

SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 17, PART 1

21ST ANNUAL MEETING
NEW ORLEANS, LOUISIANA
NOVEMBER 10–15, 1991

1991 © Society for Neuroscience

Made in the United States of America.

International Standard Book Numbers:

Part 1 ISBN 0-916110-36-2

Part 2 ISBN 0-916110-37-0

Both parts ISSN 0190-5295

Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:

Soc. Neurosci. Abstr., Vol. 17, Part 1, p. xxx, 1991.

Published by:

Abstracts in Session Order*	
Monday, November 11–Wednesday, November 13.....	1

*9,416 volunteer abstracts, 18 symposia abstracts, and 64 teaching of neuroscience abstracts.

1991 Program Committee

J. Anthony Movshon, Ph.D., *Chairperson*
New York University

Stanley J. Watson, Jr., M.D., Ph.D.
Incoming Chairperson
University of Michigan School of Medicine

David G. Amaral, Ph.D.
The Salk Institute

James E. Blankenship, Ph.D.
Marine Biomedical Institute

Martha C. Bohn, Ph.D.
National Science Foundation

Dennis W. Choi, M.D., Ph.D.
Washington University School of Medicine

Roland D. Ciaranello, M.D.
Stanford University Medical Center

Antonio R. Damasio, M.D., Ph.D.
University of Iowa College of Medicine

Eberhard E. Fetz, Ph.D.
University of Washington School of Medicine

Karl Herrup, Ph.D.
Eunice Kennedy Shriver Center

Stephen M. Highstein, M.D., Ph.D.
Washington University School of Medicine

Harvey J. Karten, M.D.
University of California School of Medicine

James E. Krause, Ph.D.
Washington University School of Medicine

Irwin B. Levitan, Ph.D.
Brandeis University

James O. McNamara, M.D.
Duke University Medical Center
V.A. Medical Center

Urs S. Rutishauser, Ph.D.
Case Western Reserve University School of
Medicine

Elaine Sanders-Bush, Ph.D.
Vanderbilt University School of Medicine

Gerard P. Smith, M.D.
Cornell University Medical College

C. Dominique Toran-Allerand, M.D.
Columbia University College of Physicians and
Surgeons

Leslie G. Ungerleider, Ph.D.
National Institutes of Health

Charles J. Vierck, Ph.D.
University of Florida Health Science Center

Monte Westerfield, Ph.D.
University of Oregon

Robert D. Wurster, Ph.D.
Loyola University of Chicago

Richard E. Zigmond, Ph.D.
Case Western Reserve University School of
Medicine

Robert H. Wurtz, Ph.D., *ex-officio*
National Institutes of Health

Joseph T. Coyle, M.D., *ex-officio*
Harvard Medical School

Story C. Landis, Ph.D., *ex-officio*
Case Western Reserve University School of
Medicine

CHRONOLOGICAL LIST OF SESSIONS

(See page xiv for Thematic List of Sessions.)

Session Number and Title	Page	Session Number and Title	Page
SUNDAY			
Decade of the Brain Public Lecture — 8:00 p.m.			
1. The Brain Basis of REM Sleep and Dreaming J.A. Hobson	No Abstract	29. Calcium channels: physiology and pharmacology I	61
MONDAY			
Symposia — 8:30 a.m.			
2. Insights into Brain and Spinal Components of the Opiate Withdrawal Syndrome <i>Chaired by:</i> J.J. Buccafusco and D.C. Marshall	1	30. Potassium channels: physiology and regulation I	64
3. Activity-Dependent Regulation of Somatosensory Processing at Thalamic and Cortical Levels in Adult Primates <i>Chaired by:</i> E.G. Jones	1	31. Ion channels: modulation and regulation I	67
Slide Sessions — 8:30 a.m.			
4. Long-term potentiation: physiology and pharmacology I	1	32. Excitatory amino acids: pharmacology I	70
5. Learning and memory—anatomy: human studies	3	33. Excitatory amino acids: receptors I	73
6. Excitatory amino acids: excitotoxicity I	5	34. GABA receptors: structure	76
7. Visual psychophysics and behavior	7	35. Catecholamine receptors: α and β	80
8. Pattern formation, compartments and boundaries I	9	36. Catecholamine receptors: dopamine I	84
9. Retina and photoreceptors: receptors and circuits	12	37. Catecholamines: dopamine release	87
10. Process outgrowth, growth cones and sprouting I	14	38. Catecholamines: general	90
11. Second messengers I	16	39. Serotonin receptors: 5HT _{1A} I	91
12. Nerve growth factor I	18	40. Second messengers II	94
13. Human cognition	20	41. Behavioral pharmacology I	97
14. Acetylcholine receptors: nicotinic	22	42. Hypothalamic-pituitary-adrenal regulation: glucocorticoid receptors	100
15. Biological rhythms and sleep I	24	43. Respiratory regulation I	102
16. Brain metabolism and blood flow I	26	44. Somatic and visceral afferents	105
17. Auditory and vestibular hair cells and epithelia	28	45. Pain modulation: behavior	107
Poster Sessions — 8:30 a.m.			
18. Neurogenesis	29	46. Pain modulation: opioids I	109
19. Cell lineage I	31	47. Subcortical visual pathways: midbrain	111
20. Cell shape and differentiation I	33	48. Visual cortex: cortical circuits	114
21. Cell shape and differentiation II	36	49. Chemical senses: peripheral mechanisms I	117
22. Axon guidance mechanisms and pathways I	39	50. Circuitry and pattern generation I	120
23. Growth factors and trophic agents I	42	51. Circuitry and pattern generation: models	123
24. Regeneration: protein correlates	47	52. Limbic system I	126
25. Transplantation: cortex	50	53. Learning and memory—anatomy I	129
26. Aging processes I	52	54. Learning and memory—anatomy II	133
27. Neuroglia and myelin I	54	55. Learning and memory—pharmacology: acetylcholine I	136
28. Cytoskeleton, transport, membrane targeting I	58	56. Neural plasticity I	139
		57. Ingestive behavior: monoamines	142
		58. Stress, hormones and the autonomic nervous system	145
		59. Monoamines and behavior: norepinephrine and serotonin	148
		60. Drugs of abuse—benzodiazepines	151
		61. Drugs of abuse—cocaine: binding and neurophysiology	153
		62. Drugs of abuse—cocaine: development	156
		63. Developmental genetic models	159
		64. Trauma: spinal cord	161
		65. Trauma I	163
		66. Trauma II	166
		67. Epilepsy: basic mechanisms I	169
		68. Epilepsy: animal models I	172
		Special Lecture — 11:45 a.m.	
		69. Patterns of Activity Mediated by Lateral Interactions in the Retina F. Werblin	No Abstract

Session Number and Title	Page
Symposia — 1:00 p.m.	
70. The Basal Ganglia in the '90s: Wedding the Neural System to Cellular and Molecular Mechanisms <i>Chaired by:</i> C.R. Gerfen	176
71. Regulation of Ion Channels <i>Chaired by:</i> L.K. Kaczmarek	176
Update Lecture — 1:00 p.m.	
72. Animal Communication Signals: Emotion or Reference? P. Marler	No Abstract
Slide Sessions — 1:00 p.m.	
73. Visual cortex: striate cortex	176
74. Formation and specificity of synapses I	178
75. Second messengers III	180
76. Axon guidance mechanisms and pathways II	182
77. Ischemia I	183
78. Visual system: retina	185
79. Peptides: receptors I	187
80. Drugs of abuse—cocaine: transporters and toxins	189
81. Ingestive behavior: molecular	191
82. Psychotherapeutic drugs	193
83. Alzheimer's disease: genetics and growth factors	195
84. Spinal cord and brainstem I	197
85. Transmitters in invertebrates: coelenterates, annelids, arthropods	198
86. Regulation of respiration and autonomic functions	200
Poster Sessions — 1:00 p.m.	
87. Cell differentiation and migration I	202
88. Cell differentiation and migration II	205
89. Process outgrowth, growth cones and sprouting II	207
90. Process outgrowth, growth cones and sprouting III	211
91. Formation and specificity of synapses II	212
92. Formation and specificity of synapses III	215
93. Formation and specificity of synapses IV	218
94. Nerve growth factor II	220
95. Growth factors and trophic agents II	223
96. Neuronal death I	227
97. Development of sensory systems I	230
98. Transplantation: general	233
99. Transplantation: spinal cord	235
100. Blood-brain barrier	237
101. Regulation of gene expression I	241
102. Pharmacology of synaptic transmission: hippocampus	244
103. Pharmacology of synaptic transmission: neurotransmitters	246
104. Synaptic transmission	248
105. Acetylcholine receptors: neuronal nicotinic I	249
106. Excitatory amino acids: anatomy and physiology I	252
107. Excitatory amino acids: anatomy and physiology II	255
108. Excitatory amino acids: pharmacology II	259
109. GABA receptors: function I	262
110. Opioids: anatomy and physiology I	265

Session Number and Title	Page
111. Catecholamines: hormonal regulation	268
112. Catecholamines: ascorbic acid	270
113. Serotonin receptors: 5HT _{1A} II	272
114. Transmitters in invertebrates: arthropods	275
115. Transmitters in invertebrates: coelenterates, worms, echinoderms	279
116. Behavioral pharmacology II	280
117. Cardiovascular regulation: peripheral mechanisms	284
118. Visceral afferents	287
119. Subcortical somatosensory pathways: brainstem	289
120. Pain pathways I	292
121. Pain modulation: opioids II	294
122. Retina and photoreceptors: photoreceptors	296
123. Auditory system: central pathways I	300
124. Auditory system: central pathways II	303
125. Cortex I	307
126. Cortex II	308
127. Vestibular system I	312
128. Vestibular system II	315
129. Comparative neuroanatomy I	319
130. Learning and memory—physiology I	322
131. Monoamines and behavior: development, ingestion and sex	325
132. Drugs of abuse—opioids: dopamine and dependence	328
133. Psychotropic drugs: sigma receptors	332
Special Lecture — 4:15 p.m.	
134. An Experimental Model of Painful Peripheral Neuropathy G.J. Bennett	No Abstract
Animals in Research Panel — 6:30 p.m.	
135. Legal Issues Related to Animal Rights Activism	No Abstract
Presidential Symposium — 8:00 p.m.	
136. Biological Basis of Visual Perception Illusory Motions S. Anstis	No Abstract
Parallel Pathways in Vision P.H. Schiller	No Abstract
Visual Motion: From Neural Circuits to Perceptual Decisions W.T. Newsome	No Abstract
TUESDAY	
Symposia — 8:30 a.m.	
137. Trophic Agents and the Development and Maintenance of Neurons <i>Chaired by:</i> R.W. Oppenheim	335
138. Neural Network Models of Vertebrate Sensorimotor Systems <i>Chaired by:</i> B.W. Peterson	335

Slide Sessions — 8:30 a.m.

139. Excitatory amino acids: receptors II	335
140. Learning and memory—anatomy: animal studies	337
141. Cardiovascular regulation I	339
142. Calcium channels: physiology and pharmacology II	341
143. Retina and photoreceptors: ganglion cells	343
144. Neuroendocrine regulation I	345
145. Transplantation: animal models of Parkinson's disease I	347
146. Second messengers IV	349
147. Alzheimer's disease: neuropathology I	351
148. Neurobiology of schizophrenia	353
149. Catecholamine receptors: noradrenergic and dopaminergic	355
150. Drugs of abuse—cocaine: genes, molecules and buprenorphine	357
151. Drugs of abuse—alcohol, barbiturates and benzodiazepines	359
152. Opioids: receptors I	361

Poster Sessions — 8:30 a.m.

