and A. Minelli*. Institute of Human Physiology, University of Ancona, Via Ranieri, I-60131 Ancona, Italy.

Phosphate activated glutaminase (PAG) provides most of the transmitter (releasable) pool of glutamate (Glu) in the CNS. In the present experiments we applied the PAG inhibitor 6-diazo-5-oxo-L-norleucine (DON) to the cerebral cortex of adult rats to test the hypothesis that Glu-immunoreactivity in cortical neurons might be a marker of Glu-ergic neurons.

DON (0.25-1 mM) was applied either intraparenchymally (0.2 μ l) or topically (2 μ l) to the parietal cortex of adult rats, and perfused transcardially with saline followed by 4% carbodiimide (in 0.1 M phosphate buffer, pH 7.4) and 4% paraformaldehyde (in the same buffer). Vibratome sections (30 μ m-thick) were then processed for Glu-immunocytochemistry as previously described (Conti et al., J. Neurosci., 7: 1887-1901, 1987). Adjacent sections were used for Nissl staining, cytochrome oxidase (C.O.) histochemistry, and neuropeptide Y (NPY) immunocytochemistry. In other animals, saline was injected in the cerebral cortex, or an empty micropipette was advanced through the cortical mantle.

Both intraparenchymal and topical application of DON abolished Glu-immunoreactivity completely, the effect being more intense in the cases in which DON was applied topically. The extent of the effect was dose-dependent: 0.25 mM produced a narrow halo of inhibition (200-300 μ m, both radially and tangentially); 0.5 mM produced inhibition in a wider cortical area (1mm radially; 2 mm tangentially), while 1 mM DON abolished Glu-immunoreactivity in all layers of a large region (about 2-3 mm wide). Controls showed that DON treatment did not change cytoarchitecture, neuronal morphology, C.O. activity and immunoreactivity to NPY, suggesting the effect is not aspecific.

Since PAG activity is mostly involved in the formation of releasable Glu, these results provide further support to the hypothesis that Glu-immunoreactivity in the cerebral cortex is related to the transmitter pool of Glu.

KYNURENIC AMINOTRANSFERASES IN HUMAN BRAIN: CHARACTERIZATION USING 3 H-KYNURENINE AS A SUBSTRATE. W. Schmidt, W.O. Whetsell, Jr., E. Okuno and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228 and ¹Vanderbilt Univ. Sch. Med., Nashville, TN 37232.

Using conventional spectrophotometric product analyses, two enzymes capable of synthesizing the neuroprotectant kynurenic acid have been identified in human brain tissue (Brain Res., 542:307, 1991). Partially purified preparations of both kynurenic aminotransferases (KAT I and KAT II) have now been used to further characterize their catalytic properties using physiological concentrations of kynurenic acid (KYN). With 2 μ M (100 nCi) 3 H-KYN (1.9 Ci/nmol) as a substrate, both KAT I and KAT II were measurable using the assay conditions elaborated for rat brain KAT (Schmidt et al., J. Neurochem., in press). pH optima were 7.4 (KAT II) and 10.0 (KAT I), respectively. KAT I, but not KAT II, showed a pronounced preference for pyruvate compared to 2-oxo-glutarate, and was potently inhibited by glutamine (IC₅₀ ~50 μ M). Apparent K_m values for KYN at optimal pH were 9 μ M (with 2-oxo-glutarate) and 670 μ M (with pyruvate) for KAT I and 1.4 mM (with either cofactor) for KAT II. These data are in excellent agreement with those obtained previously using non-radioactive substrate. The novel, more sensitive radiometric KAT assay will therefore permit the study of KAT I and KAT II in small samples of normal and pathological human brain.

Supported by grants NS 16102, NS 28236 and MH 44211.

356.11

IMMUNOCYTOCHEMISTRY OF PUTATIVE ENDOGENOUS NMDA-LIKE ANTIGEN(S) IN THE RAT CNS. J.C. Woodley*, P. Ordroneau* and P. Petrusz. Curr. in Neurobiology, Dept. of Cell Biol. and Anat., Univ. of North Carolina, Chapel Hill, NC 27599.

An antiserum against the synthetic peptide glycyl-D-aspartate (GDA) was used to search for putative endogenous ligands specific for the NMDA subtype of glutamate (Glu) receptors. Results from immunocytochemistry and ELISA (Ordroneau et al., J. Histochem. Cytochem. 38:1033, 1990) showed that the antiserum recognized the non-endogenous compounds GDA, NMDA, and D-Asp, but it did not recognize L-Glu, L-Asp or other known NMDA receptor ligands. We report here that the anti-GDA serum labels a neuronal antigen in vibratome sections of rat CNS. This antigen shows a widespread and distinct distribution that includes intense immunostaining in the neocortex, ventral striatum, hippocampus, basal ganglia, as well as the cochlear, facial, and vestibular nuclei, but relatively light staining in portions of the cerebellum, thalamus, and olfactory bulb. This distribution is consistent with the putative role of this antigen as an endogenous NMDA receptor ligand. (Supported by APA 1 T32 MH18882-03, and NS 27679).

356.8

KYNURENIC ACID PRODUCTION IN THE RAT HIPPOCAMPUS: EFFECTS OF QUINOLINATE LESION. H.-Q. Wu, H. Baran, F. Du and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228.

The production of kynurenic acid (KYNA), an endogenous broad-spectrum antagonist of excitatory amino acid receptors, was studied with biochemical and immunohistochemical techniques in quinolinic acid (QUIN)-lesioned rat hippocampus. All analyses were carried out seven days after QUIN (120 nmol/1 μ l). As compared to controls, the lesion caused a 91.8 \pm 6.5% increase in KYNA tissue content and a 67.3 \pm 4.3% increase in the activity of kynurenic aminotransferase (KAT), KYNA's biosynthetic enzyme. Immunohistochemical analysis using anti-KAT antibodies revealed a substantial increase in KAT-immunoreactivity, probably due to the proliferation of astrocytes, in the lesioned regions. Using *in vivo* microdialysis with fluorimetric KYNA detection, endogenous steady-state levels of extracellular KYNA in the normal hippocampus were found to be 90.4 \pm 10.5 fmol/30 μ l dialysate. QUIN lesions raised the basal extracellular KYNA to 212.7 \pm 19.7 fmol/30 μ l. Aminoxyacetic acid (-55% at 10 mM) and veratridine (-36% at 50 μ M), administered through the dialysis probe, decreased extracellular KYNA levels. The effect of veratridine was abolished by the QUIN lesion. These data confirm the pivotal roles of neuronal activity and astrocytic KAT in the control of extracellular KYNA levels.

Supported by USPHS grant 16102.

356.10

TRANSIENT INCREASE IN STRIATAL KYNURENATE SYNTHESIS FOLLOWING SYSTEMIC KAINATE ADMINISTRATION IN RATS. H. Baran, F. Du and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Because of the putative involvement of kynurenic acid (KYNA) in seizure processes (Neurosci. Lett., 48:273, 1984), its production from kynurenic acid (KYN) was assessed at various timepoints after the administration of the convulsant kainic acid (KA; 10 mg/kg, s.c.). KYNA synthesis was assessed by measuring kynurenic aminotransferase (KAT) activity in brain tissue homogenates, and by measuring KYNA in the medium of brain slices incubated with 50 μ M KYN (J. Neurochem., 52:1629, 1989). No change in KAT activity was observed up to 2 days following KA treatment in the striatum (S), substantia nigra (SN), hippocampus (H) and piriform cortex (PC). At 7 days, KAT was increased by 66% (S), 99% (H) and 84% (PC) as compared to controls (no change in SN). At the same timepoint, striatal slices from KA-treated rats showed a 79% increase in KYNA production. Analysis after 1 month, performed in slices only, revealed large increases in H (+227%) and PC (+380%) but not in S. Immunohistochemical analysis of the striatum 7 days after KA did not show an obvious change in KAT-immunostaining. The persistent changes in H and PC are likely due to the well-documented neuronal loss and associated astrogliosis, whereas the transient increase in striatal KYNA production indicates a functional up-regulation of KAT activity in the absence of apparent neuropathological changes. Supported by grant NS 16102.

356.12

SEROTONIN (5-HT)_{1A} BUT NOT 5-HT₂ RECEPTORS ARE ENRICHED ON CORTICAL NEURONES DESTROYED BY INTRASTRIATAL VOLKENSIN. P.T. Francis¹, M.N. Pangalos¹, R.C.A. Pearson², D.N. Middlemiss³, & D.M. Bowen⁴ (SPON. Brain Research Association). ¹Inst. Neurol., London, UK, ²Univ. Sheffield, UK and ³Merck Sharp & Dohme Research Labs., Harlow, UK.

Following striatal injection of the retrogradely transported toxin volkensin, pyramidal neurones of lower cortical layers (forming the corticostriatal pathway) are destroyed. Pyramidal cells of the upper cortical layers together with GAD mRNA positive cells (considered to be interneurons) of all layers are preserved. To investigate receptor types affected cryostat sections from 6 rats receiving 2ng of volkensin by intrastriatal injection were incubated with [3 H]-8-OH-DPAT, for the 5-HT_{1A}, and [3 H]-ketanserin for the 5-HT₂ subtypes. Specific binding density was determined, by image analysis from autoradiograms, in upper and lower cortical layers ipsilateral and contralateral to the injection site. The binding of [3 H]-8-OH-DPAT was reduced by 23% on the side ipsilateral to the striatal lesion compared to contralateral (23.6 \pm 7.6, mean \pm SEM, fmol/mg tissue vs 30.4 \pm 8.3, respectively, P=0.001 paired t-test) in lower layers but not in upper layers (22.7 \pm 8.1 vs 25.9 \pm 8.0, NS). The binding of [3 H]-ketanserin was unaffected (lower layers, ipsilateral, 27.7 \pm 2.5; contralateral, 31.7 \pm 3.5, NS and upper layers, ipsilateral, 32.2 \pm 4.8; contralateral, 31.0 \pm 4.4, NS). The lack of change in [3 H]-ketanserin binding may indicate that 5-HT₂ sites are on interneurons. The data (i) suggest glutamatergic pyramidal neurones which form the corticostriatal pathway are enriched in 5-HT_{1A} receptors, (ii) aid the interpretation of receptor changes in autopsy brain and (iii) provide clues to PET ligands for monitoring neuronal loss. Support by BRT, SERC, Wellcome Trust.

TEMPORAL RETINAL AXONS INITIALLY DO NOT MAKE DISTINCTIONS BETWEEN ROSTRAL AND CAUDAL COLICULUS D.K. Simon and D.D.M. O'Leary Molecular Neurobiology Laboratory, The Salk Institute, La Jolla CA 92037

Theories on topographic map development have emphasized the guidance of growth cones of primary axons. *In vitro* studies of the developing chick retinotectal projection show that a glycoprotein of caudal tectal membranes is repulsive for the growth of axons from temporal retina (which is topographically matched with rostral tectum) and induces the collapse of temporal growth cones (Walter et al TINS 13, '90). Related findings are reported for the mouse retinocollicular projection (Godement & Bonhoeffer, Dev 106, '89). In perinatal rats, the retinocollicular projection is topographically diffuse, suggesting that, *in vivo*, rat retinal axons initially fail to make such regional distinctions in the superior colliculus (SC) (Simon & O'Leary, Dev Bio 137, '90). We have now directly addressed this issue with "exo utero" focal Dil injections in peripheral retina to label axons as they first extend across the SC. At E18-19, the labeled axons extend, without branching, across the rostral-caudal length of the SC. Qualitative examination reveals no differences in the targeting behavior of temporal versus nasal axons. Temporal axons show no tendency to change their trajectory to avoid caudal SC; some extend as far as the caudal SC edge. The similarity in temporal and nasal axon targeting along the rostral-caudal SC axis is confirmed by quantifying their distribution along this axis. Thus, the targeting of temporal and nasal axons are indistinguishable at this stage. Growth cone morphologies are also similar for temporal and nasal axons and, for both sets, the percentage of complex growth cones is higher in rostral versus caudal SC with similar ratios for temporal and nasal axons. These *in vivo* data suggest that, at this stage, the growth cones of primary retinal axons do not respond to cues that encode position along the rostral-caudal SC axis. Instead, the elaboration of topographically ordered connections depends on the extension of interstitial collateral branches by axons that overshoot their topographically correct positions, followed by the removal of mispositioned axon segments and branches. DEVELOPMENT OF EFFERENT PROJECTIONS IN RAT VISUAL CORTEX IN VIVO AND IN VITRO. J. Bolz, J. Kehrer, and N. Novak Friedrich-Miescher Labor der Max-Planck Gesellschaft, 7400 Tübingen, Germany.

Efferent cortical projections are highly specialized. For example, cortical output neurons within a single cortical layer, but with different projection sites, participate in different intrinsic circuits, and have different morphologies. In the visual cortex, cells in layer 5 which project to the superior colliculus (SC-cells) have a long apical dendrite and a dense basal dendritic field, whereas callosally projecting (CC-) cells have a short apical dendrite and relatively few basal dendrites. These characteristic features, however, are not present during early development. Using Dil labelling in fixed rat brains, we found that SC- and CC-cells in layer 5 had similar pyramidal cell morphology up to postnatal day 4 (P4). Both cell classes had few basal dendrites, and all apical dendrites reached layer 1. Between P5 and P8, the apical dendrites of SC-cells followed the fast growing cortex, but the apical dendrites of CC-cells did not extend at the same rate. Around P10, SC- and CC-cells had developed their target-specific morphology, and the distinct differences in the patterns of basal and apical dendrites were clearly expressed. To address the question as to how these neurons acquire their morphological characteristics, we studied cortical projection neurons in a slice culture system. When cortical slices from 0-2 day-old animals were co-cultured for 8-10 days with explants from the superior colliculus, the morphology of SC-cells *in vitro* was strikingly similar to SC-cells at the corresponding age *in vivo*. These results suggest that inputs from other cortical and subcortical areas are not required for the development of target-specific pyramidal cell morphology, since these inputs are not present in culture. Further experiments will examine whether the target plays a role in defining phenotypes of cortical projection neurons.

357.5

DEVELOPMENT OF FORWARD AND FEEDBACK CONNECTIONS IN RAT VISUAL CORTEX. A. Burkhalter and T.A. Coogan, Dept. of Neurosurgery, Washington University Sch. of Med., St. Louis, MO 63110.

The majority of feedforward projections from lower to higher areas of visual cortex originate from upper layers. By contrast, feedback projections arise preferentially from lower layers. In view of the inside-out development of cortical layers we hypothesized that ontogenetically older feedback projecting cells invade their targets before the younger forward projecting cells. To test this possibility forward projections from primary visual cortex (area 17) to the extrastriate area 18a were labeled by injecting Pha-L into area 17 of 1 to 10 day old rats and sacrifice after 2 days. Feedback projections to area 17 were visualized through anterograde tracing from area 18a.

At 3 days of age (P3) growth cone tipped forward and feedback fibers were confined to layers 1 and 6. Labeling in P4 animals included layers 1, 5 and 6. Forward and feedback fibers invaded the cortical plate (CP) at P5. At P5 projection columns emerged at topographically appropriate locations of areas 17 and 18a. Forward projecting fibers branched in outer layer 1, the bottom of the CP and at the layer 5/6 border. Feedback projecting fibers ramified in inner layer 1, in the outer half of the CP and layers 5 and 6. At P12 both projections appeared more branched but far less elaborate than in adults.

Contrary to our expectation these results indicate that in rat visual cortex forward and feedback projections develop simultaneously. In addition, both projections develop with great topographic and laminar specificity and there is no evidence for competitive interactions between forward and feedback fibers. NIH EY05935.

357.2

A DEVELOPMENTAL MORPHOMETRIC AND VOLUMETRIC ANALYSIS OF AREA 18 PROJECTING LGND NEURONS IN THE POSTNATAL CAT.

L.A. Coleman and M.J. Friedlander, Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

Although the dendritic structure of neurons in the adult cat LGNd has been well characterized, relatively little is known about its development. Thus, we have studied how dendritic structure changes and how neighboring neurons of like-type interact and come to occupy defined space within the LGNd as it undergoes substantial volumetric changes during postnatal life. To minimize classification problems among immature LGNd neurons we have concentrated on the subset of geniculocortical relay neurons that project to area 18 of the primary visual cortex. Injections of fluorescently labelled latex microspheres were made into area 18 of the visual cortex in postnatal kittens aged 2 to 6.5 weeks and in adult cats. Following a 3 day survival, animals were perfused and the LGNd was sectioned at 400µm. Cortical injection sites were reconstructed. Density of labelled LGNd neurons was determined using confocal microscopy. Labelled cells were then injected intracellularly with Lucifer Yellow and HRP. Dendritic structure was analysed from a series of confocal images or from reconstructions of cells reacted for HRP. Labelled neurons were located in a discrete region with a consistent distribution (n=5 animals). In the caudal LGNd, labelled cells were located in the C laminae, while rostrally they were seen progressively more dorsal in both layers A and A1; a pattern described for adult cats (Geisert, J.Comp.Neuro. 190:793, 1980). The area 18 projecting cells were amongst the largest at all ages, their density decreased between 2 and 3 weeks postnatal, while dendritic morphology, even at 2 weeks, was consistent with adult Y-cell structure. However, features common to immature neurons, such as a greater density of dendritic spines, were seen in kittens.

DEVELOPMENT OF AFFERENT PROJECTIONS IN RAT VISUAL CORTEX IN VIVO AND IN VITRO. M.Götz, N.Novak and J.Bolz: Friedrich-Miescher Labor der Max-Planck Gesellschaft, 7400 Tübingen, Germany.

Afferent fibers from the thalamus terminate with a high degree of specificity in the cortex: each nucleus of the thalamus projects to layer 4 of a distinct area in the sensory cortex. Thalamic fibers, however, reach the cortex early in development before their target cells have been generated, and accumulate beneath the cortical plate until layer 4 has been formed. We studied the invasion of thalamic fibers together with the development of glycosylated adhesion molecules in rat cortex by combining anterograde Dil-tracing with lectin-staining. The growth of thalamic fibers correlates closely with the distribution of lectin-binding glycoproteins. From embryonic day 16 (E16) until E19 most glycosylated molecules are located in the subplate and marginal zone, and thalamic fibers are restricted to the subplate zone. During further development the expression of lectin-binding molecules spreads from the deep to the superficial layers. Thalamic axons follow the front of lectin-binding molecules and thereby grow towards their target cells in layer 4. To examine the influence of the cortex on the ingrowth of thalamic fibers, we confronted thalamic explants *in vitro* with cortical slices of different developmental stages. Fibers from thalamic explants of all ages tested (E16-P1) invade a co-cultured postnatal cortical slice and terminate in their appropriate target layer 4. In contrast, the same thalamic fibers do not invade a cortical slice prepared at E16. Quantitative growth assays demonstrated the existence of growth-permissive, membrane-bound molecules in postnatal cortex, that are not present in embryonic cortex. The differential expression of these membrane-bound molecules in the cortex regulates the invasion of thalamic axons and allows thalamic ingrowth only after layer 4 has been established. Preliminary experiments indicate that such a mechanism might also be involved in the selection of cortical areas.

EXPERIMENTALLY INDUCED ESTABLISHMENT OF VISUAL TOPOGRAPHY IN AUDITORY THALAMUS. A.W. Roe, J. Hahn, and M. Sur, Dept. of Brain & Cognitive Sci., M.I.T., Cambridge, MA 02139.

We have previously reported (Sur et al., '88) that following neonatal removal of primary retinal targets and deafferentation of the auditory thalamus (MGN) in ferrets, some retinal projections are induced to the MGN. The normal MGv (ventral or principal division of the MGN) contains a lamellar organization such that sound frequencies map in a mediolateral axis across lamellae while individual lamellae represent the same (iso) frequency. We have now investigated whether retinal projections map topographically in the MGv of "rewired" ferrets, and how the visual map relates to the lamellar organization of the nucleus.

We recorded extracellularly from visual units located in the MGv in 11 rewired ferrets and examined visual topography in the MGv by making grids of electrode penetrations spaced 250-500 µm apart. Receptive fields of visually responsive units were plotted and characterized. A two dimensional visual map was established in the MGv. Low azimuthal representations were found medially and high azimuths laterally. Elevations were mapped in a dorsal-to-ventral as well as a rostral-to-caudal gradient. These data indicate that azimuthal representations map across lamellae (congruent with the axis normally representing sound frequency), and elevations map within "isofrequency" lamellae. In contrast to the visual map in the normal LGN but consistent with the frequency map in the normal MGv, lines of projection map *within*, and not across, lamellar/laminar planes.

Thus, retinal projections induced to non-visual thalamic targets can be topographically organized. In rewired ferrets, the azimuth and elevation axes of the visual map have a predictable relationship to the frequency and isofrequency axes of representation in the normal auditory thalamus, suggesting that the orientation of topographic axes of sensory maps are specified by cues present in the target.

THALAMIC AXONS MAKE SYNAPTIC CONTACTS WITH SUBPLATE NEURONS IN CORTICAL DEVELOPMENT. K. Herrmann, A. Antonini and C.J. Shatz. Dept. Neurobiology, Stanford University School of Medicine, Stanford, CA 94305, and Dept. Physiol. UCSF, San Francisco, CA 94143.

Early in development, ingrowing thalamocortical axons arrive within the telencephalon before their ultimate target neurons in the cortical plate (CP) have migrated into position. These axons accumulate or 'wait' in the subplate (SP), a zone beneath the CP, that contains the first born neurons of the cortex, the SP neurons. EM studies have demonstrated that SP neurons receive synaptic contacts of unknown origin, although physiological evidence suggests that some of them may derive from thalamic sources.

To conclusively establish that some of these synapses derive from the thalamus, the anterograde tracer PHAL (phaseolus vulgaris leucoagglutinin) was injected iontophoretically into discrete thalamic nuclei of neonatal (P3 to P13) ferrets, and the brains were prepared for EM. Light microscopical analysis confirmed that many PHAL-labeled axons, often tipped with growth cones, are present in the SP. At P8 in ferret, some of these thalamic axons had even invaded the CP. At the EM level, labeled processes were found presynaptic, mainly to mature dendritic spines or shafts of presumed SP neurons. PHAL-labeled synaptic contacts could be seen also in the CP. These ultrastructural observations provide strong evidence that thalamocortical axons can make synaptic contacts onto SP neurons. Moreover these results suggest that functional synaptic interactions with SP neurons could play a role in the development of the appropriate thalamocortical connections. THALAMIC AND INTRACORTICAL PROJECTIONS ORIGINATE FROM SUBPLATE-1-IR AND GLUTAMATE-IR INVERTED PYRAMIDS IN THE WHITE MATTER OF DEVELOPING AND ADULT CAT NEOCORTEX. P. Wahle¹, K. Albus¹, J.R. Naegele², ¹MPI Biophysical Chemistry, 3400 Göttingen, FRG, and ²Yale Medical School, New Haven, CT 06510, USA.

MAb SUBPLATE-1 was raised against immature cat neocortical white matter (Naegele, Barnstable, Wahle, PNAS 88:330-34, '91). SUBPLATE-1 is expressed by non-GABAergic neurons of an inverted pyramidal morphology with spiny dendrites (Wahle et al., Soc. Neurosci. Abstr. 16:987, '90). The present study aims to determine the axonal projection pattern and the neurochemical phenotype of inverted pyramidal neurons in young (second postnatal week) and adult (one year and older) cats. DiI implants into cortical grey matter or thalamic nuclei of kittens label neurons of inverted pyramidal morphology in the cortical white matter. Rhodamine-conjugated latex beads injected into thalamus and neocortical grey matter of young kittens, and grey matter of adult cats were then used to label white matter cells by active retrograde transport. Immunohistochemistry with SUBPLATE-1 antibody and a glutamate antiserum (CHEMICON) was carried out. Many retrogradely labeled white matter neurons displayed glutamate-ir. In kittens some neurons retrogradely labeled from grey matter or thalamic injection sites also express the SUBPLATE-1-antigen. When retrogradely labeled white matter cells were filled intracellularly with Lucifer Yellow, all thalamic projection neurons and the vast majority of intracortical projection neurons display a spiny, inverted pyramidal morphology. The results suggest, that glutamatergic pyramidal neurons of the white matter (subplate) project to the grey matter and the thalamus during postnatal life and in adulthood. The neuron type is thus very similar to the layer VI pyramidal neurons. It differs morphologically by its mainly inverted dendritic orientation and molecularly by the developmental expression of the SUBPLATE-1 antigen.

DII LABELED INTERHEMISPHERIC FIBERS DURING RAT POSTNATAL DEVELOPMENT SHOW TRANSITORY CORPUS CALLOSUM AXON TERMINAL DISTRIBUTIONS THROUGHOUT VISUAL CORTEX IN LAMINAE I-VI. A.J. Elberger and M.M. Hester*. Department of Anatomy and Neurobiology, Univ. Tennessee Memphis, Memphis, TN 38163.

DiI labeling of the corpus callosum (CC) in neonatal rat has revealed presumed CC axon terminals within laminae I-VI throughout visual cortex area 17 (Elberger, 1990 Soc. Neurosci. Abs.); this indicates a potential for extensive CC/visual cortex interactions during early development. To determine whether a potential for such interactions exists in other species, CC axons and presumed terminals (defined by size, configuration) were labeled by placing crystals of DiI in vitro in the mid-sagittal CC of normal rats 1-4 weeks old. The distributions of CC axons in visual cortex were compared at different developmental stages.

The results show that at 1 week, CC axons penetrate supra- and infragranular layers throughout areas 17, 18a and 18b; terminals are found in laminae I-VI. By 2 weeks there is a slight reduction in the number of CC axons in area 17, with terminals still found in laminae I-VI. By 3 weeks there are significantly less CC axons in areas 17, 18a and 18b. These are reduced further at 4 weeks; by this age, CC axons in area 17 are very scarce. Thus, many transitory CC axons have an opportunity to interact with all regions of developing visual cortex in rat, as in cat. Transitory CC axons may play a critical role in normal development of visual cortex.

THE INVOLVEMENT OF SUBPLATE NEURONS IN THE FORMATION OF OCULAR DOMINANCE COLUMNS IN LAYER 4 OF THE CAT'S VISUAL CORTEX. A. Ghosh and C.J. Shatz, Dept. of Neurobiology, Stanford University, Stanford, CA 94305

During development of the mammalian visual system, axon terminals from the lateral geniculate nucleus (LGN) are initially intermixed within layer 4 of cortex and gradually segregate to give rise to ocular dominance columns. Many experiments have demonstrated that neural activity is necessary for segregation, but there are likely to be additional factors since the process of segregation can be influenced only during the critical period. Here we have investigated whether subplate neurons play a role in maintaining an environment permissive for ocular segregation within layer 4 of the cat's visual cortex. Subplate neurons are present below the cortical plate in large numbers during development, and many send ascending axon collaterals into the cortical plate, particularly into layer 4, during neonatal life.

Subplate neurons were deleted by an injection of kainic acid into the white matter during the first postnatal week, two weeks before the onset of segregation. Such an injection appears to selectively ablate subplate neurons without directly affecting other cellular elements in the region (verified by cresyl violet staining, MAP2 and GFAP immunocytochemistry). At 8-10 weeks postnatal, after segregation is normally complete, the pattern of termination of LGN axons was revealed by transneuronal transport following an intraocular injection of [3H]proline. In the absence of subplate neurons LGN axons failed to segregate into ocular dominance columns, and instead remained diffusely spread within layer 4, as they are at birth. The lack of segregation is accompanied by marked changes in the cellular organization of cortical layer 4. These changes first appear weeks after the subplate lesion indicating that they are not a direct consequence of excitotoxic damage. Our observations suggest that subplate neurons may be required for interactions which lead to the formation of ocular dominance columns within layer 4 and possibly also for the differentiation and maintenance of layer 4 neurons. CALLOSAL PROJECTION CELLS IN RAT VISUAL CORTEX EARLY IN DEVELOPMENT ARE PREDOMINANTLY INHIBITORY, GABAERGIC NEURONS. F. Kimura and R.W. Baughman. Dept Neurobiology, Harvard Med School, Boston MA 02115.

The transcallosal projection in cortex is generally thought to contain exclusively excitatory cells. We have obtained evidence, however, that this pathway contains an important inhibitory component early in development. Fluorescent latex microspheres were injected into the visual cortex of 0-1 day-old Long-Evans rat pups. The contralateral visual cortex was enzymatically dissociated at day 5 and grown in culture for at least 10 days before recording. Dual whole-cell-patch recordings of membrane potentials were obtained from pairs of cells including both corticocallosal cells and unlabelled cells. Of 44 labelled cells tested, 25 (59%) produced monosynaptic IPSPs in follower cells, 8 elicited monosynaptic EPSPs, and 11 were not directly connected. The IPSPs were blocked with 1 μ M bicuculline, persisted in 1 mM kynurenic acid, and reversed near E_{Cl^-} . Additionally we stained the cultures immunohistochemically with Gaba antiserum with the PAP technique. Of 41 labelled callosal cells, 27 (66%) showed Gaba-like immunoreactivity. Finally, we carried out the same experiments on neurons from a rat in which latex microspheres were injected on day 5, and enzymatic dissociation was done on day 6. Neither physiological nor immunohistochemical experiments showed existence of inhibitory neurons; none of 13 labelled neurons produced monosynaptic IPSPs, and none of 8 labelled neurons showed Gaba-like immunoreactivity. We conclude that there is a predominantly inhibitory transcallosal projection before about postnatal day 1, but that this is transient and is replaced by a completely excitatory projection by postnatal day 5. (EY03502 and Human Frontier Science Program)

DEVELOPMENT OF TYPE I BENZODIAZEPINE RECEPTORS IN MONKEY STRIATE CORTEX. Handrickson AE*, Shaw C*, Erickson A*, and Richards G*. *Biological Structure, U. Washington, Seattle WA 98195, †Ophthalmology, U. British Columbia, Vancouver Canada V6T1Z3, Canada, ‡Pharma Div. Preclinical Res., Hoffman-LaRoche, Basel, Switzerland.

The GABA-A receptor complex contains a benzodiazepine (BZ)-binding component which potentiates the action of GABA and can be labeled by [3H] flunitrazepam (3HFZ) for autoradiography. Studies using different types of BZ ligands have found two BZ receptors (types I and II) in immature rat brain and mainly type I in adult. Many studies using different methods have shown that the type I BZ receptor corresponds to the α 1 subunit of the GABA-A receptor. We have previously shown that 3HFZ binding appears in macaque monkey striate cortex by fetal day (F) 72 (Shaw et al. Soc. Neurosci. 1989) and rapidly reaches adult levels shortly after birth. To test whether monkey cortex also shows multiple BZ receptors during development we a) used the triazolopyridazine CL218872 (10^{-5} M) which is a specific ligand for the type I BZ receptor as a cold competitor for 3HFZ binding in fresh-frozen sections of striate cortex from F60 to adulthood, and b) immunocytochemically stained a similar developmental series of perfusion-fixed cortex with the α 1 subunit-specific monoclonal antibody bd24.

CL218872 had little effect on 3HFZ binding until F152 (birth=F170) when it eliminated binding in layer 4C and reduced that in other layers. After birth CL218872 blocked almost all labeling in layer 4C to adulthood, but 3HFZ alone showed a prominent dark band over 4C. At 8-20wk layer 3 density also was markedly reduced by CL218872 while other layers were less affected. Little specific staining for bd24 was seen until F162 when layer 4C was lightly stained. By 1d layer 4C was much darker and by 3wk staining had spread throughout all layers with 4C remaining the heaviest. At 9wk staining is intense in 6, 4A, 3, 2 and 1 with 5 and 4B much lighter; 4C remains the most intensely stained layer into adulthood but in older animals layer 2/3 is also very dark.

These two methods produce complementary results which show that the type I/ α 1/BZ receptor does not appear until late in gestation and then becomes predominant after birth, particularly in layers 4C and 2/3. The postnatal appearance and laminar location for the type I BZ receptor suggests that it could play a major role in visually-guided developmental interactions. (EY01208; MRC PG-29; B.C. Medical Services Fnd. Grant)

The Transient Columnar Expression of 5-HT_{1C} Receptors in Developing Cat Visual Cortex is Dependent upon Normal Binocular Interaction. R. H. Dyck, F. Lepore† and M. S. Cynader. Dept Ophthalmology, Univ British Columbia, Vancouver, BC, V5Z 3N9, and †Dept Psychology, Univ Montreal, Montreal, PQ, H3C 3J7, Canada.

We have previously shown that, during postnatal development of the visual cortex in cats, serotonin receptor subtypes established unique temporal gradients of expression. In addition, 5-HT_{1C} receptors, labelled with [³H]-mesulergine, exhibited a columnar pattern of expression within area 17 between postnatal days (P) 30 and 90 (Dyck and Cynader, Soc Neurosci Abstr, 16, 987).

Here we determined the overall distribution of columns in developing cat visual cortex using autoradiographic methods to localize 5-HT_{1C} receptors in tangential sections through opened and flattened cortex of P50 kittens. Furthermore, the relationship of 5-HT_{1C} columns to afferent input was assessed in P50 kittens who had undergone either eyelid suture, enucleation, optic tract section, or lateral geniculate nucleus aspiration (all performed unilaterally) prior to P10.

The distribution of 5-HT_{1C} columns in area 17 was found to be periodic (at ~1 mm intervals), and organized in bands with a predominant orientation perpendicular to the 17/18 border. 5-HT_{1C} columns were absent in visual cortex ipsilateral to the LGN aspiration; mostly absent ipsilateral to the optic tract section; virtually eliminated bilaterally following unilateral enucleation; and reduced following monocular deprivation. We conclude that the columnar expression of 5-HT_{1C} receptors in visual cortex is dependent on binocular cortical inputs during development and suggest that these 5-HT_{1C} sites are transient markers of ocular dominance bands in developing kitten striate cortex.

CALCIUM CHANNELS: PHYSIOLOGY AND PHARMACOLOGY III

358.1

MULTIPLE GATING MODES AND NORADRENERGIC MODULATION OF N-TYPE Ca²⁺ CHANNELS IN FROG SYMPATHETIC NEURONS. A.H. Delcour, D. Lipscombe* & R.W. Tsien, Dept. of Molecular and Cellular Physiology, Stanford Univ. and *Section of Physiology & Biophysics, Brown Univ.

Downmodulation of N-type Ca²⁺ channels by norepinephrine (NE) involves changes in the voltage- and time-dependence of gating. Cell-attached patch recordings (110 mM Ba) reveal multiple modes of N-type channel gating. In the low p_o mode (trace 1), p_o ~ 0.05 at -10 mV, and voltage-dependent activation occurs over a relatively depolarized range of potentials. In this mode, openings are sometimes sufficiently resolved to show a larger unitary current amplitude than openings with higher p_o. Two additional patterns of gating with higher p_o (traces 2, 3) can be distinguished by consideration of mean open and closed times (<t_o>, <t_c>) for individual sweeps: high p_o sweeps (p_o ~ 0.3) show shorter openings and longer closings while very high p_o sweeps (p_o ~ 0.6) display longer openings and briefer closings. The negative correlation between <t_o> and <t_c> points to the existence of two gating pathways; consecutive sweeps tend to show the same pattern of gating, consistent with idea of modes. With 100 μM NE in the pipette, the pattern of gating shifts toward modes of lower p_o, but within each mode the open-closed kinetics remains essentially unchanged. In addition to these patterns of gating, we sometimes see an N-type "sub-conductance" (9 pS) like those in rat

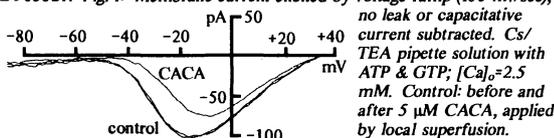

sympathetic neurons (Plummer et al., 1989). These smaller openings show N-type inactivation properties and ω-CgTx sensitivity, and activate at relatively negative potentials. NE modulation of the smaller openings is not readily apparent.

358.3

INHIBITION OF PRESYNAPTIC CALCIUM CURRENT VIA GABA_C RECEPTORS. Gary Matthews, George Ayoub, and Ruth Heidelberger. Dept. of Neurobiology & Behavior, SUNY, Stony Brook, NY 11794-5230.

Type Mb1 bipolar neurons of goldfish retina have large synaptic terminals (10-12 μm diameter), which receive feedback synapses from GABAergic amacrine cells. Previously, we showed that GABA, but not the GABA_B agonist baclofen, inhibits Ca current in these terminals (Heidelberger & Matthews, 1991, *Biophys. J.*, 51, 83a). Here, we report that the GABA analog, cis-4-amino crotonic acid (CACA), an agonist for GABA receptors that are insensitive to bicuculline and baclofen (GABA_C receptors; Drew et al., 1984, *Neurosci. Lett.*, 52, 317), mimics this action of GABA. Figure 1 shows that, like GABA, CACA shifted the activation of Ca current to more positive potentials, with peak suppression at -25 ± 1 mV (mean ± s.e.m., n=26); at more depolarized potentials, there was little effect on Ca current. The peak suppression of Ca current was 44.9 ± 4.2% (n=10) with 5 μM CACA and 25.7 ± 5.8% (n=3) with 0.5 μM. CACA did not activate GABA_A Cl conductance in bipolar neurons, so it appears to be specific for the receptors mediating GABA's inhibition of Ca current. Together with the ineffectiveness of baclofen, this suggests a physiological role for GABA_C receptors in modulation of presynaptic Ca current. Supported by NEI grant EY03821. Fig. 1: Membrane current elicited by voltage ramp (100 mV/sec);

no leak or capacitive current subtracted. Cs/TEA pipette solution with ATP & GTP; [Ca]_o = 2.5 mM. Control: before and after 5 μM CACA, applied by local superfusion.

5-HT_{1A} RECEPTOR ACTIVATION INCREASES K⁺ CHANNEL OPENING AND SIMULTANEOUSLY INHIBITS Ca²⁺ CHANNELS: DEMONSTRATION IN THE SAME DORSAL RAPHE NEURON. N.J. Penington, J.S. Kelly and A.P. Fox*. Univ. Chicago, Dept. Pharm/Phys, Chicago II, 60637, & Dept. Pharmacol. Univ. Edinburgh U.K.

We have previously reported that 5-HT_{1A} receptor activation dramatically inhibited Ca²⁺ currents in acutely isolated dorsal raphe neurons (Neuron 4, 751, 1990). Activation of the calcium current is greatly slowed by 5-HT. Occupation of the 5-HT_{1A} receptor also induced an inwardly rectifying K⁺ channel to open. The ED₅₀ for both Ca²⁺ channel inhibition and K⁺ channel activation was 30 nM 5-HT. Both effects are PTX sensitive when the cells were incubated at 35°C with the toxin (1 μg/ml) for 12 hrs. The effect of 5-HT on both K⁺ and Ca²⁺ currents was measured in isolation (consecutively) in the same cell and in other cells simultaneously. This was done by first using solutions appropriate for measuring I_K and then exchanging the external solution for one containing TEA, Ba, glucose and HEPES, a solution appropriate for measuring Ca²⁺ current in isolation. Both the inhibition of the Ca²⁺ current and the activation of 5-HT-induced K⁺ current could be observed in the same neuron. The effect on K⁺ currents but not on Ca²⁺ currents could be blocked by substituting Ba²⁺ for Ca²⁺. Thus in these cells, 5-HT decreases neuronal excitability profoundly by a simultaneous inhibition of Ca²⁺ currents and potentiation of K⁺ currents. We are investigating whether the same G-protein or two different G-proteins carry the signal from the 5-HT_{1A} receptor to the Ca²⁺ and K⁺ channels.

CALCIUM SIGNALS IN PRESYNAPTIC GLIAL CELLS CAUSED BY NERVE TERMINAL EXCITATION. B. Jahromi*, R. Robitaille and M.P. Charlton. MRC Group, Physiology Dept., Univ. of Toronto, Toronto, Canada M5S 1A8.

Glial cells are intimately associated with the nerve terminal at the frog neuromuscular junction. Each junction is covered by a few (2-5) glial cells whose fine processes wrap around the nerve terminal between active zones. While these cells are well positioned to influence the local ionic and biochemical environment of the presynaptic terminal and may thus influence synaptic transmission, little is known of their physiology.

We wondered whether these glial cells could respond to activity in the presynaptic terminal. Glial cells were loaded with the permeant Ca indicator fluo3-AM and were examined with a Biorad 600 confocal microscope using excitation at 488nm. The motor nerve was stimulated while images were obtained with the confocal microscope.

Trains of stimuli at 40 Hz for 30 sec caused a large Ca signal in the glial cells. Fluorescence from fluo3 increased in both the fine processes covering the nerve terminal and in the cell body which is several times the diameter of the terminal. The amplitude of the Ca signal depended on the frequency of nerve stimulation and the number of pulses given. The Ca signal did not occur in 0-Ca saline or in the presence of the Ca channel blocker Cd (50 μM) and is therefore not due entirely to internal release of Ca. The Ca signal does not depend on intact postsynaptic currents because these signals were obtained after application of α-bungarotoxin to block muscle contraction. Therefore, presynaptic glial cells are influenced by nerve terminal activity.

CALCIUM DEPENDENT REGULATION OF TRANSMITTER RELEASE OCCURS IN TERMINAL REGIONS OF SYMPATHETIC NEURONS. A.R. Wakade, S.V. Bhawe, A.S. Bhavne, T.D. Wakade* & D.A. Przywara. Dept. of Pharmacology, Wayne State Univ. School of Medicine, Detroit, MI 48201.

We examined the functional aspects of cell bodies and terminal regions (neurites and growth cones) of chick sympathetic neurons in culture. Release of tritiated norepinephrine ($[^3\text{H}]\text{NE}$) and intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) were determined. Effects of various pharmacological agents on $[^3\text{H}]\text{NE}$ release paralleled effects on $[\text{Ca}^{2+}]_i$ in terminal regions but not cell bodies. A new method is used to study localized uptake and release of $[^3\text{H}]\text{NE}$ in somatic versus terminal regions of neurons. Somata had very low $[^3\text{H}]\text{NE}$ uptake (0.23×10^{-6} cpm/mg protein) whereas neurites and terminals contained approximately 20 times more radioactivity. Excess K^+ and field stimulation evoked release of $[^3\text{H}]\text{NE}$ was unaffected by removal of cell bodies. Muscarine ($100 \mu\text{M}$) activated phosphoinositide hydrolysis was measured to further assess the functional integrity of the two separated regions. The increase in $[^3\text{H}]\text{-inositol}$ phosphates was more than 2 fold greater in cell bodies than terminals. These observations suggest that neurites plus growth cones are the prominent sites of uptake, storage and release of sympathetic transmitter. The data indicate that regulation of Ca^{2+} influx is distinct in the two regions and that $[\text{Ca}^{2+}]_i$ in the terminals only is related to $[^3\text{H}]\text{NE}$ release.

SYNAPSE FORMATION INDUCES CHANGES IN THE DISTRIBUTION OF CALCIUM CURRENTS IN LEECH NEURONS IN CULTURE. Cooper, R.L., Fernandez de Miguel, F.* and Adams, W.B. Dept. Pharmacology, Biocenter, Univ. of Basel, CH 4056, Switzerland. The distribution of Ca^{++} tail currents was measured by loose patch clamp in Retzius cells isolated from leech CNS. In single Retzius cells Ca^{++} currents were largest in the tips, smaller in the distal part of the soma and smallest in the mid region of the soma. When a chemical synapse was formed the tip of the postsynaptic cell showed a reduction in Ca^{++} current. Retzius cells that made electrical synapses or touched other cells without forming chemical synapses did not show this reduction in Ca^{++} current.

CALCIUM CHANNEL BLOCK BY PHOTO-RELEASED INTRACELLULAR CALCIUM. B.D. Johnson* and L. Byerly. Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

Intracellular Ca^{++} has been shown to block Ca currents in many cells throughout the animal kingdom. One of the difficulties in studying this phenomenon of Ca^{++} -dependent block has been to control intracellular Ca^{++} over the cell's own buffering system. In the present study we have used the photolabile Ca^{++} chelator DM-nitrophen to rapidly release Ca^{++} on a millisecond time scale, near the Ca channels themselves. When neurons from the snail *Lymnaea stagnalis* were whole-cell patch-clamped with a pipette containing Ca^{++} -loaded DM-nitrophen and exposed to a flash of UV light, $45 \pm 16\%$ ($N=7$) of the peak Ba^{++} current was blocked. 52% of the block occurred with a τ of 3.5 ms while the remaining 48% had a τ of 27 ms (see figure). Recovery from block proceeded with a τ of 27 s and returned to within 11% of its original amplitude. Only 5% of this irreversible block could be attributed to the damaging effects of UV light alone. Both block and recovery follow the intracellular Ca^{++} signal as measured optically and with Ca^{++} electrodes. Further work will focus on the dose-response relation and the mechanism(s) involved.

A LAMBERT-EATON MYASTHENIC SYNDROME ANTIGEN ASSOCIATED WITH PRESYNAPTIC CALCIUM CHANNELS. M.J. Seagar*, T. Hoshino*, K. Leys*, C. Leveque*, B. Lang*, Y. Kasai*, P. David*, A. Omori*, O. El Far*, N. Martin-Moutot*, K. Sato*, E. Jover, J. Newsom-Davis* and M. Takahashi. INSERM C/JF 9016, Faculté de Médecine Nord, 13326 Marseille 15, France; Mitsubishi-Kasei Inst. of Life Sciences, Tokyo, Japan and Inst. of Molecular Medicine, John Radcliffe Hospital, University of Oxford, Oxford, UK.

Lambert-Eaton myasthenic syndrome (LEMS) is an autoimmune disease of the neuromuscular junction in which pathogenic autoantibodies downregulate presynaptic calcium channels resulting in reduced ACh release and muscle weakness. Antibodies have been detected in LEMS plasma that immunoprecipitate solubilized 125I-omega conotoxin (wCgTx) receptors from human neuroblastoma membranes (Sher et al. (1989) Lancet, 2, 640). We report that LEMS IgG immunoprecipitates calcium channels from rat brain synaptic membranes. The wCgTx receptor was partially purified (approximately 250 fold) by two chromatographic steps. The LEMS antigen was identified, in Western blots of purified channel proteins, as a 58kDa protein which is distinct from the 220kDa wCgTx binding polypeptide detected by photoaffinity labeling. A monoclonal antibody, produced by immunizing mice with synaptic membranes, shared properties with some LEMS IgG and is presently being used to characterize the calcium channel associated antigen.

DURING ACTION POTENTIALS, T-TYPE Ca^{2+} CURRENTS CONTRIBUTE GREATLY TO Ca^{2+} ENTRY IN MEDIUM BUT NOT LARGE DIAMETER ACUTELY ISOLATED DRG NEURONS. R.S. Scroggs and A.P. Fox.* University of Chicago, Dept. Pharmacology/Physiology, Chicago, IL 60637

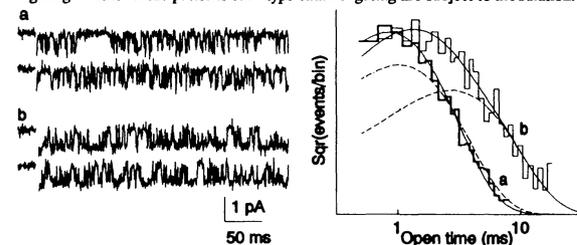

An action potential (AP) waveform (Fig. A) was used as a voltage command (holding potential -80mV , peak potential $+20\text{mV}$) to evoke Ca^{2+} currents in acutely isolated dorsal root ganglion (DRG) cells of medium ($33\text{-}38\mu\text{m}$) and large ($42\text{-}50\mu\text{m}$) diameter, using the whole cell patch clamp technique. As determined by blockade with $500\mu\text{M}$ amiloride, a large amount of current evoked by the AP protocol was conducted through T channels in medium diameter cells, which had large T currents, (Fig. B) but not in large diameter cells, which did not have T currents (Fig. C). Due to the slow de-activation kinetics of T channels, the entry of Ca^{2+} into medium diameter cells through T channels prolonged the duration of the current (Fig. B). Thus, Ca^{2+} entered medium diameter cells over a longer time period than was observed regarding large diameter cells (Fig. C). However, the total amount of charge per μm^2 surface area which entered medium diameter cells ($5.4 \text{ coul}^{-15} \pm 0.30 \text{ SE}$, $N=10$) was similar to that observed for large diameter cells ($4.2 \text{ coul}^{-15} \pm 0.68 \text{ SE}$, $N=8$). Differences in the duration of Ca^{2+} entry may alter diffusion patterns inside cells. Since DRG neurons with different diameter cell bodies may transmit different sensory modalities, the selective modulation of T channels might affect some sensory modalities more than others.

MICROSCOPIC HETEROGENEITY OF N-TYPE CALCIUM CHANNEL GATING. A.R. Rittenhouse, M.R. Plummer, and P. Hess.* Department of Cell & Molecular Physiology, Harvard Medical School, Boston, MA 02115.

Single N-type Ca channels exhibit inactivating and noninactivating bursting patterns of activity (Plummer & Hess, 1991 *Biophysics J.*, 59: 537a). Within the non-inactivating bursts, we observed heterogeneous gating during cell-attached patch recordings of differentiated PC12 cells. Several distinct kinetic patterns can be observed; 2 such patterns from the same single N-type channel are shown below. The sweeps shown in a, have a low open probability (P_o) and the mean open times are fit by a single exponential (bold line). In contrast, the activity shown in b has a higher P_o and the mean open times are fit by the sum of 2 exponentials (thin line; the individual exponentials are shown as dashed curves), with the short open times similar to those of the low P_o bursts. The high and low P_o bursting patterns of activity also can be seen within individual, noninactivating sweeps. We are investigating whether these patterns of N-type channel gating are subject to modulation.

PTX-RESISTANT G_o EXPRESSED IN PTX-TREATED NG108-15 CELLS RESCUES THE $I_{Ca,v}$ INHIBITION BY NOREPINEPHRINE. F. Belardetti, M. Rifo*, L. Yun*, R. Taussig* and A. G. Gilman*. Dept. Pharmacology, UT Southwestern, Dallas TX 75235.

G proteins couple a class of membrane bound receptors to intracellular effectors; however, their specificity for particular cellular pathways is poorly understood. An useful model system to address the question of G protein specificity is the neuroblastoma-glioma cell line NG108-15, where a variety of neurotransmitter actions converge on the voltage-dependent Ca^{2+} current ($I_{Ca,v}$) to produce inhibition. In this cell line, the $I_{Ca,v}$ inhibition by L-enkephalin (L-EK) and norepinephrine (NE) is blocked by Pertussis Toxin (PTX); suggesting that these responses are mediated by one of the PTX sensitive G proteins, G_o , G_{i1} , G_{i2} or G_{i3} . To study the role of G_o in NG108-15, we have established a NG108-15 cell line stably expressing a PTX resistant mutant G_{o2} subunit and have demonstrated that following PTX treatment of these cells, the L-EK inhibition of $I_{Ca,v}$ is still evident (Biophys. J. 59, 2, 2, 6a, 1991). We have used the same cell line to determine whether the α -adrenergic inhibition of $I_{Ca,v}$ occurs via the same pathway. In wild-type cells, NE reduced the $I_{Ca,v}$ to 76% of the control levels (n=6). In the same cell type after PTX (200 ng/ml/overnight), NE did not produce inhibition (n=5). When cells expressing the mutant G_o were employed, NE reduced the $I_{Ca,v}$ to 83% of control levels (n=5). After PTX treatment, NE still inhibited this current to 84% of control levels (n=7) in these cells. These experiments suggest that G_o might mediate the $I_{Ca,v}$ inhibition by both L-EK and NE in NG108-15 cells. We are currently using the same approach to determine whether the somatostatin and bradykinin inhibitions of $I_{Ca,v}$ occur via the same pathway.

Neuropeptide (NPY) Y1 and Y2 Receptors Mediate Opposite Actions on Nodose Neuronal Calcium Currents Via Pertussis Toxin-Sensitive Pathway(s). J.W. Wiley, R.A. Gross and R.L. Macdonald. Dept(s). Internal Medicine & Neurology, Univ. Michigan, Ann Arbor, MI.

Two different NPY receptor subtypes have been proposed, designated Y1 and Y2, based on bioassays and binding studies. [Pro34] NPY is a selective agonist for Y1 receptors while the C-terminal fragment 13-36 of NPY binds preferentially to Y2 receptors. Little is known about the electrophysiological actions of these agonists. We examined the effect of the Y1 and Y2 receptor agonists and native NPY on somal calcium currents in enzymatically dispersed postnatal rat vagal sensory (nodose) neurons using the whole cell version of the patch clamp technique. Voltage-gated calcium currents were recorded in media which blocked sodium and potassium currents. Nodose neurons exhibited three calcium current components, designated T, L and N which demonstrated distinct electrophysiological and pharmacological properties. NPY (0.1-100 nM) selective reduced the N current component in > 90% of responsive cells (52 out of 90 cells) while in < 10% of responsive cells a concentration-dependent increase in the N current component was observed. The Y2 agonist (0.1-100 nM) always decreased the N current component in 8/17 cells whereas the Y1 agonist (0.1-100 nM) uniformly increased the N current in 16/30 cells. Pretreatment with pertussis toxin (PTX; 100 ng/ml for 12 h), an inactivator of Gi/Go-type G-proteins, blocked the effect of the Y1-, Y2-agonists and NPY. In conclusion, nodose neurons express both Y1 and Y2 type NPY receptors; a Y1 agonist increased the N calcium current whereas a Y2 agonist reduced this current component. Both effects were mediated by PTX-sensitive mechanism(s).

FETAL NEURAL GRAFTING FOR THE TREATMENT OF HUNTINGTON'S DISEASE (HD) - REPORT OF THE FIRST CASE. I. Madrazo, R.E. Franco-Bourland*, C. Cuevas*, M.C. Aguilera*, F. Ostrosky-Solis*, N. Santiago*, H. Castrejón*, E. Magallón*, and G. Guizar-Sahagún*. Dept. Clin. Res. Neurol. Neurosurg., Ctr. Med. Siglo XXI, IMSS, 06725 México, D.F., México.

A neurosurgical procedure was designed and performed for the unilateral replacement of the striatum by homotopic homotransplantation of fetal striata in a patient with advanced HD, in accordance with the Mexican ethical regulations for human fetal brain grafting (Arch. Neurol. 47:1281,1990). The patient is a 37-year-old woman who first showed psychomotor alterations at the age of 28. In the last 3 years, she has shown significant continuous clinical deterioration. At the time of surgery, her scores of neurological function on the various scales (S) were: Marsden-Quinn S/12 points; Shoulson-Fahn S/stage III; disability S/65%; and AIMS/26 points. Prior to surgery, the patient was started on immunosuppression. Surgery was performed on November 2, 1990. Both striata of a 13-week-old fetus were transplanted into multiple cavities made in the ventricular wall of the right caudate nucleus of the recipient. Her recovery from surgery was uneventful.

Three months postsurgery, she showed no further neurologic deterioration compared to her preoperative state, and no damaging effect of the surgery. Some subjective signs of improvement were apparent.

LONG AXONAL GROWTH IN ADULT RAT STRIATO-NIGRO-STRATIATIAL SYSTEM FROM GRAFTS OF HUMAN NEUROBLASTS K. Victorin*, H. Sauer*, P. Brundin*, O. Lindvall*, and A. Björklund. (SPON: European Neuroscience Association) Dept. of Medical Cell Research and Restorative Neurology Unit, Dept. of Neurology, University of Lund, SWEDEN.

One approach to study factors that influence axonal growth *in vivo* is that of intracerebral neural transplantation. For instance, it has been shown that axons can extend from embryonic tissue implants into the host brain, above all if the recipient is neonatal or if the graft is placed directly into, or close to, its normal, preferably denervated, target region in an adult CNS. Although axonal growth along the normal growth trajectories does occur also when embryonic tissue is placed into its homotypic site of an adult recipient, this growth is at the most for a few millimetres, and reaches only into nearby targets. In recent experiments, we analyzed cross-species grafts of human forebrain neuroblasts, placed into the adult excitotoxically lesioned rat striatum, using an antiserum, which stains human neurofilament-positive fibres, but does not recognize rat neurofilaments (Serotec Ltd., U.K.). Using this approach, we detected extensive human neurofilament-immunoreactive fibre outgrowth along the white matter of, e.g., the host internal capsule for up to 10-20 mm, and into several of the normal target regions (Nature 347, 556-558, 1990). In a follow-up study we have now used this cross-species grafting approach to further investigate questions related to axonal growth, such as tissue type specificity, growth trajectories and polarity.

In the rat model with a dopamine-denervated striatum, preliminary findings suggest an interesting ability of human mesencephalic cells to grow along the myelinated tracts towards and into the striatum, also when placed in the internal capsule and in the substantia nigra. Grafts placed inbetween the substantia nigra and the striatum show a striking polarity and grow towards their normal target region, i.e., the striatum.

In the model with excitotoxic lesions of the rat striatum, various tissue types have been implanted into the striatum. As described previously, forebrain tissue dissected from the ganglionic eminences extends axons for long distances along the internal capsule, whereas cerebellar neurons do not. We now report that also neocortical and spinal cord tissue grow well along the internal capsule bundles.

FETAL STRIATAL CROSS-SPECIES IMPLANTS AMELIORATE ABNORMAL MOVEMENTS IN A PRIMATE MODEL OF HUNTINGTON'S DISEASE.

P. Hantrave^{1,2}, D. Riche^{*3}, M. Maziere^{*2} and O. Isacson¹ ¹ Dept of Neurology and Program of Neuroscience, Harvard Medical School and McLean Hospital, Belmont, MA, USA, ² CNRS URA1285, DRIPP, SHFJ, Hôpital d'Orsay, 91406 Orsay and ³ CNRS, Laboratoire de Physiologie Nerveuse, 91198 Gif/Yvette, France.

Recently, we developed an experimental model of Huntington's disease (HD) in primates using intrastriatal excitotoxin injections. After systemic apomorphine (1 mg/kg) a variety of abnormal movements analogous with the symptoms observed in HD patients, including dyskinesia, oro-facial dyskinesia, chorea and dystonia are observed. In the present study, the effects of neural implants on these motor symptoms were assessed. Comparison of the behavioral scores before lesion, 4 weeks after lesion and 10 weeks after grafting showed that implantation of cross-species fetal striatal cells into neuron depleted striatum of non-human primates reversed the abnormal movements observed in this animal model of HD. The abnormal movements returned after immunological rejection of the cross-species cells. In addition, in the case of transplantation with non-striatal foetal tissue (brain-stem cells) no recovery of motor function was observed. This study shows marked reductions of incidence of abnormal movements following transplantation in a primate model of HD and illustrates the potential of such an experimental approach to Huntington's disease

359.4

FETAL STRIATAL ALLOGRAFTS IN THE RHESUS MONKEY: AN ELECTRON MICROSCOPIC GOLGI STUDY.

G.A. Helm, N.E. Simmons, J.P. Bennett, Jr., P.E. Palmer, and J.A. Jane Dept of Neurosurgery, Univ. of Virginia, Charlottesville VA 22908

It is now well established that fetal neuronal transplants can lead to partial behavioral and biochemical recovery in rats with excitotoxically lesioned striata, a model of Huntington's disease. In the present study, we attempted to extend these studies into the primate. Primate fetal striatal neurons were transplanted into the ibotenic acid lesioned rhesus monkey striatum. Ten weeks after transplantation, the monkeys were transcardially perfused and graft tissue was Golgi impregnated and processed for electron microscopy. Large fetal striatal grafts contained numerous types of neurons at various degrees of differentiation. Medium-sized neurons with somatic diameters between 8 and 20 microns with occasional dendritic spines were characterized at the electron microscopic level by unindented nuclei, possibly representing immature medium spiny neurons. In addition, similar sized neurons displaying no dendritic spines contained indented nuclei, possibly representing the aspiny medium-sized neurons seen in the normal striatum. There were occasional neurons with somatic diameters between 20 and 40 microns which were characterized by indented nuclei and copious cytoplasm rich in organelles, representing the large neurons seen in the normal monkey striatum. The grafts contained developing dendrites, numerous growth cones, and mature synapses. In summary, the study demonstrated that ten weeks after transplantation fetal striatal allografts in the rhesus monkey contain neurons at various degrees of differentiation as assessed by Golgi impregnation and electron microscopy.

TRANSPLANTATION OF POLYMER ENCAPSULATED BOVINE ADRENAL CHROMAFFIN CELLS PREVENT QUINOLINIC ACID INDUCED LESIONS OF THE STRIATUM. P.R. Sanberg, D.F. Emerich, P.E. McDermott*, B.R. Frydel*, A.M. Bertino*, F.A. Kaplan, M.A. Palmatier, and L. Christenson. Cellular Transplants, Inc., Providence, RI 02906.

Excitotoxin-induced lesions of the striatum produce neural and behavioral deficits similar to Huntington's disease. It was demonstrated that certain cellular transplants can prevent striatal lesions induced by excitotoxins, possibly by release of trophic factors (Schumacker et al., *Soc. Neurosci. Abst.* 16:40, 1990). The present study examined whether xenograft adrenal chromaffin cell implants surrounded by an immunosolatory polymer membrane reduce the neurodegenerative effects of the excitotoxin quinolinic acid (QA). Isolated bovine adrenal chromaffin (BAC) cells were encapsulated within a polymeric membrane, and cut into 4mm long capsules and their ends sealed. BAC cell-containing or empty capsules were then implanted stereotactically into the striatum of Sprague-Dawley rats. One week later the animals were intrastrially injected with QA (225 nmol) or vehicle 0.8mm lateral to the implant. Body weights were recorded daily from the three experimental groups (BAC capsule/QA; empty capsule/QA; and QA alone). Thirty days after injection of QA the brains were histologically analyzed using cytochrome oxidase (metabolic activity) and Nissl stain. Both control groups lost weight following the QA lesion; however, the group implanted with BAC capsules had significantly less weight loss as a result of the QA lesion. Histologically, both control groups had ventricular dilation, neuronal loss and a complete lack of mitochondrial metabolic activity in the striatum. In contrast, the BAC implant group showed normal staining with cytochrome oxidase and relatively little neuronal loss. In conclusion, animals that received encapsulated BAC cell implants were protected from QA-induced damage in the striatum. Such a treatment may prevent progression of neuropathological damage in Huntington's disease.

359.7

TRANSPLANTS OF CULTURED ASTROCYTES ON EXCITOTOXIN-INDUCED LOCOMOTOR BEHAVIOR. M. Giordano, S.Y. Lu, D.F. Emerich, S.K. Pixlev, R.B. Norgren, M.N. Lehman and A.B. Norman. Div. of Neuroscience, Depts. Psychiatry and Anatomy. Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267 and Cellular Transplants, Inc. Providence, RI 02906

It has been reported that cultured astrocytes are able to reverse some behavioral deficits induced by lesions. The present study examined the effect of cultured astrocytes on locomotor deficits induced by bilateral kainic acid (KA) lesions of striatum.

Adult male rats (n=9) received bilateral striatal KA lesions. 10 weeks after the lesion, the rats received bilateral transplants of cultured astrocytes (3×10^6 cells) or fetal striatal tissue (E17) into the KA lesioned striata. The control group (n=7) received vehicle only. Abnormal locomotor behavior was observed in rats following the KA lesions. 5 weeks following striatal transplants, hyperlocomotor activity was reduced. 5 weeks following transplants of cultured astrocytes, abnormal rearing behavior was reduced. However, horizontal locomotor activity measures were increased after the astrocyte transplantation. Therefore, the astrocyte transplant produced differential effects on various locomotor measures. These effects of astrocyte transplants are dissimilar to the effects of fetal striatal transplants. Immunocytochemical analysis of the astrocyte transplant sites revealed heavy GFAP, OX-42 and laminin staining in the transplant areas. However, further study is necessary to firmly distinguish transplanted astrocytes from host reactive astrocytes.

359.9

MESENCEPHALIC FETAL GRAFTS RECOVER MOTOR ACTIVITY BUT NOT INHIBITORY AVOIDANCE IN STRIATAL LESIONED RATS. A.L. Piña, C. E. Ormsby*, H. M. Corzo* and F. Bermúdez-Rattoni Instituto de Fisiología Celular, UNAM. México, D.F.

Studies in our laboratory have demonstrated that striatal but not mesencephalic fetal tissue grafts, promote recovery in the ability to acquire an inhibitory avoidance (IA) task in striatal lesioned rats. In the present study, we evaluated the effects of different post-mesencephalic graft times on the recovery of IA and motor activity (MA). One group of Wistar male rats was lesioned in the dorsal striatum and another remained as unoperated control. After eight days the groups were trained for IA task and measured for an "open field" (MA) test. One week later the lesioned group was divided into two groups, receiving mesencephalic grafts (15E). The groups were retrained and tested at different recovery times post grafts (15, 30 days). The brain tissues were analyzed for AChE-histochemistry and immunocytochemistry for choline-acetyltransferase (ChAT) and Tiro sine hydroxylase (TH). Results 15 days post-graft showed that animals did not recover neither IA nor MA. However, tested 30 days post-graft the animals restored motor activity. Histological analyses showed that mesencephalic grafts have scarce AChE fibers and somas and strong TH immunoreactivity for somas, and a negative ChAT reactivity. These results suggest that specific tissue content is needed for differential recovery of motor activity and learning tasks.

INTRASTRIATAL AND INTRAVENTRICULAR FETAL STRIATAL TRANSPLANTS PROTECT AGAINST QA-INDUCED REDUCTION OF D₁ DOPAMINE RECEPTORS IN RAT STRIATUM. S.Y. Lu, P.R. Sanberg and A.B. Norman. Div. of Neuroscience, Dept. of Psychiatry, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267 and Cellular Transplant Inc. Providence, RI 02906

Neural transplants have been demonstrated to be able to reverse the behavioral deficits induced by excitotoxin lesions. The present study investigated the ability of fetal striatal transplants to prevent excitotoxin damage in the striatum. 3 groups of adult male rats received unilateral striatal transplants of 1) fetal striatal tissue (E-17) into the intact striatum (IS, n=8), 2) fetal striatal tissue into the lateral ventricle (ILV, n=8), or 3) sham transplant (vehicle only) into striatum (sham, n=9). 7 days after the transplantation, the IS and sham groups received a unilateral QA (100 nmol) lesion of the contralateral striatum. The ILV transplant group received QA in the ipsilateral striatum. 2 control groups consisted of 1) unilateral QA lesion only (QA, n=10), and 2) normal rats (NML, n=10). 21 days after the QA lesion, the B_{max} of [³H]SCH23390 binding to dopamine D₁ receptors was measured in the striata. Compared with the normal control group (100%), the B_{max} of D₁ dopamine receptors for the QA, IS, ILV and sham groups were 40%, 64%, 85%, and 58% of control values, respectively. ANOVA and post-hoc comparison revealed that intraventricular striatal transplants provided full protection against QA-induced loss of D₁ dopamine receptor binding sites, whereas intrastriatal transplants only partially protected against the QA-induced lesion in the contralateral striatum. Sham transplants did not protect against the QA-induced damage. These results suggest that fetal transplants can prevent QA-induced neuropathological changes. The close proximity of the transplant to the lesion site may improve the protection effect.

359.8

GABA RELEASE IN THE RAT STRIATUM: A COMPARISON BETWEEN INTACT, LESIONED AND GRAFTED STRIATA USING INTRACEREBRAL MICRODIALYSIS. K. Campbell, C. Lundberg*, P. Kalén*, K. Wictorin*, R.M. Mandel and A. Björklund. Dept. Med. Cell Res., U of Lund, S-22362 Lund, Sweden.

In order to characterize GABA release from intrastriatal fetal striatal grafts intracerebral microdialysis coupled to high performance liquid chromatography (HPLC) with electrochemical detection was performed on intact, excitotoxic lesioned (ibotenate 14-18 µg) and grafted (cell suspensions of fetal striatal tissue, 7-10 d post-lesion) striata. Loop type dialysis probes were implanted into either the intact, lesioned (7-10 d post-lesion) or grafted (3 mos post-transplantation) striatum at least 12 hrs before experimental manipulations. Dialysis probes were perfused at a rate of 2 µl/min and samples collected every 15-20 mins.

Excitotoxic lesions of the striatum resulted in a 75% reduction of basal GABA levels (116 fmol/20 µl dialysate) when compared to its intact counterpart (469 fmol/20 µl). The addition of KCl (100 mM) to the perfusion fluid produced an increase from the baseline greater than 55-fold in the intact striatum, which was reduced by more than 80% when Ca⁺⁺ was replaced by Mg⁺⁺ (20 mM) and by at least 50% in the presence of 1 µM TTX. The KCl response was further reduced in the lesioned striatum amounting to about 3% of the intact striatum. On the second day of experimental manipulations the addition of nipecotic acid (Nip)(0.5 mM) resulted in a 4-fold increase from basal levels in the intact striatum again reduced in the lesioned striatum by 71%. Preliminary results from grafted animals indicate a normalization of the baseline (approx. 385 fmol/20 µl) and the KCl response (108-fold increase from basal levels). The Ca⁺⁺ and TTX dependency of GABA release from striatal grafts is currently under investigation as well as a comparison between GABA release in the transplant and chronic lesions (3 mos post-lesion).

These results indicate that both basal and KCl-induced levels of extracellular striatal GABA are predominantly of neuronal origin (as much as 75 and 97%, respectively) and that intrastriatal transplants of fetal striatal tissue may completely or at least partially restore GABA release in neuronally depleted striata.

TRANSPLANTATION OF EMBRYONIC OR ADULT EGF-GENERATED MOUSE NEUROSPHERES INTO ADULT RATS WITH CORTICAL OR STRIATAL LESIONS. S. Weiss, B.A. Reynolds, W. Tetzlaff, B. Kolb and I.O. Whishaw. Neuroscience Research Group, Univ. of Calgary, Calgary, AB, Canada and Dept. of Psychology, Univ. of Lethbridge, Lethbridge, AB, Canada.

We have identified an EGF-responsive progenitor cell in the embryonic and adult mouse CNS, which will proliferate *in vitro* into a sphere (neurosphere) of undifferentiated cells that detach from the substrate after 5-7 days *in vitro* (DIV). At this stage, all the cells in the neurosphere contained nestin-like immunoreactivity, characteristic of undifferentiated neuroepithelial cells; these cells were negative for neuronal (NF, NSE) or glial (GFAP) cell markers. Two groups of rats received surgical lesions of the cortex or ibotenate lesions of the striatum. One week post-lesion, embryonic mouse cortical and embryonic or adult mouse striatal neurospheres were transplanted into the cortex and striatum, respectively, of the lesioned rats. Monoclonal antibody (M6), directed against a cell surface antigen located on mouse (but not rat) neurons, was used to identify mouse neurons in their rat hosts. Four weeks post-transplantation, M6-immunoreactive cells and fibres were detected in the lesion sites, but not in non-lesioned/non-transplanted regions of the rat CNS. These findings suggest that EGF-generated CNS progenitor cells differentiate into neurons when transplanted into lesioned adult CNS.

ELECTROPHYSIOLOGICAL CHARACTERISTICS OF EMBRYONAL CARCINOMA-DERIVED NEURONS GRAFTED INTO LESIONED ADULT RAT STRIATUM. D. S. K. Magnuson, D. J. Morasutti, W. A. Staines, M. W. McBurney and K. C. Marshall. Depts. of Physiology, Medicine and Anatomy, University of Ottawa, Ottawa, Canada. K1H 8M5.

Multipotential P19 embryonal carcinoma (EC) cells terminally differentiate into neurons, glia, and smooth muscle cells following induction by Retinoic acid (RA). Neurons from RA-induced EC-cells (*in vitro*) have previously been shown to form synapses, and to possess neurotransmitter and morphological properties reminiscent of those found in rodent forebrain neurons. In this study we have characterized the development of voltage-sensitive and neurotransmitter responses in EC-derived neurons *in vivo*.

Intracellular recordings of RA-induced EC-cells grafted into ibotenic acid lesioned adult rat striata were made within a 400µm *in vitro* brain slice. Cells recorded from 5-7d. old grafts had very high membrane input resistances (500MΩ, Rin), were not capable of maintaining a resting potential (RMP), and displayed very little rectification. The majority of cells in grafts 8-30d. old displayed rectification during depolarizing current injection, were able to maintain RMPs, had progressively decreasing Rin's (down to 150MΩ) and produced fast TTX-sensitive spikes. In younger grafts, spikes were small in amplitude, often more than 5msec in duration with negligible after-hyperpolarizations (AHPs). By 21-30days, most cells had progressed to produce "mature" action potentials of less than 2msec duration, overshooting 0mV in height, with large 10-20mV after-hyperpolarizations. Many cells in grafts older than 21 days displayed rectification during hyperpolarizing current injections. Sensitivity to L-glutamate and GABA was well developed in 8-30d. old grafts. Supported by the Canadian Centre of Excellence in Neural Regeneration and Functional Recovery.

AXONAL TRANSPORT OF PEPTIDE HORMONE ENCODING mRNAs IN THE HYPOTHALAMO-NEUROHYPOPHYSEAL TRACT OF THE RAT. E. Mohr*, S. Fehr* and D. Richter. Institut für Zellbiochemie und klinische Neurobiologie, Universität Hamburg, 2000 Hamburg, Germany.

Genes encoding vasopressin (VP) and oxytocin (OT) are highly expressed in hypothalamic magnocellular neurons which project to the posterior pituitary. The recent finding of VP and OT mRNAs in the neural lobe raises the question whether these transcripts are locally synthesized in pituitary cells or, alternatively, axonally transported from the perikarya of magnocellular neurons to the nerve terminals. Several lines of evidence support the latter concept. 1. Northern blot and *in situ* hybridization analyses indicate that VP and OT mRNAs are also present in the neural stalk which connects the hypothalamus and posterior pituitary. 2. VP primary transcripts are absent in posterior pituitary cells as documented by RNase protection experiments using a labelled probe complementary to intron I as well as by polymerase chain reaction amplification using intron I and II sequences as forward and reverse primers, respectively. These sensitive assays detect respective primary transcripts in magnocellular neurons of the hypothalamus. 3. Nuclear run on experiments performed with isolated posterior pituitary cell nuclei failed to detect VP and OT mRNAs but not β actin mRNA.

Cloning and characterization of the promoter region and gene encoding FMRFamide-like peptides in *C. elegans*. M. Rosoff and C. Li. Dept. of Biology, Boston University, Boston, MA 02215.

Approximately thirty neurons in *C. elegans* stain with an antibody specific for the RFamide moiety of the neuropeptide FMRFamide (Neurosci. Abst. 12:246). A cDNA clone whose putative translation product encodes eight potential neuropeptides was previously isolated (Neurosci. Abst. 16:305). Primer extension analysis shows that this cDNA is not full length. We are trying to isolate a full length clone from different cDNA libraries.

A λ1059 genomic library (courtesy of S. Emmons) was screened using the cDNA as a probe. Thirteen hybridizing clones were isolated and grouped into four overlapping classes by restriction mapping. A 3 kbp EcoRI fragment was subcloned from two separate overlapping lambda clones and sequenced. This fragment contains 300 bp upstream of the cDNA, the sequence corresponding to the entire cDNA, and a poly adenylation signal. We have recently isolated an additional 1.1 kbp genomic fragment upstream of the cDNA sequence. Constructs are being made to analyze the promoter region using the beta-galactosidase gene as a reporter in transgenic animals.

Concurrently, we have begun the purification of FMRFamide-like peptides from acetone extracts of mixed stage animals. Radioimmunoassays show the presence of FMRFamide-like peptides, and further characterization of the extracts by reverse phase HPLC reveals at least five peaks of FMRFamide-like immunoreactivity.

IDENTIFICATION OF MULTIPLE MEMBERS OF THE NEUROTRANSMITTER TRANSPORTER GENE FAMILY

M.M. Peak*¹, R.T. Fremeau, Jr.², M.G. Caron², and B.D. Blakely¹. Dept. of Anatomy and Cell Biology, Emory University School of Medicine¹, Atlanta GA, 30322, and Depts. of Neurobiology and Cell Biology, Duke University Medical Center², Durham NC 27110.

The cloning of a human Na⁺/norepinephrine transporter (NET) revealed significant amino acid identity between this carrier and the cloned rodent and human Na⁺/GABA transporters, suggesting the presence of a large family of related genes encoding other neurotransmitter reuptake proteins. To explore this possibility, we have utilized the polymerase chain reaction (PCR) with degenerate oligonucleotides synthesized from highly conserved regions of NET and GABA carriers to identify novel transporter sequences in rodent and human cDNA. These studies have identified 8 related species, each bearing significant amino acid identity with NET and GABA transporters. These fragments have been subsequently used as probes in high-stringency Northern and *in situ* hybridization experiments to determine both the size and cellular expression of endogenous mRNAs in the rodent CNS. Several clones selectively label neuronal populations with well characterized transmitter phenotypes. One clone selectively identifies soma in the serotonergic dorsal and median raphe, and thus is a strong candidate for the serotonin transporter. A second species exhibits a highly discrete expression pattern in the substantia nigra and ventral tegmental area, corresponding to the anticipated localization of dopamine transporter mRNA. A third clone, which hybridizes to a single 4kB mRNA on Northern blots, is expressed in cortical and hippocampal pyramidal cell layers as well as in the mitral cells of the olfactory bulb, consistent with the distribution of neuronal L-glutamate transporter mRNA. Other fragments hybridize with a more uniform and widespread cellular distribution, suggesting roles linked to intermediary metabolism and/or glial transport. Candidate clones corresponding to these initial isolates have been isolated from cDNA libraries and are presently being investigated. These data reveal the presence of multiple, related members of the neurotransmitter transporter gene family and provide new opportunities for the analysis of presynaptic regulation.

CLONING OF THE GENE ENCODING THE MITOCHONDRIAL BENZODIAZEPINE RECEPTOR. S.O. Casalotti, G. Pelaia*, D.R. Grayson, and K.E. Krueger. Fidia-Georgetown Institute for the Neurosciences, Georgetown University School of Medicine, Washington, D.C. 20007.

The mitochondrial benzodiazepine receptor (MBR) has been previously demonstrated to participate in steroid biosynthesis where an 18 kilodalton protein is responsible for the drug binding properties. The gene for this protein was isolated from a rat genomic library with the aim to correlate gene structure with functional domains and transcriptional regulation of MBR. Using the full length cDNA probe encoding the receptor mRNA six independent clones were identified, all of which showed identical internal restriction patterns with different amounts of flanking DNA indicating that each clone was derived from the same gene. Southern analysis of restriction digested rat genomic DNA confirmed the presence of a single copy of MBR per haploid genome. The sequence encoding the MBR protein is comprised of three exons where the two introns interrupt the coding sequence within potential transmembrane-spanning segments of the receptor. Approximately 3 kb has been sequenced including the flanking regions and introns. The putative 5' upstream sequence contains a CAAT box consensus sequence but other regulatory elements have not yet been identified.

CYCLIC AMP DEPENDENT REGULATION OF PROENKEPHALIN BY THE AP-1 RELATED PROTEIN JUN-D. L.A. Kobierski, H-M. Chu, Y. Tan* and M.J. Comb*. Lab. of Molecular Neurobiology, Mass. General Hospital, Harvard Med. School, Charlestown, MA 02114.

Regulation of the opioid precursor, proenkephalin, by neural activity and intracellular signaling pathways is well documented and provides a model in the nervous system for exploring the molecular mechanisms of trans-synaptic gene regulation. This gene is regulated by cAMP, phorbol ester and Ca⁺⁺-dependent second messenger pathways through an enhancer consisting of two elements called CRE-1 and CRE-2. In a C6-glioma cell line (C6-D2) stimulated with forskolin and IBMX mRNA encoding endogenous proenkephalin and a proenkephalin/chloramphenicol acetyl transferase (CAT) gene, pENKAT-12, are rapidly activated. Experiments with the protein synthesis inhibitors anisomycin and cyclohexamide suggest that this activation is independent of new protein synthesis. To identify transcription factors that may mediate this effect we have cotransfected pENKAT-12 with plasmids that constitutively express different Jun or Fos-related proteins and a plasmid that produces the catalytic subunit of protein kinase A (cPKA) into F9 and C6-glioma cell lines. By measuring CAT activity we have determined that Jun-D activates expression from pENKAT-12 10-30 fold in a cPKA-dependent manner and that activation is dependent on the CRE-2 element. Gel mobility shift assays reveal that Jun-D specifically binds a probe containing the CRE-1 and CRE-2 elements. In addition we show that in C6-D2 cells Jun-D mRNA is pre-existing and not significantly stimulated by forskolin treatment. These data support a role for Jun-D as a pre-existing factor in cells that can mediate the rapid PKA-dependent activation of the proenkephalin gene.

360.7

C-FOS AND C-JUN EXPRESSION IN THE RAT SUPERIOR CERVICAL GANGLION (SCG). J. Koistinaho¹, M. Belto-Huikko², Åke Dagerlind, R. Roivainen and T. Hökfelt. Depts of ¹Public Health and ²Biomedical Sciences, University of Tampere, 33101 Tampere, Finland and ³Department of Histology and Neurobiology, Karolinska Institute, S10401 Stockholm, Sweden.

The expression of immediate-early genes c-fos and c-jun was studied in the rat SCG using *in situ* hybridization and immunohistochemistry. In the control rats, low levels of c-fos and c-jun mRNAs were present in the SCG, but colchicine treatment enhanced the labelling. Immunohistochemistry also revealed an increased number of neurons displaying Fos-like immunoreactivity (Fos-IR) after colchicine treatment. After nicotine injection (2 mg/kg) the levels of both c-fos and c-jun mRNA were rapidly increased (after 10-15 min) and remained elevated upto 60 min. Two hours after the nicotine injection 70-80% of the neurons showed Fos-IR and most of the neurons remained Fos-IR still at 5h after the injection. A dramatic increase in the expression of these genes was also observed two days after decentralization. Although immunohistochemistry showed some enhancement in Fos-IR of the neurons, the most intense immunolabelling was localized in satellite cells, which remained weakly Fos-positive even at 8 d postoperation. The finding that all these stimulations of the SCG increased also the level of tyrosine hydroxylase mRNA suggests that a higher functional activity is associated with the expression of c-fos and c-jun in the rat sympathetic neurons.

360.9

A PROTEIN COMPLEX DIFFERING FROM THE FOS/JUN COMPLEX BINDS AT AN AP-1 VARIANT SEQUENCE IN THE DYNORPHIN PROMOTER AND IS INDUCED IN SPINAL CORD BY PERIPHERAL INFLAMMATION. M.J. Iadarola, G. Mojdehi*, J. Gu*, C.L. Yeung*, D. Levens** and R. Dubner. Neurobiology and Anesthesiology Branch, NIDR and ¹Laboratory of Pathology, NCI, NIH, Bethesda, MD 20892.

Previous studies demonstrating a co-expression of Fos protein and dynorphin in rat dorsal spinal cord after induction by peripheral inflammation suggest a possible role for Fos in dynorphin gene expression. However, the dynorphin promoter does not contain an AP-1 consensus sequence, TGAGTCA, which acts as a binding site for the Fos/Jun heterodimer. Using a 24 bp oligomer from the dynorphin promoter, we find that a protein-DNA complex forms between the variant dynorphin AP-1-like (DAP) sequence (TGCGTCA) and nuclear extracts of spinal cord or brain. The DAP complex appears to be composed of proteins in a unique combination since it was mostly resistant to further size modification or disruption when an anti-Fos antibody was added to a gel mobility shift assay. In contrast, an oligonucleotide containing an AP-1 consensus sequence from the Gibbon Ape Leukemia Virus enhancer (GALV) showed a complete further retardation when the anti-Fos antibody was added to the gel shift assay and was disrupted with an excess of antibody. Competition experiments using labeled GALV and labeled DAP sequence indicated that GALV produced a shallow displacement curve and was ~6-fold less effective than DAP in competing the variant complex when labeled DAP was the probe and vice versa, the DAP sequence was ~6-fold less effective when competing labeled GALV. These observations suggest that the DAP complex contains a protein that is distinct from Fos or Fos-related antigens. DAP complex formation was rapidly induced in spinal cord nuclear extracts from rats with an experimental peripheral inflammation. This treatment up-regulates expression of the genes for prodynorphin, proenkephalin and c-fos, suggesting a role for the variant complex in regulation of gene expression in spinal cord neurons.

Nerve Stimulation and Denervation Induce Differential Patterns of Immediate Early Gene mRNA Expression in Mouse Skeletal Muscle. S.R. Abu-Shakra, D.B. Drachman, A.J. Cole, J.M. Baraban & P.F. Worley. Dept. of Neurology, and Neuroscience, Johns Hopkins University, Baltimore MD 21205.

Many properties of skeletal muscle cells are closely regulated by motor nerves. For example, the acetylcholine receptor number, distribution and subunit composition is dependent on the state of neuromuscular synaptic transmission. However, little is known about the early regulatory events that occur in mature muscle cells in response to neuromuscular stimulation or denervation. We have examined the effects of motor nerve stimulation and denervation on the expression of 4 immediate early genes (IEGs): *c-jun*, *jun-B*, *zif268*, and *nur77*. Electrical stimulation of the sciatic nerve in a pattern that mimicked brisk intermittent exercise induced a marked rise in *zif268* and *c-jun* mRNA levels within 30-45 minutes, while *jun-B* and *nur77* mRNA levels remained unchanged. By contrast, surgical denervation resulted in a marked increase of *nur77* and *c-jun*, a slight but definite rise in *jun-B*, and no consistent change in *zif268* mRNA levels. Thus, neural stimulation and denervation lead to differential patterns of IEG expression. The selectivity of these patterns suggests that IEG expression may play an important role in regulating specific phenotypic changes in skeletal muscles that result from denervation, innervation, and various patterns of stimulation.

360.8

KAINATE-INDUCED INCREASES IN AP1 BINDING AND FRA IMMUNOREACTIVITY IN THE RAT HIPPOCAMPUS. K. Pennybacker, L. Thai, R. Fannin*, and J.S. Hong. LMN/NIEHS/NIH RTP, NC 27709. Kainate, a glutamate receptor agonist, causes seizures and induces the expression of c-fos and related antigens (FRA) in the rat hippocampus. Kainate treatment also increases the mRNA of dynorphin 3 hours after administration and enkephalin 24 hours after administration in the rat hippocampus, suggesting that FRA's binding to the AP1 element may enhance the expression of these neuropeptides. With the use of FRA-specific antibodies and AP1 DNA-binding studies, we have examined the relationships between the expression of FRA's and neuropeptides from 1.5 to 6.5 hours after kainate administration. Antibodies against the FRA's detected several proteins at the molecular weights of 60-70, 42, 40 and 35 KD. Weak FRA immunoreactivity was exhibited at 1.5 hours, while strongest immunoreactivity was observed at 6.5 hours after treatment, suggesting FRA expression was still increasing. Gelshift binding assays revealed that AP1 DNA binding increased with a time course identical to FRA immunoreactivity. In light of the extended time course required, the FRA's do not seem to be directly involved in dynorphin regulation, but still may be linked to enkephalin expression. Longer timepoints as well as DNA footprinting and AP1 crosslinking are being used to further examine whether neuropeptide expression is regulated by the FRA's.

360.10

cAMP DEPENDANT REGULATION OF THE cAMP-REGULATED ENHANCER CRE BY THE TRANSCRIPTION FACTOR ATF-1. B.P. Rehms*, K.M. Walton and B.H. Goodman*. Vollum Institute, Oregon Health Sciences University, Portland, OR, 97201.

Since the original isolation of the cAMP-dependent transcription factor CREB, several other factors have been cloned that are also able to bind to the cyclic AMP regulated enhancer (5'TGACGTCA3'). One of these factors, ATF-1, is approximately 70% identical to the CREB protein overall and is nearly 92% identical in the DNA binding and leucine zipper domains. Thus, ATF-1 and CREB may bind to the same target genes and probably can form heterodimers with each other. We have recently isolated both a full length ATF-1 clone and an alternatively spliced variant of ATF-1, termed ΔATF-1. Both ATF-1 and ΔATF-1 are present in a variety of tissues and cell lines and are capable of binding to the somatostatin CRE. Both ATF-1 and ΔATF-1 contain phosphorylation sites for protein kinase A and a domain, designated PDE 1, that can be phosphorylated by casein kinase II *in vitro* and appears to be essential for PK-A mediated transcriptional activation of CRE-containing genes. The ΔATF-1 isoform is missing a second domain, designated PDE 2, that is also required for CREB function. Transient transfection studies in F9 teratocarcinoma cells indicate that ATF-1 is as active as CREB in mediating cAMP-dependent transcriptional activation of a somatostatin CRE-CAT reporter gene. The ΔATF-1 isoform does not appear to respond to PK-A. We conclude that 1) CREB is not the only CRE-binding factor that can mediate transcriptional responsiveness to PK-A, 2) alternative RNA splicing can generate transcriptional factor isoforms with vastly different activities, 3) CREB, ATF-1, and ΔATF-1 are co-expressed in many tissues and cell lines, 4) the PDE 2 domains of CREB and ATF-1 are essential for PK-A mediated activity of these factors. We propose that ΔATF-1 may modulate ATF-1 and CREB activity.

DEVELOPMENTAL CHANGES IN *IN VIVO* RELEASE OF β -ENDORPHIN (β -END) FROM THE STALK-MEDIAN EMINENCE (S-ME) IN FEMALE RHESUS MONKEYS. E. Terasawa and S. Chongthammakun, Wisconsin Regional Primate Research Center, Univ. of Wisc., Madison, WI 53715.

Opiate peptides have been postulated to play a role in the control of LHRH release. In the present study, we have measured developmental changes in β -END release from the S-ME of female rhesus monkeys at prepubertal (n = 10), early pubertal (n = 8), and midpubertal (n = 11) ages using the push-pull perfusion method. Effects of ovariectomy (OVX) and effects of estradiol were also tested. β -END and LHRH in perfusates from the S-ME were measured by RIA. Results: 1) There were clear developmental increases in β -END release. β -END release in ovarian intact prepubertal monkeys was much smaller ($p < 0.01$) than those in early pubertal and midpubertal monkeys. 2) This developmental increase in β -END was significantly correlated ($p < 0.01$) with pubertal increase in LHRH release. 3) However, the developmental increase in β -END occurred independent of estrogen. OVX did not alter β -END levels in monkeys at any developmental stage. In contrast, OVX resulted in the elevation of LHRH release in early and midpubertal monkeys, but not in prepubertal monkeys. 4) Similarly, while estrogen injection into OVX monkeys at the early and midpubertal stages resulted in suppression of LHRH release, estrogen did not cause any significant effects on β -END release. Estrogen suppressed neither LHRH nor β -END release in prepubertal monkeys. In summary: 1) since the increase in β -END release occurs with the increase in LHRH release during puberty, low levels of LHRH release in prepubertal monkeys are not likely due to tonic inhibition by β -END neurons and 2) the negative feedback effects of estrogen on LHRH release in pubertal monkeys are not mediated by β -END. It is concluded that β -END does not appear to be involved in the onset of puberty. (Supported by NIH grants 11355, 15433, & RR00167).

GALANIN NEURONS IN THE MONKEY ARCULATE REGION DO NOT CONTAIN OR INTERACT WITH GONADOTROPIN HORMONE RELEASING HORMONE NEURONS. P.C. Goldsmith, J.E. Boggan* and K.K. Thind. Reproductive Endocrinology Center, Univ. Calif., San Francisco, CA 94143.

Galanin (GAL), a 29 amino acid peptide named for its C-terminal glycine and N-terminal alanine, has been identified in neuronal subpopulations within the arcuate (ARC) nucleus of several species. In addition, GAL has been shown to affect gonadotropin secretion and to colocalize with gonadotropin-releasing hormone (GnRH) in rat preoptic area neurons. To investigate their interrelationship in primates, we examined GAL and GnRH coexistence and neuronal interactions in the hypothalamus of female cynomolgus monkeys. Neuroendocrine (NEU) neurons were retrogradely labeled by microinjection of tracer into the median eminence. After aldehyde perfusion, series of 40 μ m frontal vibratome sections at 500 μ m intervals were collected and immunostained for GAL or GnRH with PAP, or double immunostained with PAP and colloidal gold. GAL fiber densities were highest in the anterior commissural nucleus and stria terminals, lower in the dorsal hypothalamic area, with trace amounts occurring in the medial preoptic area and periventricular nucleus. The 129 GAL neurons in a sample series of sections were confined to the posterior ARC (pARC) region. About 75% of these were NEU, similar to the 71% NEU GnRH neurons we previously reported in the ARC region (*J. Neuroendocrinol.* 2:157, 1990). Due to the presence of NEU GnRH neurons in this area, double immunostained sections of the pARC were serially thin sectioned and examined by electron microscopy. Colocalization of GAL and GnRH was not observed. GAL and GnRH elements came close together, but neither synapses, junctional specializations, nor interactions occurred. We conclude that GAL and GnRH neurons do not interact in the pARC region of the monkey hypothalamus, but might coexist or interact elsewhere, or affect gonadotropin secretion independently. (Supported by NIH HD10907).

SEX DIFFERENCES IN SEASONAL REPRODUCTIVE TRANSITIONS IN SHEEP. R.J. Wood and D.L. Foster*. Reprod Sci Prog, Depts of Physiology, Obstetrics and Gynecology, and Biology, University of Michigan, Ann Arbor, MI 48109-0404.

Both the onset of puberty in the lamb and the annual resumption of reproductive activity in adult male and female sheep are characterized by increased secretion of LH due to reduced responsiveness to steroid inhibition. The mechanisms underlying these transitions are similar in males and females. However, the timing of puberty is sexually differentiated, for males undergo a reduction in sensitivity to steroid feedback at 10 weeks of age, whereas females remain highly responsive to steroid inhibition until 30 weeks (Claypool et al, *Endocrinology* 126:1206, 1990). This sex difference is determined by androgens *in utero* (Wood et al, *Endocrinology*, in press). The present study determined if a sex difference exists in the timing of seasonal transitions in adult males and females. We compared serum LH in gonadectomized, estradiol-treated males (n=8), females (n=6), and androgenized females (n=5) from blood samples collected twice weekly for one year. As determined by a sustained increase in LH to high levels, the onset and offset of reproductive activity in males, females and androgenized females was not different. Serum LH declined on February 1 \pm 4 days, and rose again on September 3 \pm 3 days. There was a transient increase in LH (May 20 to June 23) in males, but not in females or androgenized females. These data suggest that the timing of seasonal transitions in adult male and female sheep is generally similar, despite a marked sex difference in the timing of puberty. However, subtle sex differences in these adult seasonal transitions are not determined by androgens *in utero*. (Supported by USDA 89-37240-4561 & NIH-07048, -18258)

361.2

KEOXIFENE BLOCKS THE PERIPUBERTAL STIMULATION OF GALANIN GENE EXPRESSION IN FEMALE RATS. S.M. Gabriel and L.M. Kaplan, Dept. Psychiatry, Mount Sinai School of Medicine, New York, NY 10029 and Gastrointestinal Unit, Massachusetts General Hospital, Boston, MA 02114.

Galanin is a regulatory peptide widespread in neuroendocrine tissues. In the anterior pituitary of the rat, galanin gene expression is potently enhanced by circulating estrogens. Sex differences in galanin immunoreactivity in the anterior pituitary and median eminence become apparent at puberty, coincident with elevated estrogen levels in females. We used northern blot hybridization to examine rat galanin mRNA in the hypothalamus and pituitary during the peripubertal period in rats. The induction of precocious puberty in 30 day-old female rats with pregnant mare serum gonadotropin (PMSG, 10 IU, s.c., 1000h) increased pituitary galanin mRNA more than ten-fold. This increase in galanin gene expression was blunted approximately 50% by simultaneous treatment with keoxifene (LY156758, 100 μ g, twice daily, s.c.), a potent estrogen antagonist. Because our previous studies suggested little effect of estrogen on galanin gene expression in the whole hypothalamus, we examined hypothalamic fragments containing medial basal hypothalamus (MBH), periventricular area (PVA), supraoptic area (SOA) and preoptic area (POA). Galanin gene expression in the PVA of 35 day-old female rats was two-fold higher than in males. In the immature female, galanin gene expression in the PVA increased significantly after treatment with PMSG. No sex differences or effect of PMSG were detected in the MBH, SOA, or POA. These studies indicate that estrogen stimulates galanin gene expression in a subset of hypothalamic neurons located in the PVA. Moreover, they demonstrate that the marked PMSG-induced increases in pituitary galanin gene expression are mediated by the induction of ovarian estrogen.

HYPOTHALAMIC LESIONS THAT INDUCE FEMALE PRECOCIOUS PUBERTY ACTIVATE GLIAL EXPRESSION OF THE EPIDERMAL GROWTH FACTOR RECEPTOR GENE: DIFFERENTIAL REGULATION OF ALTERNATIVELY SPLICED TRANSCRIPTS. M.P. JUNIER, D.F. HILL, *M.E. COSTA, *S.R. QJEDA. Div. Neurosci., OR Regional Primate Research Center, Beaverton, OR 97006.

We previously showed that lesions of the preoptic area-anterior hypothalamic area (POA-AHA) induce precocious puberty by activating the production of transforming growth factor alpha (TGF α) in reactive astrocytes surrounding the lesion site. TGF α was found to stimulate luteinizing hormone-releasing hormone (LHRH) release via interaction with EGF receptors (EGFR). In the present study, we determined whether expression of EGFR is affected by POA-AHA lesions. Using a cRNA probe complementary to the region where the EGFR mRNA diverges to originate an alternative transcript encoding a truncated and secreted form of EGFR, both transcripts were detected by ribonuclease protection assay in intact and lesioned POA-AHA. While levels of the intact EGFR increased 1.8-fold within a week after the lesion, no changes in the mRNA encoding the truncated form were detected. Immunoprecipitation of EGFR from hypothalamic solubilized homogenates followed by protein kinase-mediated autophosphorylation and SDS-PAGE showed that levels of the 170 kDa EGFR protein were also significantly increased by the lesion. EGFR mRNA and protein were localized by hybridization histochemistry and double labeling immunohistochemistry in a subset of reactive astrocytes around the site of the lesion. These results indicate that increased production of TGF α and up-regulation of EGFR expression in reactive astrocytes are concomitant events set in motion by POA-AHA injury. The increased availability of EGFR for ligand interaction in the face of unchanged expression of the truncated EGFR form may be critical for amplification of the TGF α stimulatory signal to occur. Supported by NIH Grants HD-25123 and RR-00163.

EXPRESSION OF cFOS IN GnRH CELLS OF THE EWE DURING INCREASED SECRETORY ACTIVITY. SM Moenter, FJ Karsch*, MN Lehman. Reprod Sci Prog and Dept Physiol, Univ Michigan, Ann Arbor 48109; Dept Anat and Cell Biol, Univ Cincinnati, OH 45267.

The proto-oncogene cFos was used as a marker of neurosecretion to test the hypothesis that cFos expression in GnRH cells of the ewe is related to neurosecretory activity. GnRH and cFos expressing cells were identified and percent co-expression determined in 3 endocrine states: GnRH surge (high sustained release, n=8), ovariectomy (ovx, high pulsatile GnRH, n=6), luteal phase (low GnRH n=6). To induce the GnRH surge, a physiologic model for the estrous cycle was used; an estradiol rise to a late-follicular phase level was given after progesterone removal. Serum LH was measured as an indicator of GnRH release. Ewes were cranially perfused with 2% paraformaldehyde; nuclear cFos was immunostained using nickel-enhanced diaminobenzidine (DAB) (black) and GnRH with unenhanced DAB (brown). In the luteal phase, LH was basal; few cells expressed cFos; these were not GnRH cells. During the surge (sustained high GnRH release), 41 \pm 8% of GnRH cells expressed cFos. Despite high, but intermittent, release after ovx, GnRH cells did not express cFos. In addition to cFos in GnRH cells, many more non-GnRH cells expressed cFos during the surge than at other times, especially in the medial preoptic/anterior hypothalamic area and ventrolateral hypothalamus. We suggest cFos expression is increased by positive feedback (surge), whereas removal of negative feedback (ovx), has little effect despite increased GnRH release in both states. Our results are also consistent with the hypothesis that estradiol induces cFos sequentially in a chain of neurons, culminating with expression in GnRH cells. NIH-HD 18337 (FJK), HD 21968 (MNL)

ESTRADIOL RECEPTOR-IMMUNOREACTIVE CELLS EXPRESS cFOS DURING THE PREOVULATORY GnRH SURGE IN THE EWES. MN Lehman, SM Moenter, KZ Doll*, X Gu*, & FJ Karsch*. Dept Anat & Cell Biol, Univ Cincinnati, OH 45267; Reprod Sci Prog and Dept Physiol, Univ Michigan, Ann Arbor 48109.

Expression of cFos in the preoptic area and hypothalamus is increased during the estradiol-induced GnRH surge of the ewe, both within GnRH neurons and other preoptic and hypothalamic cells (Moenter et al., Neurosci. Abstr., 1991). Because the location of cFos-positive cells in surge animals overlaps with that of estradiol receptor-immunoreactive (ER-IR) cells, we tested the hypothesis that some cFos-positive cells might contain ER-IR. Ewes were cranially perfused during either the GnRH surge, the luteal phase, or shortly after ovariectomy (ovx) (see Moenter et al. abstract). A dual multiple-bridge immunofluorescent procedure was used to simultaneously visualize ER (monoclonal antibody H222) and cFos (polyclonal antibody, Oncogene Sciences Inc.). During the surge, approximately half of all cFos-positive cells of the medial preoptic/anterior hypothalamic area and ventrolateral hypothalamus also contained nuclear ER-IR. The same sections contained more ER-IR cells than cFos-positive cells; thus less than 50% of all ER-IR cells in these regions were cFos-positive. Similar total numbers of ER-IR cells were seen in ovx and luteal phase animals as in surge animals, but few if any ER-IR cells in ovx or luteal phase animals expressed cFos. The results indicate functional heterogeneity among ER-IR cells, and suggest that estradiol may act either directly or indirectly upon a subset of ER-IR cells to induce cFos expression during positive feedback. NIH-HD 18337 (FJK), HD 21968 (MNL).

SERUM INHIBIN LEVELS DURING SPONTANEOUS AND PHOTOPERIODICALLY STIMULATED GONADAL RECRUDESCENCE IN THE GOLDEN HAMSTER. AE Jetton, JD Kirby, NB Schwartz and FW Turek. Dept. of Neurobiology and Physiology, Northwestern Univ., Evanston, IL 60208.

Shifts in photoperiod control dramatic changes within the reproductive system of the golden hamster. Exposure to short daylengths causes testicular regression, and continued exposure to short daylengths eventually leads to photorefractoriness which is manifested as spontaneous recrudescence of the testes. Exposure of animals to long daylengths at any time following regression and prior to spontaneous recrudescence, can actively stimulate testicular recrudescence. Previous work in the golden hamster has shown that one of the initial changes within the hypothalamic-pituitary-gonadal axis in response to photostimulation is an early rise in serum FSH levels. To investigate what role inhibin, an FSH regulatory factor, might play in testicular recrudescence, serum inhibin was measured by RIA throughout spontaneous and photically stimulated testicular recrudescence. Four groups of males were exposed to 6:18 LD for 10 weeks; two groups remained on 6:18 LD for another 16 weeks and two groups were transferred to 14:10 LD for 14 weeks. The animals were bled by cardiac puncture under anesthesia and testes widths were measured on alternate weeks. Serum inhibin levels and testes widths were analyzed by ANOVA. Testes widths were significantly increased over 10 week values by 24 weeks of 6:18 LD ($p < 0.05$); inhibin levels were not elevated by the end of the 15 week sampling period (25 weeks of 6:18 LD) ($p > 0.05$). Testes widths were significantly increased by 3 weeks and inhibin levels were significantly increased by 12 weeks after transfer to 14:10 LD compared to 10 week 6:18 LD values ($p < 0.05$). This is the first report of lowered circulating levels of inhibin during a time of known FSH stimulation; also, these studies indicate that a lack of circulating inhibin may play a permissive role in spontaneous gonadal recrudescence. HIPPOCAMPAL AND NEOCORTICAL REFRACTORINESS TO NMA STIMULATION IN THE LACTATING RAT AS REVEALED BY cFOS EXPRESSION: RECOVERY AFTER PUP REMOVAL AND BLOCKADE OF PROGESTERONE RECEPTORS. R. Abbud*, W.-S. Lee, G.E. Hoffman, and M.S. Smith. Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Lactating rats, unlike cycling rats, are refractory to NMA stimulation of LH secretion and cFos expression in the hippocampus and neocortex. To study the recovery of cFos activation in the hippocampus and neocortex in response to NMA, we examined lactating rats after pup removal, treatment with the progesterone antagonist, RU486 (5mg s.c. daily beginning on day 8 postpartum), or both. The responsiveness to four i.v. injections of NMA (40mg/kg) at 10 min intervals was examined during day 10 of lactation. LH responses and the degree of cFos expression in the postpartum groups were compared to the responses in diestrous rats. Control animals suckling 8 pups exhibited no LH stimulation or cFos expression in the hippocampus or neocortex in response to NMA. Treatment of the suckled animals with RU486 had no effect on the LH responses to NMA, but there was a significant degree of hippocampal and cortical activation, although still below diestrous levels. At 24 hr after pup removal, there was only a partial recovery of responsiveness to NMA stimulation. Full recovery was observed only in animals treated with RU486 which had their pups removed for 24 hours. In general, after pup removal, there was a good correlation between the recovery of the LH response to NMA and cFos expression in the hippocampus and neocortex. These results imply that the deficits in hippocampal and neocortical activation observed during lactation in response to NMA are mediated by the additive effects of suckling and progesterone. SERUM INHIBIN LEVELS DURING PHOTOPERIODICALLY CONTROLLED TESTICULAR REGRESSION IN THE GOLDEN HAMSTER. JD Kirby, AE Jetton, FW Turek and NB Schwartz. Dept. of Neurobiology and Physiology, Northwestern Univ., Evanston, IL 60208.

The golden hamster is a seasonally breeding species. The primary environmental cue regulating reproduction is photoperiod. Exposing male hamsters to short days (e.g., 6:18 LD) results in testicular regression and spermatogenic quiescence. Transferring photically regressed males to long days leads to gonadal recrudescence. The importance of FSH in the initiation and maintenance of spermatogenesis in the hamster is well understood. However, the mechanisms underlying the seasonal changes in FSH secretion and gonadal function remain unresolved. Gonadal peptides, inhibin and activin, are known to be involved in the regulation of FSH secretion. To investigate what role inhibin might play in these photoperiodic changes, serum inhibin was measured by RIA throughout photically induced testicular regression. The antiserum used in this assay, kindly provided by Dr. C. Rivier and Dr. W. Vale of the Salk Institute, was raised against synthetic porcine inhibin alpha (1-26)-Gly-Tyr. Parallelism of hamster serum to the porcine standard was found. Two groups of male golden hamsters were transferred from 14:10 LD to 6:18 LD. The animals were bled by cardiac puncture under anesthesia and testes widths were measured on alternate weeks for 13 weeks. Serum inhibin levels and testes widths were analyzed by ANOVA. Testes widths and serum inhibin values were significantly lowered by 6 weeks after transfer from 14:10 LD to 6:18 LD (week 0, testes widths = 11.33 ± 0.17 mm, inhibin = 2437.1 ± 459.2 pg/ml; week 6, testes widths = 7.35 ± 0.71 mm, inhibin = 658.8 ± 91.7 pg/ml; $p < 0.05$). This is the first use of inhibin as a variable in the study of photoperiodically induced changes within the hypothalamic-pituitary-gonadal axis in a rodent. These results demonstrate that daylength has a dramatic effect on circulating levels of inhibin. Supported by PHS P01 HD21921 and T32 HD07068.

USE OF cFOS AS A MARKER OF NEURONAL ACTIVATION REVEALS SEX DIFFERENCES IN RESPONSIVENESS TO NMA. M.S. Smith, W.-S. Lee, R. Abbud*, C.R. Pohl and G.E. Hoffman. Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

NMA stimulates LH secretion in both male and cycling female rats. To determine whether the patterns of neuronal activation in response to NMA are similar in females and males, we have used cFos expression as a marker of neuronal activation. NMA was administered systemically (iv, 40 mg/kg, 4 injections, 10 min apart) or intraventricularly (icv, 2 μ g/2 μ l, 4 injections, 10 min apart). In the females, similar results were observed in response to iv and icv injections of NMA; both stimulated LH secretion but did not induce cFos expression in LHRH neurons, although neurons surrounding LHRH cell bodies were activated. These same animals also had a high degree of cFos expression in the hippocampus and neocortex.

In the males, despite consistent stimulation of LH, the route of administration of NMA affected the pattern of neuronal activation. LHRH neurons expressed cFos in response to iv but not icv NMA treatment. As well, cFos expression in the hippocampus and neocortex was induced in response to iv but not icv NMA. Administration of pentobarbital before iv NMA blocked cFos expression in LHRH neurons and in the hippocampus and neocortex. The male appears to require sensory stimulation by NMA to activate the hippocampus and cortex. These results suggest that males and females may have different pathways sensitive to NMA, or that the steroid milieu may differentially alter the sensitivity to NMA stimulation. Supported by NIH grants HD14643 and HD12354 and the Samuel and Emma Winters Foundation.

GnRH INDUCES SLOW RHYTHMIC CHANGES OF MEMBRANE POTENTIAL IN RAT GONADOTROPES. Amy Tse & Bertil Hille. U of Washington, Seattle, WA 98195.

Dissociated pituitary gonadotropes identified by reverse hemolytic plaque assay are studied by whole-cell voltage clamp. Bath application of GnRH (>0.1 nM) induces a large, slowly oscillating current (frequency range: 0.06-0.3 Hz at 23°C), an effect that is competitively blocked by a specific GnRH antagonist. The oscillatory current is completely suppressed by apamin (>0.2 μ M) and only half blocked by 5 mM TEA. The reversal potential shifts ~ 57 mV per 10-fold change of external [K]. With 5 mM BAPTA in the pipette, the GnRH-induced oscillations are largely suppressed. Hence GnRH is probably inducing oscillations of $[Ca^{2+}]_i$, which open SK K(Ca) channels in a rhythmic manner. The intermittent openings of K(Ca) channels leads to cyclic alternation of membrane hyperpolarizations (from -37.4 ± 6.9 mV to -86.5 ± 5 mV; S.D.; $n = 16$) and firing of action potentials. GnRH responses become irreversible with 100 μ M internal GTP γ S and abolished with 2 mM internal GDP β S. The response is mimicked by 20 μ M internal IP $_3$ and abolished by heparin (1 mg/ml). Oscillations persist even in the absence of external Ca. Therefore, the intracellular pathway of this response involves the activation of a G protein which leads to increase in PI turnover and cyclic release of Ca^{2+} from an intracellular store. During the membrane oscillations, these cells also undergo exocytosis (presumably releasing gonadotropins) as evidenced by a rapid increase in membrane capacitance. (Supported by NS08174, HD12629 & the McKnight Foundation).

Vasoactive Intestinal Peptide (VIP) Enhances Protein Phosphorylation By Developing Sympathetic Neuroblasts. Emanuel DiCicco-Bloom, Kuo Wu & Ira B. Black, Dept. Neurosci. & Cell Biol., UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ 08854

Recent studies suggest that neuropeptides play a regulatory role in early neuronal development. In particular, VIP has been found to stimulate mitosis, neurite outgrowth and survival in embryonic day 15.5 (E15.5) rat superior cervical ganglion (SCG) neuroblasts. Further, these diverse effects *in vitro* correlate with ontogenetic expression of VIP in SCG *in vivo*. Previous studies suggest that cAMP pathways are involved since peptide stimulates nucleoside levels and cAMP analogs reproduce VIP effects. The role of protein phosphorylation was examined in the present study.

To begin examining protein kinase activity, we employed a previously defined neuroblast culture system derived from E15.5 SCG. After 24h incubation, neuroblasts were exposed to VIP (10 μ M) or vehicle for 10min., in the presence of phosphodiesterase inhibitor, 500 μ M IBMX. Following homogenization of cells in kinase buffer, samples were incubated with 32 P-ATP and protein kinase A substrate, histone H1, without and with cAMP for 3 min at 30 $^{\circ}$ C and proteins were subjected to SDS-PAGE. Autoradiography revealed H1 phosphorylation in controls that was augmented by cAMP treatment, indicating ongoing and cAMP-responsive kinase activity in neuroblast homogenates. VIP exposure increased the H1 signal 2 to 5-fold. Moreover, addition of cAMP did not augment H1 phosphorylation in VIP-treated neuroblasts, suggesting that the peptide maximally increased phosphorylation. Our observations suggest that the multiple effects of VIP on mitosis, differentiation and survival involve a cascade of events including VIP ligand-receptor binding, cAMP induction and phosphorylation of endogenous protein substrates. (Support: NIH grant HD23315, Familial Dysautonomia and Juvenile Diabetes Fdns.)

CNTF REGULATES NEUROBLAST MITOSIS, SURVIVAL, AND DIFFERENTIATION VIA MULTIPLE RESPONSE MECHANISMS. L.-M. Lee, E. DiCicco-Bloom and I.B. Black, Cornell Univ. Med. College, N.Y., N.Y., and Dept. Neurosci. and Cell Biol. UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, N.J.

Neural ontogeny consists of an apparent sequence of events including proliferation, differentiation, and selective cell death. A panoply of signals regulate each of these processes; however, only a few factors are known to regulate neuronal development at all of these stages. One such molecule is Ciliary Neurotrophic Factor (CNTF), which has been shown to inhibit mitosis, enhance survival, and foster cholinergic transmitter differentiation in developing neurons. CNTF activities, however, have been examined in different cell types and animal species, hampering definition of underlying relationships. Using a rat sympathetic neuronal model, we have investigated CNTF bioactivities in a single population at various developmental stages.

We now report that CNTF (recombinant human, Synergen) inhibits neuronal mitosis in embryonic day 15.5 (E15.5) cultures in the presence of a number of previously defined mitogens including IGF, EGF, KCl and VIP. The factor decreases 3 H-thymidine incorporation as well as the percent of neuroblasts entering the cell cycle by $\geq 40\%$, with an EC $_{50}$ of 10 pg/ml. In addition, CNTF promotes survival of E15.5 neurons independent of mitotic effects. However, the trophic effects require 100-fold greater doses (EC $_{50}$ =1ng/ml), raising the possibility that CNTF simultaneously affects mitosis and survival via different receptors.

While CNTF does not stimulate cholinergic traits in the E15.5 cultures, choline acetyltransferase (CAT) activity is increased in cultures of neonatal sympathetic neurons. CAT-induction also requires the higher dose (EC $_{50}$ =1ng/ml). In aggregate, our observations suggest that CNTF elicits diverse biological effects with differing dose-response relationships, suggesting multiple receptors and/or second messenger systems. Furthermore, the distinct ontogenetic actions of the factor may reflect selective developmental expression of different CNTF response mechanisms.