153. Molecular and pharmacological correlates of development: monoamines	363
154. Visual system: molecular mechanisms in visual cortex	365
155. Aging processes II	367
156. Staining, tract tracing and imaging I	371
157. Neuroglia and myelin II	373
158. Cytoskeleton, transport, membrane targeting II	377
159. Regulation of gene expression II	379
160. Long-term potentiation: protein kinases and second messengers	381
161. Long-term potentiation: models and mechanisms	385
162. Acetylcholine receptors: muscarinic I	388
163. Excitatory amino acids: pharmacology III	391
164. Peptides: biosynthesis, metabolism and biochemical characterization I	394
165. Peptides: biosynthesis, metabolism and biochemical characterization II	397
166. Peptides: biosynthesis, metabolism and biochemical characterization III	401
167. Peptides: biosynthesis, metabolism and biochemical characterization IV	403
168. Serotonin receptors: 5HT ₂ and 5HT _{1C}	405
169. Biogenic amines and purines	409
170. Neurotransmitter modulation: excitatory and inhibitory transmitters	411
171. Regional localization of receptors and transmitters I	414
172. Regional localization of receptors and transmitters II	417
173. Second messengers V	420
174. Behavioral pharmacology III	424
175. Hypothalamic-pituitary-gonadal regulation: LH and LHRH I	427

176. Hypothalamic-pituitary-gonadal regulation: steroids	430
177. Endocrine regulation I	432
178. Pain pathways: hyperalgesia	435
179. Pain modulation: peripheral	438
180. Visual cortex: extrastriate response properties	440
181. Auditory system: central pathways III	444
182. Auditory system: central pathways IV	447
183. Basal ganglia and thalamus I	451
184. Basal ganglia and thalamus II	454
185. Oculomotor system I	457
186. Oculomotor system II	460
187. Spinal cord and brainstem II	464
188. Spinal cord and brainstem: anatomy	467
189. Limbic system II	470
190. Brain metabolism and blood flow II	473
191. Human cognition: learning and memory	476
192. Learning and memory—anatomy III	478
193. Learning and memory—physiology II	482
194. Learning and memory—pharmacology: excitatory amino acids	485
195. Ingestive behavior: peptides	489
196. Ingestive behavior: neural, hormonal and GI	493
197. Hormonal control of behavior I	497
198. Monoamines and behavior: dopamine	500
199. Developmental genetic models: transmitter systems and second messengers	504
200. Epilepsy: animal models II	506
201. Epilepsy: basic mechanisms II	509
202. Teaching of neuroscience: courses and programs	512
203. Teaching of neuroscience: computer-based education	518
 Warner-Lambert Lecture — 11:45 a.m.	
204. Axon Guidance <i>in vitro</i> F. Bonhoeffer	No Abstract
 Symposia — 1:00 p.m.	
205. Molecular Mechanisms of Neurotransmitter Secretion <i>Chaired by:</i> G.J. Augustine	523
206. Therapeutic Potential of Neurotrophic Factors <i>Chaired by:</i> K. Nikolics	523
 Update Lecture — 1:00 p.m.	
207. Insect Models to Examine Steroid Action on the CNS J.W. Truman	No Abstract
 Slide Sessions — 1:00 p.m.	
208. Visual cortex: near extrastriate cortex	524
209. GABA receptors: function II	526
210. Catecholamines	528
211. Gene structure and function I	530
212. Process outgrowth, growth cones and sprouting IV	532
213. Neural plasticity II	534

Session Number and Title	Page
214. Nociception	536
215. Molecular and pharmacological correlates of development I	538
216. Brain metabolism and blood flow III	540
217. Ingestive behavior: CCK, bombesin and NPY	542
218. Oculomotor system III	544
219. Peptides: biosynthesis, metabolism and biochemical characterization V	546
220. Invertebrate learning and behavior I	548
221. Neuroglia and myelin III	550
 Poster Sessions — 1:00 p.m.	
222. Neurogenesis: tissue culture models	552
223. Neuronal death: axotomy	554
224. Molecular and pharmacological correlates of development in cerebellum and spinal cord	556
225. Visual system: retina and transplantation	557
226. Regeneration: molecular correlates	561
227. Regeneration: prostheses, therapeutics, function	565
228. Transplantation: new technology	568
229. Transplantation: genetically engineered cells	570
230. Membrane composition: cell surface macromolecules I	572
231. Presynaptic mechanisms: neurotransmitter release	576
232. Postsynaptic mechanisms: signalling pathways	580
233. Acetylcholine receptors: muscarinic II	583
234. Acetylcholine receptors: muscarinic III	586
235. Excitatory amino acids: pharmacology IV	587
236. Opioids: receptors II	591
237. Opioids: receptors III	595
238. Catecholamine receptors: dopamine II	598
239. Serotonin receptors: 5HT ₃	599
240. Second messengers VI	602
241. Second messengers VII	605
242. Regulation of dopamine receptors	609
243. Cardiovascular regulation: brainstem mechanisms I	611
244. Cardiovascular regulation: hypertension and endothelins	615
245. Cardiovascular regulation: spinal mechanisms	617
246. Respiratory regulation II	619
247. Subcortical somatosensory pathways: thalamus	622
248. Somatosensory cortex and thalamocortical relations	624
249. Subcortical visual pathways: LGN	627
250. Auditory and vestibular hair cells: ultrastructure, regeneration and tuning	630
251. Chemical senses: peripheral mechanisms II	633
252. Chemical senses: central pathways I	636
253. Invertebrate sensory systems	638
254. Reflex function	641
255. Spinal cord and brainstem: motoneurons	644
256. Sensorimotor integration: muscle I	648
257. Comparative neuroanatomy II	651
258. Human cognition: event-related potentials, attention, methods	654

Session Number and Title	Page
259. Learning and memory—anatomy IV	658
260. Learning and memory—physiology III	660
261. Motivation and emotion I	664
262. Biological rhythms and sleep II	665
263. Biological rhythms and sleep III	668
264. Biological rhythms and sleep IV	670
265. Biological rhythms and sleep V	673
266. Monoamines and behavior: D ₁ and D ₂ mechanisms	676
267. Drugs of abuse—cocaine: dopamine	679
268. Drugs of abuse—cocaine: monoamines and brain stimulation	682
269. Antipsychotics I	685
270. Antipsychotics II	688
271. Alzheimer's disease: neuropathology II	690
272. Alzheimer's disease: neuropathology III	693
273. Alzheimer's disease: neuropsychology	696
274. Alzheimer's disease: pharmacology and drug trials	699
275. Parkinson's disease: animal studies	701
202. Teaching of neuroscience: courses and programs	512
203. Teaching of neuroscience: computer-based education	518
 Presidential Special Lecture — 4:15 p.m.	
276. The Moving Image: New Roles for Eye Movements in Invertebrate Vision M. Land	No Abstract
 Grass Foundation Lecture and Award — 8:00 p.m.	
277. The Role of a Transient Neural Framework in the Formation of Cerebral Cortical Connections C.J. Shatz	No Abstract
 WEDNESDAY	
 Symposia — 8:30 a.m.	
278. Dynamical Behavior of Neural Systems <i>Chaired by:</i> E. Kaplan and R.M. Siegel	705
279. The Neuron Doctrine 1891 - 1991 <i>Chaired by:</i> G.M. Shepherd	705
 Slide Sessions — 8:30 a.m.	
280. Cardiovascular regulation II	705
281. Cell lineage II	707
282. Subcortical visual pathways	709
283. Nerve growth factor III	711
284. Hypothalamic-pituitary-gonadal regulation I	713
285. Neurotoxicity I	715
286. Interactions between neurotransmitters I	717
287. Serotonin receptors I	719
288. Trauma III	721
289. Regional localization of receptors and transmitters III	723

Session Number and Title	Page	Session Number and Title	Page
290. Alzheimer's disease: neurochemistry I	725	339. Brain metabolism and blood flow IV	863
291. Pain pathways II	727	340. Human cognition: hemispheric lateralization, gender differences	866
292. Biological rhythms and sleep VI	729	341. Learning and memory—anatomy V	868
293. Monoamines and behavior: human and animal	731	342. Learning and memory—pharmacology: other I	871
Poster Sessions — 8:30 a.m.			
294. Gliogenesis and differentiation	733	343. Neural plasticity III	874
295. Process outgrowth, growth cones and sprouting V	735	344. Motivation and emotion II	877
296. Process outgrowth, growth cones and sprouting VI	738	345. Biological rhythms and sleep VII	879
297. Axon guidance mechanisms and pathways III	741	346. Biological rhythms and sleep VIII	882
298. Development of neurotransmitter systems	744	347. Ingestive behavior: salt and water	883
299. Development: voltage-gated channels	747	348. Drugs of abuse—cocaine: antagonists and serotonin	886
300. Development: ligand-gated channels	749	349. Drugs of abuse—cocaine	890
301. Growth factors and trophic agents III	751	350. Genetic models of behavior	892
302. Neuronal death: disease, drugs, trauma	756	351. Developmental disorders of the nervous system I	893
303. Pattern formation, compartments and boundaries II	758	History of Neuroscience Lecture — 11:45 a.m.	
304. Molecular and pharmacological correlates of development II	762	352. The Good Old Days of Neuroanatomy; Or Were They? W.J.H. Nauta	No Abstract
305. Development of cerebral cortex and limbic system I	764	Symposia — 1:00 p.m.	
306. Visual system: cortical connections and plasticity	767	353. Molecular Biology of the Dopamine System: Heterogeneity of the Dopamine Receptors <i>Chaired by:</i> O. Civelli	895
307. Transplantation: animal models of Parkinson's disease II	769	354. How Cells Keep Time: The Molecular and Cellular Basis of Circadian Rhythms <i>Chaired by:</i> D.R. Liskowsky and L.L. Hall	895
308. Aging processes III	771	Update Lecture — 1:00 p.m.	
309. Calcium channels: molecular biology	772	355. The Problem of the Hippocampus and Space R.G.M. Morris	No Abstract
310. Calcium channels: phosphorylation	773	Slide Sessions — 1:00 p.m.	
311. Potassium channels: molecular biology I	774	356. Excitatory amino acids: anatomy and physiology III	896
312. Potassium channels: physiology and regulation II	777	357. Visual system: connections	898
313. Acetylcholine: release	780	358. Calcium channels: physiology and pharmacology III	900
314. Excitatory amino acids: excitotoxicity II	783	359. Transplantation: striatum	902
315. Excitatory amino acids: excitotoxicity III	786	360. Gene structure and function II	904
316. Excitatory amino acids: excitotoxicity IV	789	361. Hypothalamic-pituitary-gonadal regulation II	906
317. Excitatory amino acids: receptors III	793	362. Growth factors and trophic agents IV	908
318. GABA receptors: function III	796	363. Axon guidance mechanisms and pathways IV	910
319. Peptides: receptors II	799	364. Alzheimer's disease: amyloid I	911
320. Peptides: receptors III	804	365. Neural-immune interactions	913
321. Peptides: receptors IV	808	366. Stress, hormones and the autonomic nervous system: neurotransmitters	915
322. Opioids: receptors IV	812	367. Modulation of neurotransmitter receptors	916
323. Catecholamine receptors: dopamine III	815	368. Cerebellum I	918
324. Catecholamine receptors: dopamine IV	819	369. Epilepsy: human studies and animal models I	920
325. Catecholamines: dopamine I	821	Poster Sessions — 1:00 p.m.	
326. Catecholamines: biosynthesis I	824	370. Cell lineage III	922
327. Neural control of immune function	827	371. Cell lineage: genetic and biochemical markers	924
328. Neural-immune interactions: innervation and other	831	372. Process outgrowth, growth cones and sprouting VII	926
329. Temperature regulation and fever	834	373. Nerve growth factor IV	928
330. Somatosensory cortex and thalamocortical relations: physiology	837	374. Non-neuronal cells I	931
331. Somatosensory cortex and thalamocortical relations: plasticity	841	375. Non-neuronal cells II	934
332. Visual cortex: organization and connections	843		
333. Visual psychophysics and behavior: basic processes	846		
334. Basal ganglia and thalamus: electrophysiology	849		
335. Basal ganglia and thalamus: molecular	852		
336. Basal ganglia and thalamus III	855		
337. Oculomotor system IV	857		
338. Oculomotor system V	861		

Session Number and Title	Page
376. Development and regeneration of motor systems I	936
377. Development and regeneration of motor systems II	938
378. Regeneration: tissue correlates	941
379. Membrane composition: cell surface macromolecules II	945
380. Long-term potentiation: physiology and pharmacology II	948
381. Sodium channels: molecular biology	951
382. Sodium channels: physiology and pharmacology	954
383. Ion channels: modulation and regulation II	956
384. Acetylcholine receptors: neuronal nicotinic II	959
385. Peptides: anatomical localization I	962
386. Peptides: anatomical localization II	965
387. Peptides: anatomical localization III	969
388. Peptides: physiological effects I	973
389. Peptides: physiological effects II	975
390. Peptides: physiological effects III	978
391. Catecholamines: biosynthesis II	980
392. Interactions between neurotransmitters II	983
393. Interactions between neurotransmitters III	986
394. Interactions between neurotransmitters IV	989
395. Hypothalamic-pituitary-adrenal regulation I	990
396. Cardiovascular regulation: brainstem mechanisms II	993
397. Cardiovascular regulation: forebrain mechanisms and stress	997
398. Regulation of autonomic functions: genito-urinary control	1000
399. Somatic and visceral afferents: central projections	1003
400. Spinal cord	1005
401. Pain pathways: spinal and trigeminal	1008
402. Pain modulation: pharmacology I	1010
403. Retina and photoreceptors: circuits and signals	1012
404. Visual cortex: striate mechanisms	1014
405. Chemical senses: central pathways II	1017
406. Cortex: anatomy	1018
407. Cortex: lesion and stimulation	1021
408. Spinal cord and brainstem III	1023
409. Control of posture and movement I	1026
410. Control of posture and movement in humans	1031
411. Limbic system III	1035
412. Hypothalamus I	1038
413. Brainstem systems	1040
414. Learning and memory—anatomy VI	1044
415. Learning and memory—physiology IV	1045
416. Motivation and emotion III	1048
417. Neuroethology: bird song	1050
418. Invertebrate learning and behavior II	1053
419. Hormonal control of behavior II	1057
420. Neuropeptides and behavior I	1061
421. Alzheimer's disease: experimental models	1064
422. Alzheimer's disease: cytoskeleton	1067
423. Alzheimer's disease: neurochemistry II	1070
424. Parkinson's disease: animal and transplant studies	1075

Session Number and Title	Page
425. Ischemia II	1078
426. Ischemia III	1081
427. Ischemia IV	1084

Presidential Special Lecture — 4:15 p.m.

428. Visual Pattern Recognition: From Bug-Detectors to Object-Detectors. H. Barlow	No Abstract
--	-------------

THURSDAY

Symposia — 8:30 a.m.

429. Human Eye Saccades—Sensory and Cortical Factors <i>Chaired by:</i> P.E. Hallett	1088
430. Activity-Dependent Plasticity: Analysis at the Cell and Molecular Level <i>Chaired by:</i> P.G. Nelson	1088

Slide Sessions — 8:30 a.m.

431. Visual cortex: architecture and interactions	1088
432. Catecholamine receptors: dopamine V	1090
433. Ischemia V	1092
434. Hypothalamic-pituitary-adrenal regulation: molecular studies	1094
435. Ion channels: modulation and regulation III	1096
436. Regulation of autonomic functions	1098
437. Learning and memory—physiology V	1100
438. Chemical senses: peripheral mechanisms III	1102
439. Alzheimer's disease: amyloid II	1104
440. Cochlear nerve, micromechanics and receptors	1106
441. Somatosensory pathways	1108
442. Control of posture and movement II	1110
443. Cortex III	1112
444. Postsynaptic mechanisms in neurotransmission	1114

Poster Sessions — 8:30 a.m.

445. Nerve growth factor V	1116
446. Growth factors and trophic agents V	1119
447. Neuronal death II	1123
448. Molecular and pharmacological correlates of development: peptides	1125
449. Development of sensory systems II	1126
450. Development of cerebral cortex and limbic system II	1129
451. Visual system: subcortical pathways	1132
452. Transplantation: sensory systems	1137
453. Transplantation: hippocampus	1139
454. Aging processes IV	1140
455. Neuroglia and myelin IV	1143
456. Neuroglia and myelin V	1146
457. Gene structure	1150
458. Synaptic structure and function I	1152
459. Synaptic structure and function: hippocampus	1155
460. Presynaptic mechanisms: phosphorylation	1156

Session Number and Title	Page
461. Calcium channels: multiple types	1158
462. Calcium channels: conotoxins and other ligands	1160
463. Acetylcholine: CNS systems	1163
464. Excitatory amino acids: receptors IV	1165
465. GABA receptors: function IV	1169
466. Opioids: anatomy and physiology II	1171
467. Serotonin receptors II	1173
468. Serotonin I	1176
469. Serotonin II	1179
470. Neurotransmitters: molecular neurobiology	1182
471. Regulation of adrenergic receptors	1184
472. Neuroendocrine regulation II	1186
473. Endocrine regulation II	1187
474. Endocrine regulation III	1191
475. Neural-immune interactions: interleukins and neural functions	1196
476. Neural-immune interactions: stress and behavior	1200
477. Pain pathways: central	1204
478. Pain modulation: peptides and excitatory amino acids	1206
479. Visual psychophysics and behavior: higher functions and models	1209
480. Cochlea: nerve responses, transmitters and second messengers	1212
481. Chemical senses: peripheral mechanisms IV	1215
482. Basal ganglia and thalamus: unit activity	1217
483. Basal ganglia and thalamus IV	1219
484. Control of posture and movement III	1222
485. Invertebrate motor function I	1227
486. Hypothalamus II	1229
487. Human cognition: language, other	1231
488. Learning and memory—pharmacology: acetylcholine II ..	1233
489. Motivation and emotion IV	1237
490. Biological rhythms and sleep IX	1239
491. Biological rhythms and sleep X	1242
492. Neuroethology: arthropods	1243
493. Monoamines and behavior: amphetamine and others	1246
494. Drugs of abuse—amphetamine and nicotine	1248
495. Developmental disorders of the nervous system II	1251
496. Epilepsy: human studies and animal models II	1253
497. Epilepsy: anticonvulsant drugs	1255
498. Alzheimer's disease: neuroimaging and diagnostic tests	1258
499. Parkinson's disease: human studies	1259
500. Ischemia VI	1262
501. Ischemia: excitotoxicity	1265
502. Ischemia VII	1269
503. Infectious diseases	1272
504. Neurotoxicity: MPTP	1274
505. Neurotoxicity: biogenic amines	1276

Special Lecture — 11:45 a.m.

506. Homeotic Genes and the Control of Development M.P. Scott	No Abstract
--	-------------

Session Number and Title	Page
Symposia — 1:00 p.m.	
507. The Cannabinoid Receptor: Biochemistry, Anatomy and Physiology <i>Chaired by:</i> A.C. Howlett	1279
508. Specification of Cerebral Cortex During Development <i>Chaired by:</i> M. Sur and P. Rakic	1279
Update Lecture — 1:00 p.m.	
509. Obsessive Compulsive Disorder: New Perspectives J.L. Rapoport	No Abstract
Slide Sessions — 1:00 p.m.	
510. Potassium channels: molecular biology II	1279
511. Visual cortex: far extrastriate cortex	1281
512. Peptides: physiological effects IV	1283
513. Gene structure and function III	1285
514. Formation and specificity of synapses V	1287
515. Parkinson's disease	1288
516. Excitatory amino acids: pharmacology V	1291
517. Alzheimer's disease: amyloid III	1293
518. Growth factors and trophic agents VI	1295
519. Acetylcholine and acetylcholine receptors	1297
520. Basal ganglia and thalamus V	1299
521. Invertebrate learning and behavior III	1301
522. Development of cerebral cortex and limbic system III	1303
523. Transmitters in invertebrates: molluscs I	1305
Poster Sessions — 1:00 p.m.	
524. Neurogenesis: regulation	1307
525. Process outgrowth, growth cones and sprouting VIII	1309
526. Nerve growth factor VI	1312
527. Hormones and development: steroid receptors	1315
528. Hormones and development: CNS	1317
529. Hormones and development: motor neurons	1318
530. Hormones and development: thyroid hormone	1320
531. Synaptic structure and function II	1321
532. Presynaptic mechanisms	1324
533. Long-term potentiation: physiology and pharmacology III	1328
534. Ion channels: ligand-gated	1331
535. Ion channels: cell function	1334
536. Excitatory amino acids: pharmacology VI	1337
537. GABA receptors: function V	1341
538. Opioids: behavior I	1344
539. Catecholamine receptors: dopamine VI	1347
540. Catecholamines: dopamine II	1350
541. Transmitters in invertebrates: molluscs II	1355
542. Hypothalamic-pituitary-adrenal regulation II	1357
543. Hypothalamic-pituitary: control of gonadal function	1360
544. Hypothalamic-pituitary-gonadal regulation: LH and LHRH II	1362
545. Regulation of autonomic functions: gastrointestinal control	1365

Session Number and Title	Page
546. Somatic and visceral afferents: nociception.....	1367
547. Pain modulation: spinal and trigeminal	1369
548. Pain modulation: pharmacology II	1372
549. Retina and photoreceptors: ganglion cells and centrifugal control	1374
550. Subcortical visual pathways: cortical inputs and subcortical responses	1377
551. Cerebellum II	1380
552. Cerebellum III	1382
553. Control of posture and movement IV	1384
554. Invertebrate motor function II	1389
555. Sensorimotor integration: muscle II	1391
556. Learning and memory—physiology VI	1394
557. Learning and memory—pharmacology: monoamines	1397
558. Neural plasticity IV	1399
559. Neuroethology: molluscs, amphibians, mammals, models	1402
560. Neuroethology: fish	1405
561. Hormonal control of behavior III	1408
562. Hormonal control of behavior IV	1412
563. Neuropeptides and behavior II	1415
564. Drugs of abuse—ethanol	1418
565. Drugs of abuse—alcohol	1422
566. Drugs of abuse—cocaine: pharmacology	1425
567. Drugs of abuse—amphetamine	1429
568. Drugs of abuse—opioids	1432
569. Psychotherapeutics: affective disorders	1435
570. Experimental genetic models	1438
571. Epilepsy: basic mechanisms III	1439
572. Alzheimer's disease: amyloid IV	1443
573. Alzheimer's disease: amyloid V	1446
574. Degenerative disease	1449
575. Schizophrenia	1453
576. Affective illness and related disorders	1456
577. Neurotoxicity II	1458
578. Neurotoxicity: metals and free radicals	1461
579. Neurotoxicity: environmental	1464
580. Clinical CNS neurophysiology	1467

Presidential Special Lecture — 4:15 p.m.