NEUROTROPHINS NGF, BDNF AND NT-3: ACTIONS ON RAT CHOLINERGIC AND DOPAMINERGIC NEURONS *IN VITRO* AND *IN VIVO*. B. Knüsel, K.D. Beck, J.W. Winslow, L.E. Burton, K. Nikolics and F. Hefti, Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90089 and Genentech, Inc., South San Francisco, CA 94080.

Brain-derived neurotrophic factor (BDNF) stimulates differentiation of brain cholinergic and dopaminergic neurons in culture, cells whose function, in the human brain, is reduced in Alzheimer's disease and Parkinson's disease, respectively. NGF is well known to affect the same basal forebrain cholinergic, but not the mesencephalic dopaminergic neurons. We now found that neurotrophin-3 (NT-3), though only at a concentration 1000 times higher than the required NGF concentration, stimulates cholinergic, but not dopaminergic differentiation *in vitro*. Additivity experiments, and comparison of the time course of stimulation, suggest action of NT-3, but not BDNF, on the NGF receptor. K-252b, a protein kinase inhibitor previously shown to inhibit NGF actions, abolished the effects of all three neurotrophins on cholinergic neurons and of BDNF on dopaminergic cells. In contrast, the actions of bFGF and IGF-I on these cells were not abolished, suggesting that K-252b selectively interferes with neurotrophin receptor mechanisms. We presently investigate if BDNF and NT-3, similar to NGF, increase cholinergic cell survival in the fimbria-fornix lesion model of cholinergic hypofunction.

362.2

Expression of Vasoactive Intestinal Peptide (VIP) And Receptor During Early Sympathetic Ontogeny: Potential Autocrine Role. David W. Pincus, Emanuel DiCicco-Bloom & Ira B. Black, Cornell Univ. Med. Coll. NY, NY, 10021, UMDNJ/Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

While traditional models suggest that trophic agents are provided by targets, recent evidence suggests that neuronal generation and initial survival depends on local factors. Previously, we found that VIP stimulated mitosis, neurite outgrowth and survival in embryonic day 15.5 (E15.5) superior cervical ganglion (SCG) neurons. Moreover, peak expression of peptide in E15.5 SCG suggested that VIP of presynaptic or ganglionic origin plays a role in sympathetic ontogeny *in vivo*. The present data documenting expression of VIP and a putative receptor suggest an autocrine model.

To examine mechanisms, we employed a previously defined neuroblast culture system in which VIP stimulates mitosis (3 H-thymidine incorporation, 3 H-TdR) and survival. To define receptor specificity, neuroblasts, grown in control or VIP (0.3 μ M)-containing medium, were exposed to a selective antagonist, [p-Chloro-D-Phe 6 , Leu 17]-VIP (50 μ M). The antagonist completely blocked VIP-induced 3 H-TdR Inc, suggesting that the mitogenic signal was mediated via specific peptide receptors.

To characterize embryonic receptor, affinity cross-linking was performed. Mechanically dissociated SCG were incubated with 125 I VIP (10nM). Following cross-linking with bifunctional disuccinimidyl suberate (DSS), samples extracted with nonionic detergent were electrophoresed in 10% polyacrylamide gels. Autoradiography revealed a major 51 kD band not present in samples incubated with 1000-fold excess cold VIP or in the absence of DSS. Synaptic membranes from adult cerebral cortex exhibited a similar band, suggesting that E15.5 SCG and mature brain express a common VIP receptor.

To determine whether E15.5 SCG produce VIP, cultured ganglia were assayed for peptide content. After 4 days, when presynaptic terminals have degenerated, VIP increased 10-fold. While SCG production of VIP does not rule out presynaptic sources *in vivo*, the presence of peptide receptor and synthetic cholinergic in embryonic neurons supports an autocrine role for VIP in sympathetic ontogeny.

Characterization of receptors for BDNF and NT-3 in the central nervous system by affinity labeling

Enrique Escandón, Luis F. Parada* and Karoly Nikolics
Department of Developmental Biology, Genentech, Inc., South San Francisco, Ca 94080; and *Molecular Embryology Section, NCI-Frederick Cancer Research and Development Center, Frederick, Md 21702

Using heterologous cell lines expressing p145^{trkB}, the product of the trkB gene, we have shown that p145^{trkB} is a receptor for BDNF and NT-3 but not for NGF (Soppet et al. submitted). Incubation of p145^{trkB}-expressing cells with 125 I-labeled BDNF and NT-3, treated with the chemical crosslinking agent EDAC, and immunoprecipitated with specific anti-trkB antibodies reveals a single receptor complex of approximately 160 kDa. Viable cell suspensions were prepared from isolated rat hippocampus and subjected to the same affinity labeling and immunoprecipitation protocol. A crosslinked receptor complex of identical molecular size (160 kDa) was detected. However, if the immunoprecipitation step was omitted following crosslinking a more complex pattern of labeled products was revealed in the hippocampus. Three main receptor complexes of 160, 116 and 100 kDa, respectively, were found. Various brain regions showed discrete differences in the relative abundance of these complexes.

In addition, titration analysis studies suggest that the 160kDa species has a relatively higher affinity for both BDNF and NT-3 under the conditions of the crosslinking experiments. A developmental analysis indicates that BDNF and NT-3 binding activity reaches a peak of expression in early postnatal animals.

362.6

EFFECTS OF BDNF AND NT-3 ON DOPAMINERGIC AND GABAERGIC NEURONS IN RAT VENTRAL MESENCEPHALIC CULTURES. C. Hyman, M. Juhasz*, C. Jackson*, C. Radziejewski* and B.M. Lindsay, Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Rd., Tarrytown, N.Y. 10591.

We have examined the effect of neurotrophin-3 (NT-3) on the dopaminergic neurons of the ventral mesencephalon of E14 rat embryos in dissociated cell culture, under serum-free conditions. In addition, we have addressed the question of whether GABAergic neurons present in this system respond to BDNF or NT-3. Dopaminergic neuron viability was assessed by staining with antibodies to tyrosine hydroxylase (TH), and measurement of 3 H-dopamine (3 H-DA) uptake. Assay of 3 H-GABA uptake and measurement of glutamic acid decarboxylase (GAD) activity were used to monitor the survival and maturation of the GABAergic neurons. A single treatment with NT-3 at 10 ng/ml one day after placing the cells in culture resulted in a 1.8 fold increase in both the number of TH positive neurons and 3 H-DA uptake six days later. Cultures maintained for 7 days in the presence of BDNF showed a 2.7 fold increase in 3 H-GABA uptake activity when compared to control cultures. GAD activity in BDNF treated cells showed a 1.8 fold increase over that of control cultures. Similar experiments in cultures maintained in the presence or absence of NT-3 for 7 days, demonstrated an NT-3 induced 2.8 fold increase in 3 H-GABA uptake and a 2.3 fold rise in GAD activity. Thus, both BDNF and NT-3 affect dopaminergic and GABAergic neurons of the ventral mesencephalon.

362.7

BDNF mRNA EXPRESSION FOLLOWING DEAFFERENTATION OF THE HIPPOCAMPUS T. Denton, J. Day, M. Dugich-Djordjevic, P.A. Lapchak, C.E. Finch and F. Hefti University of Southern California, Andrus Gerontology Center, Dept. of Biological Sciences, Los Angeles, CA 90089

Brain Derived Neurotrophic Factor (BDNF) is a neurotrophic factor which has recently been cloned, and is available as a recombinant protein. BDNF has been shown, *in vitro*, to have trophic effects on the septal cholinergic neurons which degenerate in Alzheimer's Disease (AD). The highest concentration of BDNF mRNA in the brain is in the hippocampus, a target of the septal cholinergic projection. We are investigating changes in BDNF mRNA expression by *in situ* and Northern Blot hybridization in deafferenting lesions which model different aspects of the neurodegeneration which occurs in AD. Our results indicate that inhibition of the activity of the septal cholinergic pathway by either chronic administration of atropine (20 mg/kg/day for 10 days), or a partial stereotaxic knife lesion results in a significant down-regulation of BDNF expression (after 21 days). By contrast, a transection of the perforant pathway results in a marked increase of expression in the dentate, CA3 and CA4, with a peak at four days, followed by a return to control levels by fourteen days. These findings suggest a role for BDNF in the remodeling of the hippocampus in response to deafferenting lesions and by extension, in AD.

362.9

BASIC FIBROBLAST GROWTH FACTOR MODULATION OF NEUROTRANSMITTER INFLUENCES IN CULTURED HIPPOCAMPAL NEURONS: POTENTIATION BY GANGLIOSIDE GM1. S.D. Skaper, A. Leon and L. Facci. Fidia Research Labs, 35031 Abano Terme, Italy.

Classical mitogenic growth factors like basic fibroblast growth factor (bFGF) can influence survival of CNS neurons. The ability of bFGF to affect responsiveness of hippocampal cells to the neurotransmitter glutamate was now studied. Cultures were generated from embryonic day 18 rat hippocampus, and contained mainly pyramidal neurons. After 4-5 days in a serum-free defined medium, glutamate ($\geq 100\mu\text{M}$) became cytotoxic for these cells. Either 10ng/ml bFGF (Mattson et al., J. Neurosci. 9:3728, 1989) or 100uM ganglioside GM1 reduced this neuronal loss by 50-80% when added 24hr before glutamate. Low bFGF (0.3ng/ml) or GM1 (10uM) were ineffective. Combined incubation of these low levels of bFGF and GM1 for 24hr (but not 2hr) before glutamate addition raised the threshold of bFGF efficacy significantly. However, glutamate sensitivity of older (≥ 2 weeks) cultures was unaffected by bFGF. Facilitation of trophic factor effects by gangliosides makes the latter compounds useful tools in the study of CNS plasticity and repair processes.

362.11

A CNTF-LIKE, CHAT AND VIP-INDUCING FACTOR IS PRESENT IN DEVELOPING RAT FOOTPAD. H. Rohrer*# and M. Sendtner. Max-Planck-Institute for Psychiatry, Dept. of Neurochemistry, 8033 Martinsried, and Max-Planck-Institute for Brain Research#, 6 Frankfurt/M. 71, FRG

The sympathetic neurons innervating sweat glands in the rat footpad acquire a cholinergic phenotype under the influence of the innervated target. Ciliary neurotrophic factor (CNTF) has been previously shown to stimulate *in vitro* the cholinergic differentiation of rat and chick sympathetic neurons.

We now demonstrate that a CNTF-like, ChAT and VIP-inducing factor is present in rat footpads during the period of target-dependent cholinergic differentiation. The CNTF-like factor increases about 6-fold between postnatal days 7 and 21 and is maintained at reduced levels in adult footpad. Antibodies against CNTF eliminate about 50% of ChAT-inducing activity in footpad homogenates. Thus a CNTF-like factor and an additional cholinergic factor(s), not recognized by an antiserum against CNTF, are candidates for inducing cholinergic properties *in vivo*. Immunohistological data and denervation experiments demonstrate, however, that the CNTF-like factor is localized in Schwann cells. These results suggest that the CNTF-like factor is a less likely candidate for the sweat gland-dependent cholinergic factor.

362.8

BDNF mRNA IS DECREASED IN HIPPOCAMPUS OF INDIVIDUALS WITH ALZHEIMER'S DISEASE H. S. Phillips, J. M. Hains, M. Armanini, G. R. Laramée*, ¹S. A. Johnson, and J. W. Winslow Dept. Dev. Biol., Genentech, S.S.F., CA 94080 and ¹Andrus Gerontology Ctr., USC, L.A. CA, 90089.

In recent years, the potential of nerve growth factor as a therapeutic agent for Alzheimer's disease (AD) has gained increasing attention. To compare expression of NGF and its homologs, BDNF and NT-3, in individuals with AD vs. non-demented control individuals, we conducted *in situ* hybridization on 15 samples of human postmortem hippocampus. Of the three members of the NGF family, only BDNF demonstrated a significant decrease in hybridization intensity in AD. Decreased BDNF hybridization in dentate gyrus was highly significant ($p < .001$), and could not be accounted for on the basis of differences in donor age or sex, sample autolysis times, or loss of cell density. BDNF hybridization was also significantly reduced in the pyramidal layer of Ammon's Horn. Normalization of neurotrophin hybridization signals to those obtained with a probe to NCAM revealed that BDNF/NCAM ratios decreased roughly two fold in dentate gyrus with AD, while NGF/NCAM and NT3/NCAM showed no trend towards decreasing in AD. Decreased abundance of BDNF mRNA in hippocampus of individuals with AD was verified in a second set of samples by ribonuclease protection assay. These results suggest the possibility that a deficiency in BDNF may contribute to the progression of cell death in AD.

362.10

NUCLEAR AND CYTOPLASMIC LOCALIZATION OF BASIC FIBROBLAST GROWTH FACTOR IN ASTROCYTES AND CA2 HIPPOCAMPAL NEURONS. E.P. Eckenstein, W. R. Woodward, C. K. Meshul and R. Nishi. Oregon Health Sciences University, Portland, OR 97201

Fibroblast growth factors (FGFs) are known to stimulate mitogenesis in a variety of non-neuronal cell types and to support the survival *in vitro* of many neuronal cell types. The present study determined the distribution in the rat CNS of basic FGF (bFGF). Immunohistochemical analysis showed that bFGF-immunoreactivity was found predominantly in astrocytes throughout all regions of the CNS. In contrast, only a few neuronal populations were found to contain bFGF-immunoreactivity, most prominent among them, neurons in the CA2-area of hippocampus. This predominant localization of bFGF to astrocytes was confirmed by two other observations: 1) highly enriched cultures of astrocytes contained bFGF-immunoreactivity and -bioactivity, whereas highly enriched cultures of cerebral cortical neurons contained no detectable bFGF; and 2) neonatal rat cerebral cortex, which contains only a few differentiated astrocytes, also contained no detectable bFGF-immunoreactivity and only low amounts of bFGF-bioactivity. Light and electron microscopic analysis showed that bFGF immunoreactivity was present in the nucleus as well as the cytoplasm of astrocytes and CA2 neurons. Preparations of both nuclear and soluble fractions of brain extracts also contained bFGF-immunoreactivity and -bioactivity. These data suggest that bFGF might be involved in mediating astrocytic influences on the late postnatal maturation and plasticity in the CNS, and that the nuclear localization of bFGF within astrocytes may play an important role in the differentiation of these cells. In addition, bFGF may play a similar role in a few specific neuronal populations, such as CA2 hippocampal neurons.

362.12

EFFECTS OF BASIC FIBROBLAST GROWTH FACTOR (bFGF) AND EPIDERMAL GROWTH FACTOR (EGF) ON CELLS FROM DISSOCIATED CULTURES OF EMBRYONIC MIDBRAIN: A COMPARATIVE STUDY. D. Casper and M. Blum. Fishberg Research Center in Neurobiology, Mount Sinai School of Medicine, One Gustave Levy Place, New York, NY 10029.

EGF and bFGF are mitogens on epidermal and mesodermally derived tissue. It has also been shown that in the CNS each growth factor can be a glial mitogen, enhance neuronal survival, and stimulate neurite outgrowth in both separate and overlapping neuronal populations. We, and others have demonstrated EGF and bFGF to be mitogenic for astrocytes, and support the survival and maturation of dopaminergic neurons in cultured rat embryo mesencephalon. We also determined that bFGF was synthesized in the cultures by a nuclease protection assay for bFGF mRNA and by bFGF immunocytochemistry. In this study we investigate whether bFGF could mediate the neurotrophic and mitogenic effects of EGF, or whether their effects are distinct.

Dissociated cultures from 16 day rat embryo mesencephalon were established in defined medium. Dose response curves for EGF and bFGF were produced for cell proliferation by ³H-thymidine incorporation into DNA and for dopamine neurons by ³H-dopamine uptake. In order to block endogenous bFGF activity, antisense oligonucleotides to bFGF mRNA or neutralizing bFGF antibodies were added to control and EGF-treated cultures. Measurements of cell proliferation and dopamine uptake were made and FGF immunocytochemistry was performed. Preliminary results indicate that EGF and bFGF effects on dopamine uptake were additive.

Since mesencephalic cultures contain both the presumptive substantia nigra and ventral tegmental dopamine neurons which have distinct targets, it is possible that each cell population is differentially sensitive to growth factors. Alternatively, bFGF and EGF could act on overlapping populations of dopamine neurons by different mechanisms. This work has been supported by NRSA grant NS08600-02.

363.1

EFFECTS OF ANTI- $\beta 1$ INTEGRIN ANTIBODIES ON AXONAL OUTGROWTH FROM EMBRYONIC RETINA *IN VITRO* AND *IN VIVO*. D.S. Sakaguchi and C.E. Holt. Program in Neurosci., Dept. Zool and Genetics, Iowa State Univ., Ames, IA 50011 and Dept. of Biol., UC San Diego, La Jolla, CA 92093.

The XR1 glial cell line, isolated from *Xenopus laevis* retinal neuroepithelium, deposits a proteinaceous extracellular matrix (ECM) with potent neurite outgrowth promoting activity. To investigate a potential role for the integrins as cellular receptors for these glial cell-derived ECM components, embryonic retinal explants were cultured in the presence of polyclonal antibodies (Abs) directed against the 140 kD chick $\beta 1$ integrin subunit (from K. Yamada, NCI). The anti- $\beta 1$ Abs strongly inhibited neurite outgrowth on the glial cell-derived ECM, although neurites grew freely across nonneuronal cells surrounding the explants. The Abs were also very effective at inhibiting outgrowth on purified laminin and ECL (entactin, collagen and laminin) substrates.

To examine the possible role of integrins *in vivo*, the presumptive optic tract on one side of the embryo was exposed to anti- $\beta 1$ Abs through surgery or by direct injection of the Abs. Optic fibers from the contralateral eye followed a normal course through the Ab treated optic tract to the optic tectum revealing that the Ab does not block outgrowth. However, the Ab-treated projections tended to be delayed in their growth and to contain fewer fibers than preimmune Ab-treated controls suggesting that the anti- $\beta 1$ Abs may subtly effect axon outgrowth *in vivo*, perhaps by acting on a subset of retinal axons. We conclude that while the integrins play a major role in mediating axon outgrowth on ECM substrates *in vitro*, other molecules in addition to integrins are probably important for outgrowth *in vivo*.

363.3

NEURITE OUTGROWTH ON IMMOBILIZED AXONIN-1 IS MEDIATED BY A HETEROPHILIC INTERACTION WITH L1(G4). T.B. Kuhn, E.T. Stoeckli, M.A. Condrau, F.G. Rathjen, and P. Sonderegger. Biochemisches Institut und *Institut für Biomedizinische Technik, Universität Zürich, CH-8057 Zürich, Switzerland. **Zentrum für Molekulare Neurobiologie, D-2000 Hamburg, Germany.

The axon-associated cell adhesion molecule axonin-1 is expressed in two forms, one being glycoposphoinositol-anchored to the axonal membrane, and the other being released from the axons. When presented as a substratum for neuronal cultures, it strongly promotes neurite outgrowth. In this study, axonin-1 itself and L1(G4), which promotes neurite outgrowth in a similar fashion and is colocalized with axonin-1 in several nerve fiber tracts, were investigated with respect to a receptor function for axonin-1. Using fluorescent microspheres with covalently coupled axonin-1 or L1(G4) at their surface we showed that axonin-1 binds very specifically to L1(G4). At the sensitivity of this microspheres assay, axonin-1 does not interact with itself. Axonin-1-coated microspheres bound also to the axonal surface of cultured dorsal root ganglia neurons by interacting with L1(G4), as indicated by complete suppression by monovalent anti-L1(G4) antibodies. The interaction between neuritic L1(G4) and immobilized axonin was found to mediate the promotion of neurite growth on axonin-1, as evidenced by virtually complete arrest of neurite outgrowth in the presence of anti-L1(G4) antibodies. Convincing evidence has recently been presented that neurite growth on L1(G4) is mediated by homophilic binding of neuritic L1(G4) (Lemmon, V., K.L. Farr, and C. Lagenaur. 1989. Neuron 2, 1597-1603). Thus, both L1(G4)- and axonin-1-expressing axons may serve as "substrate pathways" for the guidance of following axons expressing L1(G4) into their target area.

GENETIC ANALYSIS OF GROWTH CONE GUIDANCE IN DROSOPHILA: FASCICLIN II FUNCTIONS AS A NEURONAL RECOGNITION MOLECULE. G. Grenningloh, J. Rehm, and C.S. Goodman, Howard Hughes Medical Inst, Dept of Molecular and Cell Biology, U. of California, Berkeley, CA 94720

Fasciclin II, a neural cell adhesion molecule of the immunoglobulin superfamily, was previously characterized and cloned in grasshopper where it is expressed during embryogenesis on the surface of a subset of axon pathways including the MP1 fascicle (Harrelson and Goodman, 1988). Here we report on the cloning, characterization, and genetic analysis of the *Drosophila* fasciclin II homologue. Sequence analysis of cDNAs indicate that the gene generates multiple forms of the protein, including a PI-linked and a transmembrane form. Monoclonal and serum antibodies reveal that *Drosophila* fasciclin II is also expressed on the MP1 pathway. We have generated two classes of mutations in the *fas II* gene: a set of lethal, protein null alleles, and a set of viable, hypomorphic alleles. In *fas II* null mutant embryos, most axon pathways develop normally and the CNS displays no gross phenotype. However, the MP1 fascicle does not develop, the MP1 and vMP2 growth cones fail to recognize one another or other axons that normally join the MP1 pathway, and these growth cones stall and do not join any other neighboring pathway. Thus, fasciclin II functions as a neuronal recognition molecule for the MP1 axon pathway. The effects of removing this single recognition molecule are remarkably similar to the previously reported effects of removing single bundles of axons (e.g. papers by Raper, Bastiani, et al., 1983-1986), namely, in the absence of either the appropriate molecule or the appropriate pathway, individual growth cones do not extend along other neighboring axon pathways.

363.2

DEVELOPING SENSORY NEURONES HAVE DISTINCT GROWTH SUBSTRATUM REQUIREMENTS. T.E. Allsopp* and A.M. Davies, Dept. of Anatomy, St. George's Hospital Medical School, Tooting, London, SW17 0RE, U.K.

Sensory neurones of the vestibular (V), geniculate (G), petrosal (P) and nodose (N) cranial ganglia extend neurites at different rates *in vitro* (N>P>G>V) when cultured on EHS laminin. This relationship correlates with the *in vivo* growth characteristics and the respective ganglionic target distances; fastest growth occurs to the furthest targets. To initiate studies of how such growth rate differences could be regulated at the molecular level, growth promoting molecules present in the environment of the differentiating neurones were assessed for their ability to support axonal growth and reproduce the growth rate difference. Cells of all four ganglionic types express the axonal growth promoting glycoprotein G4 (L1/NILE/8D9) at the early stages of gangliogenesis (stage 17/18 Hamburger and Hamilton). Immunoaffinity isolated G4 fails to support the attachment and growth of vestibular neurones from stage 18 and 23 embryos, whereas many nodose neurones from the same stages attach and grow neurites on G4. Initiation of growth on G4 is delayed compared to growth on laminin. Initial analysis suggests that growth rate on G4 is slower than that on laminin, but is faster for the population of stage 23 compared with stage 18 neurones. These observations are consistent with the hypothesis that the cranial sensory neurones differ in their intrinsic regulation of axonal growth mechanisms. Also within a distinct neuronal population cells may use different growth strategies, in relation to their time of differentiation, to ensure that they can adequately compete for target derived trophic factors.

363.4

MESOSTRIATAL DOPAMINERGIC AXONS CONTAIN HIGH LEVELS OF NILE DURING EARLY DEVELOPMENT. C. W. Shults, A. T. A. Kimber, L. Alberti, and W. B. Stallcup. *Neurology Service, VA Med. Ctr. San Diego, CA 92161; *Dept of Neurosci., UCSD, La Jolla, CA 92093; *La Jolla Cancer Res. Fndn., La Jolla, CA 92037

Our group has carried out a series of studies to identify specific cell types and molecules that control development of the mesostriatal dopaminergic (DA) system in the rat. In the present study fetal, postnatal, and adult brains were immunolabelled with both a murine monoclonal antibody that recognizes tyrosine hydroxylase (TH) and a rabbit polyclonal antiserum that recognizes the carboxyl terminus of NILE. At E14, 15, and 16, NILE-immunoreactive (NILE-IR) material outlined the surfaces of the TH-immunoreactive (TH-IR) neurons in the mesencephalon. At later ages, NILE-IR material could not be detected on the cell bodies of the DA neurons. At E14, TH-IR axons coursing from the mesencephalon rostrally were also NILE-IR. At ages E15, 16, and 18, the TH-IR axons had banded into fascicles which contained high levels of NILE-IR material, but at later ages the amount of NILE-IR material on these axons was conspicuously reduced but still detectable. In the striatum of the adult rat NILE-IR material appeared to be diffusely distributed through the neuropil. Our observations suggest that NILE plays a role in defining the paths for growth of and fasciculation of mesostriatal DA axons.

363.6

FASCICLIN 2 MEDIATES HOMOPHILIC ADHESION BETWEEN TRANSFECTED DROSOPHILA CELLS. A.L. Harrelson. Division of Biological Sciences, University of Missouri, Columbia, MO 65211.

Adhesion between cells is a critical process in the development of the nervous system. As growth cones grow out to their targets, they selectively fasciculate with specific axon bundles and cell surfaces in the local microenvironment. Fasciclin proteins are known to mediate some aspects of selective fasciculation in developing insect nervous system. The Fasciclin 2 (Fas2) protein is expressed on fasciculating longitudinal axons and is a member of the immunoglobulin gene superfamily. We constructed plasmid vectors which express full-length Fas2 protein in *Drosophila* S2 cells, under the control of a metallothionein-driven transcriptional promoter. The vector allows the expression of individual Fas2 domains in various combinations on the cell surface or secreted into the culture medium, or fused to different cytoplasmic domains.

Expression of Fas2 on the surface of normally non-adherent S2 cells causes a rapid, density-dependent increase in cell aggregation. Depending on the initial concentration of cells and the extent to which the promoter is induced, we observe increases in cell aggregates of between 2- to 50-fold. Monoclonal antibodies which bind to the immunoglobulin-related region of the protein show no effect on this aggregation. The role of the cytoplasmic domain and the specific extracellular domains which are necessary for adhesion are presently being investigated.

363.7

A ROLE FOR GLYCOSYLPHOSPHATIDYLINOSITOL-ANCHORED MEMBRANE PROTEINS IN GUIDANCE OF PIONEER NEURON AXONS *IN VIVO*. Wesley S. Chang, Kyle Serikawa*, Karen Allen* and David Bentley. Department of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

Cell-surface proteins anchored to the plasma membrane via covalently attached glycosylphosphatidylinositol (GPI) have been implicated in cell-cell recognition events in numerous systems. Treatment of grasshopper embryos with phosphatidylinositol-specific phospholipase C (PI-PLC), an enzyme that cleaves GPI-anchored proteins from the cell surface, leads to reproducible disruptions of axonal guidance by pioneer neurons, as well as defects in pre-axogenesis migration of guidepost neurons in the developing limb bud. Specifically, PI-PLC treatment induces (1) failure of T11 pioneer axons to make a highly stereotyped ventral turning response along an epithelial segment boundary, (2) loss of proximal growth orientation of T11 axons, resulting in looping, distal axonal growth, and (3) proximal migration of Cx1 guidepost neurons towards the central nervous system (CNS). These abnormal phenotypes occur with limited frequency in limb buds treated with PI-PLC, but are completely absent in control-treated embryos, indicating that the observed effects are specifically caused by the enzymatic treatment. These results suggest that GPI-anchored proteins located on the membrane of the neuronal growth cone and/or the epithelial substratum are involved in pathfinding events in the embryonic grasshopper limb bud.

363.9

THE *UNC-5* AXON GUIDANCE GENE OF *C. ELEGANS* ENCODES A PROTEIN WITH FEATURES OF A CELL ADHESION RECEPTOR. J. Culotti, A. Spence*, Y. Zhou*, C. Leung-Hagsteijn*, Medical Genetics, U. of Toronto, Ont., E. Hedgecock*, B. Stern*, Biology, Johns Hopkins U., Baltimore, MD

The *unc-5* and *unc-6* genes of *C. elegans* are required to guide dorsal migrations of neuron growth cones and mesodermal cells on the epidermis (Hedgecock et al., *Neuron* 4, 61-85, 1990). Genetically, *unc-5* and *unc-6* are interdependent. One possibility is that *unc-5* encodes a receptor for the *unc-6* protein, which we have shown to be a novel B2 laminin-like molecule. Several features of the predicted *unc-5* protein are consistent with this interpretation, including a single membrane-spanning helix, an extracellular Ig-like domain and 2 'WSX' domains found in different proteins that exhibit cell adhesion properties. The transmembrane domain has 2 cysteines at its cytoplasmic end followed by a short run of basic amino acids. A similar motif is found in certain receptors as well as the nerve growth associated protein GAP-43. In these proteins, the cysteines are palmitoylated. This modification may be required for linkage to G proteins. A 50 amino acid sequence within the predicted cytoplasmic domain is distantly related to the SH3 domains of several different proteins associated with the membrane cytoskeleton, including ones that bind to actin. Such a function for this domain in *unc-5* could provide a direct mechanical linkage to the actin-based motility system of migrating cells and growth cones.

363.8

SELECTIVE AXON FASCICULATION AND TRACT FORMATION OF MOLECULARLY DISTINCT PERIPHERAL NEURON SUB-POPULATIONS DURING LEECH EMBRYOGENESIS. I. Johansen, K.M. Johansen, D.M. Kopp†, and J. Jellies†. Department of Zoology & Genetics, Iowa State University, Ames, IA 50011 and †Neurobiology Research Center, University of Alabama, Birmingham, AL 35294.

A small population of axon tracts in the nerve roots and interganglionic connectives are formed by peripheral neurons projecting their axons into the CNS. Subpopulations of these neurons differentially express the antigens of two monoclonal antibodies, lan 3-2 and lan 4-2. These antigens are surface glycoproteins (McKay et al., *Science* 222:788), and at least the lan 3-2 antigens may be directly involved in axon tract formation since perturbation with Fab fragments of lan 3-2 disrupt normal fascicle formation (Zipser et al., *Neuron* 3:621). On Western blots lan 3-2 recognizes three protein bands with molecular weights of 130, 105, and 90 kD, whereas lan 4-2 recognizes only a single 130 kD band. Immunoprecipitation and 2D-gel analysis show that at least one 130 kD glycoprotein expresses both the lan 3-2 and 4-2 epitope, whereas the two lower molecular weight glycoproteins only carry the lan 3-2 epitope. Consequently, the two antibodies recognize different complements of surface glycoproteins. Using immunocytochemistry, light and electron microscopy we have studied the development of lan 3-2 and lan 4-2 positive axon fascicles during development in *Hirudo medicinalis*. Our results demonstrate that the lan 3-2 antibody is likely to recognize all the developing peripheral neurons, and that in day 10 embryos the central projections of their axons segregate into three separate axon fascicles. In contrast, the lan 4-2 antibody only recognizes a few peripheral neurons of distinct morphology. These neurons also send axons to the CNS; however, interestingly they limit their projections along only one of the lan 3-2 positive axon fascicles. Thus, more than one set of molecularly distinct guidance cues are likely to be involved in the normal fasciculation of peripheral neurons and these studies set the stage for comparative antibody perturbation to assess the potential role of the lan 3-2 and 4-2 antigens in this process. Supported by NIH grant NS 28857 to IJo and NIH grant NS 28603 to JJe.

MOLECULAR CORRELATES OF MECHANOSENSORY NEURAL CIRCUITRY IN THE NEMATODE CAENORHABDITIS ELEGANS. Shahid S. Siddiqui, Lab of Molec. Biol., Toyohashi Univ. of Technology, Toyohashi 441, JAPAN.

Formation of a functional neural circuitry may require both cell intrinsic and cell extrinsic factors. One way of studying these factors is to establish molecular correlates of neural networks that are amenable to a behavioral assay. Since the touch circuitry in *C. elegans* is well studied (M. Chalfie et al. 1985), we have examined the molecular correlates of the touch circuitry. Previously, we have shown immunocytochemical staining due to anti-alpha tubulin McAb (6-11B-1 G. Piperno), that stains the six touch cells (ALML, ALMR, AVM, PLML, PLMR, and PVM) and a single cell PVR, in the right lumbar ganglion. The role of PVR in the touch circuitry has not been known. We have begun laser ablation of precursor cells that give rise to the PVR cell in the embryo, and assayed the touch response of the manipulated animals by a gentle stroking with a hair. Our results show that ablation of PVR and its precursor cells in the embryo affects the response to a light touch in experimental animals (S. Siddiqui, K. Higashi & J. Miwa). These results suggest a role for PVR in the touch neural network of *C. elegans* in the tail region.

ALZHEIMER'S DISEASE: AMYLOID I

364.1

TRANSLATIONAL REGULATION OF THE AMYLOID BETA PROTEIN PRECURSOR (APP) VIA RNA-BINDING PROTEINS: EFFECTS OF AN ALZHEIMER'S MUTATION. Rudolph E. Tanzi and Bradley T. Hyman. Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

A base substitution in exon 17 of the APP gene has been reported in affected individuals in familial Alzheimer's disease (FAD) pedigrees in the U.K., the U.S., and Japan. This mutation disrupts a putative regulatory stem-loop structure in the APP mRNA. The stem-loop occurs at the 3' end of region encoding the β A4 region of APP between nucleotides 1906 and 1924 (APP695 sequence) and matches a consensus sequence of iron-response elements (IRE) present in the mRNAs for ferritin and transferrin receptor. We are testing the possibility that the IRE stem-loop in APP may be a translational regulatory element which governs APP production, and which is destabilized by the Alzheimer's-associated base substitution in exon 17. Data will be presented on 1. attempts to characterize binding proteins for the APP IRE, 2. the effect of the Alzheimer's base-substitution on protein binding to the IRE, and 3. studies of translational regulation of APP via this IRE in wild type and mutated APP message.

364.2

THE CYTOSKELETAL ASSOCIATION OF THE ALZHEIMER'S AMYLOID PRECURSOR PROTEIN (APP) AND ITS POSSIBLE FUNCTIONAL SIGNIFICANCE. L.M. Refolo, I.S. Wittenberg*, and N.K. Robakis. Dept. of Psychiatry, Mt. Sinai Med Center. N.Y. N.Y. 10029.

Recently, we reported data suggesting that APP is associated with the cytoskeleton of Type I astrocytes. Using a detergent extraction procedure to further investigate this phenomenon, we find that 50-90% of the total APP, detected in brain tissue and neural cell lines, is associated with the detergent-insoluble cytoskeleton. In addition, we find that cell surface and intracellular APP are anchored to the cytoskeleton. This association requires intact microtubules and is modulated by protein phosphorylation. Pulse-chase experiments indicate that newly synthesized APP rapidly associates with the detergent-insoluble cytoskeleton. Temperature-shift experiments indicate that the intracellular pool of cytoskeletal APP is located both in the ER and Golgi compartments. Brefeldin A, a protein transport blocker causes a dramatic shift in the amount of intracellular APP associated with the cytoskeleton. We posit that the cytoskeletal association of cell surface APP reflects specific protein interactions which may be required to fulfill its function as an adhesion molecule. In addition we propose that the association of intracellular APP with the cytoskeleton is required for normal transport and post-translational processing. Altered cytoskeletal binding of APP might result in the abnormal transport of these proteins and could lead to aberrant proteolysis and generation of amyloidogenic fragments of APP.

364.3

THE ROLE OF HEPARIN IN β -AMYLOID PRECURSOR PROTEIN (APP) MEDIATED ADHESION

Kieran C. Breen*, & John L. Waddington. Dept. of Pharmacology, University College, Belfield, Dublin 4, and Dept. of Clinical Pharmacology, Royal College of Surgeons in Ireland, Du'lin 2, Ireland.

The β -amyloid precursor protein (APP) is a glycoprotein consisting of multiple isoforms derived from a single gene by a process of alternative splicing. The membrane-bound forms of the protein have previously been implicated in the mediation of neural cell adhesion to a type IV collagen (CIV) component of the extracellular matrix. APP has been demonstrated to have a high heparin binding affinity, and the A4 polypeptide is also closely associated with heparan sulfate proteoglycans in the Alzheimer neuritic plaques.

The present study examined the role of heparin/heparan sulfate in the mediation of APP-mediated collagen adhesion. Excesses of both heparin and heparan sulfate, as well as treatment with heparinase, inhibited APP-CIV interaction. This interaction was independent of the presence of the Kunitz protease inhibitor domain of APP, and both soluble and membrane-bound forms of the protein were capable of binding CIV. These results suggest that APP collagen binding is mediated via a heparin bridge mechanism, and raises the question as to the possible role of the heparin-binding characteristics of the protein in the genesis of neuritic plaques.

364.5

HIGH AFFINITY BINDING OF EXTRACELLULAR MATRIX PROTEINS TO THE BETA AMYLOID PRECURSOR PROTEIN. R. Kisilevsky², S. Narindrasorasak¹, R.A. Altman, M.B. Fairbanks, P. Gonzalez-DeWhitt², D.E. Lowery and B. Greenberg. Queen's University, Kingston, Ontario and The Upjohn Co., Kalamazoo, Michigan.

Extracellular matrix (ECM) proteins and the Alzheimer amyloid precursor (AAP) proteins are found as components of neuritic plaque and cerebrovascular amyloid. Binding studies were conducted between the basement membrane heparan sulphate proteoglycan (HSPG) or laminin and the 695, 751, and 770 AAPs. Quantitative analyses of binding data identified a single class of binding sites for the HSPG on AAP-695 ($K_d = 9 \times 10^{-10} M$), -751 ($K_d = 10 \times 10^{-9} M$), and -770 ($K_d = 9 \times 10^{-9} M$). The "Kunitz" protease inhibitor domain in -751 and -770 may reduce the affinity of AAPs for HSPG through steric hindrance and/or conformational alterations. HSPG binding was inhibited by heparin and dextran sulphate but not by dermatan or chondroitin sulphate. HSPG protein cores, also bound to the AAPs with equally high affinity indicating that the binding site is constituted by the peptide chain rather than the carbohydrate moiety. Two classes of binding sites were identified for laminin with affinities an order of magnitude higher than HSPG. Characterization of these interactions suggest that binding between the AAPs and the ECM may be involved in the nucleation stages of Alzheimer's beta-amyloidogenesis.

HUMAN ANTIBODIES REACTIVE WITH AMYLOID BETA PROTEIN IN NEURITIC PLAQUES AND CEREBROVASCULAR AMYLOID IN ALZHEIMER'S DISEASE (AD). F. Gaskin and J. Finley* Dept. of Behavioral Medicine and Psychiatry, Univ. of Virginia Sch. of Med., Charlottesville, VA 22901

Immortalization of B cells from patients with AD, other neurodegenerative disorders, strokes and age-matched controls by Epstein-Barr virus provides cell lines secreting human monoclonal antibodies (Abs). These Abs may be representative of circulating serum Abs. This approach was undertaken by us to circumvent the difficulties in defining the specificities of serum auto-Abs unique for AD patients. These difficulties include the low concentrations of relevant Abs and the presence of other auto-Abs to cellular constituents in aged individuals. Our previous studies have identified unique anti-neurofibrillary tangle and anti-neural Abs. The nature of these reactive antigens have not been defined. In the present study, we have identified by immunofluorescence and double labeling with thioflavine S, three B cell lines from an AD patient which secrete IgM Abs reactive with neuritic plaques and blood vessels in AD temporal cortex. Absorption studies and dot blots indicate the reactive epitope is located in the region of 1-28 amino acids of the amyloid beta protein. These Abs represent the first auto-Abs against the amyloid beta protein in man. The pathological significance of these auto-reactive Abs remains to be determined. Supported by AG-06348 and the Eleanor Naylor Dana Trust (New York).

DISTRIBUTION AND CHARACTERIZATION OF AMYLOID β PROTEIN DEPOSITION IN NORMAL HUMAN AND ALZHEIMER'S DISEASED CEREBRAL CORTEX USING

^{125}I - βAP_{1-40} AS THE RADIOLOGAND P.W. Mantyh, M.E. Labenski, C.J. Allen, J.R. Ghilardi, D.C. Whitcomb, S.R. Vigna, H.V. Vinters, E.R. Stimson, C.E. Dahl, J.E. Maggio, Mol. Neurobiol. Lab (151) VA Med. Cntr, Mpls., MN 55417; GI Div., VA Med. Cntr, Durham, N.C., 27705; Dept. Pathol., UCLA, LA, CA, 90024; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115

Amyloid β protein, a 39-42 amino acid peptide, is a primary constituent of senile plaques and cerebrovascular deposits in Alzheimer's disease (AD). Recently it has been reported that amyloid β protein 1-40 (βAP_{1-40}) is neurotoxic to mature neurons in culture, suggesting a possible role for the peptide in the pathology in AD. To explore the sites at which βAP is deposited and what factors may enhance or inhibit this aggregation, we have developed an in vitro assay using ^{125}I -labeled βAP_{1-40} to characterize and localize the deposition of βAP in homogenates or thin sections of normal or AD human cortex. The deposition of the ligand to AD tissue was blocked by unlabelled βAP_{1-40} and the smaller fragment βAP_{25-35} -NH₂, while βAP_{25-35} , substance P and neurokinins A and B were essentially inactive. Autoradiography suggests that the radioligand binds to nearly every senile plaque, but almost none of the degenerating neurons, stained with thioflavin S or anti-A4. There was essentially no binding of the radioligand to normal tissue. The present assay provides a novel method to assess agents which may affect amyloid deposition in AD.

Supported by NIH grant NS-23970, NS-22961, NS-26312 DK-38216 and a VA Merit Review.

Clq BINDING TO β -AMYLOID AND AMYLOID PRECURSOR PROTEIN (APP). Joseph Rogers, James Schultz, Scott Webster, Libuse Brachova*, Pamela Ward#, and Ivan Lieberberg#. Institute for Biogerontology Research, Sun City, AZ 85372, and #Athena Neurosciences, Inc., South San Francisco, CA 94080.

The full range of classical pathway complement proteins from Clq through the membrane attack complex (MAC, C5b-C9) have been demonstrated to be profusely present in Alzheimer's disease (AD), co-localized with β -amyloid containing pathology such as neuritic plaques. Normally, classical pathway inflammation is initiated by Clq binding to Ig. However, consistent AD specific Igs have proven difficult to find. As an alternative we have noted that the classical complement pathway can be initiated by many non-Ig substrates, and we have investigated the possibility that APP and/or β -amyloid might be such substrates. Slot blots of membranes onto which solutions of APP, β -amyloid, or control substances (e.g., BSA) had been fixed were incubated with Clq, washed, and assayed with anti-Clq antibody. Clq was not detected on BSA or other control membranes. A light band of Clq immunoreactivity was observed on APP membranes, and a heavier band on β -amyloid membranes. We next investigated whether this binding was sufficiently active to survive immunoprecipitation. Conditioned media from APP transfected and untransfected cells was incubated with physiological concentrations of Clq, immunoprecipitated with anti-Clq antibody, and run on SDS gels with anti-APP detection. APP co-precipitated with Clq in the transfected but not untransfected cell line. Under normal circumstances Clq-APP binding would not necessarily initiate inflammation. However, naked β -amyloid deposits, which are profuse in AD brain, might provide an escape from both fluid phase and cellular regulatory mechanisms for complement inactivation, leading ultimately to complement-mediated destruction of nearby neurons, neurites, and synapses.

Mass spectrometric analysis of amyloid β /A4 protein of Alzheimer's disease (AD). H. Mori, M. Ogawara and K. Takio* Dept. of Neurophysiology, Tokyo Metropolitan Inst. of Gerontology, Tokyo 173, Japan *Frontier Research Program, RIKEN, Saitama 351-01, Japan

We purified β /A4 protein from AD cortex according to a new protocol which involved 10% SDS extraction at the initial step. The Western blot with anti-synthetic peptide showed closely-spaced two bands at $M_r \sim 4,200$, indicating that β /A4 was not homogeneous. After digestion of β /A4 with *Achromobacter lyticus* protease 1 (specific for Lys-X), three produced fragments were separated by reverse-phase HPLC and subjected to sequence and plasma desorption mass spectrometric analyses. The N-terminal fragment gave two sequences, β /A4 1-16 and 3-16, without any N-terminal blocking. The C-terminal fragment consisted of two major and minor sequences, β /A4 28-40 and 28-43, respectively. From these observations we conclude that (1) β /A4 1-40 is a major species; (2) The N-terminus is not blocked. Thus, previous protocols for the purification of amyloid cores may have allowed β /A4 to be modified at its N-terminus during isolation. The presence of β /A4 1-43 suggests that larger molecules may have deposited before the cleavage at Val-40 occurs.

364.9

ALZHEIMER'S AMYLOID PRECURSOR PROTEIN CONTAINS A TETRAPEPTIDE SEQUENCE -RHDS- THAT PROMOTES CELL ADHESION. J. Ghiso*, A. Rostagno* and B. Frangione. Dept of Pathology, New York University Medical Center, New York, NY, 10016.

Amyloid β , the major constituent of the fibrils composing senile plaques and vascular amyloid deposits in AD and related disorders, is an abnormal internal degradation product of a larger precursor molecule (APP). The predicted multidomain structure of the four APP isoforms, generated by alternative splicing of a single gene located on chromosome 21, correlates with that of a cell-surface receptor. Two isoforms (APP₇₅₁ and 770) contain an extra domain homologous to the Kunitz family of protease inhibitors. The secreted amino terminal fragment containing the KPI domain has been shown to be identical to nexin II, a serine protease inhibitor.

APP isoforms, nexin II and amyloid β contain the sequence RHDS, closely homologous to the conserved tetrapeptide RGDS widely distributed among cell adhesion proteins. Sequence analysis and secondary structure prediction indicate that, like the conformation described for RGDS within fibronectin, RHDS (positions 657-660 of APP₇₅₁) is located in a hydrophobic β -turn. Therefore, RHDS may well function as a cell-adhesion recognition signal and compete with RGDS for common receptors.

To test this hypothesis, synthetic peptides SP28 (amino acids 652-679), RHDS and RGDS were used to promote cell attachment and to block fibronectin-mediated adhesion in competitive inhibition experiments. Peptide SP28 (containing the RHDS segment) specifically mediated adhesion of U937 cells in a dose-dependent manner. Preincubation of the cells with SP28, RGDS and RHDS inhibited cell attachment to SP28-coated substrata. The isolated peptide RHDS in solution was able to inhibit the adhesion of U937 cells to fibronectin-coated microtiter plates, mimicking the classic RGDS binding to the $\alpha 5 \beta 1$ integrin. The data indicate that through the interaction of the tetrapeptide RHDS with an integrin-like receptor, APP/nexin II may function as a cell-adhesion protein.

364.11

TRANSGENIC MOUSE STUDIES OF ALZHEIMER AMYLOID PRECURSOR (AAP) PROTEINS AND DERIVATIVES. B.D. Greenberg, S.M. Ali*, R.A. Altman, P.A. Gonzalez-DeWhitt*, D.E. Lowery, J.M. Colvin* and H.G. Polites*. Upjohn Laboratories, Kalamazoo, MI 49001.

We are attempting to generate a transgenic mouse model for Alzheimer-type amyloidogenesis based on overexpression of AAP proteins in appropriate brain regions. We have utilized several promoter systems to express the full length and various segments of the AAP-695. A C-terminally truncated derivative begins at the natural N-terminus (Leu₁₆) and extends to Val₆₄₀, functionally deleting the C-terminal 56 residues. An N-terminal truncation begins at Glu₅₃₃ and extends to the natural C-terminus. One of the promoter systems is based on the metallothionein-growth hormone system of Swanson *et al.* (Nature 317:363 (1985)) with AAP replacing the rGH coding sequence described in that paper. The other promoter system will be described. In order to guide our efforts in mice, we have transfected human HeLa and mouse L cells with these transgenes to study expression, processing and inducibility. Two of our three transgene series are abundantly expressed and inducible in transfected cells. In addition, Northern and Western blotting analyses of AAP expression in extracts of transgenic mouse brains are ongoing, as are *in situ* hybridization and immunocytochemical analyses on brain sections. The status of these studies will also be reported.

IDENTIFICATION OF A NUCLEAR FACTOR BINDING DOMAIN THAT IS REQUIRED FOR APP PROMOTER ACTIVITY.

W.W. Quitschke and D.Y. Goldgaber, Department of Psychiatry, State University of New York at Stony Brook, Stony Brook, NY 11794.

A manifestation of Alzheimer's disease is the presence of amyloid plaques in brains of afflicted individuals. The major component of amyloid plaques is the amyloid beta protein, which is a truncated form of the larger amyloid precursor proteins (APP). Several forms of APP have been identified that are derived from the same gene by differential splicing.

To investigate the regulation of the APP gene, the promoter was analyzed for its ability to direct cell type specific expression. The APP promoter and selected deletions were placed 5' to the reporter gene chloramphenicol acetyl transferase (CAT). The promoter deletions were transfected into different cell lines that showed variant levels of endogenous APP transcripts. The transient transfection assays showed that 96 base pairs 5' to the transcriptional start site are sufficient for full cell type specific promoter activity.

In order to identify trans-acting factors that bind to this region, a promoter fragment from position -96 to +49 was analyzed by band shift assay. The ³²P-end-labeled fragment was exposed to nuclear extracts from rat brain and a human retinoblastoma cell line. Prominent and identical band shifts were observed, indicating the binding of nuclear factors to this fragment. Mapping the binding domain by DNase footprinting and methylation interference revealed a DNase protected region covering about 20 base pairs on both strands. In addition, the methylation of two G residues on each strand within this DNase protected domain interfered with factor binding. Work is currently in progress to define the role of this factor in promoter expression.

STRUCTURAL ANALYSES OF BACULOVIRUS-DERIVED ALZHEIMER AMYLOID PRECURSOR (AAP) PROTEINS.

M.B. Fairbanks¹, M.D. Prairie^{1*}, J.M. Pasternack², H.A. Zurcher-Neely^{1*}, R.L. Heinrikson^{1*}, S. Narindrasorasak³, R. Kisilevsky³, W.C. Krueger^{1*}, S.G. Younkin² and B.D. Greenberg¹. ¹Upjohn Laboratories, Kalamazoo, MI 49001; ²Inst. Pathology, Case Western Reserve University, Cleveland, OH 44106; ³Dept. Pathology, Queen's University, Kingston, Ontario.

In order to better understand the amyloidogenesis which accompanies Alzheimer's Disease (AD), we have employed the insect cell baculovirus expression system to produce quantities of the AAP proteins sufficient for biochemical and structural analyses. AAPs secreted into the conditioned medium extend from the natural amino-terminus (Leu₁₆) to several C-terminal cleavage sites within the β protein domain. Details of this C-terminal processing will be presented. Determination of AAP secondary structure utilizing circular dichroism (CD) reveal essentially identical spectra and extinction coefficients for secreted AAP-695, AAP-751 and AAP-770. Calculations derived from CD analyses show that these AAP proteins contain 32% α helix, 18% antiparallel β -sheet, 3% parallel β -sheet, 15% β -turn and 32% non-defined structure (random coil, etc.). Effects of metal ions, proteoglycans, glycosaminoglycans and extracellular matrix proteins on AAP secondary structure are underway. Relevance of these findings to AD amyloidogenesis will be discussed.

NEURAL-IMMUNE INTERACTIONS

TUMOR NECROSIS FACTOR MODULATES NOREPINEPHRINE SECRETION IN CULTURED SYMPATHETIC NEURONS. B. Soliven and J. Albert*. Dept. of Neurology and The Brain Research Institute, The University of Chicago, Chicago, IL 60637

Immune peptides/cytokines are known to be important in immunoregulatory mechanisms. These peptides also exert multiple effects on other cellular functions, including modulating hypothalamic neuronal firing rate and secretion of pituitary hormones as part of a complex immune-neural interaction. To investigate the possibility that immune peptides could alter the function of the sympathetic nervous system, we studied the effects of cytokines on the calcium-dependent release of ³H-norepinephrine (³H-NE) from cultured neonatal rat superior cervical ganglia (SCG) neurons. Incubation of SCG neurons with rat γ -interferon (100-300 U/ml)(n=8), recombinant human interleukin- 1β (0.14 nM - 0.7 nM)(n=9), or recombinant human tumor necrosis factor- α (rhTNF) (1 nM)(n=15) for 24-48 hrs had no effect on the baseline release of ³H-NE and the initial release evoked by 70 mM K⁺, when compared to untreated cells (n=16). However, a repeat K⁺-induced depolarization after 6 min resulted in a decrease of 31 \pm 5.8%(n=11) in secretion in rhTNF-treated cells, but only 4.6 \pm 5.5%(n=11) decrease in untreated cells (p < .01). The secretory response was restored in rhTNF-treated cells when the interval between the two K⁺-induced depolarizations was increased to 10 min. We conclude that rhTNF prolongs the recovery from inactivation of secretion, thereby decreases the responsiveness of the sympathetic neurons to repetitive stimulation with high K⁺ solution.

SURVIVABILITY OF MITOGENIC CELL SUSPENSION GRAFTS WITHIN THE CNS OF ATHYMIC HOST RATS. B. Baker, P. Ebert*, R. Broadwell. Div. Neurosurgery, Univ. MD, Balto., 21201.

The belief that graft survival in the CNS of immunocompetent (athymic) hosts is absolute has been investigated using monoclonal antibodies against major histocompatibility complex (MHC) classes I and II, CD4, and CD8 antigens. Cell suspensions of PC12 or canine brain tumor cell line were prepared in culture, and 250K-500K cells were grafted into the caudate/putamen of homozygous athymic Buffalo, NIH, and ACI rats; animals were sacrificed 10 days post-grafting. Cell suspension grafts were evident within the parenchyma and/or on the pial surface of host brains and appeared healthy in sections stained with toluidine blue. Immunohistochemistry revealed populations of CD4+, CD8+, and MHC class II+ cells inhabiting the grafts. Differences in numbers of immunopositive cell types varied among the rat strains. The NIH nude strain always exhibited denser populations of the immunopositive cells in the two different tumor cell lines compared to Buffalo and ACI rat strains. Numbers of immunopositive cells in the two types of cell suspension grafts varied considerably. The data suggest that homozygous athymic rats can be capable of mounting an immune response against foreign antigen introduced to their CNS. Severity of the immune response may be related to the specific strain of athymic host and to the antigenicity of grafted cells. Supported by NIH/NINDS Grant #NS18030.

INTERLEUKIN 1- β (IL1- β) INCREASES SYNAPTIC INHIBITION IN RAT HIPPOCAMPAL PYRAMIDAL NEURONS (HPNs) *IN VITRO*. Marc L. Zeise*¹, Samuel G. Madamba and George Robert Siggins. Dept. of Neuropharmacology, Scripps Clinic and Research Foundation, La Jolla, CA, U. S. A., and ¹Clinical Neuropharmacology, Max-Planck-Institute for Psychiatry, 8000 München, Germany.

IL1- β is a cytokine polypeptide produced—mainly by macrophages—after viral infection, injury or antigenic challenge. Central neurons may be exposed to IL1- β when macrophages release cytokines after viral (e.g., HIV) infection. However, its effects on neuronal physiology are unknown. Thus, we examined the action of IL1- β on rat CA1 HPNs in a slice preparation, using standard intracellular current- and voltage-clamp methods. We superfused human recombinant IL1- β (280 nM) for 10 min, followed by washout. We stimulated the stratum radiatum during current or voltage steps, and measured voltage and current amplitudes before and after the synaptic stimulation, for calculations of conductances. In all cells, IL1- β enhanced postsynaptic inhibitory conductances 35 ms after synaptic stimulation (at the peak of the early GABAergic inhibition), by more than twofold (from 370 nS to 870 nS). At 80 ms after synaptic stimulation, average conductance increased from 110 to 410 nS, suggesting that synaptic inhibition was also considerably prolonged. The IL1- β effect was most pronounced about 1 hr after superfusion. Partial recovery occurred over the next hour. Resting membrane potential, input resistance, and amplitude and threshold of action potentials were unchanged. These results suggest that IL1- β can change interneuronal communication. The increase in GABAergic synaptic transmission in the hippocampus could lead to reduced memory or learning, as in AIDS-related dementia. (Supported by the USPHS (MH-47680) and the Deutsche Forschungsgemeinschaft.)

LOCALIZATION OF TYPE I INTERLEUKIN-1 RECEPTOR MESSENGER RNA IN THE HYPOTHALAMIC-PITUITARY-ADRENAL AND GONADAL AXES. E.T. Cunningham, Jr., E. Wada, D.E. Tracey, D.B. Carter, J.F. Battey and E.B. De Souza. Neurobiology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224 (E.T.C. Jr., E.B.D.S.); Laboratory of Neurochemistry, NINDS, Bethesda, MD 20892 (E.W., J.F.B.); and the Upjohn Company, Kalamazoo, MI 49007 (D.E.T., D.B.C.).

The cytokine interleukin-1 (IL-1) has pronounced endocrine effects, including activation of the hypothalamic-pituitary-adrenal axis (HPA) and inhibition of the hypothalamic-pituitary-gonadal axis (HPG). In this study, we sought to identify areas in the brain, adrenal gland, and testis that might mediate these effects of IL-1. *In situ* hybridization was employed with ³⁵S-labeled antisense cRNA probes derived from a full-length murine T-cell Type I IL-1 receptor cDNA. With the exception of endothelial cells of post-capillary venules, the signal in the hypothalamus, including the paraventricular nucleus, was comparable to background. An intense signal was observed over the entire anterior lobe of the pituitary gland. The signal over the intermediate and posterior lobes was comparable to background. Within the testis, an intense signal was observed over virtually all interstitial cells, a majority of which are known to be of the Leydig type, and over epithelial cells of the epididymal ducts, particularly in the head region. The signal within the adrenal gland was comparable to background. These results, in conjunction with previous data demonstrating high levels of Type I IL-1 receptor mRNA in extrahypothalamic brain regions such as the hippocampus, support the notion that IL-1 may alter HPA and HPG activity at both central and peripheral sites.

365.7

THE EFFECT OF NEUROPEPTIDES ON THE PROLIFERATION AND CYTOLYTIC ACTIVITY OF HSV-SPECIFIC CYTOLYTIC T LYMPHOCYTES. J.F. Sheridan, I.D. Plaza*, R. H. Bonneau*, and R. Glasz. Dept. of Medical Microbiology & Immunology, and Oral Biology, Ohio State University, Columbus, OH 43210.

The presence of neurotransmitter receptors on immune cells suggests a potential role for neuropeptides in immune regulation. Furthermore, the possibility that cells of the immune system produce neurohormones and peptides may indicate a homeostatic role for these substances in the immune system. Although other studies have demonstrated a role for neuroendocrine products in immune function, none have examined their effects on a viral antigen-specific T cell response. The purpose of this study was to investigate the effects of the neuropeptides, VIP, SOM, and SP on the biological activity of an HSV-specific cytotoxic T cell (CTL) cell line. A murine-derived, HSV-specific, CD8⁺ cell line, designated RAB-1, was generated from HSV-immune mice. This cell line proliferated only in response to MHC-restricted, HSV-specific antigenic stimulation; withholding antigen stimulation for 2 successive passages arrested these cells in the G₀/G₁ phase of the cell cycle. Various concentrations (10⁻⁸ to 10⁻¹²M) of either VIP, SOM, or SP were added to G₀/G₁ arrested RAB-1 cells in the presence of HSV-specific stimulator cells. The kinetics of the proliferative response to antigenic stimulation was determined by [³H]-thymidine incorporation at 24, 48, 72, and 96 hours following initiation of culture. All three neuropeptides were shown to suppress proliferation from 58% to 80% as compared to control cultures at 48 and 72 hours of culture. Further studies are in progress to examine the cytolytic activity of RAB-1 cells in the presence of these neuropeptides.

INTERLEUKIN-1 INDUCED GH SECRETION IS SUPPRESSED BY NEUTRALIZATION OF ENDOGENOUS GHRH USING GRF-ANTIBODIES. LC Payne*, F. Obál, Jr.* and JM Krueger. University of Tennessee, Memphis

Growth hormone-releasing hormone (GHRH) promotes non-rapid eye movement sleep (NREMS) (1). Interleukin-1 (IL1) enhances NREMS (2) and alters growth hormone (GH) secretion via a hypothalamic mechanism (3), probably GHRH. Low doses of IL1 enhance GH release and NREMS, whereas high doses inhibit GH and NREMS in rats (4). To study the possible involvement of GHRH in the mediation of IL1-induced GH secretion, affinity-purified goat anti-rat-GRF-antibodies (GRF-Ab) (500 μ g) were injected intravenously (iv) to neutralize endogenous GHRH in conjunction with ICV injected IL1 (1- to 25 ng). Plasma GH levels were assayed by RIA. GRF-Ab suppressed GH secretion induced by low doses of IL1. Further, GRF-Ab potentiated the suppression of GH by high (or large) doses of IL1. This suggests that IL1 induces GH release via a pathway involving GHRH. These data further prompt the speculation that the sleep-promoting actions of IL1 may be mediated via GHRH neurons projecting to the basal forebrain. Regardless of whether this speculation is correct, it is currently clear that GRF-Ab can block an IL1 action.

SPECIFICITY OF INTERLEUKIN-1-MEDIATED INDUCTION OF TRANSFORMING GROWTH FACTOR-BETA (TGF- β) IN GLIA. A. da Cunha, J. Jefferson*, F.S. Jannotta* and L. Vitkovic. Lab. of Immunoregulation, NIAID, NIH, Bethesda 20892.

We previously reported that interleukin-1 (IL-1) stimulated the expression of TGF- β in rat cortical astrocytes. The objective of this study was to determine the specificity and *in vivo* relevance of this observation. Near homogeneous populations of three glial cell types, astrocytes (A), oligodendrocytes (O) and microglia (M) derived from neonatal rat cortex and grown in primary cultures were exposed to IL-1a and IL-1b (250 U/ml, 24h). TGF- β was detected immunocytochemically in cells and tissues and quantified with a biological assay in culture supernatants. IL-1a and b were assayed immunocytochemically in tissue sections of human frontal cortex and subcortical white matter. The induction of TGF- β was glial cell type-specific: (1) the amount induced differed for each cell type (O>M>A); (2) M secreted active and the other cells secreted latent TGF- β ; (3) A and M were 2- to 3-fold more, whereas O were equally, responsive to IL-1b than IL-1a. IL-1b was expressed at a higher level than IL-1a in all tissues. TGF- β was not detected in brains (n=8) with low levels of IL-1, whereas, it was dramatically elevated in those (n=6) with high levels of IL-1. TGF- β immunoreactivity appeared to be localized in glia rather than neurons. These results indicate that elevation of IL-1 in brain parenchyma may lead to the induction of TGF- β in glia.

REGULATION OF MURINE T-LYMPHOCYTE FUNCTION BY ENDOGENOUS SEROTONIN J.L. Kut*, M.R.I. Young*, J.W. Crayton, L. van de Kar, and R.C. Aroza. Section on Biological Psychiatry and Research Service, VA Hines Hospital, Hines IL, 60141 and Departments of Pathology, Pharmacology, and Psychiatry, Loyola Stritch School of Medicine, Maywood, IL 60153.

Studies have suggested that serotonin may function as an immune modulator. On further exploration of this possibility, we found that pretreatment of mice with p-chlorophenylalanine (PCPA) reduced T-cell blastogenesis to Con-A by 74%. In contrast, pretreatment of mice with tryptophan slightly increased T-cell blastogenesis, but tryptophan pretreatment plus the addition of fenfluramine (Fen) *in vitro*, increased blastogenesis by 54%. Serotonin treatment of cultured cells at low doses increased T-cell blastogenesis, whereas high-dose serotonin produced a 40-65% inhibition of blastogenesis. Similarly, high-dose Fen inhibited T-cell responses. PCPA abolished this Fen inhibition of blastogenesis. Consequently, the Fen inhibitory effect may have been mediated via endogenous spleen-cell derived serotonin. Our results suggest that this endogenous pool of serotonin may have a regulatory effect on T-cell blastogenesis. Supported by VA Merit Review (M.R.I.Y.) and RAG (J.W.C.) grants.

SEX DIFFERENCES IN STRESS EFFECTS ON CLINICAL DISEASE COURSE IN EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS (EAE). Ann C. Griffin* and Caroline C. Whitacre, Department of Medical Microbiology & Immunology, The Ohio State University, College of Medicine, Columbus, OH 43210.

EAE, often studied as a model for multiple sclerosis, is induced by a single injection of myelin basic protein (MBP) and adjuvant. In the Lewis rat, EAE is a monophasic disease with symptoms of hindlimb paralysis and perivascular infiltrates confined to the CNS. EAE is known to be mediated by MBP-specific, CD4+ lymphocytes. Levine (1962) showed that restraint stress delayed the onset and decreased the severity of clinical signs of EAE induced by whole nervous tissue in female rats. We have found that restraint stress applied during EAE is capable of suppressing clinical signs of disease in both male and female rats. Female rats exhibit a more profound suppression of disease, and appear to be more stress-reactive than males. Supporting this proposal, we found that female rats exhibit significantly higher circadian levels of corticosterone, and markedly higher levels of corticosterone in response to a single, 30-minute stress period when compared to males. To determine where stress-induced immunomodulation may affect EAE, we compared several different immunological parameters involved in EAE in stressed and non-stressed rats of both sexes. There was no evidence of stress effects on the development of CD4-bearing cells or frequency of MBP-reactive lymphocytes in rats of either sex. We are continuing to investigate other immunologic mechanisms involved in EAE that may be influenced by stress-induced hormones, such as antigen processing and presentation, and T cell receptor usage. (USPHS grants NS 23561 & MH 44660)

GLUCOCORTICOID RECEPTOR GENE EXPRESSION IN THE THYMUS IS UNDER TRANSCRIPTIONAL CONTROL OF ESTROGENS. A. Peiffer, B. Marchetti, and N. Barden. Molecular Psychogenetics, CHUL, Québec, Canada and Dept. of Pharmacology, Catania Univ. Sch. of Med., 95125 Catania, Italy.

Suppression of thymus-dependent immune functions by glucocorticoids and presence of a sexual dimorphism in the immune response underline the important role of steroid hormones in the control of immune functions. The aim of the present study was to identify the expression of the glucocorticoid receptor (GR) gene in the thymus and to determine alterations in GR mRNA concentration after ovariectomy and treatment with gonadal hormones. Using a 2.2 kb cDNA probe, we have identified an approximately 6.7 kb GR transcript in the thymus, corresponding to that seen in the rat pituitary gland. Ovariectomy results in a marked increase of GR mRNA content in rat thymic tissue, an effect which can be completely reversed by administration of 17- β -estradiol. These results suggest that estrogens act at the level of gene transcription to modify GR mRNA level in the thymus. The negative regulation of thymic GR RNA by estrogens may represent an important mechanism by which sex hormones modulate glucocorticoid action in the thymus.

STRESS, HORMONES AND THE AUTONOMIC NERVOUS SYSTEM: NEUROTRANSMITTERS

366.1

ACUTE STRESS INCREASES ^3H -AMPA BINDING TO THE AMPA/QUISQUALATE RECEPTOR IN THE HIPPOCAMPUS AND THE INCREASE IS NOT GLUCOCORTICOID-DEPENDENT. T.J. Shors, G. Tocco, K.A. Patel, M. Baudry, and R.F. Thompson. University of Southern Calif., Dept. of Psychology and Neurosciences Program, LA, CA 90089.

To determine whether the binding properties of the glutamate receptors, NMDA and AMPA/quisqualate, are altered in response to acute stress, rats (n=6) were restrained for one hour and exposed to 60, 1 sec, 1 mA tail-shocks. Rats were immediately sacrificed; brains were rapidly frozen and sectioned. Ligand receptor autoradiography was performed using ^3H -TCP and ^3H -AMPA to label NMDA and AMPA receptors, respectively. Relative to naive controls (n=6), stress significantly increased binding of AMPA, but not TCP, in CA1 radiatum and oriens, CA3 radiatum and dentate gyrus. To establish whether glucocorticoids were responsible for the increased AMPA binding in stressed rats (51 $\mu\text{g}/\text{dl}$ serum corticosterone), autoradiography was performed on brains from adrenalectomized rats (ADX), with (n=6) and without previous exposure to stress (n=6). The increase in AMPA binding was still evident in ADX rats exposed to inescapable shock and restraint despite the near absence of circulating corticosterone (<3 $\mu\text{g}/\text{dl}$), thus indicating that the stress-induced increase in AMPA binding is not glucocorticoid-dependent.

5-HT $_{1A}$, BENZODIAZEPINE-RECEPTOR ANXIOLYTICS AND α -HELICAL CRF DIFFERENTIATE GLUCOCORTICOID AND BEHAVIORAL RESPONSES TO SOCIAL STRESS. K.A. Miczek, W. Tomatzky, G.F. Koob, C. Rivier. Dept. of Psychology, Tufts University, Medford, MA 02155; Neuroscience, Res. Inst. Scripps Clinic; Peptide Biology Lab, Salk Institute, La Jolla, CA 92037.

Profound neurochemical changes are triggered when an intruder reacts to an attacking opponent and begins to cope behaviorally and physiologically with the threat of attack. Adult male Long-Evans rats confronting an aggressive "resident" for 1 h behind a protective screen, engage in submission (i.e. supine posture and ultrasounds), defense and behavioral restraint, while showing large endocrine and cardiovascular activation. After 1-5 h behavioral and physiological resting responses are re-established. Diazepam, gepirone, clonidine and α -helical CRF leave the defensive postures in reaction to the conspecific threat unaltered, even at high motorically compromising doses. Ultrasonic distress calls remain unaltered by diazepam and clonidine, but are significantly reduced by gepirone. Only clonidine attenuated the cardiovascular stress response effectively. Comparisons of rats who are stressed for the first time with experienced rats reveal no adaptation and the same pharmacological profile. Diazepam, gepirone and clonidine attenuate at low doses the ACTH and corticosterone responses to social stress, but at high diazepam and gepirone doses the ACTH/corticosterone values of socially threatened rats are further elevated suggesting a dose-dependent inversion of the endocrine anti-stress effects to a stress-intensification.

366.3

HEMODYNAMIC STRESS ACTIVATES NORADRENERGIC LOCUS COERULEUS (LC) NEURONS OF UNANESTHETIZED RATS. R.I. Valentino, A.L. Curtis, G. Aston-Jones and G. Drolet. Dept. Mental Health Sciences, Hahnemann University, Philadelphia, PA 19102.

The LC has been implicated in stress partly because it is activated by physiologic challenges. Hypotension (-55 mmHg) induced by nitroprusside infusion in halothane-anesthetized rats was temporally correlated with an 32% increase in LC discharge rate. This effect was completely prevented by local LC injection of a corticotropin-releasing factor (CRF) antagonist, suggesting mediation through local CRF release (Valentino et al, Brain Res. in press). Since anesthesia may impair cardiovascular reflexes and interfere with inputs to the LC, the effect of hemodynamic challenge on LC discharge of conscious rats was investigated. Rats were chronically implanted with LC recording electrodes, and catheters in the jugular vein and the femoral artery for nitroprusside administration and blood pressure recording, respectively. In conscious rat, the same dose of nitroprusside (0.33 $\mu\text{g}/\mu\text{l}/\text{min}$ for 15 min) that caused prolonged LC activation of anesthetized rats was less efficacious and of shorter duration in increasing LC discharge rate (24%) and in producing hypotension (-25 mmHg). However, a larger dose of nitroprusside (2.5 $\mu\text{g}/\mu\text{l}/\text{min}$ for 15 min) that produced the same level of hypotension observed in anesthetized rats (-51 mmHg), resulted in a much greater increase (92%) in LC discharge rate. The present results indicate that: 1) Nitroprusside is a less potent cardiovascular challenge in conscious rats, presumably because anesthesia blunts hemodynamic reflexes; 2) The magnitude of LC activation elicited by nitroprusside is correlated to the magnitude of hypotension; and 3) Hypotension may be a more efficacious stimulus of LC activation in conscious than in anesthetized rats. PHS Grants MH 40008, MH 00840, MH 42796, NS 24698, NARSAD (ALC), FRSQ (G.D.).

366.4

LOCUS COERULEUS (LC) ACTIVATION BY DIFFERENT PHYSIOLOGIC CHALLENGES IS MEDIATED BY DISTINCT NEUROTRANSMITTERS. M.E. Page and R.J. Valentino. Dept. of Mental Health Sciences, Hahnemann Univ., Philadelphia, PA 19102.

The LC is activated by non-noxious physiologic stimuli such as hypotension and bladder distention (Svensson et al., 1987), and noxious stimuli, i.e., footshock. The present study investigated the neurotransmitter(s) mediating LC activation by hypotension and bladder distention. Halothane-anesthetized rats, implanted with either an i.v. cannula for nitroprusside administration or with a cannula in the bladder were prepared for LC recording and i.v. drug administration. Nitroprusside infusion increased LC spontaneous discharge rate by 32 \pm 5% (n=8) and this was completely prevented by local LC injection of a corticotropin-releasing factor (CRF) antagonist, α helical CRF $_{9-41}$ (150 ng), but not saline. The excitatory amino acid antagonist, kynurenic acid (0.5 μmol , i.c.v.) did not alter LC activation by hemodynamic stress, although it completely blocked activation of the same cells by footshock. These results indicate that LC activation by hemodynamic stress requires CRF release within the LC, but not excitatory amino acid neurotransmission. Injection of 0.5 ml saline into the bladder increased bladder pressure by 72 \pm 9 mmHg (n=14) and this was associated with a 57 \pm 7% increase in LC discharge rate. In contrast to LC activation by nitroprusside, LC activation by bladder distention was not blocked by an effective antagonist dose of α helical CRF $_{9-41}$. However, kynurenic acid (0.5 μmol , i.c.v.) almost completely prevented this activation indicating that like footshock, bladder distention increases LC discharge by an excitatory amino acid mechanism. Taken together, the results demonstrate that LC activation by two physiologic challenges, hemodynamic and visceral, is mediated by separate pathways that utilize different neurotransmitters. PHS Grants MH 40008, MH 00840, and MH 42796.

CONDITIONED FEAR STRESS INCREASED DOPAMINE AND SEROTONIN METABOLISM IN THE RAT MEDIAL PREFRONTAL CORTEX. T. Inoue*, T. Koyama, T. Ohmori, and I. Yamashita*. Dep. of Psychiatry and Neurology, Hokkaido Univ. Sch. of Med., Sapporo, Japan.

The effects of electric footshock stress (EFS) and conditioned fear stress (CFS) on dopamine and serotonin metabolism in seven various brain regions of the rat were examined by measuring dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA) and 5-hydroxyindoleacetic acid (5-HIAA). EFS for 30 min increased DOPAC and HVA levels in all brain regions and increased 5-HIAA levels in the medial prefrontal cortex (mPFC), nucleus accumbens and amygdala. CFS (exposure to an environment paired previously with footshock) increased plasma corticosterone levels and defecation, and induced freezing behavior. CFS increased DOPAC levels in the mPFC, paraventricular nucleus of the hypothalamus and lateral hypothalamus, and increased 5-HIAA level in the mPFC. In contrast with EFS which increased dopamine and serotonin metabolism in several brain regions, increased metabolism of both dopamine and serotonin was especially shown in the mPFC after CFS regarded as psychological stress.

366.7

PLASMA DOPA RESPONSES IN STRESS: DEPENDENCE ON SYMPATHONEURAL ACTIVITY AND TYROSINE HYDROXYLATION

R. Kvetnansky, J. Armando*, V. K. Weise*, K. Fukuhara*, A. Deka-Starosta*, I. J. Kopin and D. S. Goldstein*. Clinical Neuroscience Branch, NINDS, NIH, Bethesda, MD 20892.

Sources of dopa in plasma and the meaning of plasma dopa levels in terms of sympathoneural function have been unclear. This study comprehensively examined plasma concentration of DOPA, the catecholamines norepinephrine (NE), epinephrine, dopamine and the catechol metabolites during immobilization stress in conscious rats. Animals were pretreated with chlorisondamine to block ganglionic neurotransmission or α -methyl-para-tyrosine to inhibit tyrosine hydroxylation, and blood was obtained either via indwelling arterial cannula or by decapitation. Immobilization produced rapid, sustained increases in plasma levels of DOPA, catecholamines and catecholamine metabolites. Chlorisondamine decreased baseline plasma DOPA and NE levels and abolished increases in plasma DOPA and NE levels during immobilization. α -methyl-para-tyrosine administration produced sustained decreases in plasma DOPA levels and markedly attenuated immobilization-induced increases in plasma DOPA levels. Similar results were seen when blood was obtained by decapitation as when obtained by indwelling arterial cannula. Bilateral adrenalectomy augmented baseline plasma levels of DOPA and NE and also augmented DOPA and NE responses during immobilization. The results indicate that during immobilization stress, increased post-ganglionic sympathoneural outflow stimulates the synthesis of DOPA in sympathetic neurones and evokes release of DOPA into circulation.

366.6

ROLE OF LOCUS COERULEUS AND SEROTONERGIC DRUG ACTIONS ON SCHEDULE-INDUCED POLYDIPSIA. C.-S. Tung*, C.-C. Lu*, C.-J. Tseng, Y.-P. Liu* and T.-H. Yin. Dept. of Physiology and Pharmacology, National Defense Medical Center, PO BOX 90048, Taiwan, ROC.

As one of the hungry animal behavior, schedule-induced polydipsia (SIP), poses a general buffering property to reduce the heightened arousal produced by schedule of intermittent feeding paradigm, it provides an opportunity to study the regulation of central nervous system in stress coping reactions. We are interested in determining the functions of locus coeruleus (LC) and pharmacological actions of serotonergic 5-HT₂ analogues on this behavior. Levels of water intake, licking, and bar presses per minute were recorded as an index of SIP activities after rats exerted one hour performance of a fixed-interval one-minute operant pellet conditioning. Our results showed SIP was attenuated by 5-HT₂ agonist, DOI (0.1; 0.5; 1 mg/kg I.P.), and activated by 5-HT₂ antagonist, RIT (2.5 mg/kg I.P.). After bilateral LC lesions, SIP was attenuated and the activating effect of RIT was abolished. In addition, SIP was found decreased in a persistent way after bilateral LC lesions followed by bilateral ventral tegmental area lesions. Neurotoxin DSP-4 also induces an inhibitory action on SIP potency. We concluded that LC is involved in central control of SIP, and the modulating effects of 5-HT₂ receptors on SIP depend upon an integrity of LC functions.

SELECTIVE INDUCTION OF TYROSINE HYDROXYLASE (TOH) IN THE SYMPATHETIC GANGLIA AND ADRENAL GLAND OF RATS IN RESPONSE TO DIFFERENT STRESS. B. K. Kiran* and I. H. Ulus. Dept. of Pharmacology, Uludağ Univ. Medical School, Bursa, Turkey.

The increase in TOH activity in the individual sympathetic ganglion (SG) and in adrenal gland (AG) utilized as an index for increased impulse flow from the central nervous system to the sympatho-adrenal system under various stress situations. Rats were exposed to different stress for four days and they were killed on 5th day. AG and twentyfour SG were dissected for measurement of their TOH activity. Forced immobilization (6 hours/daily) increased TOH activity primarily in the lumbar (L1-6) and the sacral (S1-3) SG, and in AG. Immobilization failed to alter TOH activity in the thoracic SG. Exposure to hypercapnic environment (20% O₂+25% CO₂+55% N₂, 5 hours/daily) increased TOH activity primarily in the thoracic (T1-10) SG, and in the first two lumbar (L1,2) SG. When animals kept at cold environment (4°C; 64 hours), TOH activity increased in, primarily, AG, and in the coeliac, L2 and the cervical inferior SG. Hypoglycemia, induced by 2-deoxy-D-glucose (600 mg/kg, i.p.) administration, increased TOH activity only in AG. These data indicate that the increase in impulse flow from central nervous system to the sympathetic system and AG in response to stress is not uniform. Clearly, the response is showing very high regional selectivity depending upon the type of stress situation.

MODULATION OF NEUROTRANSMITTER RECEPTORS

FURTHER *IN VIVO* EVIDENCE FOR MULTIPLE SIGMA RECEPTOR SITES. Smriti Iyengar, S.J. Mick, V.M. Dilworth, N.M. Gray, T.S. Rao and P.C. Contreras. Searle Research and Development, G. D. Searle and Co., St. Louis, MO 63198.

The effects of three ligands having potent sigma receptor affinity, ifenprodil, opipramol and BMY 14802, were evaluated on four *in vivo* neurochemical parameters, ACTH release, prolactin release and dopamine metabolism in rat and NMDA-dependent cGMP increase in mouse cerebellum. All three ligands increased dopamine metabolism in A9 and A10 regions, increased prolactin release and ACTH release and inhibited NMDA receptor dependent cGMP increases. While these effects differed from those observed with other non-benzomorphan ligands, (+) 3PPP and (-) butaclamol, they were similar to those observed with benzomorphan sigma ligands, (+) NANM and (+) pentazocine (Iyengar et al., *Neuropharmacol.* in press). However, the increases in ACTH and dopamine metabolism caused by BMY 14802, ifenprodil and opipramol were not CPP-reversible, unlike the benzomorphan ligands. The three ligands also did not reverse the effects of (+) 3PPP, (-) butaclamol or (+) pentazocine, precluding the possibility that they were antagonists at sigma sites. *In toto*, the effects of various sigma ligands tested in the four *in vivo* parameters to date, fall into three separate categories, with BMY 14802, ifenprodil and opipramol behaving like functional NMDA antagonists. Taken together with the observation that these ligands also exhibit neuroprotective properties (abstract, Contreras et al., this meeting), unlike (+) 3PPP and (-) butaclamol, we postulate that these ligands mediate antiischemic activity via a unique sigma site. This site appears to be different from the site(s) mediating the effects of benzomorphan ligands or other non-benzomorphan sigma ligands like (+) 3PPP. In conclusion, the present data further supports the concept of multiple sigma sites.

CHOLESTEROL AND PREGNENOLONE FORMATION IN INTACT GLIOMA C6 CELLS: REGULATION BY MITOCHONDRIAL BENZODIAZEPINE RECEPTOR LIGANDS (MBR). P. Guarneri, V. Papadopoulos*, B. Pan* and E. Costa. Fidia-Georgetown Institute for the Neurosciences and Dept. of Anatomy & Cell Biology, Georgetown University School of Medicine, Washington, D.C. 20007

Neurosteroids regulate GABA action on GABA_A receptors. They act as positive (tetrahydroprogesterone) or negative (pregnenolone sulfate and dehydroepiandrosterone sulfate) allosteric modulators of GABA_A receptors. In brain, the first step of neurosteroid biosynthesis occurs in glial cell mitochondria under the regulation of MBR. A novel system has been developed to study the regulation of steroid biosynthesis in glioma C6-2B cells. Cultures maintained in serum-free media were incubated with ³H-Mevalonolactone (MVA) in the presence of various concentrations of cold MVA (0-100 nmoles) and in a time-related manner were analyzed for the formation of ³H-cholesterol and ³H-pregnenolone. Mevinolin (10 uM) was used as a specific inhibitor of 3-hydroxy-3-methylglutaryl Coenzyme A reductase to decrease endogenous MVA. In order to quantify pregnenolone synthesis, cells were preincubated for 30 min with the pregnenolone metabolism inhibitors trilostane and SU-10603. Steroids were extracted from media and cell cultures and then separated through Sep-Pak Silica cartridges and Si 60 Lichrosorb HPLC column. Under these conditions, the formation of cholesterol and pregnenolone was found to be dependent on the amount of substrate (MVA) added and occurred within seconds. Preincubation of the cultures with 4'-Chlorodiazepam (10⁻⁷ M), a specific PBR ligand, significantly increased the rate of cholesterol and pregnenolone synthesis.

PHOSPHORYLATION OF MITOCHONDRIAL BENZODIAZEPINE RECEPTORS. M.E. Whalin*, V. Papadopoulos*, E. Costa, and K.E. Krueger. Fidia-Georgetown Institute for the Neurosciences and the Dept. of Anatomy & Cell Biology, Georgetown University School of Medicine, Washington, D.C. 20007.

The mitochondrial benzodiazepine receptor (MBR) appears to be active in steroid biosynthesis stimulated by ACTH and other polypeptide tropic hormones. Since the action of these hormones in the acute stimulation of steroidogenesis is transduced via activation of adenylate cyclase and cyclic AMP accumulation it was of interest to ascertain whether MBR is a substrate for protein kinase A activity. Using mitochondrial fractions from rat adrenals or the rat glioma C6 cell line, MBRs located in the outer mitochondrial membrane are phosphorylated in the presence of protein kinase A catalytic subunit. Phosphorylation is blocked by antibodies directed against the carboxyl terminal of MBR. Furthermore, a phosphorylated MBR adduct can be purified from mitochondrial membranes following digitonin solubilization and fractionation by hydroxylapatite and reverse-phase high pressure liquid chromatography. These findings demonstrate that MBR is a substrate for phosphorylation and suggest that phosphorylation/dephosphorylation of this protein might be involved in the regulation of steroidogenesis by ACTH which is apparently mediated by DBI, an intracellular protein.

SELECTIVE DOWN-REGULATION OF D2 DOPAMINE RECEPTOR mRNA IN MOUSE STRIATUM FOLLOWING CONTINUOUS INFUSION WITH THE D2 DOPAMINE AGONIST QUINPIROLE. J.F. Chen, L.W. Zhou, and B. Weiss. Div. of Neuropsychopharmacology, Dept. of Pharmacology, Medical College of Pennsylvania/EPPI, Philadelphia, PA 19129.

Abnormal activity of dopamine receptors has been implicated in the development and treatment of schizophrenia and certain motor disorders. Accordingly, the pharmacological modulation of dopamine receptors at the level of gene expression may add substantially to our understanding of the molecular mechanisms underlying the pathophysiology and treatment of these diseases. In the present study, we examined the effect of continuously infusing the specific D2 dopamine receptor agonist quinpirole on the D2 dopamine receptor mRNA in mouse striatum and compared these molecular events with behavioral effects induced by this drug. Male mice were treated with quinpirole (8 μ mol/kg/hr) for 6 days via implanted Alzet minipumps. Stereotyped behaviors were measured during the course of treatment. The animals were sacrificed, total RNA from striatum was isolated, and D2 receptor mRNA was determined by Northern analysis using a synthetic radiolabeled oligonucleotide probe complementary to the D2 receptor mRNA. The results, which support previous findings from our laboratory, showed that continuously infusing quinpirole initially produced a stereotyped behavior which disappeared with 24 hr and remained low for the 6 days of infusion. At this time there was a significant reduction in the D2 receptor mRNA in striatum. Infusing the D1 agonist SKF38393 had little effect on the D2 mRNA. These results suggest that the down-regulation of stereotyped behavior induced by quinpirole is associated with a reduction in D2 dopamine receptor mRNA in corpus striatum. (Supported by MH42148).

NEURONAL EXPRESSION OF THE β -ADRENERGIC RECEPTOR KINASE. J.L. Arriza¹, R.B. Simerly², T.M. Dawson³, S.H. Snyder³, M. Caron¹, and R.J. Lefkowitz^{1*}. ¹Howard Hughes Med. Inst., Duke Univ. Med. Center, Durham, NC 27710; ²Div. of Neurosci., Oregon Regional Primate Research Center, Beaverton, OR 97006; ³Dept. of Neurosci., Johns Hopkins Sch. of Med., Baltimore, MD 21205.

The β -adrenergic receptor kinase (β ARK) phosphorylates the agonist-occupied form of the β -adrenergic receptor and other G-protein coupled receptors to regulate receptor function in the paradigm of desensitization. The dependence of this kinase activity on receptor occupancy suggests it may be of special importance in the context of synaptic transmission. To examine this hypothesis the rat homologues of two closely related β ARK genes were characterized by molecular cloning and sequencing. The two gene products, β ARK1 and β ARK2, share 90% amino acid identity and both were demonstrated to phosphorylate purified β -adrenergic receptor. These kinase genes are predominantly expressed in the central nervous system; moreover, *in situ* hybridization histochemistry indicates that this expression is largely neuronal and that the β ARK isoforms are to a great extent co-distributed. Although β ARK1 mRNA is generally more abundant throughout the central nervous system, in a few regions, such as the substantia nigra and tectum, cellular levels of β ARK2 mRNA appear to be significantly higher. Antibodies to β ARK1 and β ARK2 were developed to determine their protein distribution by Western blot analyses and by immunohistochemistry. Immunoreactivity for both β ARK proteins was found predominantly in neurons. This staining was present in cell bodies and fibers and, most interestingly, was present at the synapse. These data support the model in which β ARK promotes the rapid desensitization of target neurotransmitter receptor systems and thus contributes to short-term synaptic plasticity.

ACETYLCHOLINE RECEPTOR ASSEMBLY IS STIMULATED BY cAMP DEPENDENT PHOSPHORYLATION OF ITS γ SUBUNIT. W. N. Green*, A. F. Ross* and T. Claudio. Department of Cellular & Molecular Physiology, Yale University School of Medicine, New Haven, CT 06510.

Different combinations of *Torpedo* acetylcholine receptor (AChR) subunits stably expressed in mouse fibroblasts were used to establish a role for phosphorylation in AChR biogenesis. When cell lines expressing fully functional AChR complexes ($\alpha_2\beta\gamma\delta$) were labeled with ³²P, only γ and δ subunits were phosphorylated. Forskolin, which causes a 2- to 3-fold increase in AChR expression by stimulating subunit assembly, increased unassembled γ phosphorylation, but had little effect on unassembled δ phosphorylation. The forskolin effect was rapid, significantly preceding its effect on expression. Of the two phosphorylated subunits, only γ was necessary for the cAMP stimulation of AChR expression. This was demonstrated by treating cell lines expressing $\alpha\beta\gamma$ or $\alpha\beta\delta$ complexes with forskolin and observing increased expression of only $\alpha\beta\gamma$ complexes. Forskolin also up-regulated the expression of $\alpha\gamma$ complexes, but not $\alpha\delta$ complexes in cells expressing just these subunits. We conclude that the cAMP-induced increase in expression of cell surface AChRs is due to phosphorylation of unassembled γ subunits which leads to increased efficiency of assembly of all four subunits, and in turn, an increase in AChR cell surface expression.

367.6

DIFFERENTIAL MODULATION OF DOPAMINE RECEPTOR SUBTYPES BY PROTEIN KINASES C AND A. Ya Fang Liu, Olivier Civelli, and Paul R. Albert. Dept. of Pharmacology and Therapeutics, McGill University, Montreal, Canada H3G-1Y6, and Vollum Institute for Advanced Biomedical Research, Portland, USA 97201.

The human dopamine-D1, -D2L, and -D2S receptors were expressed in mouse fibroblast Ltk- cells to compare their relative sensitivities to protein kinases C and A. The D1 receptor stimulated cAMP accumulation (10-fold), while both D2 subtypes inhibited cAMP. Each subtype, including D1, induced an increase of [Ca⁺⁺] via enhancement of phospholipase C activity in L cells. The rank order of potency of dopamine for the action on [Ca⁺⁺] was D2L>D2S>D1. D1-induced increases in PI turnover and [Ca⁺⁺] were enhanced (at least 2-fold) by prior activation (10³-3h) of protein kinase A with forskolin or 8-Br-cAMP, which did not alter the D2 receptor-mediated actions. In contrast, activation of protein kinase C completely abolished all actions of D1, D2S, and D2L on [Ca⁺⁺], and inhibited D1-induced cAMP accumulation, but did not alter D2S/D2L-induced inhibition of cAMP. We conclude that the dopamine-D1 and D2 receptors induce multiple signal transduction pathways in L cells which are differentially modulated by protein kinases C and A.

MODULATION OF STRIATAL OPIOID BINDING SITES BY THE WEAVER GENE. Sandra E. Loughlin and Frances M. Leslie. Departments of Anatomy and Neurobiology and of Pharmacology, University of California, Irvine, California 92717.

The weaver mutant mouse undergoes a spontaneous, early postnatal loss of dopaminergic nigro-striatal neurons. This results in a near total loss of dopaminergic terminals in the striatum by the third postnatal week (Roffler-Tarlov, et al, 1984). Previous studies have suggested that a large percentage of opioid receptors are located on dopaminergic terminals. In the present study, striatal opioid receptor subtypes were examined in normal (B6CBA-A^w-J/A background, +/+ mice) and in animals heterozygous (+/wv) and homozygous (wv/wv) for the weaver gene. Animals were sacrificed and their brains processed for autoradiographic localization of mu, delta and kappa opioid receptors using [³H] DAGO, [³H] DADLE (in the presence of D-PRO⁴ morphine) and [³H]diprenorphine (in the presence of D-PRO⁴ morphine) and DSLET, respectively. Nonspecific binding was determined with levallophan. Data were analysed by quantitative densitometry.

In the weaver mouse, mu opioid receptors in patch and matrix compartments of the adult striatum were not significantly changed relative to nonmutant controls. Delta receptors were also unchanged. In contrast, kappa receptors were significantly decreased in the weaver striatum (p < 0.001). Opioid binding density in nucleus accumbens was unchanged in weaver with respect to control. The changes associated with early postnatal, genetically programmed cell loss differ from those we have observed following 6-OHDA lesion (Smith, et al, 1991). These data suggest that only a small percentage of striatal opioid receptors are located on dopaminergic terminals and that striatal opioid receptor subtypes are differentially modulated by loss of dopaminergic innervation.

THE *MAS* ONCOGENE/ANGIOTENSIN RECEPTOR mRNA IS UPREGULATED BY SEIZURE. K.A. Martin and S. Hockfield. Sect. of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The goal of the present study was to identify and characterize structural effector genes that are regulated by neuronal activity in the adult CNS. Specifically, we have analyzed the influence of seizure activity on the expression of the *mas* oncogene/angiotensin receptor mRNA in the adult rat brain. This gene was selected because of its oncogenic properties and its localization to hippocampal neurons, a population of cells that demonstrate activity-dependent changes in molecular, morphological, and physiological properties.

As a first step in determining if the *mas* oncogene is regulated by activity we have analyzed its transcription by *in situ* hybridization histochemistry and RNase protection assay, following pentylenetetrazole-induced seizures. *In situ* hybridization analysis revealed a consistent increase in *mas* expression in both the dentate gyrus and CA fields of the hippocampus. No increase was detectable in any other brain regions. *Mas* mRNA levels were not elevated 1h post seizure, were increased at 2, 4, and 6 h and had returned to baseline levels by 24h following seizure. No change in the level of neurofilament mRNA was observed over this time course. The effect of activity on *mas* mRNA levels was confirmed and quantified by RNase protection analyses; a significant increase was observed 6h post seizure (mean increase=64%, t=3.288, p<0.03).

The observation that transcription of the *mas* oncogene/angiotensin receptor can be regulated by neuronal activity suggests that *mas* could have an important function in producing changes in cellular phenotype in response to neuronal activity. [Supported by the NSF.]

CAFFEINE SENSITIVE CALCIUM STORES IN CULTURED CEREBELLAR PURKINJE NEURONS. J.R. Brorson, D. Bleakman, S.J. Gibbons, and R.J. Miller. Department of Physiological and Pharmacological Sciences, University of Chicago, Chicago IL 60637.

Cerebellar Purkinje neurons contain high levels of the inositol 1,4,5-trisphosphate (IP₃) receptor and the ryanodine receptor, which are each thought to be associated with intracellular Ca²⁺ stores. We have examined the properties of such stores in cultured rat cerebellar neurons taken from 16 day rat embryos. In this system, about one half of the neurons could be identified as Purkinje cells as indicated by staining for the Ca²⁺ binding protein calbindin D-28k, as well as for the IP₃ and ryanodine receptors. In double immunofluorescent staining, the IP₃ and ryanodine receptors primarily colocalized with staining for calbindin. Caffeine (10mM) released Ca²⁺ from intracellular stores in about one half of the cultured neurons. This effect could be repeated only if the stores were reloaded by a depolarization-induced elevation in [Ca²⁺]_i. Ca²⁺ release by caffeine was abolished by prolonged application of ryanodine (10μM). Furthermore, we demonstrated that the caffeine sensitive Ca²⁺ stores could regulate electrophysiological events in some cells, altering patterns of spontaneous action potential firing and modulating the size of afterhyperpolarizations following evoked action potentials.

PURKINJE CELL HETEROGENEITY IN FOUR CEREBELLAR MUTATIONS REVEALED BY ZEBRIN I EXPRESSION. C. Sotelo and M. Wassef*, INSERM U. 106, 75013 Paris (France)

The differential expression of zebrin 1, an adult marker of Purkinje cell (PC) heterogeneity (Hawkes et al. 1985, Brain Res. 333 : 359), has been immunohistochemically studied in four cerebellar mutant mice: weaver (wv), reeler (rl), meander tail (mea) and staggerer (sg). Despite the severe cortical disorganization which characterizes the cortex of these granulo-prival cerebella, the pattern of zebrin I expression in wv, rl and mea is normal, whereas it is abnormal in sg. Thus, for example in the anterior lobe, the only cortical region affected in mea, the absence of granule cells (wv and mea) does not prevent the normal expression of zebrin I into three sagittal bands of clustered PCs: one medial and two symmetric lateral bands. In rl, zebrin I parcellation is also shared by the bulk of PCs remaining in the white matter (central mass). In sg - a mutation affecting only PCs - the pattern of zebrin I expression is abnormal because none of the 20% remaining PCs is zebrin I+. These observations indicate that PC heterogeneity resulting in cortical parcellation is an intrinsic property of developing PCs. (The authors are grateful to Dr R. Hawkes for the gift of the mab Q113).

ACTIVITY INDUCED EXPRESSION OF CEREBELLAR CGRP BINDING SITES. A. ROSINA*, S. MORARA*, L. PROVINI¹ and G. FORLONI² (SPON:ENA). Ist. Fisiol. Centrali Nervosi CNR, Ist. Fisiol. Gen. Chim. Biol. Fac. Farm.,² Ist. M. Negri, Milano, Italy.

High affinity binding sites for calcitonin gene-related peptide (CGRP) are present in the molecular layer of the adult cerebellum, while CGRP-like immunoreactivity can be detected in the olivocerebellar system, only at neonatal stages. We have hypothesized that the expression of CGRP binding sites can be modulated by climbing fiber activity.

Adult rats were treated with harmaline, a drug known to increase the firing rate of olivary neurons, at tremorogenic doses (25 mg/Kg, every 3h, for 12 to 36h). Quantitative autoradiography was used to assess the density variations of CGRP binding sites. The CGRP recognition site was labeled using I125-CGRP (human -CGRP).

Rats treated for 12h and allowed to survive 24h after the treatment showed a significant increase (+13%, p<0.05) of specific CGRP binding sites in the molecular layer. Further increases were recorded after longer treatments (e.g. 33%, p<0.01, after 36h). These results give evidence that the activation of climbing fibers induced by harmaline is able to modulate the expression of cerebellar CGRP binding sites.

THE ORGANIZATION OF FIBRES WITHIN THE RAT BASIS PEDUNCULI. M. Glickstein, I. Hans, C. Legg, B. Mercier, M. Ramnarayan and E. Vaudano, Department of Anatomy, University College London, Gower Street, London WC1E 6BT.

Small volumes of wheatgerm agglutinin HRP were injected into discrete areas of the cerebral cortex of rats. After two days survival time the brains were processed to reveal the location and extent of labelled fibres within the peduncles. In rats, unlike primates, the basis pedunculi fibres arise from the entire cerebral cortex. There is an orderly organization of fibres within the peduncles. Fibres originating from cells in the frontal cortex maintain a position in the ventromedial part of the peduncles. Those from the occipital and temporal cortex travel in the most dorsolateral portion. Somatosensory fibres are between these two. There is a high correlation between the volume of the peduncles which contains efferent fibres and the relative density of corticopontine cells in different regions of cortex. The organization makes it possible to study the behavioral effects of lesions which interrupt selectively the input to the cerebellum from different cortical areas.

CHARACTERIZATION OF THE GOLDFISH VESTIBULO-CEREBELLUM. A.M. Pastor*, R.R. de la Cruz*, J.L. Simpson and R. Baker. Dept. of Physiol. and Biophys., NYU Med. Ctr., New York, NY 10016.

The afferent and efferent organization of the goldfish vestibulo-cerebellum was examined by means of intra- and extracellular injection of biocytin. Axons of vestibular neurons originating either from the semicircular canals or the descending and anterior octavus nuclei terminated ipsilaterally in the eminentia granularis pars lateralis as claw-like boutons. Cerebellar injections comprising the caudal half of the corpus cerebelli revealed two main cerebellofugal targets, namely the ipsilateral vestibular nuclei and the mesencephalic periculomotor region. No terminals were seen in the oculomotor complex. Parallel fiber bundles originating from the injection site extended transversally to the contralateral vestibulo-cerebellum. The ipsilateral nuclei of the accessory optic system and contralateral inferior olive also sent afferents to the vestibulo-cerebellum. Purkinje cells, physiologically identified by their visually evoked climbing fiber response, terminated in the descending vestibular nucleus. Single unit recordings of Purkinje cells during optokinetic stimulation demonstrated reciprocally related simple/complex spike responses that were greatest for whole field rotation about axes orthogonal to the semicircular canal planes. Two types of Purkinje cell discharge patterns were seen during visual-vestibular interactions about the vertical axis. In one case, Purkinje cells coded the vectorial addition of head and eye velocity, with a slight saccadic and eye position sensitivity. The second type of Purkinje cell showed a discharge pattern related solely to eye movements. These data establish a structural and functional basis for further investigating cerebellar regulation of the goldfish vestibulo-ocular reflex.

HEMICEREBELLECTOMY INDUCES SPATIAL MEMORY

DEFICITS IN RATS. M. Molinari, L. Petrosini*, M.E. Dell'Anna*, S. Giannetti*. Inst. of Neurology, Catholic University, Rome and +Dept. of Psychology, University of Rome "La Sapienza", Rome.

The present study was aimed at investigating the effects of cerebellar lesions on spatial memory abilities in rats. Rats were hemicerbellectomized (Hcbcd) on the right side after deep anaesthesia at two developmental stages, namely at birth (postnatal day two) or in adulthood. Spatial memory abilities have been tested in adult animals by means of maze tests performed in water in order to overcome locomotory deficits due to the cerebellar lesion. In fact, while Hcbcd rats present an impaired locomotion they are very skillful in swimming. Therefore, spatial abilities were tested in a water T maze and in a Morris water maze. In both experimental groups, although in a different degree, clear deficits in solving the spatial tasks, that could not be related to the motor deficits, were present. The present report indicates that Hcb in rats affects spatial memory abilities.

THE ROLE OF SUBTHRESHOLD OSCILLATIONS IN SYNCHRONIZING NEURONAL ELECTRICAL ACTIVITY. I. Lampl* and Y. Yarom. Dept. of Neurobiology, Life Science Institute, Hebrew University, Jerusalem ISRAEL.

In our first description of membrane potential oscillations in olivary neurons it was pointed out that these subthreshold oscillations occur simultaneously and in phase in a large number of neurons. It has therefore been postulated that this phenomenon gives rise to the synchronized suprathreshold activity so characteristic of complex spike activity recorded from cerebellar Purkinje cells. In the present study the role of such subthreshold activity in synchronization of olivary activity has been studied by analyzing the integrative process that sums synaptic potentials with subthreshold sinusoidal membrane oscillations.

The work was carried out *in vitro* olivary neurons utilizing the coronal brainstem slice technique. A gated sinusoidal current source was used to elicit subthreshold sinusoidal oscillations of the membrane potential with a peak amplitude of 5-10mV and frequencies of 3-9 Hz. Bipolar metal electrodes were placed at the slice midline and used for stimulating presynaptic axons. The responses to such stimuli were characterized as short latency (1msec), fast rise time (2 msec) synaptic potentials followed by a slower wave (100 msec rise time). The maximum amplitude was about 10mV. At a given stimulus intensity the responses were reliably reproducible. The synaptic potentials were evoked at different phase relations during the sinusoidal oscillations.

A non-linear summation of the sine wave and the synaptic potential was found to occur in olivary neurons; when the synaptic potential was elicited at the trough of the sine wave or during the rising phase, a superlinear summation occurred. Furthermore, the maximum amplitude of the response occurred at the peak of the sine wave regardless of the exact time of stimulation. On the other hand, when the synaptic potentials were evoked during the falling phase of the wave, a less than linear summation occurred.

These results demonstrate the prominent role of the subthreshold activity in determination of the precise timing of the output signals, thereby synchronizing the electrical activity in the olivary nucleus.

368.6

INACTIVATION OF THE DEEP CEREBELLAR NUCLEI AFFECTS VISUOMOTOR ADAPTATION IN A VISUALLY-GUIDED TRACKING TASK.

RC MIALL*, GK KERR, JF STEIN* & J PHILLIPS. University Lab. of Physiology, Parks Road, Oxford OX1 3PT, U.K.

The cerebellum receives a large amount of visual input and is involved in motor coordination. It is not yet clear to what extent it contributes to transformation between visual and motor coordinate frames, or to recalibrating these signals for different tasks. We therefore tested a monkey's ability to perform a visually guided tracking task and to adapt to changes in the task's visual or motor aspects during reversible inactivation of the dentate or interposed nuclei.

The monkey used a joystick to follow a target displayed on a computer monitor. The motor aspects of the task were altered by increasing joystick gain, so that the arm excursion was reduced while visual inputs remained unchanged (GAIN). Alternatively, visual aspects were altered by increasing the excursion of the visual display of both target and cursor while the required arm movement remained unchanged (SCALE). Hence in both tasks the vision-to-motor ratio increased to 150% of normal; in the GAIN task the required movement changed whereas in the SCALE task it did not.

Infusion of lignocaine (7.5%, 4µl/min, <12 mins) into dentate nucleus impaired the monkey's adaptation to the GAIN change, while adaptation to the SCALE change was unaffected. Infusion into the anterior interposed nucleus affected both tasks, but the SCALE change was more severely affected. These results suggest that the process of transforming visual signals into motor responses is assisted by the cerebellum, and that visual and motor aspects of this process may be separate.

368.8

A CHOLINERGIC PATHWAY TO THE DORSAL CAP OF THE INFERIOR OLIVE OF THE RAT. N.H. Barmack, A. Burleigh*, P. Errico* and M. Fagerson*. RS Dow Neurological Sciences Institute, Good Samaritan Hospital & Medical Center, Portland, OR 97209.

The inferior olive is divided into several subnuclei that receive specific sensory information. For example, the caudal dorsal cap of the medial accessory subdivision of the inferior olive receives horizontal optokinetic information from the nucleus of the optic tract (NOT). The immediately subjacent β nucleus receives vertical vestibular information mediated by a GABAergic pathway from the descending and medial vestibular nuclei (DVN, MVN). None of the transmitters to the dorsal cap have been identified.

Using choline acetyltransferase (ChAT) immunohistochemistry, we have identified a cholinergic pathway that terminates in the dorsal cap. Following a microinjection of HRP into the dorsal cap, we observed HRP positive, but no ChAT positive cells in the NOT. However, both ChAT and HRP-labeled neurons were observed in the MVN and DVN as well as the nucleus prepositus hypoglossi (NPH). We made lesions in the vestibular nuclei by ibotenic acid injection (100-400 nl) to destroy unilaterally the presumed cells of origin of this pathway. Lesions in the caudal-medial aspect of the MVN and NPH caused an ipsilateral loss of ChAT staining in the dorsal cap. Lesions placed more laterally within the MVN or DVN failed to cause this ipsilateral loss of ChAT staining. We also injected iontophoretically the orthograde tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L) into the vestibular complex. PHA-L injections into the NPH and MVN, but not the DVN labeled terminals within the dorsal cap. Injections in the MVN and DVN labeled the β nucleus.

In sum, the dorsal cap receives a cholinergic pathway originating from the NPH-MVN. Physiological studies will reveal how this cholinergic pathway interacts with optokinetic inputs mediated by a different transmitter to these same dorsal cap neurons.

ALTERATION OF COMPLEX SPIKE SYNCHRONICITY BY MICROINJECTION OF TEA AND 5-HT INTO THE INFERIOR OLIVE STUDIED WITH MULTIPLE ELECTRODE RECORDINGS. I. Sugihara, E. J. Lang, and R. Llinás. Dept. of Physiology & Biophysics, New York University Medical Center, 550 First Avenue, New York, N.Y. 10016.

Shunting of dendro-dendritic electrotonic coupling in the olivary glomeruli by the GABAergic cerebellar nucleo-olivary projection has been proposed to underlie the spatial and temporal modification of synchronization of inferior olive (IO) neurons. In previous studies, blockade of this GABAergic system either by microinjection of picrotoxin into IO or cerebellar nuclear lesion resulted in a significant increase of the synchrony in complex spike (CS) activity throughout a given cerebellar lobule. To further investigate whether the spatial pattern of synchrony is modulated only by the GABAergic afferents to the olivary glomeruli, the excitability of IO neuron was altered by injection of K channel blockers to the IO. The excitability change was determined by multiple electrode recordings of the spontaneous CS activity from crus 2a Purkinje cells of adult anesthetized rats. Microinjection of TEA (20 mM, 1 µl) increased the average firing frequency of CS 1.5 - 4 times, but the rostro-caudal banding pattern of Purkinje cell CS activity stayed unchanged. This implies that neither the excitability nor the input resistance of the neuron specifically affect the spatial pattern of synchrony. Microinjection of 5-HT (1 mM, 1-2µl), however, produced moderate increases (two fold) in the CS synchrony throughout the lobule without changing the average CS firing frequency. Since 5-HT terminals are known to distribute mainly to distal dendrites (King et al., 1984), which give rise to most of the spines forming the olivary glomeruli (Ruigrok et al., 1990), and since 5-HT decreases K conductance in IO neurons (Llinás and Yarom, 1986), the effect of 5-HT may be considered to be an enhancer of electrotonic coupling through the olivary glomeruli.

MULTIELECTRODE RECORDINGS OF COMPLEX SPIKE ACTIVITY AND THEIR RELATIONSHIP TO SPONTANEOUS AND CORTICALLY EVOKED VIBRISAL MOVEMENTS IN THE RAT. E. J. Lang, I. Sugihara, J. P. Welsh and R. Llinás. Dept of Physiology & Biophysics, New York University Medical Center, 550 First Avenue, New York, N.Y. 10016.

The function of the inferior olive (IO) is hypothesized to be that of a timing element important in the coordination of movements. Consistent with this idea, complex spikes (CS) have been found to occur ~10 msec prior to onset of lip and tongue movements (Fukuda et al: *Soc Neurosci Abst*, 1987). The present experiments examined the relationship between vibrissal movements and the CS of Crus IIa Purkinje cells (PC). The onset of vibrissal movements was detected with a photosensor while simultaneous multielectrode recordings of CS were made. CS activity was found to increase ~10 msec prior to the onset of vibrissal movements and remained high until ~15 msec after onset.

The synchronous discharge of CS prior to movement onset may act to facilitate on going activity in other CNS areas, leading to the proper execution of a movement. To investigate this hypothesis, electrical stimulation of the vibrissal region of the motor cortex was used to evoke movements of the vibrissa. The amplitudes of the evoked movements were measured before and after microinjection of drugs into the IO. Microinjections (1µL of 1 mg/ml) of harmaline or picrotoxin into the IO resulted in a 4.5 and 6.6-fold increase, respectively, in the amplitudes of the evoked movements. Subsequent injection of 4% lidocaine reduced the amplitude approximately to control values. In cerebellectomized rats, microinjections of harmaline or picrotoxin had no effect on movement amplitude. These experiments suggest that the synchronicity of CS may combine with activity from motor cortex to help determine the amplitude of a movement. Supported by NIH grant NS13742.

FUNCTIONAL GEOMETRY OF PURKINJE CELL POPULATION RESPONSES AS REVEALED BY NEUROCOMPUTER ANALYSIS OF MULTI-UNIT RECORDINGS. Pellionisz, A.J. and Bloedel, J.R., NASA Ames Research Center, VRF 242-3, CA 94035 and Barrow Neurological Institute, 350 West Thomas Rd, Phoenix, AZ 85013

Approximately a decade ago a geometrically framed hypothesis was formulated portraying sensorimotor function as a process requiring generalized coordinate transformations that utilize non-Cartesian vectors expressed in frames of reference that are intrinsic to biological systems. The goal of this study was to experimentally determine the geometric, non-Euclidean properties characterizing the population responses of neurons in specific CNS nuclei and to relate those properties to the geometrical theory. For this purpose responses of up to 10 simultaneously recorded Purkinje cells were investigated during perturbed and unperturbed locomotion in acutely decerebrated cats.

The population responses were analyzed based on the method for calculating the non-Cartesian axes from the cross-correlogram of the neural activity of n neurons, a procedure that also yields the matrix characterizing the covariant metric tensor (*AJP*, '88 in *Cotterill, R.M. "Comp. Sim. in Brain Sci."*, Cambridge UP). Using our transputer-based neurocomputer, the Moore-Penrose generalized inverse was used to derive the contravariant metric tensor characterizing the geometry of the population response. Responses were recorded to intermittent perturbations of the forelimb as well as during the acquisition and performance of the movement conditioned to avoid an obstacle.

The results indicate that the geometry describing the population responses is expressed in non-Cartesian coordinates and that the characteristics of this geometry are comparable to characteristics of the locomotor movement. Furthermore the data reveal that the geometry of the responses is modified when the characteristics of the movement are changed either by perturbing the swing phase of the ipsilateral forelimb or by changing the treadmill speed. The initial findings suggest that the derived geometry of the population responses may be the basis for reconstructing physical invariants such as movement direction and distance. If so, this theoretical-experimental method is a candidate for deciphering the neural code internally representing invariants of the external world. Supported by NASA DDF-T4967 (*AJP*) and NS21958 (*JRB*)

MULTIELECTRODE RECORDING OF PURKINJE CELL COMPLEX SPIKES DURING CONDITIONED TONGUE PROTRUSION IN THE AWAKE RAT. J.P. Welsh, I. Sugihara, E.J. Lang, and R. Llinás. New York Univ. Med. Ctr., New York, NY 10016.

Rats were trained to protrude their tongue 7 mm in response to a 750-ms, 2-kHz tone stimulus. Training was accomplished via a 2-stage procedure consisting of 6 d of autoshaping followed by 70 d of operant conditioning with sucrose solution as the reinforcer. Increasing lengths of tongue protrusion were shaped by successive approximation during the operant phase. Tongue and mouth movements were simultaneously monitored by infrared photodetectors. Mouth opening and tongue protrusion were found to occur in a highly coordinated and stereotypic fashion, with both behaviors demonstrating a robust 7-8 Hz rhythm. Complex spikes (CSs) within cerebellar folium Crus IIa were recorded from trained rats chronically prepared for the simultaneous recording of up to 40 Purkinje cells. In the majority of Purkinje cells, the probability of CSs increased approximately 200 ms after tones that elicited tongue protrusion but not after tones that did not elicit tongue protrusion. The maximal probability of CSs occurred 75 ms before maximal tongue protrusion - approximately the time of mouth opening. The results support the hypothesis (Llinás & Sasaki, *Eur. J. Neurosci.*, 1990) that the olivo-cerebellar system operates in real-time to ensure the proper coordination of movement. (Supp. NIH NS13742 and NS08844)

EPILEPSY: HUMAN STUDIES AND ANIMAL MODELS I

369.1

GLIA CULTURED FROM HYPEREXCITABLE HUMAN EPILEPTOGENIC FOCI EXHIBIT MARKED INCREASES IN Ca^{2+} OSCILLATIONS AND INTERCELLULAR Ca^{2+} WAVES. A. H. Cornell-Bell, M. Gunel*, P.G. Thomas*, M.L. Brines*, D.D. Spencer, N. de Lanerolle*, Cell Biology, Internal Medicine, Neurosurgery, Yale Univ Sch. of Med., New Haven, CT 06510.

Tissues surgically removed from epileptogenic foci of patients with intractable epilepsy were grown in 10% FBS-DMEM-F12. Cells were obtained from: tumor (low grade glioma) and adjacent hyperexcitable and normal cortex (judged by electrical recordings). Cultures were stained for neurofilaments, GFAP, tetanus toxin, A2B5, and neuron-specific enolase. After 4-6 weeks astrocyte-enriched coverslips were loaded with the Ca^{2+} indicator Fluo-3AM and time-lapse images were collected using a Bio-Rad MRC 600 confocal scanning laser microscope. Normal cortical astrocytes exhibit dynamic, spontaneous Ca^{2+} oscillations which are more frequent than those previously studied from rat hippocampal astrocytes (Cornell-Bell and Finkbeiner, 1991). Extensive waves and oscillations (Period = 2.8 ± 0.1 sec) develop following superfusion of 100µM glutamate at an elevated frequency over baseline (period = 5.1 sec \pm 0.3 sec). Astrocytes from hyperexcitable focus exhibit spontaneous Ca^{2+} oscillations and waves with an accelerated frequency (period = $0.94 \pm .09$ sec). Following glutamate this frequency is accelerated slightly (period = 0.85 ± 0.1 sec). In dramatic contrast cells derived from tumor show few spontaneous oscillations (period = 4.4 ± 0.08 sec) and following glutamate respond with an initial spike and an attenuated Ca^{2+} response (period = 6.0 ± 0.08 sec). Inherent differences in glutamate-initiated responses persist in these cells after extended culturing suggesting the astrocyte may play an active role in development or maintenance of the seizure focus.

369.2

PRIMARY CULTURES OBTAINED FROM ADULT HUMAN EPILEPTIC BRAIN CONTAIN DIVERSE NEURONS AND GLIA. N. de Lanerolle, M. Gunel*, D. D. Spencer, Paul Q. Trombley, and M. L. Brines, Yale University School of Medicine, New Haven, CT 06510

The controlled environment during brain resection for treatment of intractable seizures offers a unique potential to examine fresh tissue obtained from a variety of normal and hyperexcitable brain regions. We wondered whether viable primary cultures could be established from this adult tissue, and whether the surviving cells exhibit any unique characteristics. To study this possibility, tissue was obtained from the operating field on ice, dissociated by mild enzymatic/mechanical disruption, plated onto coated coverslips, and maintained in either serum-enriched or defined media. At several days in vitro the cultures exhibited a varied population of cells, including many of neuronal morphology. Immunohistochemical staining for specific cell markers confirmed that a mixed population of neurons and glia were present, and patch-clamp recording documented intact neuronal activity. This neuronal pool was further characterized by immunohistochemical staining for NPY, somatostatin, and GABA; NPY was found to be widespread. These primary cultures appear to express functional receptors and exhibited striking responsiveness to activation of the protein kinase A second messenger system by dcAMP. We conclude that primary cultures are readily established from surgical specimens with a surprisingly complex and functional population of cells, including neurons. The cells are viable and responsive for at least several weeks in vitro and are thus potentially important for study of normal and pathologic physiology.

369.3

WHOLE-CELL RECORDINGS FROM HUMAN DENTATE GRANULE CELLS IN SLICES PREPARED FROM EPILEPTIC HIPPOCAMPAL SPECIMENS. **M. Isokawa and M.F. Levesque**. Brain Research Institute and Dept. of Neurology and Neurosurgery, CHS, UCLA, Los Angeles, CA 90024-1761.

Passive membrane properties and synaptic responses of human dentate granule cells were studied using patch electrodes and whole-cell recording from slices (500 μm) of surgically-resected epileptic hippocampus. In current clamp mode, the input resistance was 165-199 M Ω , and time-dependent rectification was observed with high levels of hyperpolarizing current pulses. Action potentials with amplitudes of 89-104 mV were accompanied by depolarizing afterpotentials. Excitatory and inhibitory PSPs (5.4-16.0 mV in amp., 99.5-402 msec in dur.) were generated by perforant path stimulation. Spontaneously-occurring prepotentials were also present. In voltage clamp mode, perforant path stimulation produced inward currents with amplitudes of 42-54 pA and durations of 70-135 msec at a holding potential (V_m) of -65 mV. The currents revealed dual peaks at more negative V_m . When bicuculline (10 μM) was added to the external solution, the inward currents were increased to 67-163 pA with durations of 128-178 msec ($V_m = -45$ to -30 mV). This suggests the presence of GABA_A receptor-mediated IPSCs possibly masking a large EPSC component especially at low levels of negative V_m . Further studies are in progress to provide a detailed description of excitatory and inhibitory synaptic currents in human epileptic hippocampal neurons. Supported by NIH Grant NS02808.

369.5

FLUNARIZINE BLOCKS KCL-INDUCED Ca^{2+} INFLUX INTO CEREBELLAR GRANULE CELLS THROUGH AN EFFECT ON GLUTAMATE-GATED Ca^{2+} CHANNELS. **G. A. Skeen, H. H. Wolf, E. A. Swinyard, and H. S. White**. Anticonvulsant Drug Development Program, Dept. of Pharmacol. & Toxicol., Univ. of Utah, S.L.C., UT 84108

The Ca^{2+} channel blocker flunarizine is a diphenylpiperazine with proven efficacy as an add-on anticonvulsant in a number of clinical trials involving therapy-resistant epileptic patients. The anticonvulsant mechanism of action of flunarizine is thought to be related to its ability to block the T-type voltage-sensitive Ca^{2+} channel (VSCC; Wang et al., J.P.E.T., 254:1006-1011, 1990). The present investigation was initiated in order to assess the effect of flunarizine on KCl-induced Ca^{2+} influx into primary mouse cerebellar granule cells (GC's). Granule cells grown on 25 mm aclar coverslips and maintained in culture for 7-9 days were loaded with indo-1 (5 μM) for 20 min. Depolarization of GC's with elevated KCl (55 mM) resulted in a marked increase in the free $[\text{Ca}^{2+}]_i$. This effect of KCl was dependent on the presence of extracellular Ca^{2+} and was blocked by flunarizine in a concentration-dependent and irreversible manner. In contrast, this effect of KCl was not affected by pretreatment with the L-, N-, or T-type channel blockers nimodipine, ω -conotoxin, or ethosuximide, respectively. The lack of effect with these classical VSCC blockers is consistent with the conclusion of Jalonen et al. (Br. Res., 535:33-38, 1990) that GC's do not possess VSCC's. Subsequent studies demonstrated that glutamate (1 mM) induces a $[\text{Ca}^{2+}]_i$ transient comparable to that of KCl and that flunarizine blocks glutamate-induced $[\text{Ca}^{2+}]_i$ transients at concentrations similar to those which block KCl-induced $[\text{Ca}^{2+}]_i$ transients. Further studies demonstrated that flunarizine blocks $[\text{Ca}^{2+}]_i$ transients induced by the glutamate agonists NMDA (100 μM), quisqualic acid (100 μM) and kainic acid (100 μM). These results suggest that the KCl-induced $[\text{Ca}^{2+}]_i$ is mediated by glutamate which is released from GC's upon depolarization with elevated K^+ , and that flunarizine blocks glutamate's effects. Supported by NIH Contract NOI-NS9-2328 (EAS & HHW) and NIH Grant 2R01-NS22200 (HSW) from the NINDS.

369.7

INCREASED GLUCOSE METABOLISM ASSOCIATED WITH "INTERICTAL" EEG SPIKING IN THE BICUCULLINE METHIODIDE MODEL IN RAT. **A. Handforth and D.M. Treiman***. DVAMC West Los Angeles and Dept. of Neurology, UCLA, Los Angeles, CA 90024.

There is considerable debate regarding what are "interictal" vs. "ictal" epileptiform discharges on EEG and much uncertainty about neural mechanisms of the interictal-ictal transition. Increased local cerebral glucose utilization has been employed as an indicator of "ictal" activity. We studied the effect of bicuculline methiodide (BM) on EEG and cerebral glucose metabolism using ^{14}C -2-deoxyglucose (2DG) in 29 adult male Sprague-Dawley rats. 4 epidural screw electrodes were surgically implanted over cerebral cortex in each animal. 2-4 weeks later 135-270 mg/kg BM was given i.p., followed by 25 μCi 2DG i.v. EEG was recorded continuously. 10 min after 2DG the brain was removed and sections applied to x-ray film. 5 BM animals had normal EEGs; 2DG revealed mild cortical injury under the epidural electrodes but no hypermetabolism. Of 12 BM animals demonstrating focal "interictal spiking" on EEG but no convulsive activity, 7 had focal hypermetabolism in the area of the EEG spikes. Of 12 animals with convulsions and generalized forebrain hypermetabolism, 9 had more intense hypermetabolism under one or more epidural electrodes. These data show that increased glucose utilization can occur with interictal spiking. This model also provides a useful paradigm to study seizure initiation and spread.

369.4

CONTROL OF EPILEPTIFORM BURST RATE BY THE ACTION OF THE ANTICONVULSANT 4-HYDROXY-4-PHENYLHEXAMIDE ON THE AFTERHYPERPOLARIZATION OF THE CA3 HIPPOCAMPAL CELLS. **M.F. Pacheco, A.M. Flores* and Z.J. Aguirre***. CUIB Universidad de Colima, Apdo. Post. 199, Colima, Col. 28000 Mexico.

The goal of the present study was to explore the mechanisms of action of the anticonvulsant 4-hydroxy-4-phenylhexamide (HPH), which has been recently evaluated pharmacologically (Meza-Toledo et al., *Arzneim-Forsch/Drug Res.* 40:1289-1291, 1990). Epileptiform activity was induced on guinea-pig hippocampal slices by a 15 min perfusion of 10 μM bicuculline (final concentration on normal Krebs's saline solution), and extracellular recordings were made with an AC-coupled electrometer with glass microelectrodes (2 M NaCl, 5-10 Mohms) positioned on the pyramidal stratum of the CA3 region. The effects of HPH (10 - 500 μM on normal solution, for 6 min) on burst frequency, coastline burst index, and the epileptiform burst afterhyperpolarization (AHP) were analyzed by computer programs from digitized records. HPH showed a long lasting (1-2 hr) inhibitory action on the burst frequency which was dose-dependent up to 200 μM of HPH, at which concentration the epileptiform activity was totally blocked. Such effects were correlated with an increase in the amplitude of the AHP, without a change in the number and amplitude of the spikes per burst. These results suggest that HPH might exert an anticonvulsant action by exerting a control on the epileptiform burst rate through an increase on the AHP.

7-CHLOROKYNURENIC ACID ANTAGONIZES THE ANTICONVULSANT ACTIVITY OF D-CYCLOSERINE IN MAXIMAL ELECTROSHOCK SEIZURES. **S.L. Peterson**. Dept. of Medical Pharmacology and Toxicology, Texas A&M University, College Station, Texas 77843.

D-Cycloserine is a partial agonist of strychnine-insensitive glycine receptors that freely passes the blood-brain barrier. The purpose of this study was to characterize the anticonvulsant activity of D-cycloserine in maximal electroshock seizures (MES).

MES was induced in male Wistar rats by passing a 60 Hz, 150 mA and 0.2 second duration current through saline-soaked corneal electrodes. Seizure severity was quantified by tonic hindlimb extension (THE).

The calculated ED_{50} for D-cycloserine (i.p., 1 hour) was 154 mg/kg (Litchfield and Wilcoxon analysis). None of the eleven rats treated with 250 mg/kg L-cycloserine was protected from THE. Intracerebroventricular administration of 100 μM 7-chlorokynurenic acid (specific strychnine-insensitive glycine receptor antagonist) reversed the anticonvulsant activity induced by 300 mg/kg D-cycloserine ($P < 0.05$, maximum likelihood logistic regression analysis).

The stereospecific activity and antagonism by 7-chlorokynurenic acid are evidence that D-cycloserine may act at the strychnine-insensitive glycine receptor to inhibit MES. (Supported by NIH grant 24566).

369.8

MAGNETIC RESONANCE IMAGING AND SPECTROSCOPY OF INTRACTABLE EPILEPSY IN CHILDHOOD

A.C. Onnelly, J.H. Cross, DG Gadian, GD Jackson, FJ Kirkham, and F Vargha-Khadem

Institute of Child Health and Hospital for Sick Children, Gt. Ormond St., London

Abnormalities of the hippocampus and temporal lobe are common in intractable focal epilepsy. Magnetic resonance imaging (MRI) has allowed reliable assessment of the mesial structures, particularly the hippocampus. If 1H magnetic resonance spectroscopy can monitor neuronal loss or damage through changes in the N-acetylaspartate (NAA) signal, then a combined MRI / MRS examination could contribute significantly to the localisation of epileptic foci and to our understanding of the relationship between neuronal damage and abnormal function.

MRI and MRS were carried out on 10 fully evaluated children with intractable complex partial seizures. In 8 cases, imaging showed hippocampal or temporal abnormalities, and in 7 of these MRS showed reduced NAA / Creatine ratios. There was definite evidence of bilateral abnormalities in 3 cases. MRS showed good correlation with neuropsychological profiles with regard to side of abnormality and unilateral vs bilateral involvement. Our results suggest that combined MRI and MRS could help significantly in patient management, in particular when surgical intervention is being considered.

369.9

RELATION BETWEEN GLUCOSE METABOLISM AND BLOOD FLOW IN HUMAN EPILEPTIC FOCI. W.H. Theodore, W.D. Gaillard*, P. Herscovitch Clinical Epilepsy Section, NINDS, and Nuclear Medicine Department, NIH, Bethesda MD 20892

We used positron emission tomography (PET) with 18-F-2-deoxyglucose and 15-O water to study glucose metabolism (CMRglc) and blood flow (CBF) in 10 patients with partial seizures. PET was performed on the Scanditronix PC2048-15B (resolution 6.5 mm; fifteen simultaneous slices). Patients were positioned with a thermoplastic headholder and laser guide, CBF (ml/100gm/min.) measured immediately before CMRglc (mg/100gm/min), without moving the patient, and EEG recorded continuously. CMRglc and CBF were measured in 192 6 mm regions on a standard template grouped into 26 anatomic areas on 7 slices.

Mean inferior lateral temporal (ILT) CMRglc was 6.96 ± 1.56 ipsilateral, and 7.50 ± 1.99 contralateral to the epileptic focus ($p = .11$), and CBF 43.56 ± 10.53 versus 43.14 ± 8.98 . Inferior mesial temporal (IMT) CMRglc was 5.58 ± 1.31 versus 6.06 ± 1.3 ($p = .049$). IMT CBF was 37.4 ± 9.24 versus 42.08 ± 6.99 ($p = .0036$). The ratio of CMRglc to CBF was lower ipsilateral than contralateral to the epileptic focus in ILT ($.146 \pm .023$ vs. $.158 \pm .027$; $p = .0054$) but not IMT. In thalamus, there was a trend toward lower ipsilateral CMRglc / CBF ($.138 \pm .02$ vs. $.147 \pm .026$; $p = .052$).

We found greater depression of CMRglc and CBF in mesial than lateral temporal cortex ipsilateral to epileptic foci, in contrast to previous reports. The difference in results may be explained by our higher spatial resolution scanner. Our data suggests that CMRglc may be relatively more depressed than CBF ipsilateral to epileptic foci in temporal cortex and thalamus; substrate supply may be normal, while use is impaired.

369.11

ALTERED KYNURENINE METABOLISM IN A MODEL OF CHRONIC EPILEPSY: IMMUNOHISTOCHEMICAL ANALYSIS. F. Du, E.W. Lothman, E.H. Bertram, J.M. Williamson, and R. Swarcz. Md. Psych. Res. Ctr., Baltimore, MD 21228 and Dept. Neurology, Univ. Virginia, Charlottesville, VA 22908.

The cellular localization of three enzymes critical for the metabolism of kynurenic and quinolinic acid, kynurenine aminotransferase (KAT), 3-hydroxyanthranilic acid oxygenase (3HAO), and quinolinic acid phosphoribosyltransferase (QPRT), was studied in a rat model of epilepsy with acute status epilepticus and chronic seizures (Epilepsia, 30:107, 1989). One month after status, immunoreactivities (-i) of all three enzymes were found to be reorganized in brain areas activated during status and later displaying neuronal damage. In the hippocampus, a large number of proliferated, mostly hypertrophic, glial cells exhibiting KAT-, 3HAO-, and QPRT-i were detected in all layers of CA1 where pyramidal neurons degenerated. Substantial increases in labelling were also consistently observed in several thalamic nuclei. Altered patterns of KAT-i, 3HAO-i, and QPRT-i were noticed on both sides of all brains examined, though they were less obvious on the stimulated side. In addition, extremely dense immunoreactivities occurred around severe lesions in the piriform cortex, usually contralateral to the stimulated side. These changes might reflect altered metabolism of kynurenic acid and quinolinic acid, and indicate their possible role in epileptogenesis.

HUMAN PERINATAL BRAIN DAMAGE, CORTICAL REORGANIZATION, AND DEVELOPMENTAL EPILEPSY: A GOLGI STUDY. M. Marin-Padilla. Dept. Pathology, Dartmouth Medical School, Hanover, NH 03756.

Hypoxic, ischemic, and/or hemorrhagic damage to the developing cerebral cortex could occur in prematurely born infants after prolonged neonatal asphyxia due to lungs immaturity. While severe damage often resulted in demise, less severe injuries are compatible with life and could eventually result in a variety of neurological disorders (e.g. cerebral palsy, epilepsy, mental retardation, dyslexia, blindness, minimal cortical dysfunction, and poor school performance). Neither the neuronal alterations caused by this type of injury or the degree of cortical reorganization around damaged areas have been adequately documented. For several years, I have been studying the cortex of premature infants that survive (days, weeks, month, or even years) this type of injury using the rapid Golgi method. Data is presented to illustrate that still developing neurons around damaged areas undergo a progressive reorganization in response to the anomalous local circuitry caused by the injury. Surviving neurons around the lesion, free of normal developmental constraints, respond to local circuitry demands acquiring new and often anomalous morphologic features. It is proposed that these acquired neuronal anomalies are the actual underlying cause for the developmental neurological disorders observed in these children rather than the original cortical lesion itself.

REVERSAL OF EPILEPTIC STATE BY PATTERNED ELECTRICAL STIMULATION SUGGESTED BY TRION MODEL CALCULATIONS. Xiaodan Leng*, John V. McGlann* and Gordon L. Shaw. Center for Neurobiology of Learning and Memory, Univ. of California, Irvine, CA 92717.

The trion model (Shaw et al. (1985) PNAS 82, 2364) is based on the Mountcastle columnar organizational principle of cortex. A trion represents an idealized minicolumn with three levels of firing activity and is highly structured in time and in spatial connections. A network of trions has a large repertoire of quasi-stable, periodic spatial-temporal firing patterns, MPs, which can be excited and each MP can be readily enhanced by a Hebb learning rule. A particular MP present in most repertoires has all trions firing together in synchrony, which we identify as the "Epileptic" MP, EMP. In trion model simulations, the EMP can be enhanced via the Hebb rule after electrical stimulation so that an epileptic focus with after discharge (about 3-6 Hz) is formed and spontaneous firing of the EMP occurs (as in kindling). Following this, by using two or more closely-spaced stimulating electrodes out of phase, other MPs are enhanced eliminating the dominance of the EMP.

CELL LINEAGE III

370.1

IN SITU ANALYSIS OF CRANIAL NEURAL CREST CELLS IN MICE. George N. Serbedzija, Scott E. Fraser and Marianne Bronner-Fraser. Developmental Biology Center, UC Irvine, Irvine, CA 92627

Analysis of mouse cranial neural crest cell migration and differentiation has been hampered both by the lack of a reliable cell marker and by the difficulty of manipulating the embryo *in vivo* at the stage of neural crest cell migration. In order to study cranial neural crest cell migration in the mouse, premigratory neural crest cells were labelled by injecting Dil into the amniotic cavity. Embryos were labelled on embryonic day 8 and maintained *ex vivo* in the mother for an additional 1-5 days. Hindbrain-level neural crest cells migrated ventrolaterally along three subectodermal pathways extending from the dorsal portion of the neural tube to the distal portion of each of the three branchial arches. The midbrain-level neural crest cells migrated ventrolaterally through the mesenchyme overlying the mesencephalon. Forebrain-level neural crest cells migrated ventrally through the mesenchyme between the eye and the diencephalon.

By labelling embryos at different stages of development, the duration of neural crest cell emigration from the neural folds was observed. Rostral hindbrain-level neural crest cells ceased emigrating by the 11 somite stage. neural crest cell emigration from the midbrain and caudal hindbrain regions ended by the 14 somite stage. Neural crest cells in the forebrain continued to emigrate until the 16 somite stage. In each region, cranial neural crest cells populated their derivatives in a ventral-to-dorsal order.

This overall pattern resembles that previously observed in chick embryos, however, some differences exist in the trajectories of the individual pathways.

370.2

THE DIFFERENTIATION OF NEURONAL STEM CELLS INTO LIMBIC NEURONS, *IN VITRO*. R. Ferri and P. Levitt. Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Previous transplantation studies have identified a critical period for the commitment of stem cells to express a specific limbic cortical phenotype (Barbe and Levitt, 1991, J. Neuroscience 11: 519-533). At embryonic day 12 (E12), multipotential precursor cells are uncommitted and can respond to environmental cues to produce neurons of different phenotypes but by E14 are unable to change their fate. We have developed an *in vitro* assay system to study the factors that regulate stem cell differentiation. Neuroblasts from presumptive perirhinal (limbic) and sensorimotor (non-limbic) cortices are dissected from E12 rats, dissociated, and plated in either a defined medium or glial conditioned medium. Neuronal differentiation is determined immunocytochemically by the expression of MAP2, and the phenotypic specificity is defined by the ability of the neuron to express the Limbic System Associated Membrane Protein (LAMP), a neuronal cell surface glycoprotein specific for limbic structures. Preliminary data identifying the percentage of MAP2-positive cells that are also LAMP-positive shows that LAMP expression first becomes evident after 2 days in culture, corresponding to the appropriate time when LAMP is first localized *in vivo* in the cerebral wall. Cultured limbic and nonlimbic neuroblasts will differentiate into neurons phenotypically identical to their respective *in vivo* counterparts, suggesting that the stem cells maintain an ability to differentiate into an appropriate phenotype in the absence of their complex *in vivo* milieu. Manipulations of this system will allow us to identify potential epigenetic factors regulating stem cell differentiation and leading to the formation of a distinct functional system. (Supported by NIMH Grant MH45507).

370.3

ORIGINS AND FATE OF RADIAL GLIA IN CHICK OPTIC TECTUM. G.E. Gray and J.R. Sanes. Department of Anatomy and Neurobiology, Washington University Medical School, St. Louis, MO 63110.

To continue our analysis of cell lineage in chick optic tectum (PNAS 85:7356, 1988; PNAS 87:458, 1990; Neuron 6:211, 1991), we have used retrovirus-mediated gene transfer to study the origin and fate of radial glia (RG). Retroviral infection labels progenitors with a heritable marker (*lacZ*) that is later detected histochemically in the infected cells' progeny. In these studies, retrovirus was injected on embryonic days (E) 3-8, and RG were identified morphologically and immunohistochemically (see accompanying abstract by Herman et al.) in clones analyzed on E10-20. Our main results are: 1) Clonal relatives of RG include neurons and astrocytes, but generally not other RG. Thus, these three cell types arise from a common precursor in chick optic tectum. In contrast, RG and neurons are thought to have separate progenitors in mammalian cortex. 2) Infection at any time between E3 and E8 labels RG. Thus, RG continue to be generated after the peak of neurogenesis (~E5), and after radial migration of neuroblasts has commenced (~E6). 3) Clones marked as late as E8 can contain both neurons and RG, suggesting that these lineages do not diverge. 4) During radial migration, neuroblasts are frequently in apparent contact with processes of clonally related RG. Thus, RG may guide the migration of their clonal relatives. 5) The number of labelled RG declines between E15 and hatching (E20), during which time many labelled astrocytes and "intermediate forms" appear. Thus, as in mammals, some tectal RG may transform into astrocytes. These results provide the first clonal analysis of RG lineage in any species, and suggest novel relationships between RG and neurons. (Supported by NIH.)

370.5

DEVELOPMENTALLY REGULATED AND DOMAIN-SPECIFIC ANTIGENS OF RADIAL GLIA IN CHICK OPTIC TECTUM. J.P. Herman, J.C. Victor* and J.R. Sanes. Department of Anatomy and Neurobiology, Washington University Medical School, St. Louis, MO 63110.

Radial glia (RG) are believed to guide migration of embryonic neurons to their laminar destinations. As part of a study of RG development and function (see accompanying abstracts by Gray & Sanes and Galileo et al.), we have generated and characterized monoclonal antibodies to developmentally-regulated and lamina-specific antigens of RG in chick optic tectum. They fall into three groups of two antibodies each: a) H5 and a previously generated antibody, R5 (Drager et al., J. Neurosci. 4:2025, 1984), stain the processes but not the cell bodies of RG in a uniform manner between embryonic day (E)5 and hatching (E20). *In vitro*, both reveal a dense, intracellular filamentous meshwork in tectal non-neuronal cells. On Western blots, both recognize a protein of ~51 kD. b) H28 and H29 stain RG somata and processes between E7 and E14, but not later. Moreover, H28 and H29 staining is markedly more intense in the ventricular and intermediate zones than in the laminae of the forming tectal plate. H28 and H29 recognize an intracellular epitope in cultured cells, and immunoblot a protein of ~35 kD. c) Finally, H2 and H27 recognize antigens concentrated in the most superficial processes and endfeet of RG in late (E14-E20) embryos. H27 also stains ganglion cells in E10-E14 tecta, and recognizes proteins of ~29 and ~170 kD on Western blots. Thus, antibodies H5 and R5 are good markers of RG at all stages, whereas the others define at least two antigens that are developmentally regulated and localized to discrete domains. Together, these antibodies can be used to study temporal and spatial specializations of RG that may be important to their function. (Supported by NIH, NATO, and CNRS.)

A NUCLEUS OF MOUSE HYPOTHALAMUS ORIGINATES FROM IDENTIFIED PRECURSORS IN THE NEURAL TUBE. G. Teitelman and T.A. Milner, SUNY Health Sci. Ctr., Brooklyn, NY and Cornell Univ. Med. Coll., New York, NY.

To investigate the cell lineage relationships of hypothalamic cells, we examined transgenic mice (RIP-Tag) that harbor a hybrid insulin gene comprised of the 5' flanking region of the rat insulin II gene linked to the sequences encoding an oncogene, the simian virus 40 (SV40) large T antigen (Tag). Ectopic expression of the transgene was seen in cells of the hypothalamus of embryos and adults. This study used immunocytochemical techniques to determine the phenotype of Tag⁺ cells of brain. In embryos, Tag⁺ cells first appeared at day 10 of development (E10) in the ventricular layer of the diencephalon. From E11 to E14 abundant expression of Tag was seen in both ventricular and mantle layers while at E16 only the mantle layer contained Tag⁺ cells. In adults, Tag⁺ cells were found in the arcuate nucleus of the hypothalamus. At E12 and E14, immature Tag⁺ cells contained the neuronal markers β -endorphin (BE) and tyrosine hydroxylase (TH) respectively. However, TH and BE neurons of adults did not express the oncogene. In adults, most or all the Tag⁺ cells contained the glial cell marker GFAP and had the ultrastructural morphology of astrocytes. This suggested that Tag⁺ precursors gave rise to both TH and BE neurons and astrocytes. However, while neurons contained Tag transiently during differentiation, expression of the oncogene in glial cells was permanent. We conclude that neurons and glial cells of the arcuate nucleus originate from a subset of precursor cells that become specified prior to migration. (Supported by HL18974).

RETROVIRUS-MEDIATED INTRODUCTION OF ANTISENSE INTEGRIN $\beta 1$ HALTS RADIAL MIGRATION IN CHICK OPTIC TECTUM *IN VIVO*. D.S. Galileo*, J. Majors* and J.R. Sanes. Departments of Anatomy and Neurobiology and of ¹Biochemistry, Washington University Medical School, St. Louis, MO 63110.

We have been using a recombinant retrovirus, LZ10, to study lineage and migration of cells in chick optic tectum (see accompanying abstract by Gray and Sanes). LZ10 inserts the *lacZ* gene into progenitors; its product is later detected histochemically in progeny of infected cells. Most cells in marked clones migrate along radial glia from the ventricular zone (VZ) to their laminar destinations. Here, we test the hypothesis that integrins, which are present in developing tectum and mediate cell movements elsewhere, are involved in radial migrations in tectum. We constructed a vector in which LZ10 was modified to contain an antisense sequence for the chicken $\beta 1$ integrin subunit. This virus (LZ15) or LZ10 was injected into embryonic day (E)3 tecta and the resulting clones were compared. At E6, when the tectum was still almost entirely a VZ, both LZ10- and LZ15-marked clones consisted of radially stacked cells extending across its width. By E7.5, a tectal plate (TP) had appeared and many LZ10-marked cells had entered it. In contrast, cells in LZ15-marked clones remained radially arrayed but accumulated in the VZ and failed to enter the TP. At E9, the TP had thickened considerably, and most cells in LZ10 clones (68%) lay within it. In contrast, only 22% of cells in LZ15 clones were found in the TP; most remained in the VZ. Furthermore, whereas LZ10- and LZ15-marked clones contained the same mean number of cells on E6 and E7.5, LZ15 clones contained ~50% less cells than LZ10 clones by E9. These results suggest that integrin-dependent interactions are not required for the initial stacking of cells in the VZ, but are required for migration along radial glia into the TP. In addition, cells that fail to migrate may die. (Supported by NIH.)

A MODEL FOR CEREBELLAR PURKINJE CELL LINEAGE SUPPORTS THE HYPOTHESIS THAT PURKINJE CELLS ARE DESCENDED FROM A SMALL NUMBER OF PROGENITOR CELLS. M.W. Vogel. MD Psychiatric Research Center, Baltimore, MD 21228.

To test the hypothesis that Purkinje cells (PCs) are descended from a small number of progenitor cells, a computer program was devised that simulates the numerical distribution of wild type PCs in *+Lc* \leftrightarrow wild type chimeras. The model assumes that the PC population is clonal and both the total number of clones and the number of PCs per clone can be varied. The predicted number of total PCs is compared with the total number of PCs in wild type mice. In the simulations, the mean number of PCs per clone was varied from 2 to 15,000 and the range of PC number variation was varied between 1% to 50% of the mean. Frequency histograms show that the predicted distribution of wild type PCs is multimodal, but the number of peaks and their steepness depends on the number of clones and the mean number and range of PCs per clone. The wild type PC distribution becomes more uniformly distributed as clone size decreases or the range of variability of PCs per clone increases.

In 3 different wild type mouse strains analyzed in *+Lc* chimeras, 8/10, 10/12, and 11/12 data points meet the criteria for a quantal model of PC lineage: i.e. they fall within 3 to 3.5% of an integral multiple of a quantal PC clone size (10,400, 9,200 or 7,900 PCs/clone, respectively). Monte Carlo simulations of this data show that the frequency of matching the experimental data is low for small clone sizes (e.g. for 1 to 4 PCs/clone, $p < .02$), but increases as the number of PCs per clone increases (e.g. for 10,000 \pm 1,000 PCs/clone, $p > .1$). However, the frequency of obtaining similar results decreases for all clone sizes as the range of PCs per clone increases (e.g. for 10,000 \pm 5,000 PCs/clone, $p < .02$). The results of the Monte Carlo simulations indicate that it is more likely that the wild type PCs in *+Lc* chimeras are descended from a small number of progenitor cells each of which generates similar numbers of PCs in their descendent clone.

ISOLATION OF ROD PRECURSORS FOR CELL CULTURE. J.K. Knight and P.A. Raymond. Neuroscience Program and Department of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109.

Rod precursor (RP) cells, located in the outer nuclear layer of the mature fish retina, normally give rise exclusively to rod photoreceptors. Previous experiments in our lab suggested that RPs can give rise to other cell types depending on their microenvironment. The goal of the present study is to develop an *in vitro* system for determining the effect of environment on the fate of RP cells.

Mitotic activity of RPs was enhanced by multiple punctures of the eye. After 15d, ³H-thymidine (T) or bromodeoxyuridine (BrdU) was injected intraocularly, and fish were sacrificed the next day. Retinas were isolated, cut into pieces ~ 2 mm², treated with papain and mechanically dissociated. Cells were layered onto Percoll density gradients (1.017-1.141 g/ml) and centrifuged to achieve separation of cell types. Enriched cell fractions were collected and either fixed in 4% paraformaldehyde or placed in hanging drop culture in M199 medium with 10% fetal calf serum and 1% linoleic acid at 27 C.

To determine which cell fraction contained the RPs, DNA was precipitated from ³H-T labelled retinal cells and counted in a scintillation counter. The cell fraction at 1.12 g/ml showed, on average, 8 fold higher cpm than any other fraction. To determine whether the dividing cells were RPs, we fixed cells from BrdU-injected retinas and immunostained them with anti-BrdU and NN (a monoclonal antibody which labels microglia and endothelial cells in goldfish retina); RPs are BrdU+/NN-. The 1.12 g/ml cell fractions contained both BrdU+/NN+ and BrdU+/NN- cells, indicating that some, but not all, of the dividing cells were rod precursors. Preliminary experiments demonstrated that these cells proliferated for up to 7 days in culture, as evidenced by incorporation of BrdU added to the culture medium for 16 h. Future experiments will attempt to further enrich the population of isolated RPs with the eventual goal of determining factors that regulate their differentiated fate. Supported by NIH T32EY07022 and R01EY04318.

CLONAL ORIGIN OF THE TADPOLE RETINA AND LINEAGE CHANGES AFTER ABLATION OF A MAJOR PROGENITOR. S. Huang and S. A. Moody, Dept. Anatomy & Cell Biology, Univ. Virginia, Charlottesville, VA 22908

The clonal origin of *Xenopus* tadpole retina from 32-cell embryos was quantitatively assessed by lineage tracing at st 42-44. It is derived from 4 dorsal (D) and 1 ventral (V) animal blastomeres: D111, 56.7%; D112, 18.5%; D121, 12.2%; D122, 12.0%; and V121, 0.6%. All dorsal blastomeres contributed to both retina, but the majority of their progeny were ipsilateral. The clones from each blastomere usually formed radial columns across all layers and always included more than one cell type. Descendants from each were distributed in a mosaic in all regions of the retina, however D111 and D112 contributed more to anterior retina, while the rest contributed more to posterior retina. Thus, blastomere origin restricts neither cell type nor the location of clones within the retina.

After ablation of both D111, which are the major progenitors, 60% of the tadpoles developed normal appearing eyes, but they contained a significantly smaller number of retinal cells (4968 vs. 9600) and a smaller retinal volume ($5.88 \times 10^6 \mu\text{m}^3$ vs. $7.59 \times 10^6 \mu\text{m}^3$). The surrounding blastomeres changed their retinal lineages to effect a partial compensation. Three responses were observed: 1) V111 and V122, which normally do not contribute to the retina, were induced to produce novel progeny, i.e., 16.2% and 0.2% of the retinal cells, respectively. 2) V121 and D121 drastically increased their contribution to the retina (to 55.2% and 26.2%, respectively). 3) In contrast, D112 and D122 decreased their retinal contribution (to 0.3% and 1.9%, respectively). These results demonstrate that retinal lineages are not determined during early cleavage stages. However, these lineages also are not uniformly plastic and regulatory, as demonstrated by the fact that different blastomeres have different responses to the ablation and that complete compensation is not accomplished. Supported by NS23158.

CELLULAR INTERACTIONS THAT REGULATE CELL FATE DURING GROWTH AND REGENERATION OF THE GOLDFISH RETINA. J.E. Braisted & P.A. Raymond, Dept. Anat. & Cell Biol., Univ. Mich., Ann Arbor, MI 48109

We recently demonstrated (Braisted & Raymond, 1991, *Invest Ophthalmol Vis Sci* Suppl 32:923) that dopaminergic interplexiform cells (DA IPCs) in the inner nuclear layer (INL) of the juvenile goldfish retina are permanently destroyed by intraocular injection of 6-hydroxydopamine (6OHDA), 0.14-0.29 $\mu\text{g}/\mu\text{l}$, estimated intraocular concentration. However, after exposure to 0.58 $\mu\text{g}/\mu\text{l}$, >30% of the cells in both the INL and the outer nuclear layer (ONL) are destroyed, and DA IPCs as well as other neurons in the INL and ONL regenerate. We suggested that damage to the ONL stimulated a regenerative response in the population of mitotic rod precursors in the ONL. In order to directly test this hypothesis, we specifically ablated DA IPCs, then asked whether they regenerated if rods, but no other neurons, were also ablated.

Right eyes of fish were injected with 6OHDA (0.14 $\mu\text{g}/\mu\text{l}$) on two consecutive days. This paradigm destroys DA IPCs without causing non-specific damage that leads to their regeneration. After 24 hours, tunicamycin was injected intraocularly (0.005 $\mu\text{g}/\mu\text{l}$) to destroy rods. One to 2 weeks later, rod nuclei were counted in 3 μm methacrylate sections. A 45-50% reduction in rod density was observed in ventral retina, with less damage in dorsal retina. Retinas isolated 6-7 weeks later were prepared as whole mounts and processed for immunofluorescence with antibodies to tyrosine hydroxylase (TH). Many TH-immunoreactive (TH+) cell bodies and processes were observed in control retinas (left eyes), but TH+ cells in experimental retinas were found only in the most peripheral retina, which represents new growth from the germinal zone. No regenerated TH+ cells were found in central retina.

These preliminary data suggest that rod precursors in the ONL do not alter their normal pathway of development to replace DA IPCs in the INL when damage to the ONL is limited to destruction of rods. Experiments in progress will attempt to destroy both cones and rods to further elucidate the cellular interactions involved in regulating rod precursor fate. Supported by EY04318.

CELL LINEAGE: GENETIC AND BIOCHEMICAL MARKERS

DEVELOPMENTALLY EXPRESSED ANTIGENS IN THE VENTRAL NERVE CORD OF THE MOTH, *MANDUCA SEXTA*. S.A. Monsma and R. Booker, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In response to hormonal changes during the final larval instar, holometabolous insects such as *Manduca* undergo drastic changes in behavior and physiology which lead to the adult form. In the ventral nerve cord (VNC) many immature neurons (IN cells) begin to differentiate while other cells degenerate. We have used nerve cords from wandering animals (day W2) to generate monoclonal antibodies (MAbs) against antigens expressed during this period. MAB 16H7 stains the peripheral somata of nearly all functional larval neurons as well as all nerves and connectives of fifth instar and wandering larvae; no immature IN cells are stained. On the first day of pupation (day P0), almost all surviving IN cells begin to stain and the staining of larval neurons intensifies. By the day of adult eclosion only large neurons stain reliably. Staining of the nerves and connectives remains unchanged. MAB 15B11 stains the cell bodies of many neurons of fifth instar and wandering larvae. In the thoracic ganglia 72 paired neurons are stained, while in the abdominal ganglia only 16 paired neurons are stained. 8 of these 16 neurons correspond to identified neurosecretory cells which contain the cardioacceleratory peptides or the peptide hormone bursicon. At day P0, almost all larval neurons and a few IN cells begin to stain. By the day of adult eclosion only a few neurons are stained. MAB 15G4 stains a pair of bilateral cells in each abdominal ganglion. Staining is present in all stages from fourth instar through pharate adult, with the strongest signal apparent on day P0. These cells appear to be a subset of the identified bursicon-containing cells. MAB 13F10 stains a pair of medial cells in the suboesophageal ganglion, a bilateral cell in T1 and T2, and a pair of bilateral cells in T3. Projections of the thoracic cells out the median nerve are also stained. Staining is weak in fourth and fifth instar larvae, becomes strongest by day W2 and was undiscernible by day P0 and after. MAB 5G7 stains 4 pairs of large bilateral brain cells in fifth instar larvae. Staining was absent in fourth instar larvae nor after day W2. These cells appear to be a subset of the Group IIa neurosecretory brain cells.

MUTATIONS THAT DISRUPT THE DEVELOPMENT OF CRANIAL NEURAL CREST CELLS IN THE ZEBRAFISH. T.F. Schilling*, C. Walker* and C.B. Kimmel, Institute of Neuroscience, Univ. of Oregon, Eugene, OR 97403.

Zebrafish cranial neural crest cells form sensory neurons, pigment cells and cartilage in the branchial arches. To learn the activities of genes that specify crest cell fates we have generated mutations that block the development of branchial arches and have abnormal pigmentation; the cellular bases of these defects were analyzed using cell labeling and transplantation techniques.

In two "chinless" mutations, *chw-1* and *chw-2*, cartilage and pigment cells were absent or abnormally patterned, while sensory neurons developed in their normal locations. The mutant phenotypes appeared after crest cells migrated to form branchial arch primordia suggesting that the mutations disrupt late steps in differentiation. Further, *chw-1* crest cells failed to develop normally when orthotopically transplanted into wild-type hosts, suggesting that this mutation acts autonomously in the neural crest cell lineage. A third mutation, "shorttail" *stl-1*, disrupted formation of the branchial arch primordia. Its phenotype appeared earlier, before crest migration, as a thinning of the CNS and a shortened tail bud. Older *stl-1* embryos lacked large groups of interneurons in the hindbrain suggesting that regions of the neuroepithelium, including neural tube as well as crest, were deleted. Similar to *chw-1* and *chw-2*, this mutation disrupted cranial cartilage and pigment cell development while sensory neurons appeared unaffected.

We suggest that all three mutations affect genes involved in the development of the cranial neural crest, and probably in particular crest sublineages. Supported by NIH 5T32GM07 and HD22486.

371.2

NEW MARKERS FOR STUDYING NEURAL DEVELOPMENT IN CHICK EMBRYOS. Z. Korade, W.P. Donohoe and E. Frank, Dept. of Neurobiology, Anatomy and Cell Science, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Developmental studies of the nervous system are facilitated by early markers of distinct classes of neurons and glia. In our continuing efforts to generate such markers, we have used cyclophosphamide to suppress the immune response to embryonic chick trigeminal sensory ganglia followed by immunization with membranes from E16 lumbo-sacral dorsal root ganglia (DRGs). Although this protocol has not yielded DRG-specific antibodies to date, several markers with striking developmental staining patterns have been isolated. Two are described here.

Antibody 4D8 primarily labels Schwann cells located throughout the peripheral nervous system. This staining first appears at E8, significantly later than staining with another Schwann cell marker (1E8) we have isolated. The most obvious contrast to 1E8 staining, however, is 4D8's intense labeling of the notochord from E4 until its disappearance. Although staining of Schwann cells and notochord is also characteristic of HNK-1, the patterns of HNK-1 and 4D8 labeling are quite distinct. A second difference from 1E8 is that although both markers initially stain satellite cells in DRGs, 4D8 staining persists through E21 while 1E8 staining does not.

Antibody 10D11 selectively labels the neural tube from E1 (stage 10). From the outset, the dorsal region of the tube (the neural crest) is unstained, and this lack of staining persists until well after crest cells have migrated away. As development proceeds through E4, the brightest staining is located immediately adjacent to the central canal, but cell-surface labeling is present throughout the forebrain and midbrain except at the dorsal edge of the tube. Staining intensity diminishes caudally, being confined primarily to the dorsolateral region of the neural tube. The outer circumference of the notochord is also stained, as with HNK-1. From E8, radial non-neuronal cells throughout the spinal cord are labeled with 10D11; the detailed pattern of staining is different at different levels of the neuraxis. Outside the CNS, 10D11 stains many satellite cells but no neurons in the sensory and sympathetic ganglia beginning on E12. Supported by NS24373 to EF.

371.4

CHARACTERIZATION OF FOUR HOMEODOMAIN GENES EXPRESSED IN ZEBRAFISH NEURAL CREST. M. Ekker*, M.A. Akimenko*, R. Bremiller* and M. Westerfield, Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

To study genes that are involved in the specification of neural crest cell fate in zebrafish, we have isolated three genes with homeodomains related to the mouse *Hox-7* gene, which is expressed in limb bud and neural crest cell derivatives. A fourth gene, cDNA10, with a unique homeobox was isolated in the same screen. Analysis of genomic and cDNA clones reveals that the three genes, *hox-7a*, *hox-7b* and *hox-7c*, encode similar homeodomains with more than 90% conservation at the amino acid level. Furthermore, the homeodomain of *hox-7a* is identical to that of the mouse *Hox-7* gene. However, there is little additional sequence similarity among the three genes or with related genes in other vertebrates except for the amino acid residues immediately outside the homeodomain and a short peptide located at the amino-terminal end of the protein. *In situ* hybridization of probes specific for each of the four genes to sections of zebrafish embryos demonstrates that they are expressed in regions where neural crest or crest derivatives differentiate, including the dorsal part of the neural tube (*hox-7b* & *7c*), pectoral fins (*hox-7b* & *7c*), caudal fins (*hox-7a* & *7c*), heart (*hox-7c*), jaw (cDNA10) and other brain structures (*hox-7c* & cDNA10). Expression in jaw and fin mutants is presently being analysed. Supported by HD22486.

371.5

A NOTCH HOMOLOG IN THE LEECH. B.J. Norris and D.A. Weisblat. Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720

We are interested in studying decision between the neural/epidermal fates made by ectodermal cells in early development of the leech. One approach to studying this process is to look for homologs to gene products that are involved in this decision in other organisms. One such gene product is the *Drosophila* neurogenic gene *Notch*. This gene is particularly advantageous as a *Notch* homolog has recently been isolated from *Xenopus* (*Xotch* - Coffman, et al., Science 249:1438-1441).

We have used the polymerase chain reaction (PCR) to isolate a putative homolog to *Notch*, from genomic DNA of *Helobdella triseriatis*. Oligos were designed to complement sequences (within the *cdc10/SWI6* region of the gene) that are highly conserved between *Notch* and *Xotch*. A 180 base pair fragment was amplified, cloned and sequenced, yielding a conceptual amino acid sequence that is 60% identical to *Notch* and 53% identical to *Xotch*. This PCR fragment was then used to isolate genomic DNA clones from *Helobdella*. A 1.4 kilobase fragment containing the PCR sequence was subcloned and sequenced, revealing additional putative coding sequence with strong homology to *Notch* and *Xotch*, as well as putative introns.

Preliminary nonradioactive *in situ* hybridizations show widespread transcript distribution in the leech embryo.

371.7

CLONING OF A CHICK HOMOLOG OF A *DROSOPHILA* PRONEURAL GENE. J. Helms††, J. Patrick§§, and G.D. Maxwell††. Neuroscience Program†, Departments of Anatomy† and Periodontology†, University of Connecticut Health Center, Farmington, CT 06030, and Division of Neuroscience§, Baylor College of Medicine, Houston, TX 77030

Molecular mechanisms that control cell determination and differentiation are often conserved through evolution, suggesting that genes which are required for specifying neuronal cell fates in *Drosophila* may have structural and functional homologs in vertebrate nervous systems. The *Drosophila* gene, *daughterless* (*da*), has a role in two developmental processes: sex determination and neurogenesis. *da* encodes a protein with a helix-loop-helix (HLH) motif. *da* and other HLH proteins are capable of forming homo- and heterodimers that exhibit sequence-specific DNA binding; these complexes may regulate the transcription of genes initiating neuronal precursor development. A chick brain cDNA library (generously provided by B. Ranscht) was screened by polymerase chain reaction using fully degenerate oligonucleotide primers corresponding to a conserved region of *da*. Five clones contained sequences that suggested they were members of the HLH gene family. The clone most homologous to the *da* HLH was used as a probe to re-screen the library. A 2.7 kb clone was isolated and sequenced, confirming that the clone contains a HLH region sharing 93% homology at the amino acid level with *da*. The cellular distribution of the expressed HLH gene will be characterized. This work was supported by NIH DE00157 (JH), NS13546 (JP) & NS16115 (GDM).

371.9

A NOVEL SEQUENCE EXPRESSED BY ACTIVATED T-CELLS AND NEURONS. J.A. Cohen, M. Arai, E. Luning Prak, M.B. Pryslowsky. Departments of Neurology and Pathology, Univ. of Penn., Philadelphia, PA 19104

By differential hybridization screening, we isolated a cDNA clone (F5) of a 3.6 kb mRNA induced by interleukin-2 (IL2) in a mouse helper T-cell clone (L2 cells). Northern blotting demonstrated modest F5 expression in adult mouse lymphoid tissues and, surprisingly, high levels in brain, spinal cord and eye. Expression was undetectable in other tissues including sciatic nerve. In cerebrum expression was undetectable up to 2 weeks after birth with a marked increase to adult levels on postnatal day 21. *In situ* hybridization histochemistry demonstrated high levels of F5 mRNA in large neurons in neocortex, hippocampus, diencephalon, brainstem, cerebellum, and spinal cord. Double-labelling studies confirmed that expression was restricted to neurons. Sequence analysis demonstrated a 1125 bp open reading frame encoding a 42 kDa protein with multiple potential phosphorylation sites and a nuclear translocation sequence. The F5 coding region hybridized under stringent conditions to DNA from a variety of species demonstrating substantial evolutionary conservation. However, neither the nucleic acid nor protein sequences showed homology to any previously reported sequence. F5 is a previously unreported gene, possibly encoding a nuclear regulatory protein. The function of the F5 protein and the mechanisms regulating its expression in neurons, whether by IL2 or by mechanisms distinct from those in T-cells, should be of great interest.

371.6

THE EFFECT OF NMDA ON THE EXPRESSION OF A NEW POU/HOMEODOMAIN GENE IN CEREBELLAR GRANULE NEURONS. Robert F. Bulleit. Dept. of Pharmacology, University of Maryland School of Medicine, Baltimore, MD 21201

POU/Homeobox genes encode transcriptional regulatory proteins involved in determining cellular phenotypes. Those expressed in the CNS are likely to be involved in specifying CNS cellular phenotypes. We are interested in identifying POU/Homeobox gene expressed in the mammalian CNS and also determining if their expression is modulated by NMDA. It has been suggested that activation of the NMDA subtype of glutamate receptor is required for certain aspects of CNS development. Thus, POU/Homeobox genes, whose expression is regulated by NMDA, may play key roles in these developmental processes. We have begun by using the polymerase chain reaction (PCR) to amplify and clone cDNAs encoding POU/homeodomain proteins expressed in the adult mouse cerebellum. Several POU/homeobox sequences were identified using this strategy. One of these sequences appears to be a new member of the POU/homeobox gene family and has been termed MBP-1 (mouse brain POU sequence 1). A probe generated from this sequence has been used to screen a mouse brain cDNA library in an effort to obtain cDNA clones encoding the entire MBP-1 transcript. Several positive clones have been identified. Clone MBP-1A contains the longest insert (~5.0kb). Probe synthesized from this clone has been used for northern blot analysis of RNA obtained from cultured cerebellar granule neurons. Granule neurons were cultured in serum free medium in the presence or absence of 50µM NMDA, plus or minus 100µM APV (an antagonist at the NMDA subtype of glutamate receptor) or 10µM CNQX (a non-NMDA glutamate receptor antagonist). The results indicate that treatment with NMDA increases the level of MBP-1 transcripts. APV blocks this increase while CNQX has no effect.

371.8

CHARACTERIZATION OF NOVEL cDNAs HYBRIDIZING TO mRNAs EXPRESSED IN THE DEVELOPING QUAIL RETINA. L. Bidou*, P. Crisanti* and Pessac B. Centre de Biologie Cellulaire, CNRS, 67 rue Maurice Günsbourg, 94205 Ivry sur Seine cedex, France.

The goal of this study is to isolate gene products that might be involved in neuronal quiescence and differentiation onset. We have constructed an "autosubtracted" cDNA library of mRNAs isolated from quiescent cells of a quail embryo neuroretina (NR) cell clone (K2), immortalized by a ts mutant of Rous sarcoma virus and whose proliferation stops after transfer to 41,5°C (Soc. Neurosci. Abstr. Vol. 15 part 2 p. 1129 1989).

Among the twenty recombinants which hybridize only with probes prepared from quiescent cells, we have selected four distinct clones which recognize quail mRNAs during development and after hatching. The nucleotide sequence of these partial cDNAs has no homology to sequences in the databanks. Clones p65, p62 and p64 appear specific for NR. The p65 mRNA is strongly expressed as three distinct bands of 4, 5.8 and 7 kb in post-hatching NR; p65 shows a diffuse NR signal from ED 7, and after hatching is heavily transcribed in all nuclear layers and particularly in photoreceptors; p65 is only observed in K2 cells 6 h after transfer to 41,5°C. p62 clone hybridizes to a 7 kb mRNA in ED 14 NR and to an additional band after hatching; it is strongly expressed in nuclear layers and photoreceptors, with the most intense signal in ganglion cell somas. Clones p46 and p64 recognize multiple mRNAs in a development-dependent pattern; distinct p46 and p64 mRNAs are specifically expressed in K2 cells after shift to 41,5°C. These novel cDNAs might play a role at multiple steps in NR development.

372.1

INTRINSIC PROPERTIES OF *HELISOMA* GROWTH CONES IN THE PRESENCE AND ABSENCE OF CONDITIONING FACTORS. D.L. Kania and C.S. Cohan Dept. of Anatomical Sciences, SUNY at Buffalo, Buffalo, N.Y. 14214

Previous studies investigated the cytoskeletal rearrangements at the cut end of an axon in response to conditioning factors. This study compares behavioral properties of growth cones of identified neurons in the presence and absence of conditioning factors.

We have developed an *in vitro* preparation for studying the initial effects of conditioning factors on regenerative outgrowth. Neurons B19 and B5, from the mollusc, *Helisoma trivolvis*, plated in the absence of conditioning factors form growth cones at the end of attached axon stumps. These growth cones exhibit filopodial and lamellipodial movements but do not advance across the substrate. Growth cones of neuron B19 treated with serotonin in the absence of conditioning factors lose their filopodia while growth cones of B5 do not, similar to their response in the presence of conditioning factors.

The addition of conditioning factors to the medium promotes neurite extension from approximately 50-75% of the growth cones of both attached and isolated pieces of axon. The rate of extension of the newly formed neurites was found to be comparable with rates reported from cells plated directly into conditioned medium.

Intracellular calcium levels are known to be important in the regulation of neurite outgrowth. Therefore, the effects of conditioning factors on intracellular calcium levels of the growth cones are being investigated. Preliminary results suggest that the presence of conditioning factors in the medium are related to low-level oscillations of intracellular calcium in the axon and growth cone. The magnitude of these oscillations appears to increase in isolated axons exposed to conditioning factors. Isolated axons initiate outgrowth quicker than attached axons in response to conditioning factors.

These results suggest that while neurite extension is dependent on conditioning factors, formation and intrinsic behavioral characteristics of growth cones are not. The effects of conditioning factors may be caused by changes in intracellular calcium.

PROTEIN SYNTHESIS IN ISOLATED NEURONAL GROWTH CONES IS ALTERED BY CHANGES IN INTRACELLULAR CALCIUM LEVELS. L. Davis, P. Dou, and S.B. Kater. Program in Neuronal Growth and Development and the Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

This study investigates the ways in which neuronal growth cones act independently from the cell body when growth cones encounter signals in the extracellular environment. We are focusing on protein synthesis within growth cones which could enable the rapid, local synthesis of protein components of the cellular machinery necessary in the formulation of responses to stimuli. We recently demonstrated that protein synthesis occurs in isolated growth cones of the snail *Helisoma* (Davis, L. and S.B. Kater (1990) *Soc. Neurosci. Abstr.* 16: 961) and are now exploring second messenger regulation of this process. Cultures containing growth cones isolated from buccal ganglion neuron B5 were pre-treated with the calcium ionophore 4-bromo-A23187 (1 μ M) for 5 minutes prior to pulse-labeling with 3H-leucine for 15 minutes in the presence of 4-bromo-A23187 (1 μ M) to raise intracellular calcium levels. Quantitative analyses of autoradiographs revealed that the number of silver grains (indicating the presence of 3H-proteins) over isolated growth cones was significantly increased ($p < 0.01$) in A23187 treated cultures as compared with controls. These experiments demonstrate that protein synthesis may be modulated by alterations in the intracellular calcium concentration; thus, protein synthesis in growth cones may be regulated by environmental cues that alter calcium levels. Supported by NIH postdoctoral training grant NS08445 to LD.

372.5

REGULATION OF NEURONAL GROWTH CONE FILOPODIA BY CHANGES IN INTRACELLULAR CALCIUM LEVELS. V. Rehder and S.B. Kater. Dept. of Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523

Filopodia on neuronal growth cones, historically have been regarded as sensory probes of their environment and more recently as important elements for steering growth cones towards their targets. Since the area encountered by a growth cone logically depends on the area spanned by the filopodia, an active change in filopodial length or number could result in the 'exploration' of different sample sizes of the environment at different times during development. The present study tests the regulatory role of intracellular calcium levels on filopodia. Changes in $[Ca]_i$ were directly correlated with growth cone filopodial behavior in an identified neuron from the snail *Helisoma*. Calcium influx into the cytoplasm was experimentally increased, and the $[Ca]_i$ monitored using the fluorescent calcium indicator fura-2. A rise in $[Ca]_i$ causes two distinct, concentration-dependent effects separable by their different time courses: within the first 10 minutes filopodia undergo significant elongation, while the second phase is characterized by a massive loss of filopodia in a calcium-dependent fashion. The degree of filopodial loss correlates well with the transient peak values of $[Ca]_i$ reached during each treatment. Filopodial numbers were gradually restored to pretreatment levels within two hours during continuous stimulation. A transient change of as little as 30-50 nM reliably alters filopodial disposition. This indicates that even small changes in intrinsic calcium homeostatic properties or extrinsic signals which alter calcium levels intracellularly can act as regulators of the environmental area sampled by an elongating growth cone.

372.2

CALCIUM CHANGES ASSOCIATED WITH ALTERATIONS IN GROWTH CONE MOVEMENTS OF DEPOLARIZED *HELISOMA* NEURONS. C.S. Cohan. Dept. of Anatomical Sciences, SUNY Buffalo, Buffalo, New York 14214.

It was previously shown that depolarization of outgrowing *Helisoma* neurons with high levels of K^+ results in time dependent changes in growth cone movements. In the presence of the depolarizing stimulus, neurite elongation is suppressed for a period of 45 min followed by transient recovery of elongation. In the present experiments, the calcium changes induced by the depolarization and which underlie the suppression and spontaneous recovery of elongation were studied.

Identified neurons B4 and B19 were isolated from *Helisoma* buccal ganglia and plated into culture dishes containing a neurite promoting conditioned medium. Outgrowing neurons were injected with the acid form of Fura-2 and viewed with a cooled ccd after brief exposures to 340nm and 380nm illumination. Neurons were depolarized by KCl (5, 10, and 25 mM) added to the dish after control calcium values were obtained. Calcium changes in growth cones were monitored at 15 min intervals.

Depolarization caused a dose dependent increase in calcium levels in growth cones of B4 and B19. Calcium levels in growth cones of B4 changed by 90% and 141% for depolarizations with 5 and 10mM K^+ and were significantly higher compared to growth cones of B19 which changed by 19% and 88%. This is consistent with the greater suppression of outgrowth in B4 than B19 during depolarization. However, treatment with 25mM K^+ did not produce a further increase in calcium levels even though it caused a greater suppression or even retraction of growth. The recovery phase of outgrowth was associated with a small but significant decrease in calcium levels that did not reach control levels. These data indicate that the differential effects of depolarization on neurite elongation of B4 and B19 can be explained by the magnitude of calcium changes in their growth cones. However, the sustained elevation of calcium levels during the recovery period suggests that other factors may be involved in the recovery of neurite elongation.

SMALL ELECTRIC FIELDS ALTER NEURONAL GROWTH CONE MORPHOLOGY, NAVIGATION AND CAUSE HIGHLY LOCALIZED INTRACELLULAR CALCIUM CHANGES. R.W. Davenport, S.B. Kater. Program in Neuronal Growth and Development, Department of Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523.

Previous investigators demonstrated the ability of small electric fields to alter predictably cell motility, direction of neurite outgrowth and growth cone morphology. We similarly demonstrate in identified, cultured neurons of the pond snail *Helisoma* the ability of electric fields to alter neuronal growth cone navigation (they turn toward a cathode source) and filopodia elongation (filopodia lengthen on the cathode oriented side of the growth cone). The mechanism(s) of these cellular responses remain unknown. Previous studies implicate calcium influx and/or membrane receptor redistribution as the causal mechanism to field-induced growth cone orientation. Using Fura-2 calcium imaging techniques, we provide the first direct evidence correlating a change in $[Ca]_i$ with field-induced growth cone orientation. With small, focally applied electric fields an ≈ 7 fold rise in $[Ca]_i$ occurs rapidly within about one minute and remains elevated ≈ 2 fold above rest levels as long as the electric field is sustained. This change in $[Ca]_i$ is blocked in $0[Ca]_o/EGTA$ containing media. Focally applied fields show a rapid, local change in $[Ca]_i$ on the cathode side of the growth cone. The increased $[Ca]_i$ spreads across the growth cone as a wave from the cathode to anode side, creating a brief gradient ($\approx 2-5$ min.) of $[Ca]_i$ across the growth cone. This calcium wave and gradient may be responsible for the directional changes of growth cone morphology and navigation.

372.6

INTERACTIONS AMONG EXTERNAL CALCIUM ION CONCENTRATIONS, INTRACELLULAR FREE CALCIUM ION CONCENTRATIONS, AND NEURITE GROWTH IN CULTURES OF PRIMARY AND TRANSFORMED NEURONS. J. Frank*, C. Ferguson*, L. Cabell-Kluch*, D. Shugarts*, T. Audesirk and G. Audesirk. Biology Dept., U. Colorado at Denver, Denver, CO 80217-3364.

Two primary neuronal types (embryonic rat hippocampal neurons and chick brain neurons) and two transformed neuronal types (rat B50 neuroblastoma cells of CNS origin and mouse N1E-115 neuroblastoma cells of PNS origin) were cultured in media in which calcium concentrations were varied from approximately 0.1 to 7.2 mM (0.1 to 4x normal). Both primary neuronal types showed maximum neurite initiation in media with normal calcium levels of 1.8 mM and decreased initiation in media with either higher or lower calcium concentrations. In both transformed cell types, neurite initiation was not affected by altered external calcium concentrations. Intracellular calcium measurements using fura-2 were made on rat hippocampal neurons and N1E-115 neuroblastoma cells. In hippocampal neurons, intracellular free calcium ion concentrations varied monotonically with altered external calcium. In N1E-115 cells, intracellular calcium was not affected by altered external calcium. These results indicate that (1) neurons differ in their ability to regulate intracellular calcium in the face of varied external calcium; (2) transformed neurons may have superior calcium-regulatory abilities; (3) intracellular calcium concentrations modulate neurite initiation.

372.7

CNS MYELIN NEURITE GROWTH INHIBITOR NI-35 CAUSES A LARGE TRANSIENT RISE IN INTRACELLULAR CALCIUM WHICH PRECEDES GROWTH ARREST AND COLLAPSE OF RAT DRG GROWTH CONES. M.F.Schmidt¹, C.E.Bandtlow², T.D.Hassinger¹, M.E.Schwab² and S.B.Kater¹. (1)Dept. Anatomy and Neurobiology, Colorado State University, Fort Collins, CO and (2) Brain Research Institute, University Zurich, 8029 Zurich, Switzerland.

Two proteins present in oligodendrocyte membranes and myelin exert potent inhibitory effects on growing neurites. Incorporation of one of these inhibitory proteins (NI-35) into liposomes was used to study the mechanism by which this protein mediates its inhibitory effect on neurite growth. Addition of these liposomes to cultures of dissociated rat DRG neurons causes 75% of the observed growth cones to arrest and subsequently to collapse within 60 minutes. This effect was specifically abolished by the neutralizing antibody IN-1. The collapse was significantly reduced in the presence of a cocktail of dihydropyridine calcium channel blockers. Addition of the calcium ionophore A23187 caused DRG growth cones to collapse. In order to further study the possible role of calcium in the mechanism of action of NI-35, DRG cultures were loaded with the calcium indicator Fura-2. The mean $[Ca^{2+}]_i$ in advancing growth cones was 158 ± 8 nM. Addition of NI-35 liposomes caused a large ($\bar{x} = 737 \pm 73$ nM) transient (5-10 minutes) rise in intracellular calcium which preceded growth cone collapse. As in the behavioral studies, the rise in calcium could be prevented when NI-35 liposomes were preincubated with the specific antibody IN-1. These results indicate an important role of calcium in the neurite growth inhibition produced by NI-35.

372.9

GABA_A RECEPTOR-MEDIATED CONDUCTANCES OF ADULT DORSAL ROOT GANGLION NEURONS INCREASE WITH TIME IN CULTURE. R.B. Bhisitkul, D.L. Eng, and J.D. Kocsis, Dept. of Neurology and Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510; and VAMC, West Haven, CT 06516

Adult rat dorsal root ganglion (DRG) neurons of the lumbar (L4 and L5) spinal cord were dissociated and maintained in culture up to 7-8 days. Single electrode current and voltage clamp recordings were obtained from large diameter GABA-sensitive neurons at 0-24 hours (Group 1) and at 7-8 days (Group 2). Cell body diameter and neurite extension were characterized from neurons injected with the fluorescent dye Lucifer Yellow. Group 1 cultures are characterized by an abundance of DRG neurons with few primary neurites and a paucity of fibroblasts and Schwann cells. These acutely dissociated neurons (Group 1) have deep resting potentials, large amplitude action potentials, a prominent inward rectification to applied hyperpolarizing pulses, and a distinct depolarization and inward current to applied GABA. After a week in culture (Group 2) there was massive proliferation of surrounding nonneuronal cells. Resting potential and action potential amplitude of Group 2 neurons were not statistically different from Group 1. However, there was a marked reduction in input resistance, a doubling of action potential width, an increase in the peak depolarization and current induced by bath application of GABA over a range of concentrations, a positive shift in the equilibrium potential for the GABA response and an increase in GABA-mediated conductance. The correlation of these electrophysiological changes with proliferation of surrounding nonneuronal cells supports the proposal that nonneuronal elements or their products may have a trophic influence with respect to specific physiological properties of neurons. Supported by the VA.

HIGH DOSE NMDA INDUCES RETRACTION AND LOW DOSE NMDA INDUCES ELONGATION OF RAT RETINAL GANGLION CELL (RGC) NEURITES. J. Offermann, Kunihiko Uchida* & Stuart A. Lipton. Dept. of Neurology, Children's Hosp & Progr in Neuroscience, Harvard Med Sch, Boston.

We have used real-time, computer-enhanced video microscopy to visualize the effect of varying doses of NMDA (10-100 μ M) on identified rat RGCs in vitro. Cultures were produced from 1 to 4 day-old LE rats as described previously (Leifer, Lipton et al., *Science* 1984;224:303; Cheng & Lipton, *Soc. Neurosci. Abstr.* 1989;15:650). Experiments on neurites ≥ 1 cell diameter in length were performed 4-9 hrs after cell plating. In a low $[Mg]$ bath, high dose NMDA (100 μ M) produced retraction in 43 of 73 RGC neurites (~60%). This process was, however, reversed in 1 mM external Mg, which resulted in elongation in 16 of 20 RGCs. With 10 mM EGTA and no added Ca/Mg in the bath, NMDA produced neurite retraction in only 2 of 7 RGCs (29%), suggesting that $[Ca]_o$ may be an important, albeit not mandatory, factor in retraction. In order to block retraction, we used a receptor antagonist (APV; 100 μ M) or a channel blocker (MK-801; 12 μ M). The combination of NMDA and MK-801 prevented retraction in 9/9 RGCs, with elongation actually being observed in 3 of these cells. With APV, NMDA induced retraction in only 3 of 8 RGCs (38%). In contrast to high dose, low dose NMDA (10-20 μ M) produced neurite elongation in 24 of 24 RGCs tested. As a control, 5 of 15 RGCs exhibited spontaneous neurite elongation. In 3 of 3 RGCs, neurite elongation in the presence of low dose NMDA occurred despite 10 mM EGTA and no added Ca/Mg in the bath, suggesting that external Ca may not be necessary for elongation under these conditions.

372.8

DEPOLARIZATION-INDUCED CHANGES IN INTRACELLULAR CALCIUM IN GROWTH CONES OF ACUTELY DISSOCIATED ADULT RAT SENSORY NEURONS. D.L. Eng and J.D. Kocsis, Dept. of Neurology and Sect. of Neurobiol., Yale Med. Sch., New Haven, CT 06510; and VAMC, West Haven, CT 06516

Adult rat dorsal root ganglion (DRG) neurons obtained in dissociated cell culture were used as a model of regenerating neurons to study intracellular calcium $[Ca^{2+}]_i$ changes during regeneration. DRG were dissected free of the epineurial sheath and treated in collagenase and papain followed by trituration with a siliconized glass pipette in a BSA/trypsin inhibitor cell media. The DRG cell suspension was plated on poly-ornithine/laminin coated glass coverslips and maintained in DMEM/F12, 10% FCS, 100 u/ml pen/strep cell media. Within hours after dissociation the neurons gave rise to neurites with prominent growth cones, as seen with Hoffmann modulation contrast optics, Lucifer yellow dye injection and with antineurofilament immunostaining. The neurons were viable as indicated by stable resting and action potentials. In order to study depolarization-dependent changes in intracellular Ca^{2+} , the neurons were loaded with the Ca^{2+} fluorescent dye, Fluo-3AM (cell permeant), and examined with a laser scanning confocal microscope or with an epifluorescent system while under continuous perfusion with normal Krebs solution. When the neurons were depolarized with brief bath applications of substituted Krebs containing 62 mM KCl, all three classes of DRG neurons (small, medium, and large) generated intracellular Ca^{2+} signals. The Ca^{2+} signals were prominent in cell bodies, neurites and growth cones, and they were nearly eliminated by the addition of divalent cations suggesting that transmembrane Ca^{2+} flux was primarily responsible for initiating the signals. These results indicate that soon after dissociation adult sensory neurons give rise to growth cones and neurite extension. Depolarization of these neurons leads to transmembrane fluxes of Ca^{2+} into cell bodies, neurites, and growth cones. Supported by the VA and the NMSS.

TRANSGENIC STRATEGIES TO INVESTIGATE CEREBELLAR DEVELOPMENT. K. Schilling, J. Obarlick*, R.J. Smeyne, M.H. Dickinson, and J.L. Morgan. Dept. Neurosciences, Roche Institute of Molecular Biology, 340 Kingsland Street, Nutley, NJ 07110

A quest of developmental neurobiology is to delineate the molecular entities and mechanisms that orchestrate the ontogeny of the nervous system. To approach this question, we have combined transgenic mouse strategies with a primary culture system that allows cerebellar neurons to be grown under controlled conditions. The normal morphogenesis of Purkinje cell dendrites correlates with the maturation of their electrical properties and increasing cytoplasmic calcium levels. Indeed, electrical activity appears to direct dendritic growth since agents that interfere with electrical activity and/or synaptic communication compromise normal dendrogenesis. Using cells derived from animals carrying a L7 β Gal transgene it can be shown that this Purkinje cell-specific gene product is also regulated by electrical activity in culture; indicating that activity can also influence gene expression. Using mice carrying a *fos-lacZ* fusion transgene, we have analyzed the stimuli that induce *c-fos* and characterized the responsive cell types. Combining these results we suggest that depolarization and/or synaptic activation of developing Purkinje neurons triggers a sequence of events that includes changes in cytoplasmic calcium levels and the expression of immediate-early genes. Since many cellular immediate-early genes encode transcription factors, they may provide a mechanistic link between neuronal excitation and the transactivation of L7 as well as subsequent changes in Purkinje cell morphology. We are currently using the culture system to further address this hypothesis.

372.12

Effects of Membrane Depolarization on Neurite Outgrowth and Microtubule Polymerization Equilibria in Axons and Dendrites of Sympathetic Neurons in Culture. Charles H. Keith, Department of Zoology, University of Georgia, Athens GA.

In a number of neurons in culture, depolarization, which elevates $[Ca^{++}]_i$, is correlated with a cessation of neurite outgrowth. We have hypothesized that this effect on neurite extension occurs by means of an effect on microtubule polymerization equilibria, and have developed methods to measure polymer/tubulin ratios locally in cells. These methods are based on video densitometry of microinjected rhodamine-tubulin before and after extraction of free dimer.

We find that depolarization of rat sympathetic neurons has effects dependent on the substrate on which the cells are grown. Neurites of cells grown on laminin in the presence of serum - conditions that favor dendrite growth from these cells - retract and depress their microtubule polymerization ratio on depolarization in high K^+ . By contrast, neurites grown on collagen in the absence of serum - conditions that promote the development of unipolar, axon-bearing neurons - continue growing and have unaffected polymerization ratios on depolarization. We feel that these differences between axons and dendrites are related to the differences in their microtubule-associated proteins, and may be significant in sculpting axonal and dendritic arbors during development.

372.13

INVOLVEMENT OF GABA_A RECEPTORS IN THE OUTGROWTH OF CULTURED RAT HIPPOCAMPAL NEURONS

G. Barbin, T. Jahchan*, H. Pollard* and Y. Ben-Ari.

INSERM U.29, Hôpital Port-Royal, 123 Bd Port-Royal, 75014 Paris (France)

Recent studies in our laboratory have shown a depolarizing effect of GABA in slices of the hippocampus taken from rat neonates (Ben-Ari et al., J. Physiol. 416 : 303 (1989)). In slices of the neocortex the GABA-induced depolarization is associated with a transient rise in intracellular calcium concentration (Yuste and Katz, Neuron 6 : 333 (1991)). Given the multiplicity of Ca⁺⁺ dependent biochemical mechanisms this cation is able to regulate neuritic outgrowth, and growth cone behavior.

We have explored the involvement of GABA_A receptors in the development of dissociated rat hippocampal neurons. Cells were cultured from embryonic day 18-19 hippocampal tissue in a chemically defined medium on a polylysine substratum coated with fetal calf serum. Pharmacological agents were added three hours after seeding the cells. After a culture period of two to four days cells were silver stained. For each experimental situation about 200 neurons were examined and various parameters were monitored to probe their morphology i.e. number of neurites, bifurcation points and length of processes. When cultures were exposed to 200 μM bicuculline noticeable changes were observed as compared to control cultures or cultures grown in the presence of GABA (10⁻⁵M) : i) the number of neurites emanating from the cell soma was lower, ii) the neurites were less ramified, iii) the neuritic length was reduced.

These observations (see also Michler, Int. J. Dev. Neurosci. 8 : 463 (1990)) suggest that the activation of GABA_A receptors during the early development of the rat hippocampus might sculpture neuronal architecture as it has been shown for other neurotransmitters.

NERVE GROWTH FACTOR IV

373.1

EARLY EMBRYONIC QUAIL DORSAL ROOT GANGLIA (DRG) EXPRESS HIGH AFFINITY NERVE GROWTH FACTOR (NGF) RECEPTORS. J. Speight and P. Bernd. Department of Anatomy and Cell Biology, SUNY Health Science Center, Brooklyn, NY 11203.

We have previously shown that ¹²⁵I-NGF binding to DRG, *in situ*, is first seen at embryonic day 3.5 (E3.5; stage 23) in cryostat sections of quail. High affinity NGF receptors appear to be present, because specific binding was seen at a low ¹²⁵I-NGF concentration (2 ng/ml; 80 pM). These results are surprising since other labs have shown that DRG are unresponsive to NGF prior to E5, with respect to neurite outgrowth and neuronal survival. This is presumably due to an absence of high affinity receptors. We have used two independent methods to confirm the presence of high affinity NGF receptors at this early stage. First, binding was done as above, but control sections were done with a relatively low concentration of nonradioactive NGF (200 ng/ml; 8000 pM), in addition to ¹²⁵I-NGF. Under these conditions, 80% of ¹²⁵I-NGF bound to high affinity receptors will be displaced while that bound to low affinity receptors will be unaffected. Examination of radioautographs revealed that there was a substantial decrease in the amount of binding under these control conditions. The second method involved determining whether the high molecular weight ¹²⁵I-NGF-receptor complex, which corresponds to the high affinity NGF receptor, is present. Dissociated E3.5 DRG cell suspensions were exposed to ¹²⁵I-NGF (20 ng/ml; 800 pM; 2 hr; 4°C), followed by crosslinking. Radioautographs of gels revealed the presence of both the high and low molecular weight complexes. These studies have confirmed the presence of high affinity NGF receptors in E3.5 DRG of quail. The nature of the response(s) mediated by high affinity NGF receptors at this early stage remains to be elucidated. Supported by a grant from the NSF (BNS-8896101).

373.3

NGF TREATMENT IN AGED RATS INCREASES MUSCARINIC INDUCED DOPAMINE RELEASE IN STRIATUM AND IMPROVES SELECTED ASPECTS OF MOTOR PERFORMANCE BUT NOT MAZE LEARNING. L. Williams¹, J. Joseph², E. Spangler², P. Garofalo², J.A. Oostveen¹, D. Ingram². ¹Upjohn Company, Kalamazoo, MI 49001, and ²Gerontol. Res. Ctr., NIA, NIH, Baltimore, MD 21224.

Emerging evidence supports the potential therapeutic benefits of nerve growth factor (NGF) in treating age-related neurodegenerative disorders. We used 24-mo old male F-344 rats to assess the effects of NGF (0.3 μg/day) delivered intraventricularly by osmotic pump (Alza) compared to implanted age-matched controls and untreated young controls (3 mo). About 3 wk after treatment was initiated, rats were tested in a battery of motor tasks, including open field, inclined screen, wire suspension, rotarod, that had proven to be age sensitive (A. Markowska et al. *Neurobiol. Aging*, 10:31, 1989). Motor assessment was followed by one-way avoidance training in a straight runway and then training in a 14-unit T-maze that has also provided robust evidence of age-related performance declines in rodents (D. Ingram, *Neurobiol. Aging*, 9:475, 1988). Comparing 3-mo old rats to aged controls, significant performance declines were noted across age in all tasks except the open-field test. NGF treatment improved performance only in the inclined screen test, but impaired performance in the maze task. Rats were sacrificed 1 day after completing behavioral testing, or about 4 wk after NGF treatment. Analysis of oxotremorine enhancement of K⁺-evoked release of dopamine (K⁺-ERDA) using perfused striatal slices obtained from these groups indicated greater enhancement of K⁺-ERDA in the NGF-treated and young controls than in aged controls. Analysis of choline acetyltransferase activity (ChAT) revealed an age-related decline (32%) in this marker of cholinergic function in striatum of control rats. NGF treatment in aged rats stimulated ChAT activity to levels observed in young controls.

373.2

DEVELOPMENTAL PATTERN OF NERVE GROWTH FACTOR RECEPTOR EXPRESSION IN THE SENSORY EPITHELIUM OF THE INNER EAR OF QUAIL AND MOUSE. J. Repra, T.R. Van De Water, and P. Bernd. Dept. of Anatomy and Cell Biology, SUNY Health Sci. Ctr., Brooklyn, NY 11203, and Dept. of Otolaryngology and Neuroscience, Albert Einstein College of Medicine, Bronx, N.Y. 10461.

A previous study demonstrated the presence of specific NGF receptors on the epithelium of the primordium of the inner ear (otic vesicle, OV) of 72 hr quail embryos (Bernd and Repra, 1989). The present study uses quantitative and radioautographic techniques to define NGF receptor expression throughout development, using both quail and mouse. OV and sensory epithelium obtained from quail and mouse embryos exhibited different levels of specific ¹²⁵I-NGF binding during development. Maximal levels were achieved at mid-gestation (E7 quail; E14 mouse) in the sensory epithelium of the vestibular labyrinth, and somewhat later in the cochlear duct (E10 quail; E16 mouse). By E13 (quail) or E18 (mouse), ¹²⁵I-NGF binding was minimal in both vestibular and auditory epithelia. Light microscopic radioautography demonstrated, in both quail and mouse, that NGF receptors were concentrated in areas containing differentiating sensory hair cells, as well as nerve endings. Likewise, areas of OV known to contain presumptive sensory cells bound ¹²⁵I-NGF. The apparent presence of NGF receptors on developing hair cells or nerve endings suggests that differentiation of the sensory cell population may be affected by NGF. Supported by grants from the Deafness Research Foundation (PB) and NIH (TRV; DC00088).

373.4

SURVIVAL OF ISOLATED SEPTAL CHOLINERGIC NEURONS FROM RAT EMBRYOS IN CULTURE WITHOUT NERVE GROWTH FACTOR. Doris Nonner*, Sally Temple* and John N. Barrett. Dept. of Physiology & Biophysics, Univ. of Miami Med. Sch., P.O. Box 016430, Miami, FL 33101.

Nerve growth factor (NGF) enhances cholinergic properties of some septal neurons, but it is not known whether NGF is essential for their survival. We had previously found that cells cultured from embryonic rat septum produce NGF (or NGF-like activity) in amounts sufficient to support the survival of co-cultured sympathetic ganglion neurons. To analyze the trophic requirements of septal cholinergic neurons, we studied the survival of isolated septal cells, thus removing the source(s) of NGF-like activity produced by other cells. Septal cells from day 14 embryonic rats were cultured at very low density (1 to 5 cells per culture well) in a defined medium together with an NGF-free serum fraction that promotes the survival of central neurons.

We found that many acetylcholinesterase (AChE)-positive septal neurons survived for more than 20 days isolated in cell culture. (Co-cultured dorsal-root ganglion or sympathetic ganglion neurons died within 48 hours.) Some septal progenitor cells occasionally divided in culture, giving rise to clones of AChE-positive cells. After 15 days in culture, 40-50% of the cells were intensely AChE-positive, and about the same percentage stained with antibody 192 against NGF-receptor. Addition of NGF or anti-NGF antibodies did not affect septal neuron survival, cell proliferation or number of AChE-positive neurons.

We conclude that under these culture conditions the survival of many septal neurons expressing AChE and/or NGF receptors does not depend on NGF or the presence of other cells.

373.5

EXPRESSION OF THE NGF RECEPTOR GENE BY CEREBELLAR PURKINJE NEURONS IN CULTURE IS REGULATED BY DEPOLARIZING INFLUENCES. S. Cohen-Cory, R.C. Elliott, C.F. Dreyfus and I.B. Black. Lab. of Neurobiol., Rockefeller Univ., New York, NY 10021, and Dept. of Neurosci and Cell Biol. UMDNJ-Robert Wood Johnson Med Sch., Piscataway, NJ.

Increasing evidence suggests that NGF plays an important role during cerebellar ontogeny. Purkinje cells express both low- and high-affinity NGF receptors during development, suggesting responsiveness to the trophic agent. Indeed, previous work indicates that afferent neurotransmitters and NGF interact to regulate Purkinje cell survival and morphogenesis (J. Neurosci. 11: 462-471, 1991).

To investigate mechanisms by which afferent neurotransmitters and trophic factors interact, regulation of NGF receptor gene expression by depolarizing influences was studied in dissociated cerebellar cell culture. Purkinje cells were identified immunocytochemically with anti-Calbindin D28K antibodies (a gift of Dr. S. Christakos) and were shown to express NGF-R immunoreactivity. Sensitive receptor cross-linking, and ribonuclease protection assays were employed to examine NGF receptor protein, and messenger RNA levels respectively. Exposure of neurons to pharmacologic depolarizing agents, or to the excitatory neurotransmitter aspartate substantially increased both NGF receptor mRNA and protein expression. In addition, expression of the NGF gene by cerebellar glia in culture was studied. Our results suggest that in the cerebellum, impulse activity increases Purkinje cell responsiveness to NGF by regulating NGF receptor expression, while glia may act as a potential local source of NGF synthesis. (Supported by NINDS, NICHD, March of Dimes and McKnight Fellowships).

373.7

CORTICAL NEURONS REGULATE NERVE GROWTH FACTOR SECRETION FROM CO-CULTURED ASTROGLIA. B.C. Wise, B. Tang*, and X. Vige. FGIN, Georgetown University, Washington, D.C. 20007.

Neonatal rat cortical astrocytes and neurons in primary culture synthesize and secrete nerve growth factor (NGF). The content of NGF mRNA in cortical neurons is comparable to that in astrocytes, although the ratio of secreted to cellular NGF is about 2 for neurons and 75 for astrocytes. Co-culturing neurons with astrocytes for 7 days decreased NGF secretion to 30% of the level seen in astroglia alone and to 70% of that seen in neurons alone. The neuronal inhibition on co-culture NGF secretion was dependent on time, the number of neurons plated, and was partially reversible upon selectively decreasing the number of neurons by glutamate (0.5 mM for 24 hrs) treatment. Interleukin-1 (IL-1, 10 U/ml) and the phorbol ester TPA (100 nM) stimulated by about 4- and 7-fold, respectively, NGF secretion from astrocytes while having only small effects on NGF content in neurons. The magnitude of the IL-1 stimulated NGF secretion was decreased by 65% in the co-cultures suggesting a down-regulation of astroglial responsiveness induced by the neurons. Addition of neuronal cell membranes, cytosol or neuronal conditioned medium failed to change NGF secretion from astrocytes. Thus, astroglial NGF secretion including secretion stimulated by IL-1 and TPA may be regulated by neurons.

NGF-LIKE IMMUNOREACTIVITY IN RESECTED HUMAN NEOCORTEX. K.A. Crutcher and J. Weingartner*, Dept. of Neurosurgery, Univ. of Cincinnati, Cincinnati, OH 45267.

Nerve growth factor-like immunoreactivity (NGF-LI) has been demonstrated in the CNS of rodents and non-human primates. However, there is little information on the presence of NGF-LI in human brain tissue, although NGF mRNA and NGF receptor mRNA levels have been reported. A monoclonal antibody (27/21, Boehringer) raised against purified mouse NGF has also been reported to reliably detect human recombinant NGF (Heinrich and Meyer, '88; Söderström et al. '91). We sought to determine whether NGF-LI can be detected in human brain using a 2-site ELISA. The monoclonal antibody (1G3) was raised against mouse NGF and kindly provided by Dr. William Mobley (UCSF). The polyclonal antibody was raised in a goat immunized with purified mouse NGF (provided by Dr. Mobley) and prepared by Hazelton Research Products, Inc. (Denver, PA). Samples were obtained from temporal or frontal lobe resections undertaken for the treatment of epilepsy (provided through Dr. Hwa-Shain Yeh and Dr. Michael Privitera, UC Med. Ctr.). The tissue was frozen on dry ice and stored at -70°C. The samples were thawed and homogenized at a 1:10 dilution in buffer containing 1% Tween. The ELISA was carried out as described previously using mouse NGF as the standard (Saffran et al., '89). Recoveries were assessed by adding 25 pg of mouse NGF to parallel samples. The average concentration of NGF-LI in these samples (n=19) was .33 ng/gm +/- .13 (s.d.) with an average recovery of 61%. These results indicate that NGF-LI can be detected in fresh tissue samples of human neocortex and provide a basis for further studies of NGF-LI in human neurodegenerative disorders, including Alzheimer's disease. UP-REGULATION OF NGF RECEPTOR BY BDNF AND NGF IN C6 GLIOMA CELLS.

P.E. Spoerri, L. Petrelli*, A. Negro¹, L. Facci, R. Dal Toso, A. Leon and S.D. Skaper. Fidia Research Laboratories and ¹Advanced Technology Division, Fidia S.p.A., 35031 Abano Terme, Italy.

The neuronotrophic proteins BDNF and NGF are structurally related, sharing about 50% amino acid sequence homology (Leibrock, J. et al. Nature 341:149, 1989) and the same low affinity receptor (Rodriguez - Tébar, A. et al. Neuron 4:487, 1990). In this study we investigated NGF receptor (NGF-R) immunoreactivity in cultured C6 rat glioma cells treated with mouse NGF (50ng/ml) or recombinant rat BDNF (10ng/ml). The cells were exposed to the anti-NGF-R antibody 192-IgG, followed by IgG conjugated with RITC or colloidal gold. Untreated C6 cells exhibited occasional fluorescence or gold label. Cells treated with NGF or BDNF showed significantly augmented fluorescence or gold labeling on all surfaces. We are currently examining if this up-regulation of low-affinity NGF-R by NGF and BDNF is reflected by a corresponding increase in gene transcripts for this NGF-R protein.

Nerve Growth Factor (NGF) Modifies Solitary Striatal Neurons In Culture. P.W. Coates and M.S. Walker*. Department of Cell Biology & Anatomy, Texas Tech University HSC-School of Medicine, Lubbock, TX 79430.

Central cholinergic neurons degenerate in Alzheimer's disease. Neurons from cholinergic regions other than basal forebrain, such as striatum, can be affected. NGF may reverse this process. It is difficult to adequately assess direct effects of NGF on such neurons in vivo or in vitro, since contact with other neurons and/or glia may provide NGF. In vitro, neurons typically reaggregate and make extensive connecting neurite networks and also contact glial cells. Thus, effects of cell contact and/or endogenous paracrine factors cannot be distinguished from putative effects of exogenous NGF. Our lab is using a culture model (three-dimensional hydrated collagen lattice) in which neurons easily grow and differentiate as single non-contacting cells, to determine whether such neurons from different cholinergic (and non-cholinergic) regions of fetal rat brain are independently able to respond to NGF. For this project, neurons from the striatum were used. To determine whether solitary striatal neurons express cholinergic properties without 'instructions' provided by cell contact, immunocytochemistry was used to localize the enzyme choline acetyltransferase. To determine whether there was a dose-dependent change in growth and differentiation or in survival, the neurons were cultured with and without 2.5 S NGF (10, 50 and 100 ng/ml). Quantitative measurements were obtained using image analysis. Data was analyzed using a non-parametric analysis of variance. There were significant (p < 0.05) dose-dependent increases in growth and differentiation by 48 hr. However, survival was not promoted by any dose of NGF. Results suggest that striatal neurons are intrinsically NGF-responsive with respect to growth and differentiation but not survival. Synaptic or other cell contact-mediated mechanisms are not required for the response. Axons, dendrites and complexity of receptive fields appear to be neuronal structures specifically modified by NGF. Supported by INS-TTU and NS 20802.

A NOVEL POPULATION OF NGF RECEPTOR-IR CORTICAL NEURONS IN ADVANCED AGE AND ALZHEIMER'S DISEASE. E.J. Mufson, G.A. Higgins, and J.H. Kordower, Dept. Neurological Sci., Rush Presbyterian Med.Ctr., Chicago Ill. 60612, and NIA, Bethesda MD.

In our ongoing evaluation of degenerative and regenerative processes associated with aging and dementia, we observed a novel population of cortical neurons which express the receptor and mRNA for nerve growth factor (NGF). These neurons are found preferentially within the temporal neocortex in very old (e.g 98 year old) normal patients. Furthermore, NGF receptor-immunoreactive (NGFR-ir) cortical neurons were consistently observed in Alzheimer's disease (AD) patients (n=12) of all ages. In contrast, such neurons were rarely seen in normal patients below 80 years of age (n=12). These neurons were scattered throughout all cortical lamina and morphologically appeared intermediate displaying small somata with extensive dendritic arbors. These cells appeared healthy, failing to counterstain for thioflavin-S. This is in contrast to the extensive neuronal loss and morphological degeneration seen within the AD basal forebrain. A few NGFR-ir cortical neurons were also observed within the amygdaloid complex. In contrast, virtually no such staining was seen in the AD hippocampus. Interestingly, the NGFR-ir neurons seen in cortex appeared morphologically similar to those we have recently observed in the embryonic human cortex (see adjacent abstract). These data suggest that advanced aging and AD initiate an expression of NGF receptors upon select cortical neurons which is not seen in normal adulthood. This novel synthesis of the NGF receptors may be a re-expression of a normal developmental pattern. (Support: AHAF and AG 09468)

373.11

NGF RECEPTOR-IR IN THE DEVELOPING HUMAN BRAIN J.H. Kordower, H.K. Le*, and E.J. Mufson Dept. Neurological Sci., Rush Presbyterian Med. Ctr., Dept. Anatomy & Cell Biology, Univ. Illinois School of Medicine., Chicago Ill. 60612 USA.

NGF receptor-immunoreactivity (NGFR-ir) was examined in embryonic human material (n=5; 10-26 weeks of gestation (E)) and compared to acetylcholinesterase (AChE) and diaphorase (NADPH-D) staining. Numerous NGFR-ir neurons were observed at E16 weeks within the basal forebrain (BF). Similar AChE staining was seen at E16 while NADPH-D containing BF neurons were not yet observed. At E16, NGFR-ir fibers were traced within the external capsule to layers V and VI of the cerebral cortex with beaded processes in layers II and III. At E16, NGFR-ir neurons were seen in the substantia nigra and a band of NGFR-ir was observed coursing the length of the ventral brainstem. At E19, numerous NGFR-ir neurons were observed in cortex which was enhanced at E21. Numerous NGFR-ir and AChE-containing neurons also were seen in both segments of the globus pallidus (GP) at E21. A few NGFR-ir neurons were first seen in the striatum at E21. This pattern was dissociated from AChE-containing neurons which were more numerous at this time and were also evident in the younger specimens. At E24 we observed an apparent reduction in NGFR-ir cortical cells within the infragranular layers, ir neurons were restricted to the external GP and the stained neurons in substantia nigra were replaced by fibers. In striatum at E24, we found more NGFR-ir neurons, as well as a patch-matrix pattern similar AChE and NADPH-D stained sections. Similar staining patterns, including the persistence of NGFR-ir cortical neurons, were observed at E26 weeks.

373.13

BDNF AND NT-3 ARE EXPRESSED IN SENSORY NEURONS AND MOTONEURONS DURING MOUSE EMBRYOGENESIS. L.C. Schecterson and M. Bothwell. Dept. of Physiology and Biophysics SJ-40, University of Washington, Seattle, WA 98195

The survival of sympathetic neurons, primary afferent sensory neurons and motoneurons during development is dependent upon the presence of neurotrophins and neurotrophic factors produced by the target tissues of these neurons. To identify specific cells expressing neurotrophins, *in situ* hybridization was performed on several stages of developing mouse embryos using radiolabeled NGF, BDNF and NT-3 cRNAs as probes. The results demonstrated that sympathetic neurons, sensory neurons and motoneurons also express these neurotrophins. BDNF mRNA was detected in most neurons in trigeminal ganglia and dorsal root ganglia (DRG), beginning at E15.5, and in some cells at E17.5, P1 and P3, whereas NT-3 mRNA expression was present in a fewer number of cells compared to BDNF in the DRG at E15.5. Expression of NT-3 was not detected in DRG neurons at P1 and P3. In contrast, NT-3 mRNA expression was abundant in motoneurons in the spinal cord from early stages (E 8.5) through birth. Sympathetic ganglia contained both BDNF and NT-3 mRNAs at E17.5 and P1. Expression of BDNF and NT-3 mRNAs in the developing mouse appears to be confined specifically to neurons and may be involved in either regulation of neuron-Schwann cell interactions, or in autocrine or paracrine regulation of cell survival and neuronal maturation. Alternatively, these factors may be used by the targets of these neurons.

373.15

INDUCTION OF NERVE GROWTH FACTOR (NGF) GENE EXPRESSION BY NOREPINEPHRINE (NE) IS PARTIALLY MEDIATED THROUGH N-METHYL-D-ASPARTATE (NMDA) RECEPTORS. F.M. Sessler, B.J. Gwag, R.D. Mouradian, B.D. Waterhouse, and J.E. Springer Depts. of Neurology, and Physiology and Biophysics, Hahnemann University, Philadelphia, Pa 19102.

The presence and actions of NGF in the central nervous system (CNS) support its role as a growth factor involved in neuronal plasticity. The mechanism(s) by which this neurotrophic factor is regulated is still unclear. We demonstrated in our companion study that NMDA infusions increase hippocampal NGF mRNA expression in a time-dependent fashion (Gwag et al). NMDA receptor stimulation is involved in a number of neuronal events including the induction of long term potentiation, which can be facilitated by NE. Therefore, we used RNA protection assays to determine whether NGF mRNA expression in cortex or hippocampus is altered in the presence of NE. In addition, we tested whether the effects of NE can be modified by pretreatment of the brain sections with the NMDA antagonist, 2-amino-5-phosphonvaleric acid (AP-5). Cortical and hippocampal tissue slices (300 microns) were incubated for 1 hr. at 35°C in oxygenated artificial cerebrospinal fluid (ACSF). NMDA and NE were applied at various concentrations for brief intervals and slices then allowed to incubate in ACSF for two more hours. Some sections were incubated in the presence of AP-5 prior to the application of NMDA or NE. The sections were then frozen on dry ice, total RNA isolated, and the levels of NGF mRNA determined using the RNA protection assay procedure. The application of NMDA or NE increased NGF mRNA. Interestingly, the effects of NE were partially blocked by pretreating the slices with AP-5, suggesting an indirect effect of NE. The results of these studies indicate that NGF may be under the control of both NMDA and NE neurotransmitter systems, and that these two systems may interact to further regulate the expression of this neurotrophic factor. Supported by PHS grant AG-08969 (JES), NINDS KO4 NS01233 and the Klingenstein Foundation (BDW), and BRSG 2-S07-RR07241 (FMS).

DIFFERENTIAL DISTRIBUTION AND CELLULAR COMPARTMENTALIZATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR C Wetmore¹, Y Cao², RF Pettersson², L Olson¹

¹Dept. of Histology & Neurobiology, Karolinska Institute, Box 60400, and ²Ludwig Institute for Cancer Research, Stockholm Branch, Box 60202, 10401 Stockholm, Sweden.

Brain-derived neurotrophic factor (BDNF), a member of the nerve growth factor (NGF) family of trophic factors, has been shown to affect the growth of distinct, yet somewhat overlapping populations of neurons which are known to be stimulated by NGF. Specifically, while all three family members affect the growth of neural crest sensory neurons, only BDNF has been shown to stimulate the growth of dopaminergic neurons from substantia nigra, and to increase the number and uptake of GABA-containing neurons in basal forebrain cultures.

In the present study, antibodies were raised against synthetic peptide sequences contained within pro- and mature forms of BDNF. These antibodies have been used to localize BDNF to cells which synthesize the protein, as well as cells in which BDNF mRNA has not been detected. Specifically, at the subcellular level, these antibodies recognize nuclei as well as cytoplasm of the same populations of neurons in hippocampus and cortex which contain BDNF mRNA, which give evidence of differential subcellular compartmentalization and transport of the BDNF. BDNF can also be detected in cytoplasmic granules in the perikarya of cholinergic neurons known to project to regions enriched in BDNF-synthesizing neurons. We propose that, among other places, BDNF is synthesized in hippocampal and cortical pyramidal cells and that one form of the protein enters the nucleus and may directly influence transcription factors, while another form is directed to other non-nuclear compartments.

LOW-AFFINITY NERVE GROWTH FACTOR RECEPTOR EXPRESSION IN REGENERATING AND NON-REGENERATING ADULT RAT SPINAL MOTONEURONS M. Rendé, T. Hagg, S. Varon, Dept. Biol., UCSD, La Jolla, Calif.

Somatic motoneurons (SMN) of the rat spinal cord express low-affinity NGF receptors (LNGFR) and its mRNA during developmental stages characterized by axonal growth. In the adult, only 3% of the SMN are LNGFR immunoreactive (LNGFR-IR). The potential correlation between reexpression of LNGFR-IR in adult lumbar SMN induced by sciatic nerve injury and motor axon regeneration was investigated. We established a time-course of the number of LNGFR-IR SMN following a cut lesion with resection of the distal stump (no regeneration), a crush lesion (followed by regeneration), and implantation of a silicone chamber between the cut nerve stumps (regeneration delayed relative to crush). With a cut lesion alone, the number of LNGFR-IR SMN rapidly increased to a maximum between day 1 and 7 and returned to baseline levels by day 30. After a crush lesion approximately the same number of LNGFR-IR SMN appeared with the same time-course but the progressive disappearance was delayed, so that at 30 days the most caudal neurons (which are last to reach their muscle targets), were still LNGFR-IR. With a chamber, LNGFR-IR SMN appeared 2 days later, but their disappearance was delayed even further, so that the number at 30 days was still maximal and at 60 days still above baseline. Thus, the development of the "LNGFR" response in injured motoneurons is relatively independent of the outcome of regeneration, i.e. may be regulated by a common signal. In contrast, the response is variably sustained in correlation with the duration of the axonal outgrowth process, suggesting that the LNGFR has an important function during axonal outgrowth. N-METHYL-D-ASPARTATE (NMDA) REGULATION OF NERVE GROWTH FACTOR (NGF) GENE EXPRESSION. B.J. Gwag, F.M. Sessler, R.D. Mouradian, B.D. Waterhouse and J.E. Springer, Depts. of Neurology, and Physiology and Biophysics, Hahnemann University, Philadelphia, PA 19102-1192

NGF is a neurotrophic agent that may be associated with plasticity occurring in basal forebrain cholinergic neurons and their cholinergic projection fields (e.g. hippocampus and neocortex). However, it is unclear how NGF may be regulated in the CNS. Recent studies show that neuronal production of NGF mRNA is increased in hippocampus and cortex following limbic seizures generated by electrolytic lesion or kainic acid. Based on the anatomical distribution and function of NGF in the CNS we have suggested that NGF may also play a role in plasticity associated with learning and memory. At the present time, long term potentiation is one candidate for information storage in the mammalian brain and requires the activation of NMDA receptors for induction. We used *in situ* hybridization and RNA protection assays to investigate whether NMDA can modify NGF mRNA expression. Radiolabeled antisense NGF mRNA probes were transcribed from a 771bp cDNA (a gift from S. Whittemore) and hybridized to brain sections of rats which were sacrificed at 15 min, 4, and 24 hours following hippocampal injection of NMDA. NGF mRNA levels were dramatically increased in the stratum granulosum at 4 hours but unchanged at 15 min and 24 hrs after NMDA treatment. When 2-amino-5-phosphonvaleric acid (AP-5), an NMDA antagonist, was infused into lateral ventricle 30 min prior to NMDA administration, the NMDA-induced increase of NGF mRNA was blocked. These results were confirmed using the RNA protection assay. This study demonstrates that NMDA receptor activation can alter the expression of NGF mRNA in hippocampus. Supported by PHS grant AG-08969, the Alzheimer's Disease Foundation (JES), NINDS KO4 NS01233 and the Klingenstein Foundation (BDW) and BRSG 2-S07-RR07241 (FMS).

ALTERED EXPRESSION OF NGF AND NGF-RECEPTOR IN INJURED TEETH: EFFECTS OF PRIOR DENERVATION OR GLUCOCORTICOID PRE-TREATMENT. M.R. Byers, E.F. Wheeler, M. Bothwell. Anesthesiology, Bio. Structure, Physiology and Biophysics. Univ. of Washington, Seattle, WA, USA 98195

Profuse sprouting of sensory nerve fibers occurs in adult tooth pulp by 1-4 days following injury. A possible role for nerve growth factor (NGF) in that response is suggested by the present experiments. Adult rats (n=13) were anesthetized and injured by drilling cavities halfway into molar dentin. A subsequent similar operation allowed comparison of 2 different injury times (6 hr, 1 d, 2 d or 5 d) with intact controls in each jaw. Formaldehyde-fixed tissues were decalcified and prepared for *in situ* hybridization using ³⁵S-UTP-labeled sense and antisense riboprobes for NGF and NGFR. Digital analysis of autoradiograms showed that pulpal fibroblasts co-expressed NGF and NGFR mRNAs in intact teeth. By 6 hrs after injury, NGF expression had increased 2-10x compared to adjacent intact controls (mean \pm SD, 4.5 \pm 2.6), but NGFR expression decreased close to background levels. By 2-5 days NGF mRNA expression had also decreased below normal. The inverse shifts in fibroblastic NGF and NGFR expression at 6 hrs after injury were not inhibited by prior denervation (n=3) or pre-treatment with dexamethasone (n=5). Thus the synthesis of NGF by pulpal fibroblasts during the first day after tooth injury must be regulated by endogenous mechanisms that do not require nerve fibers or arachidonic acid metabolites. The local increase in NGF in injured tooth pulp precedes neural sprouting and may stimulate it. Supported by NIH Grants DE05159, HL43397, NS23343.

PARTIAL INHIBITION OF NGF-INDUCED CHICK NEURONAL SURVIVAL BY ANTIBODIES TO PEPTIDES OF NGF. R.A. Murphy, A. Acheson, J. Haskins, E. Reklow, and R. Hodges. Dept. of Anatomy and Cell Biology and Dept. of Biochemistry. Univ. of Alberta, Edmonton, Alberta, Canada T6G 2H7.

Antibodies raised in rabbits against synthetic peptides of mouse NGF were tested against salivary NGF in chick neuron survival assays. Antibodies to residues 23-35, 59-67, and 69-79 recognized mouse NGF on Western blots, and antibodies to 23-35 and 59-67, but not 69-79, reacted with NGF in ELISAs. Conversely, antibodies to intact NGF recognized peptides 23-35 and 59-67, but not 69-79, and a monoclonal antibody (MC 27/21, Boehringer Mannheim) that blocks NGF biological activity recognized only peptide 23-35. The anti-peptide antibodies did not alter the elution position of NGF on gel filtration columns, indicating a lower affinity than antibodies to the intact protein.

Under conditions where antibodies to NGF and MC 27/21 blocked NGF-induced survival of E 10 sensory neurons, antibodies to peptides 23-35 and 69-79 were ineffective; however, anti-peptide 59-67 inhibited survival by approximately 85%. Conversely, tested in combination with NGF at a 1000 molar excess, peptide 23-35 inhibited survival by 54% and peptide 59-67, by 79%. Peptide 69-79 had no effect. On E10 sympathetic neurons, treatment either with antibodies to peptide 59-67 or with peptide 59-67 together with NGF inhibited survival by 45%. Results suggest that residues 23-35 and 59-67 play important roles in the survival promoting activity of NGF on chick neurons.

NON-NEURONAL CELLS I

NGF REGULATES GLIAL CELL NUMBER IN SEPTAL DISSOCIATED CULTURES. M. Yokoyama, I.B. Black, and C.F. Dreyfus. Cornell Univ. Med. College and Dept. Neurosci. and Cell Biol. UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, N.J.

In previous studies, we have found that low affinity NGF binding sites are associated with flat non-neuronal cells dissociated from embryonic septum and grown for 7 days. These cells were also labelled immunohistochemically using a monoclonal antibody to the NGF receptor, 192 IgG, suggesting that low affinity NGF receptors are associated with a non-neuronal population (Bernd et al., 1988).

To define the potential effect of NGF on these non-neuronal cells, septal regions from embryonic day 17 rats were dissociated and grown in fully-defined medium either in the presence or absence of NGF. As an additional control, one group of cultures was grown in the presence of cytochrome C, a compound similar in structure and physicochemical properties to the trophic agent. To define actions of NGF on the astrocyte subpopulation in these cultures, glial fibrillary acidic protein (GFAP) was used as a marker. After 7 days, NGF elicited a dramatic 9-fold increase in the number of GFAP-positive cells over control cultures or cytochrome C-treated groups.

Our results suggest that NGF increases astrocyte cell number directly or indirectly. Moreover, in related studies, we have demonstrated that during development or after a lesion, proliferating glia express the NGF gene *in vivo* (Lu et al., 1991). These data suggest that astrocytic NGF, acting in an autocrine or paracrine fashion, may regulate astrocyte cell numbers during development, or in response to injury. Presently we are investigating the mechanisms through which NGF may exert its effects. (Support: NINDS, NICHD, McKnight Foundation, JDF and March of Dimes)

NGF DOES NOT IMPROVE RECOVERY OF VISION AFTER GRADED OPTIC NERVE CRUSH.

T. Stoehr*, J. Sautter* and B.A. Sabel. Inst. Med. Psychology, Univ. of Munich, Med. School, 8000 Munich 2, Fed. Rep. of Germany. (SPON: European Neuroscience Association)

Nerve Growth Factor (NGF) is known to have neuroprotective effects after injury, enhancing survival of different cell types in the CNS, including retinal ganglion cells (Carmignoto et al., *J. Neurosci.* 9, 1989, 1263). To assess whether NGF administration also improves recovery of vision following trauma, we have now used the graded crush of the rat optic nerve as a model (Duvdevani et al. *Rest. Neurol. Neurosci.* 2, 1990, 31).

In our behavioral task rats had to learn to orient towards visual stimuli presented in all sectors of the visual field. Two groups of rats which sustained a unilateral crush of the optic nerve received intraocular injections of either NGF (2.6 μ g in 1 μ l, n=12) or saline (1 μ l, n=12) on postoperative days 0, 2 and 4. Two sham operated groups were treated accordingly (n=4, n=3). Following crush we observed an initial deficit in the rats' orienting performance, followed by near complete recovery of vision within 2 weeks. However, NGF did not affect the rate or extent of recovery.

It is conceivable that the amount of NGF, the mode or the duration of NGF-administration was not optimal. In addition, while NGF may enhance cell survival after mild optic nerve crush, a study currently under investigation, this may be of no functional benefit.

We thank FIDIA Research Laboratories for kindly providing NGF.

373.20

ANTIBODIES AGAINST NGF PEPTIDES INHIBIT THE BIOLOGICAL ACTIVITY OF FIBROBLAST-DERIVED NGF AND BDNF. A. Acheson, R.F. Alderson*, R. Hodges*, M. Russell* and R.A. Murphy. Univ. of Alberta, Dept. of Anatomy & Cell Biology, Edmonton, AB and *Regeneron Pharmaceuticals, Inc., Tarrytown, NY.

NGF is a target-derived trophic factor, and a variety of cell types secrete NGF in culture. Mouse L929 fibroblasts (L cells) secrete into conditioned medium (CM) molecules with both NGF- and BDNF-like biological activities, and express both NGF and BDNF mRNA. We have recently shown that polyclonal antibodies raised against intact salivary NGF recognize recombinant human BDNF on Western blots and inhibit both NGF- and BDNF-like biological activities present in L cell CM, as well as 65% of recombinant BDNF's survival-promoting activity *in vitro*. We have now raised antibodies against 3 peptides derived from the mouse NGF sequence and examined their ability to block L cell CM-mediated survival of E10 chick DRG neurons. L cell CM promotes the survival of 91% of DRG neurons over 3 days *in vitro*. Both anti-NGF and anti-peptide C (amino acids 69-79 of mNGF) substantially block the activity of L cell CM (-86% and -71%, respectively), whereas antibodies against peptides A (23-35) and B (59-67) were less effective (-43% and -28%, respectively). When tested on Western blots, all 3 anti-peptide antibodies recognized recombinant human BDNF, with anti-peptide C being the most effective. All 3 anti-peptide antibodies also recognized mouse salivary NGF on Western blots, with anti-peptide A being the most effective, but only anti-peptide B inhibited NGF-mediated survival (see R.A. Murphy et al., *Neurosci. Abstr.* 1991). Anti-peptide antibodies also inhibited the biological activity of BDNF on E8 DRG neurons (-34%, 51% and 40% for anti-peptides A-C respectively). Results suggest that NGF and BDNF, molecules with 50% amino acid identity, may also share functionally-important epitopes.

374.2

RECEPTORS FOR CALCITONIN GENE-RELATED PEPTIDE (CGRP) IN ASTROCYTE CULTURES FROM NEONATAL RAT BRAIN. M. Reddington, P. Lazar*, G. Raivich*, W. Streit* and G.W. Kreutzberg. Dept. of Neuromorphology, Max Planck Institute for Psychiatry, Martinsried, F.R. Germany.

Axotomy of the rat facial nerve leads to hypertrophy of astrocytes and to the proliferation of microglial cells in the facial nucleus. Since the concentration of the neuropeptide CGRP increases rapidly after axotomy in the injured motoneurons it has been suggested that CGRP might play a role in neuron-glia interaction following nerve injury (Streit et al., *Neurosci. Lett.* 101, 143-148, 1989). This possibility was examined using 9-14 day-old cultures of astrocytes obtained from neonatal rat brain. Addition of CGRP in the range 10 - 1000 nM increased the concentration of cyclic AMP by up to 20-fold in astrocyte cultures. This action was inhibited in the presence of equimolar concentrations of the CGRP receptor antagonist CGRP(8-37). Calcitonin stimulated cyclic AMP accumulation only at micromolar concentrations. Ligand binding studies using ¹²⁵I-Tyr-CGRP showed membranes derived from astrocyte cultures to have a single class of high affinity binding sites (Kd 0.3 nM). ¹²⁵I-Tyr-CGRP was displaced by unlabeled CGRP and by CGRP(8-37) but not by calcitonin. The properties of these CGRP binding sites were identical with those in membranes derived from adult rat brain. These data show that astrocytes bear functional CGRP receptors linked to adenylate cyclase and support a role for CGRP in neuron-astrocyte interaction.