581. Language and Cognition: What the Hands Reveal About the Brain U. Bellugi	No Abstract
---	-------------

FRIDAY

Symposia — 8:30 a.m.

582. Neural Grafting and Parkinson's Disease <i>Chaired by:</i> A. Bjorklund	1470
583. "Lipid Mediators" in Synaptic Transmission and Signal Transduction of Neuronal Cells: Physiological and Pathological Implications	

Session Number and Title	Page
<i>Chaired by:</i> G.Z. Feuerstein and N.G. Bazan	1470
Special Lecture — 10:30 a.m.	
584. Neural and Glial Network Interactions: Visualization in Live Brain Tissues S.J. Smith	No Abstract
Slide Sessions — 8:30 a.m.	
585. Visual system: cortical mechanisms	1470
586. Neurobiology of affective illness and related disorders	1472
587. Potassium channels: physiology and regulation III	1474
588. Neuroendocrine regulation III	1476
589. Cell lineage IV	1478
590. Staining, tract tracing and imaging II	1480
591. Regeneration	1481
592. Auditory system: central pathways V	1483
593. Presynaptic mechanisms: ion channels	1485
594. Serotonin III	1487
595. Circuitry and pattern generation II	1489
596. Epilepsy: basic mechanisms IV	1491
597. Behavioral pharmacology IV	1493
Poster Sessions — 8:30 a.m.	
598. Process outgrowth, growth cones and sprouting IX	1494
599. Nerve growth factor VII	1496
600. Growth factors and trophic agents VII	1499
601. Nutritional and prenatal factors	1503
602. Aging processes V	1507
603. Staining, tract tracing and imaging III	1509
604. Regulation of gene expression III	1512
605. Postsynaptic mechanisms	1514
606. Calcium channels: physiology and pharmacology IV	1516
607. Ion channels: chloride and other	1520
608. Ion channels: modulation and regulation IV	1522
609. Acetylcholine: synthesis and degradation	1525
610. Acetylcholine receptors: muscle nicotinic	1527
611. Acetylcholine receptors: muscarinic IV	1529
612. Excitatory amino acids: pharmacology VII	1533
613. Excitatory amino acids: receptors V	1536
614. Opioids: behavior II	1539
615. Catecholamines: locus coeruleus	1540
616. Serotonin IV	1542
617. Adenosine	1545
618. Neurotransmitter transport and release	1549
619. Biogenic amines: uptake and release	1550
620. Neurotransmitter and hormone receptors	1554
621. Hypothalamic-pituitary-adrenal regulation III	1556
622. Pain modulation: CNS	1558
623. Pain modulation: monoamines	1561
624. Retina and photoreceptors: chemistry and anatomy	1564
625. Visual cortex: stimulation and evoked responses	1568

Session Number and Title	Page	Session Number and Title	Page
626. Chemical senses: central pathways III	1569	633. Invertebrate learning and behavior IV	1589
627. Cerebellum: anatomy	1572	634. Neuropeptides and behavior III	1594
628. Cerebellum IV	1575	635. Drugs of abuse—prenatal ethanol	1596
629. Control of posture and movement V	1576	636. Drugs of abuse—cellular effects of ethanol	1599
630. Circuitry and pattern generation III	1580	637. Psychotropic agents: anxiety	1602
631. Association cortex and thalamocortical relations	1582	638. Epilepsy: basic mechanisms V	1605
632. Learning and memory—pharmacology: other II	1585	639. Neuromuscular diseases	1608

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only.)

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
Theme A: Development and Regeneration							
430.	Activity-Dependent Plasticity: Analysis at the Cell and Molecular Level	SYMP.					Thu AM
508.	Specification of Cerebral Cortex During Development	SYMP.					Thu PM
137.	Trophic Agents and the Development and Maintenance of Neurons	SYMP.		Tue AM			
26.	Aging processes I	Poster	Mon AM				
155.	Aging processes II	Poster		Tue AM			
308.	Aging processes III	Poster			Wed AM		
454.	Aging processes IV	Poster				Thu AM	
602.	Aging processes V	Poster					Fri AM
22.	Axon guidance mechanisms and pathways I	Poster	Mon AM				
76.	Axon guidance mechanisms and pathways II	Slide	Mon PM				
297.	Axon guidance mechanisms and pathways III	Poster			Wed AM		
363.	Axon guidance mechanisms and pathways IV	Slide			Wed PM		
87.	Cell differentiation and migration I	Poster	Mon PM				
88.	Cell differentiation and migration II	Poster	Mon PM				
19.	Cell lineage I	Poster	Mon AM				
281.	Cell lineage II	Slide			Wed AM		
370.	Cell lineage III	Poster			Wed PM		
589.	Cell lineage IV	Slide					Fri AM
371.	Cell lineage: genetic and biochemical markers	Poster			Wed PM		
20.	Cell shape and differentiation I	Poster	Mon AM				
21.	Cell shape and differentiation II	Poster	Mon AM				
376.	Development and regeneration of motor systems I	Poster			Wed PM		
377.	Development and regeneration of motor systems II	Poster			Wed PM		
305.	Development of cerebral cortex and limbic system I	Poster			Wed AM		
450.	Development of cerebral cortex and limbic system II	Poster				Thu AM	
522.	Development of cerebral cortex and limbic system III	Slide				Thu PM	
298.	Development of neurotransmitter systems	Poster			Wed AM		
97.	Development of sensory systems I	Poster	Mon PM				
449.	Development of sensory systems II	Poster				Thu AM	
300.	Development: ligand-gated channels	Poster			Wed AM		
299.	Development: voltage-gated channels	Poster			Wed AM		
74.	Formation and specificity of synapses I	Slide	Mon PM				
91.	Formation and specificity of synapses II	Poster	Mon PM				
92.	Formation and specificity of synapses III	Poster	Mon PM				
93.	Formation and specificity of synapses IV	Poster	Mon PM				
514.	Formation and specificity of synapses V	Slide				Thu PM	
294.	Gliogenesis and differentiation	Poster			Wed AM		
23.	Growth factors and trophic agents I	Poster	Mon AM				
95.	Growth factors and trophic agents II	Poster	Mon PM				
301.	Growth factors and trophic agents III	Poster			Wed AM		
362.	Growth factors and trophic agents IV	Slide			Wed PM		
446.	Growth factors and trophic agents V	Poster				Thu AM	
518.	Growth factors and trophic agents VI	Slide				Thu PM	
600.	Growth factors and trophic agents VII	Poster					Fri AM
528.	Hormones and development: CNS	Poster				Thu PM	
529.	Hormones and development: motor neurons	Poster				Thu PM	
527.	Hormones and development: steroid receptors	Poster				Thu PM	
530.	Hormones and development: thyroid hormone	Poster				Thu PM	
215.	Molecular and pharmacological correlates of development I	Slide		Tue PM			

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
304.	Molecular and pharmacological correlates of development II	Poster			Wed AM		
224.	Molecular and pharmacological correlates of development in cerebellum and spinal cord	Poster		Tue PM			
153.	Molecular and pharmacological correlates of development: monoamines	Poster		Tue AM			
448.	Molecular and pharmacological correlates of development: peptides	Poster				Thu AM	
12.	Nerve growth factor I	Slide	Mon AM				
94.	Nerve growth factor II	Poster	Mon PM				
283.	Nerve growth factor III	Slide			Wed AM		
373.	Nerve growth factor IV	Poster			Wed PM		
445.	Nerve growth factor V	Poster				Thu AM	
526.	Nerve growth factor VI	Poster				Thu PM	
599.	Nerve growth factor VII	Poster					Fri AM
18.	Neurogenesis	Poster	Mon AM				
524.	Neurogenesis: regulation	Poster				Thu PM	
222.	Neurogenesis: tissue culture models	Poster		Tue PM			
96.	Neuronal death I	Poster	Mon PM				
447.	Neuronal death II	Poster				Thu AM	
223.	Neuronal death: axotomy	Poster		Tue PM			
302.	Neuronal death: disease, drugs, trauma	Poster			Wed AM		
374.	Non-neuronal cells I	Poster			Wed PM		
375.	Non-neuronal cells II	Poster			Wed PM		
601.	Nutritional and prenatal factors	Poster					Fri AM
8.	Pattern formation, compartments and boundaries I	Slide	Mon AM				
303.	Pattern formation, compartments and boundaries II	Poster			Wed AM		
10.	Process outgrowth, growth cones and sprouting I	Slide	Mon AM				
89.	Process outgrowth, growth cones and sprouting II	Poster	Mon PM				
90.	Process outgrowth, growth cones and sprouting III	Poster	Mon PM				
212.	Process outgrowth, growth cones and sprouting IV	Slide		Tue PM			
295.	Process outgrowth, growth cones and sprouting V	Poster			Wed AM		
296.	Process outgrowth, growth cones and sprouting VI	Poster			Wed AM		
372.	Process outgrowth, growth cones and sprouting VII	Poster			Wed PM		
525.	Process outgrowth, growth cones and sprouting VIII	Poster				Thu PM	
598.	Process outgrowth, growth cones and sprouting IX	Poster					Fri AM
591.	Regeneration	Slide					Fri AM
226.	Regeneration: molecular correlates	Poster		Tue PM			
227.	Regeneration: prostheses, therapeutics, function	Poster		Tue PM			
24.	Regeneration: protein correlates	Poster	Mon AM				
378.	Regeneration: tissue correlates	Poster			Wed PM		
145.	Transplantation: animal models of Parkinson's disease I	Slide		Tue AM			
307.	Transplantation: animal models of Parkinson's disease II	Poster			Wed AM		
25.	Transplantation: cortex	Poster	Mon AM				
98.	Transplantation: general	Poster	Mon PM				
229.	Transplantation: genetically engineered cells	Poster		Tue PM			
453.	Transplantation: hippocampus	Poster				Thu AM	
228.	Transplantation: new technology	Poster		Tue PM			
452.	Transplantation: sensory systems	Poster				Thu AM	
99.	Transplantation: spinal cord	Poster	Mon PM				
359.	Transplantation: striatum	Slide			Wed PM		
357.	Visual system: connections	Slide			Wed PM		
306.	Visual system: cortical connections and plasticity	Poster			Wed AM		
585.	Visual system: cortical mechanisms	Slide					Fri AM
154.	Visual system: molecular mechanisms in visual cortex	Poster		Tue AM			
78.	Visual system: retina	Slide	Mon PM				

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
225.	Visual system: retina and transplantation	Poster		Tue PM			
451.	Visual system: subcortical pathways	Poster					Thu AM
Theme B: Cell Biology							
354. How Cells Keep Time: The Molecular and Cellular Basis of Circadian Rhythms							
		SYMP.			Wed PM		
100.	Blood-brain barrier	Poster	Mon PM				
28.	Cytoskeleton, transport, membrane targetting I	Poster	Mon AM				
158.	Cytoskeleton, transport, membrane targetting II	Poster		Tue AM			
457.	Gene structure	Poster					Thu AM
211.	Gene structure and function I	Slide		Tue PM			
360.	Gene structure and function II	Slide			Wed PM		
513.	Gene structure and function III	Slide					Thu PM
230.	Membrane composition: cell surface macromolecules I	Poster		Tue PM			
379.	Membrane composition: cell surface macromolecules II	Poster			Wed PM		
27.	Neuroglia and myelin I	Poster	Mon AM				
157.	Neuroglia and myelin II	Poster		Tue AM			
221.	Neuroglia and myelin III	Slide		Tue PM			
455.	Neuroglia and myelin IV	Poster					Thu AM
456.	Neuroglia and myelin V	Poster					Thu AM
101.	Regulation of gene expression I	Poster	Mon PM				
159.	Regulation of gene expression II	Poster		Tue AM			
604.	Regulation of gene expression III	Poster					Fri AM
156.	Staining, tract tracing and imaging I	Poster		Tue AM			
590.	Staining, tract tracing and imaging II	Slide					Fri AM
603.	Staining, tract tracing and imaging III	Poster					Fri AM
Theme C: Excitable Membranes and Synaptic Transmission							
205. Molecular Mechanisms of Neurotransmitter Secretion							
		SYMP.		Tue PM			
71. Regulation of Ion Channels							
		SYMP.	Mon PM				
462.	Calcium channels: conotoxins and other ligands	Poster					Thu AM
309.	Calcium channels: molecular biology	Poster			Wed AM		
461.	Calcium channels: multiple types	Poster					Thu AM
310.	Calcium channels: phosphorylation	Poster			Wed AM		
29.	Calcium channels: physiology and pharmacology I	Poster	Mon AM				
142.	Calcium channels: physiology and pharmacology II	Slide		Tue AM			
358.	Calcium channels: physiology and pharmacology III	Slide			Wed PM		
606.	Calcium channels: physiology and pharmacology IV	Poster					Fri AM
535.	Ion channels: cell function	Poster					Thu PM
607.	Ion channels: chloride and other	Poster					Fri AM
534.	Ion channels: ligand-gated	Poster					Thu PM
31.	Ion channels: modulation and regulation I	Poster	Mon AM				
383.	Ion channels: modulation and regulation II	Poster			Wed PM		
435.	Ion channels: modulation and regulation III	Slide					Thu AM
608.	Ion channels: modulation and regulation IV	Poster					Fri AM
161.	Long-term potentiation: models and mechanisms	Poster		Tue AM			
4.	Long-term potentiation: physiology and pharmacology I	Slide	Mon AM				
380.	Long-term potentiation: physiology and pharmacology II	Poster			Wed PM		
533.	Long-term potentiation: physiology and pharmacology III	Poster					Thu PM
160.	Long-term potentiation: protein kinases and second messengers	Poster		Tue AM			
102.	Pharmacology of synaptic transmission: hippocampus	Poster	Mon PM				
103.	Pharmacology of synaptic transmission: neurotransmitters	Poster	Mon PM				
605.	Postsynaptic mechanisms	Poster					Fri AM
444.	Postsynaptic mechanisms in neurotransmission	Slide					Thu AM

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
232.	Postsynaptic mechanisms: signalling pathways	Poster		Tue PM			
311.	Potassium channels: molecular biology I	Poster			Wed AM		
510.	Potassium channels: molecular biology II	Slide					Thu PM
30.	Potassium channels: physiology and regulation I	Poster	Mon AM				
312.	Potassium channels: physiology and regulation II	Poster			Wed AM		
587.	Potassium channels: physiology and regulation III	Slide					Fri AM
532.	Presynaptic mechanisms	Poster					Thu PM
593.	Presynaptic mechanisms: ion channels	Slide					Fri AM
231.	Presynaptic mechanisms: neurotransmitter release	Poster		Tue PM			
460.	Presynaptic mechanisms: phosphorylation	Poster					Thu AM
381.	Sodium channels: molecular biology	Poster			Wed PM		
382.	Sodium channels: physiology and pharmacology	Poster			Wed PM		
458.	Synaptic structure and function I	Poster					Thu AM
531.	Synaptic structure and function II	Poster					Thu PM
459.	Synaptic structure and function: hippocampus	Poster					Thu AM
104.	Synaptic transmission	Poster	Mon PM				
Theme D: Neurotransmitters, Modulators, and Receptors							
507.	The Cannabinoid Receptor: Biochemistry, Anatomy and Physiology	SYMP.					Thu PM
2.	Insights into Brain and Spinal Components of the Opiate Withdrawal Syndrome	SYMP.	Mon AM				
583.	“Lipid Mediators” in Synaptic Transmission and Signal Transduction of Neuronal Cells: Physiological and Pathological Implications	SYMP.					Fri AM
353.	Molecular Biology of the Dopamine System: Heterogeneity of the Dopamine Receptors	SYMP.			Wed PM		
519.	Acetylcholine and acetylcholine receptors	Slide					Thu PM
162.	Acetylcholine receptors: muscarinic I	Poster		Tue AM

SYMPOSIUM. INSIGHTS INTO BRAIN AND SPINAL COMPONENTS OF THE OPIATE WITHDRAWAL SYNDROME. J.J. Buccafusco, Med. Col. Georgia & DVAMC and D.C. Marshall, Pfizer Internatnl. (chairpersons); H.N. Bhargava*, Univ. Illinois; G.K. Aghajanian, Yale Univ. Sch. Med.; G.F. Koob, Scripps Clinic; E.D. London, NIDA Addiction Res. Ctr.

The purpose of this symposium is to summarize recent advances in the understanding of the central neuronal processes underlying the expression of the opiate withdrawal syndrome. Dr. Buccafusco will introduce the concept of spinal vs. brain-mediated withdrawal phenomena and discuss the role of cholinergic neurons. Dr. Bhargava will discuss the changes in specific brain and spinal opiate, dopamine and serotonin receptor subtypes associated with physical dependence and withdrawal. Different mechanisms operate in μ/k -induced tolerance-dependence and abstinence processes. Dr. Aghajanian will discuss the electrophysiological and biochemical changes within the locus coeruleus during opiate withdrawal. The activation of noradrenergic neurons during withdrawal may be related to an hypertrophied cAMP/protein kinase A system. Both excitatory amino acid inputs and intrinsic enhancement of the cAMP system may occur. Dr. Koob will present his studies which identify disruptions in operant behavior following microinjections of opiate antagonists into selective brain regions, particularly the nucleus accumbens in the morphine dependent rat. Dr. London will provide detailed analysis of brain and spinal regions most active during opiate withdrawal by employing the technique of regional cerebral glucose utilization in rats. Studies using positron emission tomography (PET) scanning to obtain objective measures of withdrawal processes in the human brain will also be discussed. It is expected that this symposium will provide a forum for the latest theories of the opiate withdrawal phenomenon and help underscore consistent trends in research findings for this area.

3

SYMPOSIUM. ACTIVITY-DEPENDENT REGULATION OF SOMATO-SENSORY PROCESSING AT THALAMIC AND CORTICAL LEVELS IN ADULT PRIMATES. E.G. Jones, UC,Irvine (Chairperson); M.M. Merzenich, UCSF; J.H. Kaas, Vanderbilt University; T.P. Pons, NIMH.

Research in the 1980s established that topographic maps in the adult brain are susceptible to reorganizational changes following peripheral deafferentation. Emerging research indicates that the areal extent of such changes can be an order of magnitude greater than previously thought. Behavioral manipulations involving enhanced usage rather than deprivation, have now also been demonstrated to influence tuning characteristics and receptive field properties of neurons that probably underlie activity dependent representational changes. In addition, morphological, chemical and molecular correlates have been demonstrated in adult brains. These may be responsible not only for the changes in representational maps that occur under activity-dependent conditions, but also for serious perturbation of sensory perception such as pain of central origin that commonly accompany chronic deafferentation.

The speakers will present evidence on the extent of reorganization that can occur in the somatosensory cortex under activity-dependent conditions. They will show that the character and extent of such reorganization depends to a large extent on the nature of a peripheral perturbations and probably on a variety of cortical and subcortical mechanisms. The remodeling of cortical representations will be considered in relation to different forms of peripheral deafferentation over short and very long periods, to stimulation of nerves, and to behaviorally relevant usage of the limbs. The differential effects of central lesions will be explored. The relative contributions of existing anatomical circuits and of regulation of gene expression for transmitters, receptors and related molecules at cortical and subcortical sites in the activity-dependent plasticity of cortical cell assemblies will be a major feature of the symposium.

LONG-TERM POTENTIATION: PHYSIOLOGY AND PHARMACOLOGY I

4.1

LTP REDUCES K⁺ CHANNEL ACTIVITY IN HIPPOCAMPAL SYNAPTOSOMES. J. Farley and A. Routtenberg. Program in Neural Science, Indiana University, Bloomington, IN 47405 and Cresap Neuroscience Laboratory, Northwestern University, Evanston, IL 60201.

Recent quantal analyses suggest that maintenance of LTP at Schaffer collateral synapses is due to enhanced neurotransmitter release from presynaptic terminals. Because K⁺ ion channels in presynaptic terminals are involved in regulation of such release at many synapses, a persistent reduction in their activities induced by tetanizing stimulation might be expected to contribute to LTP. We have examined this possibility by incorporating hippocampal synaptosomal membranes from animals that sustained LTP into planar lipid bilayers on patch electrodes. We observed near-complete elimination of the activities of several classes of large-conductance calcium-dependent K⁺ channels (Farley & Rudy, 1988, *Biophys. J.*, 53: 919-934) in membranes prepared from perforant path-dentate gyrus synapses, 1 hr following high-frequency stimulation and LTP-induction, as compared to that of sham and low-frequency stimulation controls. The low incidence of K⁺ channel activity did not appear to be due to a selective failure of vesicle fusion for LTP membranes, since calcium channel activity was often observed in these same membranes. Potassium channel activity in membranes from LTP-animals could be restored by addition of alkaline phosphatase to the bath, suggesting the involvement of a protein kinase in the persistent reduction of K⁺ channels and LTP. Supported by NIH NS 26106 to JF and NIMH 25283 and AFOSR 90-0240 to AR.

4.3

LONG TERM POTENTIATION OF AN INHIBITORY PATHWAY IN THE CNS. Y. Oda and H. Korn. INSERM, Institut Pasteur, Paris

The Teleost Mauthner(M-) cell is subjected to a strong Cl⁻ dependent inhibition carried by commissural interneurons which are excited by primary auditory afferents. Current and voltage clamp experiments have shown that following low intensity classical tetanization of the contralateral eighth nerve subthreshold for LTP of excitation in the other M-cell, IPSPs and IPSCs are enhanced for the remainder of the recording session which could exceed one hour. This potentiation reflected, in part, an increased synaptic efficacy at VIIIth N with inhibitory cells connections since i) there was an associated LTP in the LVN, ii) the presynaptic volley onto the M-cell, recorded extra- and intracellularly, was augmented simultaneously with iii) this neuron's inhibitory conductance (G_{ipsp}, peak enhancement \pm SEM = 135 \pm 19%, range 63 to 392%, n=18). M-cell input conductance, RP and collateral IPSPs remained unchanged. Several observations suggest that potentiation also occurred at inhibitory synapses themselves. Specifically, i) the slope of the relation between the input volley and G_{ipsp} could be greater after the tetanus, and ii) this effect was not found when BAPTA was injected postsynaptically. Thus LTP is not restricted to excitatory pathways.