374.3

CULTURED GLIAL CELLS FROM THE OLFACTORY BULB OF THE ADULT RAT. A. Ramón-Cueto* and M. Nieto-Sampedro. Neural Plasticity Lab., Cajal Institute, Madrid 28002, Spain. Cultures of olfactory nerve and glomerular layers (ONGL) of the adult rat olfactory bulb contained three types of cell, distinguished by both morphological and immunohistochemical criteria. One cell type was multipolar and GFAP-positive; a second type had fried egg-like morphology, reacted with antibody to ED1 and had all the features of the monocyte-microglia lineage. The third type had elongated, fusiform morphology, was GFAP and ED1-negative, laminin-positive and may be capillary endothelial cells. Trypsinization (3 min, 37 °C) of these primary cultures detached multipolar and bipolar cells only. When secondary cultures of the detached cells were set up on a glass substrate (PLL-treated labtek multiwell chambers) bipolar cells did not attach, leaving a pure culture of multipolar cells. These cells were capable of enfolding axons, were GFAP- and myelin basic protein (MBP) positive and may be the so-called ensheathing cells or Blanes glia. We have identified at least three immunologically distinct ensheathing cell populations, based on immunoreactivity with anti-NGF receptor and anti-fibronectin. The three populations were multipolar, GFAP, MBP-positive. However, one of them (about 42%) was NGFR-positive, fibronectin-negative. The other population (41 %) was NGFR-negative and fibronectin-positive. The remainder cells (about 17 %) were negative for both antibodies. The cultured ONGL cells have morphology, behavior and immunological properties very similar to those of Schwann cells. Ensheathing cells surround olfactory axons and their Schwann-like properties could account for the permissivity of the olfactory bulb to axonal growth. Supported by grant FAR89-0683 from the Ministry of Industry.

ACTIVATION OF STROMELYSIN IS REQUIRED FOR AUTOCRINE INHIBITION OF SCHWANN CELL PROLIFERATION. D. Muir and S. Varon. Dept. of Biology, University of California, San Diego.

Cultures of isolated rat sciatic nerve Schwann cells (SCs) proliferate very slowly in serum-supplemented medium. A recent report (Muir et al., 1990. *J. Cell Biol.* 109: 2663) described that SC conditioned medium (CM) contains several distinct forms of antiproliferative activity and concluded that SC proliferation *in vitro* is under negative autocrine control. This work included the isolation and partial characterization of a 55 kD neural antiproliferative protein (NAP) found in SC and Schwannoma CMs. In the present study we provide evidence that the 55 kD NAP possesses metalloprotease activity and copurifies with stromelysin immunoreactivity. The SC-derived protease shares many properties with stromelysin isolated from other sources including the ability to cleave the serum and extracellular matrix protein fibronectin (FN). Furthermore, limited proteolysis of FN by the SC-derived protease generates a FN fragment which itself expresses a potent antiproliferative activity for SCs. The antiproliferative FN fragment corresponds to the 29 kD N-terminal region of the FN molecule which is found as an active component in SC CM. Both the NAP / stromelysin and the N-terminal fragment of FN can completely and reversibly inhibit proliferation by mitogen-stimulated SCs while both are similarly ineffective at inhibiting proliferation by transformed SC lines. In addition, although both normal and transformed SC types secrete the proform of stromelysin, in contrast to normal SCs, transformed cultures do not produce activated stromelysin and thus can not generate the antiproliferative fragment of FN. These results suggest that SC-derived stromelysin, once activated, cleaves FN and generates a cryptic antiproliferative activity which maintains normal SC quiescence *in vitro*.

CELL POPULATION KINETICS IN THE SUBPENDYMAL LAYER OF THE CONTROL AND IRRADIATED MOUSE BRAIN. N.B. Manley, K.A. Frankel*, M.H. Phillips*, J.I. Fabrikant*. Lawrence Berkeley Laboratory, Berkeley, CA 94720.

The subependymal layer in the 4 week old CB6F₁ mouse brain is a "mixed" cell population proliferating with a moderately high tritiated thymidine labeling index (17.35%--26.35%), but a low mitotic index (0.5%--1.5%). Mitotic figures are seen in all three morphologically different types of cells which are in sequential stages of proliferation, differentiation and migration. The 3 types of cells are: (1) cells with small dark nucleus (SD); (2) cells with small light nucleus (SL); and (3) cells with large light nucleus (LL). Using high resolution autoradiography, we find varying grain-count decrements with time after a single pulse of tritiated thymidine. This suggests that there are varying cell cycle times among these subpopulations.

Percent -labeled mitoses curves (PLM) were derived by a best fit to the experimental data and by the computer-generated modified Barrett-Steel model. Partial brain irradiation with helium (230 MeV/amu) was confined to one cortex of the brain (0.25 x 1.5 cm along the sagittal axis). The unirradiated hemi-brain in the irradiated animal served as an internal control. Unirradiated controls were also used to compare the effects of helium-ion irradiation on the PLM curves.

Analyses of PLM curves obtained one week after irradiation with 10 Gy He and 25 Gy He indicate that this layer is made up of subpopulations with varying cell cycle times and phase durations. There is significantly more cell damage following 25 Gy He irradiation as compared to 10 Gy He.

IMPROVED YIELDS IN SCHWANN CELL CULTURES FROM ADULT RAT SCIATIC NERVES A.D. Anselin*, D.F. Davey and S.D. Corbett*, Microsurgery Research Centre, Sydney and Department of Physiology, University of Sydney, 2006, NSW Australia.

Schwann cell cultures from adult rat peripheral nerves are difficult to obtain because of the abundance of connective tissue and myelin. It has been shown that both neurons and Schwann cells are conditioned by a nerve lesion, speeding up Schwann cell proliferation and neuronal regeneration. This effect is most pronounced in the first three days after applying the lesion (Sjoberg & Kanje, *Brain Res.* 529:79-84, 1990). In this study, we have attempted to improve the yield in the culture of Schwann cells obtained from adult rat sciatic nerve by applying a conditioning lesion 1 to 10 days (inclusive) prior to isolating the cells. The left sciatic nerve in young adult Wistar rats was exposed, severed at the sciatic notch and deflected. At the appropriate survival time, the severed (conditioned) and unoperated (control) sciatic nerves (20mm each side) were excised using sterile techniques, and processed for tissue culture according to the method described by Scarpini *et al.* (*Exp. Neurol.* 102:167-176, 1988). The cells from each nerve segment were counted prior to plating on a single laminin coated well in 6-multiwell plates (Linbro). Cell counts indicate that severing the nerve prior to dissociation for culture increases the yield of Schwann cells 48 h after lesioning, and the best yields were obtained at day 5 and day 6. Furthermore, 24 h after plating, more Schwann cells isolated from the lesioned nerve than from control nerve were attached to the laminin substratum.

CONTROL OF GAP-43 EXPRESSION IN SCHWANN CELLS. H.J.S. Stewart, R. Mirsky and K.R. Jessen. (Spon: Brain Res Association). Department of Anatomy, University College London, WC1E 6BT, U.K.

It is now apparent that GAP-43 expression is not confined to periods of axonal elongation or indeed to neurones. Recently we have established that GAP-43 is expressed by Schwann cells *in vitro* and non-myelin-forming Schwann cells *in vivo*. This study examined the control of Schwann cell GAP-43 expression in the context of other non-myelin-forming Schwann cell phenotypic markers. In particular we studied the role of cAMP, a molecule thought to be of fundamental importance in Schwann cell biology on GAP-43 expression *in vitro*. Using techniques including immunoblotting and immunocytochemistry we show that Schwann cell GAP-43 expression is rapidly downregulated by cAMP and is upregulated by increasing cell density. In addition we show that the density dependence of GAP-43 expression is mediated by a Schwann cell secreted factor. Thus the control of GAP-43 expression is obviously complex and quite different from that of other non-myelin-forming Schwann cell markers. The involvement of cAMP in GAP-43 expression however, emphasizes the importance of this molecule in Schwann cell development.

374.8

DOUBLE IMMUNOPEROXIDASE (IP) SIMULTANEOUSLY DETECTS IODODEOXYURIDINE (IUDR) AND BROMODEOXYURIDINE (BUDR) IN GLIA. P.E. McKeever, I.M. Rowe*, S.J. Genik*, P.W. McLaughlin*, W.R. Mancini* and W.D. Ensminger*. Pathology Department and Upjohn Center, Univ. Michigan, Ann Arbor, MI 48109-0602.

An IP/alkaline phosphatase (AP) method provides IUDR and BUDR labeling indices (LI) on certain cells (Asai A., *et al.*, *J. Neurosurg.* 73:254, 1990; Miller MA, *et al.*, *J. Histochem. Cytochem.* 39:407, 1991). However, other tissues contain endogenous AP difficult to block, and the buffer for IP is incompatible with AP. These factors diminish the flexibility of IP/AP. To alleviate this, we developed a double IP method for IUDR and BUDR. All standard rinses were with phosphate buffered saline (PBS). After DNA denaturation and blocking endogenous peroxidase, sections were incubated 20 min in normal horse serum, followed by 30 min in Br-3 monoclonal antibody (MAb) specific for BUDR (1:1000 in PBS with 1% BSA). Sections were incubated with biotinylated horse anti-mouse IgG for 30 min, and stained with avidin-biotinylated horseradish peroxidase complex using diaminobenzidine (DAB) substrate. After acid elution of immunoglobulins, these sections were incubated with B-44 MAb which binds both BUDR and IUDR (1:10 in PBS-BSA). This was followed by indirect staining with peroxidase conjugated goat anti-mouse IgG using 3-amino-9-ethylcarbazole (AEC) substrate. The resulting red reaction product was distinctive from both brown DAB reaction product and blue hematoxylin, demonstrating a 67% growth fraction and 8% LI in a human glioma xenograft treated with IUDR and pulsed with BUDR. This was much higher than non-neoplastic glia. Since hematoxylin is the effective counterstain for halopyrimidine LI, DAB/AEC provides visually compatible double labeling when AP cannot be used.

CHARACTERIZATION OF A NOVEL GLIAL CELL ADHESION MOLECULE, G-CAM. M.H. Irwin, T.P. Murphy, and E.E. Geisert, Jr. Department of Cell Biology, Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, Alabama 35294.

Using a mAb, designated AMP1, a novel cell adhesion molecule present in rat astrocyte-astrocyte and astrocyte-oligodendrocyte contacts in culture was identified. In confluent monolayers of cultured neonatal astrocytes, AMP1 showed a discrete labeling of cell-cell contacts. The antibody does not stain neurons cultured from embryonic rat cortex nor does it reorganize under neurons plated on monolayers of astrocytes. When cultures of astrocytes were placed in Hank's balanced salts with 100 µg/ml of AMP1 the astrocyte-astrocyte contacts were severely disrupted. This was not observed in parallel cultures treated with an irrelevant mAb of the same isotype as AMP1. By immunoblot analysis, AMP1 recognized a 106 kDa protein in samples of reduced astrocytic or brain proteins. Immunoblots of 2-D gels indicated the protein has an apparent pI of 6.1. We have tentatively termed this molecule "glial cell adhesion molecule" (G-CAM), and present data demonstrating that G-CAM is distinct from the known cell adhesion molecules present on astrocytes: N-CAM, N-cadherin, or members of the $\beta 1$ integrin family. Supported by The Spinal Cord Society, The Whitehall Foundation, Inc., and PHS grant NS23613.

374.11

IMMUNOCYTOCHEMICAL DETECTION OF A NOVEL ASTROCYTE SURFACE MOLECULE IN THE TRANSECTED ADULT RAT OPTIC NERVE (ON). B. Mittal, A. Ajemian* and S. David. Centre for Research in Neuroscience, MGHRI, McGill University, Montreal, Canada, H3G 1A4.

Neurite outgrowth on astrocytes is mediated by interactions involving adhesion molecules such as laminin, N-cadherin, N-CAM and L1. We have previously characterized a novel astrocyte surface molecule using a monoclonal antibody (mAb) designated as 1A1 (Neurosci. Abst., 16:315, 1990). Monovalent fragments of this mAb were shown to inhibit neurite growth from rat cerebellar neurons on astrocytes. Immunoaffinity chromatography using detergent extracts of I^{125} -labeled astrocyte surface proteins, revealed by SDS-PAGE a major band migrating at \approx 150 kDa under both reducing and non-reducing conditions.

We now report using an indirect immunofluorescence technique that 1A1-immunoreactivity is increased in the degenerating adult rat ON. Enhanced 1A1 staining is seen on astrocytes at the site of injury 10 days after transection, and continues to spread distally along the degenerating ON with time. Weak staining is observed in normal ONs. The role of this neurite growth-promoting molecule in injury-induced axonal sprouting and in the ability of degenerated ON tissue sections to support neurite growth *in vitro* (Neuron, 5:463, 1990) is not yet known. (Supported by The Canadian MRC and The Rick Hansen Man in Motion Legacy Fund).

GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) AND ITS MRNA ARE DRAMATICALLY UP-REGULATED AFTER INTENSE NEURONAL ACTIVITY. E. B. Torre, E. Lothman and O. Steward. Depts. of Neuroscience, Neurosurgery, and Neurology Univ. of Virginia Health Sciences Center, Charlottesville VA 22908.

Intense neuronal activity produced by electrically-induced seizures leads to dramatic increases in the mRNA for GFAP (Steward et al; J. Neurosci. 10, 2373; Proc. Natl. Acad. Sci., in press). The present study evaluates whether the activity-induced up-regulation of GFAP mRNA leads to glial hypertrophy similar to that which occurs after lesions. Since increased synthesis of GFA protein is considered a marker for "reactive astrocytes", we evaluated the changes in GFA protein and its mRNA at different times after the induction of kindled seizures in adult rats.

Twelve seizures were induced over the course of 1 day via indwelling electrodes implanted in the CA3 region of the hippocampus. Messenger RNA for GFAP was evaluated by *in situ* and dot blot hybridization techniques. GFA protein in each hippocampus was quantified in western blots and dot blots using a rabbit antibody against GFAP and goat anti rabbit labeled with I^{125} .

Kindled seizures led to 4-5 fold increases in GFAP mRNA as measured by quantitative *in situ* hybridization. These increases were evident near the site of stimulation as well in distant structures in which seizures occurred as a result of synaptic activation (the contralateral hippocampus). GFAP mRNA levels were maximal 24 h after stimulation and returned to baseline by 4 days post stimulation. GFA protein levels also increased bilaterally in the hippocampus following kindled seizures, reaching their peak 1 day after the peak in GFAP mRNA levels (at 48 hours poststimulation). However, GFA protein levels remained high for at least 4 d poststimulation. This is similar to the time course of increases in GFA protein levels after lesions of the entorhinal cortex. Our results suggest that a reactive astroglial response similar to that which occurs after lesions can be elicited by intense neuronal activity.

374.10

EXPRESSION OF A NOVEL GLIAL CELL ADHESION MOLECULE, G-CAM, IN CNS DEVELOPMENT AND WOUND HEALING. T.P. Murphy, M.H. Irwin, and E.E. Geisert, Jr. Department of Cell Biology, Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, Alabama 35294.

Using the mAb AMP1 we have identified a 106 kDa protein that is involved in glial cell-cell adhesion (G-CAM). By immunoblot analysis, G-CAM expression was detected at low levels in E18 rat brain, gradually increasing to adult levels in the maturing rat CNS. At E18, AMP1 immunoreactivity was restricted to the choroid plexus and ependyma. Later in development, the labeling was observed throughout the brain, and was more intense in areas enriched in glial cells. One of the dynamic processes involving glia in the adult brain is the response to injury. To begin to define the role of G-CAM in the process of CNS wound healing, chronic CNS gliotic scars were labeled with AMP1 and examined by confocal microscopy. In the region of the gliotic scar there was a 100-fold increase in relative fluorescence intensity as compared to surrounding normal tissue, indicating that G-CAM is expressed at high levels in the immediate vicinity of the gliotic scar. Unlike N-CAM, N-cadherin and $\beta 1$ integrins, G-CAM is glial-specific, indicating that it may play a specialized role in the selective stabilization of glial interactions during the development and wound healing in the CNS. Supported by The Spinal Cord Society, The Whitehall Foundation, Inc., and PHS grant NS23613.

374.12

IMMATURE HAMSTERS INCREASE LEVELS OF VIMENTIN AND GLIAL FIBRILLARY ACIDIC PROTEIN AFTER CORTICOSPINAL AXOTOMY.

S.A. Mikucki, L. Singh* and M.M. Obinger. Dept. of Cell Biology and Anatomy, Chicago Medical School, North Chicago, IL 60064.

Astrocytes are one of the few cells which express two different intermediate filament (IF) proteins during development. Vimentin, a Type III IF is expressed in high levels in developing astrocytes where as mature astrocytes express glial fibrillary acidic protein (GFAP), another Type III IF. Recently, it has been observed that axotomizing injury to the mature central nervous system (CNS) results in increases in both vimentin and GFAP mRNAs. However, there is little information available regarding the molecular response of developing astrocytes during Wallerian degeneration in immature animals. Can immature astrocytes upregulate both vimentin and GFAP expression prior to the time in which the GFAP gene is normally induced? In the present study, we used *in situ* hybridization and immunological methods to examine whether developing astrocytes alter their normal developmental program of IF expression and increase GFAP and/or vimentin levels during Wallerian degeneration. The corticospinal tract of postnatal day 8 hamsters was unilaterally transected in the medulla just rostral to the pyramidal decussation and animals were allowed to survive for 2, 7 and 14 days after injury. Histological sections of brain stem were hybridized to a 35 S-labeled cDNA probe to GFAP mRNA and subjected to autoradiography. The results from *in situ* hybridization experiments revealed that developing astrocytes have the potential for altering their normal developmental program of GFAP expression after injury. We observed substantial increases in GFAP mRNA in the degenerating part of the corticospinal tract compared to the contralateral control as early as 2 days after injury; increase was still present at 14 days. Double-label immunofluorescence experiments examining GFAP and vimentin protein levels during Wallerian degeneration revealed pronounced increases in GFAP levels at 2 days with a less pronounced increase at 7 and 14 days after injury. Increases in vimentin levels were not as dramatic as those for GFAP and were much more confined to the degenerating tract. We believe these results are the first to demonstrate an altered developmental program of GFAP expression after CNS injury in immature hamsters.

REGIONAL DISTRIBUTION OF HUMAN BRAIN GFAP AND ChAT. Karson, C., Griffin, W.S.T., Casanova, M., Kleinman, J.E.* Department of Psychiatry & Behavioral Sci. & Pediatrics, UAMS, Little Rock, AR. 72202. Clinical Brain Disorders Branch, Wash, D.C. 20032*

GFAP, the structural protein of astrocytes and ChAT, a key enzyme in cholinergic neurotransmission, were measured in multiple regions of human brain using Western immunoblot. (N=53, age=34 ± 13 years, M/F=44/9). GFAP concentrations were higher in most rostral structures in contrast with ChAT concentrations (Table). Occipital cortex had GFAP and ChAT concentrations similar to cerebellum and pontine tegmentum.

	FP	LSTG	TH	OC	CER	PT
GFAP (ng/ug protein)	2.73± 0.78 (N=8)	2.40± 0.99 (N=8)	2.96± 1.33 (N=8)	1.33± 0.83 (N=12)	1.75± 1.14 (N=11)	1.40± 0.45 (N=22)
ChAT (ng/ug protein)	.046± .011 (N=8)	.048± .012 (N=8)	.067± .028 (N=8)	.077± .040 (N=12)	.068± .026 (N=12)	.089± .040 (N=22)

* FP=Frontal pole. LSTG=Left superior temporal gyrus. TH=Thalamus. OC=Occipital cortex. CER=Cerebellum. PT=Pontine tegmentum.

SUMMARY. GFAP and ChAT are inversely distributed in human brain which may reflect neuronal density and/or vulnerability to injury of the given brain region.

374.15

HIPPOCAMPAL 5HT INNERVATION DENSITY INFLUENCES THE EXPRESSION OF GFAP AND S-100 DETECTED BY IMMUNOCYTOCHEMISTRY. J.A. Schroer and J.H. Haring. Dept. Anat. & Neurobiol., St. Louis Univ., St. Louis, MO 63104.

Astrocytes possess receptors for 5HT that may have a role in CNS development (Whitaker-Azmitia et al., NY Acad. Sci. 600:315, 1990). A recent *in vitro* study demonstrated the regulation of astrocyte GFAP expression by 5HT (LePrince et al., Dev. Brain Res. 51:295, 1990). The purpose of this study was to determine whether altering hippocampal 5HT innervation would elicit changes in GFAP and S-100 immunocytochemistry.

Adult, male Sprague-Dawley rats received injections of 5,7-DHT (3ug in 20nl saline) or saline alone in the median raphe nucleus (MRN). After 2 or 6 weeks, rats were perfused with 4% paraformaldehyde in PBS and frozen or vibratome sections cut through the hippocampus. Sections were processed for GFAP or S-100 immunocytochemistry and analyzed stereologically using a cycloid test system (Braendgaard & Gundersen, J. Neurosci. Meth. 18:39, 1986). MRN lesions resulted in a significant decrease in hippocampal 5HT content and uptake by 2 weeks followed by a return of these parameters to low normal levels by 6 weeks. At 2 weeks, GFAP expression was significantly higher than normal but S-100 was decreased. These changes were most evident in the hilar region where GFAP increased 62% while S-100 fell to 46% of control. The increase in 5HT at 6 weeks was accompanied by a decrease in GFAP and an increase in S-100. These results are consistent with those of *in vitro* studies. Support: NS25752 and DE07734.

HEME OXYGENASE IS A HEAT SHOCK PROTEIN AND PEST PROTEIN IN RAT ASTROGLIAL CELLS. B.E. Dwyer*, R.N. Nishimura, J. deVellis and T. Yoshida*. Molecular Neurobiology Lab, Sepulveda VAMC, Sepulveda, CA 91343.

The induction and synthesis of heme oxygenase was studied in rat forebrain astrocytes and in spontaneously transformed rat astroglial cells (ATs). Unstimulated astrocytes contained significant amounts of immunostainable heme oxygenase whereas it was undetectable in ATs. Heme oxygenase was inducible in both cell types by heat shock and by submicromolar amounts of H_2O_2 . Increased synthesis correlated with elevated levels of heme oxygenase mRNA suggesting that transcription was a major site of regulation under stress conditions. Inhibition of RNA synthesis with actinomycin D or protein synthesis with cycloheximide resulted in the rapid loss of immunostainable heme oxygenase in astrocytes. Analysis of the primary structure of heme oxygenase suggest that it is a PEST protein, proteins which are targeted for rapid turnover.

KERATINS AND GFAP ARE DIFFERENTIALLY DISTRIBUTED IN THE NEUROEPITHELIUM OF THE EMBRYONIC ZEBRAFISH. R. C. Marcus and S. S. Easter Jr. Dept of Biology, University of Michigan, Ann Arbor, MI 48109.

In the embryonic zebrafish, the early axon tracts develop between 16-18h and enlarge thereafter. Application of oil to the ventricles of embryos between 15-72h reveal that axons traverse a cellular environment containing radial cells that extend from ventricular to sub-pial surfaces of the brain. Last year we reported GFAP expression in a population of these radial cells (SNA 16, 139.6). We now report that a second intermediate filament (IF) type, keratin, is also expressed in radial cells of the neuroepithelium. Frozen sections from unfixed embryos at 30, 38, 48 and 72h were labeled with anti-keratin antibodies (anti bands 3 and 7; Maggs and Scholes, J. Neurosci. 10, 1600). At all time points, radial cells in the hindbrain and spinal cord were labeled in their entirety. Cells located at the ventral midline, in the region of the floorplate, labeled most intensely. By 38h, keratins labeled the optic nerve, consistent with the observation that keratins, and not GFAP, are expressed in the glial cells of the optic nerve of adult fish. Our results demonstrate that IFs define different classes of cells in the embryonic neuroepithelium. SDS page and western blot analysis are underway to further characterize IF expression in these different cell types. Supported by R01-EY-00168 and T32-EY-007022.

INTERLEUKIN-1 β REGULATES PROENKEPHALIN GENE EXPRESSION IN ASTROCYTES IN VITRO. A. Negro, A. Tavella*, L. Facci*, L. Callegaro* and S.D. Skaper#. Advanced Technology Division and #Fidia Research Laboratories - FIDIA S.p.A., 35031 Abano Terme, Italy.

Astrocytes possess receptors for neurotransmitters and neuromodulators functionally coupled with some aspect of intracellular metabolism. Activation of cell surface receptors on astrocytes can also regulate proenkephalin mRNA levels (Melner et al., EMBO J. 9: 791, 1990). Because astroglial cells are biologically responsive to the cytokine interleukin-1 β (IL-1 β), we examined the possible influence of these molecules on the expression of opioid genes in type-I astrocytes cultured from neonatal rat brain. Proenkephalin mRNA expression was enhanced several-fold by IL-1 β in a dose-dependent manner, but not by IL-2, γ -IFN, glutamate or carbachol. IL-1 β also regulated a proenkephalin-chloramphenicol acetyltransferase fusion gene transiently transfected into astrocytes. These effects of IL-1 β were not likely due to a cyclic AMP-inducible DNA element, as IL-1 β not induce the conversion of a stellate astrocyte morphology characteristic of cyclic AMP-elevating agents such as isoproterenol. These results suggest that enhanced proenkephalin gene expression in astrocytes by IL-1 β may be important in neuroimmune interactions and following brain injury.

POSTNATAL ANGIOGENESIS AND MICROGLIAL DIFFERENTIATION IN THE RAT. S.D. Hurley* and W.J. Streit. Dept. of Neuroscience, Univ. Florida, Gainesville, FL 32610.

In the adult rat CNS microglial cells are often seen in close association with small blood vessels, and these are referred to as perivascular microglia. Theoretically, both microglia and endothelial cells are of mesodermal origin, which led us to examine the morphological relationship between endothelial and microglial cells during postnatal development. Blood vessels and microglia were visualized in brain sections using lectin staining. Microglial-endothelial contacts were far more extensive in young animals (P0-P4) than in older ones, and immature microglia demonstrated an intimate association with growing vessels. The immature microglia associated with the developing vasculature generally had ramified processes, however, amoeboid microglia in the corpus callosum were also seen to form close vascular contacts. We saw a positive correlation between the stage of vascularization and the extent of microglial branching in gray matter, i.e. more developed vascular trees were accompanied by highly branched microglial cells making extensive vascular contacts. In contrast, the corpus callosum showed a lesser degree of vascularization, fewer microglia-endothelial associations, and was predominated by amoeboid microglia until P13. Generally, gray matter regions were rapidly populated with large numbers of ramified microglial cells, except for the mitral cell layer in the olfactory bulb. A conspicuous absence of microglia in this zone during the early postnatal stages coincided with a lack of vessels. Our study shows a positive correlation between CNS vascular development and the differentiation of microglia, however, the anatomical evidence argues against a differentiation of blood monocytes into microglia, as we observed microglia in areas where blood vessels were absent.

DISTRIBUTION OF HIGH AFFINITY BINDING SITES FOR [125 I] VASCULAR ENDOTHELIAL CELL GROWTH FACTOR (VEGF) IN DEVELOPING AND ADULT RAT BRAIN AND SPINAL CORD. L.B. Jakeman, N. Ferrara*, J. Winer* and C.A. Altar. Genentech, Inc., South San Francisco, CA 94080

While several factors contribute to the complex regulation of neovascularization in the central nervous system (CNS), many of these factors have several different actions on vascular and non-vascular cells. In contrast, VEGF is a recently described mitogenic growth factor that is specific for vascular endothelial cells *in vitro* and stimulates angiogenesis *in vivo*. To determine if VEGF might play a physiological role in the CNS, the *in vitro* binding of [125 I] VEGF was examined by autoradiography in brain and spinal cord sections from adult and newborn rats.

Biologically active [125 I] VEGF bound to a single class of sites in the adult CNS. The binding was saturable and of high affinity ($K_d = 34.0 \pm 1.0$ pM) and low capacity ($B_{max} = 1.9 - 6.0$ fmol/mg protein). The binding was specific for VEGF, as it was displaced by 75 - 90% with rhVEGF (IC $_{50}$ for 80 pM [125 I]rh VEGF = 59 ± 3 pM) but not with 100 nM PDGF, EGF or basic FGF. In newborn and adult brain, the localization of specific binding sites was consistent with the distribution of large and small vessels. Binding was greater in gray matter regions than in the white matter of the corpus callosum or spinal cord tracts. The binding in adult brain and spinal cord was colocalized with vascular endothelial cells identified by factor-VIII-like immunoreactivity, but no binding was associated with ventricular ependymal cells or choroid epithelia. Although a role for VEGF in the proliferation or repair of vessels of the CNS remains to be determined, these findings strongly suggest that both developing and adult CNS vascular endothelial cells may respond to endogenous or exogenous VEGF.

375.3

EPINEPHRINE AND NOREPINEPHRINE EFFECTS ON SPLEEN LYMPHOCYTE BLAGSTOGENESIS. N. Azad*, N.V. Emanuele*, N. La Paglia*, M.R. Young*, J. W. Crayton and A.M. Lawrence*. Research, Psychiatry (Biological Psychiatry), and Medical Services, Department of Veterans Affairs, Edward Hines Jr. Hospital, Hines, IL 60141; Departments of Medicine, Biochemistry, and Pathology, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153.

Despite considerable interest in the effects of catecholamine systems on immune function, there is little direct evidence on effects of epinephrine (E) or norepinephrine (NE) upon conventional measures of lymphocyte blastogenesis. Spleen lymphocytes from 70-80 day-old male Sprague-Dawley rats were prepared on a histopaque gradient. They were cultured for 72 hrs at a concentration of one million cells per ml. in microtiter wells in sub-optimal concentration of Concanavalin-A (Con-A) and with varying concentrations of epinephrine (10^{-5} M to 10^{-8} M) and norepinephrine (10^{-4} M to 10^{-8} M). At 10^{-5} M, epinephrine enhanced Con-A-stimulated blastogenesis by $64\% \pm 10$. This stimulation was blocked completely by prazosin (10^{-5} M), suggesting a specific α -1 receptor mediated response. In contrast, norepinephrine 10^{-4} M produced a significant inhibition of Con-A-stimulated blastogenesis by $80\% \pm 5.2$. These findings support the role of catecholamines in immune system function particularly at higher concentrations and indicate a direct and differential effect. This work was supported by the Department of Veterans Affairs Medical Research Service, NIH Grant #ROI-DK-39361, and by the Claire and Leonard Tow Foundation.

ISOLATION AND CHARACTERIZATION OF HUMAN FETAL MICROGLIA IN CULTURE. F. Greco, V. Sogos*, S. Torelli*, M. G. Ennas*, A. Meloni*, G. M. Lauro*. Dept. of Cytomorphol., Inst. of Obst. & Gynecol. Medical School, CAGLIARI; Dept. Dev. Cell Biol., ROMA, Italy. We have isolated microglial cells from a culture of a 15-week-old human fetal brain. In brief, cells were dissociated after trypsinization and grown in DMEM + 10% fetal calf serum (FCS) in polylysine-pretreated dishes. After 30 days, cells were frozen in 90% FCS + 10% DMSO in liquid nitrogen. At different intervals, cells were defrosted, cultured as above for 1 week and frozen again. With this method, we obtained cell cultures at different "cell passages". Then, cells were characterized with monoclonal antibodies against the macrophage markers M1 and M5, against Fc receptor for IgG, vimentin, glial-fibrillar-acidic protein (GFA), neurofilaments (NF), galactocerebroside (GC), α -chymotrypsin, α -tryptase, lysozyme, CD4. Different tests for phagocytosis were also used. Results showed positivity for all the markers listed above, except GFA, NF, GC, CD4. Cells could actively proliferate, were stained with fluorescent RCA lectin, had phagocytic activity. Morphologically, they were either round-shaped with thin, long processes or large, flat and firmly attached to the substratum. All these results show the presence of highly purified microglia cultures.

BONE-MARROW CHIMERAS REVEAL AN ORIGIN OF CELLS FOUND IN ADULT MOUSE BRAINS AFTER INJURY, C.M. Morshead and D. van der Kooy. Neurobiology Research Group, Department of Anatomy, University of Toronto, Toronto, Ontario, Canada M5S 1A8

Injury to adult nervous tissue results in a gliotic response which is typified by the accumulation of many darkly staining cells within the tissue near the site of injury. Using an adult mouse model in which kainic acid is injected into the striatum, we see gliosis throughout the ipsilateral forebrain extending from the lateral edge of the lateral ventricle, through the striatum and into the cortex. The response is most pronounced at the kainic acid injection site. We have used this model to ask about the type and origin of the cells that respond to injury. In earlier studies we found that there are two separate populations of cells constituting the response: exogenous blood-borne cells that come into the brain through the broken blood-brain barrier and endogenous glial cells, probably microglia. We were able to manipulate these two populations separately using irradiation to eliminate the bone marrow precursors. This resulted in a selective loss of cells only at the injection site. The gliosis in the surrounding tissue remained unchanged. In order to further test our hypothesis we have made bone-marrow chimeras by injecting bone marrow cells, carrying a B-globin transgene marker, into mice that were lethally irradiated to destroy the endogenous haemopoietic population. Using the same kainic acid model described above, we have found transgenically marked blood-borne cells primarily at the site of the lesion. This supports our hypothesis that some of the large population of cells in the immediate vicinity of brain lesions are haemopoietic cells.

DEGRADATION OF IMMOBILIZED FIBRONECTIN-GELATIN SUBSTRATES BY LPS AND IL-1 STIMULATED MICROGLIA.

J. Kerin*, W.-T. Chen*, W. Monsky*, J. Yao*, C. Colton, and D. Gilbert. Georgetown Univ. Sch. of Med., Washington, DC 20007, and NINDS, NIH, Bethesda, MD 20892.

Microglia share anatomical, biochemical and functional similarity to other tissue macrophages. We examined extracellular matrix degradation under unstimulated and stimulated conditions. A primary culture of microglia was obtained from neonatal rat cerebral cortices. Microglia were plated on immobilized rhodamine-fibronectin-gelatin substrates. After adhering, the microglia were treated with a range of concentrations of lipopolysaccharide (LPS) and interleukin-1 (IL-1) diluted in DMEM. After 48 hours, the cells were stained with trypan blue to identify dead cells and then by the microglia-specific lectin, GS I-FITC. Cells were fixed and studied by light and fluorescent microscopy. Proteolytic activity was assessed by observing the number and size of fluorescent negative areas in the rhodamine-linked fibronectin associated directly with microglia. Our results showed LPS (1.0 ug/ml) treatment, and IL-1 (10.0 U/ml) treatment yielded the highest percentage of fibronectin-degrading cells with 20% and 22% respectively. The percentage of untreated cells degrading was 2%. Thus LPS and IL-1 can stimulate microglia to degrade their extracellular matrix substratum.

375.6

EFFECTS OF BLOCKING PERINEURONAL MICROGLIAL PROLIFERATION FOLLOWING PERIPHERAL AXOTOMY.

M. Svensson and H. Aldskogius*. Karolinska Institutet, Dept. of Anatomy, S-10401 Stockholm, Sweden

Peripheral axotomy causes a number of structural and metabolic changes in the neurons as well as in non-neuronal cells. Axotomized neurons become chromatolytic, lose presynaptic terminals and retract their dendrites. In parallel with these events, microglial cells proliferate and migrate towards the injured neurons and astroglial cells hypertrophy. We have investigated some aspects of the functional significance of the microglial cell response by blocking their proliferation following hypoglossal nerve transection, using intracisternal (cisterna magna) infusion of cytosine-arabioside via a subcutaneous osmotic minipump. The synaptic density on the axotomized motoneurons is reduced to the same level following blockade of the microglial reaction compared to nerve transection in control animals. Glial fibrillary acidic protein-immunoreactivity in astrocytes is not increased following nerve transection in combination with microglial blockade. Axotomy-induced nerve cell death seems to be reduced in the microglial free environment. However, the regeneration and reinnervation capacity of these motoneurons seems unaltered after blocking the microglial cell reaction. These observations suggest that: 1) microglial cells are not crucial for synaptic detachment 2) do not support regeneration 3) astrocytes may be activated by microglial cells 4) microglial cells impair survival capacity of neurons

MACROPHAGE/MICROGLIAL CELLS IN THE XENOPUS VISUAL SYSTEM. I.A. Goodbrand*, M.A. Wilson* and R.M. Gaze. ICAPB, Division of Biological Sciences, Edinburgh University, Edinburgh EH9 3JT, Scotland, U.K.

A proportion of *Xenopus* optic axons regenerate after injury. We have studied the macrophage response to optic nerve injury, using a monoclonal antibody, 5F4. This recognises macrophage/microglial cells. 5F4⁺ cells are phagocytic: they ingest pigment granules from injured melanocytes at the site of the nerve crush and Indian ink introduced through lesions of the brain. These cells appear in large numbers after nerve injury, along the course of degenerating optic axons. Increased 5F4⁺ cell activity is found in the nerve 2h postlesion (PL). The response peaks 3-7 days PL, before the retinotectal projection is restored. Three weeks PL, as the brain response diminishes, 5F4⁺ cells are found deep in the tectum and in some cases seem to pass through the ependyma into the ventricle. Six weeks PL, 5F4⁺ cells have been seen engulfing degenerating retinal ganglion cells. The rapid course of the 5F4⁺ response to optic nerve injury may assist in the production of an environment conducive to axonal regeneration in *Xenopus*.

LAMPREY GLIAL CELLS OF THE BRAIN AND SPINAL CORD CONTAIN KERATIN SE Merrick*, SJ Pleasure, D Pjak*, DI Lurie*, ME Selzer, and VM Y Lee*. Dept of Path and Instit of Neurosci, Univ. of PA, Phila., PA 19104.

The lamprey is exceptional in its capacity to undergo extensive regeneration following spinal cord transection. During this process glial scarring appears not to inhibit axonal regeneration. Since we have been unable to detect a GFAP homologue (a major component of the astroglial scar in mammals) in the lamprey CNS we embarked on studies to identify the intermediate filament (IF) proteins of lamprey glial cells as an initial step to assess the environment of glial cells in regeneration. To this end, monoclonal antibodies (mAbs) were raised to lamprey spinal cord cytoskeletal extracts and these mAbs were characterized using Western blotting and immunocytochemistry. On 2-D Western blots of spinal cord cytoskeletal extracts, five of the mAbs detected three major IF polypeptides in the MW range 45-60 kD. Further studies were conducted to determine the relationship between the lamprey glial specific antigen with other mammalian IF proteins. We found that anti-cytokeratin 8 antibody recognized two of the three polypeptides. In addition several of the glial-specific mAbs reacted with human cytokeratin 8 and 18 on Western blots. The immunocytochemical staining patterns of the glial-specific mAbs were also examined and were found to be indistinguishable on lamprey spinal cord sections. However, on brain sections two distinct patterns were observed. A subset of the mAbs only stained select glial fibers in the brain whereas others stained almost all glial cells in the brain. Interestingly, the former group of mAbs only recognized the two lower MW polypeptides on 2-D Western blots, but the latter group of mAbs recognized all three major IF polypeptides. This correlation is supported by the observation that the highest MW IF polypeptide has an increased level of expression in the brain relative to the spinal cord. Thus, the glial cells of lamprey spinal cord and brain express homologues of simple epithelia cytokeratins, but the brain IF expression pattern may be more complex than the spinal cord.

ISOLATION AND SEQUENCE ANALYSIS OF TWO INTERMEDIATE FILAMENT cDNA CLONES FROM FISH OPTIC NERVE. I Cohen*, Y Shani*, E Blaugrund* and M Schwartz. Department of Neurobiology, The Weizmann Institute of Science, Rehovot 76100, Israel.

The fish central nervous system (CNS), unlike its mammalian counterpart, is endowed with a high capacity of regeneration. This phenomenon has been attributed, at least in part, to the nature of the cells surrounding CNS nerves and their response to injury. Characterization of the structural proteins in nonneuronal cells of intact and injured nerves, might give an insight to their role in regeneration. Our model of choice is the fish optic nerve. In the present study, we isolated cDNA clones encoding fish intermediate filaments. mRNA was isolated from carp (*Cyprinus carpio*) optic nerves and analyzed by Northern blot analysis with a mouse GFAP probe. Two transcripts of approximately 2.1 and 2.3 kb, were found. A λ gt-10 library, prepared from regenerating carp optic nerve mRNA, was screened by the mouse GFAP probe. Sequencing analysis revealed that the 2.1 kb cDNA transcript is the fish vimentin, which shows 91% and 97% homology in the respective rod domain of mouse and chicken vimentin. This high homology emphasizes the evolutionary conservation of intermediate filaments among species. A partial sequence of another clone revealed that the 2.3 kb transcript is identical to fish keratin 8.

The response of non-neuronal cells to optic nerve injury in goldfish. J. Wang, J. Chako*, W. Battisti, T.C. Eckenrode* and M. Murray. Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Goldfish optic nerve axons, unlike mammalian axons, readily regenerate after axotomy. Since a permissive environment provided by non-neuronal cells associated with the optic nerve is likely to contribute to successful regeneration, it is important to characterize their normal distribution and responses to optic nerve crush. The intact optic nerve is composed of fascicles of myelinated axons. Astrocytes, are the dominant non-neuronal cell within the fascicles. Granule-laden macrophages, identified by positive staining with an antibody to complement receptor II (OX-42), are present in large numbers surrounding the nerve and between but never within the fascicles. The goldfish nerve differs from mammalian optic nerves by the presence of this resident macrophage population. Within one hour following optic nerve crush, the activated macrophages show increased immunostaining. Astrocytes also become activated; many astrocyte nuclei acquire complex and tortuous shapes with unusually prominent clumping of chromatin. Within the first week, some astrocytes have become phagocytic, while others are associated with regenerating axons. Macrophages retain an interfascicular location but are now increased in number. The early (1hr.) activation of both macrophages and astrocytes following optic nerve crush is likely to be associated with the changes in synthesis of secreted molecules which has been shown to accompany the regenerative process in goldfish optic nerve. DEVELOPMENT AND REGENERATION OF MOTOR SYSTEMS I

376.1

CALCIUM BINDING PROTEINS ARE NOT INVOLVED IN NEUROGENESIS IN THE AVIAN SONG SYSTEM

W. Zuscatter*, B. Hose and H. Scheich. Inst. of Zoology, Technical University Darmstadt, Darmstadt, FRG

Telencephalic nuclei of the vocal motor system of song birds show synaptic plasticity during vocal learning (Rausch and Scheich, 1982). One specific aspect of the functional organization of this system is the abundance of neurons containing the calcium-binding proteins parvalbumin and calbindin. Such neurons in the song system of zebra finches, are characterized by a high metabolic and electrical activity (Braun et al. 1985) and partly overlap with GABAergic neurons (Zuscatter et al., 1987). In the present study we investigated the relationship between these calcium-controlled neurons and neurogenesis, which was observed in vocal motor nuclei during the critical period of song learning (Alvarez-Buylla et al. 1988; Nordeen and Nordeen 1990). Zebra finches of different ages (20-30/40-50/50-60/adult) were injected with 3 H-thymidine for 10 days. Birds were sacrificed as adults and vibratome sections of the brains were treated immunocytochemically with antisera against parvalbumin and calbindin D28K and afterwards processed for autoradiography. Although we found a good correlation between the sensitive phase of song learning and cell mitosis in all telencephalic vocal motor nuclei, immuno-positive neurons did not show any 3 H-thymidine reaction product.

These results indicate that parvalbumin-IR and calbindin-IR neurons are born early in ontogenesis and represent stable elements within the plastic song system.

DEVELOPMENT OF THE NIGRO-TECTAL PATHWAY IN THE RAT: A TRACING WITH A FLUORESCENT CARBOCYANINE DYE. Thomas J. Mahalik and Andrew Carrier. U. of Colo. Health Sci. Ctr. Denver, Colorado 80262.

Neurons in both the zona reticulata and the zona compacta are mostly born between fetal day 14 and fetal day 16. The nigral dopaminergic neurons begin to send their axons to the caudate nucleus shortly after they arrive in the zona compacta. Little is known however, about the development of the pathway between the neurons in the zona reticulata, and the tectum. The purpose of the present study was to chart the development of the nigro-tectal pathway with the carbocyanine dye, DiI.

Fetuses were obtained at embryonic days E13, E14, E15, E18 and E19. Fetuses were emersion fixed in 4% paraformaldehyde and DiI crystals were applied either to the tectal plate, or to the ventral mesencephalon, and then were incubated in 4% paraformaldehyde for 10 to 30 days. The brains were sectioned in the sagittal plane on a cryostat. When DiI was applied to the tectum, retrogradely labeled ventral mesencephalic cell bodies were present as early as E15. No retrogradely labeled cells were present in the VM of E13 fetuses. In older fetuses, retrograde labeling of VM cell bodies after tectal application of DiI was even more robust.

UNILATERAL PERINATAL HYPOXIC-ISCHEMIC STRIATAL INJURY IN RAT RESULTS IN A DECREASED NUMBER OF IPSILATERAL NIGRAL DOPAMINERGIC NEURONS. *RE Burke and N Kenyon**. Department of Neurology, Columbia University, NY, NY, 10032.

The striatum is relatively vulnerable to hypoxic-ischemic (H-I) injury during development, and yet little is known of the lasting alterations in its neurochemical anatomy. In a unilateral rodent model, we and others have shown that biochemical and morphological markers of striatal dopaminergic (DA) fibers are preserved, consistent with the hypothesis of an excitotoxic, axon-sparing lesion. However, there has been no study of effects on the development of DA neuron cell bodies in the substantia nigra (SN). We have studied these neurons by using the immunoperoxidase technique for tyrosine hydroxylase (TH), and counting neurons in serial sections. We find that unilateral striatal H-I injury results in a significant decrease in the number of TH-positive SN neurons (Experimental(E): 598±27; Control(C)(contralateral SN): 696±12; $p = .003$, $N=8$). Nissl and immunoperoxidase staining for glial fibrillary acidic protein on adjacent SN sections excluded direct H-I injury to the nigral area. There was no difference in the number of neurons between E and C sides in animals subjected to H-I but without striatal injury, nor between right and left of Normals. In the rostro-caudal dimension, neuron loss was greatest anteriorly in Paxinos-Watson plane 4.2, where it was 30%. Neuron loss was also marked in the ventral tier of SN TH-positive neurons; those in SN reticulata were reduced by 50%. This neuron loss may be indirectly due to striatal injury, by loss of trophic support from that nucleus. NINDS NS26836, United Cerebral Palsy, Parkinson's Disease Foundation.

MYELINATED AXONS IN MUSCLE NERVES ARE UNAFFECTED BY CHANGES INDUCED IN THE MUSCLE BY TENECTOMY. *B. A. Dirks** and *M. E. DeSantis*. Univ. of Washington School of Medicine, Seattle, WA.

A piece of the triceps surae tendon was resected (tenectomy) unilaterally in rats. Nerve branches to the lateral head of the gastrocnemius and soleus (LG-S) and the medial head of the gastrocnemius (MG) muscles were examined to see whether tenectomy influenced the number and size of myelinated nerve fibers which innervated those muscles. Analysis of variance tests were done on the following variables for myelinated fibers: total number, proportion of fibers of small diameter, and mean diameters and standard deviations for the groups of smaller and larger fibers. In one group of rats, the nerve to muscle remained intact, and tenectomy was produced at various postnatal ages (6-70 days) when myelination of axons was in progress. Examination of their nerves, 7 to 18 weeks later revealed no statistically significant differences for nerve fibers when tenectomized and the sham-operated nerves were compared. The 6 day old operated rats showed a slight shift, consistent for both muscle nerves, toward smaller diameters for those myelinated fibers innervating tenectomized muscle. In a second paradigm, regenerated fibers were examined 18 weeks after tenectomy and axonotomesis had been done in adult rats. There were no statistically significant differences in the number or any of the size variables of remyelinated fibers when comparing the experimental (tenectomy and axonotomesis) and control (axonotomesis only) nerves. We conclude that tenectomy of a rodent's hind limb muscles after the first postnatal week exerted no adverse effect on the process of myelination of axons which innervate the altered peripheral target tissue.

REFLEX RECRUITMENT IN SELF-REINNERVATED MEDIAL GASTROCNEMIUS OF THE DECEREBRATE CAT. *T. C. Cope* and *B. D. Clark*. Dept. Physiol & Biophys, Hahnemann Univ., Phila. PA 19102

It is unclear how recruitment is organized following the reconstitution of motor units after nerve section. Pairwise analyses of motor unit properties and recruitment were performed as described by Clark and Cope (1990; Neurosci Abstr. 16: 888) on 5 cats whose medial gastrocnemius (MG) nerve had been cut and resutured >18 mos. previously. Only 4 out of 113 tested units could be recruited by MG stretch. In tests of 63 pairs of units recruited using electrical stimulation of the caudal cutaneous sural (CCS) nerve, the size principle correctly predicted recruitment order of units ranked by conduction velocity (CV; 36/52 pairs), maximum isometric force (48/62 pairs) and twitch contraction time (35/40 pairs). These frequencies are not significantly different from control pairs recruited with CCS stimulation or MG stretch (G-test of independence), except for CV, which was significantly lower than control recruitment by stretch. In an additional cat whose MG nerve was crushed, not cut, both stretch and CCS nerve stimulation recruited motor units consistent with the size principle at frequencies approaching controls. We conclude that following self-reinnervation, the size principle of recruitment still holds. (Supported by NIH NS21023)

376.4

REINNERVATION OF RAT TIBIALIS ANTERIOR MUSCLE BY TIBIAL NERVE AFTER PROLONGED DENERVATION OR AXOTOMY. *S. Fu** and *T. Gordon*. Dept. of Pharmacology, Division of Neuroscience, University of Alberta, Edmonton, Alberta, Canada, T6G 2S2.

To determine the role of intramuscular nerve sheaths in the success of nerve regeneration and muscle reinnervation, we sutured the axotomized tibial nerve (TiBn) to the distal stump of the cut common peroneal nerve (CPn, nerve-nerve; n-n) or to the denervated tibialis anterior (TA) muscle (nerve-muscle; n-m) and determined the number and size of motor units (MUs) in the reinnervated TA 6 months later. In addition, we investigated whether prolonged axotomy, or denervation, influences reinnervation by delaying the suture of TiBn to the CPn, or TA muscle, respectively, for 2-6 weeks. Muscles showed an average of 60% recovery of force after n-n and 10% after n-m suture, irrespective of the time of axotomy or denervation. Correspondingly, there was a larger number of MUs in the former muscles, 88 ± 6.4 (S.E.M.) compared to 11 ± 3.1 after n-m suture. Analysis of glycogen depleted MUs showed that the number of fibers increased up to 3 times after n-m suture permitting more muscle recovery than predicted from the number of MUs, but this was inadequate to compensate for poor regeneration. Spatial analysis and examination of intramuscular nerve branches (Ag/ChE stain) indicates that proximal branching of regenerating nerves is considerably less extensive after n-m suture. These data indicate 1) that intramuscular nerve sheaths provide a permissive environment for nerve regeneration as evident from the larger number of reinnervated MUs and more extensive proximal branching after n-n compared to n-m suture, however 2) since MUs increase in size (n-m), the muscle surface can support terminal branching and 3) prolonging axotomy and denervation does not alter the success of reinnervation. Supported by MRC and MDAC.

376.6

HINDLIMB SUSPENSION FOR SHORT PERIODS IMPAIRS MOTOR DEVELOPMENT IN NEONATAL RATS. *Kerry D. Walton, Daniel Lieberman, Mathew Begin and Rodolfo R. Llinás*, Dept. of Physiology & Biophysics, NYU Medical Center, 550 First Ave., New York, NY 10016

We have identified a 5-day "critical period" for motor development, P 8 to P 13 (Walton et al, IBRO abst., 1991). The motor system of neonatal rats was perturbed by unloading the hindlimbs (HL) via suspension of the pups by their tails for 20 hrs each day. Suspension was implemented from P2 to P7 (n=5), from P8 to P13 (n=6) or from P14-P19 (n=3). Swimming was used to measure motor development at all ages since a) it is present at birth, b) can be quantified, and c) does not stress antigravity over other muscles. A motion analysis program was used to determine HL joint angles during walking from P13. Suspended and littermate (LM) pups were videotaped daily from P2 to P21 and again at 2-5 months. Suspended animals were clearly distinguished from LMs. In every way (time spent swimming, speed, balance, stroke phase, and "style") swimming in the P8 to P13 suspended pups were significantly more impaired than the P2 to P7 and P14-19 group. S pups walked slower than LM and walked on their toes. During the stance phase on P13 the ankle joint subtended an angle of 180 to 160° in S pups compared to 180 to 100° in LMs. Recovery began immediately post-suspension, joint angle values approaching controls after 6 days. After 5 months S animals were still clearly distinguished from LM. Similar deficits were not seen in animals suspended P2-P7 or P14-19. Animals suspended for only a 20-24 hour period between P8-13 also showed significant deficits in balance, swimming and locomotion. Our results suggest that P8 to P13 is a critical period for motor development. However, the motor system is more adaptable than sensory systems. These data indicate that lack of the appropriate use (including both motor and sensory aspects) of hindlimb and back musculature for even 20 hours during a 5-day period critical period severely impairs motor development and that the resulting deficit is largely, but not completely compensated. Supported by NASA and The Hirsch Trust.

376.8

INTRA- AND INTERLIMB COORDINATION DURING MOTILITY IN CHICK EMBRYOS. *S.H. Chambers and N.S. Bradley*. School of Physical and Occupational Therapy, McGill Univ., Montreal, PQ, Canada H3G 1Y5.

Recent studies indicate coordinated movement can occur early in development, but these studies also identify considerable variability during spontaneous motility. We are now exploring the characteristics of this variability as a means to better understand the development of motor control in the chick. Here we report preliminary kinematic data on synchronous wing and leg movements *in ovo* at embryonic day 9.

The entire portion of continuous movement (33-42s) for each of 3 episodes (100-200s in duration) were video recorded and computer analyzed (sample rate 30Hz) to obtain joint excursions for the shoulder, elbow, hip and knee. Linear trend analyses suggest that elbow flexion/extension is closely timed with shoulder extension/flexion ($r^2=0.7$) over 8-9 consecutive cycles. Hip flexion/extension is closely timed with knee flexion/extension ($r^2=0.7$) over 6 consecutive cycles. While wing and leg movements begin and end coincidentally, cycle periods for the wing are typically shorter (3s) than for the leg (4s) and coincident timing of wing/leg cycles was found only briefly in each episode.

Initial analyses suggest that intralimb coordination is relatively reliable over an episode of spontaneous motility but that interlimb coordination may either be unstable, more complex than a simple 1:1 correspondence, or limited to chance. Further analyses will examine these possibilities. This work was supported by the McGill Faculties of Medicine and Graduate Studies, FCAR and NSERC.

DEVELOPMENT OF L-DOPA-INDUCED AIR-STEPPING IN PREWEANLING RATS: COORDINATION WITHIN AND BETWEEN LIMBS.

D.J. Stehouwer, A.E. Sickles* and C. Van Hartesveldt. Dept. of Psychology, University of Florida, Gainesville, FL 32611.

Coordination of air-stepping elicited by subcutaneous injections of L-DOPA (25 to 100 mg/kg) was studied in rats from the day of birth through 20 days of age. Results revealed a nearly linear increase in the rate of stepping from about 1.5 steps/sec at day 0 to nearly 5 steps/sec at day 20, independent of dose of L-DOPA. This increase was found to result from decreases in the duration of both retraction and protraction phases of the step cycle, but the decrease in the retraction phase was greater. The duration of retraction dropped from 60% of the step cycle on day 0 to about 45% on day 15. There was an ontogenetic increase in the amplitude of movement at the wrist, knee, and ankle joints, a slight decline in the amplitude of movement at the elbow, and little change in amplitude at either the shoulder or hip. The timing of movements at joints within each limb also changed with age. The shoulder increasingly led forelimb movements throughout development, followed by the elbow and then the wrist. Hindlimb movements were led by the hip, followed by the ankle and finally the knee, which increasingly lagged behind the other two joints of the hindlimb. At all ages, diagonal limbs moved in phase with each other and in antiphase with the contralateral limb of the same girdle during diagonal progression. However, other gaits became more prevalent between 10 and 20 days of age.

MODULATION OF LOCOMOTION THROUGH A PERIPHERAL NERVE GRAFT ACROSS A COMPLETE CHRONIC SPINAL CORD TRANSECTION IN THE ADULT RAT. N.B. Reese, E. Garcia-Rill, J.D. Houle and R.D. Skinner. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, Arkansas.

Stimulation of the mesencephalic locomotor region (MLR) in the decerebrate rat has been found to induce controlled, four-limb locomotion. This preparation was employed on rats which had received a spinal cord transection and had the spinal cord reconnected by a peripheral nerve autograft (PNG). Testing 2-3 months later showed that MLR stimulation induced forelimb but not hindlimb stepping. However, in 4/6 cases, tail pinch interrupted MLR stimulation-induced forelimb alternation, while pinna pinch, a) interrupted MLR stimulation-induced forelimb alternation, and b) induced EMG changes in hindlimb muscles. These effects disappeared once the PNG was cut. Labeling of the cut mid portion of the PNGs using DII revealed significant numbers of labeled axons entering the spinal cord through both ends of the PNG in those animals which showed the above effects. These results suggest that non-specific information which can modulate locomotion may be flowing through some PNGs across a complete, chronic spinal cord transection in the adult rat.

Corticospinal Plasticity Following Neonatal Hemipyramidotomy B.R. Clark¹, E. Theriault², and D.L. Tolbert³. Program in Physical Therapy, Sch. of Medicine, Washington Univ. St. Louis, MO¹, Depts. of Surgery (Neurosurgery) and Pediatrics, Playfair Neuroscience Unit, Univ. Toronto. Toronto, Ontario², Depts. Anatomy and Neurobiology and Surgery (Neurosurgery), Sch. of Medicine, St. Louis Univ., St. Louis, MO³.

The development of corticospinal (CS) projections in cats is characterized by the temporally protracted postnatal growth of CS axons into the spinal cord and bilateral terminations in the intermediate gray that subsequently become refined to an adult-like, mainly contralateral input by seven postnatal weeks. We have shown previously that early neonatal pyramidotomy causes redirected growth of ipsilateral late developing CS axons along aberrant pathways. We now report on the development and maturation of CS projections from the cortex opposite the lesion. Partial deafferentation of CS input to one side of the spinal intermediate gray results in the persistence of normally transient CS projections from the contralateral side. Densitometric image analysis suggests that WGA-HRP labeled CS input from the primary sensorimotor area of the opposite hemisphere is equivalent in the intermediate gray bilaterally in the cervical and lumbar enlargements. These data indicate that neonatal unilateral pyramidotomy induces the persistence of normally transient CS projections. Supported by NIH grant NS 20227 and the Canadian Paraplegic Association.

POSTNATAL DEVELOPMENT OF SYNAPTIC RESPONSES, MEMBRANE PROPERTIES AND MORPHOLOGY OF RAT NEOSTRIATAL NEURONS *IN VIVO* F. Trent and J.M. Tepper. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ, USA 07102.

In vivo intracellular recordings from neostriatal (NS) neurons were obtained in urethane-anesthetized Sprague-Dawley rat pups from birth (PD1) to PD40 and in adult males using biocytin-filled micropipettes. Most NS neurons <PD11 were not spontaneously active, but even in the youngest animals, cortical stimulation elicited an initial EPSP whose mean onset latency significantly decreased with postnatal development, but whose maximum amplitude and duration were similar to those observed in adults. In some cases cortical stimulation evoked an initial IPSP that decayed within 1-3 minutes to reveal the usual initial EPSP. Virtually all of the NS neurons recorded in neonates <PD20 failed to show the long-lasting disfacilitation succeeding the initial EPSP as well as the late rebound excitation characteristic of adult NS neurons. The fast anomalous rectification seen in mature NS neurons was almost always absent in neonates <PD11, and the proportion of anomalously rectifying neurons increased with age through PD30-40. The above differences in synaptic and membrane properties between neonatal and adult NS neurons are similar to those recently reported for fetal neostriatal neurons grafted to the kainate-lesioned neostriatum (Xu et al., *J. Neurophys.* 65:477, 1991) suggesting that the tonic excitatory input exerted by cortical afferents may be decreased or absent in neonates and contribute in part to the observed differences. Examination of filled NS neurons revealed almost all of them to be medium spiny cells as indicated by somatic and axonal morphology although the density of dendritic spines was greatly reduced and did not attain adult levels until the end of the 4th postnatal week. Local axon collaterals were present in the youngest labeled neurons examined (PD11) which failed to show the long-lasting disfacilitation succeeding the cortically-evoked EPSP. These observations suggest that NS neurons undergo a prolonged postnatal maturation *in vivo* but precede that of the cortex as indicated by the temporal disparity in the development of anomalous rectification and the later appearance of cortically-evoked disfacilitation. Supported by MH45286 and Rutgers University Research Council.

DEVELOPMENT AND REGENERATION OF MOTOR SYSTEMS II

377.1

EMERGENT CONTROL OF MANUAL AND VOCAL-MOTOR ACTIVITY IN REFERENCE TO HUMAN LANGUAGE. J. L. Locke, K. E. Bekken*, D. Wein* and L. McMinn-Larson*. Neurolinguistics Lab., Mass. Gen. Hosp., BOSTON, MA 02108

Vocal control is essential to development of spoken language. Typically, command centers in the left cerebral hemisphere are primarily responsible for speech. We report studies of human infants' development and control of vocal behavior in relation to manual activity under differing conditions of audibility. Sixty normally developing infants in equal numbers were seen prior to onset of canonical syllable production and at two intervals following onset of babbling. In experimental trials, audible or inaudible rattles were placed in left or right hands equally often. Analysis of manual activity revealed that audibility enhanced duration and stereotypy of right-handed activity in the youngest and vocally least developed subjects. The magnitude of this dextral effect declined significantly with age and vocal experience. These and other results suggest that the left cerebral hemisphere is initially dominant for audible hand activity, then relinquishes this control with the emergence of a species-specific maturational program according to which the left hemisphere assumes command of audible vocal activity several months prior to the demonstrable onset of spoken language.

377.2

TEMPORAL PATTERNS OF VARIABILITY IN TRAJECTORY, VELOCITY, AND ACCELERATION OF MOVEMENT.

S.R. Gutman*, G.L. Gottlieb, M.L. Latash. Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612

Standard deviations (SD) of angle, velocity, and acceleration of reaching movement demonstrate non-monotonic time profiles which differ in the number of maxima. The angle SD has one maximum, while the velocity and acceleration SDs show two and three peaks respectively (assuming movements without overshoots). We suggest an explanation for these findings based on random modulation of an "inner" time scale used by the motor control system for planning the movement. In the general case, SD for any kinematic variable $f(t)$ can be expressed as

$$SD(f(t)) \sim \ln f(\zeta(t)) SD(\zeta),$$

where $SD(\zeta)$ is the standard deviation of time scale factor ζ .

This leads to the following general properties of the time profile of $SD(f(t))$:

- 1) it has the same number of extrema as the derivative of $f(t)$;
- 2) these extrema are shifted to the right along the time axis.

The presence of other sources of movement variability will distort this form of $SD(t)$. It was found that the formula satisfies $SD(t)$ for reaching movements. A particular case of the general expression for $SD(t)$ was investigated with a help of kinematic model of reaching movement with an exponential trajectory (S.Gutman, G.Gottlieb (1990), Abstr. of 1st World Congr. of Biomech., v.1, p.190):

$$x(t) = D(1 - \exp(-t^2/\tau_{mov})),$$

where D is the movement distance, τ_{mov} is the movement inner time constant. The patterns of SD functions for trajectory, velocity, and acceleration demonstrate a close resemblance to the experimentally observed patterns.

The study was supported by NIH grants AR 33189 and NS 15630.

377.3

MOVEMENTS OF NEONATAL RATS: RANDOM OR ANTECEDENTS? C.R. Almlı and E.A. Strauss*. Develop. Neuropsychobiol. Lab., Washington University Medical School, St. Louis, MO 63110.

Cyclic motility patterns are ubiquitous for embryos of a variety of species, and they persist for some unknown time even after birth in rats and humans. The role played by this type of motility pattern in behavioral ontogeny is not understood, i.e., movements displayed may be random or they may be antecedents of species-specific behaviors. Neonatal rats were studied to determine if movements were random or patterned.

Newborn rats were video-taped and movements of individual body segments and "complex" movements were scored with computer during "bursts" of activity.

Results indicate that movements displayed by neonatal rats during cyclic motility may have both random (i.e., movements showed no obvious inter-relations) and antecedent (i.e., movements appear homotypical with later behaviors) components. (Conducted under NIH Guide for Care and Use of Laboratory Animals).

377.5

MOTOR BEHAVIOR IN DEVELOPING GRAY SHORT-TAILED OPOSSUMS: THE EFFECTS OF TEMPERATURE. Barbara H. Fadem, Hector O. Cordero*, Alex M. Mercado*, Jeffrey C. Pan* and Scott R. Robinson*, Department of Psychiatry, UMDNJ-New Jersey Med. School, Newark 07103 and SUNY at Binghamton, NY 13902.

Gray short-tailed opossums are useful models for studying fetal behavior since they are born at a stage neurally equivalent to gestational day 14 in rats. Neural development does not reach the level seen in newborn rats until about postnatal day (pd) 16 ("pseudobirth"). In this study, motor behavior in gray opossums was observed on the day of birth and at selected ages over the first month of postnatal life at three different environmental temperatures. It was found that frequency of forelimb movements was highest in the "prenatal" age group (pd 4-8), while curling trunk movements occurred most frequently at the age of pseudobirth (pd 12-16). Hindlimb movements first occurred between pd 12 and pd 16. Significantly more head, forelimb and curling movements were seen at the lowest temperature (25°C) than at either of the higher temperatures (37°C and 45°C); this temperature effect was more pronounced in younger animals.

These findings are discussed with respect to the ectothermic nature of the newborn marsupial and intrinsic vs. extrinsic control of fetal motor behavior.

Supported by NSF (BNS 8919601) and March of Dimes Birth Defects Foundation Basic Research Grant 1-1240 to B.H.F.

377.7

DEVELOPMENT OF NEURONAL NETWORKS IN THE LOBSTER STOMATO-GASTRIC NERVOUS SYSTEM. B. Casasnovas*, J. Cournil, P. Meyrand* and M. Moulins. Lab. de Neurobiologie et Physiologie Comparées, Univ. de Bordeaux, CNRS, Arcachon, 3312 FRANCE.

The stomatogastric nervous system (STNS) of adult Crustacea contains several neuronal networks which are now well known in terms of synaptic wiring and cellular properties. They, therefore, constitute a very good model for the study of the ontogeny of rhythm generation of the central nervous system.

Using histological and electrophysiological techniques, we have studied the embryonic development of the stomatogastric ganglion (STG) of the STNS in the lobster (*Homarus gammarus*). According to the percentage scale (fertilization 0%; hatching 100%) of Hulley & Beltz (in: *frontiers in crustacean neurobiology*, 1990), we find that the STG is morphologically developed very early, at 20% development. It contains 24-26 neurons, the main nerves are already established at this stage, and the stomodeal muscles are innervated by STG motoneurons. Moreover, the ganglion spontaneously displays a single rhythmic motor pattern which controls movement of the entire stomodeum. In contrast to the adult animal, not one of the individual STG neurons we have studied displayed intrinsic oscillatory properties; rather the embryonic motor pattern appears to be organized via an excitatory synaptic drive. An immunohistochemical investigation has shown that aminergic (Dopamine and Serotonin) STG inputs known in the adult STNS are not yet present in the embryo, while several peptidergic inputs (FMRFamide, Proctolin) are detectable. The role of these inputs in the ontogeny of the STG neuronal networks is being investigated.

377.4

THE ORIGINS OF SUPRASPINAL PROJECTIONS TO LUMBAR AND CERVICAL LEVELS OF THE SPINAL CORD AT DIFFERENT STAGES OF DEVELOPMENT IN THE GRAY SHORT-TAILED BRAZILIAN OPOSSUM, *MONODELPHIS DOMESTICA*. X.M. Wang*, X.M. Xu and G.F. Martin. Dept. of Cell Biol., Neurobiol. and Anat., The Ohio State Univ., Columbus, OH 43210.

We have employed the retrograde transport of Fast Blue (FB) to study the origins of supraspinal projections to lumbar and cervical levels of the spinal cord at different stages of development in the Brazilian short-tailed opossum, *Monodelphis domestica*. *Monodelphis* was chosen for study because its young are born in a very immature stage, 15 days after conception. When injections were made into the lumbar cord at postnatal day (PD) 1, brainstem neurons were most intensely labeled within the reticular formation of the pons and the presumptive coeruleus complex. Neurons were also labeled in the bulbar reticular formation and the vestibular nuclei, however. By PD 2, additional labeling was present within the caudal raphe and, by PD 3, within the interstitial nucleus of Cajal as well as the spinal and mesencephalic trigeminal nuclei. The red nucleus and hypothalamus were not labeled with certainty until PD 5. By PD 10, labeled neurons were present in most of the brainstem areas labeled by comparable injections in adult animals. By at least PD 7, cervical injections of FB labeled neurons in all hypothalamic and brainstem areas labeled by lumbar injections and by PD 15-17 additional labeling was present within the neocortex, the amygdala, the superior colliculus and the deep cerebellar nuclei. The growth of supraspinal axons into the spinal cord of *Monodelphis* follows the same general sequence as in the North American opossum, *Didelphis virginiana*, but specifics of the developmental time table are different. (Supported by NS-25095 and NS-10165).

377.6

THE ONTOGENIC DEVELOPMENT OF LOCOMOTOR BEHAVIORS IN THE OPOSSUM, *MONODELPHIS DOMESTICA*. A COMPARISON WITH OTHER MAMMALS. G. Cassidy, J.-F. Pflieger* and T. Cabana. Dépt. de Sciences biologiques, Université de Montréal, C.P. 6128, Succ. "A", Montréal, Canada, H3C 3J7.

The Brazilian opossum *Monodelphis domestica* is born in a more immature state than placental mammals. At birth, the forelimbs (FL) are capable of alternate, rhythmic movements which enable the newborn to climb on the mother's belly and reach a nipple. The hindlimbs (HL) are merely more developed than buds. The development of locomotor behaviors was studied in the opossum from birth until 37 days postnatal (PND), when locomotion resembles the adult pattern. The FL segments and joints are clearly visible at birth but all those of the HL do not externally appear well formed until about PND 15. The FL begin to support weight at about PND 13 and the HL a few days later. Pivoting is first observed at PND 15 and forward progression on a surface at about PND 20, but FL and HL movements are not well coordinated. Full support of the body weight is observed at about PND 33 and the mature locomotor pattern is attained a few days later. Mature quadrupedal locomotion follows the appearance of a number of sensorimotor reflexes such as grasp, body righting on a surface and forward hopping (Cassidy et al, Soc. Neurosci. 1990). These observations on the opossum are compared with our observations on the Mongolian gerbil (Cassidy et al, IBRO 1991) and those of others on the rat and the cat.

377.8

GENERATION OF RESPIRATORY AND LOCOMOTOR PATTERNS BY FETAL RAT BRAIN STEM SPINAL-CORD PREPARATION. J.L. Greer, J.C. Smith & J.L. Feldman. Systems Neurobiology Laboratory, Department of Kinesiology, UCLA, Los Angeles, CA 90024-1527.

The *in vitro* neonatal brain stem-spinal cord preparation is a powerful model for studying the neural mechanisms generating respiratory and locomotor patterns. We have now isolated the brain stem-spinal cord from fetal rats and begun to study developmental processes in these motor pattern generating networks. Fetal rats (E14-E21) were removed via cesarian section and the brain stem-spinal cords isolated and maintained *in vitro* in oxygenated mock cerebral spinal fluid solution. In some preparations, the ribcage or hindlimbs were left attached for EMG recordings of respiratory and locomotor activity, respectively. Cranial nerve (IX, X, XII) and spinal ventral root (C1-C6, T1-T5, L1-L5) activities were recorded with suction electrodes. Brain stem respiratory neurons located in the ventrolateral medulla were recorded with extracellular electrodes. Cranial, spinal motoneurons and afferent fibers were labelled *in vitro* with HRP in fetuses at different stages of development.

Fetal brain stem-spinal cord preparations generate rhythmic respiratory motoneuron and medullary neuron activity beginning early in the last trimester (E14), before complete morphological development of the motoneurons. Rhythmic limb motoneuron activity can be chemically activated (dopamine, NMDA or acetylcholine) in the fetal spinal cord as well as the isolated hemisectioned cervical and lumbar segments. Coordinated locomotor patterns were generated by late in the last trimester. With the brain stem intact, the respiratory and locomotor rhythmic activity can show synchronization. These results suggest that major components of the respiratory and locomotor pattern generating circuitry are assembled and functional in the last trimester. Supported by American Lung Association, NIH grants HL40959, HL02204, & NS27941.

377.9

SLICE CULTURES OF EARLY POSTNATAL RAT SPINAL CORD
J. Zimmer. PharmaBiotec, Institute of Neurobiology, University of Aarhus, DK-8000 Aarhus C, Denmark.

Early postnatal (P0-P4) rat spinal cord was removed in toto, cut in transverse 300 μ m thick slices and grown as slice cultures ad modum Gähwiler, either alone or in cocultures with slices of corresponding postnatal hippocampal tissue. After 3-6 weeks the slice cultures were stained histochemically for acetylcholinesterase (AChE) to visualize cholinergic fibers, or immunocytochemically for calcitonin gene related peptide (CGRP).

The spinal cord tissue survived well both in single culture and in coculture. Two types of outgrowing AChE-positive fibers were observed. One fiber type, observed in virtually all cultures, displayed irregular branching and fasciculating patterns, but a fairly limited extension onto the coverslip except when innervating adjacent hippocampal tissue. The other type of AChE-positive fibers was found in a subpopulation of cultures containing large motoneuron-like, AChE-positive cell bodies. These fibers grew for long distances on the coverslips with characteristic sharp bends and narrow loops, with little branching. They also entered the hippocampal slices, but without apparent preference for these. In parallel sets of cultures, large motoneuron-like cell bodies and fibers with a distribution similar to the last type of AChE-positive fibers were found to be CGRP-immunoreactive. CGRP-immunoreactive, extensively growing fibers arising from large cells were also found in a few cultures containing what appeared as mistakenly included dorsal root ganglion cells.

Further studies of spinal cord slice cultures, including human fetal tissue, may help establish a test system for spinal cord injury and repair.

377.11

EARLY STAGES IN THE DEVELOPMENT OF MOTOR NEURONS

A.Y. Chiu and E. Chen* Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

In order to identify early events in the differentiation of motor neurons, the expression of several developmentally regulated, neuronal molecules was investigated by immunohistochemistry on consecutive sections of cervical spinal cord. Within the embryonic rat spinal cord, motor neurons undergo their terminal mitosis on embryonic days 10 and 11 (E10 - E11), and acquire detectable levels of choline acetyltransferase (CHAT), by E11.5 (Phelps *et al.*, *J. Comp. Neurol.* 273:459). Staining with antibodies to the intermediate-size neurofilament protein revealed motor neurons extending processes out the ventral root as early as E10.5. Monoclonal antibodies to two epitopes on the cell adhesive molecule, NCAM, bound to myotomes on E10.5, and began to recognize motor neurons by E11. Two other markers of developing neurons, the growth-associated protein, GAP-43, and the surface glycoprotein, TAG-1, were also detected on young motor neurons by E11.5. Thus, within one and a half days after their final mitosis, motor neurons have acquired a number of cytoskeletal, enzymatic and cell surface components that distinguish them from other developing cells within the spinal cord. Not all of the newly acquired molecules continue to be expressed by motor neurons. E12.5 motor neurons lost immunoreactivity for TAG-1, followed a gradual reduction of NCAM and GAP-43 epitopes a day later. By E16, only neurofilament and ChAT immunoreactivity (Phelps *et al.*, *J. Comp. Neurol.* 307:1) persisted in motor neurons within the embryonic spinal cord. The transient expression of NCAM, GAP-43 and TAG-1 epitopes coincides with the period of vigorous axonal growth, and declines when motor neurons reach their targets. Loss of these antigens may signal the onset of synapse formation and a new phase in the differentiation of motor neurons. *This work was supported by HD26810 and NS18858.*

377.13

SELECTIVE DEATH OF AXIAL MUSCLE PRIMORDIA

K.W. Tosney. Biol. Dept., Univ. of Michigan, Ann Arbor, 48109.

I have discovered that the primordia of lateral body wall muscles are initially present in each segment of the chick embryo but have different, segment-specific fates. In thoracic segments, these primordia become mature at the lateral edge of the dermatomyotome by exhibiting three changes during stages 21-23. First the dermatome cells surround the lateral edges of the myotomes, then the number of myotubes increases, and then the primordia invade the lateral body wall. In contrast, in limb segments, the dermatome cells die and are phagocytosed during stages 21-23; when the dermatome cells die, the myotubes do not increase in number and the primordia do not undergo further morphogenesis. Because the death of the dermatome cells in limb segments curtails the addition of myotubes and maturation of the primordia, I suggest that the dermatome cells rather than the myotome cells are primarily responsible for the patterned development of axial muscle primordia.

What interactions control the differential fate of these primordia in thoracic and limb segments? Two embryonic surgeries identify interactions that can alter the segment-specific survival or death of the dermatome cells. When the proximal portion of a limb is deleted, the dermatome cells do not die; instead, they surround the myotome and myotubes increase in number. In contrast, when a limb is transplanted to thoracic segments, the dermatome cells die and the muscle primordia fail to mature. These results suggest that local interactions control the differential fate of axial muscle primordia and do so by supporting the survival of dermatome cells or by causing dermatome cells to die.

CLONAL HYBRID CELLS DERIVED FROM MOUSE SPINAL CORD MOTOR NEURONS. E.F. Salazar-Gruoso, S. Kim* & H. Kim*, Brain Research Institute, Department of Neurology, Univ. of Chicago, Chicago, IL 60637.

Investigations of motor neurons have in general been hampered because of the difficulty in their isolation and culture. This makes biochemical, physiological, and genetic studies seeking to define motor neuron-specific functions challenging. A potential solution to this problem is the production of clonal neural hybrid cell lines that are able to express characteristic that can typify motor neurons. Using this strategy, we have been able to immortalize embryonic mouse spinal cord motor neurons by somatic cell fusion to mouse neuroblastoma cells. We fused an aminopterin-sensitive and neomycin-resistant mouse neuroblastoma cell line (N18NEO) to isolated embryonic mouse spinal cord motor neurons. Several hybrid cell lines expressing high levels of choline acetyltransferase (Chat) enzyme activity were obtained. These cell lines were cloned twice by limiting dilution and clones expressing high levels of Chat enzyme activity were isolated. The hybrid nature of the cloned cells was confirmed by determining glucose phosphate isomerase allozymes and chromosome counts. The hybrid cells but not the neuroblastoma cell line also express high and medium neurofilament proteins, developmental characteristics typical of differentiated neurons. The availability of these embryonic clonal hybrid cells will make possible molecular, biochemical, physiologic studies that are aimed at defining motor neuron-specific properties.

377.12

ANDROGEN INDUCES MUSCLE FIBER TYPE CONVERSION IN DENERVATED LARYNGEAL MUSCLE OF *X. LAEVIS*. M. L. Marin, M. L. Tobias, D. B. Kelley. Dept. Biol. Sci., Columbia Univ., NY, NY 10027

Laryngeal muscle is the final effector for sexually dimorphic vocalizations in *Xenopus laevis* frogs. Adult male larynges produce rapid (~60Hz) trills whereas adult female larynges produce trills at a much slower rate (~6Hz). Fiber twitch type, assessed with ATPase fiber histochemistry, correlates well with these behavioral observations. Adult male laryngeal muscle contains only fast twitch fibers while adult female laryngeal muscle contains predominantly slow twitch fibers. Juvenile laryngeal muscle contains equal numbers of slow and fast twitch fibers. In response to androgen treatment, juvenile laryngeal fibers are converted from slow to fast twitch. To determine if androgen induced fiber type conversion is nerve dependent, juvenile male and female larynges were unilaterally denervated. At the time of denervation, half the animals received a testosterone pellet while the other half received no pellet. All animals were reared an additional five weeks and laryngeal muscle fibers typed using ATPase histochemistry. Following androgen treatment, larynges of both sexes contain only fast twitch muscle fibers. There was no difference in fiber type composition between the innervated and denervated sides. Denervation alone does not cause selective loss of slow twitch fibers since denervated, untreated laryngeal muscle contains both slow and fast twitch fibers. We conclude that androgen acts directly at the level of the muscle fiber to regulate myosin ATPase expression. Supported by NS 23684

ELECTROPHYSIOLOGICAL CHANGES THAT ACCOMPANY TRANS-SYNAPTICALLY INDUCED ATROPHY IN GRASSHOPPER THORACIC MUSCLES. L.L. Rankin & E.A. Arbas. ARLDN, Univ. Ariz., Tucson AZ 85721.

When grasshoppers, *Barytettix psolus*, shed a hindlimb by autotomy, certain undamaged, fully innervated thoracic muscles atrophy severely. Previous experiments indicate that: 1) severing of the leg nerve during autotomy trans-synaptically induces muscle atrophy, and 2) undamaged motoneurons (Mns) to affected muscles persist in the CNS despite atrophy of their targets. We are comparing the electrophysiological properties of the normal and atrophying neuromuscular system to uncover the basis of trans-synaptically induced atrophy.

Intracellular recordings from one of the affected muscles, tergotrochanteral muscle #133 b.c, show that a decline in resting membrane potential (e.g., from a mean of -73 mV to between -10 and -50 mV) occurs in some fibers by day 5 post-autotomy and in a majority of fibers by day 12. Junction potentials evoked in normal muscle by stimulating the motor nerve fall into at least 4 classes: 1) large, fast, non-overshooting eip's (55-70 mV amplitude, 2-5 ms rise time), 2) smaller, intermediate eip's (10-50 mV, 3-10 ms), 3) small, slow eip's (2-10 mV, 8-18 ms), and 4) small, slow iip's of variable amplitude that were based on a decreased conductance. These classes could be discriminated by differences in threshold or by fatiguing the large, fast potentials with repetitive stimulus trains. Beginning 5-6 days after autotomy, many muscle cells were depolarized and showed smaller and slower eip's, although some large, fast eip's could still be evoked. The occurrence and character of the iip's seems unaltered up to 10 days post-autotomy. It also becomes easier to discriminate thresholds of the different classes of synaptic potentials at increasing times post-autotomy. Current studies are focused on discriminating which of these effects are due to changes in the physiology of muscle cells or Mns and determining their cause. ABNORMAL THORACIC MUSCLE ORGANIZATION IN *benless* *DROSOPHILA*. R.S. Edgecomb, T.H. Yuan* and A.M. Schneiderman. Section of Neurobiology and Behavior, Cornell University, Ithaca NY 14853.

A small group of mutations isolated in *Drosophila* alters genes involved in specifying individual synaptic connections between neurons. The recessive *benless* (*ben*) mutation disrupts the synaptic connection between two neurons in the escape-response pathway of the adult: the giant fiber neuron (GF) and the motoneuron innervating the tergoprochancerteral (jump) muscle (TTM) (Thomas & Wyman, 1984, *J Neurosci* 4:530). Stimulation of this pathway normally results in an escape response with characteristic motoneuron latencies and following frequencies. In *ben* flies the TTM motoneuron responds with a longer latency and fails at a lower frequency after stimulation of the GF. We report here that *ben* also affects the development of the TTM.

In wild-type flies the origin of the TTM is invariant, attaching posteriorly to the intrascutal suture near the lateral margin of the scutum. In contrast, a small percentage (<25%) of homozygous *ben* flies exhibit variable abnormalities in the dorsal attachment of the TTM to the scutum. Its origin may be displaced anteriorly and/or medially. In female flies hemizygous for *ben*, the origin of the TTM is aberrant in over 66% of animals examined. In some cases the muscle is absent; in others it diverges and attaches at two separate sites on the scutum. The pattern of muscle fiber organization is also altered. We conclude that in addition to its role in giant fiber pathway development, the product of the *benless* gene is important for proper development of the TTM. (NSF BNS-90-09833, NIH 5-T32-NS07303)

377.16

METAMORPHOSIS OF UNPAIRED MEDIAN NEURONS IN *MANDUCA*. H.J. Pfluger and R.B. Levine. ARL Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721 and Free Univ., Koenigin-Luise-Str. 28-30, D-1000 Berlin 33, FRG.

Unpaired median neurons modulate muscle contraction in insects. We followed the fate of identified unpaired neurons in the abdomen of *Manduca*, where changes in muscles during metamorphosis suggest a modified behavioral role for these neurons. Ni⁺⁺/Co⁺⁺ backfills of peripheral nerves and intracellular Co⁺⁺ fills reveal two ventral unpaired neurons with bilateral axons in each abdominal ganglion in larvae, pupae, and adults. In larvae, the two cells project out distinct branches of the dorsal segmental nerve to non-overlapping sets of muscles. Despite the loss of some muscles and the development of others, both neurons survive metamorphosis and project to similar regions of the body wall in larvae and adults. A comparison of the dendritic structures at different stages reveals a subtle regression of fine processes at the end of larval life, followed by the elaboration of a new dendritic tree during adult development. The adult dendrites possess terminal branches with numerous varicosities, and in general were more complex than in larvae. The dendritic complexity appeared to increase for the first several days following adult emergence, even though this period is associated with the degeneration of some major body-wall muscles. Future studies will explore the function of these putative neuromodulatory cells, and how it is modified during metamorphosis. (supported by NSF and NIH grants to RBL; and a DFG travel grant to HJP.)

REGENERATION: TISSUE CORRELATES

378.1

EMBRYONIC RETINAL ABLATION AND POST-METAMORPHIC OPTIC NERVE CRUSH: RELATIONSHIP BETWEEN HEALING, EXTRA CELL DIVISION AND RESULTANT VISUOTECTAL PROJECTIONS DURING REGENERATION. L. Wunsh Underwood, P. Nelson*, E. Noelke* and C. F. Ide. Dept. of Cell and Molecular Biology, Tulane University, New Orleans, LA 70118.

We examined relationships between healing, extra cell division and resultant visuotectal pattern formation observed during *Xenopus laevis* retinal and optic nerve regeneration. Dorsal (D), nasal (N) and nasoventral (NV) 1/3 sized eye fragments were surgically created in stage 32 embryos and analyzed. Dorsal fragments either showed little cell displacement and no associated extra cell division, or showed massive cell displacements ventrally with extra cell division. Neither healing type showed duplicated projections which is predicted by the polar coordinate model. Nasal fragments always showed cell displacements ventrally with associated extra cell division, and over 90% formed duplicated projections, also predicted by the polar coordinate model. In additional studies in adult animals (NV fragments), the optic nerves of eyes with duplicated projections were crushed and allowed to regenerate for one year. Duplicated projections were restored, indicating that developmental and maturational factors are probably not responsible for duplicative pattern formation; rather, information intrinsic to the eye, possibly created during healing interactions underlies pattern duplication.

378.2

ANATOMICAL ANALYSIS OF RETINOTOPIC REFINEMENT IN A COMPRESSED RETINOTECTAL PROJECTION IN GOLDFISH WITH AND WITHOUT TTX ACTIVITY BLOCKADE. M.D. Olson and R.L. Meyer. Developmental and Cell Biology, University of California, Irvine, California 92717

When the optic nerve is crushed and the posterior half of the tectum is removed, electrophysiological analysis has shown regenerating optic fibers eventually form a complete, compressed retinotopic projection onto the remaining half tectum. In this study, we followed the progression of retinotopic refinement in half tectum, using 2nl "spot" injections of WGA-HRP into the retina. In some animals, activity was eliminated by repeated intraocular injections of TTX. Spot injections were placed such that the label would be in the posterior 1/4 of the normal tectum. At one month, label was dispersed over most of the anterior tectal remnant in both control and TTX animals. At two months, label in control animals had condensed into small clusters in the posterior end of the half tectum. At the same time, label in TTX animals had moved posteriorly, showing substantial condensation but remaining more diffuse than with activity.

These results suggest that compression may proceed directly from an early diffuse and nonretinotopic projection rather than from an orderly uncompressed projection. They also show substantial compression under TTX blockade indicating compression is generated by activity independent mechanisms.

378.3

HYPOTHALAMO-HYPOPHYSEAL TRACTS TRANSECTED IN THE LATERAL RETROCHIASMATIC AREA DEVELOP NEUROVASCULAR CONTACT ZONES. J. Carithers and H.-D. Dellmann*. Dept. of Vet. Anatomy, Iowa State Univ., Ames, IA 50011.

Neurosecretory axons regenerate into neural lobe, optic nerve or sciatic nerve transplanted into lateral retrochiasmatic lesions of the magnocellular neurosecretory tract. Now we report the establishment of neurohemal contact zones in association with explanted neural lobe, optic nerve or sciatic nerves placed into the tract at the site of lateral retrochiasmatic lesions 15 d earlier.

Regions with increased microvasculature and abundant profiles immunoreactive for neurophysin lie adjacent to all three types of grafts. The organization of such areas resembles that of neural lobe, however, their capillaries are not fenestrated. Numerous neurosecretory axons are present, and palisades of axon terminals abut the perivascular basal laminae. Glial cells partially ensheath regenerating neurosecretory axons, and some glial processes extend between terminals to the neurovascular contact zone. Terminals with many microvesicles and few neurosecretory granules provide morphological evidence of hormone release. Neurohemal contact zones that clearly incorporate grafted tissue occur only in grafted neural lobe explants, in which neurosecretory terminals are associated with fenestrated capillaries and pituicytes. Very limited development of neural lobe-like regions is occasionally seen near lesions without grafts. Supported in part by NSF BNS 8919729.

378.4

REGENERATION OF TRANSMISSION FOLLOWING LESIONS TO THE CNS OF THE NEONATAL OPOSSUM, *Monodelphis domestica*, ISOLATED AND MAINTAINED IN CULTURE. S.K.A. Woodward, J.M. Treherne, Z.M. Varga, J.M. Ritchie and J.G. Nicholls. Pharmacology Dept., Biocenter, Basel, Switzerland.

Little information is available about the ability of embryonic and neonatal mammalian CNS to regenerate after injury. Since development is still occurring and no myelin is present in the immature spinal cord it seemed that the conditions for regeneration or new growth across a lesion might be more favorable than in adults. The isolated CNS of the new-born opossum, which survives well in tissue culture, provides an accessible system for such studies.

The brain and spinal cords of three-day-old opossums were dissected and the spinal cords crushed in the lower cervical region, abolishing all through conduction. The preparations were maintained in tissue culture for up to six days. The ability of the cords to conduct action potentials was monitored during this time. Between three and four days after the lesion was made, transmission through the spinal cord was re-established. Carbocyanine dyes, HRP and silver stain are now being used to analyse changes occurring at the crush site.

PLASTICITY OF THE CATECHOLAMINERGIC SYSTEM IN THE ADULT RAT CEREBRAL CORTEX AS A RESULT OF CHOLINERGIC PATHWAY LESIONS. S. A. Welner and Z. C. Koty*. Douglas Hospital Research Centre, McGill University, Department of Psychiatry, Montreal, Quebec, Canada H4H 1R3.

It is well established that the CNS of developing organisms is capable of extensive growth and plasticity; until as recently as the last 2 decades, however, the notion that adult mammalian neurons were plastic in nature was usually not considered. The latter has recently been shown in the septo-hippocampal system; denervation of this pathway results in sprouting of sympathetic fibers into the hippocampus. In the present study, we show that similar plasticity appears to be present in adult mammalian neurons of the cerebral cortex; lesions of the cholinergic pathway from the nucleus basalis magnocellularis (NBM) to the cerebral cortex results in an elevation of cerebral cortical levels of tyrosine hydroxylase (TOH), the rate limiting enzyme in catecholamine synthesis. The experimental group consisted of male Sprague-Dawley rats, lesioned bilaterally in the NBM with 0.12M quisqualic acid and was compared to an unoperated control group. Four months following lesion, TOH activity in the fronto-parietal area of cortex was measured. Results show an approximate three-fold elevation of TOH levels in the lesioned cortex compared to the intact cortex. These results are interesting with respect to plastic changes that may occur in disease states where cortical cholinergic function is disrupted, such as with Alzheimer's disease, and may contribute to the symptomatology of the disorders. (Supported by the Alzheimer Society of Canada)

CONTRALATERAL EARLY BLINK REFLEX IN PATIENTS WITH FACIAL NERVE PALSY: EVIDENCE FOR SYNAPTIC REORGANIZATION IN THE FACIAL NUCLEUS DURING REGENERATION. R. Töpfer*, W. Nacimiento, K. Podoll*, M. B. Graeber, E. Möbius*, J. Noth and G. W. Kreutzberg. Dept. of Neurology, Alfried Krupp-Hospital, 4300 Essen, F.R.G. and Max-Planck-Institute of Psychiatry, Dept. of Neuromorphology, 8033 Martinsried, F.R.G.

50 patients with Bell's palsy and 30 patients with etiologically different symptomatic peripheral facial nerve palsy were studied by means of electrically evoked blink reflexes 1-23 days after onset of paresis. Their results were compared with a normal control group of 30 healthy subjects. In a significant number of patients (64% in Bell's palsy and 53% in symptomatic facial nerve palsy) a contralateral early blink reflex response (R1) could be elicited upon stimulation of the normal side as compared to 13% in the control group. It is suggested that this result may be explained by synaptic reorganization of the facial nucleus leading to functional unmasking of pre-existing crossed trigemino-facial reflex pathways during regeneration. This view is in line with previous experimental data in animals on the time course of structural changes in the facial nucleus after lesioning of the ipsilateral facial nerve.

SPARSE REGENERATION AFTER AXOTOMY OF CHOLINERGIC PROJECTIONS FROM PONTINE TEGMENTUM TO ANTERIOR THALAMUS. T.W. Farris and L.L. Butcher. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563.

To assess the regenerative capabilities of projection neurons of the cholinergic pontine tegmental complex (CPTC), assessed previously for cortical projections from the cholinergic basal nuclear complex (CBNC), we performed unilateral Scouten wire knife-cut axotomies of a cholinergic pathway arising from the laterodorsal tegmental nucleus and projecting to anteroventral and anteromedial thalamic nuclei in 8 week old female rats. Brain tissue was collected at 4, 7 and 14 days post-axotomy and was processed histochemically for acetylcholinesterase (AChE); immunohistochemically for choline acetyltransferase and glial fibrillary acidic protein; and for Nissl substance. Computerized densitometry performed via light microscopy showed, in all groups, the expected accumulation and depletion of AChE fiber density proximal and distal, respectively, to the thalamic knife-cut. However, unlike our findings for the CBNC projections to medial cortex, there was little recovery from axotomy-induced depletion of AChE-positive fiber density in the CPTC thalamic target regions at these time points. No AChE-positive fibers were observed to cross the cut. These data (1) indicate that CPTC neurons are less morphologically plastic than CBNC neurons; (2) provide evidence of a correlation between the regenerative and degenerative capabilities of these cholinergic neuronal populations as the CBNC degenerates in Alzheimer's disease and expresses nerve growth factor receptor whereas the CPTC does neither appreciably; and (3) demonstrate that the assessment of axotomy effects via AChE-fiber densitometry can be extended reliably to a non-cortical region as a model for testing mammalian CNS cholinergic regeneration *in vivo*. [Support: NIH NS 10928 to LLB]

MORPHOLOGICAL CHANGES IN THE TROCHLEAR NERVE FOLLOWING AXOTOMY. P. Iannuzzelli,¹ M. Murray,¹ R. Baker² and E.H. Murphy,¹ Dept. of Anatomy and Neurobiology,¹ Medical College of PA, Philadelphia, PA 19129, and Dept. of Physiology and Biophysics,² NYU Med. Center, New York, NY 10016.

In the adult cat, following axotomy of the trochlear nerve (TN), surviving trochlear motor neurons regenerate and re-innervate their target by 4 weeks post-axotomy. We used quantitative electron microscopy to examine cross sections of the regenerating TN distal to the transection. There are approximately 1,000 myelinated axons in the normal TN and the same number just distal to the lesion site in the long term (>6 mos.) regenerated nerve. At 4 weeks post-axotomy, as many as 4,000 regenerative sprouts were present in the distal nerve stump, indicating that regenerating axons branch. Most cells in the distal nerve stump showed typical Schwann cell morphology, although occasionally, cells morphologically resembling astrocytes were seen. Schwann cells appear to be associated either with regenerating axons or degenerating debris. Just distal to the lesion site Schwann cells associated with regenerating axons usually contain only one axon profile. However, the number of regenerating axons per Schwann cell increases in more distal parts of the nerve stump. Our data suggests that following axotomy regenerating axons branch as they grow distally. In addition, it appears that there are at least two distinct functional classes of Schwann cells; those associated with regenerating axons and those associated with degenerating debris, and that these functions are not overlapping. (Supported by NIH-NS24707)

PARTIALLY LESIONED RAT NIGROSTRIATAL SYSTEM - A MODEL FOR EARLY PARKINSON'S DISEASE. F.S. Kim*, K. Steece-Collier, T.J. Collier, D.L. Felten, S.Y. Felten, J.R. Sladek, Jr. Department of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642.

Rat models of Parkinson's disease have been characterized by complete or near complete unilateral destruction of the nigrostriatal pathway using the neurotoxin 6-hydroxy-dopamine (6-OHDA). We are developing and characterizing a hemi-parkinsonian rat model, using unilateral injection of 6-OHDA into the medial forebrain bundle, in which there is partial destruction of the nigrostriatal system. The behavior of such animals was characterized by ipsiversive rotation following an amphetamine injection, but no rotation following an apomorphine injection, in contrast to the contraversive rotation observed in the completely lesioned models. The mean striatal dopamine (DA) content of the partially lesioned animals, as measured with HPLC, was approximately 50% of the control side versus 20% in the completely lesioned animals. The nigral DA cell count using tyrosine hydroxylase immunocytochemistry showed similar results. The degree of cell loss of the A8 and A9 DA cell groups, rather than the A10 cell group correlated better with the observed behavior. This model better estimates the condition of the DA system in clinical Parkinson's disease and can be used to study factors influencing the progression of nigral cell death and the potential for homotopic regeneration in the illness. Supported by PO 1 NS 24032.

BEHAVIORAL RECOVERY OF THE GOLDFISH STARTLE RESPONSE AFTER SPINAL CORD CRUSH. S.J. Zottoli and M.M. Freeman*. Dept. of Biology, Williams College, Williamstown, MA 01267.

The goldfish central nervous system is capable of functional regeneration after spinal cord injury. Specifically, damage to the spinal cord may be followed by the recovery of swimming, feeding, equilibrium and startle responses (Neurosci. Abst.15: 333). We have used a high speed, digital imaging system (i.e., an image is collected every 2 ms) with computer display and analysis (Eaton et al., J. Neurosci. 8: 2758) to compare recovered startle responses with those of sham-operated controls. Fish were anesthetized, their whole spinal cord was crushed at the spinomedullary level, and they were tested for the return of startle responses by computer activation of a solenoid which moved the test tank upward. Of the 25 fish that survived to 170 postoperative days, 12 had regained startle responses. Significant differences in a number of movement parameters existed between startle responses of these experimental fish and sham-operated controls. The differences included: lower frequency of response, longer latency from stimulus presentation to initiation of the response, and smaller body angle and distance traveled by the center of mass 70 ms after the initiation of the response. The recovered startle responses were lost in 5 fish on re-crush of the spinal cord.

The return of the startle response in goldfish is due to regeneration of the central nervous system. We speculate that the longer response latency and the reduced movement of recovered startle responses may compromise the animal's ability to escape predators. Thus, the use of the term "functional regeneration" may be inappropriate in this case. Supported by NSF grant BNS-8809445.

REGENERATION OF AXOTOMIZED NEURONS AFTER SPINAL CORD LESIONS IN NEWBORN RATS: A QUANTITATIVE DOUBLE-LABELING STUDY. B.S. Bregman and H. Bernstein-Goral. Dept. Anatomy and Cell Biology, Georgetown Univ. Sch. Med., Washington, D.C. 20007

Transplants (TP) of fetal spinal cord tissue support the survival and growth of immature axotomized brainstem-spinal neurons. Both late-developing and regenerating neurons contribute to this transplant induced anatomical plasticity (Bregman and Bernstein-Goral, 1991, Exp. Neurol. 112: 49-63). The current study was designed to 1) determine the magnitude of the regenerative response and 2) test the hypothesis that the long distance growth beyond the site of a neonatal lesion plus transplant is by late-developing neurons, whereas regenerating neurons project to spinal cord levels immediately caudal to the transplant. We used temporally spaced retrograde tracing with the fluorescent dyes fast blue (FB) and diamidino yellow (DY) to address this issue. Spinal projecting neurons were axotomized and labeled with FB at 2 dpn. The source of FB was removed and a spinal cord TP was placed into the lesion site. 3-6 wks later DY was injected into the spinal cord bilaterally either <5mm or 10-15mm caudal to the TP. Cell counts show that 28% of the neurons in the red nucleus, 32% of the neurons in the locus coeruleus and 37% of the neurons in the raphe nuclei regenerated within 5mm caudal to the TP. Furthermore, after DY injections up to 15 mm caudal to the TP, a substantial population of regenerating neurons (7-9%) was identified in each of the brainstem nuclei examined. Thus, the hypothesis that the long distance growth beyond the transplant is solely by late-developing neurons was not supported. Rather, both regenerating neurons and late-developing neurons extended axons long distances caudal to the lesion site. Surprisingly, the proportion of regenerating neurons was similar in each of the 3 brainstem-spinal nuclei examined. Supported by NIH grants NS 19259, NS 27054 and NS 01356 to BSB.

CHANGES IN VENTRAL HORN NEURON SIZE AND INNERVATION DURING TAIL REGENERATION IN THE LIZARD ANOLIS CAROLINENSIS. M.T. Duffy, B.M. Davis, D.R. Liebich* and S.B. Simpson, Jr. Dept. of Biological Sciences, University of Illinois at Chicago, 60680; Anatomy & Neurobiology, Chandler Medical Center, University of Kentucky, Lexington, 40536.

We have previously shown that ventral horn (VH) neuron somata in normal tail spinal cord rostral to large regenerated tails (≥ 6 cm) are significantly hypertrophied compared to normal ($329.7 \pm 38 \mu^2$ vs $154.8 \pm 24 \mu^2$) and receive more axosomatic contacts (18.35 ± 1.6 vs 9.04 ± 0.8). We also wished to know if changes in VH neuron size were correlated with changes in synaptic input. For these experiments we chose lizards autotomized two months previously in which regenerating tail segments were ≤ 10 mm (mean length = 8 mm). Preliminary data indicates that mean VH neuron size ($n=6$) in these animals is greater than in normal tailed lizards ($302 \pm 36 \mu^2$ vs $154.8 \pm 24 \mu^2$; $p < .01$) and is equal to that of neurons rostral to large mature regenerated tails. The number of synaptic bouton contacts on these somata is slightly increased over normal (12.5 ± 1.6 vs 9.04 ± 0.8 ; $p=.13$) but significantly decreased when compared to larger mature regenerates ($p < .01$).

These results suggest that changes in neuron size and innervation may be independent of one another in Anolis lizards. However, these results might also indicate that changes in neuron size and central innervation are not complete at two months post-autotomy. Further studies of intermediate stages of regeneration will be needed to show when such changes are complete.

GROWTH OF PROCESSES ACROSS SPINAL CORD LESIONS IN XENOPUS CNS EXPLANTS. D.L. Norris, M.S. Beattie, and J.C. Bresnahan. Neuroscience Program and Dept. CBNA, The Ohio State Univ., Columbus, OH 43210.

Brainstem/spinal cord explants were dissected out of Xenopus tadpoles (stage 50-51) following MS-222 anesthesia. Explants were severed at the brainstem-spinal cord junction and placed into collagen gels with the cut ends of the pieces in apposition. Explant cultures were maintained in dilute L-15 culture medium, pH 7.8, at 24° . Cultures were fixed in 4% paraformaldehyde after 8 days. Crystals of DiI were placed into the spinal cord caudal to the lesion to back-label brainstem neurons whose axons had grown across the lesion. DiI was allowed to diffuse for 3 (n=3) or 12 (n=8) days. Explants were examined using confocal laser microscopy. Several small, round neurons with processes extending into the lesion site could be seen within most brainstem explants; 3 explants also contained larger labeled cells with laterally-oriented dendrites. These results complement previous studies demonstrating growth of descending processes across spinal cord transections in Xenopus tadpoles (Beattie et al., 1990), and suggest that explant cultures can be used to study Xenopus CNS regenerative processes. (NS-10165)

CHANGES IN VENTRAL HORN SYNAPSES IN SALAMANDER SPINAL CORD FOLLOWING THORACIC TRANSECTION WITH CORRELATIONS TO BEHAVIOR. L.K. Garner, M.C. Anderson, J. *Ayers and B.M. Davis. Dept. of Anatomy & Neurobiology, Univ. of Kentucky, Med. Ctr., Lexington, KY 40536. * Marine Sci. Inst., Northeastern Univ. Nahant, MA 01908.

To determine if new spinal circuitry produced by regeneration was the same as that produced by embryogenesis, four groups of adult newts (Notophthalmus viridescens) were processed and analyzed for EM: 1) unoperated newts (containing spinal circuitry produced by normal development), 2) acute thoracic transected newts (7-21d post-lesion), 3) regenerated newts (exhibiting various degrees of function), and 4) retranssected newts (recovered newts re-lesioned at original site). The number of synapses/100 μ^2 and the average area of the bouton profile was measured in lumbar ventral horn at the level of spinal nerve 16-18. Only boutons that contained synaptic specializations (active zones and vesicle accumulation) were included. Analysis of normal newts ($n=4$) revealed 4.6 ± 0.7 synapses/100 μ^2 (average bouton area = $1.5 \pm 0.4 \mu^2$). Following thoracic transection the number of synapses decreases up to 33% with no change in bouton size. To date, two newts 3mo post-transection have been analyzed. In newt #1, the size and number of boutons were normal (4.6 syn/100 μ^2 , ave. size = $1.1 \mu^2$). However, newt #2 had only 1.1 syn/100 μ^2 , but average bouton size was twice normal ($2.4 \mu^2$). We are now performing kinematic analysis to relate these changes to recovery of function. Supported by NS25617 to BMD.

DEVELOPMENT OF REGENERATED DORSAL ROOTS WITHIN FETAL SPINAL CORD TRANSPLANTS.

Y.ITOH¹, TSUGAWARA¹, MKOWADA¹, A.TESSLER². ¹Dept. of Neurosurg, Akita Univ, Akita 010, Japan, and ²Philadelphia VA Med. Ctr. and Dept. of Anat. and Neurobiol., The Med. Coll. of Pennsylvania, Philadelphia, PA 19129.

Adult rat dorsal roots regenerate into transplants of fetal spinal cord (FSC) and form synapses, but the time course of regenerated axon growth within transplants is unknown. In this study we used calcitonin gene-related peptide (CGRP) immunohistochemistry to label regenerated dorsal roots in FSC transplants and stereological analysis to evaluate the development of transplant neuropil. Transplants of E14 spinal cord were introduced into a hemisection cavity aspirated in the lumbar enlargement of adult Sprague-Dawley rats, and the adjacent L4/L5 dorsal root was cut and juxtaposed to the transplant. Sagittal vibratome sections were prepared for CGRP immunohistochemistry after survivals of 14 days to over 1 year. The area fraction of transplant neuropil occupied by regenerated CGRP-containing myelinated axons and axon terminals increases for the first 3 months and then persists unchanged for over 1 year. The area fraction occupied by regenerated CGRP-containing unmyelinated axons does not change through 1 year, nor does the area fraction occupied by perikarya and dendrites within the transplant. Myelinated dorsal roots therefore grow for several months within the transplants, and the innervation established by regenerated axons increases over the same period and is permanent. Supported by VA Medical Research Service, NIH grant NS24707, and USAMRDC grant 51930002.

SPINAL MOTONEURON MORPHOLOGY AND RETROGRADE AXONAL TRANSPORT AFTER SCIATIC NERVE TRANSECTION/REPAIR. L. Lipworth*, N.H. Evans* and C.M. Bowe. Dept. Clinical Neurosciences, Brown Univ., Providence, R I 02912

Morphological changes and enhanced retrograde labelling with HRP are reported in spinal motoneurons (SMNs) examined at 10-12 months after nerve crush. In the present study, the morphology and the retrograde labelling characteristics of rat SMNs were evaluated at 10 months following unilateral, sciatic nerve transection and repair with a guidance channel. Distinct retrograde labelling agents were employed to identify SMNs innervating muscles in the sciatic nerve distribution and SMNs of origin for regenerated axons. Two weeks prior to sacrifice, Fluorogold was applied bilaterally to the muscles of interest; 2 days before sacrifice, regenerated and control sciatic nerves were transected distal to the guidance channel and exposed to HRP. No morphological abnormalities were seen in the ipsilateral SMNs. However, compared to the contralateral side, the total number of ipsilateral SMNs was reduced by 17% and the number of double-labelled SMNs was decreased by 33%. There was an increase in the number of ipsilateral SMNs exhibiting only fluorescent labelling. Lengthening the time interval between HRP application and sacrifice resulted in a reduced discrepancy in HRP labelling between the two sides and an increased deposition of HRP-reaction product in the ipsilateral, but not the contralateral, cells. In contrast to the nerve crush lesion model, axonal regeneration after nerve transection/repair is not associated with clear morphological changes in SMNs but retrograde axonal transport mechanisms appear to be compromised.

378.17

CUTANEOUS, MUSCULAR AND ARTICULAR NERVE FIBRE REGENERATION AFTER RAT SCIATIC NERVE LESIONS. C. Hildebrand, and B. Povlsen. Dept. of Cell Biology, and Dept. of Hand and Plastic Surgery, Faculty of Health Sciences, S-581 85 Linköping, Sweden.

In young adult rats the right sciatic nerve was subjected to a crush lesion 5 mm below the tendon of the internal obturator muscle. In other animals the nerve was divided. The cut ends were rejoined using 9-0 nylon sutures. Some rats served as normal controls. After 3 months survival all animals were perfused with glutaraldehyde. Specimens from the sural nerve (SN), the lateral gastrocnemius nerve (LGN) and the posterior articular nerve of the knee joint (PAN) were processed for electron microscopy (EM). For each nerve all myelinated (MA) and unmyelinated (UA) axons were counted on EM prints (x 2100) from thin cross-sections. Following a crush lesion the SN shows a 15% increase in the proportion of MA but a 25% decrease in the proportion of UA. In the LGN both MA and UA increase by 30-35%. The PAN, on the other hand, presents a 60% increase of MA, and the proportion of UAP more than doubles. In the divided and sutured SN the MA increase 40% while the UA decrease 40%. In the LGN the MA and the UA increase 180% and 83% respectively. The PAN shows a 30% increase of the MA but the proportion of UA does not change. These results show that the outcome of axonal regeneration is markedly different in functionally different branches of a mixed major nerve trunk.

378.19

POSTINJURY DISAPPEARANCE OF ASTROCYTES AND ARREST OF AXONAL GROWTH MAY BE INTERCONNECTED. E. Blaugrund*, R. Duvdevani*, V. Lavie and M. Schwartz. Department of Neurobiology, The Weizmann Institute of Science, Rehovot 76100, Israel.

An injury to the mammalian central nervous system results in loss of function, due to its inability to regenerate. It has been postulated that adult mammalian central neurons have the ability to regenerate, but the surrounding glial cells are either inhibitory or non-supportive for their growth. In this study, we closely examined the spatial and temporal relationship among injured/growing axons, astrocytes and phagocytic cells after crush of the adult rat optic nerve. This was carried out by immunohistology at the light microscope, using anti-GFAP and ED-1 antibodies for identifying astrocytes and macrophages, respectively. Transmission electron microscopy was used for estimating the number of these cells and for evaluating abortive axonal growth. Two days after the crush, a massive death of astrocytes occurred at the crush site. After a week, the crush site was very poor in astrocytes and filled with macrophages, while the proximal and distal areas contained many astrocytes and few macrophages. In the proximal site, growth cones observed at this stage were seen in close proximity to both astrocytes and phagocytes, while in the crush site area, which contained only few astrocytes and many phagocytes, almost no growth cones could be observed. We, therefore, suggest that disappearance of astrocytes from the crush site and the arrest of abortive axonal growth may be interconnected.

EFFECT OF NEURAL TRANSECTION ON REFLEX RESPONSES IN CRAYFISH. J. Hernández-Falcón, V. Campos-Lozada*, and B. Fuentes-Pardo. Depto. Fisiología, Fac. Medicina, UNAM. México, D. F. Apdo. Postal 70-250. MEXICO.

The aim of this work was to obtain physiological evidence about neural regeneration mechanisms in crayfish after the transection of the abdominal neural chain. Here, both tail flip reflex and righting reflex (complex fast responses involving a wide group of muscles) were measured before and after the neural cord transection at the 1st, 4th or 6th level of the abdominal chain. Immediately after transection a sustained tail flexion was observed resulting, at the long-term, in uropod destruction. Shortly after transection, the tail flip reflex was diminished or even abolished; 45 days after, a slight recovery could be detected. About 20-30 days after the neural transection, righting reflex latency increased; from this moment on it decreased approaching initial values. These results suggest that neural transection results in neural degeneration followed by a physiological recovery involving a neural regeneration.

GLIAL RESPONSE TO DORSAL ROOT LESION IN THE IRRADIATED SPINAL CORD. T.J. Sims and S.A. Gilmore. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR. 72205-7199.

Exposure of the lumbar spinal cord in early postnatal rats to x-rays induces a marked reduction in the normal glial populations in the irradiated region. The present study was undertaken to determine what effects this reduction of glia has on the glial scar formation that follows root injury in the normal spinal cord. Rat pups were irradiated on postnatal day 3 with a single 4000R dose of x-rays over the lumbar spinal cord. At 20 days following irradiation the L4 dorsal root was lesioned by crushing once and then freezing and thawing twice. Non-irradiated littermates were subjected to the same lesioning procedures and served as controls. Between 60 and 90 days following the lesion, the rats were perfused with fixative and the L4 spinal cord segments were prepared for ultrastructural examination. There was a distinct difference in the extent of the astrocyte response between the irradiated and the non-irradiated rats following dorsal root injury. In the non-irradiated rats, a thick astrocytic scar formed over the dorsal horn. The scar was composed of multiple layers of astrocyte processes with numerous gap junctions interposed. This astrocytic response was not confined to the surface of the spinal cord but extended into regions normally considered as PNS. In irradiated rats, astrocytes formed a glia limitans with an irregular contour and did not develop a thick astrocytic scar. Gap junctions occurred less frequently than in non-irradiated spinal cord. The presence of many small diameter axons just below the surface of the cord, along with larger myelinated axons interposed between processes of the glia limitans, is consistent with an earlier report that axons are capable of regrowing into the irradiated spinal cord (Sims and Gilmore, 1990). Mechanisms involved in conversion of the irradiated spinal cord to a permissive substrate for axonal regrowth are only partly understood; the reduction in the astrocyte population and the absence of scar formation no doubt play important roles. Supported by PVA Grant 745 from the Spinal Cord Research Foundation and NIH Grant NS 04761.

CULTURED SCHWANN CELLS WILL MYELINATE CNS AXONS WHEN IMPLANTED INTO THE BRAINS OF ADULT RATS. C.T. Montgomery* and J.A. Robson. Department of Anatomy and Cell Biology, SUNY Health Science Center, Syracuse, NY 13210.

Schwann cells play an important role in axonal regeneration in the PNS and they can support axonal growth in the CNS of adult animals. The present study examines the morphological relationships between CNS axons and implanted Schwann cells. Cultured Schwann cells were transferred to tubes made of polycarbonate film. Each tube was then implanted into the brain of an adult rat in a manner that supports growth of CNS axons (J. Neurosci. Meth. 32:135-141, 1990). Six months later the tubes were fixed and prepared for electron microscopy.

The tubes are filled with tissue including a central, dense structure that resembles a small peripheral nerve. This central "nerve" is surrounded by a perineurial sheath and is filled with myelin figures. The perineurial cells have a prominent basal lamina and form tight junctions at their appositions. The core of these nerves is divided into small compartments by cells resembling the perineurial cells. Each compartment contains longitudinally oriented bundles of collagen and most contain axons of different sizes. All axons are surrounded by Schwann cells. Some axons are myelinated and others are unmyelinated. Unlike normal peripheral nerves some small axons (<1µm) are heavily myelinated. (Supported by EY03490 and NATO 0235/87)

RECRUITMENT OF RETICULOSPINAL NEURONS DURING SWIMMING COMMAND MICROSTIMULATION IN LAMPREY. S. Jordan and J. Avers. Marine Science Center, Northeastern Univ., East Point, Nahant, MA 01908

We have developed procedures for the analysis of functional activity of giant Müller reticulospinal neurons (RNs) to examine their recruitment patterns in response to electrical microstimulation of brainstem locomotor centers in normal and recovering spinally transected specimens. Specimens are prepared for *in vivo* recording by implantation of fine wire electrodes in the spinal canal. Spontaneous activity was recorded from specimens in a large tray which were video-taped from above while the RN activity was recorded with a VCR. We perform correlated acquisition of undulatory movement and electrophysiological signals from video media and subject it to image motion analysis and signal processing. 3-D Cluster analysis of the proximal and distal spike amplitudes and inter-electrode latencies of RN action potentials (APs) allows segmentation of the APs of individual RNs, determine their discharge patterns and directly relate them to features of ongoing behavior. Specimens are then prepared for focal brainstem microstimulation. An anterior isthmus cluster (PLR) and an anterior medial tract (MLR) are stimulated at varying strengths and patterns using a double barreled glass microelectrode to evoke undulatory behavior. The undulations and RN responses were recorded as above for spontaneous behavior. RN APs are subsequently identified by focal stimulation of their cell bodies in the brainstem and correlated cluster analysis. Our results indicate that: (1) Although evoked swimming closely approximates normal swimming, the evoked RN populations are overlapping subsets of the normal population, (2) Increasingly intense microstimuli have diverse effects on different elements within the subsets. (3) In regenerated cords where recovered RN activity is observed PLR stimulation evokes a similar subset to that observed spontaneously. Supported by NSF Grant DIR-8917532

CHARACTERIZATION OF AXONAL REGENERATION IN THE ABDOMINAL GANGLION OF *APLYSIA*. J.F. Hamilton and S.M. Fredman. Department of Physiology, Meharry Medical College, Nashville, TN 37208.

The ability of neurons in the abdominal ganglion of *Aplysia* to regenerate their axons following branchial nerve crush was studied in 21 ganglia using retrograde staining and intracellular injection of nickel-lysine. Regeneration, as evidenced by retrogradely stained neurons, was first observed by postlesion day 15. The number of stained neurons in ganglia with crushes increased thereafter until postlesion day 33. The number of stained neurons in the abdominal ganglia of experimental animals was always less than that of controls (66% at postlesion day 56). More axonal regeneration was seen in the hemiganglion ipsilateral to the branchial nerve. In control abdominal ganglia, neurons with somata in the 50-100 μm range comprise the majority (51%) of cells in the ganglia, while the larger cells (200 μm -500 μm) in the ganglia are only 4%. The regeneration of cells in the 50-100 μm range was first noted at post lesion day 15, but the number of cells in this range never returned to control levels (115 \pm 2 cells in control v. 73 \pm 17 cells at post lesion day 56). While regeneration of 200 μm -500 μm cells did not begin until postlesion day 28, the number regenerating approached control levels by post lesion day 42 (Control 9.3 \pm 3.5 cells v. 4 \pm 1.7 cells at postlesion day 42). Neuron R2 (200-500 μm) was shown by intracellular dye injection and antidromic action potentials to have an axon in the branchial nerve in all control ganglia and in all experimental ganglia allowed to regenerate for greater than 32 days. This study suggests that in *Aplysia*, complete axonal regeneration does not occur in the adult CNS and that there may be intrinsic differences in the ability of neurons to regrow axons. (Supported by NINDS Grant NS28199 to SMF. JFH is a American Psychological Association Fellow).

REGULATION OF SYNAPTOSOMAL MEMBRANE CHOLESTEROL. A.M. Rao* and W.G. Wood. VA Medical Center, GRECC, and Dept. of Pharmacology, Univ. of Minnesota, School of Medicine, Minneapolis, MN 55417.

The kinetics of cholesterol transport have been well established in non-neuronal membranes. There are few if any studies on cholesterol transport in neuronal membranes. The purpose of the experiments reported here was to determine the kinetics of cholesterol transport in synaptosomes and how such transport may be regulated. Synaptosomes were isolated from brain of C57BL mice. Cholesterol transport was accomplished using radiolabeled small unilamellar vesicles incubated with synaptosomes. The $t_{1/2}$ of cholesterol exchange was 9 hr between SUV and synaptosomes. The amount of the exchangeable pool of cholesterol was approximately 40% in synaptosomes. Both the $t_{1/2}$ of exchange and the exchangeable pool were altered by phosphatidylserine (PS) and sphingomyelin (SM). PS facilitated exchange and SM slowed exchange and reduced the exchangeable pool. Membrane cholesterol is not uniformly distributed but consists of cholesterol poor and rich domains. Synaptic plasma membrane (SPM) cholesterol has recently been shown to be asymmetrically distributed between the exofacial and cytofacial membrane leaflets. PS a cytofacial phospholipid and SM an exofacial phospholipid may be involved in the asymmetric regulation of SPM cholesterol. Supported in part by the Dept. of V.A. and NIAAA 07292 (WGW).

FATTY-ACID COMPOSITION OF RAT ASTROCYTES AND NEURONS IN PRIMARY CULTURE: EFFECTS OF EXOGENOUS LINOLEIC ACID. M.G. Murphy and Z. Byszko*. Department of Physiology and Biophysics, Dalhousie University, Halifax, Nova Scotia Canada B3H 4H7

We have analyzed the phospholipid fatty-acid compositions of rat-brain astrocytes and neurons that were cultured for 9 days in the absence or presence of exogenous linoleic acid (LA, 35 μM). The mol% of the major saturates (16:0, 18:0) and monoenes (16:1, 18:1) were similar in both cell types; the monoene content of both was reduced significantly by exposure to LA. The mol% of the major polyunsaturates (PUFA) were:

Fatty acid	Astrocytes		Neurons	
	-LA	+LA	-LA	+LA
18:2 ω 6	1.1	7.5	1.3	4.2
20:3 ω 6	0.3	1.1	0.2	1.0
20:3 ω 9	0.9	0.2	0.5	0.2
20:4 ω 6	7.7	13.3	5.9	5.8
22:4 ω 6	1.4	3.1	2.8	2.9
22:5 ω 6	1.1	1.2	1.3	1.2
22:5 ω 3	0.8	1.5	0.5	0.4
22:6 ω 3	2.9	2.7	6.0	4.1

Whether discrepancies in the metabolism of PUFA in these cells are related to cell-type-specific functions is not known. (Supported by the MRC)

379.2

PALMITOYLATION OF THE α -SUBUNIT OF G_o , A MAJOR NEURAL G PROTEIN. M. Parenti, C. Newman*, G. Milligan*** and A. I. Magee*. Dept. Pharmacol., Sch. Med., Univ. Milan, Milan, Italy, *Lab. Eukaryotic Mol. Genet., NIMR, Mill Hill, London and ***Dept. Biochem., Univ. Glasgow, Glasgow, U.K.

G_o is a heterotrimeric G protein mostly found in neural tissues and presumably involved in transmembrane signalling. In order to perform its function G_o must associate with the cytoplasmic face of the plasma membrane. This association may be partly mediated by the $\beta\gamma$ -subunits and the amide linkage of myristic acid to the N-terminus of the α -subunit. We now report that $G_{o\alpha}$ is post-translationally modified by the linkage of an additional fatty acid, palmitic acid. Palmitoylation, as well as myristoylation, of $G_{o\alpha}$ were detected in two neural cell lines such as PC 12 and neuroblastoma x glioma NG 108-15 hybrid cells differentiated with dibutyryl cyclicAMP. These cells were metabolically labelled with tritiated fatty acids and the protein was immunoprecipitated with polyclonal antisera raised against a purified brain Gi/Go preparation or specific peptide sequences. The attachment of palmitic acid, via a thioester bond, did not occur on the cysteine residue four amino acids from the C-terminus, since palmitoylation of $G_{o\alpha}$ could be detected even by *in vivo* pertussis toxin-catalyzed ADP-ribosylation of this site in differentiated NG 108-15 cells.

A MONOCLONAL ANTIBODY THAT RECOGNIZES PHOSPHATIDYLINOSITOL-LINKED PRESYNAPTIC ACHE S. Wright and P.D. Kushner ALS Research Foundation, Pacific Presbyterian Medical Center, San Francisco, CA 94115

Tor 23 is a monoclonal antibody derived from the cholinergic synaptosome preparation of the *Torpedo* ray that has been shown to delineate the external surface of a precise subset of neurons in the rat CNS. This subset has both motor system and cholinergic overlaps. Previously we reported that Tor 23 recognized *Torpedo* presynaptic acetylcholinesterase (AChE). With other AChE antibodies, we confirm the identification of the Tor 23 antigen in the *Torpedo* as AChE. Furthermore, phosphatidylinositol specific phospholipase-C treatment of the membrane liberates the AChE identified by Tor 23. The epitope of the AChE molecule identified by Tor 23 is not sensitive to lipase treatment, lipid extraction, or treatments with endoglycosidases F or H; the epitope is sensitive to trypsin, N-glycanase, and Triton X-100. These results indicate that Tor 23 identifies a specific structural conformation of the presynaptic AChE molecule and suggests that this conformation plays a significant role in determining the uniqueness of this form.

SELECTIVE ACETYLCHOLINESTERASE mRNA ACCUMULATION AT THE AVIAN NEUROMUSCULAR JUNCTION: RELATIONSHIP TO NUCLEAR DOMAINS. R.K. Lee*, B.J. Jasmin, and R.L. Rotundo. Dept. of Cell Biol. & Anatomy, U. of Miami School of Medicine, Miami, FL 33101.

Acetylcholinesterase (AChE) exists as a family of oligomeric forms encoded by a single gene. In skeletal muscle fibers the asymmetric form is concentrated at the neuromuscular junction. The molecular mechanisms underlying such selective accumulation of AChE molecules are unknown, but may include transcriptional as well as translational and post-translational mechanisms. To determine the relative abundance of AChE mRNA in junctional versus extrajunctional regions of quail PLD muscle fibers we developed a sensitive polymerase chain reaction-based (PCR) assay using primers designed to specifically amplify the asymmetric AChE form transcript. The 5' (AC1) and 3' (AC3) primers are located in exon 1 of the common coding region and exon 3a encoding the asymmetric carboxyl terminus, respectively, and amplify a 352 nt target region confirmed by restriction enzyme mapping. Neuromuscular junctions, identified by AChE histochemistry, and extrajunctional regions were microdissected, the mRNA reverse transcribed and amplified, and the products analyzed by gel electrophoresis. Results consistently show higher levels of AChE mRNA in innervated regions thus suggesting compartmentalization of AChE gene expression. These data support the hypothesis that transcription of genes encoding synaptic proteins is spatially regulated and confined to nuclei within the subsynaptic sarcoplasm. Supported by grants from the NIH and MDA to R.L.R..

Electrical Stimulation of Rat Striatum Decreases the Phospholipid Levels and the Levels of Choline Containing Metabolites. S.A. Farber, & R. J. Wurtman. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

Cholinergic neurons are especially vulnerable in certain neurologic disorders, including Alzheimer's disease (AD). They also have the unique property of utilizing choline (Ch) for two purposes, i.e. synthesis of both the neurotransmitter acetylcholine (ACh) and membrane phospholipids (PL). We previously showed that prolonged stimulation of rat brain slices rich in cholinergic neurons was associated with sustained ACh release, but caused a progressive decrease in membrane PL. Present studies were designed to determine whether the reduction in PL (which can be prevented by adding sufficient Ch to the medium) reflected decreased synthesis or accelerated degradation. We observed that electrical stimulation, in the absence of choline, decreased levels of phosphocholine (PCh) by 19% (n=4, p<.01), and levels of ¹⁴C-PCh in tissue by 27% (n=3, p<.01). Tissue levels of the PC metabolite glycerophosphocholine (GPCh) declined by 42% (n=4, p<.01). This could reflect slowed degradation of PL or, more likely, accelerated harvesting of Ch from GPCh. Prolonged stimulation of the tissue also caused depletion of ACh which varied with stimulation time and current (at 75 mA there was a 44 % reduction, n=4, p<.05). Supported by NIMH grant NH-28783.

CALCIUM AFFECTS EXOGENOUS GANGLIOSIDE BINDING TO CORTICAL SLICES UNDER RESTING AND STIMULATING CONDITIONS. L. R. Wolf* and L. N. Irwin. Dept. Biol., Simmons Col., Boston, MA 02115, and Dept. Biol. Sci., Univ. of Texas at El Paso, El Paso, TX 79668.

Gangliosides and calcium ions bind reversibly under physiological conditions. The possibility that this interaction could have functional consequences was studied by measuring ganglioside turnover in cortical slices of brain tissue perfused with varying concentrations of calcium and potassium. Mildly depolarizing levels of K⁺, or a reduction of [Ca⁺⁺] in the perfusing solution, increased release of exogenously incorporated gangliosides. In cortical slices from chronically hypocalcemic rats, more exogenous gangliosides were bound under low [Ca⁺⁺] than under normal [Ca⁺⁺] perfusion. We speculate that brain cells adapt to chronic hypocalcemia by altering the nature of calcium-ganglioside interactions in the plasma membrane. These results provide direct support for the historical notion of a functional interaction between gangliosides and calcium ions related to the excitatory state of brain cells. PRODUCTION OF DIACYLGLYCEROL BY EXOGENOUS PHOSPHOLIPASE C STIMULATES CTP:PHOSPHOCHOLINE CYTIDYLYLTRANSFERASE ACTIVITY AND PHOSPHATIDYLCHOLINE SYNTHESIS IN HUMAN NEUROBLASTOMA CELLS. B.E. Slack, J. Breu* and R.J. Wurtman, Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge MA 02139.

The involvement of endogenous diacylglycerol (DAG) production in the stimulation of phosphatidylcholine (PtdCho) synthesis by exogenous phospholipase C (PLC) was examined in LA-N-2 neuroblastoma cells. PLC treatment (0.1 U/ml) of intact cells stimulated CTP:phosphocholine cytidylyltransferase activity significantly more effectively than did maximal concentrations (1 mM) of sn-1,2-dioctanoylglycerol (diC₈). The effects of PLC and oleic acid were additive, but those of PLC and diC₈ were not, suggesting that diC₈ and PLC might act via a common mechanism. The time course of activation of cytidylyltransferase by PLC paralleled that of [³H]DAG production in cells preloaded with [³H]oleic acid. DAG mass was similarly increased. Significant elevations in [³H]oleic acid were not detected until time points after those at which cytidylyltransferase was maximally activated. No significant reduction in total or [³H]PtdCho was elicited by 0.1 U/ml PLC; but higher concentrations (0.5 U/ml) significantly reduced total PtdCho content. The stimulation of cytidylyltransferase activity by PLC or by diC₈ was associated with enhanced incorporation of [methyl-¹⁴C]choline into PtdCho. The effect of diC₈ was largely due to increased formation of [¹⁴C]diC₈PtdCho. The results indicate that the generation of DAG by exogenous PLC activates cytidylyltransferase activity in neuronal cells under conditions in which membrane PtdCho content is not measurably reduced.

CHANGES OF RAT STRIATAL MEMBRANE MORPHOLOGY AND STEROID CONTENT DURING THE ESTROUS CYCLE. M. Morissette^{1,2}, L.M. Garcia-Segura³, A. Bélanger^{2*}, and T. Di Paolo¹. ¹Dept. Mol. Endocrinol., CHUL Res. Centre, G1V 4G2 and ²Sch. Pharm., Laval Uni., G1K 7P4, Québec, Canada, ³Instituto Cajal, C.S.I.C., Dr Arce 37, 28002, Madrid, Spain.

The membrane effects of sexual steroid hormones on the rat striatum during the estrous cycle was evaluated by freeze-fracture methodology. In addition, the steroid content was simultaneously investigated in the serum, striatum and in the rest of the brain. As previously described, serum 17 β -estradiol (E2) concentrations peak in proestrus while progesterone (PROG) was high in diestrus and proestrus PM (PPM). Interestingly, we found a similar E2 and PROG pattern in the striatum and the rest of the brain. E2 and PROG concentrations in the striatum and the rest of the brain were significantly correlated with serum levels. In a freeze-fracture study, a significant difference in the content of intramembrane protein particles (IMP) in dendritic shafts was found during the estrous cycle. The numerical density of large (>10nm) IMPs was increased in diestrus I and II and in PPM compared to estrus, proestrus AM and ovariectomized (OVX) rats. In contrast, the numerical density of small (<10nm) IMPs was decreased in cycling animals compared to OVX rats and showed a fall in PM and then a progressive increase in the following days to reach a peak in proestrus AM. None of the above mentioned changes were observed in the membranes of dendritic spines. We observed, for the first time, that both, striatum E2 and PROG levels, fluctuated during the estrous cycle with a pattern similar to serum levels and this was associated with changes of IMP number of striatal plasma membrane suggesting that these steroids could play a direct action in this brain structure. Supported by the MRC of Canada and DGICYT of Spain.

STUDIES ON SIALYLTRANSFERASE ACTIVITY (SAT-1) IN DEVELOPING MUSCLE AND BRAIN. L.D. Cambron and K.C. Leskawa. Dept. Anatomical Sciences & Neurobiology, University of Louisville, Louisville, KY 40292

Others have suggested that cell surface glycosyltransferases may play a role in development of brain, and this has been demonstrated in studies of cell interactions in nonneural systems. We have recently found that addition of UDP-dialdehyde also blocks myoblast membrane fusion, implicating a role for surface glycosyltransferases in myogenesis. Upon direct assay of glycosyltransferases in myoblasts exposed to UDP-dialdehyde, several activities were found to be inhibited, including SAT-1. This was curious because the normal donor for this reaction is a CMP-sugar and not a UDP-sugar.

To pursue this we analyzed SAT-1 activity, which catalyzes the formation of ganglioside GM3 from lactosylceramide and CMP-sialic acid, using microsomal preparations from homogenates of 14 day chick embryos. Various compounds were examined for inhibitory actions (0 to 1000 μ M). It was found that both UDP-dialdehyde and CMP-dialdehyde inhibited SAT-1 activity, with CMP-dialdehyde being only slightly more effective at low concentrations (50 and 100 μ M). A similar situation was observed with the addition of nucleotides alone (CMP and UDP), each resulting in approximately 50% inhibition with CMP being only slightly more effective. Addition of UDP-Gal and UDP-GalNAc also resulted in approximately 25% inhibition of SAT-1 activity.

Taken together, these results suggest: (1) a direct role for membrane GSLs in myoblast membrane fusion; (2) the involvement of surface glycosyltransferases, including SAT-1; and (3) that the active site in SAT-1 may not be very selective for the nucleotide portion of the donor nucleotide sugar. Supported by NIH grant NS21057

DIFFERENTIAL DISTRIBUTION OF mRNA for Na, K-ATPase SUBUNIT ISOFORMS IN THE RAT CEREBELLUM. W.R. Anderson* and W.L. Stahl. VA Medical Center and Univ. of Washington Sch. Med., Seattle, WA 98108

The Na, K-ATPase is an integral membrane protein composed of α and β subunits, with multiple isoforms of each subunit. Utilizing *in situ* hybridization techniques we have attempted to identify the cellular distribution of subunit mRNA within neural tissue. With synthetic oligonucleotide probes (Filuk et al., Neurosci. Res. Comm. 5: 155-162, 1989) directed against mRNA for the $\alpha 1$, $\alpha 2$, $\alpha 3$, $\beta 1$, and $\beta 2$ subunit isoforms for the Na, K-ATPase we have examined adult rat cerebellum. Our results from brain sections show differences in distribution between subunit isoforms. In cerebellum labelling with all probes was restricted to neuronal cell layers with none seen in fiber tracts. The $\alpha 1$ probe labelled more heavily in the cerebellum than elsewhere in the brain and was heaviest in the granule cell layer. The $\alpha 2$ probe labelled at comparable levels in the cerebellum and throughout the rest of the brain. In the cerebellum the most intense labelling was associated with the Purkinje cell layer. The $\alpha 3$ probe showed a pattern of distribution similar to that of the $\alpha 2$ probe. The $\beta 1$ probe showed high levels of labelling in the cerebellum that were roughly similar to those in the rest of the brain. The highest levels were also associated with the Purkinje cell layer. The $\beta 2$ probe showed much higher levels of labelling in the cerebellum than elsewhere in brain. Labelling was low in the Purkinje cell layer. The most striking finding is the high level of labelling of $\alpha 1$ and $\beta 2$ mRNA in cerebellum compared to other brain structures. (Supported in part by the VA and NIH.)

PERIPHERAL BENZODIAZEPINE RECEPTOR LIGANDS ACTIVATE DNA POLYMERASE γ ACTIVITY OF CULTURED GLIOMA CELLS.

T. Shiraiishi, K. L. Black and D. P. Becker. Division of Neurosurgery and Brain Research Institute, Univ. of California, Los Angeles, CA 90024.

We have previously reported that ligands for peripheral benzodiazepine receptor increase the number of mitochondria and dividing mitochondria of cultured glioma cells. To further elucidate the effect on mitochondrial proliferation, DNA polymerase α (replicates nuclear DNA), β (repairs nuclear DNA) and γ (replicates mitochondrial DNA) activities were determined.

C6 rat glioma cells were incubated in medium with 10% calf serum (S+ group) or serum free medium alone (S- group), or serum free medium plus 10 nM of either PK11195 or Ro5-4864 (both peripheral type ligands; PBL group), or clonazepam (central type ligand; CBL group) for from 3 to 72 hr. The homogenates from crude cell extracts were incubated with the polymerase α , β and γ assay mixture and radioactivity was counted in liquid scintillation counter.

In S+ and PBL group, polymerase α activity increased within 24 hr to approximately 220 and 20% of initial activity, respectively. Polymerase β activity remained nearly constant in each group. In PBL group, polymerase γ activity increased to reach a maximum (approximately five folds of the initial value) after 3 and 6 hours and then decreased again, while in other group no major changes with time were observed.

These findings suggested that peripheral benzodiazepine receptor might activate DNA polymerase γ activity and be involved in mitochondrial DNA duplication.

IDENTIFICATION AND LOCALIZATION OF A NEW MEMBRANE TYROSINE KINASE RECEPTOR IN THE AVIAN NERVOUS SYSTEM: E. B. Pasquale*, I. J. Deerinck*, S. J. Singer* and M. H. Ellisman. Departments of Neurosciences Ψ , and Biology Σ , University of Calif., San Diego; La Jolla Cancer Research Foundation Φ , La Jolla, Calif.

It is now clear that protein tyrosine kinases play very crucial roles in the cascade of events involved in signal transduction during embryonic development. However, tyrosine kinases are also expressed at high levels in non-proliferating cells, such as neurons and platelets. Among adult tissues, the brain contains the highest levels of protein tyrosine kinase activity, comparable to those found in embryonic tissues. By screening a chicken embryo expression library with antibodies to phosphotyrosine a novel membrane-bound tyrosine kinase receptor of the Eph family (Hirai, et al., Science 238:1717, 1987), Cck5, was identified and its c-DNA sequenced (E.B.P., to be published). Cck5 is developmentally regulated and predominantly expressed in chicken embryonic and adult brain. The abundant expression of Cck5 in embryonic tissues and in the adult CNS strongly suggest that its expression is important for the function of many cell types. In order to determine the precise cellular distribution of Cck5 in the CNS specific antibodies were made to a synthetic peptide and a Cck5- β galactosidase fusion protein. Although specific immunoreactivity was detected in many regions of the 1 day postnatal and 17 day embryonic chicken CNS, the highest concentration of Cck5 was found in the molecular layer of the cerebellum. High resolution light and electron microscopic studies demonstrate this immunoreactivity to be associated with the axons of mature granule cells, (parallel fibers) and with the cell bodies of immature granule cells (before migration to the granular layer). Some immunoreactivity is also observed in post-migratory granule cells at embryonic day 17, but not at postnatal day 1. Although the molecular layer of the brain is particularly rich in synapses, Cck5 appears concentrated in the non-synaptic portions of the parallel fiber axons. This distribution of Cck5 suggests a role for tyrosine phosphorylation either in the regulation of the function of parallel fibers or in their associations with neighboring cells.

379.12

UBIQUITOUS CELLULAR AND REGIONAL DISTRIBUTION OF (NA,K)-ATPase $\alpha 2$ ISOFORM mRNA IN THE RAT NERVOUS SYSTEM. D.J.Fink, V.Hieber, C.Siegel and M.Mata. Department of Neurology, University of Michigan, and GRECC VAMC, Ann Arbor, MI 48105

We have used an RNA probe directed against the unique 3' untranslated region of (Na,K)-ATPase $\alpha 2$ cDNA to study the localization and expression of the mRNA for this isoform of the catalytic subunit of (Na,K)-ATPase at the cellular level in the nervous system of the rat.

Within the brain, $\alpha 2$ mRNA was found diffusely in all brain regions. Unlike mRNA for $\alpha 1$ and $\alpha 3$ isoforms, $\alpha 2$ mRNA was abundant generally in glia as well as neurons, and was found in the meninges. In the cerebellum $\alpha 2$ mRNA was found in nearly all cell types including Bergmann glia. Label was sparse, however, in Purkinje cells.

In the spinal cord $\alpha 2$ mRNA was found in all cells including neurons, astrocytes of the gray matter, and oligodendroglial cells of the long tracts of spinal cord. In the dorsal root ganglia (DRG) both neurons and satellite cells contained $\alpha 2$ mRNA, and in the peripheral nerve Schwann cells contained $\alpha 2$ mRNA.

These results demonstrate a nearly ubiquitous regional and cellular distribution for the $\alpha 2$ isoform mRNA in the nervous system, and suggest that $\alpha 2$ may be the principal glial and Schwann cell isoform of (Na,K)-ATPase. In addition, these results demonstrate $\alpha 2$ mRNA to be present in variable amounts in most neuronal cell types.

379.14

Expression of a novel T-cell molecule, 4-1BB, in the brain. B. S. Kwon*, C. F. Pu*, Z. Zhou*, K. Kim*, Y.-J. Kim*, and F. C. Zhou. Department of Anatomy and Department of Microbiology and Immunology, and Walther Oncology Center, Indiana University School of Medicine, 635 Barnhill Drive, Indianapolis, IN 46202.

The cDNA clone 4-1BB was isolated from T-lymphocytes by a modified differential screening procedure. The potential 4-1BB protein (4-1BBP) contains features seen in known receptor proteins and a region of amino acids similar to those in the nerve growth factor receptor, Drosophila gene *sina*, and Dictyostelium gene DG17. We have obtained polyclonal antibodies against a hydrophilic region of 4-1BBP and examined its distribution in the brain. The specific expression pattern of 4-1BBP in the brain was identified in the gray matter where neuronal cell bodies, dendrites, and fiber terminals reside but was almost entirely absent in the white matter where axonal fibers dwell. A peculiar rosette pattern was observed in a granular layer of cerebellum and to be scattered in the stria terminalis. The staining pattern strongly resembled the receptor/nerve terminals in the brain and in the peripheral nervous system. This study suggests that the 4-1BBP is a novel receptor which may be associated with brain function and is another example of a cell surface molecule which is found in both the immune and nervous systems.

379.16

EXPRESSION OF TWO GLUCOSE TRANSPORTER ISOFORMS, GLUT1 AND GLUT3, IN CULTURED CEREBELLAR NEURONS. F. Maher, T. Davies* and I.A. Simpson*. NIDDK, NIH, Bethesda, MD 20892.

Expression of different isoforms of the facilitative glucose transporter was investigated in primary cultures of rat cerebellar granule neurons. During neuron development from day 2 to day 8 *in vitro* uptake of ^3H -2-deoxyglucose increased from 250 ± 67 to 910 ± 99 pmol/min/ 10^6 cells. Expression of mRNAs for GLUT1 (2.8kb) and GLUT3 (4kb) was detected by Northern blot analysis. Both transcripts increased to peak expression at day 4, followed by a decline. Western blotting showed that expression of the glucose transporter isoforms GLUT1 (45kD) and GLUT3 (45kD) increased by 10-15-fold from day 2 to day 8. Transporter isoforms GLUT2 and GLUT4 were not expressed in neurons. The concentration of glucose in the medium did not markedly alter the rate of 2-deoxyglucose uptake or the levels of GLUT1 or GLUT3. Immunofluorescence staining showed localization of GLUT3 at the neuronal plasma membrane whereas GLUT1 appeared both at the plasma membrane and in the cytoplasm. GFAP⁺-astrocytes were GLUT3-negative and GLUT1-positive in extended 16 day cultures. In this neuron culture system GLUT3 appears to be more abundant than GLUT1 suggesting a predominant role for the GLUT3 isoform in neuronal glucose transport.

379.17

MEMBRANE AND CYTOSKELETAL LOCALIZATION OF DYSTROPHIN IN CULTURED RAT MYOTUBES. G. M. Dmytrenko, D. W. Pumplin* and R. J. Bloch*. Departments of Neurology, Anatomy and Physiology, University of Maryland School of Medicine, Baltimore 21201

Dystrophin's location and its interactions with the cytoskeleton and cell membrane were examined in primary cultures of neonatal rat myotubes. Fixed and permeabilized intact myotubes displayed specific anti-dystrophin labeling along the sarcolemma. Substrate-associated membrane (SAM) containing acetylcholine receptor (AChR) clusters was isolated from myotubes by detergent extraction or physical shear. Immunofluorescence microscopy demonstrated that anti-dystrophin label in SAM devoid of AChR was diffusely punctate. In AChR clusters, dystrophin label was present within AChR rich domains to a variable extent, but was usually absent from adjacent AChR-poor domains. At the ultrastructural level, immunogold labeling of sheared myotubes demonstrated that dystrophin was present in a meshwork closely applied to the inner surface of the cell membrane of AChR domains. Overlying actin filaments that attached to this meshwork were not labeled. When intact myotubes were exposed to media containing inhibitors of energy metabolism or lacking calcium, AChR cluster organization was disrupted and dystrophin label appeared diffusely punctate throughout myotube SAM. Exposing SAM to buffers of low ionic strength or high pH also disrupted AChR organization, but did not remove dystrophin label. Chymotrypsin treatment of SAM removed dystrophin label completely. We compared these results with the extraction profiles for other cytoskeletal components of AChR clusters, namely actin, β -spectrin, and the 58 K and 43 K proteins. Dystrophin was more resistant to extraction than any of these cytoskeletal elements. Thus, dystrophin is spatially related to the cytoskeletal network associated with AChR organization and may interact with this network. However, dystrophin is tightly bound to the cell membrane by mechanisms independent of the other proteins known to be within this network.

Supported by an NIH grant to GMD, and NIH and MDA grants to DWP and RJB.

REGULATION OF SARCOLEMMA DYSTROPHIN IN THE CARDIAC AND SKELETAL MUSCLES OF CHF-146 STRAIN DYSTROPHIC HAMSTERS (DH) BY DILTIAZEM THERAPY. S.K. Bhattacharya, T.A. Adamec*, P.L. Johnson, D.L. Lovett*, R.K. Handa, and M.P. Gupta. Surgical Research Lab, University of Tennessee, Memphis, TN 38163.

Membrane-mediated chronic cellular degeneration plays a fundamental pathogenetic role in hereditary muscular dystrophy (HMD). We have shown that Diltiazem (DTZM) (80 mg/kg BW/d, ip.) reduced membrane-mediated necrosis and histopathology in the heart (HT) and rectus femoris (RF) muscle of DH (*J. Neurol. Sci.*, 8:238, 1990). Dystrophin (DYST), a sarcolemmal bound protein (400 kD), is shown to be missing in Duchenne muscular dystrophy (DMD) and Becker's MD (BMD), mdx-mice, xmd-dogs (*Nature*, 333:861, 1988), and in DH (*FASEB*, 5(5):A1053, 1991). However, the specificity of DYST and its association with HMD remains ill-defined. DYST anomalies have not been found in other dystrophic mice and chickens, and in most forms of human muscular dystrophies, except in DMD and BMD. Using immunohistochemical techniques and NCL-DYS1/DYS2 monoclonal antibodies from Novocastra Lab (Newcastle upon Tyne, UK), we studied DYST regulation in DH and normal hamsters by chronic ip. DTZM therapy. *In situ* frozen HT, RF, and gastrocnemius (GN) biopsies were used. We conclude that DYST staining is significantly reduced and discontinuous in the cardiac and skeletal muscles of DH, although less severely than seen in patients with DMD or BMD. Concomitant with numerous salutary effects, improved morphology and longevity, ip. DTZM therapy also enhances DYST staining in the myocardium, rectus femoris, and gastrocnemius muscles of DH. (Supported by NIH Grant #AR-38540)

A DEFECTIVE HSV VECTOR TARGETS A LYMPHOCYTE PROTEIN TO NEURONAL AND GLIAL PLASMA MEMBRANES. R.J. Wyborski¹, P.D. Olivo^{2*}, J.M. Nerbonne¹, S. Gallamore¹, D. Gottlieb¹, Departments of ¹Anatomy & Neurobiology, ²Internal Medicine, ³Molecular Biology & Pharmacology, Washington University, St. Louis MO 63110

The plasma membrane plays a fundamental role in the cell biology of neurons and glia. By expressing membrane proteins coded by cloned DNA the composition and function of the plasma membrane can be manipulated to gain greater understanding of the roles of proteins in physiological function. We have used a defective HSV vector to target the lymphocyte cell surface protein CD8 to the surface of cultured cortical neurons and glial cells. A defective Herpes was constructed in which a cDNA coding for the entire length of CD8 was inserted downstream of the Herpes alpha 4 promoter. Stocks of the defective virus were prepared using the ICP6 delta helper virus. Cultures of dispersed rat visual cortical neurons grown on astrocytes were infected with vector. After infection (24-48 hrs) living cells were stained with a monoclonal antibody to CD8. Stained cells were detected in cultures infected with the vector but not in uninfected cells or cells infected with HSV alone. Glial cells were intensely stained throughout the plasma membrane. Neurons were intensely stained with both somata and processes carrying the antigen. These results demonstrate that neurons and glia can synthesize the lymphocyte protein CD8 and that they have the necessary molecular machinery to transport it to the cell surface. They also show that it is possible to identify living neurons and glia expressing genes introduced by a herpes vector by including a membrane protein marker in the vector.

INPUT SPECIFIC INDUCTION AND PRECLUSION OF NMDA RECEPTOR INDEPENDENT LTP IN AREA CA1 OF RAT HIPPOCAMPUS. L. Grover & T. Teyler. Neurobiol. Dept., N.E. Ohio Univ. Col. of Med., Rootstown, OH 44272.

A frequency dependent, NMDA receptor independent component of LTP (non-NMDA_R LTP) can be induced in area CA1 (Grover & Teyler, *Nature*, 1990). It seemed possible that non-NMDA_R LTP might differ in some characteristics from NMDA receptor dependent LTP (NMDA_R LTP). We therefore asked if non-NMDA_R LTP would show input specific induction, as previously shown for NMDA_R LTP. In the presence of APV (to block NMDA_R LTP) we stimulated 2 independent afferent inputs. Tetanization of one input induced non-NMDA_R LTP only in that input, with the second input showing no LTP. However, non-NMDA_R LTP induction in one input precluded non-NMDA_R LTP when the second input was subsequently tetanized, but did not preclude NMDA_R LTP (induced after APV washout). Preclusion of non-NMDA_R LTP, but not NMDA_R LTP, may reflect differences in spatial distribution of post-synaptic Ca²⁺ influx. Supported by NIH grant NS28698.

VISUAL CORTICAL SYNAPTIC PLASTICITY IN THE KITTEN: A STUDY USING ANTAGONISTS *IN VITRO*. T.P. Hicks and K.-I. Ito. Dept. of Psychology, UNCG, Greensboro, N.C. 27412-5001.

In order better to understand the synaptic mechanisms at work underlying long-term changes (LTP, LTD) in synaptic transmission in neocortex, we recorded responses from layers II/III before and after tetanic stimulation of the white matter in tissue slices from young kittens and assessed the effects of the amino acid antagonists, AP5, DNQX, BMI, 2-OH-Sac, D-Ser and 7-Cl-Kyn on different components of these evoked potentials. A survey of stimulation parameters in our system showed 10 Hz, 2 min to be optimal for generating LTP. Evoked responses were separated by computer calculation into antidromic and synaptic components, following data collection during perfusion with Ca²⁺-free media. The data show complex and strikingly different effects of each of these selective antagonists on different components of the synaptic responses. All blockers interfered to greater or lesser extents with some aspect of the responses; the data with drugs acting on the glycine site show that D-serine enhances, but 7-Cl-Kyn doesn't suppress, low-frequency synaptic transmission - one of several basic observations at variance with what is seen in hippocampus.

380.3

INDUCTION OF LONG-TERM POTENTIATION (LTP) WITHOUT NMDA RECEPTOR INVOLVEMENT IN VISUAL CORTEX OF JUVENILE AND ADULT RATS. V.A. Aroniadou, L.M. Grover, and T.J. Teyler. Neurobio. Dept. NE Ohio Col. Med., Rootstown, OH 44272.

In slices of rat visual cortex, white matter stimulation elicited a two-component field potential in layer III, with peak latencies 5-8ms (EPSP1) and 12-19ms (EPSP2). AP5 applied to the bath or at the recording site, caused a reduction/blockade (reversible) of EPSP2. EPSP2 may be generated polysynaptically via an input arising from infragranular layers. Bath applied DNQX revealed a DNQX-resistant/AP5-blocked component (EPSP1b) with onset latency of EPSP1, and peak at 10-23ms. Compared to juveniles, adults showed reduced sensitivity of EPSP2 to AP5 and lower relative amplitude of EPSP1b. In juvenile cortex tetanic stimulation of the white matter in normal medium induced LTP of EPSP1 (173-449%). In AP5, LTP of EPSP1 (136-200%) was induced only when EPSP2 was not blocked by AP5 (37% of slices); no change or depression (LTD) was observed in the remaining slices. In adult cortex, LTP of EPSP1 was induced following tetanus either in normal medium (139-208%), or in AP5 (137-270%). When maximally potentiated, under any of the above conditions, EPSP1 was unaffected by bath applied AP5. In some slices EPSP2 also expressed LTP. Following tetanus in DNQX, the isolated NMDA receptor-mediated component (EPSP1b) expressed LTP or LTD; the direction of change appeared to relate to both age and stimulus intensity. In visual cortex of either juvenile or adult rats LTP can be induced without reduction of inhibition or participation of NMDA receptors. These results suggest that reduced expression of NMDA receptor activity in adult neocortex may be accompanied by enhanced efficiency of other LTP inducing mechanisms. Supported by NS28698.

AN INCREASE IN THE AFFINITY OF THE AMPA RECEPTOR FOR AGONISTS IS ASSOCIATED WITH INCREASED SYNAPTIC RESPONSES IN CA1 NEURONS. K. Shahi and M. Baudry. Neuroscience Program, USC, Los Angeles, CA.

A number of manipulations has been shown to modify the affinity of ligands for the AMPA subtype of glutamate receptors and it has been proposed that the long-term potentiation (LTP) of synaptic transmission observed in the CA1 region of the hippocampus is due to a change in receptor properties. It is therefore of critical importance to determine whether changes in binding properties of agonists for the AMPA receptors are accompanied by modifications of the physiological responses elicited by agonists. It has been shown that the chaotropic ion SCN⁻ produces a large and reversible increase in the affinity of agonists for the AMPA receptors. We determined the effect of iontophoretically applied SCN⁻ on the characteristics of synaptic potentials recorded extracellularly in the dendrites and cell body layer of CA1 in the hippocampal slice preparation. Picrotoxin was included to eliminate possible effects of SCN⁻ on GABA currents. Brief applications of SCN⁻ produced a rapid and reversible increase in the slope and amplitude of EPSPs as well as an increase in population spike amplitude; these effects were absent when NaCl was substituted for NaSCN. Antidromic responses and paired pulse facilitation remained unchanged during SCN⁻ application. These results suggest that an increase in the affinity of the AMPA receptor for glutamate is accompanied by increased physiological responses elicited by glutamate and provides further support for the hypothesis that LTP is due to a change in receptor properties. (Supported by Grant BNS 96284 from NSF).

LTP, BUT NOT PRE-SYNAPTIC FACILITATION, CHANGES THE EFFECTS OF A DRUG THAT ENHANCES AMPA RECEPTOR CURRENTS. U. Staubli¹, P. Xiao*, M. Kessler, J. Ambros-Ingerson* and G. Lynch. ¹McGill University, Dept. Psychology, Montreal, QC H3A 1B1, and University of California, Center for the Neurobiology of Learning and Memory, Irvine, CA 92717.

We recently reported that the response enhancing action of the nootropic compound aniracetam is reduced in synapses expressing long-term potentiation (Staubli et al., Psychobiol. 18: 377, 1990). Here we present data from hippocampal slices showing that the percent facilitation produced by aniracetam remains constant in the presence of treatments known to augment response size by increasing transmitter release (i.e., changes in extracellular calcium, 4-aminopyridine and paired pulse facilitation) but is reduced following induction of LTP. Aniracetam displayed a regional variation in its effect: it had a significantly smaller facilitating action in CA3-CA3 synapses than it did in CA3-CA1 or perforant path-dentate gyrus synapses. The drug did not affect NMDA receptor mediated synaptic responses but did cause a small (5-10%) and statistically significant decrease in [³H]AMPA binding. Other nootropics did not produce aniracetam-like effects.

These observations indicate that aniracetam produces a selective facilitation of AMPA receptors which, given its small effect on binding, is probably due to an enhancement of channel conductance. These conclusions are in accord with the original results obtained by Ito et al. (J. Physiol. 424: 533, 1990). The finding that LTP, but not pre-synaptic manipulations that increase the size of field EPSPs, alters the actions of aniracetam strongly suggests that LTP is also due to a receptor change. A mathematical model of synaptic transmission and dendritic currents has been used to identify the types of receptor changes that reproduce the observed interaction between aniracetam and LTP. AN NMDA ANTAGONIST, CPP, BLOCKS ASSOCIATIVE AND NON-ASSOCIATIVE LONG-TERM DEPRESSION IN THE DENTATE GYRUS. B. R. CHRISTIE AND W. C. ABRAHAM. Department of Psychology and the Neuroscience Research Centre, University of Otago, Dunedin, New Zealand.

The present study evaluated associative and non-associative synaptic interactions between the medial (MPP) and lateral (LPP) perforant path projections to the ipsilateral dentate gyrus (DG) in barbiturate anaesthetized rats. Associative interactions were investigated using 5 Hz bursts of short 100 Hz trains delivered to one path in association with single pulses, administered to the other path, spaced equidistantly between the bursts. Non-associative interactions were studied using the conditioning trains or the single pulses alone. Data are presented as the mean \pm SEM percent change from baseline at 30 minutes post-tetanus. Application of the single pulses as a 5 Hz train produced a homosynaptic EPSP increase (LTP) when delivered to either pathway (MPP: 9.9 \pm 3.3%; LPP: 8.7 \pm 3.8%), but did not induce heterosynaptic depression (LTD). In the non-associative paradigm, MPP tetanization produced LTP of the MPP responses (26.1 \pm 4.8%) and LTD in the LPP (-15.9 \pm 4.2%), while LPP tetanization produced LTP in the LPP (35.2 \pm 14.9%) and to a lesser extent, LTD in the MPP (-3.9 \pm 3.4%). The associative paradigm also produced LTP of the conditioned pathway (MPP: 18.5 \pm 2.9%; LPP: 47.8 \pm 6.6%) and similar LTD to that seen in the non-associative condition (LPP: -18.4 \pm 4.2%; MPP: -4.7 \pm 8.6%). No significant differences were found between the effects produced by the associative and the non-associative paradigms, and both were found to produce equivalent depression in previously tetanized pathways (Associative: MPP: -16.5 \pm 6.7%; LPP: -23.3 \pm 4.7%; Non-Associative: MPP: -15.7 \pm 6.8%; LPP: -17.4 \pm 4.5%). Both associative and non-associative LTP and LTD were blocked by the competitive NMDA antagonist CPP (10 mg/kg; administered i.p. 2hrs prior to tetanization). These data suggest that associatively and non-associatively induced synaptic depression in the dentate gyrus involve similar mechanisms, including NMDA receptor activation.

HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) IS ASSOCIATED WITH INCREASED [³H]-AMPA BINDING IN RATS. S. Maren, G. Tocco, T. J. Shors, M. Baudry, and R. F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

The nature of synaptic modifications underlying long-term potentiation (LTP) is a vigorously debated issue; evidence for both presynaptic and postsynaptic modifications has been reported. In the following we report an increase in [³H]-alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA) binding following the induction of LTP in perforant path-granule cell synapses of anesthetized rats. Male Long-Evans rats were implanted stereotaxically with a bipolar stimulating electrode in the perforant path and a recording electrode in the hilus of the dentate gyrus. Animals received either low-frequency stimulation (200 pulses at 1 Hz; n=5), low intensity theta burst stimulation (TBS; 10 40 ms 400 Hz bursts at 5 Hz, intensity sufficient to elicit a 1 mV population spike [PS]; n=6), or high intensity TBS (intensity twice that which elicited a maximal PS; n=5). One hour following stimulation the rats were sacrificed and their brains rapidly dissected and frozen. Quantitative autoradiography of [³H]-AMPA and [³H]-N-(1-[thienyl]cyclohexyl)piperidine (TCP) binding to 10 μ m coronal sections was used to examine AMPA and N-methyl-D-aspartate (NMDA) receptors, respectively. Bilateral increases in [³H]-AMPA binding were observed in CA₁ oriens and radiatum, CA₃ radiatum, dentate gyrus, hilus, and cerebral cortex in animals exhibiting LTP (low intensity TBS group). Pretreatment of rats with the noncompetitive NMDA antagonist ketamine (30 mg/kg; n=3) eliminated both the increases in [³H]-AMPA binding and LTP. No significant changes in [³H]-TCP binding were observed in any treatment group. These results indicate that *in vivo* LTP is associated with a selective modification of the binding properties of AMPA, but not NMDA receptors in the rat hippocampus. Long-term potentiation (LTP) induced by metabotropic receptor activation coupled with subthreshold tetanus

Otani S*, Aniksztejn L*, Represa A. & Ben-Ari Y.

INSERM U29, 123 Boulevard de Port-Royal, Paris, FRANCE

The involvement of metabotropic receptors in LTP was investigated in rat CA1 slices. Bath-application of the metabotropic receptor agonist *trans*-(+)-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD, 50 μ M) caused a transient depression of the field EPSP. However, *trans*-ACPD produced LTP when it was coupled with a weak tetanus (50 Hz, 0.25-0.5 s) (12/15 slices). Weak tetanus itself was subthreshold for LTP, producing only short-term potentiation (STP). Coupling a weak tetanus with α -amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA, 5 μ M, n=6) or N-methyl-D-aspartate (NMDA, 10 μ M, n=4) did not produce LTP. Furthermore, although STP was also induced by combined application of AMPA and NMDA, coapplication of *trans*-ACPD (50 μ M) with these agents could not produce LTP. From these results, we conclude that this form of LTP (LTP_M) is induced by activation of metabotropic receptors and coupled weak tetanization.

STP was blocked by D(-)-2-amino-5-phosphopentanoic acid (AP5, 50 μ M). In this condition, LTP_M was not induced (n=4). Similarly, 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX, 10 μ M) blocked LTP_M (n=2). LTP_M was also observed intracellularly without changes in input resistance and spike threshold (n=5).

Metabotropic receptor activation results in release of Ca²⁺ from the internal store. Our results suggest that the elevation of (Ca²⁺)_i by metabotropic receptor activation is additive to a rise of (Ca²⁺)_i following NMDA receptor activation and induces LTP_M. Whether this is a common feature with conventional, tetanus-induced LTP is under current investigation.

LONG-LASTING MODULATION OF SYNAPTIC TRANSMISSION BY A SELECTIVE METABOTROPIC GLUTAMATE RECEPTOR AGONIST IN DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS *IN VITRO*.

F. Zheng and J.P. Gallagher, Dept. of Pharmacol. and Toxicol., Univ. of Texas Medical Branch, Galveston, TX 77550.

We have previously demonstrated (Zheng and Gallagher, Soc. Neurosci. Abstr. 16, 653.) that induction of long-term potentiation in the DLSN was not blocked by the selective NMDA receptor antagonist APV, but is blocked by a putative metabotropic glutamate receptor antagonist L-2-amino-4-phosphonobutyrate (APB).

In the present study, we applied *trans*-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD), a selective agonist of metabotropic glutamate receptors to DLSN neurons recorded intracellularly from rat forebrain coronal slices. Transient application of ACPD induced a concentration dependent depolarization followed by a hyperpolarization. At higher concentrations, ACPD elicited an oscillation of membrane potentials and burst firing. Superfusion of 20 μ M (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD), the active enantiomer of ACPD, produced an additional action, namely, it initiated a slow afterdepolarization probably through the unmasking of a calcium-activated non-selective cation current. Superfusion of 1S,3R-ACPD (20-40 μ M) for a period of 8-10 min resulted in a long-lasting potentiation of synaptic transmission subsequent to washout. EPSP amplitudes were increased to 150% of control following a 30-50 min washout of 1S,3R-ACPD. However, at higher concentrations, 1S,3R-ACPD caused a long-lasting depression of synaptic transmission; EPSP amplitudes were reduced to 60% of control even after a 60 min washout period.

These results demonstrate that activation of metabotropic glutamate receptors can produce a concentration-dependent dual modulatory action upon both the firing pattern and synaptic transmission in rat DLSN neurons. Such actions may play an important role in neuronal plasticity at this synapse.

380.11

TRIAZOLAM AND DIAZEPAM BLOCK LTP IN RAT HIPPOCAMPAL AND PIRIFORM CORTEX SLICES. S. Del Cerro, Min Jung and G. Lynch, Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717, U.S.A.

The present experiments tested for possible links between long-term potentiation (LTP) and the amnesic action of benzodiazepines. The effects of diazepam and triazolam, two benzodiazepines with a different pharmacological and clinical properties, were tested on LTP in slices of hippocampus and piriform cortex. Infusion of 50 μ M of both drugs blocked LTP but via different mechanisms. Diazepam reduced the increase in burst responses that occurs during the theta pattern stimulation used to induce the potentiation effect; the drug thus appears to interfere with the initial triggering events for LTP. This may reflect the known action of diazepam on GABA mediated inhibitory potentials. Triazolam did not alter burst responses in hippocampus or the development of LTP in piriform cortex; however, the LTP that resulted decayed back to baseline in 15-30 minutes. We suggest that the effects of triazolam on plasticity are mediated by its actions as an antagonist of the platelet activating factor receptor, since non-benzodiazepine blockers of the receptor also prevent the induction of LTP (del Cerro et al, Behav. Neural Biol, 1990, 54, 213-217). These results provide a plausible explanation for the amnesic effects of benzodiazepines and further support the role of LTP in memory encoding in animals and humans.

Supported by the U.S. Air Force Office of Scientific Research (AFOSR 89-0383) to G. Lynch. S. del Cerro is the recipient of the FESN (Fondation pour l'Etude du Systeme Nerveux Central et Peripherique, Geneva, Switzerland) Fellowship on Learning and Memory.

MODULATION OF THE HIPPOCAMPAL COMMISSURAL-CA3 LONG-TERM POTENTIATION BY SEROTONIN F. Villani* and D. Johnston, Div. of Neuroscience, Baylor Coll. of Med., Houston, Tx 77030.

Synaptic transmission in the hippocampus is modulated by subcortical afferents. This study investigates the modulatory effect of serotonin (5-HT) on long-term potentiation (LTP) induction in the hippocampus. The commissural/associational (C/A) input to CA3 was measured by extracellular field potentials in rat hippocampal slices. The intensity of the high frequency stimulation (HFS) was adjusted to yield population EPSPs of about 1 mV. Following induction of LTP (142 \pm 9% of pre-tetanus pEPSP slopes measured at 1 hour post-tetanus, n=6), perfusion for 30-45 minutes with 1 μ M 5-HT had little or no effect on synaptic transmission (96 \pm 3% of the pre-perfusion pEPSP slopes, n=7). HFS in the presence of 5-HT, however, did not produce any further LTP (108 \pm 8%, n=7), whereas HFS performed after prolonged wash-out of 5-HT did induce LTP (123 \pm 12%, n=6). In a second set of experiments GABA_A transmission was blocked by application of 10 μ M picrotoxin and 10 μ M bicuculline. 5-HT perfusion, following control LTP (166 \pm 13%, n=8), induced a small but significant decrease in synaptic transmission (89 \pm 4%, n=7). HFS in the presence of 5-HT did not induce further LTP (101 \pm 6%, n=7), whereas after prolonged wash-out HFS induced significant potentiation (116 \pm 4%, n=5). In other experiments 5-HT perfusion before inducing LTP caused a small decrease in synaptic transmission (90 \pm 5%, n=5). LTP was blocked by 5-HT (106 \pm 6%, n=5), but LTP was observed after wash-out (119 \pm 3%, n=4). Perfusion with the 5-HT antagonist methysergide (1 μ M) did not affect normal synaptic transmission (95 \pm 2%, n=4), but did block the effect of 5-HT on the induction of LTP (139 \pm 12%, n=4). We conclude that the activation of serotonergic receptors blocks the induction of LTP at the C/A-CA3 synapse. (MH44754)

EFFECT OF AGING AND METABOTROPIC GLUTAMATE RECEPTOR ANTAGONISTS ON CA1 LTP

Y. Izumi, D.B. Clifford & C.F. Zorumski, Depts. of Psychiatry and Neurology, Washington Univ. Med. School, St. Louis MO 63110

In 30 day old postnatal rats (P30), the metabotropic glutamate receptor antagonist, 2-amino-3-phosphonopropionate (AP3), blocks LTP in the CA1 hippocampal region when administered for 5 min immediately after delivery of the electrical tetanus. Similarly, 1 μ M NMDA also blocks LTP when administered posttetanically. The NMDA-mediated inhibition is reversed by coapplication of trans-amino-1,3-cyclopentanedicarboxylic acid (ACPD). We have studied developmental aspects of metabotropic receptor involvement in CA1 LTP by examining the effects of AP3, AP4 and NMDA in hippocampal slices prepared from 15, 30, 60 and 90 day old albino rats.

A single 1 sec, 100 Hz tetanus delivered to the Schaffer collateral pathway induces stable LTP (\geq 20% increase in EPSP slope) lasting 60 min or longer in 86% of slices from P15-P30 animals (N=14), compared to 17% of P90 slices (N=6). Additionally, the potentiation produced in P90 slices decreases from 20 to 60 min after the tetanus. While posttetanic application of 1 μ M NMDA blocked LTP in all slices from P15-P30 animals (N=11), there was no inhibition in slices from P60-P90 animals. Similarly, 100 μ M AP3 and 100 μ M AP4 inhibited LTP in P15-P30 slices but were less effective in P60 slices.

These results suggest that aging affects the generation of CA1 LTP, even in slices from relatively young rats. Additionally, antagonists of metabotropic glutamate receptors are more effective blockers of LTP in slices from 15-30 day old postnatal animals.

INDUCTION OF LONG-TERM DEPRESSION UNDER BICUCULLINE AT EC-DG SYNAPSES BY COMMISSURAL CONDITIONING. D.X. Zhang and W.B. Levy, Dept. of Neurosurgery, Health Sciences Center, Box 420, University of Virginia, Charlottesville, VA 22908

Long-term potentiation (LTP) of EC-DG responses concomitantly induces long-term depression (LTD) of inactive commissural synapses in the dentate gyrus. We find a symmetric effect: activation of the commissural pathway induces LTD of EC-DG responses (Zhang & Levy, in prep.). As reported by many authors using the paired-pulse technique, commissural stimulation can depress the EC-DG responses by a GABAergic mechanism. Therefore, using a bicuculline-containing recording electrode, to block GABAergic inhibition, we examined the effect of conditioning the commissural pathway on the EC-DG responses. The experiment used 15 urethane-anesthetized albino rats. There was 1 bicuculline-containing recording electrode in the left DG, and there were 3 stimulating electrodes (one in the right anterior DG symmetric with the recording electrode, one in the right posterior DG and one in the left angular bundle). In each of the 15 rats, the first conditioning of the commissural pathway (13 anterior placements, 2 posterior placements) induced LTD of EC-DG responses. In 9 of the 15 animals the initial EC-DG responses showed two or more population spikes (multispikes) in response to a single test activation. Such multispikes indicate the effectiveness of the bicuculline treatment. In each of these 9 rats, activation of the anterior commissural pathway induced LTD of the EC-DG responses. The decreased EC-DG slope (4.51 \pm 1.23%, n=9, p<0.01) is the same change seen without bicuculline. In 8 of these 9 rats, there was also LTD of the EC-DG response p-spike amplitude. The results imply that this kind of LTD does not depend on GABA-A synaptic activation.

Supported by NIH NS 15488 and NIMH RSDA MH00622 to WBL.

ANTAGONISTS OF THE PLATELET-ACTIVATING FACTOR (PAF) RECEPTOR BLOCK LONG-TERM POTENTIATION IN HIPPOCAMPAL SLICES. A. Arai and G. Lynch, Center for the Neurobiology of Learning and Memory, University of California, Irvine CA 92717.

Platelet-activating factor (PAF) is a naturally occurring alkyl-ether phospholipid with a variety of biological activities. In particular, PAF regulates calcium mobilization by interacting with a specific receptor and through this mechanism controls shape change and aggregation in platelets and secretion in several cell types. Recently, binding sites for PAF have been identified in synaptosome fractions from brain (Marcheselli et al., J.Biol.Chem. 265:9140, 1990) and PAF was found to increase calcium influx in cultured neuronal cells (Kornecki and Ehrlich, Science 2:1792, 1988). These findings suggest that PAF plays a role in neuronal function.

Long-term potentiation (LTP) involves calcium activated processes and produces changes in synapse morphology. The similarity to the processes controlled by PAF in platelets prompted us to test the effect of antagonists and agonists of the PAF receptor on the formation of LTP in field CA1 of rat hippocampal slices. The antagonist trans-BTD (trans-2,5-bis-(3,4,5-trimethoxyphenyl)-1,3-dioxolane) at concentrations of 8-16 μ M blocked LTP while the same concentration of a stereo-isomer (cis-BTD) with low affinity for PAF receptors was without effect. The blockade of LTP by trans-BTD was partially reversed by simultaneous application of the non-metabolizable receptor agonist carbamyl-PAF. Trans-BTD at the concentration sufficient to block LTP did not change paired-pulse facilitation, burst responses during the induction of LTP and NMDA receptor mediated responses. It thus appears that trans-BTD interferes with LTP at some step after induction and initial expression. CV3988, an antagonist structurally related to PAF also attenuated LTP. These results suggest that activation of PAF receptors contributes to the stabilization of LTP, possibly via an effect on intracellular calcium levels.

PLATELET-ACTIVATING FACTOR AUGMENTS EXCITATORY SYNAPTIC TRANSMISSION IN CULTURED RAT HIPPOCAMPAL NEURONS. G.D. Clark¹, L.T. Happel², C.F. Zorumski³ & N.G. Bazan⁴. ^{1,2}Depts. of Neurol., ²Neurosurg., ³Physiol. ⁴Ophthal. & ^{1,2,4}Neurosci., LSU Med. Ctr., New Orleans, LA 70112. ³Depts. of Psych., Anat. & Neurobiol., Wash. Univ., St. Louis, MO 63110.

A platelet-activating factor (PAF) antagonist has been shown to block the formation of long-term potentiation (LTP) in the hippocampus. Additionally, PAF binds to distinct brain microsomal and synaptosomal sites. We have tested the hypothesis that PAF increases synaptic release of excitatory transmitter in cultured rat postnatal hippocampal neurons. Perfusion of 1 μ M methyl carbamyl PAF, a nonhydrolyzable PAF, significantly augmented evoked excitatory synaptic currents in a reversible manner. 1 μ M BN-52021, a ginkgolide with antagonist activity at the synaptosomal PAF binding site, blocked this effect of 1 μ M methyl carbamyl PAF. No effect of PAF was seen on evoked inhibitory currents. Spontaneous miniature excitatory postsynaptic currents markedly increased in frequency, but not amplitude, during perfusion of 1 μ M methyl carbamyl PAF. These results indicate that PAF probably acts by a presynaptic mechanism and at a specific binding site to augment excitatory synaptic transmission.

380.17

THE NITRIC OXIDE SYNTHASE INHIBITOR N^ω-NITRO-L-ARGININE REDUCES THE MAGNITUDE OF LONG-TERM POTENTIATION IN THE DENTATE GYRUS BUT NOT IN AREA CA1 OF THE HIPPOCAMPUS IN VITRO. M.L. Errington*, Y.-G. Li*, H. Matthies**, J.H. Williams* and T.V.P. Bliss. Division of Neurophysiology and Neuropharmacology, National Institute for Medical Research, Mill Hill, London, NW7 1AA, UK and *Inst. of Pharmacology and Toxicology, Medical Academy, Leipziger Str. 44, 3090 Magdeburg, Germany.

NMDA releases nitric oxide from hippocampal slices (East et al., Neurosci. Lett. 123, 17, 1991), raising the possibility that nitric oxide (NO) may act as an early retrograde messenger in long-term potentiation (LTP). The enzyme NO synthase, which promotes the conversion of L-arginine to NO and citrulline, is differentially distributed in the hippocampus, with higher levels in the dentate gyrus than in the hippocampus proper (Snyder et al., TIPS 12, 125, 1991). We have investigated the effect of the NO synthase inhibitor N^ω-Nitro-L-arginine (NARG) on the induction of LTP in the dentate gyrus and area CA1 of rat hippocampal slices. Stimulating electrodes (S1 and S2) were placed to activate separate but converging pathways, and the population EPSP and spike recorded with extracellular electrodes. LTP was induced by 3 trains of 4 bursts of 5 pulses at 100 Hz, burst interval 200 msec, train interval 1.5 min. Pathway S1 was tetanized during perfusion with control medium; pathway S2 was tetanized after perfusion had been switched to a medium containing NARG. NARG did not affect the amplitude of evoked potentials in either region at the concentrations used. In area CA1, the magnitude of LTP was not affected by NARG at concentrations of 100 μ M (n=3) or 200 μ M (n=6). However, in experiments on dentate minislices (perfused with medium containing 4mM Ca²⁺, 3.5mM Mg²⁺ and 100 μ M picrotoxin) the magnitude of LTP of both population EPSP and population spike was consistently less in the pathway (S2) tetanized in the presence of 50 μ M NARG (mean percentage increase (\pm SEM) measured 10-20 min after the tetani to S1 and S2 was 77.2 (16.1) and 13.4 (6.2) respectively for the EPSP (n=9; p<0.005, 2-tailed t-test) and 166.0 (38.5) and 57.7 (13.2) for the population spike (n=7, p<0.05)). These results suggest that in the dentate gyrus, in contrast to area CA1, NO is necessary for the full expression of LTP.

380.16

EFFECT OF EXOGENOUS GM1 GANGLIOSIDE ON LTP IN RAT HIPPOCAMPAL SLICES PERFUSED WITH DIFFERENT CONCENTRATIONS OF CALCIUM. H.-M. Hwang, J.-T. Wang*, and T. H. Chiu*. Dept. of Anatomy, Chang Gung Medical College, Taoyuan, Taiwan, R.O.C.

Exogenous application of GM1 ganglioside was found to enhance synaptic transmission in the hippocampus. The present study examined its effect on long-term potentiation (LTP) of rat hippocampal slices perfused with different concentrations of calcium. LTP magnitude was measured as an increase in population spike amplitude, recorded from CA1 pyramidal cells, over the baseline after tetanic stimulation on Schaffer collateral by 3 trains of 100 Hz at an interval of 1 min. In perfusion with 2.5 mM calcium, GM1-treated slices, 50 μ M for 1 hr, appeared to be more potentiated than untreated ones. At 5.0 mM calcium, field potentials in a fast decay were recorded. No LTP or only post-tetanic potentiation was induced. GM1 seemed not only to stabilize evoked responses but also to reinstate LTP. At 1.0 mM calcium, LTP could not be induced and retrieved by GM1 treatment. Once calcium was raised to 2.5 mM, LTP could be recovered without further tetanic stimulation. Thus, exogenous GM1 might incorporate into synaptic membrane to participate LTP induction.

LTP AND VACCINIA VIRUS INFECTION OF SELECTED TARGETS IN THE HIPPOCAMPAL SLICE. D.L. Pettit & R. Malinow. Neuroscience Program and Dept. of Physiology & Biophysics, University of Iowa.

LTP is initiated at the postsynaptic membrane in the CA1 region of the hippocampus, but the location of the long-term modifications underlying LTP remains unclear. We are developing a system for introducing biochemical agents into selected pre or postsynaptic targets. Introduction of agents like pseudosubstrate protein kinase inhibitors into presynaptic cells would allow us to test the contribution of kinase activity to these long-term modifications.

We are using a vaccinia virus to infect specific targets in the rat hippocampal slice. This virus carries a gene for beta-galactosidase inserted next to early and late vaccinia promoters (generously provided by Dr. Bernard Moss). The virus is introduced into the extracellular space of the CA3 region by multiple picospritzer injections. Following incubation, the slices were fixed in paraformaldehyde and stained for the presence of beta-galactosidase with X-gal. We see staining, as early as 3 1/2 hours after infection and as late as 8 hours, localized to the injection site.

To test whether slices infected with virus are still capable of LTP we infected the CA3 and CA4 regions of slices and incubated at least 3 1/2 hours. Stimulating electrodes were placed in the CA3-CA4 cell body layer, at the site of injection, and the subiculum, stimulating fibers that would be unlikely to be infected. Recordings were made from CA1 cells with the whole-cell voltage clamp technique. We were able to induce LTP in both pathways for up to 10 hours after infection.

SODIUM CHANNELS: MOLECULAR BIOLOGY

381.1

EXPRESSION AND CHARACTERIZATION OF UNLINKED CHIMERIC SODIUM CHANNELS. M.M. Stephan, J.F. Potts, W.M. James and W.S. Agnew. Dept. of Cell. and Mole. Physiology, Yale Univ. School of Medicine, New Haven, CT 06510.

Sodium channel isoforms vary in their primary structure and pharmacological properties, and may vary in their sensitivity to modulation by second messenger systems. Not all isoforms are readily expressed in frog oocytes; the eel electroplax channel is not functional in this system, while the rat skeletal muscle channel is. Unlinked chimeras have been used to explore these observations. Partial channel constructs encoding only domains I and II or domains III and IV were prepared from μ I and eel cDNA's and used to make mRNA (cRNA). Co-injection of eel cRNA encoding domains I and II with μ I cRNA encoding domains III and IV gave rise to typical sodium currents. Expression of the inverse combination, μ I domains I and II with eel domains III and IV, did not result in detectable sodium current. If failure to express the eel channel is due to interactions with oocyte regulatory enzymes such as protein kinases, our results may localize the site of this effect to domains III and IV. These results demonstrate the feasibility of using interspecies chimeras, linked or unlinked, to localize regions responsible for functional attributes such as sensitivity to toxins, drugs, or neuromodulatory factors.

381.2

FUNCTIONAL EXPRESSION OF THE μ I SODIUM CHANNEL IN A TRANSFORMED HUMAN KIDNEY CELL LINE. IDENTIFICATION AND ISOLATION OF BIOSYNTHETIC INTERMEDIATES. C. Ukoumadu and W.S. Agnew. Yale University School of medicine, New Haven, CT 06510.

We describe a method for efficient transient expression of the rat skeletal muscle sodium channel, μ I in a mammalian cell line; 40-60% of cells express currents of upto 10 nA and are reactive immunocytochemically (Ukoumadu et al, *Biophys.J.*, 59,69a(1991); Ukoumadu et al; submitted). The cells are suitable for biochemical characterization of sodium channel biosynthesis and functional characterization. Pulse chase experiments suggest the presence of at least 3 distinguishable forms of the channel protein enroute to the cell surface. A core peptide of Mr~210 kDa is seen when co-translational N-linked glycosylation is inhibited with tunicamycin. This product is insensitive to Endo H, Endo F, and Neuraminidase. A second product which is sensitive to Endo H but not neuraminidase is the predominant form in the cell. It has an Mr~220-240 KDa, and appears to be retained in the ER until degradation some 10 hours later. Adsorption of cell lysates to wheat germ agglutinin (WGA) shows the presence of a third form of Mr~250 KDa which may represent the cell surface form. A majority of the synthesized protein is associated with intracellular membranes and we may now explore whether the intracellular forms are electrophysiologically and/or pharmacologically functional.

381.3

MOLECULAR CLONING AND CHROMOSOMAL LOCALIZATION OF HUMAN BRAIN SODIUM CHANNEL SUBTYPES. C.M. Lu, L. Han¹, T.A. Rado² & G.B. Brown. Department of Psychiatry and Behavioral Neurobiology, ¹Laboratory of Medical Genetics & ²Division of Hematology/Oncology, University of Alabama at Birmingham, Birmingham, AL 35294.

We have previously reported the cloning and physical mapping of a human brain sodium channel gene segment (Proc. Natl. Acad. Sci. USA 88, pp 335-339, 1991). The reported 212bp clone shares 86%, 91%, and 86% homology with rat brain sodium channel subtypes I, II and III, and is located on chromosome 2q22-q23 by chromosome microdissection PCR (CMPCR). Anchored PCR has been used to synthesize four additional 0.9kb clones starting with the 212bp sequence. Analysis of these clones suggests that three of them represent a single segment of the human brain sodium channel gene (equivalent to amino acid 1709 to 2005 in rat brain sodium channel II). The sequence of these clones shares 77% 85% and 82% homology with rat brain sodium channel subtypes I, II and III respectively. The sequence of the fourth clone shows 73%, 75% and 72% homology to rat brain sodium channel I, II and III, indicating the possible existence of at least one other human brain sodium channel subtype. When a pair of human sodium channel specific primers was used in a PCR sib selection experiment for screening a human brain cDNA library, a 1.3kb clone was isolated which shares 90%, 85% and 85% homology with rat brain sodium channel subtypes I, II and III respectively (equivalent to amino acid 1518 to 1940 in rat brain sodium channel I). Based on the degree of sequence homology with rat brain sodium channel genes, we named the consensus 0.9kb clone as human brain sodium channel II (HBSC II) and the 1.3kb clone as human brain sodium channel I (HBSC I). Homology between HBSC II and I is 87.5%. Using HBSC I specific primers for CMPCR, the gene was mapped to the same locus as HBSC II. This report is the first evidence for the existence of at least two and possibly three sodium channel subtypes in human brain tissue.

381.5

NA⁺ CHANNEL ISOTYPES IN RAT DORSAL ROOT GANGLION NEURONS IDENTIFIED BY ELECTROPHYSIOLOGICAL AND MOLECULAR BIOLOGICAL TECHNIQUES. Caffrey J.M., Brown L.D., Emanuel J.G.R., Eng D.L., Waxman S.G. and V.P. Kocsis. Dept. of Neurology, Yale Univ. Sch. Med., New Haven, CT 06510; V.A. Med. Cntr., W. Haven CT. 16516

Expression of Na⁺ currents with distinctive kinetic and pharmacological properties can be correlated with defined size classes of rat dorsal root ganglion (DRG) neurons. Neurons are enzymatically isolated from early post-natal (days 1-3, 7-9, 14-16) and at adult animals and maintained in short-term (1-4days) primary culture. A single TTX-sensitive Na⁺ current (V_h = -87.5mV; 6msec > τ_h > 0.4msec) is detectable in outside-out patches excised from large cells (*A-type*: adult diameter > 50μm). Rapidly-inactivating, TTX-sensitive Na⁺ current (V_h = -85mV; 0.7msec > τ_h > 0.3msec) and slowly-activating and -inactivating, TTX-resistant Na⁺ current (V_h = -45mV; 24msec > τ_h > 1msec) are always expressed in small cells (*C-type* neurons: adult diameter < 30μm), measured in whole-cell current and excised patches. Neurons of intermediate size either express the single current type found in large neurons or the two found in small neurons. To further define these channels, Na⁺ channel mRNA is visualized in cultured DRG neurons by *in situ* hybridization histochemistry using PCR-derived, non-radioactively-labeled probes. "Generic" Na⁺ channel probe is ≥90% homologous with brain forms I, II, and III; "form-specific" probes are ≤73% homologous with one another. Correlations between message and channel expression are being established. V.A. Med. Ctr. supported.

EXPRESSION OF THE GENE FOR THE RAT BRAIN SODIUM CHANNEL IIA ALPHA SUBUNIT IN CHINESE HAMSTER OVARY (CHO) CELLS. P.H. Lalik*, D.S. Krafte and R.B. Ciccarelli. Depts. of Molecular Biology and Cardiovascular Pharmacology, Sterling Research Group, 81 Columbia Turnpike, Rensselaer, NY, 12144.

In order to carry out protein structure-function studies with ion channels, we constructed a plasmid for inducible expression of the rat brain sodium channel Iia alpha subunit gene in mammalian cells. A 6 kb Sall fragment was removed from pVA2580 (A.L. Goldin, U.C. Irvine) and was inserted into pMAMneo (Clontech). The resulting plasmid, pPHL110, contained the sodium channel gene under transcriptional control of the MMTV LTR. Transfection of pPHL110 in CHO cells followed by induction with dexamethasone resulted in transient expression of sodium channel mRNA as determined by PCR analysis. Sodium channel function was confirmed by a whole cell patch clamp assay. Isolation of inducible CHO cell lines stably expressing the gene was then attempted. Following transfection, 50 cell lines resistant to G418 were selected and were screened by immunoblot assay with an antibody (R. Levinson, U. Colorado) specific to the sp19 region of the sodium channel. Sodium channel gene expression was also analyzed in these cell lines by PCR analysis of mRNA. Evaluation of sodium channel function is being determined by a patch clamp assay. Positive results with both the immunoblot assay and the PCR assay indicate that the sodium channel gene was successfully incorporated into several of these cell lines.

381.4

MOLECULAR CLONING, SEQUENCE ANALYSIS AND CHROMOSOMAL LOCALIZATION OF GENES ENCODING VOLTAGE GATED SODIUM CHANNELS FROM HUMAN BRAIN CORTEX. D.H. Ware,†* S.C. Lee,†* C.M.I. Ahmed,†* C.B. Wagner-McPherson,†* G.A. Evans,‡ and M. Montal,† †Biology and Physics, University of California, San Diego; ‡The Salk Institute for Biological Studies, La Jolla, CA 92037 USA

Several different cDNAs encoding human brain sodium channel proteins were isolated. Overlapping cDNAs were used to determine the sequence of a full length clone denoted class 1. The cDNA begins 145 bp upstream from the start of the open reading frame and ends approximately 2000 bp 3' to the termination codon. The complete primary structure was deduced from sequence analysis of the cDNA. The sequence defines an open reading frame that encodes a 2005 amino acid protein which exhibits 80%, 80% and 77% nucleotide sequence homology with type I, II, and III rat sodium channels, respectively. Homology between human and rat genes is even higher, 82%, 97% and 86%, and all of the 52 amino acid substitutions found in the human gene are located in variable regions of the rat brain II gene. A 1.6 kb fragment of the 3' noncoding region maps the corresponding structural gene to human chromosome 2.

A cDNA for the second class begins at amino acid 1100 when compared to rat brain II and contains approximately 800 bp of 3' noncoding region. Deduced amino acid sequence shows 95%, 94% and 93% homology with respect to type I, II, and III rat brain genes. To map the corresponding structural gene, primers to 3' noncoding region were synthesized and the polymerase chain reaction was used to amplify the gene in human-hamster somatic cell hybrids. The class 2 cDNA was localized to human chromosome 2. A genomic cosmid clone was isolated corresponding to the 3' end of the class 2 cDNA and used to localize the class 2 cDNA to 2q23-q24 by *in situ* suppression hybridization with human metaphase chromosomes.

381.6

FUNCTIONAL EXPRESSION AND AMINO ACID SEQUENCE OF THE TETRODOTOXIN-INSENSITIVE HUMAN CARDIAC MUSCLE SODIUM CHANNEL. R.G. Kallen, L. Chen, M.E. Gellens, A.L. George, Jr., M. Chahine, R. Horn, R.L. Barchi. Dept. of Biochemistry and Biophysics and Medicine and Mahoney Institute for Neurological Sciences, U of Penn School of Medicine, Phila., PA 19104-6059; Neurosci. Dept., Roche Institute, Nutley, NJ 07110

One rat voltage-sensitive sodium channel subtype (SkM2) is tetrodotoxin-insensitive (TTX-I) and constitutes the predominant mRNA present in adult heart and immature skeletal muscle (Kallen et al. Neuron 4, 233-242 (1990)). SkM2 also constitutes up to 40% of the sodium channel mRNA in denervated skeletal muscle. Using the rat SkM2 probe we have identified overlapping cDNA clones from an adult human heart cDNA library and determined the complete nucleotide sequence for the short 5'-UT (150bp), the 6kb coding region and almost all of the 3'UT (2.5kb). The human heart sodium channel (HH1) compared to those of rat SkM1 and SkM2 revealed approximately 72% and 92% overall amino acid sequence homology, respectively.

% HOMOLOGY OF HH1

Subtype	N-ter	D1	ID1-2	D2	ID2-3	D3	ID3-4	D4	C-ter
SkM1	57	70	21	79	28	80	86	86	45
SkM2	95	97	85	96	83	87	100	98	87

Antisense RNA transcribed from the 3'-UT region of HH1 constituted a subtype-specific probe for Northern blots and hybridizes to a ~9.5kb transcript in human atrium and ventricle RNA but no transcripts were detected in human skeletal muscle, brain or myometrium RNA. Sense transcripts from a full-length cDNA clone were expressed in *X. laevis* oocytes. Macroscopic currents were recorded both with a 2-microelectrode voltage clamp and with macro-patches in the outside-out configuration. The currents had apparently normal kinetics of activation and inactivation, and were tetrodotoxin-insensitive (10μM caused ~57% reduction of the peak current at -10mV). Single channel currents in outside-out patches (150mM Na⁺, 1.5mM Ca²⁺, 22°C) had a conductance of ~22pS, by comparison with 10pS for rat SkM2 and 32pS for rat SkM1.

IDENTIFICATION OF A PUTATIVE NA⁺ CHANNEL cDNA IN THE JELLYFISH *CYANEA CAPILLATA*. M.A. Holman, R.M. Greenberg, W.A.S. Bonert* and P.A.V. Anderson. Whitney Laboratory, University of Florida, 9505 Ocean Shore Blvd., St. Augustine, FL 32086.

Cyanea capillata is a coelenterate whose neurons contain Na⁺ channels with unusual pharmacological properties. The predominant inward current in these cells is a fast, transient current that is carried exclusively by Na⁺, but is completely insensitive to standard Na⁺ channel blockers such as TTX, STX, and BTX. However, this current is blocked by common Ca²⁺ channel blockers such as Cd²⁺, Nicardipine, verapamil, and W7.

The purpose of this study is to examine these channels at the molecular level. Poly A⁺ RNA was extracted from neuron-enriched tissue and a cDNA library constructed. Primers were designed from highly conserved regions in the last transmembrane segment of domains III and IV of known Na⁺ channels. These primers were used for PCR amplification of sequences from the cDNA library. A putative Na⁺ channel cDNA has been identified and partially sequenced. The conceptual translation thus far shows open reading frames of over 100 amino acids with extensive similarity to known Na⁺ channels. The amplified sequence will be used as a homologous probe to obtain the full length cDNA. The complete sequence of this clone, along with expression of its cRNA in *Xenopus* oocytes, will allow a more complete understanding of the novel properties of this Na⁺ channel.

MOLECULAR CHARACTERIZATION OF A RAT GLIAL Na CHANNEL ISOFORM. G.Dos Santos*, S.Gautron*, A.Koulakoff*, D.Pinto-Henrique*, P.Ascher* and Y.Berwald-Netter*. Collège de France, 75231 Paris; ^o Ecole Normale Supérieure, 75005 Paris, France.

Astroglial cells and Schwann cells (Sch cs) from rats and mice express in culture voltage-gated Na channels (Na Ch) that are relatively insensitive to TTX (Rev.: Berwald-Netter et al., in: Astrocytes, Acad. Press 1986). To explore whether the glial channels correspond to any of the 3 rat brain Na Ch isoforms identified by Numa et al. (1986,1988) we performed molecular hybridizations of mRNA extracts from cultured rat astroglia or neurons with the isoform-specific cDNA probes and with a highly conserved "common" probe. All were ~ 400 nt long; all hybridized to 9-9.5 kb neuronal mRNA; only the common probe gave a hybridization signal with glial mRNA, at 7.5 kb. This probe was thus used to screen a glial cDNA library. About 5 kb of contiguous glial cDNA were cloned and sequenced. Its nt and deduced amino acid composition are remarkably similar to rat brain and muscle Na Ch in overall structure. It spans 3 out of 4 Na Ch domains (1st 5' domain is yet to be cloned) plus a 3' non-coding region. The sequence homology of putative transmembrane segments varies from 36% to 91% and indicates a gene product unambiguously distinct from the previously defined brain and muscle Na Ch isoforms. A "glial Na Ch" probe was generated by subcloning a 480 nt 3' segment and used to explore the tissue distribution of the corresponding mRNA. By RNase protection assay an identical sequence was detected in rat brain and cultured Sch cs. By Northern blot the RNA identified is in all cases 7.5 kb. It is present in a fairly high amount in DRGs and cardiac muscle and in low amount in fetal skeletal muscle. In situ hybridization in cultures of rat brain cells showed labeling of astroglia but not neurons and in cultures of DRGs of both neurons and Sch cs. Altogether the data are consistent with the "glial" channel being a new TTX-insensitive Na Ch isoform.

[¹⁴C]-GUANIDINE INFLUX AND [³H]-BATRACHOTOXININ BINDING IN CHO CELLS EXPRESSING THE ALPHA SUBUNIT OF TYPE IIA Na⁺ CHANNELS. D.K. Boyd, R.D. Schwarz, D. Dooley, J. West* and W.A. Catterall. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI. and ¹Dept. of Pharmacology, University of Washington, Seattle, WA.

Recently, the alpha subunit of Type IIA Na⁺ channels has been cloned and stably expressed in high numbers using CHO (C81-11) cells (Scheuer, et al., Biophys. J. 59:262a, 1991). Electrophysiological experiments have shown that these cells have Na⁺ currents of 5-20nA with characteristics similar to those of native Na⁺ channels. To further characterize these cells, measurements of ion flux and receptor binding were performed. Using [¹⁴C]-guanidine as the tracer, it was found that there was a time and concentration-dependent stimulation of influx produced by veratridine which was potentiated by alpha scorpion venom. Tetrodotoxin (TTX) fully reversed this stimulation. Representative anti-convulsants, local anesthetics, and antiarrhythmics also blocked ion flux with varying potencies. The cells were also characterized in an assay measuring [³H]-batrachotoxinin (BTX) receptor binding. A comparison of results obtained in [³H]-BTX binding and those from ion flux showed a reasonable correlation between the two assays. Thus, understanding the function and pharmacology of Type IIA Na⁺ channels will be greatly facilitated by the use of C81-11 cells.

PROTEIN KINASE A MODULATES SODIUM CHANNEL FUNCTION IN XENOPUS OOCYTES. R.D. Smith and A.L. Goldin. Dept of Microbiology & Molecular Genetics, U. California, Irvine, CA 92717.

The rat brain Na⁺ channel is a substrate for protein kinase A (PKA) *in vivo*, allowing for the possibility of functional modulation by PKA phosphorylation. To test this possibility, we have examined the effects of PKA activation on Na⁺ currents resulting from expression of the rat IIA clone in *Xenopus* oocytes using two electrode voltage clamping. PKA was activated by increased cAMP levels resulting from either isoproterenol stimulation of a co-expressed β_2 -adrenergic receptor, or perfusion with dibutyryl cAMP. Whole cell Na⁺ currents were increased by 20-50% within fifteen minutes following PKA activation by either of these procedures. The current increases were blocked by Protein Kinase Inhibitor, a specific inhibitor of PKA, indicating that the increase was due to activation of PKA. The current-voltage relationship was not significantly altered by PKA induction. When uninjected oocytes were injected with phosphatase, Na⁺ currents were decreased by about 60%, suggesting that basal Na⁺ current levels were dependent on phosphorylation. To determine if the modulation by PKA was mediated by direct phosphorylation of the Na⁺ channel α subunit, five PKA consensus sites located within the intracellular linker region between domains I and II of the α subunit were modified by site-directed mutagenesis. A mutant altered at all five sites expressed currents that were dramatically decreased in amplitude compared to wild-type, without a shift in the current-voltage relationship. Alterations at individual PKA sites resulted in variable effects on current amplitude, depending on which of the sites were modified. Data for all of the mutants with altered PKA consensus sites will be presented.

DEVELOPMENTALLY REGULATED ALTERNATIVE RNA SPLICING OF THE RAT BRAIN SODIUM CHANNEL MRNA. R. Sarao, S. K. Gupta, V. J. Auld and R. J. Dunn. Centre for Research in Neuroscience, Montreal General Hospital, McGill University, 1650 Cedar Avenue, Montreal, Quebec M3G 1A4

Four distinct cDNAs encoding the α -subunit of the sodium channel have been isolated from the mammalian brain. Two rat cDNAs, named RII and RIIA, are almost identical throughout the coding regions, with a divergence of 36 nucleotides (or 2%) over a coding region of 6 kb. A cluster of 20 divergent bases, in a short 90 nucleotide segment within the homology domain I, results in silent mutations in the two encoded proteins except for position 564, which specifies Asn 209 in the RII and Asp 209 in the RIIA sequences respectively. We now demonstrate that this 90 nucleotide segment is encoded twice in the RII/RIIA genomic sequence. The mutually exclusive splicing event that gives rise to the two cDNAs is developmentally regulated, with RII mRNAs being abundant at birth, and RIIA mRNAs gradually replacing RII mRNAs as post-natal development proceeds. The two mRNAs also appear to have different regional distributions in the developing rat brain. These results suggest that the maturation dependent splicing observed in the RII/RIIA sodium channel may serve to modulate channel properties in a significant manner during neuronal development.

381.12

MUTATION OF A SINGLE PHOSPHORYLATION SITE BLOCKS THE ACTION OF PROTEIN KINASE C ON RAT BRAIN TYPE IIA SODIUM CHANNELS. J. W. West*, R. Numann*, T. Scheuer and W. A. Catterall. Dept. of Pharmacology, U. of Washington, Seattle, WA 98195

Diacylglycerol activators of protein kinase C reduce sodium current and slow the inactivation of rat brain type IIA sodium channels¹. A predicted cytoplasmic loop between homologous domains III and IV has been implicated in the inactivation process. This loop contains a consensus sequence for phosphorylation by protein kinase C. We have mutated S1506A in this site by oligonucleotide-directed mutagenesis to render it unavailable for phosphorylation by the kinase. Plasmids containing the control and mutant Rat brain type IIA sodium channel α subunit cDNAs have been stably expressed in Chinese Hamster Ovary (CHO) cells by calcium phosphate-mediated transfection. Both control and mutant cell lines stably express large sodium currents (>2 nA) when examined by whole cell voltage clamp. Effects of the diacylglycerol activator OAG (1-oleoyl-2-acetyl-sn-glycerol) were examined by recording macroscopic currents in cell attached patches. In the control cell line 25 μ M OAG caused a large reduction in sodium current amplitude as well as slowing its inactivation. In two independent clonal isolates of stably expressing mutant cell lines sodium current was unaffected by the activator, even at concentrations as high as 100 μ M. It appears that phosphorylation of SER1506 is essential for sodium channel modulation by protein kinase C.

THE SODIUM CHANNEL III-IV LINKER MAY SUBSTITUTE FOR THE AMINO TERMINAL "INACTIVATION BALL" IN THE SHAKER H4 POTASSIUM CHANNEL. D.E. Patton and A.L. Goldin. Dept of Microbiology & Molecular Genetics, U. California, Irvine, CA 92717.

The short cytoplasmic linker that connects domains III and IV of the voltage-gated sodium channel is thought to be involved in the fast inactivation process. At present, the mechanism by which this linker region is involved in the inactivation process is unclear. The amino terminal region of the *Shaker* B potassium channel has been shown to mediate the fast inactivation process in potassium channels in a manner similar to the "ball and chain" mechanism proposed by Armstrong and Bezanilla (J. Gen. Physiol., 1977, 70:567). To test if the III-IV linker of sodium channels and the amino terminus of *Shaker* potassium channels serve similar functions, a chimeric ion channel was constructed with the III-IV linker of the rat IIA sodium channel substituting for the first 11 amino acids of the *Shaker* H4 (ShH4) potassium channel (ShH4 Δ 11Nall-IV). For comparison, a mutant ShH4 potassium channel with the first 11 amino acids deleted was also constructed (ShH4 Δ 11). Macroscopic currents through these channels expressed in *Xenopus* oocytes were characterized using two microelectrode voltage clamp techniques. The ShH4 Δ 11Nall-IV channel inactivated more rapidly than the ShH4 Δ 11 channel, although still more slowly than ShH4. In addition, depolarizations to potentials more positive than +10 mV induced a fast phase of inactivation in ShH4 Δ 11Nall-IV that was not present in ShH4 Δ 11. These results suggest that the III-IV linker of the rat IIA sodium channel and the amino terminal "ball" region of the ShH4 potassium channel may serve similar functions in the inactivation process.

SODIUM CHANNEL STRUCTURE/FUNCTION: EFFECTS OF NEGATIVE CHARGE MUTATIONS ON BLOCK BY TTX. K.J. Kontis and A.L. Goldin. Dept of Microbiology & Molecular Genetics, U. California, Irvine, CA, 92717.

Sodium channels have structural similarities to other voltage-gated channels, but they are highly selective for sodium and are specifically blocked by externally applied tetrodotoxin (TTX). The site for TTX binding is thought to be in close proximity to the actual pore, since chemical modifications of the channel which affect TTX binding also reduce inward current (Sigworth et al., 1980, Nature 283:293). Stühmer et al. (FEBS Lett., 1989, 259:213) have shown that neutralization of a negatively charged amino acid at position 387 in the α subunit results in resistance to TTX and reduced inward current. We have used site-directed mutagenesis to investigate the role in TTX binding and ion permeation of negatively charged amino acids between the proposed transmembrane segments S5 and S6 in domain II. We have neutralized the negatively charged amino acids at positions 927, 942 and 945 of the rat IIA sodium channel α subunit, and have analyzed these mutants in *Xenopus* oocytes using two electrode voltage clamping. The D927N mutation resulted in sodium channels with TTX sensitivity equivalent to wild-type. The E942Q and E945Q mutations resulted in channels which were inhibited by TTX with an apparent K_D higher than 10 μ M, compared to 18 nM for the wild-type channel and D927N. In all three cases the gating characteristics of the mutants were not significantly different from wild-type. However, macroscopic currents resulting from injection of RNA from mutant E942Q were approximately five-fold lower than those resulting from injection of equivalent amounts of wild-type RNA. The unitary conductance and selectivity of these mutants are currently being analyzed, along with the effects of additional mutations in the S5-S6 region.

SODIUM CHANNELS: PHYSIOLOGY AND PHARMACOLOGY

382.1

VOLTAGE-DEPENDENT CURRENTS IN *STERNOPYGUS* ELECTROCYTES VARY WITH ACTION POTENTIAL DURATION. M.B. Ferrari and H.H. Zakon. Dept. of Zoology, Univ. of Texas, Austin, TX 78712.

In *Sternopygus macrurus*, electrocyte action potential (AP) waveform and duration are under the control of steroid hormones. Since electrocyte AP durations can range from 4 to 14 ms, electrocytes can serve as a model system in which to study the biophysical basis of steroid-mediated changes in cell excitability.

A two-microelectrode current- and voltage-clamp setup was used to examine the APs and ionic currents of *Sternopygus* electrocytes in a semi-intact preparation. Using various voltage clamp protocols from a holding potential of -80 mV, we observed a TTX-sensitive sodium current, a delayed outward current, a transient outward current, an inward rectifier current, and a large linear leakage. The sodium and delayed outward currents had the largest relative magnitudes, with peak sodium ranging from 171 to 900 nA near 0 mV. Sodium current characteristics were similar to those described for vertebrate skeletal muscle. The delayed outward current displayed activation kinetics similar to a delayed rectifier potassium current and did not inactivate. The transient outward current was seen in only a few cells and was of small magnitude. The inward rectifier current shows a steep voltage-sensitive inactivation around -60 mV and accounts for the 2-5 fold increase in input resistance observed during current clamp depolarizations.

Electrocyte AP durations ranged from 5.1 to 13.5 ms with a corresponding change in the relative contributions of the described currents. Cells with long duration APs had much slower sodium inactivation kinetics and had little or no delayed outward current. Conversely, cells with short duration APs had faster sodium inactivation kinetics and larger delayed outward currents. These observations suggest that sodium current kinetics and delayed outward current magnitude are significant factors in determining electrocyte AP duration and waveform. Supported by NIH and ONR.

SLOW SODIUM CONDUCTANCE IN IONIC CONTROL OF CONDUCTION IN MYELINATED AXON: A COMPUTATIONAL MODEL. F. Pongracz, S.G. Waxman, G.M. Shepherd and J.D. Kocsis. Sect. of Neurobiol. and Dept. of Neurology, Yale Medical Sch., New Haven, CT 06510 and Neuroscience Research Center, VAMC, West Haven, CT 06516

Myelinated axons may express fast and slow Na^+ and K^+ channels with distinct membrane localization. To study the functional role of slow Na^+ channels, we developed a computational model of a myelinated axon with 16 nodes containing a variety of kinetically distinct Na^+ and K^+ channels. Nodal, paranodal, and internodal regions have been represented with different electrical properties. The periaxonal space has been represented by a serial shunt path and voltage- and concentration-dependent K^+ leak through the paranodal loops and internodal myelin.

The model predicts that the depolarizing afterpotential and burst generating properties of the axons are regulated by a small slow Na^+ current. During blockade of the fast K^+ current, this slow Na^+ component of the nodal and paranodal currents abruptly increased concurrent with impulse burst activity. In accordance with experimental data, the model predicts that increased activation of the slow Na^+ current can activate a prolonged K^+ current. The model also showed that a heterogeneous distribution of slow Na^+ current within the nodal and paranodal regions could elicit spike burst activity which could propagate in a retrograde direction.

These results suggest a highly sensitive ionic control of transmission in myelinated axons, presumably mediated by activation of fast and slow components of Na^+ current, together with fast and slow K^+ conductance, which may modulate the conduction properties and excitability of myelinated axons and their terminals. Supported in part by the NIH, VA and the NMSS.

NOVEL INACTIVATION CHARACTERISTICS OF SODIUM CURRENT IN GUINEA-PIG CELIAC GANGLION NEURONS. S.L. Purnyn*, S.R. Knoper and D. L. Kreulen. Dept. Pharmacology, University of Arizona, Tucson, AZ USA.

The characteristics of the fast sodium current were determined in dissociated guinea-pig celiac ganglion neurons after 1-4 days in primary culture. Whole cell currents were measured at 22°C. Fast inward current was reversibly blocked by tetrodotoxin (KD: 8.7 ± 2.1 nM). Sodium current activation and inactivation processes were fit to modified Boltzmann equations. Steady-state activation and inactivation parameters were similar to those described for other types of neurons. Activation parameters for the half activation potential ($V_{1/2}$) and slope factor (K) were -31 mV and 6.0, respectively. Half inactivation potential and inactivation slope factor were -65 mV and 7.2, respectively. Unlike other neurons, including mammalian sympathetic neurons, the time constant of inactivation depended on the direction of approach to the conditioning potential. The removal of inactivation evaluated with a 2-impulse protocol resulted in a time constant of inactivation of 55 ± 5 ms whereas inactivation evaluated with a single impulse protocol resulted in an inactivation time constant of 218 ± 21 ms. (V_m : -60 mV). These differences are statistically significant at $p < 0.01$ (group t-test). These studies demonstrate some unique kinetic characteristics of sodium currents in neurons from the guinea pig celiac ganglion and suggest that the Hodgkin-Huxley model may have to be modified to fit these characteristics completely. Support: HL27781, Az.Dis. Cont. Res.Comm.

CALCULATIONS OF QUANTUM TUNNELING BETWEEN CLOSED AND OPEN STATES OF SODIUM CHANNELS. P. J. Marshall*, C. C. Chancey*, and S. A. George. Physics Department and Neuroscience Program, Amherst College, Amherst MA 01002.

Transitions between states of ion channels have previously been considered in terms of classical statistical mechanics. However, transitions in many systems, including some organic molecules, are known to occur by quantum mechanical tunneling. We estimated times for sodium channel activation by tunneling, using the structural models of Catterall and Guy. We calculated coulomb interactions between the S4 α -helix and negative charges on nearest neighbor helices, and included longer range interactions by adding a background electric field. Periodic pairing of charges between the S4 and adjacent helices in the model causes the resting and depolarized states of the channel to correspond to local minima in the S4 potential energy curve. Harmonic potentials closely fit the deviations from each local minimum. Tunneling rates between bound states of each harmonic potential were calculated using a WKB approximation. At 37°C, for an interhelix axial spacing of 10 Å, and with sufficient electric field to account for the voltage dependence of activation, a tunneling time of 1 msec was computed for a single S4 segment. When more than a single S4 helix was included, tunneling times remained within the range of observed transition times. Thus quantum tunneling is possible in this channel. If tunneling turns out to be prevalent in sodium channel transitions, the framework for understanding neural function will have to expand to include quantum concepts.

VENOM FROM *CONUS TEXTILE* ACTIVATES A TETRODOTOXIN-SENSITIVE INWARD CURRENT IN BAG CELL NEURONS OF *APLYSIA*. G.F. Wilson, T.F. Fisher, W.J. Joiner, B.M. Olivera, and L.K. Kaczmarek. Dept. of Pharmacology and Sect. of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510 and ²Dept. of Biology, University of Utah, Salt Lake City, UT 84112.

A crude preparation of venom from the marine snail *Conus textile* (CiTx) elicits a spontaneous afterdischarge when applied extracellularly to bag cell neuron (BCN) clusters of *Aplysia*. In BCNs that have been isolated and maintained in primary culture, CiTx causes a long-lasting depolarization averaging 33 mV in normal seawater (n=12). This effect appears to be due to CiTx activation of a voltage-dependent inward current carried primarily by Na⁺ ions, since the depolarization disappears entirely when N-methyl-D-glucamine replaces Na⁺ in the bath (n=4) and since both depolarization and current are blocked by TTX (n=8). Although the effective TTX concentration is similar to that required for block of *Aplysia* voltage-dependent sodium currents (100 μM) which reverse at ~+50 mV, the TTX-sensitive, CiTx-activated inward current reverses nearer to 0 mV and the cation permeability (Na⁺ > TEA > Tris > N-methyl-D-glucamine) of the response appears more similar to that of Ca-activated non-specific cation channels [Partridge and Swandulla (1988) *INS* 11, 69-72] than that of traditional sodium channels. Indeed, the CiTx-induced depolarization is partially eliminated when intracellular Ca²⁺ is buffered to low levels by including 20 mM EGTA, 4.14 mM Ca²⁺ in patch pipettes (n=8). In addition, in excised outside/out patches, we have characterized a ~30 pS channel similar to the CiTx-activated current in its reversal potential and ionic selectivity. Preliminary evidence suggests that this channel could be the target of the toxin.

EFFECTS OF ALKALOID TOXINS ON THE ION CONDUCTING PROPERTIES OF PURIFIED SODIUM CHANNELS. H.C. Wartenberg^{1*}, A. Hernandez^{1*}, B.W. Urban², and D.S. Duch^{1*}, ¹Cornell University Medical College, New York, N.Y.; and ²Univ. Bonn, F.R. of Germany.

As previously reported (Duch et al., 1991, *Biophys. J.*, 59:259a), grayanotoxin-modified (GTx) eel electroplax sodium channels in planar bilayers have single channel conductances of 15-16 pS (500mM NaCl), smaller than batrachotoxin-modified (BTx) channels, but larger than in the presence of veratridine (VTD). However, while the BTx and VTD-modified channels have linear and symmetrical I-V relations, GTx-modified channels are symmetrical and superlinear, especially at potentials greater than +/-100mV. A comparison of the conductance-ion concentration relationships of the three toxins in symmetrical sodium solutions indicated similar shaped rectangular hyperbolas for all three toxins, with similar half-saturating concentrations. In addition, GTx-modified channels also show pre-opening and pre-closing bursts of 40-50 pS conductance before a significant fraction of open-closed transitions, which were voltage-dependent and not observed with BTx or VTD. These bursts may represent toxin binding and unbinding events.

EFFECTS OF SCORPION VENOM, SEA ANEMONE TOXIN, AND CHLORPROMAZINE ON TETRODOTOXIN-SENSITIVE AND TETRODOTOXIN-RESISTANT SODIUM CHANNELS. M.-L. Roy and T. Narahashi, Dept. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

Dorsal root ganglion neurons acutely dissociated from 3-10-day-old rats express TTX-sensitive (TTX-S, K_d~1 nM) and TTX-resistant (TTX-R, K_d~100 μM) sodium channels in varying proportions. These current types differ in their activation and inactivation kinetics (Roy and Narahashi, *Neurosci. Abstr.* 16: 181, 1990), as well as their responses to divalent cations and lidocaine (Roy and Narahashi, *Biophys. J.* 59: 263a, 1991). Scorpion venom and sea anemone toxin, but not chlorpromazine, have now been found to exert differential actions on these two channel types. Currents were recorded using the whole cell patch clamp technique. *Leiurus quinquestriatus* scorpion venom and sea anemone toxin ATX-II (1-100 nM) each inhibited TTX-S current inactivation, but failed to affect TTX-R current. This may indicate that the TTX-R and TTX-S channels differ in two distinct neurotoxin receptor sites. Tonic block (K_d~100 nM) and use-dependent block of TTX-R and TTX-S channels by chlorpromazine were comparable, indicating that this drug's site of action is conserved in both channel types. The comparison of TTX-S and TTX-R sodium channel properties is of importance in discerning the role of these channels in CNS development and drug action. Supported by NIH grants R01 NS14144 and F31 MH09839.

382.6

ALLOSTERIC EFFECTS ON [³H]BATRACHOTOXININ-A ORTHO-AZIDO-BENZOATE PHOTOAFFINITY LABELING OF THE RAT BRAIN SODIUM CHANNEL. T.L. Casebolt and G.B. Brown, Dept. of Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, AL 35294.

Neurotoxins have classically been used to identify and characterize voltage-sensitive sodium channels. The characteristic selectivity, site-specificity, and high affinity binding of neurotoxins have allowed the dissection of both channel function and structure. Site 1, which is bound externally by tetrodotoxin (TTX) and saxitoxin (STX), and site 3, which is selective for alpha-polypeptide neurotoxins from scorpion and sea anemone, interact with the batrachotoxin (BTX) binding site on the sodium channel as measured by [³H]batrachotoxinin-A 20-alpha-benzoate ([³H] BTX-B) binding. Using a photolabile derivative of BTX, [³H]batrachotoxinin-A ortho-azidobenzoate ([³H] BTX-OAB), the specific labeling of lipid and protein components of the BTX binding site can be quantified. In general, the binding behavior of [³H] BTX-OAB parallels the binding behavior of [³H]BTX-B and requires the addition of scorpion toxin (ScTx) to enhance ligand binding. To investigate the allosteric effects of site 1 neurotoxins on specific covalent lipid and protein binding, we measured photoaffinity labeling of [³H] BTX-OAB in the presence of ScTx at room temperature and at 37°C in the presence and absence of 1 μM TTX. Addition of TTX increased the specific incorporation of [³H]BTX-OAB into protein components from less than 1% to as much as 15%, with a corresponding drop in lipid incorporation. Increasing incubation temperature from 25°C to 37°C had a similar but less marked effect. Specific protein labeling was localized on a 270 Kdal protein, presumably the alpha subunit of the sodium channel protein. These results support the proposal that the BTX binding site is located at the lipid-protein interface such that treatments which induce conformational changes in the sodium channel protein (i.e. addition of TTX) or altered membrane fluidity (such as increased incubation temperatures) can result in a redistribution of BTX binding sites in the protein and lipid domains of voltage-sensitive sodium channels.

ALLETHRIN EFFECTS ON TETRODOTOXIN RESISTANT SODIUM CHANNELS IN RAT DORSAL ROOT GANGLION CELLS. K. S. Ginsburg and T. Narahashi, Dept. Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611

To study the mechanism of action of allethrin, a pyrethroid insecticide, on Na⁺ channels, we recorded whole cell TTX resistant Na⁺ currents from newborn rat DRG cells, at 11, 18, and 27°C. Tail currents recorded with allethrin (10 μM) present decayed biexponentially. Both time constants (100 μsec and 4 msec at 18°) increased as temperature decreased. The amplitude of the slow phase developed with a time constant of about 200 sec on application of allethrin and declined at a similar rate on washout. With pulses of increasing duration, the amplitude of the slow phase first increased, then decreased. The amplitude ratio of the slow phase to the fast phase increased with pulse duration. The pulse duration giving maximum amplitude decreased with increasing temperature and was 3 msec at 18°. However, the maximum slow phase conductance, expressed as a fraction of the peak conductance during the depolarization, did not change with temperature. Thus, changes in the extent of allethrin modified conductance may not explain the temperature dependence of allethrin toxicity. Supported by NS14143.

INHIBITION OF SODIUM CHANNEL CURRENT BY THE ANTICONVULSANT U-54494A IN MOUSE NEUROBLASTOMA CELLS. Yu Zhu and Wha Bin Im, CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001

The benzamide U-54494A has been reported to act as a non-analgesic anticonvulsant in intact animal studies (VonVoigtlander et al. *J. Pharm. Exp. Ther.* 243:542, 1987). To better understand the mechanism of its anticonvulsant action, the effects of U-54494A on the voltage-gated sodium channel current were investigated by using the whole-cell patch clamp technique in mouse neuroblastoma cells (NIE-115). U-54494A tonically blocked the TTX-sensitive Na current with an IC₅₀ of 72 μM and a t_{1/2} of 2.2 min. Its block of the Na channel was fully reversible. U-54494A shifted the steady-state inactivation of the Na channel 3mV to the more hyperpolarized potential, but had no effect on the steady-state activation of the channel. The drug did not alter the kinetics of the channel activation and inactivation, but appeared to interact with the open and inactivated states of the channel, as evidenced by the use-dependent block even with a very short depolarization (<1 ms) and the slow recovery from the steady-state inactivation (τ=2.7 s). Our results suggest that block of the Na channel by U-54494A, especially the use-dependent block, is an important pharmacological basis in the treatment of certain types of seizures during which the excitability of neurons is excessive.

382.11

TETRODOTOXIN-SENSITIVE SODIUM CURRENTS IN FLATWORM NEURONS. Kevin L. Blair and Peter A.V. Anderson. Whitney Laboratory, University of Florida, St. Augustine, FL 32086.

Platyhelminthes (the flatworms), the simplest organisms to exhibit cephalization and discrete central and peripheral nervous systems, are believed to express tetrodotoxin (TTX)-sensitive and insensitive Na⁺ channels in their cephalic neurons. Voltage-gated ionic currents in neurons dispersed from the brains of the flatworm *Bdelloura candida* were characterized using the whole-cell voltage-clamp technique. Cells ranging from 15 to 30 microns in diameter were studied and found to possess two inward Na⁺ currents. The more prominent current was a fast-activating, fast-inactivating current with a threshold voltage of -25 mV. It reached peak current at 0 to +5 mV and reversed at +55 to +65 mV in a normal Na⁺ and Ca²⁺ sea water (E_{Na} = +58 mV). This current was half inactivated (V_{1/2}) by a 50 ms pre-pulse to -30 mV. A non-inactivating current, roughly 10% of the amplitude of the inactivating current, was also present and exhibited similar voltage sensitivities, except that it was not inactivated by pre-pulses up to 500 ms in duration. This non-inactivating current was never observed to "run-down".

When the [Na⁺] of the bath was decreased, the peak amplitude of both the inactivating and non-inactivating currents decreased and their reversal potentials shifted to the left with E_{Na}, indicating that Na⁺ was the dominant carrier ion. Furthermore, both of these currents were blocked by TTX, with IC₅₀'s of 30 nM. Thus, contrary to previous reports, flatworms appear to express only tetrodotoxin-sensitive Na⁺ channels in their cephalic neurons. Supported by NSF grant BNS 88-05885.

382.13

[³H]PD 85,639 IS A HIGH AFFINITY LIGAND FOR RAT BRAIN SODIUM CHANNEL. W.J. Thomson¹, S.J. Hays², R.D. Schwarz², J.L. Hicks², and W.A. Catterall¹. 1) Dept. of Pharmacology, Univ. Wash., Seattle, WA, 98195; 2) Parke Davis Research Div., Warner Lambert Co., Ann Arbor, MI 48103.

PD 85,639 (N-[3-(2,6-dimethyl-1-piperazinyl)propyl]-α-phenylbenzeneacetamide) is structurally related to local anesthetics and blocks veratridine-stimulated ¹⁴C-guanidine influx in brain slices. In this study, the binding of [³H]PD 85,639 to both rat brain synaptosomes and purified sodium channel (NaCh) reconstituted into phospholipid vesicles has been characterized.

Specific binding of [³H]PD 85,639 to both synaptosomes and reconstituted NaCh is optimal at pH 9.0 (75-90% of total binding). At this pH, the uncharged form predominates. PD 85,639 competes for [³H]PD 85,639 binding to synaptosomes is best fit by a two site model with EC₅₀ values of 40nM (40%) and 14μM (60%). Batrachotoxin and α-LqTx V both decrease binding to synaptosomes with EC₅₀ values similar to their K_d values for neurotoxin receptors 3 and 4, respectively. Both neurotoxins also inhibit [³H]PD 85,639 binding to reconstituted NaCh. These data provide evidence that PD 85,639 binds specifically to NaCh. The drugs etidocaine, tetracaine, prilocaine, tocainide, bupivacaine, mepivacaine and verapamil also compete for [³H]PD 85,639 binding to both synaptosomes and reconstituted vesicles. Etidocaine, tetracaine, and verapamil competition for binding to synaptosomes is best fit by a two site model in which there is a high affinity (1-2nM) and a lower affinity (10-50μM) component of displacement. In contrast, competition curves for the other local anesthetics are best fit by a one site model with EC₅₀ values between 40-150μM.

The time course of [³H]PD 85,639 binding to synaptosomes is monoexponential and rapid with a t_{1/2} of 1 minute. With incubations longer than 30 minutes, binding decreases to 50-70% of that observed at 2 minutes. Association of [³H]PD 85,639 with reconstituted NaCh is slower with a t_{1/2} of 8 minutes and remains stable up to 3 hours of incubation. Dissociation of [³H]PD 85,639 from synaptosomes and reconstituted NaCh initiated by 100μM PD 85,639 is biexponential consisting of a fast (t_{1/2} = 0.6 min, 60%) and a slow (t_{1/2} = 46 min, 40%) component of decay. Dissociation of [³H]PD 85,639 from synaptosomes initiated by 100 μM tetracaine has identical kinetics. The rate of dissociation of ligand from synaptosomes is not altered by the inclusion of 100μM tetracaine in addition to 100μM PD 85,639 suggesting that both drugs bind to the same binding site.

These results indicate that [³H]PD 85,639 is a useful high affinity ligand to further study the NaCh. It will be of interest to further establish that this compound interacts with the local anesthetic receptor and whether the different binding sites for PD 85,639 correspond to different states or different isoforms of the NaCh.

382.12

ELEVATED EXPRESSION OF TYPE II SODIUM CHANNELS IN HYPOMYELINATED TRACTS OF *Shiverer* MICE. R.E. Westenbroek¹, J.L. Noebels², and W.A. Catterall¹. ¹Department of Pharmacology, University of Washington, Seattle, WA 98195, and ²Developmental Neurogenetics Laboratory, Department of Neurology, Baylor College of Medicine, Houston, TX 77030.

The voltage sensitive sodium channel is a transmembrane protein responsible for the rising phase of the action potential in electrically excitable tissue. In the *Shiverer* mouse, a deletion at the *Shiverer* locus (chr 18) results in the absence of myelin basic protein gene expression and development of hyperexcitability. It has recently been demonstrated using [³H]-saxitoxin binding methods that the large caliber fiber pathways in the brain of the *Shiverer* mutant exhibit a relatively high density of sodium channels as compared to normal mice (Noebels et al., *Soc. Neurosci. Abstr.* 15:1365, 1989). Affinity-purified anti-peptide antibodies which distinguish between the α subunits of rat brain sodium channel subtypes I, II, and III and an antibody against synthetic peptide SP20 which recognizes the α subunit of all three subtypes, were used in combination with indirect peroxidase-antiperoxidase technique to investigate the distribution of the three sodium channel subtypes in normal and *Shiverer* mice. Staining with anti-SP20 was similar in normal and mutant mice except for relatively dense staining of hypomyelinated fiber tracts in the mutant which is absent in normal mice. This difference in staining was most evident in the corpus callosum, internal capsule, fimbria, fornix and cerebellum. Subtype-specific antibodies revealed that Type I is expressed in cell bodies of projection neurons throughout the brain, Type II is expressed mainly in axons and Type III is expressed in scattered neurons in the cortex and other nuclei in the normal mouse brain as previously observed in rat brain (Westenbroek et al., *Neuron* 3:695-704, 1989). In *Shiverer* mice, the pattern of expression remained unchanged for Types I and III. However, there was intense staining for Type II in hypomyelinated fiber tracts including corpus callosum, internal capsule, fimbria, fornix and cerebellum which was not observed in normal mice. These results provide further support for our previous conclusion that Type II sodium channels are preferentially localized in axons of brain neurons and suggest that upregulation of the number of Type II channels in hypomyelinated fiber tracts may contribute to the hyperexcitable phenotype of the adult *Shiverer* mouse.