4.2

ANGIOTENSIN II BLOCKS LONG-TERM POTENTIATION.

J.B. Denny, J. Polan-Curtain, D.L. Armstrong and M.J. Wayner. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249.

We have found that injection of 1 μ l of 4.78 μ M angiotensin II in artificial cerebrospinal fluid (ACSF) immediately above the hippocampus in the rat blocks the induction of long-term potentiation (LTP) in perforant path-stimulated dentate granule cells. This effect was completely eliminated if the specific angiotensin antagonist saralasin was also present in the injected solution at a concentration of 239 μ M. Saralasin injected alone resulted in enhanced excitability in the dentate gyrus, but as was the case with the inhibitory action of angiotensin II, the effect was only observable after tetanic stimulation. Both angiotensin II and saralasin had no effect on baseline synaptic transmission. Angiotensin III also blocked LTP induction but required concentrations 40-50 fold greater than those using angiotensin II. These results suggest that angiotensin II is released in the hippocampus following tetanic stimulation and that it serves to modulate LTP through an inhibitory action. A ten-fold lower dose of angiotensin II was not effective in blocking LTP, and the ratio of saralasin to angiotensin II was required to be fifty-fold as given above. A lower ratio of saralasin to angiotensin II (five-fold) resulted in partial blockade of LTP.

Synaptic Ca²⁺-responses restricted to postsynaptic spines of central neurons are NMDA-receptor dependent. W. Müller and J.A. Connor. Dept. of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110

Ca²⁺ and NMDA-receptor dependent synaptic plasticity, e.g. long-term-potentiation, has met considerable interest as a possible substrate for associative memory. Independent plasticity of adjacent synapses on the same postsynaptic dendrite would boost the performance of such a memory network. The synaptic independence might depend on NMDA-receptor mediated Ca²⁺-influx specifically into activated postsynaptic spines. High resolution microfluorometry of fura-2-injected CA3 pyramidal neurons in guinea pig hippocampal slice revealed that synaptic stimulation can indeed elicit very uneven Ca²⁺-accumulations in postsynaptic spiny dendrites, eventually being clearly restricted to single postsynaptic spines. Stronger stimulation elicits more widespread Ca²⁺ accumulations with significant concentration peaks in activated spines. The NMDA-receptor antagonist AP-5 effectively antagonized synaptically evoked Ca²⁺ responses in spines of distal dendrites. Repeated train stimulation led, facilitated by picrotoxin, eventually to the expression of sustained spine or dendritic Ca²⁺ gradients, indicating long lasting postsynaptic changes. Our results demonstrate a space and time dependent microstructure of postsynaptic Ca²⁺ responses that we surmise is significant for neuronal memory capabilities.

AN INHIBITOR OF NITRIC OXIDE SYNTHETASE PREVENTS LONG-TERM POTENTIATION (LTP). E.M. Schuman and D.V. Madison. Dept. of Molecular and Cellular Physiology, Stanford School of Medicine, Stanford, CA 94305.

While LTP in the CA1-Schaffer collateral synapse in the hippocampus is induced by postsynaptic factors, recent evidence suggests that LTP may be expressed by presynaptic alterations in neurotransmitter release. If the induction of LTP is postsynaptic and the expression is presynaptic then this necessitates some sort of back-communication from the post to the presynaptic neuron. We have been conducting studies which investigate whether the diffusible molecule nitric oxide, NO, might function in such a capacity. We first tested whether an inhibitor of NO synthetase, N-methyl-L-arginine (L-NMMA) blocks or otherwise attenuates LTP. Extracellular application of L-NMMA (100 μ M) effectively prevented tetanus-induced potentiation of the field epsp, whereas an inactive isomer N-methyl-D-arginine, (D-NMMA), was ineffective in preventing LTP. Extracellular application of hemoglobin (100 μ M) also blocked LTP of the field epsp. Since hemoglobin is a large protein which is unable to cross cell membranes this result implies that NO must travel extracellularly to exert its effect. To determine the site of NO synthetase activity, we have introduced L-NMMA into the postsynaptic neuron via an intracellular recording electrode. Confirming the above results, we found that we were unable to produce LTP by the pairing technique (postsynaptic depolarization coupled with presynaptic stimulation, 1 Hz). Surprisingly, however, the postsynaptic inhibitor did not prevent LTP induced by tetanus. One interpretation of this finding is that during tetanic stimulation many neurons generate NO which can then travel to the neighboring presynaptic terminal(s) of the inhibited neuron to produce LTP. Further substantiation for this idea is gained from whole cell studies of LTP. It is known that the ability to achieve LTP by the pairing technique is seriously compromised following dialysis of the postsynaptic neuron (20-30 min.). We have confirmed this finding but have found that following a failure to induce LTP by pairing, we can reliably induce LTP by tetanus.

4.7

OSCILLATIONS IN SYNAPTIC TRANSMISSION AND LONG-TERM POTENTIATION. Neal Hessler and Roberto Malinow. Neuroscience Program and Dept of Physiology and Biophysics, University of Iowa.

Oscillations in quantal content have been described in the neuromuscular junction (Meiri and Rahamimoff, 1978). Similar oscillations in mean amplitude of elicited synaptic currents are observed at the Shaffer collateral/CA1 synapse in the hippocampal slice, using minimal stimulation and whole-cell recordings (Malinow, 1991). The oscillations in transmission have a period that ranges from 2-15 min for different experiments and they appear to be of presynaptic origin as in-phase oscillations are seen in mean²/variance, percent synaptic failures, and paired pulse facilitation. Oscillation of one or more of these measures can occur with little change in mean transmission, showing that apparent stationarity in mean transmission does not guarantee stationarity in underlying mechanisms, placing greater restrictions on use of traditional quantal analysis. In most cases, some oscillatory activity is seen in the absence of induced LTP. However, in about 30% of experiments, little oscillatory activity is seen prior to LTP; pairing pre- and postsynaptic activity triggers oscillations in addition to LTP. Quantification of these non-stationarities is being pursued using Fourier analysis and chaotic models. The correlation between different potentiated pathways and relation between pre-existing oscillations and likelihood of obtaining LTP is being examined. Oscillations of transmission may reflect presynaptic calcium oscillations and could functionally associate different inputs potentiated at the same time.

4.9

ROLE OF MEMBRANE POTENTIAL AND CALCIUM IN THE INDUCTION OF LONG-TERM POTENTIATION (LTP). D. J. Perkel, T. Manabe* and R. A. Nicoll. Depts. Pharmacol. and Physiol., UCSF, San Francisco, CA 94143.

It is widely accepted that one early step in the induction of LTP of synaptic transmission in hippocampal CA1 neurons is an influx of calcium ions through NMDA receptors. We have studied the effects of manipulating postsynaptic membrane potential, and presumably postsynaptic calcium concentration, on LTP induction.

We have recorded excitatory postsynaptic currents from CA1 neurons in slices of guinea pig hippocampus using the "blind" whole-cell voltage-clamp technique and Cs-based intracellular solutions. To induce LTP we have paired low-frequency synaptic stimulation with steady postsynaptic depolarization to different membrane potentials ("pairing"). One synaptic pathway onto each cell was paired at its reversal potential (RP; 0 to +20 mV) and served as an internal calibration for the amount of potentiation generated in another pathway, which was paired at a test potential (-40 mV or +100 mV). Pairing at +100 mV produced approximately 20% of the potentiation induced by pairing near the RP (cf. Malenka et al., *Science* 242:81, 1988), while pairing at -40 mV was also less effective than pairing at the RP. The voltage-dependence of calcium entry induced by synaptic activation of NMDA receptors is not known, but our results suggest that the calcium level achieved by pairing at the RP may exceed that at -40 mV.

Although previous studies have found that postsynaptic calcium-spike activity alone does not affect synaptic efficacy, we have found that prolonged (3 sec, 0.2 Hz, 20 pulses) postsynaptic voltage pulses to 0 mV, chosen to maximize calcium entry through voltage-dependent calcium channels, can enhance synaptic transmission. This phenomenon is transient, lasting approximately 10 - 30 min., and is resistant to D-APV (25 μ M). Although additional data linking this enhancement to LTP are required, the effects of membrane potential in enhancing transmission provide further support for a role for calcium in regulating synaptic efficacy.

4.6

THE FREQUENCY OF NMDA RECEPTOR ACTIVATION INFLUENCES THE STABILIZATION OF LTP. A. Colino*, Y.-Y. Huang, and R.C. Malenka. Dept.'s of Psychiatry & Physiology, Univ. of California, San Francisco, CA. 94143.

A defining feature of LTP is the stability of the increase in synaptic efficacy. To determine the interval over which the processes activated by a single EPSP can be integrated and result in stable LTP, NMDA receptor-dependent processes were activated by pairing synaptic stimulation with postsynaptic depolarization and a fixed number of pairings were performed at intervals ranging from 2 seconds to 1 minute. Using field recordings and a brief tetanus to an independent conditioning pathway to evoke postsynaptic depolarization, a single pairing routinely elicited a modest potentiation of synaptic transmission which decayed to baseline within 3-10 minutes (STP). Ten pairings at 1 minute intervals rarely resulted in stable LTP (1 of 7) while ten pairings given at 2-10 second intervals routinely resulted in LTP (13 of 17). A 30 second interval gave mixed results (5 of 9 resulted in stable LTP). Similar experiments were also performed on single cells using whole-cell recording. Two independent inputs were alternatively activated to obtain stable baselines. The cell was then depolarized and one input stimulated every 40-60 seconds while the other input received the same number of stimuli every 5-10 seconds. Because whole-cell recording may result in "wash-out" of important intracellular constituents, the pairing at shorter intervals was started at the end of the longer interval pairings. In 6 of 8 cells, the shorter interval pairings resulted in stable LTP while the longer interval pairings resulted in STP.

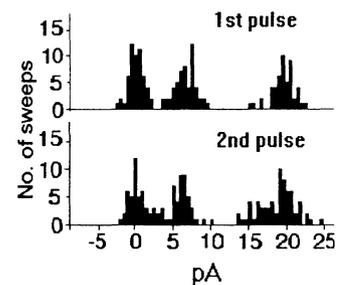

These results suggest that following synaptic stimulation of the NMDA receptor sufficient to elicit STP (but not LTP), processes are activated that can be integrated over a period of approximately one minute and result in stable LTP. This "integration period" likely depends on induction conditions (e.g. magnitude of postsynaptic calcium increase) and is another parameter which may prove to be important when considering the mechanisms and role of LTP.

4.8

RESOLUTION OF SYNAPTIC FLUCTUATIONS USING WHOLE CELL PATCH CLAMPING IN THE HIPPOCAMPUS. D.M. Kullmann*, T. Manabe*, P. Renner* & R.A. Nicoll. Depts. Pharmacol. & Physiol., UCSF, CA 94143.