382.14

PD 85639: A POTENT INHIBITOR OF NA⁺ INFLUX INTO RAT NEOCORTEX SLICES. S. J. Hays¹, R.D. Schwarz², D.K. Boyd¹, L. Coughenour¹, D. Dooley¹, D. Rock¹, C. Taylor¹, M. Vartanian¹, and W. Moog². Parke-Davis Pharm. Res Div., Warner-Lambert Co., Ann Arbor, MI.

Binding to specific sites associated with Na⁺ channels appears to be involved in the pharmacological action of anticonvulsant, local anesthetic, and antiarrhythmic agents. As part of a search to identify Na⁺ channel blockers, PD 85639, N-[3-(2,6-dimethyl-1-piperidinyl)propyl]-α-phenylbenzeneacetamide, was tested for its ability to inhibit veratridine-stimulated influx of ¹⁴C-guanidine into rat neocortical slices. It was found to be a potent influx inhibitor (IC₅₀ = 2nM) with the inhibition curve possessing both high (nM) and low (μM) affinity components. PD 85639 was also able to potentially inhibit ³H-batrachotoxin binding with an IC₅₀ = 142nM. In contrast, PD 85639 (1 and 10μM) failed to inhibit electrically-evoked [³H]-NE release from rat neocortical slices, whereas tetrodotoxin (TTX) was active at 1μM. Electrophysiologically, the compound (10μM and above) reduced sodium-dependent action potentials in cultured rat spinal cord neurons and in rat sciatic nerve. Block was partly use-dependent with slow recovery. Depolarizations from veratridine were reduced and shifted to higher veratridine concentration by 10μM. Thus, PD 85639 is a more potent blocker of veratridine-induced ion flux than of sodium channel-dependent physiological responses. In vivo, PD 85639 failed to cause anticonvulsant effects at doses up to lethality (10mg/kg, IV). Thus, PD 85639 represents a new and potent tool in the investigation of Na⁺ channel structure and function.

ION CHANNELS: MODULATION AND REGULATION II

383.1

METABOTROPIC GLUTAMATE RECEPTOR MODULATES HIGH-THRESHOLD CALCIUM CURRENT OF NEURONS ACUTELY ISOLATED FROM RAT NEOCORTEX. R.J. Sayer, P.C. Schwandt, and W.E. Crill. Dept. of Physiology & Biophysics, Univ. of Washington Sch. of Med., Seattle, WA 98195.

In addition to their rapid ionotropic actions, excitatory amino acids can affect neuronal excitability over a slower time course. We investigated the effects of quisqualate on the high-threshold Ca²⁺ current of neocortical neurons. Slices of dorsal frontoparietal neocortex from 14-28 day old rats were treated with papain and triturated. Whole-cell recordings were made at 20-23°C and the recording pipette solution included 10 mM EGTA. Ca²⁺ currents, evoked by steps from -60 mV to -20 or -10 mV, were reduced by glutamate and quisqualate. Quisqualate (20 μM) applied by puffer pipette to 16 neurons reduced the peak Ca²⁺ current by a mean of 31% (range 11-50%). Suppression of the current took 3-5 min to fully develop and was readily reversible by washing. AMPA (100 μM) was ineffective (n=4). In the presence of CNQX (50 μM) and DL-APV (100 μM), sequential applications of quisqualate (20 μM) and the metabotropic glutamate receptor agonist *trans*-ACPD (300 μM) produced comparable reductions (n=5, mean decrease 33% and 29% respectively). We conclude that quisqualate is acting via the metabotropic glutamate receptor. Qualitatively similar, but smaller, responses have been reported for cultured hippocampal neurons (Lester & Jahr, 1990, *Neuron* 4: 741-749). Supported by NINDS grants NS16792 & NS20482.

383.2

TEMPERATURE DEPENDENT BLOCK OF NMDA RESPONSES BY TTX, STX AND PHENYTOIN. M.J. McLean and A.W. Wamil. Dept. of Neurology, Vanderbilt Univ. Med. Ctr., Nashville, TN 37212

We studied the effects of tetrodotoxin (TTX), saxitoxin (STX), and phenytoin (PT) - three sodium channel blockers - on the responses of mouse spinal cord neurons in cell culture to NMDA at different temperatures with intracellular electrophysiological techniques. Neurons were quiescent in 7 mM Mg⁺⁺-containing phosphate buffer. Pressure application of 10⁻⁵-10⁻³ M NMDA (3 sec) elicited depolarizing waves with action potential firing. STX, TTX, and PT blocked responses to serially applied NMDA in use- and concentration-dependent manner at 37°C. At 33°C, block by TTX (1.5x10⁻⁸ M) and STX (10⁻⁸ M) did not occur. Increased PT concentrations (≥ten times) were required to produce use-dependent block at the reduced temperature, with or without TTX. Thus, NMDA block by toxins was temperature dependent and concentration-dependence of block by PT was shifted to the right by cooling.

383.3

SUSTAINED POTENTIATION OF NMDA RECEPTOR MEDIATED-GLUTAMATE RESPONSES THROUGH ACTIVATION OF PROTEIN KINASE C BY A μ -OPIOID. Li Chen¹ and Li-Yen Mae Huang^{1,2}, Marine Biomedical Institute¹ and Department of Physiology and Biophysics², University of Texas Medical Branch, Galveston, TX. 77550

The μ -opioid receptor agonist, D-Ala²-MePhe⁴-Gly-ol⁵-enkephalin (DAGO), was found to decrease glutamate release and to potentiate the glutamate-activated currents in trigeminal neurons (Chen & Huang, *Neurosci Abstr.* 16:60, 1990). We have studied the postsynaptic modulation of NMDA-activated responses by DAGO in greater detail. All the experiments were performed on spinal trigeminal neurons in thin medullary slices using patch recording technique. DAGO caused a sustained increase in glutamate-activated currents that were mediated by NMDA receptors. To determine which second messenger system might mediate the sustained actions of DAGO, we studied the effects of the intracellularly applied protein kinase A (PKA) and protein kinase C (PKC) on NMDA-activated responses. PKA had no effect on NMDA-activated currents. On the other hand, PKC mimicked the effect of DAGO; a specific PKC inhibitor interrupted the sustained potentiation produced by DAGO. These results suggested that PKC plays a key role in mediating the action of the μ -opioid peptide. Supported by grants: NS23061 and RCDA NS01050.

RUNDOWN OF NMDA CURRENTS: DEPENDENCE ON ATP AND CALCIUM. C.Rosenmund, P.Legendre[†] & G.L.Westbrook, †INSERM, U261, Paris; Vollum Institute, Oregon Health Sciences University, Portland, OR.

Progressive loss of activity can occur during whole-cell recording of both voltage- and ligand-gated ion channels. In the case of voltage-dependent Ca channels and GABA channels, this can be reversed by adding ATP to the patch pipette, an effect attributed to phosphorylation of the channel or a modulatory protein. Rundown of NMDA currents also occurs, and has been reported to be reversed with ATP, but insensitive to [Ca²⁺]_i (MacDonald et al., *J.Physiol.* 414,17,1989). However increases in [Ca²⁺]_i partially inactivate NMDA currents (see Legendre et al., adjacent poster), thus we examined whether ATP-dependent rundown of NMDA channels is also Ca-dependent. Whole-cell recordings were made on cultured rat hippocampal neurons. Intracellular dialysis was maximized using 1-2 M Ω pipettes while continuously monitoring the access resistance. Timed pulses of NMDA (10 μ M, 0.3-3sec, 2/minute) were delivered using flow pipes controlled by a piezoelectric device. Glycine was 10 μ M with no added Mg. "ATP" solutions contained ATP 4, Mg 4-6, phosphocreatine 20, creatine kinase 50 U/ml, [Ca²⁺]_i was 20 nM (BAPTA 2.4, Ca 0.4).

In normal solutions (2 nM Ca) without ATP, NMDA currents decreased to 40-60% of control over 30 minutes. Rundown was reversible, use-dependent, and was reduced by lowering [Ca²⁺]_i or increasing the intracellular buffer. Essentially no desensitization or rundown was seen in Ca-free solutions. Dialysis with ATP prevented rundown in Ca-containing solutions, but the addition of alkaline phosphatase (100 μ M/ml) or kinase inhibitors (staurosporine, 1 μ M or calmidazolium, 10-20 μ M) to the patch solution did not reverse the effect of ATP, suggesting a mechanism other than phosphorylation. However, vanadate (50 μ M) or reduction of extracellular sodium induced rapid rundown. It is plausible that ATP maintains NMDA responses by reducing Ca accumulation via a membrane ATPase or the Na/Ca exchanger. Supported by USPHS and the McKnight Foundation.

383.7

MODULATION OF ELECTRICAL SYNAPSES BETWEEN CULTURED *APLYSIA* NEURONS BY IMMUNOGLOBULIN. M. P. Wilson*, G. M. Carrow and I. B. Levitan. Dept. of Biochemistry and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Electrical synapses form between *Aplysia* neurons in primary cell culture with high frequency and characteristic synaptic strength. We show that the strength of electrical synapses, measured as the junctional conductance between the cells, is much reduced when the neuron pairs are grown in the presence of nanomolar concentrations of an immunoglobulin fraction (IG) prepared from rabbit serum. By contrast, IG-depleted serum does not affect synaptic strength. Monovalent Fab fragments derived from the IG fraction similarly decrease the strength of electrical synapses. Furthermore Fab fragments reversibly block the modulation of synaptic strength by concanavalin A, a plant lectin that increases the junctional conductance between weakly coupled pairs of *Aplysia* neurons (Carrow and Levitan, *J. Neurosci.* 9(1989)3657-3664). SDS-polyacrylamide gel electrophoresis analysis demonstrates that more than 98% of the protein in the IG fraction is immunoglobulin and that no IG remains in the depleted serum. The results suggest that the inhibition of electrical coupling by mammalian serum reported in other cell culture systems is likely due to IG. These actions of IG on formation and modulation of electrical synapses may provide clues about molecular mechanisms of synaptic plasticity. Supported by NS25366 to I.B.L.

CALCIUM-DEPENDENT INACTIVATION OF NMDA CHANNELS. P.Legendre[†], C.Rosenmund & G.Westbrook, †INSERM U261, Paris, France and Vollum Institute, Oregon Health Sciences Univ., Portland, OR.

Calcium is permeant through N-methyl-D-aspartate (NMDA) channels and can also lead to inactivation of the whole-cell current. We examined Ca-dependent inactivation of NMDA channels using whole-cell voltage clamp and cell-attached recording on cultured hippocampal neurons. An ATP regeneration solution was included in the patch pipette to retard current 'rundown'. In normal extracellular Ca (1-2 mM), 10 μ M glycine and no added Mg, macroscopic currents evoked by 15 second applications of NMDA (10-100 μ M) inactivated slowly following an initial peak. At -50 mV in cells buffered to [Ca²⁺]_i < 10⁻⁸ M with 10 mM EGTA, the inactivation time constant was \approx 4 sec. Inactivation could be removed by holding the membrane potentials at +40 mV or by reducing the extracellular Ca (\leq 0.2 mM), suggesting that inactivation resulted from transmembrane calcium influx. The fraction of the peak current that inactivated was dependent on the extracellular calcium concentration, reaching a maximal inhibition of 43% at 1.3 mM [Ca]_o. Further increases in [Ca]_o accelerated the inactivation time constant without altering the maximal inactivation. Inactivation was significantly slower using BAPTA compared to EGTA, suggesting that the measured inactivation time constant reflects primarily the rate of [Ca]_i buffering.

Inactivation was present following substitution of Ba or Sr for Ca; and was not blocked by intracellular perfusion with phosphatase inhibitors including fluoride, okadaic acid or calmidazolium. Raising intracellular Ca via KCl-induced depolarization also resulted in decrease in channel activity in cell-attached patches, suggesting that Ca-dependent inactivation occurs in intact cells and can be triggered by calcium entry through nearby voltage-gated calcium channels. This mechanism could play a role in down regulation of postsynaptic calcium entry during sustained synaptic activity and may reflect a direct action of Ca on the NMDA channel. Supported by INSERM, USPHS and the McKnight Foundation.

CONCAVALIN-A AND INSULIN ACT VIA DIFFERENT MECHANISMS TO AFFECT GLUTAMATE RESPONSES IN *APLYSIA* NEURONS. P.S.Katz and I.B.Levitan. Department of Biochemistry and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

The plant lectin concanavalin A (Con A) causes neurons from the marine mollusc, *Aplysia californica*, to respond to glutamate application with an inward cation current that reverses near zero mV (Keheo, *Nature*, 274: 866-9, 1978). We investigated the mechanism underlying this effect. Responses of neurons in primary cell culture to pressure-applied glutamate were recorded with two electrode voltage clamp. In each of over 70 trials, application of Con A (50 μ g/ml) to the bath caused the inward current response to glutamate. However, when the interior of the cell was perfused with a whole cell patch electrode prior to Con A application, 5 of 8 cells did not develop this inward current response to glutamate. When the neuron was perfused after the establishment of the inward current response, 17 of 26 cells partially or completely lost the response. Thus, the induction of this response by Con A is dependent upon a diffusible substance in the cell.

Con A is known to bind to insulin receptors and insulin-like peptides are present in *Aplysia* (Van Minnen and Schallig, *Cell Tiss. Res.*, 260: 381-6, 1990). However, bovine insulin (Sigma) did not mimic or antagonize the effect of Con A, but instead acted in a dose-dependent fashion to block another glutamate-evoked current, carried by Cl⁻.

PHOSPHORYLATION SHIFTS UNITARY CONDUCTANCE OF CONNEXIN43 GAP JUNCTION CHANNELS. A.P.Moreno, G.I. Fishman*, J. Saez, E.L. Hertzberg and D.C. Spray. Einstein College of Medicine, Bronx, NY 10461

The gap junction proteins found between oligodendrocytes and between certain neurons (connexin32) and between astrocytes (connexin43) are phosphoproteins. Phosphorylating agents display various actions on gap junctional conductance (g_j) in different tissues. To explore the effects of these treatments on a known connexin, we transfected a communication-deficient cell line (SKHep1, derived from a highly metastatic human hepatoma) with cDNA encoding human connexin43 (hCx43). Clones of stable transfectants were isolated in which Northern and Western blots and g_j measurements verified abundant connexin43 expression. Treatment with the phosphorylating agents TPA (a tumor promoting phorbol ester that activates kinase c), 8 Br-cAMP (a membrane permeant cAMP analogue that activates kinase a), forskolin (which activates adenylyl cyclase), and okadaic acid (which inhibits phosphatases and increased hCx43 phosphorylation) or with staurosporine (which inhibits kinase activation and decreased hCx43 phosphorylation) did not appreciably change g_j between pairs of these cells. All these agents, however, had marked effects on unitary junctional conductance (γ_j). hCx43-transfected cells exhibit two γ_j values, 60 and 90 pS; phosphorylating agents favored the 60 pS and less voltage dependent state, while staurosporine favored the 90 pS and more voltage dependent state. Mutants expressing truncated hCx43 (phosphorylation sites removed) exhibited voltage dependence that was similar to the parental hCx43 and single values of γ_j . We conclude that phosphorylation of hCx43 reduces the unitary conductance of gap junction channels and reduces their voltage dependence and that these phosphorylation sites are not required for insertion or assembly of hCx43 into functional channels.

REDUCTION OF $[Ca^{2+}]$ NEAR THE PLASMA MEMBRANE FOLLOWING INFLUX IN AIT-20 PITUITARY CELLS. S.J. Korn and R. Horn. Neurosciences Dept., Roche Inst. of Molec. Biol., Nutley, N.J. 07110.

The duration of calcium-dependent chloride currents ($I_{Cl(Ca)}$) in voltage clamped AIT-20 pituitary cells was used as an indirect measure of the timecourse of $[Ca^{2+}]$ reduction near the plasma membrane following Ca^{2+} influx through plasma membrane Ca^{2+} channels. Increasing extracellular pH (pH_0) from 7.3 to 8.0 reversibly prolonged $I_{Cl(Ca)}$ tail currents in perforated patch recordings from cells bathed in Na^+ -free solutions. This prolongation was prevented in standard whole cell recordings when the pipet solution contained 0.5 mM EGTA. The prolongation was not due to alteration of intracellular pH, since it still occurred when intracellular pH was buffered with 80 mM HEPES. The prolongation occurred by a mechanism other than by a direct action on Ca^{2+} channels, since tail currents were prolonged when pH_0 was changed rapidly during the tail current, long after all Ca^{2+} channels were closed. The prolongation of $I_{Cl(Ca)}$ was not due to a direct action on Cl^- channels, since changing to pH_0 8 did not prolong Cl^- tail currents when intracellular $[Ca^{2+}]$ was fixed. Raising pH_0 did, however, prolong depolarization-evoked $[Ca^{2+}]$ transients, measured directly with the Ca^{2+} indicator dye, fura-2. Taken together, these data demonstrate the presence of a Na^+ -independent, pH_0 -sensitive mechanism for reduction of $[Ca^{2+}]$ following influx through Ca^{2+} channels. We suggest that this mechanism is the plasma membrane Ca^{2+} ATPase.

KINETIC DIFFERENCES BETWEEN THE ONSET AND RECOVERY OF Ca^{2+} -DEPENDENT CALCIUM CHANNEL INACTIVATION. M.W. Fryer and R.S. Zucker. Dept. of Mol. & Cell Biology, Univ. of Calif., Berkeley, CA 94720.

We have previously shown that a rapid drop in $[Ca^{2+}]_i$ during a long depolarizing pulse did not cause a step increase in calcium current (I_{Ca}) but merely reduced the subsequent rate of inactivation (Fryer & Zucker, Soc. Neurosci. Abs. 16:1171, 1990). In this study we have investigated the onset kinetics of Ca^{2+} -dependent inactivation of I_{Ca} by suddenly increasing $[Ca^{2+}]_i$ with caged Ca^{2+} . Identified neurons from the dorsal surface of the Aplysia abdominal ganglion were pressure injected with 60% Ca^{2+} -loaded DM-Nitrophen to a final concentration of approximately 2-5mM. A brief, intense light flash given during a voltage step from -60mV to -5mV induced a large (60%), rapid, step-like decrease in I_{Ca} that could be well fitted by the sum of two exponentials ($\tau_1=3.4ms$, $\tau_2=72.3ms$). Similar rapid effects were seen using Pa^{2+} as the charge carrier. A rapid $[Ca^{2+}]_i$ drop elicited by photolysis of the caged BAPTA derivative Diazo-4 had no effect on I_{Ca} . A flash given 20ms before the voltage step typically reduced the peak I_{Ca} by 50% but had little effect on the normalized decay of I_{Ca} . The results show that the onset kinetics of I_{Ca} inactivation induced by photoreleased Ca^{2+} are fast and the recovery kinetics of inactivation seen after rapid $[Ca^{2+}]_i$ buffering are slow. The much slower rate limiting step for recovery might reflect the re-phosphorylation rate of inactivated calcium channels. Supported by an NIMH/MRC C.J. Martin Fellowship to MF and NIH Grant NS 15114.

SINGLE CHANNEL STUDY OF A Ca-ACTIVATED K CURRENT ASSOCIATED WITH RAS-INDUCED TRANSFORMATION. Y. Huang*, D. McDonald* and S. Rane. Dept. of Biological Sciences, Purdue University, West Lafayette, IN 47907.

Ras oncogene transformation of fibroblast cell lines correlates with constitutive appearance of a Ca-activated K current recorded by whole-cell patch clamp. Little or no K current is available for activation in confluent normal cells (Amer.J.Physiol. 260: C104-C112, 1991). Passage of normal cells and maintenance in fresh serum greatly increases activatable current (after 2 days), coincident with an increase in rate of cell division. Also, proliferation is inhibited by TEA in the growth medium at concentrations which also block the K current.

To better understand regulation of the Ca-activated K current and its role in cell proliferation we have characterized it at the single channel level. More than 85% of inside-out patches from ras-transformed cells contain a channel class which is highly-selective for K over Na ($P_{Na:P_K} << 0.02$); requires $\geq 0.1 \mu M$ intracellular free Ca for activation; shows an increase in opening probability up to $10 \mu M$ free Ca; and, displays little or no voltage-dependence. These characteristics are consistent with those of the whole-cell, Ca-activated K current. The channel is inwardly rectifying in symmetric 150 mM K (33/17 pS at E_m -60/60 mV, respectively). In outside-outside patches, replacement of extracellular 150 mM K with 37 mM K results in a more linear I-V curve, consistent with the linear appearance of whole-cell Ca-activated ramp currents in asymmetric K. Therefore, the physiology of the whole-cell and single channel currents from ras-transformed cells are identical. Pharmacological identity of these currents is being tested by applying blockers for the whole-cell current to outside-out patches containing the K channel. The selective appearance of the channel with ras transformation or mitogenic stimulation suggests a modulatory role for activated ras protein. This idea will be tested by application of purified protein to confluent, nontransformed cells in both whole-cell and single channel recording configurations.

LIMITATIONS IMPOSED UPON CHANNEL ACTIVATION BY LOCAL Ca^{2+} CONCENTRATION: A MODELLING STUDY. L.D. Partridge, D. Swandulla* & T.H. Müller*. Dept. of Physiology, Univ. of New Mexico, Albuquerque, NM 87131 & Dept. of Membrane Biophysics, Max-Planck-Institute, D-3400 Göttingen, FRG.

The rapid rise in intracellular Ca^{2+} concentration that occurs during activity of many neurons is responsible for the subsequent activation of potassium, chloride, and non-specific cation (CAN) channels. Details of Ca^{2+} binding to these channels is not well understood. We have modelled the local environment of CAN channels with data from molluscan neurons in an attempt to determine some of the conditions for direct channel activation that result from the punctate delivery of Ca^{2+} into the cell through voltage-activated calcium channels.

Ca^{2+} concentration in the vicinity of an open calcium channel was calculated as a function of distance and time assuming diffusion from a point source into a semi-infinite space that contains a fixed Ca^{2+} buffer. Interaction of Ca^{2+} with CAN channels was modelled by using either a Hill equation or a concerted allosteric interaction. In the model, calcium and CAN channels were placed in a hexagonal array at either their measured average inter-channel spacing or clustered more closely together than this distance. Whole-cell CAN current was calculated as a function of inter-channel spacing and the K_D , Hill coefficient, or allosteric constant of Ca^{2+} 's interaction with the CAN channel and then compared with the CAN currents measured in bursting *Helix* neurons. The necessity for channel clustering was a very sensitive function of K_D , n, or the allosteric constant with clustering values for expected values of these constants. These predictions are consistent with our patch clamp studies where infrequent patches that contained CAN channels each had an average of 3.4 channels.

INHIBITION OF ODOR-SENSITIVE CYCLIC NUCLEOTIDE GATED CHANNELS BY INTRACELLULAR Ca^{2+} : A POSSIBLE MECHANISM FOR SENSORY ADAPTATION. F. Zufall*, S. Firestein, H.F. Gerardo* and G.M. Shepherd. Section of Neurobiology, Yale University School of Medicine, 333 Cedar St., New Haven, CT, 06510 and Physiological Institute Technical University, D-8000 Munich 40 Germany.

We have previously described an odor-sensitive cation channel in salamander olfactory receptor neurons which can also be gated by the cyclic nucleotides cAMP and cGMP. This ion channels is believed to mediate olfactory transduction in vertebrates.

Here we report that intracellular calcium directly regulates the activity of this channel. With 100 nM Ca^{2+} present on both sides of the membrane, a saturating concentration of cAMP (0.1 mM) applied to an inside-out patch elicited strong channel activation with an open probability of about 0.6. When the intracellular Ca^{2+} concentration was raised to 3mM, channel activity markedly decreased, to an open probability of 0.09. This effect was reversible and did not require ATP. The IC_{50} value for the Ca^{2+} mediated channel inhibition was approximately 1mM. The decrease in the mean open probability was correlated with an increase in channel closed time; neither open time nor channel amplitude were affected in 3mM Ca^{2+} . Other non-desensitizing channel properties, such as cyclic nucleotide sensitivity, were also unaffected by Ca^{2+} . This effect of odor-sensitive channel inhibition by intracellular Ca^{2+} provides a mechanism which may contribute to sensory adaptation in olfaction.

A cyclic nucleotide gated channel has also been identified in isolated rat olfactory receptor neurons and preliminary analysis suggests that it possesses similar properties to those found in amphibia. Supported by NIH DC 00086, DC00920 and Deutsche Forschungsgemeinschaft.

PROSTAGLANDIN E_2 SELECTIVELY INHIBITS CALCIUM-ACTIVATED POTASSIUM CHANNELS IN RAT BRAIN SYNAPTOSOMES. J. Ren* and C.G. Benishin, Department of Physiology, Faculty of Medicine, University of Alberta, Edmonton, Alberta CANADA, T6G 2H7.

This study was designed to determine whether prostaglandin E_2 (PGE_2) is capable of affecting certain nerve ending potassium channels, and its subcellular mechanism. ^{86}Rb was used to quantitate nerve ending potassium channel activities as described previously (Benishin et al, Mol. Pharmacol. 34:152, 1988). Synaptosomes were pretreated for 30 min with PGE_2 (1 μM) before the efflux study was initiated. The results showed that PGE_2 could inhibit the calcium-activated component of ^{86}Rb efflux (Ca-K) in a dose-related manner, but had no effect on the resting or voltage stimulated components. This inhibition could be reversed by the protein kinase C inhibitor H7 (10 μM). PGE_2 did not inhibit synaptosomal ^{45}Ca uptake suggesting that the action of PGE_2 is not secondary to inhibition of voltage-gated calcium channels. These results suggest that PGE_2 modulates nerve ending potassium channels, and that protein kinase C may be involved.

AN ASSAY FOR NICOTINIC RECEPTOR FUNCTION IN MOUSE BRAIN BY MEASUREMENT OF ION FLUX. M.J. Marks, S.R. Grady* and A.C. Collins Institute for Behavioral Genetics, University of Colorado, Boulder, CO.

A widely applicable, convenient, and sensitive biochemical assay for nicotinic receptor function in the central nervous system has been difficult to establish. Since nicotinic receptors are ligand gated-ion channels, an assay using nicotine-induced ^{86}Rb efflux to measure receptor activation has been developed. Synaptosomes were prepared from mouse midbrain (thalamus and mesencephalon) by Percoll gradient centrifugation. The synaptosomal fraction prepared in this manner was enriched in [^3H]nicotine binding and could actively accumulate ^{86}Rb by a ouabain-sensitive process. The rate of ^{86}Rb release from the tissue was monitored by superfusion. ^{86}Rb efflux was stimulated by nicotine in a time- and concentration-dependent fashion. Using a 2 min stimulus period the EC_{50} for nicotine was about 1 μM . The nicotine-induced increase in ion efflux was completely inhibited by 10 μM mecamylamine. The extent of mecamylamine inhibition was dependent upon time of exposure to the antagonist. The results indicate that functional nicotinic receptors in mouse brain can be measured using a simple *in vitro* assay system. Supported by DA 03194 and DA-00116.

FUNCTIONAL STUDIES OF NEURONAL NICOTINIC RECEPTORS IN CHICK BRAIN SLICES. L.L. McMahon, W.R. Weaver* and V.A. Chiappinelli. Dept. of Pharmacological and Physiological Science, Saint Louis University School of Medicine, St. Louis, MO 63104.

We have recently identified a kappa-bungarotoxin-insensitive neuronal nicotinic response in the mesencephalic lateral spiriform nucleus (SPL) of the newly hatched chick (Sorenson, E.M. and Chiappinelli, V.A., *Neuron* 5:307, 1990). Using conventional intracellular and whole cell patch-clamp recording techniques, we have further examined the functional properties of nicotinic receptors in SPL neurons. Electrical stimulation of a cholinergic fiber tract located laterally to the SPL (Sorenson, E.M., et. al., *J. Comp. Neurol.* 281:641, 1989) via an ultrasmall bipolar stimulating electrode elicited subthreshold and superthreshold responses from SPL neurons with a latency of 3-5 msec. These responses were blocked in the presence of 100 μM CdCl₂, demonstrating their synaptic nature. In addition, the nicotinic antagonists d-tubocurarine (50 μM) and dihydro- β -erythroidine (100 μM) substantially blocked these responses, indicating that they were mediated by nicotinic receptors. Muscarinic receptors were continuously blocked during all of these experiments by the presence of 1 μM atropine in the perfusion buffer. Nicotinic responses to the exogenously applied agonist carbachol were detected as early as 14 days of incubation. The chick SPL is thus a good model system for the pharmacological and developmental examination of central neuronal nicotinic acetylcholine receptors. Supported by NIH Grant NS17574 to VAC.

RAPID ENHANCEMENT OF ACETYLCHOLINE (ACh) RESPONSES IN CHICK CILIARY GANGLION NEURONS. D.Gurantz, A.T. Harootunian*, R.Y. Tsien, V.E. Dionne*, J.F. Margiotta*. Dept. of Pharmacology, UCSD, La Jolla, CA 92093 and *Dept. of Physiology & Biophysics, Mt. Sinai. New York, NY 10029

Incubation of ciliary ganglion neurons in 8Br-cAMP and IBMX for 6h results in a 2-fold increase in ACh-induced conductance. When cAMP is applied intracellularly, a 50-70% increase in the ACh response is observed after only 2-5 min. Here we examined the effect of two agents, bovine serum albumin (BSA) and vasoactive intestinal peptide (VIP). BSA but not globulin or ovalbumin induced a dose dependent increase in the ACh response that was maximal (3.5-fold) with 10 mg/ml BSA within 5 min. The BSA and cAMP effects were not additive, suggesting that their signals ultimately converge on a common downstream site. Using a new cAMP imaging technique (Adams et al., *Nature* 349:694, 1991) we found no increase in cAMP levels in the neurons following treatment with BSA for up to 30 min. VIP, a cAMP-elevating neuro-peptide present in avian ciliary ganglia, did cause a significant increase in cAMP within 1 min (18/19 cells). VIP treatment also rapidly increased the ACh-induced conductance by ~40% ($p < 0.004$, $n = 34$), similar to that seen previously following intracellular injection of cAMP. The cAMP-dependent and independent modulation of ACh responsiveness suggests that ciliary ganglion neurons may use a variety of first messengers and signaling pathways in modulating synaptic input. Supported by NIH NS20962, NS27177, NS24417 and HHMI.

384.2

NICOTINE INDUCES C-FOS EXPRESSION IN RAT BRAIN AND DIMINISHES THE RESPONSES TO METRAZOLE. B. Sharp*, S. Beyer*, K. McAllen*, S. Nicol and S. Mattu. Endocrine-Neuroscience Res. Lab., Dept. of Medicine, Hennepin Cnty. Med. Ctr. and U. of Minnesota, Mpls., MN 55415

c-Fos mRNA and protein are rapidly expressed in the CNS in response to a variety of acute neuronal stimuli, including metrazole. The capacity of nicotine to induce c-fos mRNA expression and to modify the response to metrazole was determined using total RNA extracted from 6 regions of rat brain (pyriform, C8 and cerebellar cortex and hippocampus, dentate gyrus and medial habenula). c-Fos was detected after hybridization of dot blots or Northern transfers and quantified by computerized videodensitometry. One half hour after a single dose of nicotine (0.5-2.0 mg/kg b.w.), c-fos mRNA levels significantly increased by approximately 2-8 fold; the magnitudes were dose and region-dependent. The hippocampus, dentate gyrus and medial habenula were most sensitive and responsive. c-Fos mRNA levels remained elevated for 1h and then receded toward baseline by 2h. A single pre-treatment dose of nicotine (2 mg/kg) failed to alter the c-fos response to metrazole (40 mg/kg) delivered 2h later. Three doses of nicotine, administered 2h apart followed by metrazole 2h later, appeared to reduce the c-fos response by 50% only in the hippocampus ($p < 0.05$). In contrast, after injecting nicotine 3x/d for 10d, the response to metrazole was significantly attenuated in all 6 brain regions and the hippocampus appeared to be most affected (decreased by 66-90%). In summary, nicotine-induced c-fos expression is dose and region dependent, and chronic exposure to nicotine desensitizes the c-fos response to another ion channel-dependant (gaba receptor) neuronal stimulant, metrazole.

384.4

AN UNUSUAL CHOLINERGIC RESPONSE IN COCHLEAR HAIR CELLS. P.A. Fuchs and B.W. Murrow. Dept. Physiology, U. Colorado Med. School, Denver, CO 80262

Sensory receptor (hair) cells of the cochlea are subject to efferent neuronal regulation. Outer hair cells of mammals and birds are thought to be inhibited by the release of ACh from the efferent neurons. We have isolated outer hair cells (short hair cells - SHCs) from the chick's cochlea and examined their responses to cholinergic agonists under voltage-clamp. Both ACh and carbachol elicited outward currents from SHCs voltage clamped at -40 mV. The reversal potential of the outward current varied with changing K concentration and the instantaneous I-V relation was "N-shaped". That is, the K current grew with increasing driving force, up to a maximum near -10 mV (E_K at -80 mV). At increasingly positive membrane potentials the K current diminished, virtually disappearing at +20 mV. A similar I-V relation is displayed by Ca-dependent K current activated by voltage-gated Ca channels in these cells. Indeed, in many of the responses to ACh a small inward current could be seen to precede the larger K current, and this early inward current was more easily seen when the K current was reduced by replacement of internal K with Cs. These observations suggest that ACh might elicit K current in chick hair cells by causing Ca influx. In keeping with this suggestion, the response to ACh was dependent on external Ca and could not be elicited when external Ca was replaced with Mg.

ACh and carbachol had similar effects, however, neither nicotine nor muscarine (100 μM) produced any current on cells that responded well to 100 μM ACh. Curare (3 μM), atropine (3 μM), and tetraethyl ammonium (1 mM) all blocked the ACh response. Purified samples of 1 μM α - or β -bungarotoxin (Biotin) completely and reversibly blocked the response to 100 μM ACh. Supported by NIDCD DC00276.

FUNCTIONAL DESENSITIZATION OF DOPAMINE RELEASE FOLLOWING STIMULATION BY L-NICOTINE IN MOUSE STRIATAL SYNAPTOSOMES. S.R. GRADY, M.J. MARKS, AND A.C. COLLINS Institute for Behavioral Genetics, University of Colorado, Boulder, CO.

It has been proposed that upregulation of nicotinic receptor binding sites in response to chronic nicotine treatment could be caused by chronic receptor desensitization (Marks et al., 1983, *J. Pharm. Exp. Ther.* 226:817-825). To investigate whether mouse brain receptors can functionally desensitize, experiments were conducted using a continuous perfusion method of measuring release of previously loaded ^3H -dopamine from mouse striatal synaptosomes. Using various time intervals of L-nicotine stimulation, it was found that the maximum dopamine release obtainable in 5 min was 3 units above baseline (where 1 unit is 1 min of unstimulated baseline release) or 0.6 units/min, while a 1 min stimulation could release 1.4 units indicating that desensitization does occur. Other experiments indicated that at least 12-15 units could be released by nicotine under the proper conditions; therefore it is unlikely that the apparent desensitization was caused solely by depletion. Initial rate calculations from data obtained with 0.2 to 1 min stimulations indicate a maximum theoretical rate in the absence of desensitization of 10 units/min with an EC_{50} of 2.5 μM . Using 5-10 min exposures, desensitization appeared to be 1st order with a half-time of about 1 min and an EC_{50} of about 1 μM . Apparent first order recovery from desensitization had a half-time of about 10 min. The results indicate that dopamine release is desensitized by nicotine at concentrations similar to those that stimulate release. Supported by DA-03194, DA-00116, and AA-06391.

NOVEL MODULATION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS BY CALCIUM. M. Amador*, S. Vernino*, C. Luetje, J. Patrick and J.A. Dani, Department of Molecular Physiology and Biophysics and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Nicotinic acetylcholine receptors (nAChRs) expressed in *Xenopus* oocytes were studied using two-electrode voltage clamp. The current through muscle nAChRs decreases when the extracellular calcium concentration is elevated. This decrease is consistent with the high affinity but low conductance of the muscle nAChR channel for Ca^{2+} . Ca^{2+} occupies the channel and decreases the single-channel currents that underlie the ACh-induced macroscopic currents. The current through neuronal nAChRs, however, increases dramatically as $[Ca^{2+}]_o$ is increased and decreases as $[Ca^{2+}]_o$ is decreased. Ba^{2+} and Mg^{2+} do not substitute for Ca^{2+} . Increasing $[Ba^{2+}]_o$ or $[Mg^{2+}]_o$ decreases the current through both neuronal and muscle nAChRs. All $\alpha\beta$ -subunit combinations that form functional neuronal nAChR channels in oocytes are modulated by calcium.

To verify the results, neuronal nAChRs were examined in bovine chromaffin cells and PC-12 cells. Ca^{2+} -enhancement of ACh-induced currents is seen even when excised patches or whole cells are internally dialyzed with simple electrolyte solutions containing calcium chelators. Onset of and recovery from calcium enhancement are rapid and repeatable for as long as the giga-ohm seal lasts. The calcium modulation is seen over a wide range of voltage. Taken together these results indicate that a Ca^{2+} -dependent intracellular cascade is not a likely mechanism for the modulation of neuronal nAChRs. Supported by MDA, Whitaker Foundation, BRSG, and NIH.

NEURONAL NICOTINIC RECEPTOR BINDING IN RAT BRAIN: A COMPARISON OF THREE RADIOLIGANDS D.J. Anderson and S.P. Americ, Neuroscience, Pharmaceutical Discovery Division, ABBOTT Laboratories, Abbott Park, IL 60064-3500.

Neuronal nicotinic receptors (nAChRs) have been defined with the nicotinic agonists, $[3H]$ -(-)nicotine ($[3H]$ -NIC) and $[3H]$ -methyl-carbamylcholine ($[3H]$ -MCC). These ligands are plagued with problems of stability and reproducibility. Recently, a new tritiated ligand, $[3H]$ -(-)cytisine ($[3H]$ -CYT), has become available (Pabreza, et al., *Mol. Pharmacol.*, 39:9-12, 1991). CYT is a very high ($K_i = 0.1$ nM) affinity agonist that is very selective for the nicotinic receptor. Bmax and Kd values were determined for $[3H]$ -CYT, $[3H]$ -MCC, and $[3H]$ -NIC from Scatchard analysis using a brain membrane enriched fraction prepared from Sprague-Dawley rats. Subsequently, the affinities of 11 reference compounds were determined against each ligand from concentration-inhibition curves. Correlations of affinities for each ligand were calculated to probe possible relationships between populations of receptor subtypes. To validate selectivity for nAChRs cholinergic receptors, the same series was tested against $[3H]$ -QNB, a muscarinic receptor antagonist. Scatchard analysis indicated a one-site model for the three nicotinic ligands. Respective Kd values for $[3H]$ -CYT, $[3H]$ -MCC, and $[3H]$ -NIC were 0.13 nM, 1.0 nM, and 0.75 nM, while Bmax values were 126, 66, and 113 fmol/mg protein. The rank order potencies of Ki values against all three ligands were (ranging from 0.13 to 200,000 nM): CYT > (-)NIC, lobeline, MCC > DMPP, (+)NIC, > carbachol, arecoline > > THA, oxotremorine > > heptyl-physostigmine. Correlations between the three nicotinic ligands revealed close agreement of profiles with all slopes very near to 1.0 and all r^2 values >0.95. In contrast, most of the reference compounds had weak affinity for $[3H]$ -QNB (Ki s ranging from 1000-300,000 nM). Remarkably, CYT was 3,000,000-fold selective for the nAChR. These data suggest that $[3H]$ -CYT, $[3H]$ -MCC, and $[3H]$ -NIC bind to the same population of nAChRs in rat whole membrane preparations.

METHYLLYCACONITINE (MLA) A POWERFUL ANTAGONIST OF NICOTINIC ACETYLCHOLINE RECEPTORS. D. Bertrand, S. Bertrand*, M. Ballivet and S. Wonnacott, Dpt of Physiology, Medical School, 1 Rue Michel Servet, 1211 Geneva 4, Switzerland.

The natural insecticide MLA from the plant *Delphinium brownii* is an antagonist of cholinergic transmission in invertebrates. We have investigated the effects of MLA on avian neuronal nicotinic acetylcholine receptors (nAChRs). MLA was assayed on $\alpha 4/\alpha 1$, $\alpha 3/\alpha 1$ and $\alpha 7$ receptors expressed in *Xenopus* oocytes following nuclear injection with chicken cDNAs. Application of MLA alone had no effects on the holding current in any cells we tested. However, when MLA was applied simultaneously with acetylcholine (ACh) a reduction of the response was observed. Receptors formed with $\alpha 3/\alpha 1$ are more sensitive to MLA than $\alpha 4/\alpha 1$. Application, in perfusion, of 10 μM MLA on $\alpha 3/\alpha 1$ abolished currents evoked by ACh (1 μM). The onset and recovery from MLA was fast and indistinguishable from the perfusion time. The homo-oligomeric nAChR formed by $\alpha 7$ was extremely sensitive to MLA, much more so than $\alpha 3/\alpha 1$ or muscle ($\alpha \beta \delta$) nAChR. $\alpha 7$ receptors expressed in *Xenopus* oocytes were measured by ^{125}I - α -bungarotoxin binding to individual oocytes: there was excellent correlation between toxin binding and ACh-induced currents. Toxin binding was totally displaced by 1 μM MLA.

HIGH CALCIUM PERMEABILITY OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS. S. Vernino*, M. Amador*, D.S. Zatechka*, K. Flood*, C. Luetje, J. Patrick and J.A. Dani, Department of Molecular Physiology and Biophysics and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Three different sets of experiments indicate that the neuronal nicotinic acetylcholine receptor (nAChR) channel has a higher Ca^{2+} permeability than the muscle nAChR. In the first set of experiments, nAChRs expressed in *Xenopus* oocytes were studied using two-electrode voltage clamp. Macroscopic currents through neuronal nAChR channels expressed in oocytes cause a Ca^{2+} -dependent activation of an endogenous Cl^- conductance. The results indicate that Ca^{2+} is entering the oocyte through neuronal nAChRs, and then, the Ca^{2+} activates the Cl^- conductance. Under the same experimental conditions, currents through muscle nAChRs did not activate this Ca^{2+} -dependent Cl^- conductance. In a second set of experiments, oocytes and cultured cells were used to measure reversal potentials as $[Ca^{2+}]_o$ increased from 1.8 to 18 mM. The magnitude of these reversal potential shifts indicate that the Ca^{2+} permeability of the neuronal nAChR is intermediate between the muscle nAChR and the NMDA-subtype of glutamate receptor. In a third set of experiments, simultaneous current measurements and optical measurements of $[Ca^{2+}]_i$ with fura-2 indicate that the neuronal nAChR of bovine chromaffin cells conducts Ca^{2+} well. A large fluorescent fura-2 signal is seen when neuronal nAChRs are activated by the nicotinic agonist, DMPP, in the presence of atropine. Supported by MDA, Whitaker Foundation, BRSG, and NIH.

METHYLLYCACONITINE (MLA) IS A POTENT ANTAGONIST OF NICOTINIC ACETYLCHOLINE RECEPTORS (AChR) ON RAT HIPPOCAMPAL NEURONS: SINGLE CHANNEL STUDIES. E.F.R. Pereira^{1,2}, S. Wonnacott³ and E.X. Albuquerque^{1,2}, ¹Dept. Pharmacol. Exptl. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201; ²Lab. Mol. Pharmacol. II, IBCCF, Brazil 21944; ³Dept. Biochem., Univ. Bath, Bath, England BA2 7AY.

Recent biochemical studies have shown that an alkaloid extracted from seeds of the *D. brownii*, MLA, is a potent competitive blocker of α -BGT binding to AChR in mammalian brain (*FEBS Lett.*, 226:357, 1990). In addition, preliminary studies demonstrated that nicotinic agonists activate single channel and whole-cell currents in hippocampal pyramidal cells (*FEBS Lett.*, 222:63, 1987; *Eur. J. Pharmacol.*, 191:505, 1990). Here, we evaluated AntX-activated single channel currents recorded from outside-out patches excised from fetal rat hippocampal neurons grown in culture for 20-30 days. The effects of MLA on these currents were analyzed. All solutions contained TTX (0.1 μM), atropine (1 μM) and APV (50 μM), and were delivered via a glass mini-pipe connected to a perfusion system. AntX (1 μM) activated single channel currents that appeared mainly as brief, isolated events. The most predominant conductance was 22 pS. The channel open times were fitted to a single exponential function whereas the closed and burst times showed double exponential distributions. Open times appeared to be voltage dependent such that they increased with membrane hyperpolarization. MLA (1-100 fM) had no effect on open times of AntX-activated single channel currents. However, MLA significantly reduced the frequency of channel openings. This effect was concentration-dependent, and in the presence of 1 pM MLA practically no channel activation was detected. Such an effect was completely reversed after wash-out. Therefore, our electrophysiological results confirm that MLA is an important probe for AChRs present in the CNS. Support: U.S. Army Med. Res. & Devel. Comm. Contr. DAMD17-88-C-8119 & USPHS NS25296. CAPES Fellow, Brazil (EFRP).

NON-COMPETITIVE INHIBITORS ALTER NICOTINIC ACETYLCHOLINE RECEPTOR AFFINITY FOR AGONIST. M.W. Stephens, S. Wonnacott & P. Whiting* Dept. Biochem., Univ. Bath, Bath BA2 7AY UK *Merck, Sharp & Dohme, Harlow CM20 2QR UK

The anti-convulsant MK801, and mecamylamine, a ganglionic antagonist, are believed to operate by physically blocking the ionophore of NMDA and nicotinic acetylcholine (nACh) receptors respectively. (-)- $[3H]$ -Nicotine, which labels the $\alpha 4\beta 2$ subtype of neuronal nAChR, binds to a detergent (Triton X-100) extract of rat brain membranes with parameters $K_d=12\pm 2$ nM, $B_{max}=90\pm 15$ fmol/mg protein (n=13). MK801 (500 μM), shown to crossreact with nAChR channels, reduces affinity for $[3H]$ nicotine ($K_d=30\pm 4$ nM; n=3) by a decrease in association rate (the dissociation rate remains unchanged); the number of sites (B_{max}) is comparable to control. Mecamylamine (60-600 μM) induces a curved scatchard plot, characteristic of positive cooperativity. DHBE, a competitive antagonist, reduces B_{max} in a predictable fashion, whilst K_d is unaltered. Thus, non-competitive inhibitors can influence agonist binding, but may operate by differing molecular mechanisms.

Functional correlates have been explored by ion flux assay, using a stably transfected mouse cell line expressing avian $\alpha 4$ and $\beta 2$ subunits.

384.13

EFFECT OF NONCOMPETITIVE BLOCKING DRUGS ON LIGAND BINDING TO NEURONAL NICOTINIC RECEPTOR. B.A. Dodson and L.M. Braswell.

Dept. of Anesthesia, UCSF, San Francisco, CA 94143-0648
This study examines the effect of chlorpromazine, haloperidol, pentazocine, d-tubocurarine, diazepam, pentobarbital and diphenylhydantoin (DPH) on high affinity postsynaptic nicotinic, cholinergic binding to synaptosomes prepared from freshly dissected rat cerebral cortex. The binding of L-³H-nicotine (15 nM) to neuronal nicotinic acetylcholine receptors (nAChR) (200 µL 5% brain homogenate, 250-280 µg protein) with and without drug (10⁻⁹ to 10⁻³ M) was determined by centrifugation assay. Experiments were performed in triplicate in TRIS/HEPES buffer, pH 7.4 at 0°C. Nonspecific binding was defined as that occurring in the presence of excess (1 ml) L-nicotine with specific binding defined as the difference between total and nonspecific binding (~45-50% of total binding). With the exception of DPH, all of the drugs tested inhibited L-³H-nicotine binding in a concentration-dependent, saturable fashion consistent with a mass action mechanism with EC₅₀s for half maximal inhibitions similar to that of the competitive antagonist d-tubocurarine (60 µM) and a rank order of haloperidol < diazepam < chlorpromazine < d-tubocurarine < pentazocine < pentobarbital. They did, however, vary in efficacy with maximum inhibitions ranging from < 20% of control binding (chlorpromazine and pentobarbital) to approximately 50% of control (haloperidol, diazepam and pentazocine). By contrast, DPH had minimal effects (< 10% of control) at its saturation limits (10⁻⁴ M). These results are similar to those reported for *Torpedo* nAChR as well as for GABA_A receptors (Schwartz RD Biochem Pharmacol 37:3369-3375, 1988) and support the hypothesis of functional as well as structural homology between nicotinic and GABA_A receptor-gated ion channels. 384.15

THE EFFECTS OF DITHIOTHREITOL (DTT), A REDUCING AGENT, ON THE INHIBITORY NICOTINIC RECEPTOR ON RAT DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS. E.M. Sorenson and J.P. Gallagher. Dept of Pharmacol. and Toxicol., Univ. of Texas Med. Br., Galveston, TX 77550.

This laboratory has previously demonstrated that nicotinic agonists produce a direct inhibitory response at rat DLSN neurons (Wong and Gallagher, *Nature* 341:439, 1989 and *J. Physiol. (Lond.)* 436:325, 1991). To determine whether the agonist binding site on this novel inhibitory nicotinic receptor has structural similarities to that on excitatory nicotinic receptors, we have examined the effects of DTT on the inhibitory response. DTT abolishes excitatory nicotinic responses by reducing a disulfide bond at cysteines 192 and 193 in the alpha subunits of excitatory receptors. This disulfide bond is essential for agonist activation of the receptors (Kao et al., *J. Bio. Chem.* 259:11662, 1984; Loring et al., *J. Neurosci.* 9:2423, 1989).

Standard intracellular recording techniques were used to record from DLSN neurons in the *in vitro* brain slice. A control response to 1,1-methyl-4-phenylpiperazinium (DMPP), a nicotinic agonist, was obtained. The slice was then superfused with 1mM DTT at pH 8.0 for 20 min and the response to DMPP was retested. DTT did not abolish the response to DMPP (n=5). The effects of DTT on the response of each neuron to serotonin (5-HT) or N-methyl-D-aspartate (NMDA) were also tested. 5-HT_{1A} responses were unaffected but the NMDA responses were potentiated, as has been reported by others (Aizenman et al., *Neuron* 2:1257, 1989). The DTT treatment was also effective in abolishing an excitatory nicotinic response found in rat vestibular neurons.

We conclude that, unlike excitatory nicotinic receptors, the inhibitory nicotinic receptor on DLSN neurons does not require a disulfide bond at the agonist binding site for receptor activation.

ENRICHMENT OF PRESYNAPTIC CHOLINERGIC RECEPTOR BINDING SITES ON PERCOLL GRADIENTS S. Wonnacott & G. Wilkie*. Dept. Biochem., Univ. Bath, Bath BA2 7AY, UK.

Subcellular fractionation of brain tissue on Percoll discontinuous density gradients resolves intact nerve terminals (synaptosomes) from membrane fragments of pre- and postsynaptic origin¹. This contrasts with isopycnic procedures, in which membranes and synaptosomes are recovered in the same fraction.

We have characterised Percoll gradient fractions from rat cortex with respect to marker enzymes for plasma membranes (AChE), synaptosomes (occluded lactate dehydrogenase) and mitochondria (succinate dehydrogenase). The fractions were assayed for muscarinic and nicotinic cholinergic ligand binding sites. Whereas muscarinic receptors labelled with [³H]QNB and [³H]pirenzepine are enriched in the membrane fractions at the top of the gradient, specific binding of the nicotinic ligands [³H]nicotine and [³H]cytisine has a biphasic distribution, with enrichment also in the nerve terminal fractions. This is consistent with a predominantly presynaptic localisation of nicotinic receptors in the CNS, in accordance with their role in mediating transmitter release. The muscarinic agonist [³H]oxotremorine-M displayed a similar biphasic profile, indicating that this fractionation technique may be useful in discriminating presynaptic binding sites.

EFFECTS OF A NOVEL NITROMETHYLENE INSECTICIDE ON COCKROACH NICOTINIC SINGLE CHANNELS.

1. H. Cheung, 2. E.W. Harris and 1. D.J. Beadle*.

¹School Biol & Mol Sci, Oxford Polytechnic, Oxford UK & ²Biology Dept., Fisons Pharmaceut., Rochester, NY USA

The suggested site of action of the nitromethylene heterocycle (NMH) insecticides is at the nicotinic acetylcholine receptor. A potent new NMH insecticide, Compound I produced prolonged inward currents under voltage-clamped conditions. Both acetylcholine and Compound I produced transient inward currents, but the rate of current inactivation for acetylcholine was much faster than for Compound I. Single-channel studies were therefore performed to reveal the mechanism of action of Compound I.

Under cell-attached patch, Compound I induced unitary currents similar to those induced by acetylcholine at both resting and hyperpolarizing potentials. At resting potential, two categories of unitary currents were observed for both acetylcholine (1.66±0.34 & 2.83±0.37 pA) and Compound I (1.89±0.4 & 3.42±0.4 pA). With a 60mV hyperpolarization, the mean amplitudes and mean open-times increased for both acetylcholine and Compound I. The probability of channel opening was higher for Compound I (0.096±0.004 vs. 0.042±0.007). Compound I also induced unitary currents with a longer mean open-time than did acetylcholine.

These results suggest that NMH insecticides may act by prolonging nicotinic channel-opening. The longer mean open-time observed in the presence of Compound I may explain the slow inactivation observed under whole-cell voltage-clamp studies.

EFFECTS OF REPLACEMENT OF BUFFER Na WITH N-METHYL-D-GLUCAMINE (NMDG) ON NICOTINE-INDUCED CHANGES IN SYNAPTOSOMAL ACCUMULATION OF [³H]TETRAPHENYLPHOSPHONIUM (³H-TTP). C.J. Hillard and J.L. Pounds*. Dept. of Pharmacology, Medical College of WI, Milwaukee, WI 53226.

³H-TTP is a membrane permeant, lipophilic cation which accumulates in synaptosomes and can be used to estimate membrane potential difference. We have demonstrated that nicotine and four other nicotinic agonists decrease the accumulation of ³H-TTP in synaptosomes from rat cerebral cortex, suggesting that these agonists depolarize the synaptic plasma membrane. This effect of nicotine is blocked by the ganglionic blockers mecamylamine and hexamethonium but not by atropine. If the mechanism of action of nicotine in the CNS is the same as at peripheral nicotinic cholinergic receptors (nAChR), the effect of nicotine on ³H-TTP accumulation ought to be sodium dependent. In this series of experiments, we have replaced sodium in the incubation buffer with NMDG. Removal of buffer sodium resulted in an increase in the synaptic membrane potential difference calculated using the concentration gradient of ³H-TTP from -58 mV to -76 mV. Veratridine (60 µM), which produced a 40% decrease in ³H-TTP accumulation in the presence of sodium, produced a 15% decrease in NMDG buffer. The depolarizing effect of increasing extrasynaptosomal potassium concentration was identical in both buffers. The decrease in ³H-TTP accumulation produced by nicotine (100 µM) was enhanced in the NMDG buffer (42 fmol/0.4 mg protein compared to 18 fmol/0.4 mg protein in sodium buffer). If buffer KCl concentration was increased to 12 mM to reduce the initial membrane potential to -64 mV, nicotine decreased ³H-TTP accumulation by 15 fmol/0.4 mg protein. Therefore, replacement of buffer sodium with NMDG did not diminish the effect of nicotine on membrane depolarization. However, since the effect of nicotine was found to be dependent on initial membrane potential, these studies raise the possibility NMDG may itself enter and depolarize the synaptosome through the nAChR ionophore. NICOTINIC RECEPTORS IN RAT CEREBRAL CORTEX ARE ASSOCIATED WITH THALAMOCORTICAL AFFERENTS. P.B.S. Clarke. Dept. of Pharmacology, McGill Univ., Montreal, Canada H3G 1Y6.

Nicotinic receptors labelled with ³H-nicotine are prominent in most thalamic nuclei and in layers III/IV of cerebral cortex, which receive a major thalamic input (Clarke et al 1984). To test whether cortical nicotinic receptors are located on afferent terminals from thalamus, male Wistar rats were infused unilaterally with excitotoxic doses of N-methyl-D-aspartate (NMDA) under anaesthesia into one of four sites: anterior thalamus, ventral thalamus, medial geniculate nucleus or dorsal lateral geniculate nucleus. Control subjects received phosphate buffer. After one week survival, brain sections were processed for ³H-nicotine receptor autoradiography. Within thalamic nuclei infused with NMDA, ³H-nicotine binding appeared little altered or unchanged, despite a marked loss of neurons. In contrast, there was a substantial reduction in ³H-nicotine binding in ipsilateral cerebral cortex, localized to the projection zone of the thalamic nuclei that had been lesioned. Thus, in several cortical areas, nicotinic receptors that are labelled with high affinity by ³H-nicotine appear to reside on thalamocortical inputs. Supported by MRC (Canada).

MECHANISM OF THE HYPERTENSIVE RESPONSE TO CENTRAL INJECTION OF NICOTINE. J.J. Buccafusco. Dept. Pharmacology & Toxicology, Medical College of Georgia & the Department of Veterans Affairs Medical Center, Augusta, GA 30912.

The purpose of this study was to examine the effects of nicotine administered directly into the CNS on mean arterial pressure (MAP) and heart rate (HR) to avoid the direct peripheral action of the drug. Also, since nicotine has been reported to enhance the release of endogenous brain acetylcholine, we sought to determine the role of this mechanism in mediating the cardiovascular response. Rats were previously implanted with intracerebroventricular (icv) cannula guides and an arterial line (iliac artery). One week later each animal received a series of increasing doses of nicotine (or saline vehicle) from 2-100 µg (in a 10 µl volume) with each dose separated by at least one day. MAP increased immediately following all doses of nicotine, however, the maximal response was obtained following the 50 µg dose. In general, the response began immediately after injection and peaked within 2-3 min and returned to baseline within about 15 min. HR changes were often not dramatic and highly variable. In order to examine the dependence of the pressor response to nicotine on brain acetylcholine, rats were pretreated with 20 µg (icv) of hemicholinium-3 (HC-3) 1 hr prior to nicotine to deplete endogenous acetylcholine. HC-3 pretreatment resulted in a significant reduction in the magnitude and duration of the pressor response to nicotine. Likewise, pretreatment with atropine inhibited the pressor response to subsequent injection of nicotine. These data support the concept that icv injection of nicotine induces a pressor response through the release of endogenous acetylcholine possibly acting on central muscarinic receptors. Supported by HL30046 and the Dep. Vet. Affairs Med. Ctr.

PEPTIDES: ANATOMICAL LOCALIZATION I

385.1

THREE-DIMENSIONAL RECONSTRUCTION OF THE NEUROPEPTIDE NETWORK IN THE HUMAN CAUDATE NUCLEUS. M.S. Manley, S.J. Young, M.E. Martone, and P.M. Groves, Depts. Psychiatry & Neurosciences, Univ. Calif. San Diego, La Jolla, CA 92093-0603.

Studies of rat and cat striatum have established the existence of a patch, or striosomal compartment, embedded in a surrounding matrix region. We have examined the distribution of neuropeptide markers for leucine enkephalin (LENK), Substance P (SP) and calbindin D (CaBD) in alternate 70µ sections of formalin-fixed postmortem tissue from the head of the human caudate nucleus, using computer-assisted three-dimensional reconstruction. Reconstructions were derived from camera lucida drawings outlining striatal regions of high or low immunoreactivity. Consistent with previous studies, LENK immunoreactivity in the human dorsal striatum appeared annular in contrast to the more homogeneously labeled regions seen in the cat. Similar to the cat, reconstructions revealed the existence of considerable long-range order. Patches appeared aligned over distances of several millimeters to form long, horizontally oriented tubular structures in the dorsolateral caudate nucleus, with occasional orthogonal interconnecting crossbridges between the tubular structures. LENK-immunoreactive elements tended to fill the matrix in the ventromedial caudate and nucleus accumbens. In this area, LENK-poor areas are in register with CaBD-poor areas, which are known to correspond to striosomes, and can be followed over successive serial sections to similarly reveal tubular structures. As seen in rat and cat, CaBD-poor patches were more distinctly demarcated ventrally and generally smaller than LENK-patches. Reconstructions derived from this marker revealed a network similar to the LENK network in the dorsal striatum. The distribution of SP staining appeared complex. For example, in the mid-ventral caudate, SP-poor zones were in register with enkephalin-rich patches, while in the dorsal caudate some SP-rich zones were in register with LENK patches. Thus, the pattern of SP staining corresponds in a complicated way to the LENK network. This network is strikingly similar across individuals and may relate to the segregation and/or integration of parallel striatal circuits. Catecholamine (CA) input to stress responsive, c-fos containing paraventricular (PVN) neurons. S. Pretel and D.T. Piekut. Neuroendocrine Unit, University of Rochester, Rochester, N.Y. 14642

Peptide (e.g. enkephalin, CRF) containing neurons of the PVN are known to receive CA input. CA release, in particular that of noradrenaline (NA), is important for the modulation of stress response behavior. We have examined the CA input to PVN neurons of the hypothalamus that are specifically responsive to nociceptive stress.

Under ether anaesthesia, nociceptive primary afferents of the rat hindfoot were activated through application of mustard oil. Two-3hrs later, the animals were transcardially perfused with phosphate buffer followed by 4% paraformaldehyde. Vibratome cut 40µm tissue sections were processed for double-label immunocytochemistry using the Vectastain ABC Kit. C-fos like immunoreactivity (antibodies kindly provided by Drs. Slammon and Curran) was localized first, followed by dopamine-β-hydroxylase (DBH) or phenylethanolamine-N-methyltransferase (PNMT; both, Eugene, Inc.) using the regular or nickel enhanced 3,3' diaminobenzidine procedure. Some double-labeled sections were subsequently embedded in plastic (Immunobed, Inc.) and processed for semi-thin (1-2µm) sections.

The results showed c-fos labeled neurons predominantly in the parvocellular nuclei of the PVN and numerous DBH labeled fibers in the PVN, particularly in the dorsal and medial nuclei. PNMT labeled fibers were less numerous. However, the location of fibers labeled for either enzyme overlapped that of c-fos labeled neurons, as visible in 40µm sections. Analysis of semi-thin sections showed that numerous DBH as well as PNMT immunoreactive fibers were located in close anatomical proximity to c-fos positive neurons. This suggests that CA are able to potentially modulate the activity of stress responsive, i.e. c-fos containing PVN neurons. NS18626

385.2

RELATIONSHIPS OF PEPTIDE-CONTAINING NERVE FIBRES WITH NORADRENERGIC AND PUTATIVE CHOLINERGIC PELVIC NEURONS. J.R. Keast, Dept. Physiol. & Pharmacol., Univ. Queensland, Qld. 4072, Australia.

The major pelvic ganglion (MPG) of the male rat contains cholinergic and noradrenergic postganglionic neurons which supply the reproductive, lower urinary and digestive organs. Many peptides are also found in somata and nerve fibres of the MPG. These neurons receive inputs from either sympathetic or parasympathetic preganglionic neurons, and possibly also collaterals from visceral primary afferent axons. In the present study multiple staining immunohistochemical analyses of fixed MPG sections were carried out to determine the pattern of distribution of these nerve fibres with somata of different neurochemical types. Four main groups of neurons could be identified: noradrenergic neurons containing neuropeptide Y (NPY), and three groups of non-noradrenergic (putative cholinergic) neurons, those with NPY, those with vasoactive intestinal peptide (VIP) and a smaller group of enkephalin neurons (ENK); the latter contained various other combinations of additional peptides (galanin (GAL), substance P (SP), NPY and VIP). The peptides studied in varicose nerve fibres were ENK, GAL, SP, somatostatin (SOM), cholecystokinin (CCK) and bombesin (BOM). Each group of these peptide-containing fibres (except some ENK and fewer GAL) were closely associated almost exclusively with putative cholinergic neurons - very few noradrenergic neurons were surrounded by peptide containing fibres. Further specific associations were demonstrated within the non-noradrenergic neurons, with the majority of SOM and CCK fibres associated with non-noradrenergic NPY neurons and most SP fibres associated with VIP somata.

These results suggest that preganglionic inputs to noradrenergic neurons either contain no peptide or a peptide not included in this study. Furthermore, peptide markers for different subsets of preganglionic inputs to putative cholinergic neurons have been demonstrated, and may represent different functional pathways. Sensory fibres (represented by SP distribution) are also likely to communicate with a select group of MPG neurons. This information has provided further insights into the organization of neural pathways to the pelvic organs.

PROJECTIONS OF THE COMMISSURAL NUCLEUS OF THE SOLITARY TRACT DEMONSTRATED BY PHA-L. L.J. Sim and S.A. Joseph. The Neuroendocrine Unit, University of Rochester, Rochester, N.Y. 14642.

The commissural nucleus of the solitary tract (cNTS) participates in central autonomic control via catecholamine and opioid mechanisms. A small opiocortin neuronal pool has been identified in the cNTS and projects locally to brainstem nuclei. This is in contrast to the large arcuate opiocortin pool, from which we have previously identified extensive projections to the telencephalon, diencephalon, periaqueductal gray (PAG) and midline brainstem nuclei. This study was performed to expand upon our previous studies of the NTS opiocortin system by elucidating cNTS efferents and determining the relationship to specific neurons in terminal fields. PHA-L was iontophoresed into cNTS and immunocytochemically localized with subsequent dual immunostaining for peptides and transmitters. PHA-L-immunoreactive (-ir) fibers with terminals were identified in the bed nucleus of the stria terminalis, periventricular thalamus, hypothalamus and amygdala. In the brainstem, PHA-L-ir fibers and terminals were identified the PAG, lateral parabrachial nucleus, locus coeruleus/Barrington's nucleus and NTS, as well as lateral pontine and medullary nuclei important in cardiovascular function. Dual immunostaining revealed a correlation between NTS terminal fields and catecholaminergic cell groups. PHA-L-ir terminals were also identified in putative contact with peptidergic neurons in the brainstem. We provide neuroanatomical evidence that the cNTS can influence autonomic function. (Supported by USPHS DA07232, NS 21323 & AHA 87 1011)

385.5

EFFERENT PROJECTIONS FROM THE PARABRACHIAL NUCLEAR COMPLEX: CONNECTIVITY WITH NEUROPEPTIDERGIC FOREBRAIN STRUCTURES. S.A. Joseph and L.J. Sim. Neuroendocrine Unit, University of Rochester, Rochester, N.Y. 14642.

Electrophysiological studies have shown that either directly or as a relay site the parabrachial nuclear complex communicates with important forebrain structures which modulate autonomic information. The parabrachial nucleus and its subdivisions have been singled out as an important pivot by which visceral afferent information is relayed to forebrain centers.

For this study we have utilized a sensitive anterograde tracer to elucidate connectivity from this complex and by dual labeling we have identified neurochemical substances which possibly mediate the connectivity. *Phaseolus vulgaris* leucoagglutinin (PHA-L), an anterograde tracing lectin, was iontophoresed into discrete regions of the parabrachial nuclear organization for subsequent analysis of the efferent terminations from the nuclear complex and their putative contact with neuropeptidergic neuronal elements. This analysis was performed using single and dual immunocytochemistry.

The study demonstrates parabrachial projections to periaqueductal grey, locus coeruleus, amygdala, bed nucleus of the stria terminalis and the paraventricular nucleus. With dual immunocytochemistry, some of these efferent terminals were seen in close proximity to CRF and enkephalin containing neuronal elements in the forebrain. These studies substantiate the supposition that the parabrachial autonomic center communicates with centers in the forebrain known to be important in regulating certain autonomic mechanisms. (Supported by American Heart Association #871011 and NIH NS21323 grants.)

385.7

ATRIAL NATRIURETIC PEPTIDE (ANP)-POSITIVE NEURONS OF THE CANINE ISLANDS OF CALLEJA COMPLEX (ICC) ARE COMPONENTS OF THE VENTRAL PALLIDUM. J. Kennedy*, L. Compton*, B.H. Turner and J.C. McKenzie*. Dept. of Anatomy, Coll. of Medicine, Howard University, Washington, DC, 20059.

ANP has been localized in the ICC, distinct structures in the olfactory tubercle with unknown function. The purpose of the present study was to define the type and distribution of ANP-positive neurons in the canine ICC and to characterize these neurons by identification of their afferents. Dogs (6) were deeply anesthetized with sodium pentobarbital and perfused with saline followed by 4% formaldehyde. Brains were removed, blocked, immersed in sucrose and sectioned at 50 µm on a freezing microtome. Sections through the olfactory tubercle were incubated in ANP antibody (1:10,000) for 72 h at 4° C and processed by the ABC technique. Serial sections were immunostained for ANP, Substance P (SP, 1:2,000) and met-enkephalin (mENK, 1:10,000). Some sections were double stained for ANP and either tyrosine hydroxylase (TH), SP, mENK or neuropeptide Y (NPY) using the ABC and glucose oxidase (GO) techniques. ANP was localized in large neurons of the core, cap and arched bridge regions of the ICC. These neurons were similar in morphology to large neurons of the pallidum which also stained for ANP. Immunoreactivity for TH did not overlap with ANP-positive neurons. ANP-positive neurons were enmeshed within networks of SP- and mENK-positive fibers. It is concluded that ANP-positive neurons of the ICC are similar to large pallidal neurons in morphology, immunoreactivity and innervation, and may represent the most ventral portion of the pallidum. Supported by NIH grant HL45241 and a grant from Howard University.

COMPARATIVE FETAL DEVELOPMENT OF TACHYKININS IN THE BED NUCLEUS OF STRIA TERMINALIS AND AMYGDALA OF THE CAT. M.K. Boylan and R.S. Fisher. MRRC and Dept. of Anatomy, UCLA, Los Angeles, CA 90024.

The bed nucleus of the stria terminalis (BNST) and the central and medial nuclei of the amygdala are considered to be related developmentally. Similarities in their cytoarchitecture, connections and neuropeptide content have been characterized in the adult. Developmental studies indicate similar neuronal morphogenesis in these regions. However, neurochemical development in these structures has not been detailed. In order to test the hypothesis that the BNST and amygdala are developmentally related, we compared the ontogeny of tachykinin immunoreactivity (TK-I) within these regions in 18 fetal (F) kittens from F30-F60 (gestation in cat is 65 days). The anterior BNST (antBNST) is known to receive TK axons from the central amygdaloid nucleus (CNA), while the posterior BNST (postBNST) receives TK input mainly from the medial amygdaloid nucleus (MNA). The results of this study indicate that developmental TK expression in the antBNST parallels that in the CNA, and the postBNST parallels TK expression in the MNA. At F45, the MNA undergoes a significant increase in TK neuronal and fiber frequency, correlated with increased fiber density laterally in the postBNST, with more frequent cells medially and ventrally. Likewise, as CNA neurons increase substantially by F50, fibers become abundant in the lateral antBNST and cells more numerous in the middle and ventral regions. In addition, TK growth cones and fibers are seen entering the amygdala from the postBNST and visa versa, as early as F30, constituting a known reciprocal TK pathway. Thus, the development of TKs in the amygdala and BNST are closely related, and may influence the early ontogeny of the amygdala/BNST system. Supported by USPHS Grants NS 24596 and HD 05958.

SEXUAL DIFFERENCES IN THE PEPTIDERGIC INNERVATION OF THE QUAIL SEPTAL REGION UNDER VARIOUS HORMONAL CONDITIONS. C. Viglietti-Panzica, N. Aste, A. Fasolo, J. Balthazart and G.C. Panzica. Dept. Human Anatomy & Physiology, and Dept. Animal Biology, I-10126 Torino, Italy, Lab. Biochemistry, Univ. Liège, B-4020 Liège, Belgium.

A large population of LH-RH immunoreactive neurons was identified within the septal region of the Japanese quail (Cell Tissue Res., 253, 327-335, 1988), suggesting a direct involvement of this area in the control of avian reproduction. We have now analyzed the immunocytochemical distribution of four peptidergic systems [vasotocin (VT), corticotropin-releasing factor, substance P, and neuropeptide Y] within the quail septal region. The immunoreactivity showed a peculiar distribution in several nuclei, and some of them [lateral septum (SL), nucleus of the pallial commissure, and nucleus of the stria terminalis (nST)] contained more than two of the considered peptides. The VT innervation of SL and nST is sexually dimorphic: a dense network of immunoreactive fibres was seen in adult sexually stimulated males but not in females. The VT immunoreactivity was virtually absent when male quail were put in a short day photoperiod or were castrated and it was restored to the original level in castrated males by silastic implants of testosterone (T). No immunoreactivity was observed in adult sexually stimulated females, or in the other female groups (exposed to short-day, ovariectomized, or treated with T). In conclusion, present results suggest a direct role of peptidergic systems in regulating septal circuitries, and the possibility of their dependency by the levels of circulating sex hormones. Supported by EEC (SC1-0230CITT), CNR (89.03043.04, 90.02456.04), MURST 40%, and FRFC (9.4601.90 and 2.9003.91).

THE EFFECT OF BILATERAL ELECTROLYTIC LESIONS OF THE CENTRAL AMYGDALOID NUCLEUS ON THE CONCENTRATION OF CORTICOTROPIN-RELEASING FACTOR (CRF) IN MICRODISSECTED BRAIN REGIONS. S.M. Koepler, C.D. Kiltz, M.J. Owens, G.N. Ervin, G. Bisette, and C.B. Nemeroff. Depts. Pharmacol. and Psychiat., Duke University Medical Center, Durham, NC 27710.

The projection fields of CRF-containing perikarya in the rat central nucleus of the amygdala (Ce) were studied using a combination of electrolytic lesioning methods, microdissection techniques and radioimmunoassay. After bilateral electrolytic lesions of the Ce, CRF concentrations were measured by a sensitive and specific radioimmunoassay (RIA) in the locus coeruleus, entorhinal cortex, prefrontal cortex, paraventricular nucleus, dorsal and ventral bed nucleus of the stria terminalis, arcuate nucleus and median eminence, lateral septal nucleus, lateral and ventromedial hypothalamic nuclei, dorsal and ventral parabrachial nuclei, and the nucleus of the solitary tract. Ce lesions significantly decreased the CRF concentration in the locus coeruleus (LC) and was the only brain region altered. This suggests the existence of a CRF pathway from the Ce to the LC which may mediate stress responsiveness. Plasma corticosterone concentrations of the lesioned rats were significantly increased when compared to the control animals. Subsequent studies will determine whether the marked increase in CRF concentrations in the LC after stress can be attenuated in rats with Ce lesions. (Supported by NIMH MH-42088).

DISTRIBUTION OF NEUROKININ B IN THE CENTRAL NERVOUS SYSTEM OF THE MALE SYRIAN HAMSTER. C. B. Newton and J.M. Swann. Dept. of Biol. Sci., Rutgers University, Newark, NJ 07102.

The three mammalian tachykinins are encoded by two genes. PPT-A encodes for substance P and substance K, while PPT-B encodes for neurokinin B (NKB). While the distribution of substance P in cells and fibers of the CNS of the rat and the hamster has been extensively described, the distribution of NKB in the hamster has not been reported. Studies utilizing in situ hybridization suggest that mRNA for PPT-A and PPT-B are expressed in overlapping areas. However, it has not been conclusively demonstrated whether or not substance P and NKB co-occur within the same neurons. In the present study we used immunohistochemistry and double label immunofluorescence to determine the location of neurokinin B and the extent of its co-occurrence with substance P in the cells and fibers of the male hamster CNS.

Colchicine treated tissue from adult male Syrian hamsters was either immunolabelled for NKB with polyclonal antisera to peptide 2, a fragment of the NKB precursor protein, (generously donated by Dr. J. Krause, Washington University) or immunolabelled for substance P using a monoclonal antiserum (Acrurate Scientific).

Heaviest cell and fiber labelling obtained with the peptide 2 antisera was located in the medial habenular. NKB fibers exiting this nucleus formed a heavily labelled projection to the interpeduncular nucleus via the tassel-like retroflexus. Light to moderate cell and fiber labelling was found in the cingulate and frontal cortex, ventral and external bed nucleus of the stria terminalis, lateral preoptic area, lateral hypothalamic area, anterior hypothalamic area, ventral tegmental area, central grey, paraventricular and arcuate nuclei. Fiber labelling was also found in the infra limbic and dorsal peduncular cortex, tenia tecta, shell of the accumbens, basolateral, central and intercalated nuclei of the amygdala and the substantia nigra pars reticulata. Substance P containing cells are located in the medial and lateral septum, medial and lateral subdivisions of the BNST, the medial preoptic area, the medial, cortical and central nuclei of the amygdala, and the ventromedial hypothalamic nucleus. Colchicine treated tissue that was double labelled for substance P and NKB failed to reveal colocalization of these peptides in neurons or fibers of the hamster CNS. Thus, PPT-A and PPT-B are expressed in the cells and fibers of the hamster CNS but do not appear to be colocalized within these structures. Supported by MPRC-B 3 S06 GMO8223-06S2.

SUBSTANCE P IMMUNOREACTIVITY IN THE MYENTERIC AND SUBMUCOSAL PLEXUS FOLLOWING APPLICATION OF BENZYLDIMETHYLTRIDECEYLAMMONIUM CHLORIDE DIHYDRATE TO THE DUODENAL SEROSA. E.H. South and P.D. Huff*. Dept. of Food Sci. & Toxicol., Univ. of Idaho, Moscow, ID 83843.

Serosal application of benzyltrimethyltetradecylammonium chloride dihydrate (BAC) to the serosa of discrete regions of rat intestine ablates the myenteric plexus without an apparent reduction in neuron number in the submucosal plexus (Herman and Bass, 1989). The neuropeptide, substance P, is found in both the submucosal and myenteric plexus as well as extrinsic nerves in the gut wall and, thus, may serve as a peptide marker for selective damage to the myenteric plexus. We found that bathing the duodenal serosa in a 2mM solution of BAC ablated substance P-like immunoreactivity (SPLI) along the entire extent of the duodenal myenteric plexus. SPLI in the submucosal plexus was not diminished in the duodenum or in the adjacent or distal myenteric and submucosal plexus of the jejunum. The rats tolerated the BAC treatment well, recovered to presurgery body weight within 10 days of BAC treatment and were equivalent in weight to control rats twelve wks after BAC treatment when whole mounts were prepared for assessment of SPLI. The BAC denervated duodenum may provide a model for use in acute or chronic examinations of the anatomical or functional contribution of the myenteric plexus to intestinal function.

POSSIBLE SOURCES OF SP REINNERVATION IN THE DEAFFERENTED TRIGEMINAL SPINAL NUCLEUS. J.D. Stover*, C.A. Schwab*, K.D. Hoffmann* and M.A. Matthews (LSU School of Dentistry, New Orleans, LA, USA).

To study the likely role of neurons exhibiting SP-like immunoreactivity (SPLIR) in deafferentation pain, the contribution of cervical and trigeminal primary afferents to recovery of SPLIR in trigeminal subnucleus caudalis (Vc) was assessed in 13 cats. Animals underwent either retrogasserian rhizotomy, cervical tractotomy or a combination trigeminal and cervical tractotomies. One cat served as a control. After perfusion and fixation at 11 and 45 days postoperatively, serial trigeminal brainstem sections were incubated in monoclonal SP antiserum and then reacted in avidin-biotin ABC solution for demonstration of SPLIR.

Loss of SPLIR was moderate to severe in middle and rostral Vc in rhizotomized cats and in middle and caudal Vc in cats subjected to cervical tractotomy, with predominant loss in the lateral Vc. Cats receiving two tractotomies showed moderate loss of SPLIR in middle Vc, with significant dorsomedial retention. In all cases SPLIR was retained in the trigeminal interstitial nuclear complex. Large, punctate boutons consistent with previously described glomerular terminals were much reduced at 11 days, however recovered at 45 days. Heavily labeled cell bodies were seen throughout Vc after tractotomies.

We conclude that an increased metabolic activity of intrinsic SP-containing neurons in Vc may correlate with expansion of terminal projections within the subnucleus, thus potentiating deafferentation pain. This study was supported by NIH Grants, DE00199, DE08052 and BRSG Grant RR 05704.

ULTRASTRUCTURAL CHARACTERIZATION OF THE DENSITY AND DISTRIBUTION OF BETA-ENDORPHINERGIC NEURONAL ELEMENTS IN THE ROSTRAL FOREBRAIN OF THE FEMALE C57BL/6J MOUSE. M.M. Miller, O. Zingg* and L. Zhu.* Departments of Obstetrics and Gynecology, Experimental Medicine and Anatomy, McGill University, Montreal, Quebec.

Beta-endorphin is synthesized in a subpopulation of neurons in the arcuate nucleus of the hypothalamus which send projections to the rostral forebrain. The present ultrastructural study was designed to determine the density and distribution of beta-endorphinergic (B-EP) neuronal elements in the preoptic area (POA) and diagonal band of Broca (DBB), regions known to be important to reproductive function. Sections from five normally cycling female C57BL/6J mice (2 mo old) were evaluated at proestrus using a pre-embedding immunogold labeling technique. Vibratome sections from regions including the rostral DBB through the caudal POA were incubated with rabbit anti B-EP followed by protein-A gold and processed for immunocytochemical labeling. Ultrathin tissue sections were analysed for density and distribution of labeled neuronal elements. All neuronal elements from all photomicrographs were classified according to category and counted. Categories included neurons, dendrites, axons, and glia. Immunolabeled neuronal elements were also counted and classified. Both density and distribution of gold-containing structures were similar in the POA and DBB. The total number of B-EP-containing neuronal elements was 2.1% of all identified structures. Among axons, 1.8% were labeled, while 1.5% of all terminals examined contained B-EP. Immunoreactive terminals only rarely impinged upon neuronal perikarya. Gold label was found in 3.6% of all dendrites and 1.9% of all neurons within examined regions. In no case were myelinated axons or glia labeled. The present study indicates that the rostral forebrain of the C57BL/6J mouse demonstrates a B-EP-containing network which is separate from that already identified in the arcuate nucleus in this strain of mouse. SUBSTANCE P DELINEATES CYTOARCHITECTONIC SUBDIVISIONS OF THE SOLITARY NUCLEAR COMPLEX AND THE INTERMEDIATE RETICULAR ZONE OF THE MEDULLA OBLONGATA IN THE HUMAN. D.A. McRitchie*, I. Türk, X-F. Huang* and G. Paxinos, Schools of Anatomy and Psychology, University of New South Wales, Kensington, NSW 2033, Sydney, Australia.

The solitary nuclear complex (Sol) and the intermediate reticular zone (IRZ) contain high levels of substance P-like immunoreactivity (SP-LI). We investigated the distribution of SP-LI in four brainstems from adult patients with no known neurological disorders. SP-LI was found in both small diameter varicose fibers as well as in medium and large diameter non-varicose fibers, and in small to medium sized cells. Of the ten subnuclei comprising Sol, the most dense SP-LI was found in the intermediate, medial, dorsal, and subregions of the dorsolateral nuclei. Moderate SP-LI was observed in the paracommissural and gelatinous nuclei and the remainder of the dorsolateral nucleus. Sparse SP-LI was recorded in the commissural, ventral and ventrolateral nuclei, while the interstitial nucleus and the solitary tract itself displayed very sparse immunoreactivity. All subnuclei, with the exception of the paracommissural and ventrolateral nuclei, contained medium sized, spindle shaped, bipolar and bitufted SP-LI neurons. Only the nucleus gelatinosus contained a high density of SP-LI cells. The IRZ displayed two parallel layers, with the external (lateral) lamina displaying high SP-LI. SP-LI positive neurons were mostly found in the part of the IRZ between the ambiguus nucleus and the solitary/vagal nuclear complex. The above findings demonstrate that the pattern of SP-LI in these two autonomic control regions of the medulla closely follows their cytoarchitectonic boundaries and accentuates the internal subdivisions of these regions. Supported by the National Heart Foundation and the National Health and Medical Research Council of Australia.

RELATIONSHIP BETWEEN LEU-ENKEPHALIN AFFERENTS AND A10 DOPAMINERGIC NEURONS: LIGHT AND ELECTRON MICROSCOPIC EXAMINATION. C.-L. Liang* and D.C. German. Dept. of Psychiat., UT Southwestern Medical Cntr., Dallas, TX.

Previous studies have indicated that opioid peptides are located within the midbrain regions containing the ventral tegmental area (nucleus A10) dopaminergic (DA) neurons. The present experiment sought to determine the synaptic relationship between leu-enkephalin (LE)-containing terminals and A10 DA neurons in the rat. Midbrain sections were double stained for LE (1:1000) and tyrosine hydroxylase (TH; 1:4000) using the peroxidase antiperoxidase and silver-intensified colloidal gold reactions, respectively. At the light microscope level, dense LE fiber and terminal immunoreactivity was observed within all of the A10 subnuclei (interfascicular n., paragravis n., central linear n., ventral tegmental area, parabrachialis pigmentosus n.). At the EM level, there were direct synaptic contacts between LE axon terminals and DA dendrites. Two types of LE boutons, symmetric and asymmetric, could be identified. LE terminals also contacted DA somata and unlabeled dendrites. These findings indicate that LE, or related opioid peptides, can directly influence A10 DA neurons. Supported by DA-05314.

DISTRIBUTION OF [LEU]ENKEPHALIN AND [MET]ENKEPHALIN IN BRAIN REGIONS OF THE TWO-DAY-OLD CHICK. P.J. Colombo, G. Schulteis, E.L. Bennett, J.L. Martinez, Jr., & M.R. Rosenzweig. Dept. of Psychology, Univ. of California, Berkeley, CA 94720

Chick brains were dissected into five regions and examined independently for [leu]enkephalin (LE) and [met]enkephalin (ME) content by radioimmunoassay. The brain regions examined were these: cerebellum (CER), optic tectum (OT), brain stem (BS), dorsal forebrain (DF) and ventral forebrain (VF). DF contained the neostriatum and ectostriatum. VF contained the mammalian basal ganglia homologues lobus parolfactorius and paleostriatum augmentatum. Values for both LE and ME were significantly different in each brain region examined except BS and VF and followed this descending rank order: BS = VF > OT > DF > CER. Values for ME were significantly higher than for LE in all brain regions except CER which was near the lower limit for detection. These findings suggest that the regional differences in enkephalin concentrations in chick brain are similar to those reported for mammalian brain.

OPIOID IMMUNOREACTIVITY IN THE NERVOUS SYSTEM OF *C. ELEGANS*
 Z. Aguilar*, E. Pirots*¹, N. Maidment¹, J.R. Mancillas and C.J. Evans.¹
 Brain Research Institute and Departments of Psychiatry¹, Anatomy and
 Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024

The vertebrate opioid system has evolved a complex array of ligands and receptors. Three known opioid precursors, namely POMC, proenkephalin and prodynorphin have been extremely well characterized from amphibians to man. Characterizing the opioids in invertebrates is of interest from a molecular evolutionary standpoint and may identify primary behavioral goals of the endogenous opioid system. We have developed an immunoassay which identifies all vertebrate opioid peptides and used this assay to probe acid/acetone extracts of *C. elegans*. Immunoreactive material co-chromatographing on Sephadex G50 with enkephalins was detected and is presently being further characterized.

To localize opioids in *C. elegans*, we used immunocytochemistry with antibodies against enkephalin. Leu-enkephalin (-ir) was observed in a) two bilaterally symmetrical cells in a position consistent with that of the IL2DL and IL2DR (inner labial sensilla neurons presumed to be chemoreceptors) and b) two bilaterally symmetrical neurons in a slightly dorsal midbody position, which could be the ALM mechanosensory receptors, or the CAN neurons, believed to regulate the excretory canal.

The non-selective opiate etorphine was tested for its effects on locomotion, swimming, feeding and egg-laying behaviors. No significant effects were observed. We are currently evaluating opiate effects on chemoreception, chemotaxis and osmoregulation. Supported by NIDA and a grant from the Keck Foundation.

EXPRESSION OF GASTRIN-RELEASING PEPTIDE IN THE RAT BRAIN: IMMUNOHISTOCHEMICAL ANALYSIS WITH AN ANTISERUM AGAINST C-TERMINAL EXTENSION PEPTIDE.
 P. Panula and J.F. Battey. Department of Anatomy, Univ. Helsinki and Laboratory of Neurochemistry, NINCDS, Bethesda, Maryland, USA.

A specific antiserum against the C-terminal extension peptide of GRP (GRP-CEP) was used to elucidate its distribution in the rat brain. In colchicine-treated rats, a prominent group of neurons in the paraventricular nucleus displayed strong GRP-CEP-ir. Faintly immunoreactive neurons were seen in the suprachiasmatic nucleus. Immunoreactive neurons were also found in the medial preoptic area, lateral hypothalamus, amygdala, central grey and dorsolateral tegmental nucleus. A few neurons were seen in the cerebral cortex and anterior olfactory nucleus. Immunoreactive nerve fibers were dense in the hypothalamus and some medullary nuclei. Occasional fibers were seen in the zona compacta but not in the zona reticulata of the substantia nigra. The distribution of GRP-CEP was not entirely identical to the distribution of GRP mRNA in normal rat brain or immunohistochemical distribution of GRP/bombesin-like immunoreactivity. Intraventricular injection of colchicine may affect expression of GRP in the brain.

DISTRIBUTION AND SEASONAL VARIATIONS OF THE IMMUNOREACTIVITY TO LEU- AND MET- ENKEPHALINS IN THE PERIOESOPHAGEAL GANGLIA OF THE SNAIL *Helix aspersa*. M. León-Olea*, M. Sánchez-Alvarez*, F. Camacho* and F.J. Alvarez-Leefmans. División de Inv. en Neurociencias, Instituto Mexicano de Psiquiatría, AP 14370, México, D.F.

The snail *Helix aspersa* has been subjected to intense neurobiological research, thus it was of interest to investigate the presence and the distribution of enkephalins in this organism. Given the distribution, we studied changes in the intensity of the immunoreactivity (IR) to enkephalins along the year. Thirty-five snail ganglia were used in a two year interval. The ganglia were extracted, fixed and cut into 10 µm thick slices. The indirect immunofluorescence method was used. Leu-enkephalin IR was found in neurons and fibers of the parietal, pleural and cerebral ganglia; fibers were also present in pedal ganglia. Met-enkephalin IR was present in cells and fibers of all ganglia, and in fibers of cerebro-pedal and cerebro-pleural connectives. Our data show a seasonal variation in the IR to enkephalins, having its lowest intensity in winter. This work and other studies carried out in less evolved invertebrates show that enkephalins are present in these organisms as neuro-modulators.

This work was financially supported by Dr. F. Pellicer project Conacyt P228CCOX891549 and Dr. M. Condés-Lara project Conacyt P228CCOX891536.

THE COLLOIDAL GOLD TECHNIQUE FOR THE CELLULAR LOCALIZATION OF GSH RECEPTORS. N. Guo and C. Shaw, Dept. of Ophthalmol., Univ. of British Columbia, Vancouver, B.C., Canada V6T 1Z3

Previous studies have shown that biotinyl-glutathione (GSH) binding sites are present in the white matter of the brain and thus suggested that GSH receptors might be on glial cells. Radioligand receptor assay performed on cultured astrocytes revealed the characteristics for a receptor, such as saturable and reversible binding, ligand specificity, and high affinity (Guo et al, 1991). Although these results suggested that there might be GSH receptors on astrocytes, they did not allow a direct cellular resolution.

To confirm that GSH receptors exist on astrocytes, appropriate cytochemical techniques are used. In the present study, the colloidal gold method was performed on the primary cultures of astrocytes to visualize the GSH receptors at the cellular level. Streptavidin-gold was used to bind to biotinyl-GSH molecules bound by their receptors on the cells. On addition of silver enhancer, precipitation of metallic silver occurred, which enlarged the colloidal gold label normally visible only at the electron microscopy level, yielding high-contrast signals visible by light microscopy. The colloidal gold decoration of biotin-GSH-GSH receptor complex revealed that these receptors were on both astrocytic cell bodies and their processes. Double staining with GFAP-Rhodamine showed that all cells which were stained by colloidal gold-silver were immunoreactive to GFAP, i.e. these cells which possess GSH receptors were astrocytes. Many GFAP positive cells, which look smaller and have not differentiated their processes, are colloidal gold negative, implying that these cells do not have GSH receptors at that ontogenic stage.

PEPTIDES: ANATOMICAL LOCALIZATION II

386.1

IMMUNOHISTOCHEMICAL DEMONSTRATION OF PRO-NEUROTENSIN/NEUROMEDIN N PROCESSING INTERMEDIATES IN RAT BRAIN. J. Woulfe, L. Lafortune*, P. Kitabgi and A. Beaudet. Dept. of Neurol. and Neurosurg., McGill University, Montreal, Quebec, H3A 2B4 and CNRS, Sophia Antipolis, 06560, France.

The neurotensin (NT)/neuromedin N (NN) precursor molecule possesses 4 lys-arg dibasic residues which represent potential sites of cleavage by maturation enzymes. Two of these sites flank a non-NT/NN-containing segment located between amino acids 87 and 140 within the precursor's primary sequence. Region-specific antisera generated against the exposed N-(KLPLVL;K6L) and C-terminal (EKEEVI;E6I) sequences of this segment were employed to immunohistochemically examine its topographic distribution relative to that of endogenous NT in serial adjacent sections through the rat brain. E6I and K6L immunoreactivity (IR) was detected in both nerve cell bodies and axon terminals. Both antigens were confined to areas displaying NT-IR suggesting a cellular co-distribution of E6I, K6L and NT. The intensity of E6I-IR in axon terminals was comparable to that of NT in all regions examined. However, there were far fewer E6I-IR cell bodies. K6L-IR in both axon terminals and cell bodies was consistently weak relative to that of E6I and NT. The differential intensity of E6I-IR in axon terminals versus perikarya suggests that the maturation cleavage exposing the E6I sequence occurs further distal to the cell body than that giving rise to NT. The relatively weak K6L-IR suggests that cleavage of the dibasic site adjacent to the K6L sequence may occur differentially in a restricted sub-population of NT-synthesizing neurons. The ability to detect both the N- and C-terminal extremities of the 87-140 precursor fragment in axon terminals suggests that it may represent an independent, biologically-active peptide.

386.2

ULTRASTRUCTURAL LOCALIZATION OF NEUROTENSIN IMMUNOREACTIVITY IN THE CAT NUCLEUS SOLITARIUS. B. E. MALEY, Dept. of Anatomy and Neurobiology, Univ. of Kentucky Med. Ctr., Lexington, KY 40536-0084.

Neurotensin immunoreactivity has been reported in neurons and axons in the cat nucleus solitarius at the light microscopic level. The nucleus solitarius is known to be involved in the central regulation of cardiovascular function. Neurotensin plays a role in this regulation, although the morphological basis for its action is not understood. The present study was intended to define the specific synaptic circuits involving neurotensin in the nucleus solitarius. All animals used in the present study were perfused with 4% paraformaldehyde and 0.5% glutaraldehyde in phosphate buffer, pH 7.4. The nucleus solitarius was isolated, cut on a vibrating microtome and immunostained with neurotensin antiserum using the PAP method.

Neurotensin was localized to synaptic terminals and axons throughout the various regions of the nucleus solitarius. The reaction product was typically associated with synaptic vesicles in terminals that contacted various size dendrites, spines, cell bodies and other axons. The majority of labelled terminals contacted spines and distal regions of the dendritic tree. Very few of the synaptic contacts involved proximal dendrites or the neuron's cell body. Results of this study indicate that neurotensin is present in presynaptic terminals in the cat nucleus solitarius, suggesting a possible role for it in the synaptic circuitry of this neural region. The morphological characteristics of neurotensin labelled terminals is very similar to that of other peptidergic terminals in the cat's nucleus solitarius. However, its pattern of termination is distinctive, suggesting that the pattern of synaptic contacts is a critical component of the circuitry in the nucleus solitarius.

386.3

NEUROTENSIN IMMUNOREACTIVITY IN THE POSTERIOR CINGULATE AND RETROSPLENIAL REGIONS OF THE MONKEY. K. Satoh, H. Matsumura* and M. Narita*, Dept. of Psychiatry, Shiga Univ. of Medical Science, Otsu 520-21, Japan.

The tridecapeptide, neurotensin, has been demonstrated in the forebrain limbic structures of many mammalian species, including primates. In the present study, we examined the anatomical organization of neurotensin-containing fiber networks in the posterior cingulate and retrosplenial regions of the *Macaca fuscata* by immunoperoxidase histochemistry. In the caudal half of the cingulate cortex, a zone of dense deposit of granular, neurotensin-containing puncta was observed in a subdivision of area 29l (Insauti). This neurotensin-rich field occupied the lateral part of its layer IV with a wedge-like appearance in the coronal sections. This area was clearly demarcated and the density of fibers appeared to be much higher than that observed in the nucleus accumbens. This field extended caudally to the level of the retrosplenial cortex, and made a curve around the caudal portion of the corpus callosum. After a ventro-rostral swift, the dense neurotensin-containing fiber network occupied a large area in the medial temporal region, and appeared to emerge with another neurotensin-rich field in the presubiculum. Such characteristic, regional distribution was not observed in other cortical systems that contained either substance P, somatostatin or tyrosine hydroxylase. The present study revealed that the cortical neurotensin system is distributed specifically to certain regions of the primate limbic structures. (Supported by grants from the ministry of education, science and culture.)

DISTINCT PATTERNS OF CALCITONIN GENE-RELATED PEPTIDE IMMUNOREACTIVITY (CGRP-IR) IN THE MAMMALIAN PANCREAS. R. De Giorgio, C. Sternini, K. Anderson, P.C. Watt*, F.C. Brunnicardi*, A.L. Widdison*, H.A. Reber*, and V.L.W. Go*, CURE, Depts. of Med. & Surg., UCLA & VAMC at Wadsworth & Sepulveda, Los Angeles, CA 90073.

In rodent pancreas, CGRP-IR has been reported in nerves and islet cells. The aim of this study was to evaluate whether neuronal and endocrine CGRP-IR structures are a common feature of mammalian pancreas. CGRP-IR is present in nerve fibers innervating the parenchyma and vasculature of different species with varying densities (rat, mouse, and rabbit >> pig, guinea pig, cat >> dog > human). CGRP-IR is not detected in intrapancreatic ganglion cells, indicating an extrinsic origin of CGRP innervation. In human pancreas, CGRP-IR fibers are mainly restricted to intrapancreatic ganglia. In the pig, islets are devoid of CGRP innervation. Only the rat pancreas contains CGRP-IR islet D cells. No immunoreaction is detectable in islet cells of pig or rabbit pancreas. In other species, islet B cells are labeled with rabbit CGRP antibodies. However, this staining is abolished by incubating the tissue at 37°C (which does not affect D cell and neuronal labeling) and is not reproducible with guinea pig or mouse CGRP antibodies (which strongly stain nerve fibers in each species and D cells in rat). Whereas the presence of CGRP-IR nerves is a common feature of mammalian pancreas, CGRP-IR endocrine cells appear to be restricted to the rat pancreas. Supported by NIH grant DK38752.

386.7

ASSOCIATIONS BETWEEN CGRP-IMMUNOREACTIVE FIBERS AND NPY-IMMUNOREACTIVE NEURONS THAT PROJECT FROM THE PELVIC PARACERVICAL GANGLION TO THE CERVIX AND BLADDER. R.E. Papka, D.L. McNeill and D. Quiver*, Dept. Anatomical Sciences, Univ. of Oklahoma, Oklahoma City, OK 73190.

We are attempting to determine if neurons in the paracervical ganglia (PG) which contain the same neurotransmitter code, but project to different end organs, receive similar or different patterns of input by identifiable nerves. Our preliminary work compared neurons that project to uterine cervix (cervical neurons) with those that project to urinary bladder (bladder neurons); specifically we focused on perikarya containing neuropeptide Y (NPY)-immunoreactivity (I) which are associated with calcitonin gene-related peptide (CGRP)-I fibers. The retrograde axonal tracers fluorogold and fast blue were used to identify cervical- versus bladder-neurons. After 7-14 days the PG were removed and sectioned on a cryostat. Sections containing tracer-labeled cells were double immunostained for NPY and CGRP. Counts of the following cells were made: (1) tracer-labeled cervical-neurons, (2) NPY-I cervical-neurons, (3) cervical-neurons associated with CGRP-I fibers and (4) cervical-NPY-I-neurons associated with CGRP-I fibers. Similar counts were made for bladder NPY-I neurons. Preliminary data indicate: (1) of the tracer-labeled-cervical-neurons about 50% were NPY-I, about 44% were associated with CGRP-I fibers and about 32% were both NPY-I and associated with CGRP-I fibers and (2) of the tracer-labeled-bladder neurons about 67% were NPY-I, about 51% were associated with CGRP-I fibers and about 37% were both NPY-I and associated with CGRP-I fibers. (Supported by NIH Grant NS22526 and the Presbyterian Health Foundation).

NEURON-GLIA INTERACTIONS IN THE REGULATION OF OXYTOCIN AND VASOPRESSIN RELEASE FROM THE RAT NEURAL LOBE. C.J.C. Boersma, M.A.F. Sonnemans* and F.W. van Leeuwen, Neth. Inst. for Brain Res., Amsterdam, the Netherlands.

The release of oxytocin (OT) and vasopressin (VP) from the neural lobe (NL) is modulated by both opioid peptides and OT/VP itself. Apart from these peptides, relatively high levels of F8Fa-ir peptide immunoreactive (F8Fa-ir) peptides are present, which become undetectable after osmotic stress. We tried to find morphological evidence for VP and F8Fa-ir peptide involvement in this regulation mechanism. For staining of F8Fa-ir nerve terminals we used a polyclonal antiserum (kindly provided by H-Y.T. Yang), raised to synthetic F8Fa. VP and F8Fa-ir nerve terminals were shown to make synaptoid contact with pituitary cells. With a combination of preembedding peroxidase staining for F8Fa and a postembedding immunogold labeling for the C-terminal part of VP-Neurophysin (VP-NP), it was shown that F8Fa-ir peptides were colocalized with VP-NP in the same granules. The present results suggest that VP and F8Fa-ir peptides can be co-released and that both might modulate OT and VP release indirectly, with the pituitary cell as an intermediate link.

ONTOGENY OF CALCITONIN GENE-RELATED PEPTIDE-LIKE IMMUNOREACTIVITY IN THE RAT PANCREAS.

K.C. Hunt and C. Sternini, Departments of Anatomy & Cell Biology and Medicine and CURE/DDC, UCLA School of Medicine and VAMC - Wadsworth, Los Angeles, CA 90024.

Calcitonin gene-related peptide-like immunoreactivity (CGRP-LI) has previously been observed in the adult rat in endocrine cells at the periphery of the islets of Langerhans and in afferent fibers innervating the endocrine and exocrine pancreas and blood vessels. The purpose of this study was to trace the development of this pattern. Sprague-Dawley rats at embryonic (E) days 12-21 (the day of discovery of the vaginal plug = day 0) and postnatal days 0-4, 8, 12, and 16 were processed for CGRP immunoreactivity using the avidin-biotin technique. Specificity controls included normal serum and preabsorption of CGRP antibody to CGRP, gastrin, and other pancreatic peptides. CGRP-LI was observed in scattered cells within the pancreas at E12. Nerve fibers adjacent to blood vessels in connective tissue associated with the pancreas stained for CGRP-LI at E16. CGRP-LI could be found in fiber bundles in the exocrine pancreas at E17 and in thin fibers in the endocrine pancreas at E18. By E20, the islets of Langerhans had assumed their adult form and CGRP-LI was observed in cells at their periphery. Thus, the adult pattern of CGRP-LI is completed prior to the birth of the rat.

CALCITONIN GENE-RELATED PEPTIDE AND GALANIN IMMUNOREACTIVITY IN NERVES OF THE RAT UTERUS: LOCALIZATION, CO-LOCALIZATION AND EFFECTS ON UTERINE CONTRACTION. R.L. Shew and R.E. Papka, Department of Anatomical Sciences, University of Oklahoma, Health Sciences Center, Oklahoma City, OK 73190.

Immunoreactivity to the neuropeptides galanin (GAL) and calcitonin gene-related peptide (CGRP) were examined in nerves in the rat uterus as a prelude to studying their effects on uterine contractility. GAL-immunoreactivity (GAL-I) and CGRP-I were localized in myometrial nerves throughout the uterine horns. CGRP-I nerves were the most prevalent. Double labeling revealed GAL- and CGRP-I co-exist in a sub-population of uterine nerve fibers; e.g. GAL-I was not present in all CGRP-I nerves. Effects of these neuropeptides on uterine contractility was examined *in vitro* on uterine horns from diethylstilbestrol-treated rats (50 µg/rat, i.p., 14-16 hours prior to the study). GAL (10⁻⁶ to 10⁻⁸ M) stimulated uterine contraction in a dose-related manner, while CGRP had no effect on baseline uterine tension. However, CGRP (10⁻⁷ M) reduced GAL-stimulated (10⁻⁷ M) uterine contraction by 92.5%. These results demonstrate that GAL- and CGRP-I are present in, and co-exist in some, uterine nerves, presumably afferent nerves. Both GAL and CGRP could be released from the afferent fibers in an "efferent" fashion and affect uterine contractility; GAL having a contractile effect and CGRP having a relaxing effect. (Supported in part by NIH grant NS 22526 and Presbyterian Health Foundation).

386.9

SPROUTING OF CALCITONIN GENE-RELATED PEPTIDE-LIKE IMMUNOREACTIVE (CGRP-LI) NERVES IN RAT CORNEAS FOLLOWING NEONATAL ADMINISTRATION OF CAPSAICIN (CAP). C.E. Marfurt and M.A. Jones. Northwest Center for Medical Education, Indiana University School of Medicine, Gary, IN 46408.

Trigeminal sensory nerve fibers exert important trophic effects on the corneal epithelium, perhaps by releasing axonally transported neuropeptides. In the present study, we investigated the initial loss, and subsequent return, of corneal CGRP-LI nerve fibers following neonatal CAP administration, and the relationship between these changes and the development of neuropathic keratitis. Seventy-five newborn rats were given CAP (50mg/kg, i.p.) on each of the first 3 days of life. CGRP-LI corneal nerves began to degenerate within 1 hour of CAP administration and disappeared totally by 36 hours. Over the next 3-4 weeks, a dramatic reinnervation of the cornea took place and by 6-8 weeks the CGRP-LI innervation density approached, and occasionally exceeded, that of age-matched control corneas. However, the morphology and pattern of CGRP-LI innervation was abnormal, and included numerous myelinated axons, a robust subepithelial plexus of filamentous, randomly oriented fibers, and occasional "hyperinnervation" of the epithelium by unusually large numbers of densely packed basal epithelial lashes. Retrograde transport of WGA-HRP from the central cornea in control and CAP-treated adult animals labeled 121 and 35 cells, respectively in the trigeminal ganglion, representing a cell loss of approximately 70% in the CAP animals. Chronic keratitis, often with extensive neovascularization, developed in all of the CAP treated animals by approximately 3 weeks, reached a maximum between 4-6 weeks, and showed gradual improvement thereafter. However, the keratitis never completely disappeared, even after 15 months. In conclusion, these data show that CGRP-LI, CAP-resistant corneal nerve fibers undergo extensive sprouting following subtotal corneal sensory denervation. However, the resultant reinnervation is morphologically altered and, for reasons unknown, functionally incapable of preventing or totally reversing the keratitis. This research was supported by NIH grant EY05717 to C.F.M.

CO-LOCALIZATION OF CGRP AND GALANIN IN THE TROCHLEAR NUCLEUS OF THE CAT. Wang, X.H.¹, Iannuzzi, P.¹, Baker, R.² and Murphy, E.H.¹ ¹Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA, 19129, and ²Department of Physiology and Biophysics, NYU Medical Center, New York, 10016.

The neuropeptides, Calcitonin Gene Related Peptide (CGRP) and Galanin (GAL), are expressed in spinal and brainstem motoneurons. In hypoglossal and facial motoneurons, CGRP and GAL are expressed in separate populations of neurons (Moore 1989). In order to determine the generality of this observation for all brainstem motoneurons, we have examined the distribution of CGRP and GAL in trochlear motor neurons (TMNs) in the adult cat. In order to intensify the visualization of the peptides we pretreated the cats with colchicine. CGRP and GAL were visualized by using immunocytochemical methods on adjacent sections. The percentage of CGRP+ and GAL+ neurons was determined by counting the number of CGRP+ or GAL+ neurons and comparing this number to the total number of neurons counted in adjacent Nissl stained sections. Approximately 90% of TMNs showed CGRP immunoreactivity and 30% of TMNs showed GAL immunoreactivity. Comparing the distributions of these two neuropeptides, we conclude that there is a small population of motor neurons in the cat trochlear nucleus in which CGRP and GAL are co-localized. The immunoreactivity of both CGRP+ and GAL+ motoneurons is increased following axotomy (Wang et 1990, Moore 1989). Although the function of these peptides is not fully understood, they may play a role in modulating the action of both normal and axotomized cholinergic motoneurons. Supported by NS24707 to EHM and EY20007 to RGB.

CHANGES IN BRAINSTEM CGRP AFTER SEVENTH AND EIGHTH NERVE LESIONS. K.W. Brewer¹, A.M. Thompson^{1,2}, K.R. Moore¹, J.M. Byers¹, C.D. Ross¹, and Q.C. Thompson^{1,2}. Depts. of ¹Otorhinolaryngology and ²Anatomical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

Cranial nerve motor nuclei contain moderate amounts of the neuropeptide, calcitonin gene-related peptide (CGRP). Previous studies suggest that CGRP may serve as a neuromodulator of CNS events following peripheral nerve transection. The present study investigated the effect of seventh and eighth cranial nerve lesions on the presence of CGRP in brainstem. To examine this relationship, guinea pigs were anesthetized and subjected to unilateral cochlear removal, vestibular end organ ablation, and seventh nerve transection. They were then allowed to survive 1-5 days before intracardial perfusion. Formalin-fixed cryostat sections were collected through the brainstem and incubated in rabbit anti-CGRP (Amersham) with the Vectastain ABC kit and protocol.

Cranial nuclei including vagus (X), glossopharyngeal (IX), facial (VII), abducens (VI), trigeminal (V), trochlear (IV), and oculomotor (III) and olivocochlear (auditory VIII) and vestibular (vestibular VIII) efferents were analyzed for side to side differences. Motor nuclei III, VI, and VII were significantly different with increased CGRP staining on the side ipsilateral to the lesion in VI and VII and contralateral to the lesion in III.

Since no peripheral damage occurred to any structure other than those related to the VII and VIII nerves, the changes observed in motor nuclei III and VI may be related to the underlying processes causing eye nystagmus secondary to VIIIth nerve ablation. Greater staining motor nuclei in VI ipsilateral and III contralateral to the lesion is consistent with an eye movement having a slow phase velocity toward the side of the lesion.

CALCITONIN GENE-RELATED PEPTIDE DEPLETION IN SENSORY NERVE AND GANGLIA OF DIABETIC BB-RATS. L.C. Russell^{1,2}, X.M. Dong^{*2}, R.P. Lee¹, M. Byers³ and K.J. Burchiel⁴. ¹Veterans Affairs Med. Ctr. and ²Dept. of Neurological Surgery, ³Dept. of Anesthesiology and Biological Structure, University of Washington, Seattle, WA 98195, and ⁴Oregon Health Sciences Univ., Portland OR. Immunocytochemical studies of skin biopsies from diabetic patients have revealed calcitonin gene-related peptide (CGRP) depletion in peripheral C-fibers (Levy, D.M. et al., 1989). Therefore we studied the distribution of CGRP immunoreactivity (CGRP-I) in sensory peripheral nerve and dorsal root ganglia in the spontaneously diabetic BB Wistar rat. Saphenous nerve and L5 and L6 dorsal root ganglia were obtained from diabetic BB rats which had been maintained hyperglycemic for 9 or 12 months, or nondiabetic littermates. Samples were then prepared for routine immunocytochemistry. CGRP-I was detected in saphenous nerve from control rats but not in nerve from rats which had been diabetic either 9 or 12 months. CGRP-I was also detected in approximately 50% of the DRG cells from both control and 9 month diabetic rats, but was not found in DRG from rats which had been hyperglycemic for 12 months. These findings indicate that axonal CGRP depletion precedes this peptide's depletion from sensory ganglia in the sequelae of diabetic polyneuropathy.

386.12

EFFECT OF SELECTIVE DEAFFERENTATION OF CONVERGENT INPUTS ON TRIGEMINAL CGRP DISTRIBUTION. C.A. Schwab^{*}, J.D. Stover^{*}, K.D. Hoffmann^{*} and M.A. Matthews. Depts. of Anatomy and Oral and Maxillofacial Surgery, LSU Medical Center, New Orleans, LA 70119.

Combinations of lesions designed to interrupt trigeminal and/or cervical inputs to the cat's spinal trigeminal nucleus reveal extensive overlapping fiber degeneration in the spinal tract together with distinctive changes in the immunocytochemical labeling pattern of calcitonin gene-related peptide at 11, 30, 45 and 60 days following surgery.

CGRP-containing cervical inputs to the subnucleus caudalis were shown by cervical tractotomy to be most prominent in the dorsomedial and ventrolateral portion of the caudal and middle 1/3 of the subnucleus whereas lesions of trigeminal inputs revealed that CGRP-containing trigeminal inputs predominate in the dorsolateral and lateral portions of the rostral and middle 2/3 of the subnucleus. Combined trigeminal and cervical tractotomies showed that CGRP inputs to the dorsomedial portion of the middle 1/3 of the subnucleus are least disturbed by the lesions used in this study. This is an area in which concentrations of convergent nociceptive inputs have been demonstrated previously using electrophysiological methods.

It is concluded that the anatomical divergence of cervical primary afferents from their point of entry into the CNS with an overlap onto trigeminal nuclei may provide a substrate for pathological alterations in receptive field size and spontaneous hyperactivity seen with clinical pain syndromes.

GALANIN IMMUNOREACTIVITY IN THE MONKEY AND HUMAN BRAIN H.K. Le^{*}, C. Anderson, E.J. Mufson, and J. H. Kordower, Department of Anatomy & Cell Biology, Univ. Illinois School of Medicine., Department of Neurological Sciences., Rush Presbyterian Medical Center., Chicago Ill. 60612 USA

Galanin-immunoreactivity (GAL-ir) was examined throughout the brain and spinal cord of Cebus monkeys, baboons and humans. In nonhuman primates, GAL-ir perikarya were observed within the basal forebrain. A dense continuum of neurons and processes were found extending from the bed nucleus of stria terminalis, through the substantia innominata, to the ventral portion of the bed nucleus. Small GAL-ir neurons were also seen within the caudate and putamen. In the diencephalon, GAL-ir neurons were also seen within the suprachiasmatic, periventricular, paraventricular, and arcuate nuclei as well as the lateral hypothalamic area. In the brain stem, GAL-ir cell bodies were seen within the mesencephalic nucleus of the trigeminal nerve (V), nucleus of the solitary tract and hypoglossal nucleus. Fibers were observed within the nucleus of the descending tract of V extending caudally to include its spinal cord analog within the substantia gelatinosa. GAL-ir were also seen within spinal cord anterior horn cells. GAL-ir differs between monkeys and humans within the basal forebrain (Kordower and Mufson, *J. Comp. Neurol.* 294: 281-292, 1990). Another dramatic difference in GAL-ir between these species is the observation that numerous GAL-ir neurons are seen in the human supraoptic nucleus while monkeys only display a dense fiber plexus in this region. We are presently investigating further the scope of GAL-ir species differences between monkeys and humans.

386.15

DISTRIBUTION OF GALANIN-LIKE IMMUNOREACTIVITY IN THE ADULT AND DEVELOPING BRAZILIAN OPOSSUM BRAIN. J.K. Elmquist, C.A. Fox, and C.D. Jacobson. Department of Veterinary Anatomy, Iowa State University, Ames, IA 50011.

We have studied the anatomical distribution of galanin immunoreactive (GAL IR) cell bodies and fibers in the brain of the adult and developing Brazilian short-tailed opossum, *Monodelphis domestica*. *Monodelphis* is a marsupial whose young are born in a very immature, accessible state making it an ideal model to study development of the brain. Galanin polyclonal antibodies obtained from CRB and Peninsula were utilized in an indirect immunohistochemical technique to identify GAL IR structures in intact animals. Somata containing GAL IR were seen in the hypothalamus and brainstem while fibers were seen in the hypothalamus, thalamus, midbrain, and brainstem in the adult brain. Specifically, GAL IR cell bodies were consistently seen in the bed nucleus of the stria terminalis, medial preoptic area, and arcuate, dorsomedial, paraventricular, periventricular, and supraoptic hypothalamic nuclei. In the brainstem somata were seen in the nucleus of the solitary tract. Dense collections of GAL IR fibers were seen in the median eminence and the above areas. In the developing brain, GAL IR somata and fibers were seen as early as day 1 postnatal (PN). By days 5 and 10 PN there was a robust expression of GAL IR fibers and cell bodies in specific regions of the brain. These results indicate that galanin is present and may play a role during development of the brain.

386.17

PREFERENTIAL LOCALIZATION OF A GALANIN-LIKE PEPTIDE IN AUTONOMIC CELL BODIES OF FROG CNS. S.M. Henry, D. Peruzzi and C.J. Forehand. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Galanin is a biologically active neuropeptide with a widespread distribution in the nervous system of a variety of species. In amphibians, galanin-like immunoreactivity (gal-IR) is prominent in peripheral autonomic neurons (McKeon et al., *Cell Tiss. Res.* 262:461, '90; Morris et al., *Neurosci. Lett.* 102:142, '89); however, its localization in amphibian CNS is unknown. We have examined the distribution of galanin in frog CNS by fluorescence immunohistochemical staining.

Cell body staining was noted in several autonomic regions of the CNS. Labeled somata were observed in the hypothalamus in the preoptic nucleus, paraventricular nucleus and the tuberal region. Cells containing a galanin-like peptide were also observed in an area medial to the solitary tract and in a subpopulation of sympathetic preganglionic neurons. Galanin positive fiber systems were abundant throughout the tegmentum of the brain stem, but were not seen in the cerebellum and were sparsely present in the tectum.

All somata that demonstrated gal-IR were localized in regions involved in control of autonomic function. Thus, galanin may be a neuromodulator in this system in frogs. Colocalization studies are underway to further characterize the role of this neuropeptide in frog CNS.

386.19

TRIGEMINAL TRACTOTOMY DOES NOT ALTER CCK LEVELS, BUT DOES ALTER CCK, GASTRIN, CGRP AND SP IMMUNOSTAINING, IN NORMAL AND NEONATALLY DEAFFERENTED ADULT MEDULLARY DORSAL HORN. M.C. Beinfeld, D.S. Zahm, N.L. Chiaia, & M.F. Jacquin. *Pharm. & Physiol., Anat. & Neurobiol.*, St. Louis Univ., MO 63104; *Anatomy, Med. Coll. Ohio, Toledo, Ohio* 43699.

Recent in situ hybridization studies have questioned the primary afferent origin of dorsal horn CCK. CCK8-specific radioimmunoassay (RIA) and immunohistochemical (IHC) methods were used 4-10 days following left trigeminal tractotomy at the obex to test the hypothesis that medullary dorsal horn CCK arises from higher-order neurons. Caudal to the lesion, RIA of punches from superficial laminae in 9 rats revealed a 15% decrease in CCK (L vs R: 1.04 ± 0.73 vs 1.22 ± 1.14 ng/mg; $p > .05$); IHC revealed modest reductions in CCK, Gastrin, and SP terminals (N=5). CGRP terminal staining was virtually eliminated. CCK labeling in inner lamina II was unaffected. Only Gastrin (courtesy of Dr. J. Walsh) labeled dorsal horn cells (inner lamina II) and their numbers were reduced. Rostral to the lesion, IHC staining did not reveal axotomy-induced sprouting. In 16 other adults with left infraorbital nerve cut at birth, similar lesion and RIA methods revealed a 20% increase in CCK caudal to the tractotomy (L vs R: 2.74 ± 1.93 vs 2.29 ± 1.62 ng/mg; $p > .05$); in 4 others processed for IHC, peptide staining was reduced as in the tractotomy-alone cases. These data suggest that 1) most CCK in medullary dorsal horn is of higher-order origin, 2) neonatal deafferentation-induced increases in medullary CCK (Beinfeld et al., *Neurosci. Abstr.* 16, '90) reflect reorganization of higher-order inputs, and 3) higher-order SP inputs to medullary dorsal horn are robust. Support: NIH DE07734, DE07662, NS18667, NS23805, DE08971.

386.16

GALANIN-LIKE IMMUNOREACTIVITY OCCURS IN RAT VAGAL SENSORY NEURONS. N. Calingasan and S. Ritter. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Galanin (GAL), a 29 amino acid peptide originally isolated from the porcine upper small intestine, is widely distributed in the rat central nervous system, including the nucleus of the solitary tract (NTS). Although vagal sensory neurons terminate in the NTS, it is not known whether these neurons contain GAL in the rat. Therefore, we attempted to determine the presence of GAL in the sensory neurons of the vagus nerve. We employed avidin-biotin-peroxidase immunocytochemistry using an antiserum raised in rabbits against synthetic GAL and preadsorbed controls to study the occurrence and distribution of GAL in colchicine-treated nodose ganglia of adult rats. GAL-like immunoreactive cell bodies were observed in nodose ganglia, possibly comprising about 10 - 15% of the total ganglion cell population. They were unevenly scattered, but were concentrated mostly in the rostral pole. Nodose ganglionectomy reduced GAL immunostaining in certain regions of the ipsilateral NTS but this observation was not conclusive. These findings demonstrate that GAL may serve as a neurotransmitter in rat vagal sensory neurons.

COLOCALIZATION OF GALANIN AND VASOPRESSIN mRNA IN THE MEDIAL AMYGDALA OF THE RAT. M.A. Miller, P.E. Kolb*, M.A. Raskind. Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195.

Galanin (GAL) and vasopressin (VP) have previously been colocalized in magnocellular neurons of the supraoptic (SON) and paraventricular (PVN) nuclei by both immunocytochemical and in situ hybridization techniques. Here we provide the first evidence for the colocalization of GAL and VP mRNAs in the steroid sensitive VP cells of the medial amygdala (AMe). Coronal brain sections (20 μ m) through the AMe were double labeled for VP and GAL mRNAs using RNA probes labeled with digoxigenin-UTP (VP) and 35 S-UTP (GAL). Radioactive grains were detected over VP cells in the AMe indicating the presence of GAL gene expression. To avoid artifacts induced in darkfield by the digoxigenin color reagent, grains were visualized using reflected-light polarization. Double-labeling of AMe cells was determined to be specific since 1) radio-labeled cells were detected in the same region of the AMe in slides assayed for GAL only 2) digoxigenin labeled VP cells in other brain regions (SCN and parts of the PVN) did not appear to contain grains and 3) distributions of mRNAs for GAL and VP were the same as has been reported previously. The observation that VP and GAL are coexpressed in the AMe permits studies on the coregulation of these peptides under various physiological conditions.

386.20

ORIGIN OF THE CHOLECYSTOKININ (CCK) IMMUNOREACTIVE (ir) TERMINALS IN THE RAT THALAMIC RETICULAR NUCLEUS (RTN). G. Battaglia, S. De Biasi*, A. Amadeo* and C. Frassoni*. Neurological Institute "C. Besta", Milano, Italy; *Dept. of Physiology and Biochemistry, Univ. of Milano, Italy.

Recent immunocytochemical studies reveal that the rat RTN is densely innervated by CCKir fibers. The origin of these afferents has been investigated in the present study by means of light and EM immunocytochemistry, combined with the retrograde transport of WGApoHRP-gold. Small CCKir terminals contact both distal and proximal dendrites, and also cell bodies, throughout the entire rostrocaudal extent of RTN. CCKir neurons are present in different brain areas known to project to the thalamus. Some pyramidal or multipolar neurons are CCKir in layer V and VI of the cerebral cortex. CCKir neurons are also present in the cholinergic mesopontine tegmental nuclei (PPTg and LDTg), and in the amygdaloid complex, particularly in the dorsal division of the medial amygdaloid nucleus (MePD). Tracing experiments reveal the presence of double-labeled CCKir neurons in PPTg and MePD, after WGApoHRP-gold injection in RTN. The present experiments suggest that different brain areas give origin to the CCKir terminals in RTN. Further experiments are in progress to evaluate the contribution by each of these areas to the CCK innervation of RTN.

386.21

ONTOGENY OF CHOLECYSTOKININ-LIKE IMMUNOREACTIVITY IN THE BRAZILIAN SHORT-TAILED OPOSSUM BRAIN. C. A. Fox, M. M. Jeyapalan* and C. D. Jacobson. Department of Veterinary Anatomy, Iowa State University, Ames, IA 50011.

We have studied the anatomical distribution of cholecystokinin immunoreactive (CCK IR) somata and fibers in the brain of the adult and developing Brazilian short-tailed opossum, *Monodelphis domestica*. A nickel enhanced, avidin-biotin, indirect immunohistochemical technique was used to identify CCK IR structures. Cholecystokinin immunoreactive cell bodies were located throughout the cerebral cortex and hippocampus of adult opossums. Somata containing CCK immunoreactivity were also observed in the hypothalamus, thalamus, midbrain, and brainstem. Cholecystokinin immunoreactive fibers had a wide distribution in the adult *Monodelphis* brain. The earliest expression of CCK immunoreactivity was found in fibers in the dorsal brainstem of 5 day old opossum pups. Cholecystokinin immunoreactive somata were observed in the brainstem on day 10 of postnatal life (10PN). Most regions of the hypothalamus did not contain CCK IR until 35PN. An exception to this was the medial preoptic area (MPA). The male MPA had CCK IR cells and fibers on 25PN. However, the female MPA did not contain significant CCK IR elements until the 60PN time point. A broad spectrum of patterns of onset of CCK expression was observed in the opossum brain. The early occurrence, wide distribution, and varied ontogenesis of CCK IR structures indicates CCK may be involved in several different functions in the adult and developing opossum brain.

PEPTIDES: ANATOMICAL LOCALIZATION III

387.1

NEUROPEPTIDE-Y IMMUNOREACTIVITY IN THE BRAIN OF THE FROG RANA PIPIENS. C.J. Tyler, K.V. Fife, and G.J. DeVries. Neuroscience and Behavior Program, Univ. Of Massachusetts, Amherst, MA 01003

Immunocytochemistry was used to characterize the presence of neuropeptide Y (NPY) in the frog brain, placing emphasis on the assessment of NPY in primary retinal terminal fields and thalamic nuclear groups postsynaptic to primary retinal terminal zones.

Preliminary observations revealed the presence of NPY-like immunoreactive perikarya in tectal layer 4, ventral portion of tectal layer 6, anterior portions of posterocentral and posterolateral nuclei, suprachiasmatic nucleus (SCN), and anterior portion of the ventromedial thalamic nucleus. In addition, labelled perikarya were located in the glossopharyngeal nerve motor nucleus, nucleus cerebelli, nucleus of the medial longitudinal fasciculus, the ventral, dorsal, and lateral hypothalamic nuclei, and the medial, dorsal, and lateral pallidum. The hypothalamic nuclei contained the largest population of labelled cells while the SCN contained cells with the most intense perikaryal labelling.

Although most areas of the brain contained light, homogeneous immunoreactive (IR) puncta accompanied by scattered IR fibers, certain areas were markedly different in NPY fiber and puncta labelling. While both divisions of the optic tract were relatively devoid of immunoreactivity, tectal layers 3 and 5, the ventral third and dorsal margin of tectal layer 6, and the dorsal portion of tectal layer 9 displayed dense IR puncta. Both immuno-negative nucleus isthmi and rostral visual nucleus were offset by their dense puncta-labelled surrounds. The SCN and the anterior thalamic nucleus contained a denser concentration of puncta and fibers. While both the nucleus and neuropil of Bellonci appeared to be relatively immuno-negative, the Corpus geniculatum contained IR puncta only within its central core. Intense fiber and puncta labelling in the medial and lateral amygdala, accessory olfactory tract, and lateral forebrain bundle, separated these structures from other forebrain areas. (Supported by NSF Grant BNS 8619670 to K.V.F.)

387.3

NEUROPEPTIDE Y IMMUNOCYTOCHEMICAL EXPRESSION IN HUMAN NEOCORTEX. W.E. Kaufmann and N.A. Cuello*. Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Neuropeptide Y is the most abundant neuropeptide in human cortex and is expressed by intrinsic (nonpyramidal) neurons. Its distribution in some cortical areas and its changes in degenerative diseases have become a recent focus of interest. Studies of monkeys suggest differences in distribution between primary sensory and association neocortices. Therefore, we studied the neuropeptide Y cell body and axonal immunoreactivity in six normative subjects (control individuals for Alzheimer's disease), comparing different association cortical areas with primary somatosensory, visual, and motor regions. The relative distribution of elements was analyzed in each individual. Associational areas showed a more profuse and randomly oriented fiber pattern, particularly prefrontal cortex, as well as neurons with a complex dendritic tree. In contrast, primary regions exhibited a rather laminar axonal arrangement and simplified cells. It seems that cortical areas involved in cognitive functions have a richer neuropeptide Y network than those processing sensory information.

387.2

DISTRIBUTION OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVE PERIKARYA IN THE FELINE HYPOTHALAMUS AND FOREBRAIN. V.J. Massari, Y. Tizabi, Z.Z. Song*, H. M. Rhee#, & P. J. Gatti. Dept. of Pharmacology, Howard University, College of Medicine, Washington, D.C. 20059, and #Food & Drug Administration, Rockville, MD. 27457

Neuropeptide Y (NPY) is considered to be a neurotransmitter candidate in the central nervous system. Hypothalamic NPY may be involved in the regulation of the hypothalamo-pituitary-adrenal axis through regulation of the secretion of ACTH. NPY is also believed to influence other hypothalamic functions such as reproduction, feeding, and control of fluid homeostasis. We have therefore examined the distribution of NPY-like immunoreactivity (NPY-LI) in the cat hypothalamus and forebrain. Four adult male mongrel cats were anesthetized with 50mg/kg pentobarbital and perfused with 2 liters of phosphate buffered saline (PBS) and 3 liters of 4% paraformaldehyde in PBS. Frozen sections (50µ) were cut in a cryostat and processed using an avidin-biotin based immunoperoxidase method. The largest number of NPY-LI cells in the hypothalamus were observed in the arcuate nucleus. NPY-LI cells were also seen in the lateral hypothalamic area, paraventricular nucleus, suprachiasmatic nucleus, and anterior hypothalamic nucleus. NPY-LI cells were also observed in the cerebral cortex, caudate nucleus, putamen, claustrum, olfactory tubercle, bed nucleus of the stria terminalis, nucleus of the anterior commissure, nucleus accumbens, amygdala, dentate gyrus, and several thalamic nuclei. These data indicate that NPY-LI cells have a wider distribution in the feline hypothalamus and forebrain than was previously suggested. Supported by The American Heart Association

SOMATOSTATIN AND NEUROPEPTIDE Y ARE COLOCALIZED BUT NOT COEXTENSIVE WITHIN THE RAT CAUDATE-PUTAMEN. C.C.G. Naus, W.J. Rushlow and B.A. Flumerfelt. Department of Anatomy, University of Western Ontario, London, Canada N6A 5C1.

It has been reported previously that somatostatin (SS) and neuropeptide Y (NPY) are colocalized in the rat striatum within neurons of the medium-sized aspiny category. Experiments involving the selective lesioning of glutamatergic and dopaminergic inputs, however, yield conflicting results with respect to both mRNA and protein expression. Furthermore, topographical data for NPY and SS neurons conflict with respect to the medial to lateral gradient described for SS. This suggests that although both neuroactive substances may be colocalized they are not coextensive. In order to investigate this possibility, the striatum of five adult female Wistar rats (260-280g) were sectioned at 40 µm on the freezing microtome. NPY (Incstar) was then localized immunocytochemically and visualized by the ABC-peroxidase technique using 3,3'-diaminobenzidine (DAB) as the chromogen. *In situ* hybridization was then carried out on the immunostained sections using an [³⁵S]-labelled anti-sense riboprobe for somatostatin. The hybridization signal was detected using autoradiography. Examination of the sections revealed that a large proportion of the neurons labelled immunocytochemically for NPY were also positive for SS mRNA. However, a significant proportion of neurons containing SS mRNA did not display detectable NPY immunoreactivity. The mismatch between *in situ* signal and immunocytochemically labelled neurons could be seen throughout the striatum but was most concentrated in the ventral and central caudate-putamen. These results suggest that although SS and NPY are frequently colocalized within the neostriatum they are not coextensive.

ALL SOMATOSTATIN INTERNEURONS IN THE RAT CAUDATE-PUTAMEN CONTAIN SOMATOSTATIN-28 BUT NOT ALL CONTAIN SOMATOSTATIN-14. W.J. Rushlow, C.C.G. Naus and B.A. Flumerfelt. Department of Anatomy, University of Western Ontario, London, Canada N6A 5C1.

In the rat striatum, both somatostatin-28 (SS28) and somatostatin-14 (SS14) are found within neurons of the medium-sized aspiny category. SS28 is likely produced within these cells by the cleavage of prosomatostatin at an Arg site while SS14 is obtained by cleavage of SS28 at an Arg-Lys dibasic site (Benoit R., *Metabolism* 39(9) suppl.2: 30-32, 1990). The difference in the type of cleavage sites between the two forms of somatostatin raises the possibility that two different subpopulations of these neurons may exist. In order to investigate this possibility, the striatum of five adult female Wistar rats (260-280g) were sectioned at 40µm on the freezing microtome. SS14 and SS28 were then localized immunocytochemically on alternate sections using antisera S310 or S309 respectively (kindly provided by Dr. R. Benoit) and visualized by the ABC-peroxidase technique using 3,3'-diaminobenzidine tetrahydrochloride as the chromogen. *In situ* hybridization was carried out on the immunostained sections using an [³⁵S]-labelled anti-sense riboprobe for somatostatin. The hybridization signal was detected using autoradiography. For the SS28 immunostained sections, the positive grain densities were all localized to immunostained neurons. In the SS14 immunostained sections, however, a significant proportion of the grain clusters were found overlying neurons where no reaction product was present. Further investigation revealed that the SS14 deficient region is most pronounced in a wide medial to lateral band in the dorsal caudate-putamen (just beneath the corpus callosum) and the medial aspect of the striatum (dorsal to ventral adjacent to lateral ventricle). These results suggest that two subpopulations of somatostatin neurons exist within the striatum; one containing only SS28, and one containing both SS14 and SS28 (the precursor of SS14). Supported by NSERC (C.C.G.N.) and MRC (B.A.F.).

VASOPRESSIN AND CRF IMMUNOSTAINING FOLLOWING ADRENALECTOMY IN SYRIAN HAMSTER HYPOTHALAMUS. S.N. Del Paine and R.L. Meisel. Dept. of Psychological Sciences, Purdue University, West Lafayette, IN 47907.

In a continuing effort to determine why compensatory growth following unilateral adrenalectomy is lacking in hamsters, we examined the roles of vasopressin (VP) and CRF in pituitary-adrenal regulation. Immunocytochemistry for VP and CRF was conducted in alternate 50 µm sections through the PVN using primary antibodies to arg-VP and oCRF and a peroxidase-based Vector ABC kit. Immunostaining was qualitatively and quantitatively assessed in female Syrian hamsters that were either intact, bilaterally (5 days), or unilaterally (5 days) adrenalectomized. Preliminary results indicated a wide distribution of intense VP immunostaining regardless of treatment. The most salient VP fiber and cell body staining was observed throughout all levels of the PVN and supraoptic nucleus as well as in the suprachiasmatic, retrochiasmatic, nucleus circularis, lateral and anterior hypothalamic areas. In addition, both bilateral and unilateral adrenalectomy appeared to increase the number of VP immunostaining PVN neurons as compared to intact controls. Furthermore, bilateral adrenalectomy appeared to change the distribution of the VP-immunostained neurons in the PVN, possibly by increasing the number of parvocellular VP-stained neurons. Virtually no staining of CRF neurons was observed in intact and unilateral adrenalectomized hamsters, whereas CRF was observed in PVN neurons following bilateral adrenalectomy. Bilateral, but not unilateral, adrenalectomy appears to be a potent trigger for ACTH secretagogues in the Syrian hamster hypothalamus.

VASOACTIVE INTESTINAL PEPTIDE (VIP)- AND NEUROPEPTIDE Y (NPY)-LIKE IMMUNOREACTIVITY (IR) IN NORMAL AND SYMPATHETICALLY DENERVATED RAT PINEAL GLAND. S.J. Piszczkiewicz, C. Baldwin and R.E. Zigmond. Dept. of Neurosciences, Case Western Reserve Univ., School of Medicine, Cleveland, OH 44106.

The rat pineal gland is innervated primarily by the superior cervical ganglia (SCG). This innervation drives the diurnal rhythm of pineal melatonin production by regulating serotonin N-acetyltransferase (NAT) activity. Either bilateral transection of the post-ganglionic axons in the internal carotid nerve (ICNX) or removal of the ganglia (SCGX) abolishes this rhythm. While norepinephrine (NE) release appears to be mainly responsible for the increase in NAT activity, other transmitters, such as VIP, may also be involved. VIP-IR, found in nerve fibers in the pineal, has been proposed to originate, at least in part, from VIPergic neurons in the SCG (*Soc. Neuro. Abstr.* 15:836). VIP stimulates NAT activity *in vivo* in gerbil pineals and in cultured rat pinealocytes. Thus, VIP originating in the SCG may be released in the pineal and act synergistically with NE to increase NAT activity.

To examine the origin of the VIPergic input to the gland, pineals were removed and assayed for VIP- and NPY-IR by radioimmunoassay 48 hr post-ICNX. NPY is present in nerve fibers in the pineal and is known to disappear from the pineal following SCGX. The NPY-IR was reduced in the ICNX groups to 11% of the control or sham-operated groups. No significant differences in VIP-IR were found among any of the groups, although there was a large variability (about 25%) within each group. The identity of the 2 peptides in the pineal extracts were authenticated by HPLC. Additionally, bilateral SCGX were performed and the pineals removed 1-6 weeks later and examined immunohistochemically. The density of VIP-IR fibers was highly variable with no apparent difference in pineals from both control and SCGX animals. These data suggest that VIP innervation to the rat pineal gland is variable and does not originate to a significant extent from the SCG. Therefore, the origin of VIP fibers in the pineal, the control of its release *in vivo*, and verification of its role in the *in vivo* regulation of NAT remain to be elucidated. SOMATOSTATIN-IMMUNOREACTIVITY IN THE HIPPOCAMPUS OF MOUSE, RAT, GUINEA PIG, AND RABBIT. P.S. Buckmaster¹, D.D. Kunkel², M.E. Gross² and P.A. Schwartzkroin^{1,2}. Depts. of ¹Physiology & Biophysics, and ²Neurological Surgery, Univ. of Washington, Seattle, WA 98195.

We have examined the somatostatin-immunoreactivity of hippocampi of animals commonly used for electrophysiological studies to determine if there are regional or species-specific variations. Animals (adult female) were deeply anesthetized (100 mg/kg pentobarbital IP) and perfused with fixative. After cryoprotection, hippocampi were removed, slightly flattened, and sectioned at 40 µ perpendicular to the septo-temporal axis. Sections from 5 evenly spaced regions along the septo-temporal axis were processed with an antibody against part of the precursor molecule of somatostatin (SS320, kindly provided by Dr. R. Benoit) and the ABC method. Sections from all regions and from all species were processed together to eliminate variations in immunostaining that occur between runs. The pattern of somatostatin-immunoreactivity is generally quite similar across the four species examined: 1) There are more somatostatin-positive somata and a denser fiber plexus in the ventral hippocampus; 2) The majority of the somatostatin-positive somata occur in the hilus of the dentate gyrus and in stratum oriens and alveus of CA1 and CA3; 3) There is a dense somatostatin-positive plexus in stratum lacunosum-moleculare of CA1. However, there are some interesting species variations: 1) Mice and rats have proportionally more somatostatin-immunoreactive neurons in stratum lucidum of CA3 than rabbit and guinea pig; 2) Rats, guinea pigs, and rabbits have a dense somatostatin-positive fiber plexus in the outer molecular layer of the dentate gyrus, but mice do not. The functional significance of these differences is unknown.

ABSENCE OF ADRENALECTOMY INDUCED ALTERATIONS IN CRF/VASOPRESSIN NEUROSECRETORY VESICLE MORPHOLOGY IN HOMOZYGOUS BRATTLEBORO RATS. J.Z. Kiss and L.T. Bertini*. Dpt. of Morphology, Univ. of Geneva, Sch. of Med., Geneva Switzerland.

Dense core vesicle /DCV/ provide a mechanism whereby neurohormones are packaged and secreted in discrete quanta. The regulation of the amount of neurohormones released may in part be controlled by vesicle size which in turn determines the number of molecules per quanta. We previously reported that hypophysiotropic corticotropin-releasing factor /CRF/ neurons are capable to alter the size of DCV after removal of glucocorticoid negative feedback by adrenalectomy /ADX/. ADX results in a progressive increase in the mean volume of DCV to about three times normal. Changes in size are accompanied by a substantial increase in immunoreactive sites for vasopressin /VP/ co-packaged with CRF in the same DCV compartment.

To determine as to whether changes in size of the DCV is simply due to elevated intravesicular concentrations of VP, we conducted a quantitative electron microscopic study to estimate the size distribution of CRF positive vesicles in adrenalectomized homozygous Brattleboro rats that lacks vasopressin. CRF immunoreactivity was present within a 95nm vesicle population in both homozygous and heterozygous /control/ rats. In heterozygous rats CRF was co-packaged with VP in the same DCV, and ADX induced a significant increase in the mean vesicle diameter. However, in homozygous rats the size distribution of CRF positive vesicles was not affected by ADX. These results are consistent with the hypothesis that the biosynthesis of neurosecretory material itself determines the quantal size of DCV.

VASOACTIVE INTESTINAL PEPTIDE IN PROLACTIN-DEFICIENT DWARF MOUSE PITUITARY. C.J. Phelps, D.L. Hurley, M.Y. Vaccarella* and A.J. Carrillo. Depts. of Anatomy, Tulane Univ. Sch. Med., New Orleans, LA 70112, and NEOUCOM, Rootstown, OH 44272.

Ames (df/df) dwarf mice manifest a spontaneous homozygous mutation in which prolactin (PRL) is not expressed. Since recent evidence supports a role for VIP as a PRL-stimulating factor, and a pituitary source for PRL-regulating VIP, it was of interest to examine whether pituitary VIP was altered in dwarfs. Immunoreactive VIP in df/df and normal (DF/?) littermate mouse pituitaries was investigated using ICC and RIA techniques, using the same VIP antiserum (Carrillo *et al.*, *ENDO* 128:131, 1991) in both assays. For ICC, paraffin-embedded sections of adult glands (both sexes) were incubated in a-VIP at 1:2000, developed using the ABC method, and visualized using either DAB with NiSO₄ or Texas red-labeled avidin. For additional PRL ICC, sections were incubated in a-mPRL (1:5000, A.F. Parlow) and visualized with DAB or fluorescein-labeled avidin, respectively. VIP immunostaining in both DF/? and df/df anterior pituitaries was diffuse, of low intensity, and widespread. VIP and PRL were in distinct cells in normal mice, and VIP was apparent in dwarf gland where PRL cells are absent. In posterior pituitary, staining suggestive of neural fibres was present and was particularly intense in dwarfs. For RIA measurement, neurointermediate (NIL) and anterior lobes were dissected and assayed separately, in supernatants of HCl-treated, boiled extracts. Anterior pituitaries averaged 391.3±86.2 pg VIP for normals and 6.8±1.6 pg VIP for dwarfs. NIL averaged 6.9±1.0 pg in normals and 7.6±3.83 pg in dwarfs. Taken together, the results suggest that VIP in the tiny dwarf mouse anterior pituitary is diminished relative to size, and that VIP localization and content in dwarf posterior pituitary is comparable to that of normal mice.

VASOACTIVE INTESTINAL PEPTIDE IN PROLACTIN-DEFICIENT DWARF MOUSE BRAIN: IMMUNOCYTOCHEMICAL AND RIA ASSESSMENT. H. Dalcik, D.L. Hurley, A.J. Carrillo, and C.L. Phelps, Depts. of Anatomy, Tulane Univ. Sch. Med., New Orleans, LA 70112, and NEOUCOM, Rootstown, OH 44272. Ames dwarf mice contain a recessive mutation which, in the homozygous condition (df/df), results in absence of pituitary prolactin (PRL). Previous studies have indicated that factors which inhibit GH or PRL secretion are absent in the brains of dwarf mice. Recent reports have documented the role of VIP as a PRL-stimulating factor. Thus, it was of interest to examine immunoreactive VIP in PRL-deficient df/df compared with normal (DF/?) littermate brain. For ICC, some mice were treated with ICV colchicine (30mg/ml) prior to sacrifice. Thirty μ m brain sections from perfused adults (both sexes) were processed using anti-VIP serum (1:3000, Incstar and Carrillo *et al.*, ENDO 128:131, 1991) and ABC technique (Vectastain), and visualized using DAB. For RIA measurement, blocks of neocortex, and of dorsal (including paraventricular nucleus, PVN) and basal (including median eminence) hypothalamus were dissected from 2 mm-thick coronal sections of fresh frozen brain, and were assayed in supernatants of HCl-treated, boiled extracts; protein levels were measured in precipitates. VIP-immunoreactive cell bodies were found primarily in neocortex, limbic system, pyriform and entorhinal cortex, and suprachiasmatic nuclei (SCN). Dense fiber patterns were observed in amygdala, bed nucleus of stria terminalis, and SCN. Upon colchicine treatment, additional VIP cell bodies were visualized, particularly in PVN and periventricular areas. Small numbers of fibers were present in hypothalamic internal median eminence, and vertical profiles of VIP immunoreactivity, suggestive of "tanyctic" cells, extended through the median eminence. Immunostaining with both antisera, in both sexes, and in df/df and DF/? brains was comparable. VIP levels averaged (pg/ μ g protein): cortex 11.2 \pm 1.3 (DF/?), 14.4 \pm 1.0 (df/df); dorsal hypothalamus 1.5 \pm 0.2 (DF/?), 1.6 \pm 0.3 (df/df); ventral hypothalamus 2.6 \pm 0.3 (DF/?), 4.0 \pm 1.0 (df/df). Taken together, the results indicate that VIP measured in the ventral hypothalamus appears not to be perikaryal, and that brain VIP localization and content is unaltered in PRL-deficient Ames dwarf mouse. Supported by NIH grant NS25987 (CJP) and Ohio Board of Regents (AJC)

IMAGE ANALYSIS OF VASOACTIVE INTESTINAL POLYPEPTIDE IMMUNOREACTIVE (VIP-IR) NEURONS IN THE MOUSE BARRELFIELD CORTEX K. Zilles, F. Hajós, A. Csillag, Mihaly Kálman, and Axel Schleicher, Dept. Anatomy, Univ. Köln, D-5000 Köln 41, F.R.G.

The radial orientation of VIP-IR dendrites in the rat visual cortex suggests, that VIP neurons may play a regulatory role in columnar cortical units (Magistretti and Morrison, *Neuroscience* 24: 367, 1988). However, Hajós *et al.* (*Anat. Embryol.* 178:197, 1988) demonstrated a distribution of VIP-IR boutons with no signs of a columnar organization. The present observation tests the hypothesis of a cortical-column associated function of VIP by immunohistochemistry in the barrelfield cortex of the mouse, a cortical area with an anatomically demonstrable columnar organization. Tangential sections were stained with a VIP-antiserum using avidin-biotin and DAB for visualization. A barrel-like distribution of the VIP-IR structures was found. In order to analyze quantitatively the distribution of VIP-IR boutons within single barrels, we have used a previously published image analyzing technique (Hajós *et al.*, *Anat. Embryol.* 176:207, 1988) for automatic measurement. The results demonstrate for the first time the columnar distribution of VIP-IR boutons. The highest density of boutons is found in the septum region of a barrel with a lower density in the periphery of the barrel core and the lowest density in the center of the core region. Since VIP-IR boutons are rarely found, where the highest density of synapses with the primary afferent fibers occurs (core), but most densely packed where the blood vessel density is maximal (septum), our results are in accordance with a presumed metabolic regulatory function of VIP in cortical columns. Supported by the DFG (ZI 192/6-3) and the Hung. Acad. Sci.

A STUDY OF GnRH NEURONS THAT PROJECT TO THE MEDIAL BASAL HYPOTHALAMUS IN THE MALE DJUNGARIAN HAMSTER. K.L. Buchanan, M.A. Kirby, S.M. Yellon. Div. Perinatal Biology, Depts. Anat., Physiol., and Peds., Loma Linda Univ., Sch. of Med., Loma Linda, CA 92350.

In the Djungarian hamster at the onset of puberty (15 to 20d of age), increased gonadotropin secretion suggests well established GnRH projections to the medial basal hypothalamus (MBH). As part of a developmental study to determine the distribution and morphology of GnRH neurons which terminate in the MBH, 15d males in long days (16L:8D; n=4) were intracardially perfused with 4% paraformaldehyde. Brains were removed and crystals of Dil, a fluorescent tract tracer, were implanted directly into the median eminence. After 8 weeks in phosphate buffer in the dark, brains were sectioned (60 μ m) and immunocytochemistry performed for GnRH (0.02% saponin for 0.5-1h prior to incubation with LRI antisera) using the fluorescent marker avidin-biotin. The majority of GnRH cells were found in the rostral forebrain, i.e., the medial preoptic area, diagonal band of Broca, and septal regions. Of these GnRH somata, 68% contained Dil indicating a projection to the MBH. Regions closer to the Dil implant site, the lateral preoptic area and rostral hypothalamus, had fewer GnRH cells labelled with Dil (26%). Morphologically, GnRH somata were bipolar or unipolar and present in a 2:1 ratio, respectively. Both subtypes were labelled with Dil in proportion to this ratio. Later in development, the brains from postpubertal 40d males (n=4) were processed as described above. Again, bipolar and unipolar GnRH cells were Dil labelled in a 2:1 ratio. However, compared to 15d males, fewer GnRH perikarya were labelled with Dil in all areas, e.g. rostral forebrain (34.1%), especially the medial preoptic area (40d: 13% vs 15d: 48%). These data suggest that the MBH is innervated primarily by rostral forebrain GnRH cell bodies, both bipolar and unipolar. Findings raise the possibility that GnRH neuronal projections involved in the control of gonadotropin secretion change with maturation. (NIH HD22479)

A LIGHT- (LM) AND ELECTRON-MICROSCOPIC (EM) STUDY OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) NEURONS IN A CIRCUVENTRICULAR ORGAN OF THE CHICK. W.M. Saidel, and W.J. Kuenzel. Dept. of Poultry Science, Univ. of Maryland, College Park, MD 20742.

The lateral septal organ (LSO) of the chick is composed of lateral and medial components. The lateral component is marked by a vascularized ependyma that is conspicuous with nissl staining. The ependyma of the medial component located adjacent to the lateral septal area includes approximately 1000 cerebrospinal-fluid (CSF) contacting neurons of about 12 μ m in diameter that immunostain for VIP. Both LM and EM analyses show that the VIP immunoreactive (VIPir) perikarya are situated directly beneath the ependymal cells. A typical CSF-contacting, VIPir-neuron extends a long, club-like neurite through the ependymal layer into the supraependymal region of the lateral ventricle. The club-like process is surrounded by cilia extending from ependymal cells. These neurons appear to project to the septal area where a dense VIPir neuropil is found. A third cell type with a distinctive shape and nuclear appearance is located in the LSO along the ependymal wall where VIPir cells are present. The function of these neurons is unknown. They may be encephalic photoreceptors (Silver *et al.*, *Cell Tissue Res.* (1988)253:189). Supported by USDA Grant #90-37240-5506.

MAMMALIAN FMRF-NH,-LIKE PEPTIDE, FLFPQRF-NH,, IN PERIPHERAL SYSTEM. H.-Y.T. Yang, E.A. Majafe and J.M. Zhu. Lab. of Biochem. Genetics, NIMH Neurosci. Ctr. @ St. Elizabeths, Wash. DC 20032

FLFPQRF-NH,, neuropeptide FF (NPFF) detected initially by the FMRF-NH, antiserum, was isolated from bovine brain. NPFF is widely distributed in CNS and accumulating evidence suggests that NPFF may function as an antipiate in the CNS. In the peripheral system, NPFF can increase blood pressure and inhibit insulin secretion from pancreas, however, whether there is NPFF in peripheral tissue is unknown. In this study, presence of NPFF in rat peripheral tissues including superior cervical ganglia, plasma, vas deferens, adrenal and pancreas was examined by HPLC coupled with NPFF RIA. NPFF was detected in plasma and superior cervical ganglia (0.10 \pm 0.011 pmol/mg prot.) but not in other tissues. Analysis of pancreatic extract revealed two major forms of NPFF immunoreactive peptides which were also reactive to FMRF-NH, antiserum but were not identical to NPFF or FMRF-NH,. Other investigators have found that FMRF-NH, (μ M) and NPFF (nM) can inhibit pancreatic insulin secretion. Whether pancreatic FMRF-NH,-like peptides have a similar inhibitory effect on insulin secretion remains to be determined.

NOVEL SITES OF MELANIN CONCENTRATING HORMONE mRNA AND PEPTIDE EXPRESSION IN LACTATING RATS. S. Knollema, W. Vale and P.E. Sawchenko. The Salk Institute, La Jolla, CA 92037 and *University of Groningen, The Netherlands.

The deduced structure of the rat melanin-concentrating hormone (MCH) precursor (*Endocrinology* 125:2056, 1989) predicted the existence of at least two peptides that may be processed from it, one similar to teleost MCH and a second novel neuropeptide, NEI. Cellular localization studies confirmed that prepro-MCH (ppMCH) mRNA and the MCH and NEI peptides are expressed predominantly in cells in the dorsolateral hypothalamic area with minor contingents seen in the olfactory tubercle and pons. A moderate MCH- and NEI-IR axonal projection to the median eminence and, particularly, to oxytocin-rich regions of the posterior pituitary suggested some anatomical heterogeneity of ppMCH-expressing neurons in the hypothalamus, and an involvement in neuroendocrine function. In the present study, immuno- and hybridization histochemical methods were used to follow MCH gene and peptide expression as a function of reproductive status in female rats. Nursing dams sacrificed after 6-21 days of lactation displayed ppMCH mRNA and MCH- and NEI-IR in rostral, oxytocin-rich aspects of the paraventricular nucleus of the hypothalamus, and in a discrete, ventromedial, aspect of the medial part of the medial preoptic nucleus. This apparent induction was not apparent in animals sacrificed 7 days after weaning, during late pregnancy, or at any point in the estrous cycle. No frank alterations in ppMCH mRNA were evident in the dorsolateral hypothalamus as a function of reproductive status. The loci and apparent state-dependency of the induction of MCH mRNA and peptide expression suggests a role for these gene products in the control of lactation.

IMMUNOHISTOCHEMICAL LOCALIZATION OF PANCREASTATIN IN RAT PANCREATIC ISLETS

Y.N. Wang, J.Chou*, Y.X. Zhu*, D. Chang* and J.K. Chang*

Peninsula Laboratories, Inc., Belmont, CA 94002

Pancreastatin is a pancreatic peptide isolated from the porcine pancreas (K. Tatemoto et al., Nature 324: 476, 1986). It has been reported that pancreastatin in vitro inhibits glucose-induced insulin release. Immunohistochemical studies have shown that pancreastatin was located in porcine endocrine cells: pancreas, gut and pituitary. In the present study, using a specific antiserum against rat pancreastatin, we investigated the localization of pancreastatin in rat pancreatic islets by immunofluorescence techniques. The rats were perfused with 4% paraformaldehyde. The pancreas was sectioned at 10µm or 5µm (serial sections) on a cryostat. The tissue sections were processed by an indirect immunofluorescence method. Pancreastatin-like immunoreactivity was observed in β-cells of the rat pancreatic islets. Serial sections of the pancreas showed that pancreastatin and insulin co-existed in β-cells of the rat islets. Our results suggest that pancreastatin may play important roles in the regulation of β-cell function and carbohydrate metabolism.

ALTERATION IN CALBINDIN EXPRESSION IN THE CAUDATE PUTAMEN AND N. ACCUMBENS OF GENETICALLY EPILEPTIC PRONE RATS (GEPR 3 AND 9) P. Montpied, L. Winsky, and D.M. Jacobowitz

(NSB and LCS, NIMH, Bethesda, MD 20892)

It has been acknowledged that genetic factors may significantly contribute to the generation of seizure activity. In view of the role of Ca⁺⁺ in neuronal excitability it is feasible that some of the genetically determined alterations may involve calcium dependent mechanisms. Calbindin (CB) and calretinin (CR) are neuronal peptides with high affinity for Ca⁺⁺ and it has been suggested that they function as intraneuronal Ca⁺⁺ buffering systems. In situ hybridization histochemistry has been used to selectively label the neurons expressing either of the two peptides. The regional and cellular distribution of the CB and CR mRNAs for the most part do not overlap. The level of expression of the mRNA coding for the two peptides was quantified in control rat versus Genetically Epileptic Prone Rats: GEPR-3 and GEPR-9. These two strains of rats had been genetically selected to have enhanced susceptibility to audiogenic seizure (GEPR9 > GEPR3). CB mRNA is highly expressed in the ventral part of the caudate putamen and n. accumbens. A quantitative analysis in this region was performed since a visual variation of the labelling was apparent. Based on densitometric measurements of autoradiograms and grain counting of emulsion dipped slides we estimated the alteration in the basal level of expression of CB mRNA in the GEPR rats to be as follows: GEPR-3 (N=3, mean = -30.2 % +/- 4.3 (p < 0.05); GEPR-9 (N=3, mean = -59.8 % +/- 3.4 (p < 0.001)). The corresponding levels of expression of CB was assessed using western blot semi-quantitative method. No apparent difference was observed between the 2 strains of GEPR rats; however a significant reduction in calbindin peptide immunodetection was observed in these strains compared to control rats. The results suggest that prior to the induction of seizure, the basal level of expression of CB mRNA in the ventral caudate putamen / n. accumbens is decreased and correlates with the severity of the seizure susceptibility.

ISOLATION OF A PORCINE cDNA CLONE FOR THE TRYPSIN INHIBITOR PEPTIDE LIKE PEC-60: WIDE SPREAD EXPRESSION AND PRESENCE OF THE PEC-60 PEPTIDE ALSO IN THE IMMUNE SYSTEM.

M. Metsis, A. Cintra*, V. Solfrini*, P. Ernfors, F. Bortolotti*, D. Morrasutti*, C.-G. Östenson**, S. Efendic**, B. Agerberth***, V. Mutt***, H. Persson and K. Fuxe*. Dept of Molecular Neurobiology, *Histology and Neurobiology, **Endocrinology, and ***Biochemistry, Karolinska Institute, 104 01 Stockholm, Sweden

A porcine cDNA clone of the trypsin-inhibitor like peptide PEC-60 which may serve as a neuropeptide signaling molecule (Fuxe et al. 1990, Soc Neurosci Abstr 16, 800) was isolated. The deduced amino acid sequence revealed a 87 amino acid long precursor protein that includes a 27 amino acid signal sequence. RNA blot analysis showed that the porcine PEC-60 gene is abundantly expressed in the pig as a 0.7 Kb mRNA in duodenum, bone marrow and peripheral blood cells. Lower levels were found in spleen. Immunohistochemical studies in the pig using a rabbit antiserum against PEC-60 (No. 2510) in combination with an immunofluorescence or an immunoperoxidase protocol demonstrated very strong cytoplasmic specific PEC-60 like immunoreactivity (IR) in the goblet cells of the columnar epithelium of the duodenum and in probable epithelioid cells of the marrow of the thymus. A moderate degree of specific PEC-60 like IR was observed in the cytoplasm of islands of adrenal medullary gland cells present mainly in the marginal part close to the adrenal cortex as well as in the cytoplasm of sympathetic ganglion cells of the superior cervical ganglion, in which also scattered strongly PEC-60 like IR cells were present, probably representing SIF cells. After absorption with PEC-60 no PEC-60 like IR could be demonstrated in the various tissues analyzed. The results indicate a role of PEC-60 like peptides not only in the neuronal, gastrointestinal and endocrine systems but also in the immune system. The results open up the possibility that PEC-60 like peptides could act to produce coordinated responses in the major regulatory systems of the body besides having a local role.

NEURONS IN THE SUBSTANTIA NIGRA OF RAT, MONKEY, AND HUMAN CONTAIN ACIDIC FIBROBLAST GROWTH FACTOR.

A.J. Bean, R. Elde, Y. Cao*, C. Oellig*, R. Pettersson*, and T. Hökfelt. Department of Histology and Neurobiology, Karolinska Institute, and *Ludwig Inst. for Cancer Research, S-104 01 Stockholm, Sweden.

Acidic fibroblast growth factor (aFGF) is one of a family of growth factors which have been characterized based on their mitogenic potential. In contrast to other FGF's, aFGF has been isolated from a limited number of tissues. We have used in situ hybridization histochemistry as well as Northern and Western blotting techniques to study the localization of aFGF mRNA and protein in rat, monkey, and human brain.

aFGF mRNA positive neurons were found principally in motor nuclei from the brainstem to the spinal cord in rat and monkey. In addition, cells containing aFGF mRNA were observed in the substantia nigra. aFGF mRNA was found in a subpopulation of nigral cells in both rat and monkey brain, although in the monkey not many nigral cells contained detectable aFGF mRNA. Unilateral 6-OHDA pretreatment of the rat substantia nigra (8µg/4ul, 2 weeks prior to sacrifice) produced a loss of both TH mRNA and aFGF mRNA on the lesioned side. Nigral localization of aFGF (mRNA and protein) was also observed in the human substantia nigra. These data suggest that some mesencephalic dopamine-containing neurons contain aFGF.

These studies were supported in part by the PMA Foundation and The Scottish Rite Schizophrenia Research Program.

PARVALBUMIN-IMMUNOREACTIVE STRUCTURES IN THE ENTORHINAL CORTEX OF THE HUMAN ADULT.

E. Braak, S. Schmidt*, H. Braak, M. Celio*

Dept. Anatomy., J.W. Goethe University, D-6000 Frankfurt/M. 70, Germany; *Inst. Histology, University, CH-1700 Freiburg, Switzerland

Frontal sections of the adult human entorhinal cortex were incubated with anti-parvalbumin. Parvalbumin-immunoreactive neurons occur in all layers. The neurons in the external principal layers (pre-α, pre-β, pre-γ) outnumber those within the inner ones (pri-α, pri-β, pri-γ). Small, medium-sized and large somata can be distinguished. They are either multipolar or bipolar in shape. Axon initial segments of several pyramidal neurons in layers pre-β, pri-α and pri-γ are enwrapped by immunoreactive fibres. The density of immunoreactive fibres is already high within the cellular islands of the upper cellular layer (layer pre-α) and increases further to a dense plexus in layer pre-γ. Towards the lamina dissecans the fiber density decreases abruptly and remains to be low in the inner layers. All observed immunoreactive cells belong to the class of non-pyramidal neurons, some of them are chandelier cells.

CHOLECYSTOKININ (CCK) ANTAGONISTS DECREASE THE SUSCEPTIBILITY OF RAT CAUDATE TO KCL-INDUCED SLOW WAVE DEPOLARIZATION. K. Kedzie*, J. Wilkerson*, R. Kasser and K. Renner, Dept. of Biomedical Sciences, Southwest Missouri State Univ., Springfield, MO 65804.

The effect of sulfated CCK octapeptide (CCK-8S) on the generation of slow wave depolarization (SWD) in the rat caudate (CPU) was studied using *in vivo* voltammetry. Pressure-ejection of 50 μ M CCK-8S into the CPU induced signals recorded with Nafion-coated carbon fiber electrodes (CFM). Based on *in vitro* selectivity properties of the CFMs, these signals were predominantly due to increases in dopamine (DA). The similar propagation rates of signals induced by CCK-8S (2.2 ± 0.3 mm/min) and 100 mM KCl (1.8 ± 0.2 mm/min) suggests that the CCK-8S-induced signals represent a SWD. The CPU failed to respond to a second CCK-8S stimulus. Dose-dependent decreases in KCl-induced DA signals were recorded following *i.v.* proglumide (4-64 mg/kg) and lorglumide (Rotta Labs., 20-640 μ g/kg). KCl-induced signals returned to 69% of pre-lorglumide signals after 130 min. These results suggest that the susceptibility of the CPU to KCl-induced SWD is enhanced by CCK-8S. Studies testing this possibility are in progress. (Supported by MH-44893)

EFFECTS OF THE NEUROPEPTIDE CHOLECYSTOKININ ON THE GOLDFISH MAUTHNER CELL. D. P. Yox, M. J. Titmus, and D. S. Faber, Neurobiology Laboratory, Dept. of Physiology, State University of New York at Buffalo, Buffalo, NY 14214.

Current evidence suggests that neuroactive peptides may act to modulate the effects of nonpeptide neurotransmitters. In the medulla of the goldfish, antibodies against the neuropeptide cholecystokinin (CCK) were used to identify the presence of CCK-like immunoreactivity in proximity to the Mauthner (M-) cell. CCK-like immunoreactive varicosities were observed in close proximity to the M-cell body and the lateral dendrite. To examine the physiological effects of locally applied CCK, we pressure ejected solutions of CCK (30-60 μ M) near the M-cell soma or lateral dendrite while recording intracellularly from the same respective areas. Local application of CCK near the M-cell body (N=3) was accompanied by an enhanced input resistance, as evidenced by an increase ($23.7 \pm 5.0\%$) in antidromic spike height and by single electrode voltage clamp. In contrast, local application of CCK to the lateral dendrite caused a decrease in input resistance (N=3), as evidenced by a decrease in antidromic spike height ($-22.7 \pm 9.4\%$) and a similar reduction in excitatory and inhibitory synaptic responses. In both cases, the resting membrane potential was either unchanged or slightly hyperpolarized. Local application of the CCK vehicle had no effects on input resistance or resting membrane potential. These data support the hypothesis that CCK is a neuromodulator at the M-cell membrane. While the effects of CCK alone may be difficult to interpret, the role of CCK at this level may be to modulate the effects of other transmitters such as dopamine or GABA. BOMBESIN INHIBITORY EFFECT ON GASTRIC VAGAL EFFERENT DISCHARGE (GVED). E. Yoshida-Yoneda, J.Y. Wei, and Y. Taché, CURE/VA Medical Center, Dept. of Medicine and Brain Res. Inst., UCLA, CA 90073.

Surgical and pharmacological studies indicate that central and peripheral bombesin actions on gastric function and food intake involve the autonomic nervous system. In the present study we use electrophysiological approach to investigate whether central and peripheral injection of bombesin will influence GVED.

Male SD rats were anesthetized with urethane (1.25g/kg im). A microdissection technique was used to isolate efferent fibers from the ventral gastric branch of the vagus. Strands were cut distally to record efferent multi-unit activity. Three minute peak changes from basal GVED were calculated. Bombesin and saline were injected intravenously (iv) or intracisternally (ic) through a catheter into the cisterna magna.

Bombesin ic (6.2, 62, 620, 6200 pmol, n=5) induced a dose-dependent inhibitory effect on GVED ($100.2 \pm 11.4\%$, $77.5 \pm 9.5\%$, $50.3 \pm 3.5\%$, $42.5 \pm 3.1\%$, respectively). Bombesin iv (6.2×10^4 , 6.2×10^2 and 62 pmol n=4) also suppressed GVED ($68.0 \pm 3.9\%$, $76.5 \pm 7.2\%$, $38.8 \pm 9.5\%$, respectively). Bombesin iv produced stronger inhibition compared with ic. Continuously iv infusion of bombesin monoclonal antibody 2A11 did not reduce the inhibitory effect ($61.3 \pm 14.1\%$, n=5) of ic bombesin (620 pmol) compared with control ($41.5 \pm 14.1\%$, n=5), whereas the antibody blocked the inhibition of iv bombesin in the same animal. Bombesin (62 pmol, iv) reduced VED recorded from cervical fibers to $24.8 \pm 6.1\%$; a second bombesin injection following bilateral cervical vagotomy below the site of recording reduced by 56% the inhibitory effect of bombesin (n=4). In control group (n=4), two successive injections of bombesin had similar inhibitory effect.

These data indicate that (1) bombesin acts in the brain to decrease GVED, (2) bombesin iv exerts a potent inhibitory effect on GVED which is probably mediated in part through an action on vagal afferent.

GASTRIC SALINE LOADS AND CELIAC ARTERY CHOLECYSTOKININ INFUSIONS ACT SYNERGISTICALLY TO STIMULATE GASTRIC VAGAL AFFERENT ACTIVITY IN RATS. G.J. Schwartz, P.R. McHugh & T.H. Moran, Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

We have previously demonstrated that doses of cholecystokinin (CCK) ineffective in inhibiting food intake when given alone become effective when paired with a non-nutrient gastric load. To determine whether the gastric vagal afferent response to CCK is also modified by the presence of gastric loads, we examined the neurophysiological responses of single cervical vagal afferent fibers with gastric receptive fields that responded to both gastric loads and CCK (N=6). Anesthetized rats received 1) a range of intra-celiac artery infusions of CCK alone (10-1000 pmol), 2) various intragastric physiological saline loads alone (2-7 ml), and 3) combinations of CCK and gastric loads. Doses of CCK that were subthreshold when given alone always increased vagal afferent discharge rates when given in combination with gastric loads. Doses of CCK that were effective alone elicited greater discharge rates when combined with a load, whether or not the load alone elicited an increase in discharge rate. Thus, the presence of a gastric load 1) lowered the threshold CCK dose required to elicit an increase in vagal afferent discharge rate, and 2) always magnified the discharge rate elicited by suprathreshold doses of CCK. These results demonstrate a peripheral integration of CCK- and load- elicited signals at the level of the afferent vagus, and may provide a mechanism for the synergistic actions of gastric loads and CCK in the inhibition of food intake. IN VITRO EXCITATION OF RAT NODOSE GANGLION CELLS BY CHOLECYSTOKININ OCTAPEPTIDE. N. J. Dun and S. Y. Wu*, Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Cholecystokinin (CCK) has been implicated as one of the putative transmitters involved in the production of satiety by acting on vagal afferents. Current/voltage clamp recordings from isolated rat nodose ganglion cells show that pressure applications of CCK octapeptide (CCK-8) evoke in the large majority of ganglion cells a rapid depolarization or a fast inward current and in a few cells a slow depolarization or a slow inward current. The fast response is associated with a fall of input resistance and is increased by membrane hyperpolarization. The extrapolated reversal potential is about -10 mV. This response is reduced in a Na^+ -free, Tris-Cl solution and by d-tubocurarine but is not reduced in a low Cl^- solution. The slow response is associated with an increase of membrane resistance and is decreased by hyperpolarization; the extrapolated reversal potential is around -90 mV. The results suggest that CCK-8 produces two types of depolarizing response in rat nodose ganglion cells, probably by acting on two distinct types of receptors. The fast response appears to be caused by an increase of cation conductance, whereas the slow response is likely to be due to a reduction of membrane K^+ conductance. BOMBESIN-INDUCED HYPOTHERMIA IN HYPOGLYCEMIC RATS: A DOSE-RESPONSE STUDY. AM Babcock¹, P. Lomax², and TW Moody³, ¹Dept. of Psych., Univ. of S. AL, Mobile, AL 36688; ²Dept. of Pharm., UCLA Sch of Med, Los Angeles, CA 90024; ³Dept. of Biochem, George Washington Univ Med Center, Washington D.C. 20037.

Infusion of bombesin (BOM) at a dose of 50 ng or more into the POA produces hypothermia in rats made hypoglycemic with insulin (Babcock et al., '89 *Pharm. Biochem. & Behav* 34, 539). The present Exp examined the dose-response relationship of this hypothermic action. Using a randomized block design, 5 insulin-pretreated rats (10U/kg; *i.m.*) received POA microinfusions of BOM (0, 5, 12, 25, 50 ng/.25 μ l). Rectal temperatures (T_{re}) were measured prior to insulin and at 60 mins following BOM. Treatments were separated by at least 2 days. BOM produced a significant reduction in T_{re} ($F(4,16) = 3.817$ $p < .02$) that was dose-related ($r = .58$ $p < .002$). Our findings support the notion that the POA is a sensitive site for BOM-induced hypothermia under hypoglycemic conditions. We are presently examining the ability of (Psi^{13,14}, Leu¹⁴)BOM to antagonize the response (data to be presented).

EFFECT OF CHOLECYSTOKININ ON GENE EXPRESSION IN THE RAT BRAIN. R. Miyoshi, S. Kito, T. Nomoto*, M. Weiser and T.H. Joh. Dept. of Pharmacol., Tokyo Women's Med. Coll., Tokyo 162, Division of Health Sciences, Univ. of the Air, Chiba 260, Japan and Lab. of Molecular Neurobiology, Cornell Univ. Med. Coll., New York 10605, U.S.A.

Excitation of cells by means of growth factors and others causes changes of gene expression which result in long-term response of cells. The response is due to sequential induction of mRNAs, involving the proto-oncogenes. Clinically, it has been observed that a single dosis of caerulein, an analog of cholecystokinin-8, causes improvement of involuntary movements lasting for much longer period than being expected from its short half-life time in circulating blood. We investigated effects of caerulein on changes of gene expression in the rat brain through in situ hybridization. Intraperitoneal injection of caerulein did not affect basal levels of c-fos and c-jun mRNAs. It is known that administration of convulsants such as pentylenetetrazole (PTZ) causes rapid increases of proto-oncogenes in the rat brain. In our experiments, increases of c-fos and c-jun mRNAs were observed in the hippocampus and cerebral cortex one hour after PTZ injection. Administration of caerulein one hour prior to PTZ decreased the effect of PTZ on the expression of the mRNAs. It is considered that clinically-experienced long-term effects of caerulein are the results of such changes of gene expression.

TRH-INDUCED GASTRIC MOTILITY INCREASES ARE MEDIATED BY A CHOLINERGIC MECHANISM IN YOUNG RATS. M.M. Heitkemper*, E.F. Bond*, K. Gruver*, & A. Horita. Depts. of Physiological Nursing & Pharmacology, University of Washington, Seattle, WA 98195

Centrally administered thyrotropin releasing hormone (TRH) increases gastric motility and small intestine transit in rats as young as 14 days (D). Prior treatment with serotonin (5-HT) blocking agents decreases TRH-induced intestinal transit increases in adult rats. This study examined effects of 5-HT blocking agents xylamidine 10mg/kg, ketanserin 5mg/kg, cyproheptadine 1.5mg/kg, and the anticholinergic atropine 2mg/kg on TRH-induced gastric contractile activity in rats 7, 10, 14, & 21D. Rats treated with p-chlorophenylalanine (PCPA) 48 hrs prior were also studied. Rats were anesthetized (urethane, 1.25mg/kg). A tension transducer was implanted on the anterior gastric corpus. After 1hr baseline recording, test rats were injected with blocker IP. Control and PCPA treated rats received no pretreatment. After 30min TRH in saline (5 or 10µg in 0.6µl) or saline was injected intracisternally and motility recorded. Data were expressed relative to baseline. In 10, 14, and 21D rats TRH produced a significant increase in gastric contractile activity. In all age groups, cyproheptadine inhibited TRH-induced increases in gastric motility. However, inhibition was not observed with xylamidine, ketanserin or PCPA. Atropine blocked TRH-induced gastric motility indicating TRH stimulation of gastric motility is via a cholinergic mechanism in young rats (<21D). (Supported by N00007, NCNR, NIH).

PREPROTRH 53-74 STIMULATES PRIMARY CULTURES OF RAT ANTERIOR PITUITARY TO ENTER EARLY S-PHASE. R. Toni, M. Vitale*, S. Mosca*, L. Zamai*, A. M. Martelli*, L. Cocco*. Insts. Human Anatomy and Ort. Rizzoli, University of Bologna, Italy.

The N-terminal fragment of the thyrotropin-releasing hormone precursor, preproTRH 53-74 (pYT22) has been identified in axon terminals in the rat median eminence but its physiological role is still unknown. To determine whether pYT22 may influence the growth of anterior pituitary cells we studied its effect on the incorporation of the synthetic analogue of thymidine, bromodeoxyuridine (BrdU) in the nuclei of cells from primary cultures of rat anterior pituitary. Primary adenohypophyseal cell cultures were grown 72 hs, then the cells incubated in serum-free medium with 100 nM pYT22 up to 18 hs plus 100 µM BrdU in the last 12 hs. The percentage of DNA replicating cells was identified by flow cytometry, using directly FITC-conjugated antibodies to BrdU and a bivariate DNA/BrdU analysis focused on early S-phase vs G0/G1. Primary cultures treated with pYT22 showed 58.9% (control 44.9%) and 46.0% (control 34.5%) of cells in early S-phase after 12 and 18 hs of treatment, respectively. These results show that pYT22 increases the number of cultured adenohypophyseal cells that enter early S-phase and suggest that it may play a role on growth regulation of anterior pituitary.

ALTERATION OF JEJUNAL ABSORPTION OF AMINO ACIDS BY INTRACEREBRAL INJECTIONS OF VASOACTIVE INTESTINAL PEPTIDE (VIP). C.F. Nassar*, S. Itani*, N.E. Saadé and S.J. Jabbur. Fac. of Med., American University of Beirut, Lebanon.

High concentrations of VIP were found in the gut and in areas of the central nervous system involved in processing visceral information. Intravenous injection of 11.2 ng/Kg/min produced an immediate and maintained decrease in the absorption of amino acids in the jejunum similar to that produced by ulcerogenic agents (Nassar, C.F. et al., FASEB J. 2:734, 1988) but without an apparent ulceration.

To investigate whether this effect is neurally mediated, 11.2 ng/Kg of VIP were stereotaxically microinjected either in the lateral ventricle (n=5 rats) or in the dorsal motor nucleus of the vagus (n=5 rats). Amino acid absorption in a jejunal segment was determined, for 2-3 hrs following injections using the single-pass perfusion technique and labelled alanine as the permanent probe (Nassar, C.F. et al., Comp. Biochem. Physiol. 89:61, 1988). The results show a significant decrease in alanine absorption (P<0.05) from 0.2 µmole/20 min.cm to 0.12-0.11 µmole/20 min.cm in both injected groups. Water movement across the jejunal segment did not show a significant change resulting from these injections.

These results demonstrate that alteration of jejunal absorption by VIP is neurally mediated and may act, at least partially, through the parasympathetic system. (Supported by grants from LNRC and DTSabbagh Fund).

388.10

THYROTROPIN RELEASING HORMONE (TRH) EXCITES THE CHOLINERGIC SYSTEM ORIGINATING IN THE NUCLEUS BASALIS OF MEYNERT.

A. Suzuki* and M. Kurosawa. Department of Autonomic Nervous System, Tokyo Metropolitan Institute of Gerontology, Tokyo 173, Japan.

It has been reported that cerebral blood flow (CBF) increases following either an intravenous or a central administration of thyrotropin releasing hormone (TRH) in anesthetized animals. The study in our laboratory has recently suggested that the cholinergic vasodilator system contributes to the TRH-induced increase in the CBF in the cortex¹⁾. The present experiment aimed to clarify whether TRH actually excites cholinergic neurons originating in the nucleus basalis of Meynert (NBM) and projecting to the cortex and eventually increases extracellular concentration of acetylcholine (ACh) in the cortex using anesthetized rats. Single neurons in the NBM were identified by antidromic stimulation of their axons in the cortex. ACh was measured using a microdialysis method. Intravenous administrations of 300 µg/kg and 3,000 µg/kg of TRH increased both the nerve activity and the concentration of ACh dose-dependently. 30 µg/kg of TRH was ineffective to the both parameters. The results suggest that the TRH-induced activation of the cholinergic fibers originating in the NBM is involved in the TRH-induced increases in the cortical CBF.

SOMATOSTATIN (SST) INHIBITS NICOTINIC CHOLINOCEPTOR MEDIATED OESOPHAGOMOTOR ACTIVITY IN VIVO. Y.T. Wang, R.S. Neuman and D. Bieger, Fac. of Med., Memorial Univ. of Nfld. St. John's, NF Canada A1B 3V6

Work from this lab has revealed the presence of excitatory nicotinic cholinergic receptors on oesophagomotor neurons of the ambigular compact formation (AMB_c) of the rat. *In vitro*, AMB_c neurons respond to acetylcholine (ACh) with a fast depolarisation that is reversibly inhibited by SST, unlike the response to S-glutamate (GLU). Here we report oesophagomotor responses evoked by application of these substances at deglutitive sites in the solitary and ambiguous complex of the intact urethane-anesthetized rat (adult male Sprague-Dawley). ACh (0.5 M), S-glutamate (0.2 M) and SST (0.001 M) were dissolved in artificial cerebrospinal fluid and injected in volumes of 20-100 µl from three-barreled glass micropipettes (tip dia < 10 µm). Oesophageal responses to ACh and GLU ejection in AMB_c usually consisted of short-latency, single, nonpropulsive pressure waves and showed little evidence of desensitisation when evoked at 2-3 min intervals. SST (0.1-0.3 pmol) produced a feeble, inconsistent oesophageal pressure wave following which the ACh response was reversibly inhibited, whereas that to GLU was slightly enhanced or unchanged. The SST-ACh antagonism showed dose-dependence and surmountability. Interestingly, SST did not eliminate facilitation by ACh of GLU responses. In contrast, SST and ACh displayed no inhibitory interaction at solitary oesophagomotor sites, where ACh responses are mediated by muscarinic cholinergic receptors. In conclusion, SST produces a selective inhibition of nicotinic cholinergic activity at the level of the AMB_c. As this peptide has been demonstrated in a subpopulation of solitary premotor neurons projecting to the AMB_c, our observations strengthen the hypothesis that SST plays a role in the generation of oesophageal peristalsis. NPY INHIBITS FEEDFORWARD IPSP'S IN HIPPOCAMPUS BY REDUCING EXCITATORY INPUT TO INTERNEURONS. G.J. Klapstein and W.F. Colmers. Dept of Pharmacology, Univ. of Alberta, Edmonton, T6G 2H7. Neuropeptide Y (NPY) has been shown to selectively inhibit excitatory synaptic transmission in the *in vitro* hippocampus by a presynaptic mechanism. However, orthodromically-evoked IPSP's are also reduced by NPY in area CA1. To examine whether NPY's action was due to a direct effect on the interneurons mediating the GABAergic (A and B receptor mediated) IPSP's, we examined focally-evoked monosynaptic IPSP's in principal neurons in hippocampus under pharmacological blockade of excitatory amino acid neurotransmission. Intracellular recordings were made from pyramidal neurons in areas CA1 and CA3 of transverse (450 μ m) slices of hippocampus, maintained submerged in oxygenated buffer at 34°C. Synaptic potentials were evoked with a pair of sharpened tungsten electrodes mounted on independent micromanipulators, permitting optimal placement. All components of the feedforward EPSP-IPSP (E/I) complex evoked by stimulation of stratum radiatum in CA1 were inhibited equally by NPY (1 μ M). However, when IPSP's (having both GABA_A and GABA_B components) were isolated by the presence of CNQX (10 μ M) and APV (50 μ M), NPY had no effects. Isolated IPSP's evoked in CA3 pyramidal neurons were similarly unaffected by application of the peptide. As previously reported, NPY caused no detectable changes in the properties of the postsynaptic neurons.

The simplest explanation for the observed results is that NPY presynaptically inhibits excitatory inputs to interneurons mediating the feedforward IPSP in area CA1. NPY does not appear to act on the interneurons themselves. The results help clarify the role of NPY in the hippocampus by helping define the synaptic connections subject to its influence.

THE SITE AND MECHANISM OF ACTION OF NEUROPEPTIDE Y IN CULTURED RAT HIPPOCAMPAL NEURONS. D. Bleakman, N. L. Harrison, W.F. Colmers and R.L. Miller. Dept. of Pharmacol. and Physiol. Sci., and [†]Dept. of Anesthesia and Critical Care, Univ. of Chicago, Chicago, IL 60637 and [‡]Dept. of Pharmacol., Univ. of Alberta, Edmonton, Canada.

We have examined the effects of neuropeptide Y (NPY) on synaptic transmission and [Ca²⁺]_i signals in rat hippocampal neurons (E17) grown in cell culture. Using combined whole cell patch clamp/Fura-2 based microfluorimetry we were able to observe frequent fluctuations in [Ca²⁺]_i which corresponded to spontaneous synaptic activity. These fluctuations were inhibited by tetrodotoxin (1 μ M), and combinations of CNQX (10 μ M) and APV (50 μ M) indicating that they were the result of glutamatergic transmission occurring between neurons. [Ca²⁺]_i fluctuations and spontaneous activity were also abolished by Ni²⁺(200 μ M) and reduced by baclofen (10 μ M), NPY (100nM) and fragments of NPY implicating the involvement of the Y2 receptor. Following treatment of cells with pertussis toxin, the effects of baclofen, NPY and NPY fragments were reduced. NPY had no effect on somal Ba²⁺ or Ca²⁺ currents measured in hippocampal neurons under whole cell voltage clamp even in the presence of GTP- γ S. Furthermore, NPY (100nM) had no effect on the cell soma [Ca²⁺]_i signal accompanying the Ca²⁺ current in these cells even though Ba²⁺ currents were inhibited by both Cd²⁺ (200 μ M) and baclofen (10 μ M). Current clamp recordings from neurons demonstrated the occurrence of spontaneous E.P.S.P.s and action potential firing which was accompanied by increases in [Ca²⁺]_i. This activity and the accompanying [Ca²⁺]_i signal was reduced by NPY (100nM), NPY fragments and baclofen (10 μ M). However, when increases in [Ca²⁺]_i were induced by trains of evoked action potentials in the presence of CNQX and APV, NPY (100nM) had no effect on these cell soma [Ca²⁺]_i signals. Hence, NPY is able to inhibit excitatory neurotransmission in these neurons through a pertussis toxin sensitive mechanism although no effect of NPY on Ca²⁺ influx into the cell soma of these neurons was discernable.

THE DEPRESSOR EFFECT OF INTRATHECAL NEUROPEPTIDE Y DEPENDS ON SPINAL CATECHOLAMINES. X. Chen and T.C. Westfall Dept. Pharmacol. & Physiol. Science, Saint Louis Univ. Sch. of Med., St. Louis, MO 63104

We have shown previously that the intrathecal (int) injection of NPY C-terminal fragments produces a depressor effect similar to NPY. In the present study, we examined the ability of the fragments to block the response to NPY and evaluated the role of spinal catecholamines (CA) in mediating the depressor effect of NPY. For int injections, the atlanto-occipital membrane was exposed by a midline incision, a PE-10 catheter was inserted 6 cm down the thoracic spinal subarachnoid space (T10). Drugs were dissolved in saline and slowly injected at a volume of 5 μ l followed by 5 μ l of vehicle to wash the catheter. Co-administration of NPY¹⁴⁻³⁶ (1.0 nmol) and NPY (0.1 nmol) did not affect the depressor effect of int NPY. NPY¹⁸⁻³⁶, also behaved in a similar manner as NPY¹⁴⁻³⁶ suggesting that these fragments do not possess antagonistic or partial agonistic activity. [Leu³¹,Pro³⁴]-NPY has been shown to be a specific Y₁ receptor ligand. Int injection of the Y₁ ligand (0.1 and 1.0 nmol) did not significantly change arterial pressure (AP) suggesting that the depressor effect of NPY is not mediated by spinal Y₁ receptors and further supports the hypothesis that Y₂ receptors are involved. Some rats were pretreated with an int injection of 6-OHDA (20 μ g) and the effect of NPY tested after 7 days. At the end of each experiment, rats were decapitated and a spinal thoracic-lumbar segment (about T₆-L₃), brain and heart were removed and prepared for monoamine measurement. Int 6-OHDA pretreatment significantly depleted norepinephrine (NE) (81%) and epinephrine (EPI) (46.5%) in the spinal cord but not in the brain and heart. Such pretreatment completely blocked the depressor effect of int NPY suggesting that NE and EPI play an important role in mediating the depressor effect of NPY. (Supported by HL 26319 and HL 35202).

NEUROPEPTIDE Y (NPY) DOES NOT ALTER POSTSYNAPTIC NMDA CURRENTS IN PYRAMIDAL NEURONS OF AREA CA3 OF THE RAT HIPPOCAMPAL SLICE. A.R. McQuiston and W.F. Colmers. Dept of Pharmacology, Univ. of Alberta, Edmonton, T6G 2H7.

NPY affects synaptic transmission in hippocampus by a presynaptic mechanism. Recently authors have postulated that NPY may also act at the sigma and PCP receptors. Binding studies have shown inconsistent results, some investigators finding specific high affinity binding of NPY to the sigma and PCP receptors while others did not. Ionophoretically-applied NPY increases the rate of firing of rat hippocampal CA3 pyramidal neurons evoked by iontophoresis of NMDA *in vivo*, consistent with the idea that NPY acts at the PCP receptor. However, these studies are in direct contrast to studies from our laboratory showing that NPY has no postsynaptic actions in area CA1, including no effect on the response to iontophoretically-applied glutamate.

To test whether NPY affected NMDA conductances, we used the tight-seal, whole-cell technique to record responses of pyramidal neurons in area CA3 of submerged hippocampal slices (450 μ m, 34°C) to iontophoretically applied NMDA. The intracellular solution contained (in mM) Cs-glucuronate, 135; HEPES, 10; EGTA, 5.5; MgCl₂, 2; pH 7.2-7.3. TTX (500 nM) was applied in the perfusate to block Na⁺ currents. NMDA (50 mM, pH 8.0) was applied by brief (<10 msec) pulses of negative current (50-120 nA) to proximal dendrites of CA3 cells. Under these conditions bath application of NPY (1 μ M) did not alter the response to NMDA. However, in other experiments, bath application of NPY (1 μ M, in the presence of 50 μ M picrotoxin) inhibited EPSC's evoked by extracellular stimulation of the mossy fibers, consistent with earlier work.

The results show that NPY does not alter NMDA currents and is thus unlikely to be a ligand at the PCP receptor. The role for NPY in hippocampus thus appears to be only its inhibition of synaptic transmission.

NPY AND SIGMA LIGANDS ACT IN THE PARAVENTRICULAR NUCLEUS TO BLOCK CRF-INHIBITED GASTRIC ACID SECRETION IN URETHANE ANESTHETIZED RATS. M. Gué*, J.L. Junien*, S. M. Yoneda*, H. Mönikes*, L. Diop† and Y. Taché. CURE/VA Wadsworth Medical Center, Department of Medicine and Brain Research Institute UCLA, Los Angeles, CA 90073 / [‡]Institut de Recherche Jouveinal, 1 Rue de Moissons, Fresnes, France

CRF has been shown to inhibit gastric acid secretion after injection into the cerebral spinal fluid, with a site of action in the PVN. Since NPY and sigma ligand act through a common receptor to antagonize stress and CRF-induced colonic hyperactivity, the aim of this study was to evaluate whether NPY and JO 1784 a specific sigma ligand can alter the CRF-inhibited gastric secretion by acting in the PVN.

Gastric output was recorded with a double-lumen cannula every 10 min. by flushing the gastric lumen. Intracisternal (IC) injection of NPY or JO 1784 (0.01 to 0.5 μ g in 5 μ l) was performed 10 min before IC injection of CRF. In a second series of experiments unilateral microinjection of NPY or JO 1784 (30 ng in 50 nl) into the PVN was done 10 min before microinjection of CRF (3 μ g) into the PVN. Immediately after IC or microinjections, pentagastrin (10 μ g/kg/hr) was infused through the femoral vein for 2 hours. Acid output was determined by titration of the flushed perfusate with 0.1 NaOH to pH 7.0.

Intracisternal injection of CRF resulted in an inhibition of 71.6% of the gastric output in the rat when acid secretion was stimulated by IV infusion of pentagastrin. The inhibitory effect of CRF was dose dependently blocked by concomitant IC injection of JO 1784 or NPY (0.01 to 0.1 μ g) the complete reversal was obtained at a dosage of 0.1 μ g. CRF microfused into the PVN (3 μ g) also reduced by 88.3% the gastric output acid stimulated by pentagastrin. Microinjection into the PVN of NPY (30 ng) or JO 1784 (30 ng) had no effect on acid secretion but abolished the inhibitory effect of CRF.

These results indicate that central administration of NPY and JO 1784 abolished CRF-induced inhibition of gastric acid secretion in urethane anesthetized rats and that they act directly on PVN structures to exert their inhibitory effect on CRF.

ANTAGONISM OF THE ACTIONS OF [11-36]NPY AND [LEU³¹PRO³⁴]NPY (LP) AT Y2 AND Y1 RECEPTORS IN THE RAT MESENTERIC ARTERIAL BED. M.A. McAuley*, A. Howlett and T.C. Westfall. Dept. of Pharmacol. and Physiol. Sci., Saint Louis Univ. Sch. of Medicine, St. Louis MO 63104.

Earlier investigation of the vascular actions of Neuropeptide Y (NPY), led us to propose that distinct NPY receptors mediated the pre- and postsynaptic actions of this peptide in the isolated and perfused rat mesenteric arterial bed. In this model of the vascular neuroeffector synapse, a presynaptic NPY receptor was previously designated Y2 based on the ability of NPY C-terminal fragments to mimic the attenuation of the periarterial nerve-stimulated (PNS) release of norepinephrine. At high concentrations the intact peptide but not C-terminal fragments could potentiate the nerve stimulated increase in perfusion pressure and thus in accordance with other studies, the postsynaptic receptors were classified as Y1 receptors. In the present study further examination of the involvement of these putative receptor subtypes in the actions of NPY has revealed a more complicated organization of these receptor subtypes in this preparation. Perfusion of [11-36]NPY (10⁻¹⁰-10⁻⁸M) produced a concentration-related potentiation of the increase in perfusion pressure elicited by subsequent administration of norepinephrine (NE) alone, suggesting the existence of a postsynaptic Y2 receptor. This potentiation had a latency of onset of 8 mins, reached a maximum at 30 mins and was abolished by Phenolamine(Phen), attenuated by Benextramine(Benxt) but not significantly altered by the novel NPY antagonist PYX-1. The reputedly Y1 selective NPY analogue LP(10⁻¹⁰-10⁻⁷M) attenuated the PNS release of NE indicating that the Y1 subtype may also be located presynaptically. Moreover LP produced an immediate potentiation of the increase in perfusion pressure elicited by exogenous NE substantiating the presence of a postsynaptic Y1 receptor. This action was also differentially effected by Phen., Benxt. and PYX-1. Supported in part by HL 26319 and HL 35202.

NPY(13-36) AND [LEU-PRO]NPY CONSTRICT RAT FEMORAL ARTERY RINGS, AND PROTECT NPY FROM BENEXTRAMINE BLOCKADE, BY ACTING AT Y1 AND Y2 RECEPTORS. R.E. Tessel, D. Xu, D.W. Miller, and M.B. Dougherty. Depts. of Pharmacol. & Toxicol. and Med. Chem., Univ. of Kansas, Lawrence, KS 66045-2505.

Rings were attached to transducers (Time 0) and equilibrated in warmed physiological buffer prior to being maximally contracted with 10 μ M norepinephrine both 30 and 60 min after Time 0. 70 min after Time 0, tissues were exposed to 1.0 μ M of NPY, NPY(13-36), [Leu³¹-Pro³⁶]NPY (LP-NPY) or vehicle 5 min prior to a 10-min exposure to benextramine (BXT; 10 μ M) or saline. A cumulative concentration-effect curve for one of the above three peptides (0.001-1.0 μ M) was then constructed beginning 95 min after Time 0. Except during drug or peptide exposure, buffer was changed every 10 min. All three NPY congeners induced concentration-dependent constriction and with similar apparent EC₅₀'s (60 +/- 19, 38 +/- 12 and 44 +/- 9 nM for NPY, NPY (13-36) and LP-NPY, respectively). BXT essentially abolished these effects, probably irreversibly. All three peptides protected NPY from BXT blockade, and desensitized NPY-induced constriction. In contrast, NPY and LP-NPY desensitized LP-NPY-induced responses and protected them from BXT-induced blockade but NPY(13-36) did neither. These data suggest that: 1) postsynaptic vascular Y2 receptors do exist; 2) rat femoral arteries contain both Y1 and Y2 constriction-mediating, BXT-sensitive receptors; 3) NPY is an agonist at both receptors; and 4) NPY(13-36) and LP-NPY are selective Y2 and Y1 agonists, respectively, in the rat vasculature. AMYLIN INCREASES TRANSPORT OF TYROSINE AND TRYPTOPHAN INTO BRAIN. A. Balasubramaniam*, F.S. Zhang*, I. Thomas* and W.T. Chance. Dept. Surgery, Univ. of Cincinnati Med. Ctr. and VA Med. Ctr., Cincinnati, OH.

Amylin (AMY) is a 37 amino acid peptide of the CGRP family isolated from pancreatic amyloid deposits of type II diabetic patients. We reported anorexia, elevated tryptophan (TRP) and increased metabolism of monoamines following intrahypothalamic (iht) injection of AMY (Brain Res. 539:352, 1991). In the present study, we specifically investigated whether iht AMY would further increase brain concentrations of TRP and tyrosine (TYR) following their systemic injection. Following the implantation of hypothalamic cannulae, groups (n=5-7/gp) of adult, male, SD rats were treated (ip) with either 50 mg/kg each of TRP and TYR ethyl ester or saline (SAL) followed (15 min) by either iht AMY (2 μ g) or CSF (2 μ l). Sixty min later all rats were decapitated and the levels of monoamines, precursors and metabolites were determined by HPLC-EC. Striatal concentrations of TYR were elevated (p<0.05) by 39%, while TRP levels were increased 69% in AMY-treated TYR-TRP rats as compared to the SAL-TYR-TRP group. Levels of DOPAC and HVA were also elevated significantly by 21% and 44% in these rats. Similar alterations in TYR and TRP were observed in the hypothalamus of AMY-TYR-TRP rats. These results suggest that blood-brain-barrier transport of TYR and TRP may be increased by iht AMY. Supported by Dept. of Veterans Affairs and PHS #CA 48057.

GALANIN CAUSES A HYPERPOLARIZATION OF LOCUS COERULEUS NEURONS IN THE *IN VITRO* BRAIN SLICE. Vincent A. Pieribone¹, Ulo Langel², Tamas Bartfai² and Tomas Hökfelt¹. ¹Dept. of Histology and Neurobiology, Karolinska Institutet & ²Dept. of Biochem., Arrhenius Lab. Stockholm, Sweden.

Both anatomic and physiologic studies indicate that LC neurons form axo- and dendro-dendritic synapses with surrounding LC neurons. This has led to the proposal that LC neurons modulate their own discharge through the feedback release of noradrenaline (NA) onto surrounding LC neurons. Since virtually all NA containing neurons of the LC also contain and may release the neuropeptide galanin (GAL), the present study sought to determine what, if any effects GAL has on the membrane properties of LC neurons recorded in the *in vitro* brain slice preparation. Horizontal slices (300 μ m thick) containing the LC were cut on a Vibratome and immediately transferred to a slice chamber. Slices were maintained at 37°C in a Ringer's solution containing (in mM): 124 NaCl, 2.5 KCl, 1.3 MgSO₄, 1.24 NaH₂PO₄, 2.4 CaCl₂, 25 NaHCO₃ and 10 glucose and saturated with 95% O₂ / 5% CO₂. Neurons of the LC were impaled with microelectrodes containing K⁺ acetate (DC resistances of 90-110 megohms). Precise quantities (100-1000 nl) of a GAL solution (10⁻⁵ M) were applied from a calibrated micropipette positioned adjacent (100 μ m) to the recording electrode. The resting membrane potential and input impedance of cells were monitored during GAL application. GAL caused a dose dependent hyperpolarization and decrease in membrane impedance in all LC neurons tested. Since the hyperpolarization could be reversed in neurons in which the resting potential was held at about -95 mV, it appears that GAL increases K⁺ conductance in these neurons. Further characterization of GAL effects on LC neurons will be reported. In addition, a putative peptide antagonist of 20 amino acids with nM affinity for CNS GAL receptors reversed the GAL induced hyperpolarization. VAP was supported by an NSF (INT-8908720) and a Fogarty (1 F20 TWO 1586-01) post-doctoral fellowship.

EFFECT OF CALCITONIN GENE-RELATED PEPTIDE ON HYPOXIA IN THE RAT HIPPOCAMPUS IN VITRO. F.Z. Wang and A.S. Ding, Dept. of Neurobiology, Institute of Basic Medical Sciences, Beijing 100850, China

The effects of calcitonin gene-related peptide on hypoxia were examined in the rat hippocampal slice. When hippocampal slice was immersed in the superfusing medium with 95%O₂ + 5%CO₂ (normoxic), the field population spike (FPS) was recorded in CA₁ pyramidal cells by stimulating Schaffer collateral pathways. The FPS was gradually abolished following the hypoxia produced by superfusing hypoxia medium with 95%N₂ + 5%CO₂ mixture. At 150ml/min flow of hypoxia mixture the average time when the FPS was initially attenuated and completely abolished were 3.80±1.01 min and 4.90±1.21min respectively (N=27), when the flow was increased to 200 ml/min, the average time were 2.46±0.80min and 4.33±1.54min respectively. While the FPS vanished, its latency extended and its duration increased. In addition, the presynaptic responses disappeared subsequently. When oxygen was recharged the FPS in the most slices (80%) failed to recover after 20 min of hypoxic superfusion. When 4nM β -CGRP-containing medium was superfused to the slice before hypoxia, the time at which FPS began to attenuate and completely abolished were postponed. They were 6.70±3.40 min and 15.96±2.64min respectively. 100% of slices appeared FPS again when they reoxygenated after 20 min of hypoxic and the percentage was 70% when hypoxic exposure lasted 40 min (N=10). Superfusion of CGRP during the period of hypoxia also increased the recovery of FPS.

The results show that the time of FPS's attenuating and vanishing varied according to the degree of hypoxic exposure, therefore, it may be used as a comparable parameter of hypoxia. Also, neuropeptide-CGRP has apparently protective effect when hippocampus was exposed to hypoxia *in vitro*.

A PEPTIDE ANTAGONIST BLOCKS THE SPINAL EFFECT OF INTRATHECAL GALANIN IN RATS

U. Langel¹*, T. Bartfai¹, X.-J. Xu² and Z. Wiesenfeld-Hallin², ¹Dept. of Biochem., Stockholm University, and ² Dept. of Clin. Neurophysiol., Karolinska Institute, Huddinge, Sweden.

The neuropeptide galanin (GAL) applied intrathecally (i.t.) has a complex effect on spinal flexor reflex excitability. At low doses (3 and 30 pmol) i.t. GAL purely facilitates the reflex, whereas at higher doses (300 pmol and 3 nmol), facilitation followed by depression or pure depression occurs (Brain Res., 486, 1989, 205-213). We have presented evidence that GAL, which is present in primary afferents and spinal cord interneurons, acts as a functional antagonist of the excitatory neuropeptides substance P and calcitonin gene-related peptide and blocks the C-afferent conditioning stimulus (CS) induced central facilitation of reflex excitability (Eur. J. Neurosci., 2, 1990, 733-743).

We now report that a peptide antagonist to GAL has been developed. This GAL antagonist applied i.t. at 30 pmol - 3 nmol reduces the facilitatory effect of 30 pmol i.t. GAL on the flexor reflex in a dose-dependent fashion. The inhibitory effect of this dose of GAL on the C-afferent CS-induced central facilitation is also reversed by this GAL antagonist.

Since GAL has a variety of functions in the CNS and other systems, an antagonist of GAL may prove to be experimentally and clinically useful.

ENDOGENOUS GALANIN (GAL) MODULATES THE GONADOTROPIN AND PROLACTIN (PRL) PROESTROUS SURGES IN THE RAT. F.J. López, E.H. Meade, A. Daniels and A. Negro-Vilar. Reproductive Neuroendocrinology Section, LMNI, NIEHS, NIH. Research Triangle Park, NC 27709.

Studies from our laboratory have clearly demonstrated that GAL is secreted to the hypophyseal portal circulation and that plays an important role in controlling gonadotropin secretion by both stimulating LHRH release from nerve terminals of the median eminence and acting directly at the level of the pituitary gland stimulating and enhancing LHRH-induced LH secretion. We have utilized passive immunoneutralization using an anti rat GAL sera raised in sheep in order to evaluate the role of endogenous GAL in the events leading to the preovulatory surges of gonadotropins and PRL. Female rats receiving either 1 ml normal sheep serum (NSS) or GAL antiserum (GAL-AS) i.v. were bled through an indwelling intraatrial cannula at hourly intervals from 1400 to 2300 h on the day of proestrus. GAL-AS administration significantly reduced by 40% the preovulatory LH surge as measured by the area under the curve. Analysis of the time points revealed statistically significant lower LH levels at 1700, 1900 and 2000 h in GAL-AS-treated animals. The FSH surge was not altered (area under the curve and maximum FSH levels) by GAL-AS treatment, although GAL-AS-treated animals presented lower FSH levels at 1700 h. In contrast, the PRL proestrous surge was dramatically reduced by passive immunization against GAL. Statistically significant differences were observed in the area under the curve and at 1700, 1800, 1900, 2000, 2100 and 2200 h in the GAL-AS-treated group. Our results indicate that endogenous GAL participates in mechanisms leading to a full expression of the LH and PRL preovulatory surges.

INHIBITION OF ENDOGENOUS GLUTAMATE AND ASPARTATE RELEASE IN RAT HIPPOCAMPUS BY GALANIN

S. Zini*, M.P. Roisin*, E. Tremblay and Y. Ben-Ari. INSERM U29, 123 boulevard de Port-Royal, 75014 Paris, France.

Galanin, a 29 amino-acid peptide, has potent inhibitory effects in the central nervous system, notably in the hippocampus where it modulates the release of acetylcholine via presynaptic receptors (Fisone, et al., 1987). Since excitatory amino-acids (EAA) play an important role in the synaptic transmission of the hippocampus, we have examined the effect of galanin on endogenous EAA release.

Superfused rat hippocampal slices were used to investigate the effect of galanin in the K^+ -evoked release of endogenous glutamate and aspartate. Preincubation of slices during 15 min with 1 μ M of the (1-16) biologically active galanin fragment reduced the basal efflux of EAA of 20%. The stimulation of the slices by 50 mM K^+ during 6 min induced an increase of the EAA release by 250-300%. In the presence of galanin (1 μ M) K^+ -evoked release of glutamate and aspartate were reduced by 70% and 50% respectively (n = 5), with a half-maximal effective concentration in the nM range.

These results suggest a modulation of EAA release by galanin in the hippocampus. This peptide could constitute a metabolic stress regulator which protects against excessive neurotransmitter release, notably during ischemic situations.

Fisone, G., et al., Proc. Natl. Acad. Sci., 1987, 84, 7339-7343.

THE EFFECT OF ALTERING ADENYLATE CYCLASE ACTIVITY ON THE RESPONSE OF ANTRAL CIRCULAR MUSCLE TO SUBSTANCE P (SP).

H.-S. Feng* and A. Qiyang. Department of Medicine/G.I. Section, University of Pennsylvania, Philadelphia, PA 19104.

SP causes a contractile response in the antral circular muscle in cats. The mechanism of this action is unknown. In this study, the aims were to determine 1) the site of action of SP in the circular muscle and 2) the involvement of the adenylate cyclase system in the action of SP.

Methods: Circular muscle strips from the antrum in cats were mounted in individual muscle bath chambers and attached to force transducers after removal of the mucosa. Contractile responses of the strips to SP and drugs were examined at isometric maximal tension expressed as Grams Force x min/gram tissue \pm SEM. **Results:** SP 10^{-7} M and 10^{-6} M caused a contractile response. Neither atropine (10^{-6} M) nor tetrodotoxin (TTX 10^{-6} M) blocked this response. There was no significant difference between the response to SP 10^{-7} M and to SP after atropine (3.57 ± 0.52 and 4.02 ± 0.71 , n=6), nor between the responses to SP 10^{-6} M with or without atropine (9.37 ± 1.48 and 10.29 ± 0.73 , n=6). Similar responses were seen with TTX. Exposure of muscle strips to forskolin 10^{-5} M significantly increased the response to SP 10^{-7} M from 2.72 ± 0.83 to 10.52 ± 1.44 (n=8, p=0.001). Theophylline 10^{-5} M also increased the response to SP 10^{-7} M from 3.04 ± 1.18 to 14.54 ± 2.91 (n=8, p=0.002). In contrast, 2',3'-dideoxyadenosine 10^{-4} M decreased but did not abolish the response to SP 10^{-7} M from 9.90 ± 1.62 to 2.72 ± 0.83 (n=7, p=0.013). **Conclusions:** SP acts at the antral circular muscle via smooth muscle receptors. In view of the known inhibitory effects of c-AMP on smooth muscle contraction, we postulate that the enhancing effect of increasing c-AMP is mediated via an interacting neural pathway.

HISTAMINE RELEASE INDUCED BY SUBSTANCE P AND CGRP 8-37 FROM RAT PERITONEAL MAST CELLS

K. Tuominen*, H. Uusitalo* and A. Zschauer. Department of Anatomy, Eye Res. Lab., University of Helsinki, Finland

The effect of substance P (SP) and calcitonin gene-related peptide fragment 8-37 (CGRP 8-37) on histamine (HA) release from rat peritoneal mast cells was studied and compared to those of compound 48/80 (C48/80). Rat peritoneal mast cells were incubated 10 min with SP, CGRP 8-37 or C48/80 in normal Tyrode's solution (Na^+ 137 mM) or Na^+ -substituted solutions in the presence (1.5 mM) or absence (+1 mM EGTA) of extracellular calcium ($[Ca^{2+}]_o$). The effects of different Ca^{2+} blockers were studied. HA concentration was assayed enzymatically.

The results demonstrated that 10 μ M SP and CGRP 8-37 in the concentration of 1 μ M induce HA release which is $[Na^+]_o$ -dependent and inhibited by $[Ca^{2+}]_o$, whereas a higher CGRP 8-37 concentration (10 μ M) and C48/80 (5 μ g/ml) induced HA release is dependent on $[Ca^{2+}]_o$ and is not influenced by changes in $[Na^+]_o$.

Supported by TEKES, Helsinki.

EFFECTS OF NEONATAL TREATMENT WITH TYR-MIF-1, MORPHICEPTIN, AND MORPHINE ON DEVELOPMENT, TAIL-FLICK AND BLOOD-BRAIN BARRIER TRANSPORT. W.A. Banks*, J.E. Zadina, L.M. Harrison, M.A. Oleshansky¹, J.W. Holaday¹, and A.J. Kastin. VAMC and Department of Medicine and Neuroscience Training Prog, Tulane U. Sch. of Med, New Orleans, LA 70146 and Walter Reed Army Medical Center.

Morphine (M) and endogenous peptides are known to alter developmental processes, inducing changes that can endure into adulthood. Morphiceptin (Mcp) binds to mu opiate receptors and to non-opiate sites labeled by Tyr-MIF-1 (TM), a brain peptide known to modulate opiate effects. M, Mcp, TM, M+TM, and Mcp+TM (50 μ g, sc) were given to rats during the first week of life. Animals given M alone or in combination with TM had significantly lower body weights for the first 3 weeks of life and reduced eye opening on day 16. Rats given M+TM had hypersensitive tail flick responses on day 3. Locomotor, passive avoidance, and rotorod behaviors were not altered by the neonatal treatments. Brain catecholamines, their metabolites, and Tyr-MIF-1 concentrations were also not altered at day 23. On day 23, transport of ^{125}I -Tyr-MIF-1 out of the brain was significantly increased by neonatal M, an effect significantly potentiated by neonatal TM. These results indicate that neonatal administration of peptides and opiates can affect later peptide transport as well as selected developmental landmarks.

389.16

RELEASE OF FLFQPQRF-NH₂, A MAMMALIAN FMRF-NH₂-LIKE PEPTIDE, FROM RAT SPINAL CORDS BY SUBSTANCE P. J.M. Zhu and H.-Y.T. Yang. Lab. of Biochem. Genetics, NIMH Neuroscience Center at St. Elizabeths, Washington D.C. 20032.

The mammalian FMRF-NH₂-like peptide, FLFQPQRF-NH₂ (NPFF) initially isolated from bovine brain,² was found to reduce rat tail flick latencies and modulate opiate mediated analgesia. NPFF immunoreactive nerve terminals and NPFF receptors are highly localized in superficial laminae of dorsal spinal cords. Previously we have found that NPFF release from rat spinal cords can be evoked by 56 mM KCl. In this study, effects of various transmitters on secretions of NPFF were investigated by *in vitro* superfusions of rat spinal cords. Substance P significantly increased the efflux of NPFF-immunoreactivity from the spinal cord in a dose dependent manner while substance K, noradrenaline, serotonin and morphine failed to show the effect. HPLC analysis of the superfusate after the substance P revealed two NPFF immunoreactive peaks and one of them was eluted in the position of NPFF. These results together with the biological activity and anatomical location of NPFF suggest that NPFF in the spinal cord may have a role in sensory transmission.

390.1

INTERRUPTION OF THE MEDIAL FOREBRAIN BUNDLE (MFB) REDUCES ANGIOTENSIN II RECEPTOR BINDING IN THE RAT FOREBRAIN. R.C. Speth, K.L. Grove, K.N. Stephenson*, W.F. Ganong and M.K. Steele. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520 and Dept. of Physiology, University of California, San Francisco, CA 94143.

Angiotensin II (AII) regulates luteinizing hormone (LH) release in the female rat via its actions on AII receptors (AIIR) in or near the ventral portion of the bed nucleus of the stria terminalis (BSTV) of the brain (Steele, *Neuroendo.* 46:401; Grove et al., *Neuroendo.* 53:339). To determine the cellular structures that contain the AIIR binding sites in the rat forebrain, inputs from the brainstem via the MFB were unilaterally cut with a knife. Two weeks later rats were sacrificed and AIIR binding was determined by *in vitro* receptor autoradiography using [¹²⁵I]-Sar¹,Ile⁸ AII in the piriform cortex (PC), BSTV, medial preoptic n. (MPO), lateral septum (LS), paraventricular n. of the hypothalamus (PVN) and ventrolateral hypothalamus (VLH).

Nucleus	Ipsilat. Side	Contralat. Side.	% Decrease
PC	318±179	423±224	26±13
BSTV	196±80	288±103	30±17*
MPO	381±218	394±217	3±15
LS	241±52	242±54	3±7
PVN	775±403	795±317	6±14
VLH	322±205	371±173	19±19

* p < 0.01 paired t test. Values are mean±SD fmol/g, n = 9

These data suggest that some forebrain AIIR, including those in brain areas that regulate LH release, are in part located presynaptically on the terminals of axons that ascend in the MFB.

390.3

DIFFERENTIAL DRINKING RESPONSES TO CHRONIC INFUSION OF ANGIOTENSIN III IN SPONTANEOUSLY HYPERTENSIVE AND NORMOTENSIVE RATS. Julie Y.H. Chan, Jing-Shiou Yang* and Samuel H.H. Chan. Inst. of Pharmacology, National Yang-Ming Medical College, and Dept. of Medical Research, Veterans General Hospital-Taipei, Taipei, Taiwan, R.O.C.

We evaluated the chronic effect of angiotensin III (AIII) in the elicitation of drinking behavior in spontaneously hypertensive (SH) and normotensive Wistar-Kyoto (WKY) rats, using conscious, freely moving male animals that have been instrumented with an intracerebroventricular (i.c.v.) cannula connected to an osmotic minipump for 7-day application. Chronic infusion of AIII (5 or 10 pmol/min) elicited robust, dose-dependent and Ile⁸-AIII (100 pmol/min, as specific antagonist)-reversible dipsogenesis in both SH and WKY rats. However, the drinking response in the SHR exhibited a sharp decline after 3 days of AIII infusion, during which acute AIII (80 pmol, i.c.v.) challenges also failed to induce dipsogenesis. Chronic i.c.v. infusion of bestatin (150 pmol/min), an aminopeptidase inhibitor, did not by itself discernibly affect basal drinking. When combined with AIII (5 or 10 pmol/min), however, bestatin respectively augmented and suppressed the dipsogenic response of WKY and SH rats to the heptapeptide. These results suggest that chronic administration of AIII did not produce sustained drinking behavior in SHR because of the development of early desensitization of the AIII receptors.

390.5

INVOLVEMENT OF NUCLEUS TRACTUS SOLITARIUS IN ANGIOTENSIN III-INDUCED SUPPRESSION OF BARORECEPTOR REFLEX RESPONSE IN THE RAT. Samuel H.H. Chan, K.S. Lin* and Julie Y.H. Chan. Institute of Pharmacology, National Yang-Ming Medical College, and Department of Medical Research, Veterans General Hospital-Taipei, Taipei, Taiwan, R.O.C.

Previous work from our laboratory suggests that the endogenous angiotensin III (AIII) exerts a tonic inhibitory action on the baroreceptor reflex (BRR) response. The present study further examined the role of the nucleus tractus solitarius (NTS), the terminal site of the baroreceptor afferents, in this process. Adult, male Sprague-Dawley rats anesthetized with pentobarbital sodium were used. Bilateral microinjection of AIII (40 pmol) into the NTS significantly inhibited the BRR response. On the other hand, local application of the specific AIII antagonist, Ile⁸-AIII (1.6 nmol), appreciably augmented the same reflex. In addition, intracerebroventricular administration of AIII (100 pmol) and Ile⁸-AIII (100 nmol) respectively suppressed and enhanced the responsiveness of the arterial pressure-related neurons in the NTS to transient hypertension induced by phenylephrine (5 µg/kg, i.v.). Similar results were obtained when AIII or Ile⁸-AIII was given microtophoretically. Based on these findings, it is possible that neurons which contain AIII may decrease the BRR response by tonically reducing the sensitivity of baroreceptive neurons in the NTS to arterial pressure perturbations.

ANGIOTENSIN RECEPTOR SUBTYPES, WATER INTAKE AND LH AND PROLACTIN SECRETION IN FEMALE RATS. M.K. Steele. Physiology Department, University of California, San Francisco, 94143.

These experiments were done to determine which of the recently identified Ang II receptor subtypes (AT-1 or AT-2) mediates the stimulation of LH secretion, the inhibition of prolactin release and the dipsogenesis induced by third cerebroventricular (icv) administration of Ang II in female rats.

Icv cannulae were implanted at least one week prior to use in experiments. Estradiol benzoate and progesterone were administered 72 h, and a jugular cannula implanted 48 h, prior to the experiment. The animals were non-stressed, conscious and had access to food and water during blood withdrawal. Either artificial cerebrospinal fluid or 10, 50, 100, 500 or 1000 ng of DUP 753 (AT-1 antagonist, Dupont) or of PD 123177 (AT-2 antagonist, Parke Davis) was administered icv, followed 10 minutes later by Ang II (100 ng). Multiple blood samples were taken for determination of plasma LH and prolactin levels. Water intake was also measured.

Ang II-induced water intake was attenuated (65%) by 1000 ng DUP 753; lower doses of DUP and all of the doses of PD had no effect.

Ang II-induced inhibition of prolactin was prevented by 1000 ng of both DUP and PD. The prolactin-reducing effects of Ang II were unaffected by lower doses of either drug.

Ang II-induced stimulation of LH was attenuated in a dose-dependent manner by both DUP and PD: 1000 ng totally abolished the stimulation while 100 ng prevented the rise by about 50%; 10 ng had no effect.

These data demonstrate that water intake induced by Ang II is mediated by the AT-1 receptor subtype. Both AT-1 and AT-2 receptor subtypes mediate the effects of Ang II on LH and prolactin. Ang II-induced LH release shows greater sensitivity than water intake to blockade of the AT-1 receptor.

DRINKING RESPONSE IN RATS TO THE INTRAVENTRICULAR INJECTION OF VARIOUS ANALOGS OF ANGIOTENSIN. D.G. Changaris* L. T. Harrison* and R. S. Levy. Departments of Neurology and Biochemistry and The Laboratory of Biological Psychiatry, University of Louisville School of Medicine, Louisville, Kentucky 40292.

Rats will drink when angiotensin II (AII) is injected into the brain's third ventricle. For the endogenous generation of AII to initiate drinking, the prevailing view is that the hydrolysis of a dipeptide from the decapeptide angiotensin I (AI) by the brain's angiotensin converting enzyme is required. However, we have found that other angiotensin analogs initiate drinking when injected intraventricularly into male Sprague Dawley rats. Des-leu angiotensin I (des-leu AI) initiates a drinking response, but the D-his substituted nonapeptide is not nearly as potent a dipsogen. Similarly, AI initiates a drinking response, but the D-leu substituted decapeptide is not nearly as potent a dipsogen. Since both the AI and des-leu AI responses are blocked by captopril, and since we have found that des-leu AI is not a substrate for converting enzyme, this would indicate the existence of an alternate pathway for the synthesis of AII that requires a two-step hydrolysis of leucine and histidine from AI. Changes in the conformation of the N-terminus by injecting the D-asp substituted des-leu AI does not affect the drinking response. (Supported by NIH-CIDA 5 KO8 SO1164; VA DOD 003; and the Humana Centers of Excellence - Humana Heart Institute International.)

ANGIOTENSIN CONVERTING ENZYME (ACE) AND ANGIOTENSIN II (AT) RECEPTORS ARE REGULATED BY ESTROGEN IN THE ANTERIOR PITUITARY OF THE FEMALE RAT. A.M. Seltzer, F.M.A. Correa, M. Steele and J.M. Saavedra. Section on Pharmacology, Laboratory of Clinical Science, NIMH, Bethesda, MD 20892.

We have studied anterior pituitary ACE and AT receptors during the estrous cycle, in ovariectomized (OVX) rats, and after estrogen replacement (17-β-estradiol, 0.05 mg pellets, s.c., for 1 week). ACE binding was determined by quantitative autoradiography after incubation of pituitary sections with the ACE inhibitor [¹²⁵I]351A. ACE activity was measured by a radioenzymatic method using [¹⁴C]hippuryl-L-histidyl-L-leucine. AT receptors were quantified by autoradiography after incubation of pituitary sections with the AT agonist [¹²⁵I]Sar¹-AT. There were no differences in ACE binding or activity during the estrous cycle. Both the binding to and the activity of ACE were increased in OVX rats when compared to normally cycling animals, and they were both returned to normal after estrogen replacement. Marked differences in AT receptor expression occurred during the estrous cycle, with concentrations highest in the metestrous phase (metestrous>diestrous>estrous>proestrous). OVX produced a large increase in the anterior pituitary AT receptor number, and the AT receptor concentration was markedly reduced after estrogen replacement. Our results indicate a dual regulation of the anterior pituitary AT system by estrogen, both at the level of the peptide synthesis and AT receptor number.

REGIONAL *C-FOS* EXPRESSION IN THE AV3V, HYPOTHALAMUS AND AMYGDALA FOLLOWING INTRAVENTRICULAR ANGIOTENSIN II AND ITS MODULATION BY DRINKING. J. Herbert, S.R. Howes* and P.M. Stacey*, Department of Anatomy, University of Cambridge, CB2 3DY, UK

The release of angiotensin II (AII) both centrally and peripherally has been implicated in the behavioural and physiological response to hypovolaemic stress. A number of sites of action, including the pre-optic area and the so-called 'anterior region of the third ventricle' (AV3V) have been defined by either lesion or local application of AII. We have studied the expression of *c-fos* protein immunohistochemically in the limbic system following intraventricular (icv) infusion of AII to determine the pattern of activation and whether this is altered by allowing the animals to drink. In the first experiment, either 1000 or 250 pmols AII were infused and animals examined 60 minutes later; water was removed during this interval. Both doses induced high levels of *c-fos* expression in a band of neurons extending from the OVLT ventrally through the medial septum to the sub-fornical organ dorsally; that is, corresponding to AV3V. There were also high levels of *c-fos* in the hypothalamic paraventricular nucleus (PVN), principally in the lateral magnocellular group of cells (though some parvocellular areas showed activity) in the supraoptic nucleus (SON), and in the central nucleus of the amygdala. *C-fos* also increased in the ventral BNST. Allowing animals access to water during the 60 minutes following AII infusion modified the pattern of *c-fos* expression. *C-fos* was reduced dramatically in the SON and the magnocellular PVN, but not in the AV3V and the other areas examined. If water was withheld for 15 minutes, and then allowed, *c-fos* expression was not altered. Much greater amounts of 0.9% saline than water were ingested following icv AII, but had no effect on *c-fos* in the PVN or SON. These experiments show that this peptide induces highly localised expression of *c-fos* in areas known to be concerned with its diuretic and endocrine actions, and that this pattern is selectively altered by allowing the animal to drink either hypo- or isotonic solutions.

Ca²⁺ HOMEOSTASIS IN CEREBRAL CORTICAL NEURONS OF EMBRYONIC RAT BRAIN: LACK OF PEPTIDERGIC EFFECT. M.L. Koenig, M.A. DeCoster, and M.A. Oleshansky. Medical Neurosciences Branch, Div. Neuropsych., Walter Reed Army Inst. Research, Wash. DC 20307-5100.

Peptides have been found to be the primary neurotransmitter in some types of neurons and are co-released with "classical" neurotransmitters in many others. Since many peptides have been shown to have neuromodulatory activity, we have investigated the possibility that at least part of the peptidergic effect may be attributable to alterations in intraneuronal Ca²⁺ homeostasis. Cortical neurons were isolated from fetal rat brains, loaded with a membrane-permeable form of the Ca²⁺ indicator fluo-3, and peptide-induced changes in intraneuronal Ca²⁺ were monitored using the ACAS 570 interactive laser cytometer (Meridian Instr., Okemos, MI). Sequential image scans of fields containing 5-10 neurons were used to construct kinetic profiles of peptidergic effects. Identification and verification of the viability of individual neurons was made by exposing the cells to a depolarizing (15 mM) solution of KCl. None of 10 peptides, shown in other studies to have neuromodulatory properties, had any effect on basal or depolarization-dependent levels of free Ca²⁺ over time periods of 5-10 min. The peptides studied (10⁻⁷ to 10⁻⁶ M) were arginine vasopressin, cholecystokinin, corticotropin releasing hormone, neuropeptide Y, neurotensin, somatostatin, thyrotropin releasing hormone, vasoactive intestinal peptide, endothelin, and parathyroid hormone. The possibility that some or all of the peptides may have effects measurable only over longer time periods and/or on receptor-gated Ca²⁺ fluxes is currently being investigated.

COMPARISON OF THE EFFECTS OF SOUND STRESS (SS) WITH THOSE OF INTRACRANIAL CORTICOTROPIN RELEASING FACTOR (CRF) ON RAT BRAIN TRYPTOPHAN HYDROXYLASE (TrpH). K.C. Corley, T.H. Phan* and M.C. Boadle-Biber.

Dept. Physiol., Va Commonwealth University, Richmond, VA 23298.

In the present study, we tested whether repeated intracranial CRF mimics the effect of repeated SS on TrpH activity. An acute, 1-h exposure to SS produces a rapidly reversible increase in cortical and midbrain TrpH activity which can be abolished *in vitro* by incubation with alkaline phosphatase¹. This effect can be mimicked by a single intracranial injection of CRF into the amygdala². In contrast, repeated SS results in increased enzyme activity which is stable for at least 24 h and is unaffected by incubation with alkaline phosphatase, *in vitro*¹. A more detailed examination of the time course of this more stable increase in enzyme activity now reveals that the 85% increase at 24 h was down to 70% at 28 h, 50% at 32 h, 31% at 36 h and had disappeared after 48 h.

The effects of repeated CRF were assessed by the injection on 3 successive days of CRF (0.5 ug/2ul per side) into the amygdaloid central nucleus via bilateral guide cannulae implanted 3 days earlier under surgical anesthesia. The increase in TrpH activity in these animals, sacrificed immediately after the last injection, was alkaline reversible and no different than that obtained from animals after a single CRF injection. Thus the long-lasting increase in TrpH after repeated SS was not observed after repeated injections of CRF, a finding that suggests that this peptide does not play a role in this effect of SS on enzyme activity.

CELLULAR TARGETS FOR PEPTIDERGIC TRANSMISSION IN THE HIPPOCAMPUS. T. Smock, Albeck, D., Cooper, R., Garritano, J., Marrs, J., K., Minerbo, G., and Alvarado, M. Behav. Neurosci. Prog., Dept. of Psych., Univ. of Colorado, Boulder, CO 80309.

A peptide similar in structure to vasopressin or oxytocin acts as a transmitter in the rat hippocampus (*Br. Res.*, 1990, 511: 7 and 15, *Peptides*, 1991, 12: 47 and 53). The peptidergic fibers arise in the amygdala and project mostly to the ventral hippocampus. In this study we sampled CA1 pyramidal cells in both the ventral and the dorsal hippocampus and granule cells in the dentate gyrus to determine the anatomical specificity of responsiveness to the peptide.