Several studies of synaptic transmission in the hippocampus based on amplitude fluctuations have relied on untested assumptions to estimate the quantal parameters (see Korn et al., *Nature*, 350, 282). Using minimal stimulation of stratum radiatum, we have obtained whole-cell voltage clamp recordings from guinea-pig CA1 cells which often show clear separation between transmission failures and EPSCs. In some cases the EPSCs are further seen to fluctuate between discrete amplitudes, which are not always separated by a constant increment. Paired-pulse facilitation is consistently accompanied by a reduction in the probability of transmission failure. It is therefore unlikely that the failures are due exclusively to intermittent excitation of the presynaptic fibers. We are currently using the nystatin perforated patch technique to prolong the time during which EPSC fluctuations can be recorded. The figure shows the peak amplitudes of 160 trials (paired pulses, 60 ms delay).

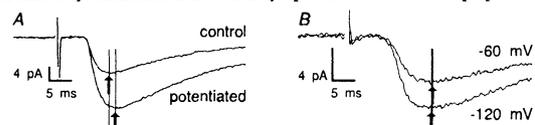

Supported by the NIMH, AES, HFSP and Smith & Nephew Foundation.

4.10

THE ONSET OF THE EXCITATORY POSTSYNAPTIC CURRENT IS SLOWED DURING LONG-TERM POTENTIATION J.A. Kauer, F.E. Schweizer, D.D. Friel & R.W. Tsien. Dept. of Mol. & Cell. Physiology, Stanford University, Stanford CA 94305.

We have used whole-cell voltage clamp recordings and minimal stimulation to look for changes in the time course of EPSCs in CA1 pyramidal cells during long term potentiation. LTP was induced by pairing postsynaptic depolarization with continued afferent stimulation (2 Hz). EPSC amplitude and total charge increased upon induction of LTP (4, averages of 20 EPSCs before and during LTP). Little or no change was detected in EPSC latency or time constant of decay. However, the onset of the EPSC became slower and the time to peak was increased during LTP. Time-to-peak (arrows) increased by 1.7±0.8 ms, or 25±10% (N=11), a change that was maintained during LTP. The difference in time course was still observed when comparing EPSCs of similar amplitude taken before and after LTP. Control experiments showed no such slowing in time course when the EPSC amplitude was increased by postsynaptic hyperpolarization (B, averages of 20 EPSCs each). These results might signify recruitment of slow/distant synapses or presynaptic modifications such as (1) spike broadening, (2) decreased calcium buffering, or (3) changes in the release machinery. Thus, it is unlikely that LTP is caused by recruitment of additional synaptic units with invariant properties.

4.11

QUANTAL AMPLITUDE REMAINS CONSTANT WITH LONG-TERM POTENTIATION IN RAT HIPPOCAMPAL SLICES. F.E. Schweizer, J.A. Kauer, D.D. Friel, & R.W. Tsien. Dept. of Mol. and Cell. Physiology, Stanford University, Stanford, CA 94305.

Long-term potentiation is characterized by a persistent increase in synaptic current, but it remains controversial whether this arises from enhanced quantal content (number of unit events) or increased quantal size (amplitude of unit event). To address this issue we estimated quantal size from amplitude histograms of EPSCs recorded with whole cell voltage clamp from CA1 pyramidal cells (minimal afferent stimulation at 2 Hz). Fitting each EPSC with the sum of two exponentials aided accurate estimation of EPSC amplitude. A small proportion of records was excluded from the analysis on the basis of excessive baseline noise, spontaneous events, or unusual onset latency. Amplitude histograms were constructed from 500-1000 records and showed peaks of roughly equal spacing. Histograms were judged robust if independent histograms made from every other data point or from consecutive portions of the epoch showed close agreement in peak locations. We used maximum likelihood analysis to estimate the position and width of peaks. Typically, we found a quantal size of 1-2 pA at -70 mV; quantal variance was negligible relative to recording noise, in agreement with Larkman et al. (1991).

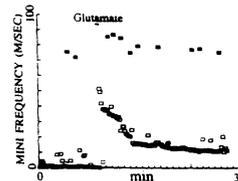

Mean EPSC amplitude increased by 30-50% when the postsynaptic neuron was hyperpolarized from -60 to -110 mV. The corresponding amplitude histograms showed an increase in quantal size with hyperpolarization in proportion to the enhancement of mean EPSC amplitude. This result gives confidence in our ability to estimate quantal size under varying experimental conditions.

LTP was induced by depolarizing the postsynaptic neuron during continued afferent stimulation. In experiments where robust peaks were observed before and during LTP, mean EPSC amplitude increased to at least 150% of control. In contrast, peak spacing did not change with LTP. These results support the idea that LTP is caused by an increase in quantal content rather than an increase in quantal size.

4.12

PRESYNAPTIC EXPRESSION MECHANISM OF LONG-TERM POTENTIATION OF MINIATURE EPSC FREQUENCY IN CULTURED HIPPOCAMPAL NEURONS. A. Malgaroli & R. W. Tsien, Department of Molecular and Cellular Physiology, Stanford CA 94305.

Analysis of miniature excitatory postsynaptic currents offers novel information about mechanisms of LTP expression. We made whole-cell recordings from rat hippocampal pyramidal cells in culture and directly applied glutamate to induce a global synaptic enhancement. Like the amplitude of evoked responses, the frequency of mini epscs was strongly increased (2- to 10-fold in 41/60 experiments). The rise in mini frequency (1 μ M TTX present) was (1) persistent up to the end of the recording (up to 80 min), (2) prevented by strong postsynaptic hyperpolarization (Mg^{2+} present), (3) prevented by block of NMDA receptors with MK801 (10 μ M). Several observations support the idea that postsynaptic responsiveness remained unchanged during LTP of mini frequency. (1) The distribution of mini amplitudes was not significantly changed. (2) Responses to brief puffs of glutamate or AMPA stayed the same. (3) When vesicle release from nerve terminals was evoked by brief challenges with hypertonic solutions, the peak mini frequency response (\blacksquare) was barely increased by glutamate-induced potentiation ($n=6$), in contrast to the 4-10 fold increase in spontaneous mini

frequency (\square). These findings run contrary to expectations for expression of LTP by purely postsynaptic recruitment of latent spines or previously inactive receptor clusters. Instead, the near-occlusion between mini potentiation by glutamate and by hypertonicity suggest actions involving the same rate-limiting step along the presynaptic secretory pathway.

LEARNING AND MEMORY—ANATOMY: HUMAN STUDIES

5.1

PATIENTS WITH ALZHEIMER'S DISEASE SHOW NORMAL PRIMING IN PERCEPTUAL IDENTIFICATION OF PSEUDOWORDS. M.M. Keane, J.D.E. Gabrieli, J.H. Growdon, and S. Corkin. Dept. of Brain and Cognitive Sciences and Clinical Research Center, MIT, Cambridge, MA 02139; Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Previously, we reported that patients with Alzheimer's disease (AD) showed normal priming in perceptual identification of briefly presented words. The aim of the current study was to determine whether normal perceptual priming in AD extended to pseudowords. The subjects of study included 12 AD patients (mild to severe), and 12 normal control subjects (NCS). The stimuli were 128 three-letter pseudowords that conformed to the rules of English orthography; 64 were used in a perceptual priming task and the other 64 were used in a recognition memory task. Prior to a perceptual identification or recognition task, 32 pseudowords were presented in a study list. In the perceptual identification task, subjects were asked to identify 64 briefly presented, masked pseudowords, of which half had appeared in the prior study list and half had not. Priming was reflected in enhanced performance with studied compared to unstudied pseudowords. In the recognition task, 34 pseudowords were presented one at a time; subjects were asked to indicate which ones had appeared in the prior study list. Relative to NCS, AD patients showed impaired recognition memory and normal priming. We conclude that intact perceptual priming in AD extends to novel stimuli; that perceptual priming of words and pseudowords may reflect the operation of a unitary neural mechanism (which is independent of the mechanism supporting recognition memory); and that such priming may depend upon posterior (occipital) circuits that are relatively preserved in AD.

INTACT PERCEPTUAL PRIMING OF NOVEL INFORMATION IN AMNESIA AFTER A SINGLE STUDY TRIAL. F. Haist,^{1,2} G. Musesen¹ & L.R. Squire.¹ ¹VA Med. Ctr. and ²UCSD Dept. of Psychiatry, La Jolla, CA 92161, and ³SDSU Dept. of Psychology, San Diego, CA.

Amnesic patients, who are severely impaired on conventional tests that assess explicit (declarative) memory, can exhibit entirely normal performance on implicit (nondeclarative) memory tests that do not require conscious recollection of prior events. For example, amnesic patients exhibit intact priming, i.e., an improved ability to detect or identify stimuli based on recent encounters with them. It has been unclear whether implicit memory can support the acquisition of novel information or whether implicit memory depends on the activation of pre-existing knowledge structures. We examined whether priming can support the acquisition of novel verbal information presented for only a single study trial. At test, amnesic patients ($n=10$) and normal subjects ($n=15$) were shown words and pronounceable nonwords for an average of 51 msec and 118 msec, respectively. Half of the items had been studied once prior to test and half had not been encountered previously. The presentation time was sufficient to permit about 50% of the unstudied items to be identified correctly. Amnesic patients and normal subjects identified significantly more studied words than unstudied words (27% and 24% facilitation, respectively) and also identified more studied nonwords than unstudied nonwords (18% and 20% facilitation, respectively). These results support the idea that perceptual priming depends on changes in early-stage perceptual priming systems and that these changes can result in the acquisition of new information, not simply the activation of pre-existing knowledge.

5.2

INTACT REPETITION PRIMING FOR TIME TO NAME PICTURES IN PATIENTS WITH ALZHEIMER'S DISEASE: DISSOCIATIONS FROM RECOGNITION MEMORY AND FROM WORD-COMPLETION PRIMING. J.D.E. Gabrieli, W.S. Francis*, D.A. Grosse*, and R.S. Wilson. Rush Alzheimer's Disease Center and Department of Neurological Sciences, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612.

Patients with Alzheimer's disease (AD) have impaired memory and reduced repetition priming (influence of repeated processing of a stimulus) on word-completion tests. There are reports of intact magnitudes of perceptual priming in AD, but these findings have been complicated by AD patients' baseline performance deficits. In the present study, 12 AD patients and 12 normal control (NC) subjects named 58 pictures of objects and animals; naming latencies were recorded. Next, subjects saw 29 pairs of pictures in a two-choice recognition memory test. Finally, subjects named the remaining 29 drawings named earlier but not included in the recognition test. The measure of priming was the reduction in time to name the repeated pictures. The AD patients were significantly less accurate on the recognition memory test than the NC subjects, but had a normal magnitude of priming without a significant difference in baseline naming latency. The same AD patients exhibited impaired priming on two word-completion tasks (one had the names of the pictures as the stimuli). The unambiguous dissociation between preserved picture-naming priming and impaired word-completion priming reveals that separable memory systems subserved distinct components of repetition priming. This result is consistent with the notion that perceptually-based repetition priming remains intact in early AD, perhaps due to selective sparing of posterior cortical areas that mediate perceptual priming. Supported by Alzheimer's Association and Illinois Department of Public Health.

5.4

INTACT, LONG-LASTING FACILITATION OF PICTURE NAMING IN AMNESIC PATIENTS. C.B. Cave and L.R. Squire, VA Med Ctr, and Dept of Psychiatry, UCSD, La Jolla, CA 92093.