With acute single-unit recording techniques and ratemeter analysis we studied six pyramidal cells in ventral CA1 (AP 6.0, ML 5.8, 6.0 deep) and ten cells in dorsal CA1 (AP 4.4, ML 2.9, 2.0 deep). Three of the six ventral pyramidal cells were inhibited following electrical activation of the peptidergic pathway, and seven of the ten dorsal pyramidal cells were inhibited. We made use of the fact that the influence of peptidergic transmission is invariably repeatable within experiments to test for antagonist blockade. The signal in all three ventral units was blocked by a specific anti-oxytocic antagonist and two of three dorsal units tested showed antagonist blockade. To ascertain the responsiveness of granule cells we performed field potential recording in the dentate gyrus, activated the peptidergic pathway, moved to field potential recordings in CA1, and activated it again. In each of three such experiments, peptidergic inhibition was apparent in CA1 but not in the dentate gyrus.

These results indicate that the neural targets of the peptide transmitter include pyramidal cells throughout the hippocampus (and, by inference, interneurons) but do not include granule cells. As for peptidergic transmission in other systems (e.g., ELH in *Aplysia*, LHRH in frog autonomic ganglia), the peptide targets in our system include cells that are close to the sites of release as well as targets that are remote from the sites of release.

INSULIN, GLUCAGON AND SOMATOSTATIN IN THE CONTROL OF ENERGY METABOLISM. J. Menéndez and D. Atrens*. Dept. of Psychology, University of Sydney, NSW 2006, Australia.

Although there is a great deal of information on the effects of insulin, glucagon and somatostatin on carbohydrate, fat and protein metabolism, there is little information on how these peptides modulate thermogenesis and substrate utilisation. The present study analyses the effects on these parameters of systemic injections of insulin (4-8 U/kg), glucagon (25-100 ug/kg) and somatostatin (0.5-10 ug/kg). Energy expenditure (EE) and respiratory quotient (RQ) were respectively used as indices of thermogenesis and energy substrate utilisation. They were calculated in an open-circuit calorimeter from oxygen consumption, carbon dioxide production and locomotor activity. An increase in RQ indicates the preferential combustion of carbohydrates, and even the synthesis of fat from carbohydrate when values are above 1.00. A decrease in RQ indicates the preferential combustion of fat. 4 U/kg insulin had no effect, while 8 U/kg insulin increased both EE and RQ. Glucagon also increased EE and RQ, though in a more clear dose-related manner. Somatostatin decreased RQ and EE. Neither peptide affected locomotor activity which indicates that the effects on EE and RQ represent primary metabolic effects on thermogenesis and substrate utilisation. The conclusions are: 1- Insulin, glucagon and somatostatin are key regulators of thermogenesis and energy substrate utilisation; 2- Insulin and glucagon have similar metabolic roles in terms of thermogenesis and fat deposition (despite well-known opposite effects on carbohydrate metabolism and blood glucose levels); 3- Somatostatin is antithermogenic and fat depleting; these effects add to other reported somatostatin's anti-insulin and anti-glucagon effects. The present data support, therefore, the view of a more complex role for insulin and glucagon. They can no longer be simply considered as anabolic or catabolic in nature. This assertion is further supported by new data showing that the metabolic effects of insulin (Menéndez and Atrens, *Brain Research*, in press) and glucagon (Menéndez and Atrens, in preparation) injected into the paraventricular nucleus of the hypothalamus are opposite to their systemic metabolic effects. IMMUNOCYTOCHEMICAL ANALYSIS OF NEUROPEPTIDE CHANGES IN RAT CEREBROVASCULAR AND DURAL NERVES AFTER EXPERIMENTAL SAH. A.G. ARAND*, L.L. LANKER, W. ZIOCCARILLO*, AND J.T. KELLER. Depts. Neurosurg, U. Cincinnati, The Christ Hosp., J.N.G. Inst. Med. Res and Mayfield Neurol Inst. Cincinnati, OH 45219.

Previous studies have demonstrated the presence of a robust cerebral and dural perivascular neural network containing multiple neurotransmitters/neuropeptides, believed to be involved in the regulation of cerebral blood flow. Changes in the concentration of various neuropeptides after experimental subarachnoid hemorrhage (SAH), due to as yet undefined mechanism(s), has been documented previously in cerebral vessels and recently in the dura mater. The purpose of this study was to simultaneously examine changes in cerebrovascular and dural neuropeptide concentrations after cisternal injection of 0.3 ml of autologous arterial blood (experimental) or 0.3 ml. buffered lactated ringers (sham) in male Sprague-Dawley rats. Changes in calcitonin gene related peptide (CGRP), substance P (SP), and neuropeptide Y (NPY) staining of cerebral and dural vessels were examined and evaluated by independent observers at 6, 24, and 48 hours after SAH. CGRP was reduced in cerebral vessels at 6 hours and returned to normal at 24 hours. In the dura CGRP staining remained unchanged in all time periods. A marked decrease in SP and NPY immunostaining was noted at 6 hrs in cerebral vessels and dura of all animals. SP immunostaining in both tissues returned to control (normal) levels at 48 hours, while NPY staining had not yet reached control levels. The similar changes in experimental and sham SP and NPY animals suggests a general physiologic response eg. increased intracranial pressure to SAH. Furthermore differences of CGRP immunostaining in cerebral versus dural vessels suggests that changes in dural CGRP immunostaining may in part be mediated by a central neural mechanism.

THE EFFECT OF CENTRALLY ADMINISTERED ATRIAL NATRIURETIC POLYPEPTIDE (ANP) ON ANTERIOR PITUITARY HORMONE RELEASE IN RATS. L.A. De Luca Jr., L.Y. Ma*, J.Y. Liu*, Z.M. Qi*, B.Z. Ho*, M.L. Zhang*, S.Q. Xi*, Z.S. Wang*, with advice of E. Stellar and A.N. Epstein. Tianjin Medical College, P.R. China, and University of Pennsylvania.

ANP immunoreactivity is present in many areas of the central nervous system, including anterior pituitary. The possibility of a role for ANP in the control of anterior pituitary prompted us to investigate the effect of ANP on the hormonal release of this gland. Female Sprague-Dawley rats were injected intracerebroventricularly with ANP 2 µg or 4 µg/4µl or vehicle. Twenty minutes after the injections, the animals were decapitated, blood was collected and the pituitaries were rapidly removed. Administration of ANP resulted in a significant dose-related increase in plasma growth hormone (GH) level, and, in contrast, the GH content in the anterior pituitary was significantly reduced by injection of 4 µg ANP. Injection of 2 µg of ANP caused a highly significant plasma increase, and anterior pituitary decrease in prolactin levels. ANP had no effect on serum or anterior pituitary levels of thyroid stimulating hormone, nor did it affect the level of follicle stimulating hormone in the anterior pituitary. These results suggest a role for ANP in the control of anterior pituitary hormone secretion. Further studies are necessary to elucidate the mechanisms of action of ANP on the anterior pituitary and its significance.

NEUROPEPTIDE FF DOES NOT CLEARLY ANTAGONIZE THE EFFECTS OF MORPHINE ON CEREBRAL MONOAMINES. M. Attila, U. Vuorela*, L. Kivipelto*, P. Panula and L. Ahtee. Div. of Pharmacology and Toxicology, Dept. of Pharmacy, and Dept. of Anatomy, Univ. of Helsinki, SF-00170 Helsinki, Finland.

Neuropeptide FF (NFF) isolated from bovine brain attenuates morphine-induced tail-flick latency (Yang et al. Proc.Natl.Acad.Sci.USA 1985;82:7757). Because morphine alters cerebral monoamine metabolism (Ahtee et al. J.Pharmacol. Exp.Ther. 1989;249:303) we have studied the interaction of NFF with morphine on cerebral monoamine metabolism. Male Wistar rats were given 10 mg/kg of morphine or saline (s.c.; 30 min before decapitation) followed by three injections of saline or NFF (10 µg in 20 µl saline) i.c.v. at 30, 20 and 10 min before decapitation. The NFF tended to potentiate the morphine-induced decrease in hypothalamic noradrenaline (NA) as well as the increase of the NA metabolite, sulphated MOPEG. In the caudate putamen NFF attenuated the morphine-induced elevation of the acidic dopamine (DA) metabolites, DOPAC and HVA as well as potentiated the morphine-induced elevation of 5-hydroxytryptamine (5-HT) metabolite 5-HIAA. These results suggest that NFF might attenuate morphine-induced increase in striatal DA turnover, but tends to enhance morphine's effects on NA and 5-HT turnover.

390.14

SIGMA LIGAND (JO 1784) REDUCES CRF-INDUCED INHIBITION OF GASTRIC ACID SECRETION AND GASTRIC EMPTYING IN CONSCIOUS RATS. M. Yoneda, M. Gué, H. Yang and Y. Taché. CURE/VA Medical Center, Dept. of Medicine and Brain Res. Inst., UCLA, Los Angeles, CA 90073.

Sigma binding sites have been characterized most extensively in brain though their presence has also been recognized in several peripheral tissues, including the digestive tract. Sigma ligands recently have been reported to block central CRF-induced colonic motor activation in conscious rats. The aim of this study is to investigate whether a specific interaction between JO 1784, a specific sigma ligand, and CRF can be demonstrated in relation to central CRF-induced alterations of gastric acid secretion and emptying.

Under ether anesthesia rats were injected intracranially (ic) or intravenously (iv) either with saline or JO 1784 (0.05-5 µg ic, 50 µg iv) immediately followed by another ic or iv injection of saline or CRF (5 µg ic, 20 µg iv). The pylorus was ligated and rats were sacrificed 2 h after for measurement of gastric acid secretion. In another experiment, rats were injected ic with saline or JO 1784 (0.5-50 µg) followed by ic saline or CRF (0.6 µg), and then 1.5 ml of a non-caloric solution was given orally and 20 min after rats were sacrificed for measurement of gastric emptying.

JO 1784 (5 µg ic or 50 µg iv) had no effect on basal acid secretion in conscious, pylorus-ligated rats. CRF (5 µg ic or 20 µg iv) inhibited gastric acid secretion by 95 and 90%, respectively. JO 1784 (0.05-0.5 µg ic) reversed dose-dependently ic CRF-induced gastric acid inhibition. The maximum reversal effect of ic JO 1784 (0.5 µg) against ic CRF (5 µg) was 28%. JO 1784 (50 µg iv) against ic CRF (5 µg) and ic JO 1784 (5 µg) against iv CRF (20 µg) had no effect on gastric acid secretion. JO 1784 (0.5-5 µg ic) reversed dose-dependently ic CRF (0.6 µg)-induced gastric emptying inhibition. The maximum reversal effect of ic JO 1784 (5 µg) against ic CRF (0.6 µg) on gastric emptying was 44%. These results suggest that the sigma ligand, JO 1784, acts in the brain to partially abolish the inhibitory effect of central CRF on both gastric acid secretion and gastric emptying in conscious rats.

390.16

NALOXONE INDUCED MODIFICATION OF OXYTOCIN RELEASE FROM SPINAL CORD SYNAPTOSOMAL PREPARATION BY HIGH KCl STIMULUS. M. M. Daddona* and Jaya Haldar. Dept. of Biology, St. John's Univ., Jamaica, NY 11439.

Previous experimentation carried out by our laboratory demonstrated for the first time that high KCl can effectively release oxytocin (OT) from spinal cord (SC) synaptosomal preparations. We have also established that the release pattern varied: 1) between the two pellets which were isolated at different centrifugation speed, 2) among the different SC regions and posterior pituitary of the individual pellets.

Recent experimentation was designed to determine if the secretory process resulting in the various OT release patterns: a) was calcium dependent, b) regulated by endogenous SC opioids. Rat SC was separated into cervical, thoracic and lumbosacral regions. Synaptosomes were prepared in 270 mM buffered sucrose. Samples were collected at 3,100g (pellet 2) and 12,000g (pellet 3). The pellets were incubated for 15 min. in artificial CSF for controls and with 56 mM KCl for stimulus. a) The role of opioid peptides in KCl-induced OT-release from synaptosomal preparations was investigated by the addition of naloxone (2 µM) to both pellets 1 minute prior to the incubation with stimulus solution. b) In studying calcium dependency EGTA was added to all solutions used. OT concentration was determined by radioimmunoassay. Current data demonstrates that the patterns of OT release from SC synaptosomes are increased by the addition of 2µM naloxone to the pellets one minute prior to the application of the high KCl stimulus. Furthermore, it shows that the KCl-induced OT release is calcium dependent. Such findings further support a role for oxytocin as a neurotransmitter. They also suggest the involvement of endogenous opioids in the release of OT from nerve terminals within the spinal cord. (Supported by NIH grant DK-40160)

CATECHOLAMINES: BIOSYNTHESIS II

391.1

EXPRESSION OF DIFFERENT FORMS OF TYROSINE HYDROXYLASE IN MONKEY AND HUMAN BRAIN. D.S. Melchitzky, M.I. Scolieri*, J.W. Haycock and D.A. Lewis. Depts. of Behav. Neurosci. and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15213 and Dept. of Biochem. and Mol. Biol., Louisiana State Univ., New Orleans, LA 70119.

A single gene for tyrosine hydroxylase (TH) gives rise to a single form of TH mRNA in most species. However, in humans alternative splicing produces four distinct TH mRNAs. Translation of these mRNAs into different isoforms of TH has recently been demonstrated in human adrenal medulla (J.W. Haycock, *J Neurochem* 56:2139, 1991). In this study, polyclonal antisera directed against the unique amino acid sequences of the four types of human TH, and antibodies that recognize sequences common to all forms of TH, were used in immunohistochemical and Western analyses to determine the cell specific expression of TH isoforms in human and monkey (*M. mulatta* and *M. fascicularis*) brain and adrenal medulla. The specificity of each antiserum for its target TH isoform was demonstrated in competition experiments in all species. All four isoforms of TH were present in human and monkey adrenal medulla, but only types 1 and 2 were detected in brain. Both TH isoforms were present in most catecholaminergic neurons and processes. However, some structures of the ventral mesencephalon may contain only one TH isoform; dual labeling studies are in progress. These findings demonstrate that at least two isoforms of TH are expressed in human and monkey brain and suggest that additional mechanisms for the regulation of catecholamine biosynthesis may exist in primate brain.

391.2

EFFECT OF ACUTE AND CHRONIC ADMINISTRATION OF NICOTINE ON TYROSINE HYDROXYLASE ACTIVITY IN RAT ADRENAL MEDULLA. A.W. Tank, L.H. Fossom and C. Sterling*. Univ. of Rochester Med. Ctr., Rochester, NY 14642.

A single injection of 2.3 mg/kg nicotine is associated with a 2-3 fold activation of rat adrenal tyrosine hydroxylase (TH). This activation is not blocked by prior administration of 15 mg/kg hexamethonium. A single injection of 2.3 mg/kg nicotine also activates TH in denervated adrenal glands; however, hexamethonium completely blocks this activation in the denervated gland. When rats are repeatedly injected with nicotine (1.0 or 2.3 mg/kg) once every 30 min for 3 hr, adrenal TH activity remains persistently elevated 3-4 fold over controls; however, TH is not activated in denervated adrenal glands 3 hr after repeated injections of nicotine. These results suggest that the systemic administration of nicotine activates adrenal TH by at least two mechanisms: (1) direct stimulation of nicotinic receptors on adrenal chromaffin cells; and (2) stimulation of non-nicotinic receptors on chromaffin cells by neurotransmitters released from the splanchnic nerve. Interestingly, after 3 days of chronic infusion with 48 mg/kg/day nicotine via Alzet osmotic pumps, complex changes occur in the adrenal medulla, such that TH enzyme levels are induced approximately 2-fold and this elevated level of enzyme is activated when the rat is administered a challenge injection of 2.3 mg/kg nicotine. (Supported by DA05014, DA07232 and AHA grant 89-050G).

392.1

NMDA-EVOKED INCREASES IN $[Ca^{2+}]_i$ IN RAT SPINAL CORD NEURONS ARE ENHANCED BY TACHYKININS. K.I. Rusin, D. Bleakman, P.S. Chard, R.J. Miller, and M. Randic. Dept. of Vet. Physiol. Pharmacol., Iowa State Univ., Ames, IA 50011 and Dept. of Pharmacol. Physiol. Sci., Univ. of Chicago, Chicago, IL 60637*.

Tachykinins enhance the responses of rat dorsal horn (DH) neurons to N-methyl-D-aspartate (NMDA) (Neurosci. Lett., 117:74-80, 1990) but the mechanism underlying this effect remains unclear. In order to address this question we have monitored the effects of tachykinins and NMDA on intracellular free Ca^{2+} concentration ($[Ca^{2+}]_i$) in acutely isolated rat DH neurons using Fura-2 based microfluorimetry. The $[Ca^{2+}]_i$ was monitored in single DH neurons perfused with a physiological solution containing no added Mg^{2+} and 0.5 μ M TTX. Drugs were applied rapidly with a large Y-tube to the entire neuron. In confirmation of previous findings NMDA, glutamate (50-100 μ M) and substance P (SP) (2-10nM) by themselves induced increases in the peak $[Ca^{2+}]_i$ in a proportion of DH neurons, whereas neurokinin A (NKA) (2nM) was without effect. The peak of the NMDA-evoked increase in $[Ca^{2+}]_i$ was potentiated up to 285% (in 7 of 8 cells) by 2nM SP applied for periods of 2-4 min, and this effect lasted up to 90 min. Subsequent applications of SP failed to elicit similar increases in the NMDA response. SP had no effect on either 50mM K^+ or kainate (20 μ M)-induced increases in $[Ca^{2+}]_i$. Glutamate-evoked increases in $[Ca^{2+}]_i$ were also enhanced by SP. To determine the subclass of tachykinin receptors involved in the SP effect, we compared the effect of SP, which acts primarily at the NK1 class of tachykinin receptor, with that of NKA which has higher affinity than SP for NK2 and NK3 receptors. We found that in the same DH cells that responded to SP, NKA (2nM) also enhanced the NMDA-evoked increases in $[Ca^{2+}]_i$, suggesting that the responses to the tachykinins are mediated by the activation of both NK1 and NK2 receptors. These results provide direct evidence that tachykinins enhance NMDA evoked increases in $[Ca^{2+}]_i$ in spinal cord neurons. (Supported by NIH and NSF).

392.3

NMDA-EVOKED RELEASE OF ENDOGENOUS ADENOSINE FROM THE RAT HIPPOCAMPUS IN VIVO. Y. Chen* and T.W. Stone, Dept. of Pharmacology, Glasgow University, Glasgow, U.K. G12 8QQ (Spon. Brain Research Association, U.K.)

Adenosine (Ado), as an inhibitory neuromodulator in the CNS, exhibits a role in protecting neurons from excitotoxicity and ischaemia. To assess the endogenous release of Ado during abnormal neuronal excitation, in vivo microdialysis was employed, using a probe implanted in the ventral hippocampus of an anaesthetized rat. Ado was analyzed on HPLC with UV detection. Perfusion of NMDA (0.1-25mM), K^+ (100mM) and veratridine (100 μ M) for 5min evoked a 2-15 fold increase of the purines from the basal level. Incorporation of verapamil (100 μ M), Cd^{++} (300 μ M) did not alter the basal release, although they attenuated the evoked release, suggesting a Ca^{++} -independent releasable pool of Ado. The NMDA evoked release was dose-dependent, and was completely blocked by APV. In addition, much of the K^+ evoked response was also prevented by APV. The results demonstrate the endogenous release of Ado from the hippocampus by neuroexcitants, and also indicate a large contribution of NMDA receptors to the release.

MECHANISM OF CRF DEPRESSION OF QUISQUALTE RESPONSE IN CULTURED CEREBELLAR PURKINJE NEURONS. E.A. Fox and D.L. Gruol. Res. Inst. of the Scripps Clinic, La Jolla, CA, 92037.

We previously showed that corticotrophin-releasing-factor (CRF) depressed quisqualate (Quis)-induced biphasic responses (increased firing rate followed by decreased firing rate and then recovery) in rat cerebellar Purkinje neurons (PNs; Neurosci. Abst. 16:521, 1990). In the present study intracellular recordings were used to determine whether CRF depressed the Quis-induced increase in firing rate by preventing the underlying membrane depolarization. CRF effects on PN membrane properties were also examined.

The major findings were that CRF did not decrease the Quis-induced membrane depolarization and that CRF prevented the repetitive spiking induced by depolarizing current steps. CRF also decreased the amplitude of the off response evoked at the termination of a hyperpolarizing current pulse and the afterhyperpolarization evoked at the termination of a depolarizing pulse. CRF antagonists (CRF (9-41) and CRF (12-41)) applied in combination with CRF did not block these CRF effects and applied alone acted as partial agonists.

These results suggest that CRF depresses the PN response to Quis by altering a conductance that contributes to spike generation. We are currently studying this with voltage clamp recording and calcium imaging. The significance of CRF suppression of excitatory-amino-acid responses in PNs may be that it contributes to the long term depression observed at the parallel fiber-PN synapse after repeated pairing of parallel and climbing fiber activation. Grant #NS21777 and #AA0756.

MODULATION OF NMDA-INDUCED CURRENTS BY SUBSTANCE P: EFFECTS OF SPANTIDE II AND GLYCINE. M. Randic, K.I. Rusin, and P.D. Ruy. Dept. of Vet. Physiology and Pharmacology, Iowa State University, Ames, IA 50011.

In acutely isolated spinal dorsal horn neurons of the rat, SP enhances N-methyl-D-aspartate (NMDA)-induced current responses recorded under whole-cell voltage-clamp conditions (Neurosci. Lett., 117:74-80 1990). Molecular mechanisms underlying the SP effect have yet to be elucidated. We have used a novel tachykinin antagonist spantide II (D-NicLys¹, 3-Pal³, D-Ci²Phe², Asn⁶, D-Trp^{7,9}, Nle¹¹-SP), glycine and 7-chlorokynurenic acid to examine the possibility that the modulation of the NMDA-induced current by SP may involve interaction of the tachykinin receptors with the strychnine-insensitive glycine binding site located at the NMDA receptor-ion channel complex. Glycine is thought to act either as a co-agonist or a regulator of the rate of desensitization of NMDA receptors. Spantide II (10nM) co-administered with NMDA (100 μ M) slightly depressed the NMDA-induced current (86.3 \pm 2.9%, n=11), but effectively blocked the SP (2nM)-induced potentiation of the responses of dorsal horn neurons to NMDA (n=6). In the presence of glycine (0.1 μ M), the SP-evoked increase of the NMDA-induced current was prevented (n=18). 7-Chlorokynurenic acid (2 μ M), a competitive antagonist at the glycine modulatory site of the NMDA receptor, led to a re-establishment of the SP effect. These results are consistent with a possibility that tachykinins might directly modulate the NMDA receptor-ion channel complex, either by interacting with the regulatory site(s) or by acting through a distinct cellular site. (Supported by NS 26352 and BNS 841 8042).

392.4

EFFECT OF LUTEINIZING HORMONE-RELEASING HORMONE ON IN VIVO RELEASE OF NEUROTRANSMITTERS FROM THE RAT HIPPOCAMPUS. M. Shimoyama, R. Miyoshi and S. Kito. University of the Air, Chiba 260, Japan and Department of Pharmacology, Tokyo Women's Medical College, Tokyo 162, Japan.

The function of luteinizing hormone-releasing hormone (LHRH) of the hypothalamus is well documented and the mechanism of its action is fully understood. However, the role of LHRH being played in the central nervous system is yet unclear. It has been reported that the hippocampus contains the highest density of LHRH receptors of the brain, while LHRH immunoreactivities are by no means rich in this brain area. To elucidate the role of LHRH in the hippocampus, we investigated the effect of LHRH on neurotransmitter release from the rat hippocampus using an intracerebral dialysis technique in combination with HPLC and an electrochemical detector.

LHRH was dissolved in perfusion medium and administered into the rat hippocampus via a dialysis tube. LHRH had no effect on the levels of acetylcholine₆ in hippocampal perfusates. In contrast, LHRH (10^{-5} , 10^{-6} M) caused a significant decrease of levels of glutamate (-37, -34%, respectively, $p < 0.05$).

It was assumed that LHRH was playing a role in the hippocampal function by interacting with the glutamatergic system.

NOREPINEPHRINE ALTERS MEMBRANE RESPONSES OF LAYER V CORTICAL NEURONS TO EXCITATORY SYNAPTIC INPUTS. R.D. Mouradian, F.M. Sessler, B.J. Gwag, J.E. Springer and B.D. Waterhouse. Depts. of Physiol. & Biophys. and Neurology, Hahnemann Univ., Phila., PA, 19102-1192

Previous studies from our laboratory indicate that under *in vivo* conditions subliminal synaptic inputs to sensory cortical neurons can be "gated" by norepinephrine (NE). Under *in vitro* conditions, locally applied NE can reveal robust excitatory responses of somatosensory cortical neurons to otherwise subthreshold iontophoretic doses of glutamate or NMDA. The present study was conducted to examine the effects of NE on synaptically-evoked membrane responses of layer V somatosensory cortical neurons. Intracellular recordings were made from a submerged brain slice preparation. Excitatory post-synaptic potentials (EPSPs) were evoked via a bipolar stimulating electrode (0.02-0.5 mA, 0.05-0.2 ms) placed in the cortical white matter. Experiments were performed under current clamp conditions to control for small depolarizations (1-4 mV) that sometimes accompany bath application of NE. The amplitude of EPSPs evoked by stimuli which were subthreshold for spike generation were increased during bath application of NE (10 μ M). In many instances the probability of spiking in response to otherwise subthreshold stimuli was markedly enhanced during NE at 10 μ M. By contrast, a higher concentration of NE (100 μ M) reversibly suppressed both EPSP amplitude and spiking evoked by synaptic stimulation. In several experiments stimulus-evoked spiking and EPSPs could be partially antagonized by bath application of the NMDA receptor blocker, 2-amino 5-phosphonovaleric acid (APV, 50 μ M), suggesting that the pathway activated was glutamatergic. These results provide further support for the possibility that noradrenergically activated mechanisms can regulate the threshold for spike generation in neocortical neurons. Since, NE-induced enhancement of membrane responsiveness to synaptic input was observed under current clamp conditions and at levels of stimulation subthreshold for evoking spikes, the mechanism(s) underlying this facilitation seem unlikely to be dependent upon membrane depolarization or blockade of accommodation. A possibility that is under investigation is that these effects involve direct actions on spike generating mechanisms and/or presynaptic release. Overall, these results suggest that noradrenergic enhancement of cortical neuronal excitability may be expressed as a shift in the ability of the membrane to respond to excitatory synaptic stimuli. (Supported by AFOSR-87-0138, NINCDS 18081 and Klingenstein Foundation award to B.D.W.)

TEMPORAL CHANGES IN TYROSINE HYDROXYLASE (TH) mRNA LEVELS FOLLOWING ELECTRICAL STIMULATION (ES) OF A1-NORADRENERGIC NEURONS. J.-J. Liaw, J.-R. He and C.A. Barraclough. Dept. Physiology, Sch. Med., Univ. Maryland, Baltimore, MD 21201.

TH is the rate limiting enzyme for synthesis of norepinephrine (NE) and stimuli which release NE also may increase TH mRNA. To establish, further, whether the increased release of hypothalamic NE is accompanied by an increase in TH mRNA levels, we electrically activated A1 neurons using stimuli which increase NE release. The following groups were studied: unstimulated or sham-stimulated controls and ES rats. All sham or ES male rats were anesthetized with chloral hydrate, and a coaxial electrode was stereotaxically inserted into the right medullary A1 region. In the sham group, no stimulation was performed, whereas, other rats received 20 min of ES in the right A1 area. TH mRNA levels were measured in untreated controls and 1, 6 and 12 h after sham or ES. *In situ* hybridization was performed and message levels were analyzed by quantitative image analysis. TH mRNA levels in untreated and sham-stimulated controls did not differ at anytime time period nor did mRNA levels in right versus left A1 regions. One hour after ES, TH mRNA levels had increase in right but not left A1 cells. By 6 h, TH mRNA levels were significantly higher in right A1 neurons compared to 0 or 1 h values and a small increase in message had occurred in left A1 cells. Twelve hours after ES, TH mRNA levels remained high but did not differ from 6 h values on either right or left side of brain. Thus, stimuli which activate NE release also increase transcription of TH mRNA. HD-02138.

THE EFFECT OF CHRONIC HALOPERIDOL ADMINISTRATION ON TYROSINE HYDROXYLASE (TH) ACTIVITY, mRNA, AND PROTEIN LEVELS. H.M. Hallak, A.J. Azzaro, K.E. Vrana. Depts. Biochemistry and Neurology, West Virginia University HSC, Morgantown, WV 26506.

The nigrostriatal dopamine (DA) pathway has an important function in regulation of normal motor control. Administration of DA receptor antagonists is known to alter DA synthesis presumably through the rate-limiting TH-catalyzed step. This study was designed to determine the effect of haloperidol (a DA receptor antagonist) on TH activity, TH protein and TH mRNA levels in the substantia nigra (SN) and TH activity and protein in the corpus striatum (CS) of rats. After 21 days of haloperidol administration (1mg/kg/day s.c.), TH mRNA in the SN increased five fold in comparison to control. TH activity and TH protein was not changed significantly from control in the SN or CS. Experiments performed with polysomes showed that this increase in TH mRNA was not reflected in an increase in mRNA bound to ribosomes. This suggests that a translational-block may be an additional mechanism for the regulation of DA synthesis in the CNS. (Supported by NIH #GM-38931).

CULTURE OF E14 MESENCEPHALIC DOPAMINERGIC CELLS: A HIGH YIELD OF TYROSINE HYDROXYLASE POSITIVE CELLS. K. Shimoda and J.W. Commissiong. Lab. Biochem. Gen., Center for Neurosci., St.Eliz. Hosp. Washington, D.C. 20032. and NIH-NINDS-CNB, Bldg.10/5N214, Bethesda, MD. 20892.

In the E14 rat brain, a <2.0 mm³, region of the ventral mesencephalon, containing > 90% of the DA, was dissected, pooled in oxygenated culture medium (DMEM/F12 1:1, 10% FCS, 4 mM glutamine), and mechanically dispersed. Cell viability, was 65-75%. 5.0 x 10⁵ Cells/well, were cultured in 8-well chamber slides (Lab-Tek) coated with poly-D-lysine. At 1, 3, 5, 7, 10 and 14 days after plating, the cells were immunostained with a mouse primary tyrosine hydroxylase (TH) monoclonal antibody (Boehringer-Mannheim), and an FITC-conjugated secondary antibody, raised against mouse IgG. The % of TH +ve cells at the days listed above was 4.1, 5.0, 4.8, 8.0, 9.1 and 6.9 respectively. Treatment of the cells with a rat striatal extract, caused a significant (p<0.01) increase in the % of TH +ve cells at 3 and 5 days, but not at 7 and 10 days. This procedure can be used to make cultures with >5% TH +ve dopaminergic cells, at 5 to 10 days after plating, for a variety of studies.

DIFFERENTIAL REGULATION OF LOCUS COERULEUS (LC) LEVELS OF TYROSINE HYDROXYLASE (TH) BY CHRONIC STRESS AND ANTIDEPRESSANT TREATMENT IN TWO DIFFERENT STRAINS OF RATS. K.R. Melia and R.S. Duman. Laboratory of Molecular Psychiatry, Dept. of Psychiatry, Yale Univ. School of Med., New Haven CT 06508.

The tendency for stress to precipitate and/or exacerbate major depression is widely accepted. However, the literature supporting this relationship is inconsistent. Such inconsistencies might result from genetically based individual differences in vulnerability to the deleterious effects of stress.

Previous studies have identified LC TH as a common site of regulation by chronic stress and antidepressant treatments. In the present experiments we investigated the effects of chronic cold stress or chronic imipramine (a tricyclic antidepressant) on LC levels of TH in two different strains of outbred rats: Sprague Dawley and Wistar (Camm). While chronic stress produced a significant increase of 34% (p < .03) in LC TH of Sprague Dawleys, chronic stress had no effect on LC TH in Wistar rats. Chronic imipramine treatment produced a significant 44% (p < .005) decrease in LC levels of TH in Sprague Dawleys, but had no effect on LC TH in Wistar rats. Consistent with these biochemical data, behavioral studies using the Porsolt swim test revealed differences in basal rates of immobility between the two rat strains. More importantly, imipramine produced an expected 66% decrease in immobility in Sprague Dawley rats (p < .05), but had no effect on immobility in Wistar rats.

The present experiments demonstrate a differential effect of chronic stress and antidepressant treatment on the neurochemistry and behavior of two different strains of rats. These findings, together with clinical studies implicating the noradrenergic system in responses to stress and major depression, raise the possibility that variation in the responsivity of this system to perturbations may underly individual differences in vulnerability to stress-related psychiatric disorders.

391.12

TYROSINE HYDROXYLASE (TH) mRNA IS TRANSIENTLY DECREASED FOLLOWING CHRONIC SELEGILINE (DEPRENYL) ADMINISTRATION IN RAT BRAIN. S.L. Vrana, A.J. Azzaro and K.E. Vrana. Depts. of Behavioral Medicine/Psychiatry, Neurology and Biochemistry, West Virginia Univ., Morgantown, WV 26506.

Selegiline, a selective monoamine oxidase type B (MAO-B) inhibitor, decreases TH activity in the rat nigrostriatal (NS) pathway. Selegiline administration (0.1 mg/kg s.c.) for 3, 7, 14 or 21 days decreased TH activity in the terminal fields (corpus striatum; CS) of the dopamine-containing NS pathway, which recovered by 14 days. TH activity was decreased in the cell bodies (substantia nigra; SN) of the NS pathway throughout the entire treatment period. We tested whether the decrease in TH activity was mediated by a decrease in TH mRNA. Northern blot and RNA dot blot analyses (using a TH-specific cDNA probe) of SN homogenates revealed a significant decrease in TH mRNA at 3, 7 and 14 days of selegiline treatment as compared with controls. Conversely, after 21 days of selegiline, TH mRNA levels were significantly higher (3-fold) than controls which was not reflected in SN TH activity. It is possible that the recovery in TH activity in CS is a result of increased TH protein transport from the SN to the CS, or that TH exists in a more stabilized state.

392.1

NMDA-EVOKED INCREASES IN $[Ca^{2+}]_i$ IN RAT SPINAL CORD NEURONS ARE ENHANCED BY TACHYKININS. K.I. Rusin, D. Bleakman, P.S. Chard, R.J. Miller, and M. Randic. Dept. of Vet. Physiol. Pharmacol., Iowa State Univ., Ames, IA 50011 and Dept. of Pharmacol. Physiol. Sci., Univ. of Chicago, Chicago, IL 60637*.

Tachykinins enhance the responses of rat dorsal horn (DH) neurons to N-methyl-D-aspartate (NMDA) (Neurosci. Lett., 117:74-80, 1990) but the mechanism underlying this effect remains unclear. In order to address this question we have monitored the effects of tachykinins and NMDA on intracellular free Ca^{2+} concentration ($[Ca^{2+}]_i$) in acutely isolated rat DH neurons using Fura-2 based microfluorimetry. The $[Ca^{2+}]_i$ was monitored in single DH neurons perfused with a physiological solution containing no added Mg^{2+} and 0.5 μ M TTX. Drugs were applied rapidly with a large Y-tube to the entire neuron. In confirmation of previous findings NMDA, glutamate (50-100 μ M) and substance P (SP) (2-10nM) by themselves induced increases in the peak $[Ca^{2+}]_i$ in a proportion of DH neurons, whereas neurokinin A (NKA) (2nM) was without effect. The peak of the NMDA-evoked increase in $[Ca^{2+}]_i$ was potentiated up to 285% (in 7 of 8 cells) by 2nM SP applied for periods of 2-4 min, and this effect lasted up to 90 min. Subsequent applications of SP failed to elicit similar increases in the NMDA response. SP had no effect on either 50mM K^+ or kainate (20 μ M)-induced increases in $[Ca^{2+}]_i$. Glutamate-evoked increases in $[Ca^{2+}]_i$ were also enhanced by SP. To determine the subclass of tachykinin receptors involved in the SP effect, we compared the effect of SP, which acts primarily at the NK1 class of tachykinin receptor, with that of NKA which has higher affinity than SP for NK2 and NK3 receptors. We found that in the same DH cells that responded to SP, NKA (2nM) also enhanced the NMDA-evoked increases in $[Ca^{2+}]_i$, suggesting that the responses to the tachykinins are mediated by the activation of both NK1 and NK2 receptors. These results provide direct evidence that tachykinins enhance NMDA evoked increases in $[Ca^{2+}]_i$ in spinal cord neurons. (Supported by NIH and NSF).

392.3

NMDA-EVOKED RELEASE OF ENDOGENOUS ADENOSINE FROM THE RAT HIPPOCAMPUS IN VIVO. Y. Chen* and T.W. Stone, Dept. of Pharmacology, Glasgow University, Glasgow, U.K. G12 8QQ (Spon. Brain Research Association, U.K.)

Adenosine (Ado), as an inhibitory neuromodulator in the CNS, exhibits a role in protecting neurons from excitotoxicity and ischaemia. To assess the endogenous release of Ado during abnormal neuronal excitation, in vivo microdialysis was employed, using a probe implanted in the ventral hippocampus of an anaesthetized rat. Ado was analyzed on HPLC with UV detection. Perfusion of NMDA (0.1-25mM), K^+ (100mM) and veratridine (100 μ M) for 5min evoked a 2-15 fold increase of the purines from the basal level. Incorporation of verapamil (100 μ M), Cd^{++} (300 μ M) did not alter the basal release, although they attenuated the evoked release, suggesting a Ca^{++} -independent releasable pool of Ado. The NMDA evoked release was dose-dependent, and was completely blocked by APV. In addition, much of the K^+ evoked response was also prevented by APV. The results demonstrate the endogenous release of Ado from the hippocampus by neuroexcitants, and also indicate a large contribution of NMDA receptors to the release.

MECHANISM OF CRF DEPRESSION OF QUISQUALTE RESPONSE IN CULTURED CEREBELLAR PURKINJE NEURONS. E.A. Fox and D.L. Gruol. Res. Inst. of the Scripps Clinic, La Jolla, CA, 92037.

We previously showed that corticotrophin-releasing-factor (CRF) depressed quisqualate (Quis)-induced biphasic responses (increased firing rate followed by decreased firing rate and then recovery) in rat cerebellar Purkinje neurons (PNs; Neurosci. Abst. 16:521, 1990). In the present study intracellular recordings were used to determine whether CRF depressed the Quis-induced increase in firing rate by preventing the underlying membrane depolarization. CRF effects on PN membrane properties were also examined.

The major findings were that CRF did not decrease the Quis-induced membrane depolarization and that CRF prevented the repetitive spiking induced by depolarizing current steps. CRF also decreased the amplitude of the off response evoked at the termination of a hyperpolarizing current pulse and the afterhyperpolarization evoked at the termination of a depolarizing pulse. CRF antagonists (CRF (9-41) and CRF (12-41)) applied in combination with CRF did not block these CRF effects and applied alone acted as partial agonists.

These results suggest that CRF depresses the PN response to Quis by altering a conductance that contributes to spike generation. We are currently studying this with voltage clamp recording and calcium imaging. The significance of CRF suppression of excitatory-amino-acid responses in PNs may be that it contributes to the long term depression observed at the parallel fiber-PN synapse after repeated pairing of parallel and climbing fiber activation. Grant #NS21777 and #AA0756.

392.2

MODULATION OF NMDA-INDUCED CURRENTS BY SUBSTANCE P: EFFECTS OF SPANTIDE II AND GLYCINE. M. Randic, K.I. Rusin, and P.D. Ruy. Dept. of Vet. Physiology and Pharmacology, Iowa State University, Ames, IA 50011.

In acutely isolated spinal dorsal horn neurons of the rat, SP enhances N-methyl-D-aspartate (NMDA)-induced current responses recorded under whole-cell voltage-clamp conditions (Neurosci. Lett., 117:74-80 1990). Molecular mechanisms underlying the SP effect have yet to be elucidated. We have used a novel tachykinin antagonist spantide II (D-NicLys¹, 3-Pal³, D-Ci²Phe², Asn⁶, D-Trp^{7,9}, Nle¹¹-SP), glycine and 7-chlorokynurenic acid to examine the possibility that the modulation of the NMDA-induced current by SP may involve interaction of the tachykinin receptors with the strychnine-insensitive glycine binding site located at the NMDA receptor-ion channel complex. Glycine is thought to act either as a co-agonist or a regulator of the rate of desensitization of NMDA receptors. Spantide II (10nM) co-administered with NMDA (100 μ M) slightly depressed the NMDA-induced current (86.3 \pm 2.9%, n=11), but effectively blocked the SP (2nM)-induced potentiation of the responses of dorsal horn neurons to NMDA (n=6). In the presence of glycine (0.1 μ M), the SP-evoked increase of the NMDA-induced current was prevented (n=18). 7-Chlorokynurenic acid (2 μ M), a competitive antagonist at the glycine modulatory site of the NMDA receptor, led to a re-establishment of the SP effect. These results are consistent with a possibility that tachykinins might directly modulate the NMDA receptor-ion channel complex, either by interacting with the regulatory site(s) or by acting through a distinct cellular site. (Supported by NS 26352 and BNS 841 8042).

392.4

EFFECT OF LUTEINIZING HORMONE-RELEASING HORMONE ON IN VIVO RELEASE OF NEUROTRANSMITTERS FROM THE RAT HIPPOCAMPUS. M. Shimoyama, R. Miyoshi and S. Kito. University of the Air, Chiba 260, Japan and Department of Pharmacology, Tokyo Women's Medical College, Tokyo 162, Japan.

The function of luteinizing hormone-releasing hormone (LHRH) of the hypothalamus is well documented and the mechanism of its action is fully understood. However, the role of LHRH being played in the central nervous system is yet unclear. It has been reported that the hippocampus contains the highest density of LHRH receptors of the brain, while LHRH immunoreactivities are by no means rich in this brain area. To elucidate the role of LHRH in the hippocampus, we investigated the effect of LHRH on neurotransmitter release from the rat hippocampus using an intracerebral dialysis technique in combination with HPLC and an electrochemical detector.

LHRH was dissolved in perfusion medium and administered into the rat hippocampus via a dialysis tube. LHRH had no effect on the levels of acetylcholine₆ in hippocampal perfusates. In contrast, LHRH (10^{-5} , 10^{-6} M) caused a significant decrease of levels of glutamate (-37, -34%, respectively, $p < 0.05$).

It was assumed that LHRH was playing a role in the hippocampal function by interacting with the glutamatergic system.

NOREPINEPHRINE ALTERS MEMBRANE RESPONSES OF LAYER V CORTICAL NEURONS TO EXCITATORY SYNAPTIC INPUTS. R.D. Mouradian, F.M. Sessler, B.J. Gwag, J.E. Springer and B.D. Waterhouse. Depts. of Physiol. & Biophys. and Neurology, Hahnemann Univ., Phila., PA, 19102-1192

Previous studies from our laboratory indicate that under *in vivo* conditions subliminal synaptic inputs to sensory cortical neurons can be "gated" by norepinephrine (NE). Under *in vitro* conditions, locally applied NE can reveal robust excitatory responses of somatosensory cortical neurons to otherwise subthreshold iontophoretic doses of glutamate or NMDA. The present study was conducted to examine the effects of NE on synaptically-evoked membrane responses of layer V somatosensory cortical neurons. Intracellular recordings were made from a submerged brain slice preparation. Excitatory post-synaptic potentials (EPSPs) were evoked via a bipolar stimulating electrode (0.02-0.5 mA, 0.05-0.2 ms) placed in the cortical white matter. Experiments were performed under current clamp conditions to control for small depolarizations (1-4 mV) that sometimes accompany bath application of NE. The amplitude of EPSPs evoked by stimuli which were subthreshold for spike generation were increased during bath application of NE (10 μ M). In many instances the probability of spiking in response to otherwise subthreshold stimuli was markedly enhanced during NE at 10 μ M. By contrast, a higher concentration of NE (100 μ M) reversibly suppressed both EPSP amplitude and spiking evoked by synaptic stimulation. In several experiments stimulus-evoked spiking and EPSPs could be partially antagonized by bath application of the NMDA receptor blocker, 2-amino 5-phosphonovaleric acid (APV, 50 μ M), suggesting that the pathway activated was glutamatergic. These results provide further support for the possibility that noradrenergically activated mechanisms can regulate the threshold for spike generation in neocortical neurons. Since, NE-induced enhancement of membrane responsiveness to synaptic input was observed under current clamp conditions and at levels of stimulation subthreshold for evoking spikes, the mechanism(s) underlying this facilitation seem unlikely to be dependent upon membrane depolarization or blockade of accommodation. A possibility that is under investigation is that these effects involve direct actions on spike generating mechanisms and/or presynaptic release. Overall, these results suggest that noradrenergic enhancement of cortical neuronal excitability may be expressed as a shift in the ability of the membrane to respond to excitatory synaptic stimuli. (Supported by AFOSR-87-0138, NINCDS 18081 and Klingenstein Foundation award to B.D.W.)

ACTIONS OF SEROTONIN ON GLUTAMATERGIC SYNAPTIC TRANSMISSION IN LAYERS III AND IV OF RAT BARRELFIELD CORTEX. W. Liu, F.M. Sessler, C.S. Lin and B.D. Waterhouse, Dept. Physiol and Biophys. Hahnemann Univ., Phila., PA 19102

Serotonin (5-HT) containing neurons in the dorsal raphe nucleus are the source of an extensive network of fibers that are found in all regions and all layers of the neocortex. Despite the well documented anatomy of this cortical serotonergic innervation, the potential impact of 5-HT release on heterogeneous populations of neurons in functionally distinct regions of the cortex is unclear. In the present investigation we have examined the effects of 5-HT on amino acid neurotransmitter-induced and synaptically-evoked responses of cortical neurons in the "barrelfield" region of rat somatosensory cortex. Both intra- and extracellular recordings were made from cortical neurons in layers III and IV using a submerged *in vitro* brain slice preparation. Excitatory postsynaptic potentials (EPSPs) were evoked in cells by stimulating the cortical white matter (0.04-0.5mA, 0.1-0.2ms). In all cases, EPSPs displayed conventional voltage-dependence, being increased with membrane hyperpolarization and decreased with membrane depolarization. Bath application of 5-HT (30µM) reversibly suppressed the amplitude and duration of these EPSPs and abolished the action potentials induced by EPSPs which were otherwise suprathreshold for spike generation. 5-HT also reduced the membrane depolarizing effect of locally applied glutamate. In each of these experimental situations, resting membrane potential and rheobase were unchanged during 5-HT perfusion. Under extracellular recording conditions, microiontophoretic application of 5-HT at ejection currents (5-20nA), which caused little or no suppression of background firing, produced marked suppression of glutamate-evoked excitatory discharges. Similar suppressant effects were observed when 5-HT was interacted with excitatory neuronal responses to NMDA, kainate or quisqualate. Our results indicate that 5-HT can suppress glutamate-evoked excitatory responses of somatosensory cortical neurons without directly changing membrane excitability. These data are consistent with the hypothesis that serotonergic afferents to the neocortex may play a role in regulating the flow of sensory information through local sensory circuits by way of an action on glutamatergic synaptic transmission. (Supported by AFOSR 870138 and an award from the Klingenstein Foundation to BDW)

EPINEPHRINE FACILITATES GLUTAMATE-INDUCED RESPONSES IN ACUTELY DISSOCIATED FROG MOTONEURONS. S. Adachi*, J.I. Oka, T. Nagao* and H. Fukuda*. Dept. of Toxicology and Pharmacology, Fac. of Pharmaceutical Sciences, Univ. of Tokyo, Tokyo 113, JAPAN.

Epinephrine (Epi) functions as the major catecholaminergic neurotransmitter in frogs, and has been reported to augment spinal reflexes. We previously reported that Epi causes slow depolarization with an increase and a decrease in input resistance by suppression of K⁺-conductances via α₁-adrenergic receptor and induction of Na⁺-dependent inward current via β-adrenergic receptor, respectively, in a single motoneurons dissociated from frog. The purpose of this study was to elucidate the modulating effects of Epi on the responsiveness of motoneurons to glutamate (Glu). Whole-cell patch clamp technique was applied to the motoneurons acutely dissociated from adult bullfrogs (*Rana catesbeiana*) with trypsin and collagenase. Motoneurons were identified by retrograde labelling with Evance blue. Epi (10⁻⁶M) facilitated Glu (3x10⁻⁴M)-, quisqualate (Qui, 3x10⁻⁵M)- or kainate (Kai, 10⁻⁵M)-induced depolarization. At the holding potential of -70 mV, Epi augmented Glu-induced inward currents, but did not affect Qui- or Kai-induced inward currents. These results suggest that Epi facilitates the responses of motoneurons to Glu through modulation of passive membrane electrical properties of motoneurons and through direct enhancement of Glu-, presumably NMDA-, induced currents.

392.11

GLUTAMATE RELEASES HYPOTHALAMIC NOREPINEPHRINE: II MODULATION BY 5-HT. J. Goldfarb, P. Blandina, D. Johnson*, J. Walcott* and J. P. Green, Department of Pharmacology, Mount Sinai School of Medicine, City University of New York, N. Y., N. Y. 10029

Hypothalamic slices (400 µ) from male Sprague-Dawley rats (200 g) were perfused with a Mg²⁺-free medium containing nomifensine (10 µM) and tyrosine (50 µM). Spontaneous release of endogenous norepinephrine (NE), measured by HPLC-ECD after alumina extraction, averaged 0.1 pmol/3min/mg protein. Glutamate (GLU) (1 mM) more than doubled the rate of NE release, presumably by activation of NMDA receptors (see previous abstract). Preincubation with 5-HT (1 and 10 µM) produced no change in spontaneous NE release but reduced the GLU-induced NE release by about 60-70%. This effect was mimicked by 2-CH₃-5-HT (10µM), and blocked by ICS 205-930 (2nM) but not by ritanserin (1µM), thus suggesting that activation of 5-HT₃ receptors reduces GLU-evoked NE release. Whereas ritanserin (or another 5-HT_{1C}/5-HT₂ antagonist) must be present to observe 5-HT-induced inhibition of K⁺-evoked NE release (Blandina et al., J. Pharmacol. Exp. Ther. 256: 341-347, 1991), there is no such requirement for 5-HT inhibition of GLU-evoked NE release. Supported by grants DA 07135 and DA 04507 from N.I.D.A.

INTERACTIONS BETWEEN CENTRAL GLUTAMATERGIC, CATECHOLAMINERGIC AND CHOLINERGIC SYSTEMS WITH REGARD TO PSYCHOMOTOR FUNCTIONS. M. Carlsson, A. Carlsson* and A. Svensson*. Dept. of Pharmacology, University of Göteborg, P.O. Box 33031, S-400 33 Göteborg, Sweden.

The purpose of the present investigation was to study the effects of simultaneous manipulations of central cholinergic, adrenergic and glutamatergic systems on locomotion in an animal model of Parkinson's disease.

Mice were deprived of their monoamine stores by pretreatment with the monoamine depletor reserpine and the catecholamine synthesis inhibitor α-methyl-p-tyrosine, given 18 h and 60 min., respectively, before the acute experiment. Traditionally, only dopaminergic agonists have been shown to reverse the akinesia thus produced. However, in the present study it is demonstrated that if a muscarinic receptor antagonist (atropine or biperiden) is combined with an α-adrenergic agonist/α-adrenergic agonist precursor (clonidine or L-α-methyl-DOPA), a marked locomotor stimulation can be achieved, although either agent given alone is ineffective. Adding an NMDA antagonist (MK-801, ketamine or SDZ EAA494) to the combination biperiden+clonidine resulted in further potentiation of the locomotor stimulatory effects.

From our findings it can be inferred that (1) DA is not indispensable for initiation and execution of locomotion, (2) central glutamatergic and catecholaminergic systems are functionally opposed with regard to locomotion - possibly this antagonistic interaction takes place within the striatum, in analogy to the presumed cholinergic/dopaminergic antagonism within this structure.

GLUTAMATE RELEASES HYPOTHALAMIC NOREPINEPHRINE: I MODULATION BY GLYCINE. D. Johnson*, J. Goldfarb, J. Walcott* and P. Blandina. Department of Pharmacology, Mount Sinai School of Medicine, City University of New York, N.Y., N.Y. 10029

Hypothalamic slices (400 µ) from male Sprague-Dawley rats (200g) were perfused with a Mg²⁺-free medium containing nomifensine (10µM) and tyrosine (50µM). Spontaneous release of endogenous norepinephrine (NE), measured by HPLC-ECD after alumina extraction, averaged 0.1 pmol/3min/mg protein. Both 1 and 3 mM glutamate (GLU) more than doubled NE release. GLU effect was totally Ca²⁺-dependant, and abolished by 0.1 µM tetrodotoxin. Preincubation of slices with 1.2 mM Mg²⁺, 30 µM 2-amino-5-phosphonopentanoate, or 30 nM MK-801 completely blocked GLU effects, suggesting mediation by an NMDA receptor. Preincubation with 100 µM kynurenic acid (KYN) reduced GLU-evoked NE release, suggesting the presence of endogenous glycine (GLY) modulation. However, up to 100 µM, GLY did not reduce the inhibitory effect of 100 µM KYN. Glycine alone produced no effect, yet simultaneous perfusion with GLY (10-100µM) and GLU (1mM) greatly reduced GLU-evoked NE release. This effect was not blocked by 100 µM strychnine (STR), thus suggesting that GLY inhibits NMDA-mediated release of NE through a STR-insensitive mechanism.

Supported by grants (DA 07135 and DA 04507) from N.I.D.A.

THE EFFECT OF MK-801 ON DOPAMINE METABOLISM OF RAT MEDIAL FRONTAL CORTEX.

A. Kashiwa*, T. Nishikawa*, A. Umino*, K. Yamamoto and K. Takahashi.

Div. Mental Disorder Res., Natl. Inst. Neurosci. NCNP, Tokyo, 187 and Psychiatric Res. Inst. of Tokyo, Tokyo, 156, Japan.

An acute intraperitoneal injection of MK-801 caused a tetrodotoxin-reversible increase in extracellular release of dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) in the dialysates from rat medial frontal cortex. Intra-frontal cortex infusion of the drug via dialysis tubing also augmented the cortical DA release. Moreover, there was an increase in the tissue content of DOPAC and HVA with acceleration of DA utilization in the cortical area after systemic administration of MK-801. These results suggest that MK-801 facilitates DA metabolism in the medial frontal cortex by increasing impulse flow in the DA neurons projecting to the prefrontal region. Since MK-801 is a selective non-competitive antagonist of NMDA receptor, the present study supports the view that the NMDA receptor may be involved in a tonic inhibitory control of the DA neurons in the medial frontal cortex.

392.13

THE PHARMACOLOGICAL PROFILE OF GLUTAMATE-EVOKED ASCORBIC ACID EFFLUX MEASURED BY IN VIVO ELECTROCHEMISTRY. J. Cammack, B. Ghasemzadeh, and R.N. Adams. Departments of Pharmacology and Chemistry, University of Kansas, Lawrence KS 66045.

A recently described in vivo voltammetric electrode selectively records rapid changes in extracellular fluid (ECF) levels of ascorbic acid. Using this detector, the nature of glutamate induced efflux of ascorbate into ECF was investigated using pharmacological tools. Ascorbate signals were shown to be directly related to amounts of microinjected glutamate. Blockers of glutamate reuptake homocysteic acid and d,l-threo-B-hydroxy-aspartic acid virtually eliminate the ascorbate signal. A more specific reuptake blocker (the stilbene isothiocyanate derivative, SITS, which blocks glial transport of glutamate) does not completely inhibit ascorbate efflux though, suggesting that ascorbic acid exchange during glutamate transport is both neuronal and glial in nature. Other pharmacological experiments indicate that excitatory amino acid receptors are not involved in the glutamate elicited ascorbate efflux. The possible role(s) of brain ascorbate in the general functioning of the pervasive glutamate neurotransmitter systems are discussed.

SIGMA RECEPTOR AGONISTS INHIBIT N-METHYL-D-ASPARTATE (NMDA)-STIMULATED [³H]DOPAMINE ([³H]DA) RELEASE FROM RAT STRIATAL SLICES. G.M. Gonzalez, D. Sachdeva, and L.L. Werling. Dept. Pharmacology, The George Washington University Medical Ctr., Washington, D.C. 20037.

We have previously reported the stimulation of preloaded [³H]DA release from rat striatum by NMDA receptor/channel activators in a static incubation system. We now have confirmed the properties of NMDA receptor regulation of [³H]DA release from this tissue using a superfusion system. Striata were dissected, chopped, and washed in Mg²⁺-free modified Krebs-HEPES buffer, then incubated with 15 nM [³H]DA for 30 min. Tissue was washed and resuspended in buffer containing nomifensine (10 μM) and domperidone (1 μM) to prevent reuptake and feedback inhibition by released [³H]DA. Slices were loaded into superfusion chambers and superfused with buffer to establish a low, stable baseline release. Tissue was stimulated to release [³H]DA by 2 min exposures to 25 μM NMDA.

The sigma agonists (+)-pentazocine and (+)-SKF10,047 inhibited NMDA-stimulated [³H]DA release from rat striatal slices in a concentration dependent manner. Although (+)-SKF10,047 has significant affinity for the phencyclidine (PCP) receptor located within the NMDA-gated cation channel, (+)-pentazocine has negligible affinity for the PCP receptor. Naloxone (1 μM) did not reverse the inhibition by 10 μM (+)-pentazocine, obviating any contribution by opioid receptors. In contrast, the sigma antagonists ditolylguanidine (DTG), haloperidol and BMY14,802 reversed inhibition by (+)-pentazocine. These data suggest a potential involvement of sigma receptors in regulation of DA release from striatum. (Supported by an NIH BRSG to LLW.)

Increase of Free Radicals (OH[•]), glutamate and 5-HT in artery and vein of dog after ischemia/reperfusion/insult. B. Delbarre, G. Delbarre and F. Calinon*. Faculté de Médecine, 37032, Tours, France.

In addition to their effect on parenchymal tissue, OH[•] impair vascular function. To determine the effect of ischemia reperfusion insults (IRI) on the vessels, we have used Beagle anesthetized (Nembutal = 40 mg.kg⁻¹). After 5 min occlusion and 5 min reperfusion, carotid, femoral artery and femoral vein were dissected. We have determined the levels of glutamate (Xu, X., J. Liquid Chromatog., 9, 2253, 1986), 5-HT (Rips, R., Progress in HPLC, Vol.2 : 375-94, 1986) and OH[•] (Floyd R.A., J. Free Radic. Biol. & Med., 2 : 13, 1986). After IRI, glutamate, 5-HT and OH[•] were significantly increased in arteries and vein. The vascular effect of OH[•] may be mediated by inhibition of synthesis of 5-HT by and oxydative mechanism and of glutamate by an action at the level of glutamate system (Oliver, C.N., Proc. Natl. Acad. Sci., 87 : 5144-7, 1986).

In conclusion, after IR, in artery and vein of dog, simultaneous increase of OH[•], glutamate and 5-HT may be explained by the direct action of OH[•].

Percentage of increase versus control dog (n = 5)

	Femoral vein	Femoral artery	Carotid
OH [•]	299.36 *	548.70 *	169.54 *
Glutamate	415.25 *	381.21 ***	194.08**
5-HT	195.58 **	291.95 **	511.54**

Unpaired Student t test, p < 0.05*, p < 0.01**, p < 0.001**

392.14

A MICRODIALYSIS STUDY ON AGE-RELATED CHANGES IN STRIATAL GLUTAMATE RELEASE. B.A. Donzanti, J.F. Hite*, B.K. Yamamoto. Pharmacology Dept., Battelle Memorial Institute, Columbus, Ohio 43201 and Dept. of Psychiatry, School of Medicine, Case Western Reserve University, Cleveland, Ohio 44106.

We have previously shown that D-2 receptor agonists can inhibit K⁺-evoked glutamate release in vivo from the striatum. Thus, a decline in D-2 receptors, which occurs during the course of natural aging, may lead to the enhanced release of glutamate, a known excitotoxin. In an attempt to examine this potential mechanism of age-related cell death, the present study will determine: 1) if in vivo glutamate release is altered with age and 2) whether a D-2 agonist (LY163502) and antagonist (sulpiride) will differentially alter glutamate release in an age-dependent manner. Male Fischer 344 rats (4, 12, 18, and 26 months old) were anesthetized with urethane and placed in a stereotaxic frame. Microdialysis probes were placed in either the lateral or medial striatum and perfused at a rate of 1.5 μl/min with artificial CSF. Basal, drug-induced, and K⁺-evoked glutamate release was examined at 20 min intervals using HPLC-EC analysis. It was observed that: 1) lateral, but not medial, basal glutamate release increases with age; 2) KCl (80 mM)-evoked glutamate release in the lateral striatum was not influenced by age; and 3) the direct infusion of sulpiride (500 μM) and LY163502 (1 μM) did not alter basal glutamate release. We are currently determining whether these drugs will alter K⁺-evoked glutamate release. Thus, the data suggest that elevated glutamate release could be a plausible explanation for age-related striatal cell loss; however, a role for D-2 receptors in this process remains unclear. (Supported by AFAR grant).

392.16

COMBINED ANTAGONISM OF MUSCARINIC AND NMDA SYSTEMS IMPAIRS MAZE LEARNING IN RATS. P. Garofalo, E.L. Spangler, K. Yamagami, D.K. Ingram. Gerontol. Res. Ctr., NIA, NIH, Baltimore, MD 21224

The cholinergic muscarinic antagonist scopolamine (SCOP) impairs learning in a variety of tasks. Similarly the glutamatergic antagonist dizocipiline (DIZO), which is specific to the N-methyl-D-aspartate (NMDA) ion channel, impairs learning in several complex tasks. Thus, both the cholinergic and glutamatergic systems appear involved in memory processes. The present study assessed the interaction between the two systems in acquisition of a 14-unit T-maze that has provided robust evidence of age-related memory impairment (Ingram, Neurobiol. Aging, 1: 9475, 1988). Young (3 mo) male F-344 rats were pretrained in 1-way active avoidance to a criterion (13 avoidances/15 trials). About 24 hr later each rat received an injection of either saline, SCOP (125 μg/kg i.p.), DIZO (12.5 μg/kg s.c.) or a combination of the drugs at these doses, 30 and 20 min, respectively, before they began training (15 trials) in the T-maze. The rat had to run through 5 maze segments each within 10 sec to avoid footshock (0.8 mA). Measures of maze performance included errors, alternation errors, runtime, shock duration and frequency. The individual doses of either SCOP or DIZO had no effects on any maze variable; whereas, the combination treatment at these doses produced marked increases in maze errors without effects on other noncognitive performance variables (run time, shock frequency and shock duration). Our results clearly support the hypothesis of an interaction between the two systems. Although our data do not address the nature of this interaction, results indicate that the cumulative impact of blockade of muscarinic and NMDA receptors is significantly greater than blockade of each one alone. Thus, it is possible that the decline in memory that occurs in aging might be due to relatively minor deficiencies in both systems and could suggest novel therapeutic strategies targeting both systems.

392.18

SIMULTANEOUS MEASUREMENT OF THE MONOAMINE AND AMINO ACIDERGIC PATHWAYS IN BRAIN TISSUE. P.H. Gamache*, M.J. During*, C.N. Svendsen*, and I.N. Acworth*. ¹ESA Inc., Bedford, MA 01730. ²Section Neurosurgery, Yale Univ., Sch. of Med., New Haven, CT 06510.

Normal brain function results from the interplay of several distinct neurotransmitter systems. Although many techniques are available for the measurement of a specific class of neurochemicals, analysis of several classes involves separate sample processing protocols and multiple analytical systems. Practical and temporal constraints may thus prevent an accurate assessment of possible underlying neurochemical relationships. The objective of this study is to gain maximum information about the amino acidergic and monoaminergic pathways from a single sample in one analysis. We have developed a technique which is based on HPLC with coulometric array detection. Automated sample delivery, derivatization of amino acids with OPA/BME, and column switching sequences present the analytes for separation and detection. Multiple series coulometric detectors, set at different oxidative potentials, increase the resolution provided by reverse phase chromatography. Using external standards, comparison of the electrochemical "signature" across the detector array is used in conjunction with retention time for each sample peak to aid in identification and peak purity assessment. We have investigated tissue levels of neurochemicals from 5 brain regions of the adult male Sprague-Dawley rat. Representative data from 100 μl of a hippocampal tissue extract is shown below:

	n mole/g Tissue	Ratio Assay %	n mole/g Tissue	Ratio Assay %
Aspartate	232	96	HVA	0.03
Dopamine	0.26	98	5HTAA	1.84
Dipic	0.09	—	Serotonin	2.55
GABA	600	9	Norepinephrine	2.08
Glutamate	1232	99	Tauine	1385
Glycine	135	100		

Comparable ratio accuracy data has been obtained from the brain stem, cerebellum, corpus striatum, and cortex. This data suggests that unique insight into the relationship between amino acidergic and monoaminergic neurotransmitter pathways can be obtained.

FURTHER INVESTIGATIONS FOR RAPIDLY DETERMINING MULTIPLE NEUROCHEMICAL SPECIES USING A NEUROBIOLOGICAL ANALYZER.

DOUGLAS J. TURK and C. LEROY BLANK, Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK, USA, 73019.

The separation and determination of a variety of catecholamine, indoleamine and acetylcholine related neurochemicals and metabolites has previously been demonstrated using a multiple column, multiple electrode Neurobiological Analyzer, NEUBA (see related abstract in Society for Neuroscience, November, 1990). The Neurobiological Analyzer provides a three dimensional separation of potential, current and time for the analysis of electroactive species during a single thirty minute chromatogram.

Improvements with this instrument have included the ability to deconvolute overlapping peaks resulting in a truly three dimensional separation for any given analysis along with the development of an electrochemical reference library of close to two hundred compounds on each of three systems. Computer controlled potential, current offset and autoranging capabilities and overall improved operating conditions have resulted in a detection limit of approximately 10 femtomoles (at a S/N ratio of 2) for most neurochemical species.

A practical application with the Neurobiological Analyzer has been the qualitative analysis and quantitative assay of a variety of neurochemical species of urine samples from normal and hypertensive children (diagnosed either by WISCR or STARTLE criteria). The three dimensional nature of NEUBA greatly simplifies the analysis and data handling for these samples and facilitates the determination of a possible chemical categorization of ADHD subgroups.

INTERACTIONS BETWEEN NEUROTRANSMITTERS III

393.1

DOPAMINE/NEUROTENSIN INTERACTIONS IN THE RAT STRIATUM. *Mary Ann Chapman and Ronald E. See*. Dept. of Psychology, Washington State University, Pullman, WA, 99164-4820

Several lines of research indicate that neurotensin (NT) acts as a neuromodulator of dopamine function in the striatum. This study employed an intracranial microdialysis technique in order to more precisely characterize these interactions. Female, Sprague-Dawley rats were anesthetized with Equithesin and bilateral guide cannulae implanted (A +0.2, L +3.1, V -5.0). Following one week of recovery, microdialysis probes with 3 mm of exposed dialysis membrane were inserted into the guide cannulae and perfused with Ringer's solution. Samples were collected at 20 min intervals throughout the experiments. One group of rats was treated with 3 incremental concentrations of NT (0.1, 1.0, 10.0 μ M). Each concentration of NT was flowed out the dialysis membrane for one hour and was followed by 80 min. of perfusion with Ringer's solution alone. Another group of rats was given an IP injection of quinpirole (0.03 mg/kg) during infusion of NT (0.1 μ M) into the striatum. This dose has previously been shown to decrease DA release by 50%. Samples were injected onto an HPLC column and analyzed for DA, DOPAC, and HVA using electrochemical detection. Neurotensin (10 μ M) produced an increase in DA levels. The low concentration of NT blocked the quinpirole-induced decrease in DA but not DOPAC and HVA. Further interactions between neurotensin and dopamine will be discussed.

393.3

NEUROTENSIN MODULATION OF DOPAMINE INHIBITION IN THE RAT BRAIN: AN IONTOPHORETIC ANALYSIS. *M. Beauregard, A. Ferron and L. Descarries*. Centre de recherche en sciences neurologiques, Dép. physiologie, Univ. de Montréal, Montréal (Québec), CANADA H3C 3J7.

Biochemical and behavioral data have suggested functional interactions between dopamine (DA) and neurotensin (NT) in regions of the brain receiving a separate and/or coexistent innervation by these two transmitters. To further elucidate these interactions, the effects of iontophoretically applied DA and NT were measured and compared in the prefrontal (PF) and anterior cingulate (ACg) cortex (coexistent innervation), and in the neostriatum (NS) and nucleus accumbens (Acb) (distinct innervation) of urethane-anesthetized rats. Under similar conditions of application (50 nA during 50 s), most spontaneously firing neurons were inhibited by DA (decrease of 40% or more) in all four regions, whereas NT had no apparent effect on the same cells, except for a few units in Acb (3/21), which were also depressed by the peptide. When DA and NT were concomitantly administered, the percentage of maximal inhibition induced by DA was modified in a majority of the units tested (66/93). A 30% or more decrease in DA responsiveness was observed in 100% of ACg (24/24), 74% of PF (20/27) and 48% (10/21) of Acb units. In NS, DA responsiveness was increased by NT in 60% of the units (12/20). In every region, all remaining neurons showed less than 30% changes in DA responsiveness and were therefore considered as unaffected by NT. Inhibitions induced by the DA agonists SKF 38393 (D1) and LY 171555 (D2) were also decreased during simultaneous application of NT in ACg (30/30 and 4/8 units, respectively). These results support the likelihood of DA and NT interactions in every brain region innervated by these two transmitters. Why DA and NT interactions might have opposite effects in NS versus PF, ACg and Acb remains to be determined. (Supported by Fonds internes de la Faculté de médecine and MRC grant MT-3544).

393.2

HIGH AFFINITY REUPTAKE OF DOPAMINE IN RAT NUCLEUS ACCUMBENS SLICES IS MODULATED BY THE PEPTIDE DES-ENKEPHALIN- γ -ENDORPHIN

E. Ronken, and V.M. Wiegant. Rudolf Magnus Institute, Dept. of Pharmacology, University of Utrecht, The Netherlands

γ -Endorphin (γ E) and N⁶-acetyl- γ E are endogenous neuropeptides in rat brain, and express non-opioid biological activity upon central or peripheral administration. These properties are shared by N-terminally truncated, opioid-inactive congeners like des-Tyr¹- γ E (DT γ E;BE(2-17)), and des-enkephalin- γ E (DE γ E;BE(6-17)), and are thought to act through modulation of the mesolimbic dopamine system. Non-opioid γ -type endorphins do not display affinity for dopamine receptors, and no conclusive evidence has been found for modulation of dopamine release. Recently, specific binding sites for non-opioid γ -type endorphins have been characterized, preferentially located mesocorticolimbic brain structures.

In slice preparations of rat nucleus accumbens (20 μ m x 20 μ m) active, GBR12909-sensitive [³H]dopamine uptake kinetics were studied and uptake was found to be concentration-dependently inhibited by DE γ E (EC₅₀=20nM) to a maximum of 52% at saturation concentrations of dopamine. In contrast, the structurally related peptide DE α E (BE(6-16); 1 μ M) was found to be inactive. DE γ E both affected maximal uptake rate and observed K_m, suggesting the presence in the rat nucleus accumbens several distinct dopamine carrier systems, one of which is sensitive to γ -type endorphins. Interestingly, DE γ E inhibited the [³H]noradrenaline uptake in both accumbens and striatal slices, whereas no effect of DE γ E was observed on dopamine uptake in striatal slices. At present, the molecular mechanism with which DE γ E interferes with uptake of catecholamines in brain tissue is unknown, modulation of reuptake systems-particularly in meso(cortico)limbic dopaminergic projection areas-may underlie the biological actions of γ -type endorphins.

Support by the Dutch Society for Scientific Research (N.W.O. Grant 900-543-063).

393.4

SPECIFICITY OF THE INCREASE IN NEUROTENSIN CONCENTRATIONS AFTER CHRONIC ANTIPSYCHOTIC DRUG TREATMENT. *B. Myers, B. Levant, G. Bisette and C.B. Nemeroff*. Duke Univ. Med. Center, Durham, NC 27710

Neurotensin (NT) is an endogenous brain and gut peptide that shares many CNS effects with antipsychotic drugs. This study examined the specificity of the antipsychotic-drug induced increase in NT concentrations in the rat nucleus accumbens and caudate nucleus. After sub-chronic (once daily for three weeks) or acute (once) intraperitoneal injection of either the antipsychotic drug, haloperidol (1mg/kg), the benzodiazepine anxiolytic, chlordiazepoxide (25mg/kg), the tricyclic antidepressant, desipramine (10mg/kg), or the antihistamine, diphenhydramine (acute treatment only with three injections of 20mg/kg, i.p. every six hours), six discrete brain regions were dissected and assayed: nucleus accumbens, anterior and posterior caudate nucleus, frontal cortex, amygdala and substantia nigra/ventral tegmental area. Regional mean NT concentrations were expressed as pg NT/mg protein.

As previously reported, sub-chronic and acute treatment with haloperidol significantly increased NT concentrations in the nucleus accumbens and the caudate nucleus. Neither chronic nor acute treatment with desipramine, chlordiazepoxide or acute treatment with diphenhydramine affected NT concentrations in any of the brain regions examined. Regionally specific alterations in NT concentration are not seen with drugs that possess effects similar to the side effects often observed with antipsychotic drug treatment. Thus these NT concentration alterations may mediate some of the therapeutic effects of antipsychotic drug administration. (Supported by NIMH MH-39415).

393.5

ANGIOTENSIN II INCREASES DOPAMINE RELEASE FROM RAT STRIATAL SLICES *IN VITRO*. A.L. Jewell, S.T. Buxton, L.L. Leibe, L.A. Cassis* and L.P. Dvoskin. College of Pharmacy, University of Kentucky, Lexington, KY 40536-0082.

Components of the renin-angiotensin system including angiotensinogen, angiotensin converting enzyme, angiotensin II (AII) immunoreactivity and AII receptors have been localized in striatum. Recently, we reported (Dvoskin, Naunyn-Schmiedeberg's Arch. Pharmacol., in press, 1991) that *in vitro* superfusion with DuP 753 (0.1 - 10 nM), a specific nonpeptide AII-1 receptor antagonist, decreased endogenous dopamine (DA) and dihydroxyphenylacetic acid (DOPAC) overflow from rat striatal slices. These concentrations of DuP 753 did not alter either DA uptake or MAO activity, suggesting a direct effect of DuP 753 to decrease DA release. Furthermore, these results suggest that endogenous AII may modulate DA neurotransmission in striatum. Therefore, the present study determined if exogenous AII modulates DA release in superfused rat striatal slices. In the absence of BSA, high concentrations (1 and 10 μ M) of AII robustly increased (49-fold) the outflow of endogenous DOPAC in striatal superfusate. In the presence of BSA, much lower concentrations (0.1 nM) of AII increased (1.5-fold) the outflow of tritium in striatal slices preloaded with [³H]DA. Therefore, these results suggest that AII modulates DA release in striatum. (Supported by NIH LBI R29-HL-41954)

MODULATION OF STRIATAL ACETYLCHOLINE RELEASE BY DOPAMINE AFTER 6-HYDROXYDOPAMINE. D. Jackson, B.A. Vogta*, and M.J. Zigmond, Department of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA. 15260

Striatal acetylcholine (ACh) interneurons are in close proximity to (inhibitory) nigral dopamine (DA) afferents. In the present study, we have examined the capacity of DA released from residual terminals to modulate the overflow of ACh formed from labelled choline. Striatal slices (350 μ m) were prepared from rats given the neurotoxin, 6-hydroxydopamine (6-OHDA, 8 μ g), along the nigrostriatal pathway. ACh efflux in response to electrical field depolarization was enhanced by the D2 antagonist sulpiride (1 μ M SLP, 94+5%) and inhibited by the DA uptake blocker, nomifensine (10 μ M NOMI, 51+4%) in slices from untreated rats. The effects of these drugs were reduced in slices from rats lesioned with 6-OHDA 3-6 days before sacrifice (1 μ M SLP, 22+7%, NOMI, 24+2%). ACh efflux in slices from rats lesioned 1-2 months earlier with 6-OHDA was similar to efflux in slices from intact rats (1 μ M SLP, 60+9%, NOMI, 36+1%). Inhibition of ACh efflux by the DA agonist, apomorphine (APO, 10⁻⁴-10⁻⁵ M), was greater in slices from rats lesioned 1-2 months earlier with 6-OHDA than in slices from intact rats or acute 6-OHDA rats. These data suggest that destruction of nigrostriatal DA neurons reduces effectiveness of endogenous DA to act on striatal targets but that over time adaptations involving residual terminals and upregulation of D2 receptors occur leading to a restoration of at least some dopaminergic functions.

393.9

INCREASE IN GASTRIN-RELEASING PEPTIDE (GRP) IN RAT BRAIN AFTER INTERRUPTION OF DOPAMINE PATHWAYS PRODUCED BY D1/2 ANTAGONISTS AND 6-HYDROXYDOPAMINE. A.Masui, M.Sadamatsu*, K.Tsunashima*, N.Yanaiharu* and N.Kato. Dept. of Psychiatry, Shiga Univ. of Med. Science, Otsu 520-21, Japan.

Various neuropeptides such as bombesin (BN), substance P and somatostatin are known to induce excessive grooming in which BN was most potent (this Meeting, 1989). Since haloperidol (HAL; a D1/2 antagonist) suppresses this behavior, the involvement of dopaminergic (DA) transmission has been suggested. We examined the effect of DA interruption induced by HAL and 6-hydroxydopamine (6-OH-DA) on the brain immunoreactive GRP (IR-GRP), mammalian BN, in rats. Chronic HAL treatment via osmotic pump induced the increase of IR-GRP in the striatum and mesolimbic area. The elevation of IR-GRP in the mesolimbic area was also noted following 6-OH-DA *icv* treatment. Between SCH23390 (D1 antagonist) and sulpiride (D2), SCH23390 appeared to more preferentially affect brain IR-GRP. This finding is coincident with the behavioral study in which D1 antagonist selectively inhibits the excessive grooming induced by several peptides. It will be of interest that somatostatin was increased after 6-OH-DA treatment in the same study.

393.6

EFFECT OF APOMORPHINE ON EXTRACELLULAR GABA LEVELS IN THE VENTRAL PALLIDUM OF RATS WITH 6OHDA LESIONS OF THE NUCLEUS ACCUMBENS. A.J. Bourdelais and P.W. Kalivas. Dept. of VCAPP, Washington State University, Pullman, Washington 99164.

Apomorphine (APO) stimulated locomotor activity in the rat is greatly enhanced following lesions of the nucleus accumbens (NA) dopamine (DA) terminals using 6OHDA. This increased behavioral response is thought to be due to the action of APO on supersensitive DA receptors, resulting from the reduction of extracellular DA in the NA. Further experimental evidence has shown that DA terminals in the NA synapse on GABA-containing cell bodies located in the NA, and that these GABAergic neurons project to the ventral pallidum (VP). It has also been demonstrated that these GABA neurons are involved in psychostimulant induced locomotor activity, and are inhibited by DA neurotransmission in the NA. The purpose of this study was to determine if DA in the NA regulates GABA release in the VP. To accomplish this, we utilized the DA supersensitivity model described by Swerdlow and Koob, 1984. Bilateral DA lesions of the NA were made with 6OHDA. Alterations of the extracellular GABA levels in the VP were measured using microdialysis in conscious freely moving rats following the systemic administration of APO. A significant (88%) depletion of DA in the NA was found following 6OHDA injection into the NA. There was a slight but not significant increase in basal GABA levels in the VP of 6OHDA-lesioned rats. APO induced a significant decrease in basal GABA levels in the VP of both 6OHDA- and sham-lesioned rats, this decrease was augmented in the 6OHDA-lesioned animals. Behavioral augmentation following APO administration was seen in only the 6OHDA-lesioned rats.

EFFECT OF ENDOGENOUS EXCITATORY AMINO ACIDS ON THE OUTFLOW OF DOPAMINE IN THE NUCLEUS ACCUMBENS. D. Daly*, K.D. Youngren, and B. Moghaddam, Department of Psychiatry and Neuroscience Program, Yale University School of Medicine, New Haven, CT 06510, and West Haven VA Medical Center, West Haven, CT 06516.

Intracerebral microdialysis was utilized to assess the effect of endogenous excitatory amino acids - glutamate (GLU) and aspartate (ASP) - on the extracellular level of dopamine in the rat nucleus accumbens. Addition of 5 and 10 mM GLU through the microdialysis probe increased the outflow of dopamine by nearly 200%. The increase was not significantly different between the two doses. The stimulatory effect of GLU at both 5 and 10 mM was partially blocked by the non-NMDA antagonist CNQX (100 μ M through the dialysis probe), but not by the NMDA antagonist APV (up to 1 mM). ASP, in contrast to GLU, displayed a dose dependent effect on dopamine release at the doses tested (1 - 10 mM). ASP-stimulated dopamine release was partially blocked by both the NMDA and non-NMDA antagonists, APV and CNQX, respectively. Perfusion of TTX concomitantly with either GLU or ASP completely inhibited the excitatory effect of these amino acids on dopamine release. These results indicate that in the nucleus accumbens, ASP and GLU enhance dopamine outflow through distinct trans-synaptic mechanisms. Supported in part by VA Centers for Schizophrenia & Alcoholism.

POSSIBLE ROLE FOR ADENOSINE AS A NEUROMODULATOR OF METHAMPHETAMINE EFFECTS. K.T. DelleDonne, R.E. Heikkila, D.E. Riordan* and P.K. Sonsalla. Department of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

Adenosine is an inhibitory modulator of neuronal activity whose action at its receptors is blocked by the methylxanthine caffeine. Substantial evidence indicates that adenosine is a neuroprotectant against glutamate-mediated neurodegeneration. Repeated high doses of methamphetamine (METH) to mice cause damage to neostriatal dopaminergic neurons and there is evidence that both dopamine and glutamate play a role in the production of METH toxicity. The purpose of these studies was to assess if treatment with chronic or acute caffeine alters METH-induced neurotoxicity. Pretreatment of mice with caffeine prior to each injection of METH resulted in a dose-related potentiation of METH-induced decrements in neostriatal dopamine content and tyrosine hydroxylase activity. In contrast, chronic pretreatment of mice for four weeks with caffeine followed by drug wash-out caused a significant attenuation of METH-induced toxicity. Chronic caffeine treatment did not alter neostriatal levels of METH but did up-regulate the number of adenosine A₁ receptors. These results suggest that adenosine may be able to modulate METH-induced dopaminergic neurotoxicity in the mouse neostriatum. Effects of adenosine on either dopaminergic or glutamatergic neurotransmission may underlie its protectant properties.

393.11

EFFECT OF INTRAPALLIDAL MORPHINE INJECTIONS ON EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS (NAC). C. Spyriaki and Y.E. Anagnostakis. Lab. of Pharmacology, Medical School, University of Crete, 71409 Heraklion, GR.

The Ventral Pallidum (VP) has direct and indirect projections to the region of the ventral mesencephalon containing dopamine perikarya and to certain terminal fields, including the NAC. The present study was undertaken in order to examine the functional properties of some of these projections and to associate locomotor stimulant response seen in earlier studies following intrapallidal morphine, with possible alterations in the activity of the mesolimbic dopamine (DA) system. Microdialysis probes (2.3 mm) were implanted unilaterally in the nucleus accumbens (AP: +1.6 L: -1.5, V: -8.2 from bregma) and in the ipsilateral ventral pallidum (AP: -0.3 L: -2.5 V: -8.5 from bregma) of Sprague-Dawley male rats (N=10). The day following the probe implantation, dopamine (DA) and metabolites (DOPAC, HVA) were determined in NAC dialysates using HPLC-E.C. (ESA) coupled. Samples were collected at 45 min intervals (flow rate: 0.75 μ l/min) over 3 and 6 hrs before and after challenging the rats with morphine (10 μ l of 2.6, 4.0 and 26 mM) through the pallidal dialysis probe, respectively. Basal levels were for DA 0.1 pmol, for DOPAC 29 pmol, and for HVA 6.5 pmol/20 μ l. Increased KCl 50 mM for 10 min in the perfusate medium (artificial CSF) induced a 500% increase of DA. Basal and K⁺ evoked release of DA was reduced in the absence of Ca⁺⁺ in the perfusate medium. We have found that injections of morphine at concentrations higher than 2.6 mM into the ventral pallidum increased levels of DA, DOPAC and HVA in the NAC (20 - 100%) in a dose-dependent manner. The results show that stimulation of VP with morphine modulates the mesolimbic DA system. These findings suggest that the increased locomotion seen in earlier studies following intrapallidal morphine is associated with enhancement of DA overflow in the NAC.

393.13

NICOTINE EFFECT ON LOCOMOTOR ACTIVITY IS REDUCED BY DOPAMINE RECEPTOR BLOCKADE. E. J. Cline and C. Ksir. Department of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY 82071.

We previously reported (*Soc. Neurosci. Abstr.*, 14, 1137, 1988) that rats tested for ambulatory activity did not show a diminished response to 0.2 mg/kg nicotine after pretreatment with α -flupenthixol (FPT), a dopamine receptor antagonist. This was puzzling in light of evidence indicating that the mesolimbic dopamine system is important for the locomotor stimulant effects of nicotine (e.g. Clarke *et al.*, *IPET.*, 246, 701-708, 1988).

The current experiment used a different measure of locomotor activity and a different sequence of drug testing. Rats were maintained on daily saline or nicotine injections, and FPT effects were assessed in twice-weekly test sessions. Saline or FPT (0.05, 0.1, 0.2, and 0.4 mg/kg) was followed 90 min later by a test dose of 0.2 mg/kg nicotine or saline, and activity was monitored for one hour. The same animals were then tested for their response to 1.0 mg/kg d-amphetamine after saline, 0.05, and 0.1 mg/kg FPT.

FPT produced significant diminution of the locomotor response to both nicotine and amphetamine, even at the lowest dose tested. These results are consistent with the notion that dopaminergic mechanisms are involved in the expression of increased locomotor activity following nicotine injections.

393.15

IN-VIVO FACILITATION OF DOPAMINE (DA) RELEASE BY SEROTONIN (5-HT): STUDIES ON CALCIUM DEPENDENCE AND RECEPTOR SELECTIVITY. S. Benloucif, M.J. Keegan* and M.P. Galloway. Cellular and Clinical Neurobiology Program, Lafayette Clinic, Dept. Psychiatry, Wayne State University School of Medicine, Detroit, MI 48207.

Electrophysiological and behavioral evidence indicates that 5-HT can both facilitate and inhibit DA activity. Previously, we reported that striatal infusion of 5-HT₁ agonists increased DA release as measured by in-vivo microdialysis. This report describes the calcium dependence and receptor selectivity of this facilitation. Agents were dissolved in artificial CSF and perfused through microdialysis probes located in the anterior lateral striata of chloral hydrate anesthetized rats. Drug-induced changes in levels of DA and metabolites were monitored in 20 min. fractions by HPLC-EC and compared with control responses from the contralateral striatum. Perfusion of the calcium channel blocker cadmium (0.1 mM for 1 h) attenuated by 40% the 5-HT (10 μ M) induced facilitation of DA release ($p < .01$, $n = 5$). Perfusion of barium (2 mM), cesium (3 mM), or nifedipine (0.1 mM) did not block the elevation of DA levels ($n = 3 - 5$ each). Treatment with antagonists selective for 5-HT receptor subtypes indicated selectivity for the 5-HT₁ subtype. Perfusion of the 5-HT₂ antagonist ritanserin (100 μ M) did not attenuate DA facilitation by 5-HT ($n = 4$). While the 5-HT₂ antagonist MDL 72222 (100 μ M) reduced 5-HT induced potentiation of DA release by 50% ($p < .05$, $n = 5$), the 5-HT₂ antagonist ICS 205930 (100 μ M) did not block enhanced DA release caused by the 5-HT₂ agonist 2-methyl-5HT (50 μ M, $n = 5$). In contrast, the 5-HT₁ antagonist pindolol (100 μ M) reversed by 50% the facilitation of DA release by both 5-HT (10 μ M, $p < .05$, $n = 5$) and the 5-HT₁ agonist RU 24969 (50 μ M, $n = 3$). (Supported by DA-04120, and the State of Michigan Dept. of Mental Health).

DARPP-32 is phosphorylated by GABA and dopamine in rat substantia nigra. Gretchen L. Snyder, Shelley Halpain, and Paul Greengard, Lab. of Molec. and Cell. Neurosci., The Rockefeller Univ., New York, NY 10021. DARPP-32 (dopamine- and cAMP-regulated phosphoprotein, Mr=32,000) is enriched in dopaminergic cells such as the cell bodies (striatum) and terminals (substantia nigra) of striatonigral neurons and is phosphorylated by cAMP-dependent protein kinase. We used an antibody selective for phosphorylated DARPP-32 (mab 23) to study the regulation of phospho-DARPP-32 by DA and GABA in rat substantia nigra. Minces of nigra were incubated in warm, oxygenated RPMI-1640 medium 30 min prior to addition of drugs for 2-5 min. Tissue was frozen, then sonicated in hot 1% SDS for 10 min. Proteins were separated by SDS-PAGE, transferred to nitrocellulose, immunoblotted with mab 23, and phospho-DARPP-32 detected with ¹²⁵I-protein A. DARPP-32 was identified in SDS homogenates as a doublet of Mr=32 kD. GABA (100 μ M, 2 min) increased phospho-DARPP-32 in the upper band of the doublet but not in the lower band. This effect was reduced by 5 min pretreatment with the GABA-A antagonist, picrotoxin (100 μ M), but not by phaclofen, a GABA-B antagonist (100 μ M). L-DOPA (1-100 μ M) and the dopamine D-1 agonist, SKF 38393 (1-100 μ M), each increased phospho-DARPP-32 in both bands of the doublet. These data suggest that GABA and DA release in the nigra may influence activity of striatonigral terminals through differential effects on the phosphorylation of DARPP-32.

DEPLETION OF BRAIN SEROTONIN BY PCPA AFFECTS DOPAMINE AND SEROTONIN SYSTEMS DIFFERENTIALLY AS REFLECTED BY BEHAVIOR AND NEUROCHEMISTRY IN PIGEONS L. Zhang and J. E. Barrett. Dept. of Psychiatry, USUHS., Bethesda, MD 20814.

Serotonin (5-HT)-depleted pigeons were subjected to behavioral and biochemical studies. In the behavioral procedure, a multiple fixed interval (FI 3 min) fixed ratio (FR 30) schedule was employed. The 5-HT_{1A} agonist 8-OH-DPAT (0.3 mg/kg) and the dopamine (DA) agonist pibedil (3.0 mg/kg) were tested before, during and after 5-HT depletion produced by systemic injection of pCPA (150 mg/kg/day for 3 days). Response rate increases produced initially by 8-OH-DPAT were not changed during pCPA treatment. Fourteen days later, 8-OH-DPAT produced increases in FI rates even higher than those before pCPA. Response rate increases produced by pibedil initially were attenuated during pCPA but 14 days later the pibedil effects were recovered. This suggests that 5-HT depletion results in less sensitivity to DA agonists and during 5-HT recovery induces supersensitivity to 5-HT_{1A} agonists. PCPA decreased the 5-HT metabolite 5-HIAA and the DA metabolite DOPAC. These findings suggest that 5-HT depletion either directly or indirectly affects DA system as well. Supported by DA 02873.

393.16

THE EFFECT OF NEUROTENSIN AND HALOPERIDOL ON BODY TEMPERATURE, OXYGEN CONSUMPTION AND HEAT EXCHANGE IN THE RAT. C. M. Handler, E. B. Geller and M. W. Adler. Dept. of Pharmacology, Temple University School of Medicine, Philadelphia, PA. 19140.

The neuropeptide neurotensin (NT; pGlu-Leu-Tyr-Glu-Asn-Lys-Pro-Arg-Arg-Pro-Tyr-Ile-Leu) was injected ICV into the right lateral ventricle of unrestrained, male, S-D rats. At an ambient temperature of 20 \pm 1°C, brain surface temperature (T_{bs}), oxygen consumption (VO₂), and heat exchange (Q) were measured for three hours post-injection in a gradient-layer calorimeter. A dose of 0.025 μ g neurotensin (0.0149 nmol) did not cause any significant alterations in T_{bs}, VO₂, or Q. Both 0.125 μ g (0.0747 nmol) and 0.625 μ g (0.373 nmol) of neurotensin significantly reduced T_{bs} during the post-injection period when compared to baseline control levels. VO₂ and Q were also reduced during the period of hypothermia. Haloperidol (H) is a dopamine receptor (D₂>D₁) antagonist (and a sigma receptor ligand). A dose of 2 mg/kg (IP) produced slight reductions in the levels of T_{bs}, VO₂, and Q. Haloperidol (30 min pre-treatment), in combination with neurotensin, resulted in a decrease in VO₂ prior to the hypothermic episodes and an increase just before recovery. Q was depressed during the entire post-injection period. At the doses used, the combination of haloperidol and neurotensin does not appear to be other than additive with respect to the magnitude of the hypothermia while the duration of the hypothermic period is shortened.

drug/dose	n	onset of hypothermia	duration of hypothermia	max Δ T \pm SE
H2.0 mg/kg	4	30 min	135 min	-0.36 \pm 0.20°C
0.125 μ g NT	3	30 min	150 min	-1.04 \pm 0.46°C
H+0.125 μ g NT	2	15 min	75 min	-1.42 \pm 0.15°C
0.625 μ g NT	5	0 min	>180 min	-0.67 \pm 0.60°C
H+0.625 μ g NT	3	0 min	135 min	-1.48 \pm 1.00°C

This attenuation of the duration of neurotensin-induced hypothermia results from a smaller decrease in levels of VO₂ and a continuous reduction in Q, resulting in the return of T_{bs} to pre-injection baseline levels. The data support the hypothesis that neurotensin, acting in conjunction with dopamine receptors, has a significant effect on thermoregulation. SEROTONIN UPTAKE INHIBITION INCREASES PREPROTACHYKININ mRNA AND DECREASES TRYPTOPHAN HYDROXYLASE ACTIVITY IN EMBRYONIC MEDULLARY RAPHE EXPLANTS. L.A. Riley, R.P. Hart and G.M. Jonakait, Dept. of Biol. Sci., Rutgers Univ., Newark, NJ 07102.

Almost all serotonin-containing neurons in the medullary raphe also contain Substance P, but its role and regulation there is not well understood. We have sought to determine whether changes in 5-HT levels affect the biosynthesis of colocalized SP. In previous studies, we have shown that pharmacological manipulations of 5-HT levels *in vivo* change the steady state levels of the mRNA coding for the prohormone precursor of SP, preprotachykinin (PPT; Walker et al., Mol. Brain Res. 8:113 1990; Riley et al., Mol. Cell. Neurosci., in press).

Changes effected by altered 5-HT levels may be due secondarily to changes in serotonergic neurotransmission. In order to test this hypothesis directly, we have begun to use a culture system in which medullary raphe neurons are grown as organotypic explants where complicating afferent input to the raphe can be kept to a minimum. Raphe are discretely dissected from rat medullae at embryonic day 16 and grown in Maximow-slide depression chambers as lying-drop preparations. In these explants, levels of SP, PPT mRNA and tryptophan hydroxylase (TPH; first enzyme in 5-HT biosynthesis) activity are stable over the first 10 days in culture. Growth for 5 days in the presence of the specific 5-HT uptake inhibitor norzimelidine increased levels of PPT mRNA $48 \pm 9\%$ ($p < 0.01$) as measured by a sensitive nuclease protection assay. TPH activity decreased $66 \pm 6\%$ ($p < 0.05$) while levels of SP-like immunoreactivity were unchanged. Since raphe neurons are the only SP-containing neurons in the explant, these data suggest that 5-HT, while regulating its own biosynthesis, simultaneously regulates the biosynthesis of its colocalized peptide partner. Supported by MH43365 and TSA.

IN VIVO PRESYNAPTIC MODULATION OF SEROTONERGIC TRANSMISSION BY α_2 -ADRENOCEPTORS IN THE RAT HIPPOCAMPUS. R. Mongeau, P. Blier and C. de Montigny, Neurobiological Psychiatry Unit, Dept. of Psychiatry, McGill University, Montréal, Québec, Canada H3A 1A1

In vitro studies have demonstrated the presence of inhibitory noradrenergic (NE) α_2 -heteroreceptors on 5-HT terminals modulating the release of [3 H]5-HT in rat brain slices. This modulation, nevertheless, remained to be documented *in vivo*. The effect of the activation of these NE heteroreceptors was thus studied by comparing the effectiveness of the electrical stimulation (200 pulses: 0.5 msec, 300 μ A, 1 Hz) of the ascending 5-HT pathway in suppressing the firing activity of dorsal hippocampus pyramidal neurons prior to, and following, the intravenous administration of NE agents. Desipramine (2 mg/kg), a selective NE reuptake blocker, reduced the efficacy of the stimulation; this effect was completely reversed by the α_2 -adrenergic antagonist yohimbine (500 μ g/kg), a preferential ligand for the phenylethylamine site, but was only partially reversed by idazoxan (500 μ g/kg), a preferential ligand for the imidazoline site. Small doses of the α_2 -adrenergic agonist clonidine (2-10 μ g/kg) enhanced the efficacy of the stimulation, while high doses (100-400 μ g/kg) reduced it. These incremental and the decremental effects of clonidine were reversed by 0.1 and 1 mg/kg of yohimbine, respectively. These results suggest that low doses of clonidine preferentially activate α_2 -autoreceptors on NE neurons resulting in a reduction of the tonic inhibitory effect of endogenous NE on 5-HT transmission, while higher doses of clonidine would decrease 5-HT transmission through the activation of α_2 -heteroreceptors on 5-HT terminals. This interpretation is consistent with the report of Maura et al. (Eur. J. Pharmacol. 116: 335, 1985) showing that the affinity of clonidine is 10 times higher for α_2 -autoreceptors on NE terminals than for α_2 -heteroreceptors on 5-HT terminals.

IPSPs IN PYRAMIDAL CELLS IN PIRIFORM CORTEX EVOKED BY MONOAMINE EXCITATION OF INTERNEURONS DEMONSTRATE A CONVERGENCE OF INPUTS. R.L. Gellman and G. K. Aghajanian, Depts. of Psychiatry and Pharmacology; Yale University, New Haven, CT 06510.

Previous work demonstrated a subpopulation of interneurons on the border of layers II/III in piriform cortex that are excited by serotonin (5-HT) via 5-HT₂ receptors. Excitation of these interneurons induces IPSPs (inhibitory post-synaptic potentials) in pyramidal cells (layer II). The present study looked at the effects of three different monoamines on the layer II/III interneuron-pyramidal cell network. In brain slices, brief bath applications of 100 μ M 5-HT, dopamine (DA) or norepinephrine (NE) produced an increase in firing rate in 30-40% of extracellularly recorded interneurons, a decrease in 10% and no effect in the remainder. Of the interneurons that did respond, 52% responded to all three of the monoamines, 13% responded to two and 35% responded only to a single transmitter. These data suggest that responsivity to applied monoamines can define subpopulations of interneurons.

Intracellular recordings from layer II pyramidal cells (n=29) using KCl filled electrodes demonstrated spontaneous, bicuculline-sensitive reverse IPSPs. 5-HT, NE or DA increased IPSPs in 65%, 45% or 24% of cells respectively. The number of IPSPs increased in response to all three monoamines in 39% of the cells, to two in 28% and to one in 33%. The pattern of IPSPs evoked by the monoamines was unique for each cell. Typically, within a given pyramidal cell, the array of IPSPs evoked by one monoamine contained amplitudes common to that evoked by the other monoamines as well as unique amplitudes, suggesting that multiple interneurons had been activated.

We propose that the specific pattern of IPSPs seen in a pyramidal cell responding to more than one monoamine demonstrates a convergence of inputs from different populations of interneurons onto that pyramidal cell.

394.2

DOSE-DEPENDENT EFFECTS OF THE SEROTONIN₂ RECEPTOR ANTAGONIST, RITANSERIN, ON TISSUE AND DIALYSATE LEVELS OF DOPAMINE AND SEROTONIN IN THE RAT BRAIN. L. L. DEVAUD, DIV. OF PHARMACOLOGY, WELLCOME RESEARCH LABS, RESEARCH TRIANGLE PARK, N C 27709

Ritanserin (RIT) was used to study the serotonin (5-HT) component of neurotransmitter modulation in relation to atypical antipsychotics, which have both 5-HT₂ and dopamine₂ (DA₂) receptor antagonist activities. Systemic RIT potently decreased tissue levels of DA and 5-HT with a maximal effect of 21.4 or 22.2% reduction, respectively. It had no consistent effects on DOPAC, HVA or 5-HIAA levels. ED₅₀ values were 0.27 mg/kg (0.21-0.35)mg/kg for DA and 0.39(0.15-1.0)mg/kg for 5-HT in the nucleus accumbens. Similar potencies were noted for RIT in the frontal cortex. No dose response was seen in the striatum. In general, these findings correspond to RIT-induced increases in DA levels in dialysate from the nucleus accumbens and the frontal cortex collected from freely moving animals. At 60 min after a dose of 0.3mg/kg, RIT increased DA 147 ± 22 above baseline while 0.63mg/kg RIT increased DA 213 ± 58 . RIT treatment also increased DA and 5-HT release in the frontal cortex. No effects of RIT were noted on dialyzed DA or 5-HT levels collected from the striatum. These results show that selective 5-HT₂ receptor antagonism modulates DA and 5-HT neurotransmission in a dose-dependent and site-selective manner.

THE "5HT/NE LINK" BEYOND THE BETA ADRENOCEPTOR. A. Eiring*, D.H. Manier* and F. Sulser. Vanderbilt Univ. Sch. of Med., Nashville, TN 37232.

C₆ rat glioma cells cultured in Ham's F-10 medium were used as a model system to study the interaction of aminergic signals beyond the beta-adrenoceptor. In confirmation of the results obtained by Yoshikawa and Sabol (Mol. Brain Res. 1, 75-83, 1986), the beta-adrenoceptor mediated expression of preproenkephalin A (ppEK) mRNA in C₆ rat glioma cells is markedly enhanced by glucocorticoids. Isoproterenol caused a long lasting increase in the formation of cyclic AMP and a 3,6 and 9 fold enhancement in the ppEK mRNA steady state levels at 2,4 and 8 hours of incubation respectively. Serotonin, (5HT) while exerting no effect on beta-adrenoceptor density or K_D values and only slightly attenuating the isoproterenol enhanced formation of cyclic AMP, had no effect on the steady state level of ppEK mRNA but markedly reduced the beta agonist induced increase. The 5HT receptor subtype mediating the antagonistic response to the beta signal remains to be determined. The results demonstrate the convergence of aminergic signals beyond the beta-adrenoceptor and its importance in the regulation of gene expression (Supported by USPHS grant MH-29228).

INTERACTIONS BETWEEN RESPONSES MEDIATED BY SIMULTANEOUS ACTIVATION OF ADENOSINE A₂ AND ALPHA₁ ADRENERGIC RECEPTORS (AAR).

H.L. Wiener, G.P. Thalody* and S. Maayani. Dept. Pharm. Sci. (HLW & GPT), St. John's Univ., Jamaica, NY 11439 and Depts. Anesthesiol. (HLW & SM), and Pharmacol. (SM), Mt. Sinai Sch. Med., CUNY, New York, NY, 10029.

Blood vessel tone is regulated by the action of different substances, such as neurotransmitters, blood-borne compounds, and agents released from the vascular endothelium. Some characteristics of the interactions between responses mediated by two of these substances are reported in this communication. Two membrane receptors, the adenosine (AD) A₂ and the AAR, were chosen as a model to study functional antagonism, measured as operational partial agonism, in the adventitia- and endothelium-denuded isolated rabbit thoracic aorta. AD agonists (AD, cyclohexyladenosine (CHA), methyladenosine (MeAD), 5'-N-ethylcarboxamidoadenosine (NECA), and R(-)-N₆-(2-phenylisopropyl)adenosine (R-PIA)) did not affect basal tissue tone; they did, however, relax aortic rings pre-contracted with the AAR agonist phenylephrine (PE). The AD receptor mediating this functional antagonism was tentatively classified as the AD A₂ receptor based on the rank order of potency: NECA > AD = CHA = R-PIA > MeAD. The fractional relaxation (relaxation/contraction; R/C) mediated by each drug was inversely proportional to PE concentration in naive tissues, and was greater in tissues following partial AAR alkylation with dibenamine, indicating that the magnitude of functional antagonism measured as operational partial agonism, is inversely dependent on the contractile stimulus. The concentration dependence and saturability of R/C elicited by AD A₂ agonists indicates the involvement of a drug-receptor complex in the generation of the relaxation response. We propose that in a given tissue the efficacy of distinct endogenous substances is mutually and continuously altered when they activate their respective receptors. These interactions are the underlying mechanisms of the resultant physiological responses. (GM-34852).

EFFECTS OF REPEATED ADMINISTRATION OF AZAPIRONES ON CNS MONOAMINES IN RATS.

D. Hoganson*, K. J. Sufka, E. P. Finnerty and J. Giordano. Dept. of Biology and Neuropharmacology Lab., COPHS, Drake Univ., Des Moines, IA 50311.

Using HPLC-EC techniques, the effects of 1-28 days of treatment with the azapirone 5-HT_{1A} agonists, buspirone or gepirone (1.0 mg/kg; ip) on monoamine (MA) levels in cortex, brainstem and spinal cord were studied. In the cortex and brainstem, buspirone produced peak MA changes at days 1 and 7. In these loci, MA changes returned to basal levels by 28 days of treatment. In the spinal cord, no effects were detected prior to the occurrence of peak changes at 14 and 28 treatment days. Gepirone produced peak MA changes in the cortex and brainstem at 1 and 7 days, with a returned to baseline levels by days 14 and 28. Gepirone-induced MA changes in the spinal cord occurred at 14 days, and persisted to 28 days of treatment.

ROLE OF CALCIUM IN THE MODULATION OF NE-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS BY cAMP AND ADENOSINE. L. B. Schachter¹ and B. B. Wolfe². Depts. of Pharmacology, ¹U. of Pennsylvania, Philadelphia, PA. 19104, and ²Georgetown U., Washington, D.C. 20007.

In DDT₁ smooth muscle cells the adenosine A₁-selective agonist cyclopentyladenosine (CPA) induced a twofold potentiation of norepinephrine-stimulated (NE-stimulated) phosphatidylinositol (PI) turnover, whereas the activation of adenosine A₁ receptors in the absence of NE had no significant effect upon PI turnover. This behavior occurred in the absence of extracellular calcium and was not blocked by calcium channel blockers. However, pretreatment with the membrane-permeant calcium chelator, Quin-2 AM, blocked the potentiation, suggestive of a role for intracellular calcium in the potentiation phenomenon. In the presence of a calcium ionophore, CPA stimulated PI hydrolysis in a calcium dependent manner, without the addition of NE.

Both 8-bromo cAMP and forskolin were able to selectively inhibit the potentiation of NE-stimulated PI hydrolysis, due to CPA, without significantly affecting the stimulation by NE alone. Measurement of the intracellular calcium transient response to NE with Fura-2 revealed that forskolin reduced both the magnitude and the duration of the rise in intracellular calcium.

The data are supportive of a model for the activation of PI hydrolysis via two different pathways: 1) a CPA-stimulated pathway which requires increased intracellular calcium, and 2) a NE-stimulated pathway, active at basal calcium. The level of intracellular calcium, and thus the magnitude of CPA-stimulated PI hydrolysis, can be regulated via [cAMP]. (NS-26934 and GM-31155)

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION I

Fornix-lesions do not affect diurnal rhythms, stress responsiveness or ACTH sensitivity to corticosterone (B) feedback in rats with fixed B replacement. M.J. Bradbury & M.F. Dallman*. Div. Neuroscience, UCSF, San Francisco CA 94143.

While B shapes both circadian rhythms and stress-induced ACTH responses, the sites in the CNS at which B acts to control ACTH are not known. Although some reports implicate a hippocampal site [through hippocampectomy or fornix-lesions (FL)], others do not find effects of such surgery on ACTH or B (for review, see Jacobson & Sapolsky, 1991). First, we damaged either the dorsal fornix (df) (n=5 rats), the df and 1/2 to 3/4 of the ventral hippocampal commissure (VHC) (n=9), the df and the columns of the posterior fornix (n=4) or the overlying cortex (CL) (n=4). In the morning 4 days after the lesion, there were no differences in plasma B among the groups (B \leq 1.4 μ g/dl in all but 2 rats). Next, rats were provided with chronic catheters; in 9, the df and the VHC were completely lesioned (FL). 7 rats were CL and 3 were only cannulated. The diurnal rhythm of B was the same among the groups days 1-6 after surgery. In both expts, thymus and adrenal weights were the same in all groups, providing no evidence for prolonged stimulation of B. Finally, we asked whether FL rats would be as sensitive to fixed negative feedback as CL rats. 2 days after cannulation and FL or CL, rats were ADX and given either 20% B pellets (n: FL=5, CL=7) or 25% pellets (n: FL=3, CL=5). The diurnal rhythm of ACTH was not different among the groups 4-7 days after ADX. On day 8, rats were exposed to hypoxia (10% O₂) for ~55 min and then to room air for 45 min. The rising phase of ACTH, the peak ACTH response and the decrease of ACTH after hypoxia in FL and CL rats were the same. Initial B in FL and CL rats was the same within pellet doses. From these data, we conclude that the fornix lesions we made did not disrupt a major B-mediated feedback pathway during the times examined.

THE EFFECTS OF NEONATAL HANDLING ON SEROTONIN TURNOVER AND RECEPTOR BINDING. J.W.Smythe, W.Rowe and M.J.MEANNEY. Dept. of Psychiatry, McGill Univ., Douglas Hospital Res. Centre, Montreal, Quebec, Canada H4H 1R3

Neonatal rats handled during the first week postnatally exhibit increased glucocorticoid (GC) receptor densities in hippocampus (HPC) and frontal cortex. Cultured fetal HPC cells also possess higher GC receptor densities following exposure to serotonin (5HT), an effect mediated via 5HT₂ receptors. Handled (H) rats manifest increased 5HT turnover in HPC, leading us to ask if this effect is selective for the HPC and whether it involves changes in 5HT₂ receptor densities. Brain tissue obtained from H or non-handled (NH) rats was assayed by HPLC for 5HT and 5HIAA content, and 5HT₂ binding was assessed using 3H-ketanserin (3H-KET) as ligand. The 5HT/5HIAA ratio was higher in H than in NH rats in frontal cortex and HPC, but not in hypothalamus or amygdala, regions unaffected by handling. 3H-KET binding in the frontal cortex did not differ between groups, since neither Kd's nor Bmax's varied. Thus handling could alter GC receptor densities by affecting 5HT turnover in specific brain regions, but not by altering 5HT₂ receptor densities.

MORPHOLOGICAL EVIDENCE FOR HIPPOCAMPAL INTERACTION WITH THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS

W.E. Cullinan, J.P. Herman, and S.J. Watson. University of Michigan, Mental Health Research Institute, Ann Arbor, MI, 48109-0720.

Recent data have implicated the hippocampal formation in the negative feedback inhibition of the hypothalamic-pituitary-adrenal (HPA) axis, suggesting inhibitory influences on the neurons of the medioparvocellular division of the hypothalamic paraventricular nucleus (PVN). However, hippocampal efferents apparently do not reach the PVN, and are generally thought to be excitatory, suggesting that the effects are mediated by one or more intervening neurons. A possible site of such an interaction is the bed nucleus of the stria terminalis (BST), which is known to receive hippocampal input, project to the PVN, and to contain a rich population of GABA neurons. This possibility was examined in the present experiments. Iontophoretic injections of the retrograde tracer Fluoro-gold were made in the PVN in male rats. Injections of the anterograde tracer Phaseolus vulgaris-leucoagglutinin (PHA-L) were delivered to the ipsilateral ventral subiculum. Light microscopic PHA-L/Fluoro-gold double-labeling studies suggested hippocampal input to PVN-projecting neurons in the BST. To test the possibility that PVN-projecting neurons in the BST contain the neurotransmitter GABA, sections from cases containing Fluoro-gold injections in the PVN were processed for *in situ* hybridization for glutamic acid decarboxylase, the GABA synthesizing enzyme. Double-labeled neurons were detected in the BST, rostromedial portion of the zona incerta, as well as in several other regions of the medial basal hypothalamus. The findings are consistent with the notion that hippocampal influence on the HPA axis may be mediated in part by the BST. Supported by DA02265 and MH422251.

INHIBITORY EFFECT OF CENTRALLY ADMINISTERED SEROTONIN-1_A AGONISTS UPON ADRENOCORTICAL SECRETION.

Jon E. Welch*, Adrian J. Dunn and David Saphier. Department of Pharmacology, LSU Medical Center, P.O. Box 33932, Shreveport, LA 71130.

Serotonin (5-HT) has generally been considered to serve a facilitatory role in the CNS regulation of adrenocortical secretion. Numerous studies have shown that administration of 5-HT_{1A} receptor agonists increase plasma corticosterone (CS) concentrations in rats, however the mechanism by which this response is elicited has not been demonstrated to date. Rats were prepared with a cannula implanted above the lateral cerebral ventricle, or bilateral cannulae above the hypothalamic paraventricular nuclei (PVN), the site of corticotropin-releasing factor (CRF)-secreting neurons regulating adrenocortical secretion. The 5-HT_{1A} agonists 8-OH-DPAT and ipsapirone caused significant decreases in plasma CS levels at all doses tested (5-20 nmol), as compared with saline-treated control rats, under sodium pentobarbital anesthesia. In contrast, intraperitoneal injection of 8-OH-DPAT (2 μ mol/kg) increased plasma CS concentrations, and this effect was not prevented by prior central administration of the 5-HT_{1A} antagonists, NAN-190 or spiroxatrine (20 nmol). Pretreatment of animals with 6-hydroxydopamine, injected via the PVN cannulae, caused a large depletion in local norepinephrine content, without affecting 5-HT content, and abolished the CS responses following peripheral 8-OH-DPAT administration. In view of the adrenocortical activating effects of hypotensive stimuli, this suggests that the well-documented hemodynamic responses following 5-HT_{1A} receptor stimulation were probably responsible for the adrenocortical responses observed. Our data indicate that 5-HT_{1A} receptor stimulation within the CNS decreases adrenocortical secretion, perhaps via a direct effect in the PVN involving CRF-secreting neurons therein.