Eleven amnesic patients and 9 control subjects were shown 130 pictures, one at a time, and named the pictures as quickly as possible. Then both 2 and 7 days later, 50 new pictures were presented together with 50 old pictures, and subjects again named them as quickly as possible. Control subjects and patients named previously seen pictures significantly faster than pictures not seen before (facilitation = 120 msec for controls, and 129 msec for patients). Similar facilitation was observed at each delay. In contrast, at both delays, amnesic patients were much poorer than control subjects at recognizing items that had been seen previously. Normal picture-naming facilitation in amnesic patients, together with their poor recognition performance, provides a striking dissociation between long-lasting repetition priming and explicit memory.

Facilitation of picture naming could depend on repetition of the same visual percept or on repetition of any visual stimulus that has the same name. In a second study, 14 normal subjects named pictures once and again 3 minutes later. At the second test, the pictures were of 4 types randomly intermixed: 1) pictures identical to those seen earlier; 2) pictures presented earlier, but changed in size or shading; 3) different examples of the objects presented earlier (e.g. a beagle instead of a retriever, but both identified as "dog"); or 4) pictures not presented previously. Facilitation was found to be based both on repetition of object names and on repetition of exact visual percepts. Repeated items (whether unchanged or different in size, shading, or example) were named significantly faster than new items, indicating facilitation due to the repetition of object names (regardless of the specific physical appearance of the stimuli). Identical pictures were named significantly more rapidly than pictures that were changed in size or shading, or pictures that were different examples of previously presented objects. This finding indicates that additional facilitation is also supported by repetition of exact visual percepts.

5.5

NORMAL ACQUISITION OF COLOR-WORD ASSOCIATIONS IN AMNESIC PATIENTS. G. Musen & L.R. Squire. VA Med Ctr & UCSD Psychiatry Dept., La Jolla, CA 92093.

Recent research has considered whether implicit (nondeclarative) memory can support the learning of new associations. Acquisition of novel word pairs (such as valley-trophy) occurs in both normal subjects and amnesic patients after multiple study trials (Musen & Squire, Soc. Neurosci. Abstr. 16:287, 1990). We investigated whether the learning of new associations might also occur for stimuli other than word pairs. We used a color naming task in which 7 color words (e.g., red, green, blue) were presented in an incongruent color, i.e., the word *green* was printed in the color *red* as in the familiar Stroop paradigm. Amnesic patients and age-matched control subjects named the color a word was printed in as quickly as possible. Each color word was presented 6 times, always in the same incongruent color. Thus, the word *green* was always printed in the color *red*. Then the color-word associations changed such that the word *green* was always printed in the color *blue*. Amnesic patients and control subjects improved with repetition to the same extent. Specifically, the time required to name each color decreased gradually across the 6 repetitions of the color words (amnesic patients from 712 msec to 580 msec; control subjects from 760 msec to 632 msec). Naming times then increased when the color-word associations changed (amnesic patients 683 msec; control subjects 632 msec). This study provides evidence for gradual acquisition of new associations in implicit (nondeclarative) memory across multiple trials.

5.7

A FUNCTIONAL ANATOMICAL STUDY OF HUMAN MEMORY. L. Squire*, J. Ojemann, F. Miezin, S. Petersen, T. Videen, and M. Raichle. *UCSD Dept. of Psychiat., VA Med. Ctr., San Diego, CA, 92161. Dept. of Neurol. and Neurol. Surg. Washington Univ. Med. Ctr., St. Louis, MO 63110.

We studied regional cerebral blood flow using the [¹⁵O] H₂O method while normal subjects performed four closely similar tasks. In each task, subjects saw words and then saw 3-letter word stems. Local blood flow was monitored during a 40-sec period while subjects 1) silently viewed word stems; 2) completed stems to form the first words to come to mind, but the stems could not form study words (baseline); 3) completed stems and half of them could form study words (priming); or 4) tried to recall study words, and half of the stems could form these words (memory). There were three major findings: 1) The memory task engaged the right hippocampal region (but not the amygdala), when the memory task was compared to either baseline or a fixation-point condition. The right hemispheric locus suggests that performance is driven by the visual characteristics of the words rather than by semantic or phonetic analysis. 2) Right prefrontal cortex was also activated in the memory minus baseline condition. 3) In the priming minus baseline comparison, there was reduction in blood flow in the right posterior cortex. The results provide the first evidence for selective activation of the human hippocampal region in association with memory function. The results also provide a specific proposal about the neural basis of priming: following presentation of a stimulus, less neural activity is required to process the same stimulus.

5.9

NAME DROPPING: RETRIEVAL OF PROPER OR COMMON NOUNS DEPENDS ON DIFFERENT SYSTEMS IN LEFT TEMPORAL CORTEX. A.R. Damasio, J.P. Brandt, D. Tranel, & H. Damasio. Div. of Cognitive Neuroscience, University of Iowa College of Medicine, Iowa City, IA 52242.

Damage to human temporal cortices causes striking dissociations between retrieval of concepts and of the nouns they denote. We present new evidence on the dissociation between retrieval of *common* and *proper* nouns. Visual recognition and naming were investigated in (a) 30 controls, and (b) 14 subjects with lesions in left or right inferotemporal (IT) region or temporal pole (area 38). Stimuli were 77 *unique* entities (familiar faces, whose naming requires a proper noun) and 155 *non-unique* entities (which require a common noun). Results: (1) Damage to *both* left area 38 and IT impairs retrieval of both proper *and* common nouns, but spares recognition. (2) Damage restricted to left area 38 (sparing IT) impairs retrieval of *proper* nouns but allows normal retrieval of *common* nouns (recognition of unique entities is intact). (3) Damage to right 38/IT does not seem to affect naming. We propose that the lesions disrupt a bidirectional access device which operates as a third party mediator between *concept retrieval systems* and *word reactivation systems*. Such devices are based in left temporal cortices, and appear to be placed hierarchically, e.g., the device concerned with proper nouns depends on a cortical station located more anteriorly than the one concerned with common nouns.

5.6

NORMAL ACQUISITION OF AN ARTIFICIAL GRAMMAR BY AMNESIC PATIENTS. B.J. Knowlton, S. Ramus, & L.R. Squire. VA Med. Ctr. and Dept. of Psychiatry, UCSD, La Jolla, CA 92093.

Study of amnesic patients has revealed a distinction between explicit (declarative) memory, and implicit (nondeclarative) memory. Examples of implicit memory include skill learning, priming, and simple forms of conditioning. Normal subjects can acquire an artificial grammar based on rules that determine the order of letters within letter strings. Conscious knowledge of the rules appears inadequate to account for performance, suggesting that this learning is implicit. If so, amnesic patients should be capable of acquiring artificial grammars normally, despite their severely impaired explicit memory. Ten amnesic patients and 13 control subjects were shown 23 letter strings, which were formed according to a finite-state rule system. After 5 min, subjects were told that the items had been formed according to a complex set of rules, and they were instructed to decide for each of 46 new items whether the item obeyed these rules. Control subjects classified 65.0% of these new items correctly, compared to 62.0% for the patients. In contrast, the patients performed much worse than control subjects on a 46-item recognition test for the letter strings that had been presented (73.1% vs. 59.6%, $p < .005$). These results provide strong evidence that artificial grammar acquisition is based on implicit memory, and that the learning of such rules depends on brain structures other than those damaged in amnesia.

SUCCESSFUL EYEBLINK CLASSICAL CONDITIONING IN H.M. D. S. Woodruff-Pak¹ & S. Corkin². Department of Psychology, Temple University¹, Philadelphia, PA 19126 & Department of Brain and Cognitive Sciences and Clinical Research Center, MIT², Cambridge, MA 02142

Amnesic patients with medial temporal-diencephalic lesions show impaired explicit memory (recall and recognition) but normal implicit memory (skill learning and priming), suggesting that the latter capacities do not require hippocampal integrity. Another kind of implicit memory performance, classical conditioning, does not depend upon the hippocampus in rabbits and may not in humans as well. We therefore evaluated classical conditioning in the amnesic patient, H.M. (aged 64). He had undergone bilateral removal of medial temporal-lobe structures (including the anterior 8 cm of the hippocampus) in 1953 for seizure control; long-term dilantin therapy is believed to have damaged his cerebellar vermis and hemispheres. First, in a *delay paradigm* we used a 500 msec, 1 KHz, 80 dB SPL tone conditioned stimulus (CS), followed 400 msec after its onset by a 5 psi, 100 msec corneal airpuff unconditioned stimulus (US). In a series of 90-trial, 45-minute sessions, H.M. required 473 trials to reach learning criterion, producing 10 consecutive conditioned responses (CRs). Throughout 8 sessions, he never recalled or recognized the conditioning apparatus or procedure. A healthy 66-year-old control subject reach learning criterion in 316 trials. Five weeks after training in the delay paradigm we conditioned H.M. in a *trace paradigm* (250 msec, 1 KHz, 80 dB SPL tone CS, 500 msec blank "trace" period, 100 msec corneal airpuff US). He reached criterion in 91 trials. We then repeated the initial *delay paradigm*, and H.M. attained criterion in 277 trials. We conclude that humans (like rabbits) can acquire the eyeblink CR without the hippocampus intact. Cerebellar hemispheric atrophy may have slowed H.M.'s acquisition. Supported by grants from the Alzheimer's Association and from NIH, RR-00088.

OVERT AND COVERT FACE RECOGNITION: A DOUBLE DISSOCIATION. D. Tranel, H. Damasio, & A.R. Damasio. Div. of Cognitive Neuroscience, University of Iowa College of Medicine, Iowa City, IA 52242.

Familiar faces are normally recognized at *both* overt and covert levels but one of the two levels may be missing. In the most typical dissociation, patients with face agnosia caused by occipito-temporal damage cannot perform recognition of the identity of familiar faces at *overt* level. However, many such patients can give discriminatory *covert* responses to the familiar faces they fail to identify. For example, in 4 face agnosics we found that the average skin conductance response (SCR) to familiar faces was $0.66 \mu S$, while the average SCR to unfamiliar faces was $0.04 \mu S$. We now report the opposite dissociation: a patient who has entirely normal *overt* identification of familiar faces but who fails to generate discriminatory *covert* responses to those faces. The patient [EVR-318] has bilateral ventromedial frontal lesions. His *overt* face identity recognition is 100% correct, in both retrograde and anterograde compartments. At *covert* level, however, he is profoundly impaired: SCR magnitudes generated to familiar retrograde and anterograde faces, respectively, were $0.04 \mu S$ and $0.00 \mu S$ (despite normal SCRs to "orienting" stimuli). Taken together, these findings indicate that the neural systems which process the somatic-based valence of stimuli, are separate from and parallel to those which process the factual, non-somatic information associated with those same stimuli.

5.11

MEMORY PROFILE OF A BILATERAL DIENCEPHALIC INFARCT PATIENT WITH PRESERVED INTELLIGENCE AND SEVERE AMNESIC DISTURBANCES. H.J. Markowitsch¹, D.Y. von Cramon² and U. Schuri^{1,2} (SPON: ENA),
¹Department of Psychology, Ruhr-University Bochum, P.O.B. 102148, D-4630 Bochum and
²Department of Neuropsychology, City Hospital Munich-Bogenhausen, D-8000 Munich, Germany

The case of a patient with above-average intelligence and an IQ-MQ difference of 40 points is documented. Extensive neuroradiological material of his focal bilateral brain damage in the dorsal diencephalon is available. A wide range of tests on all aspects of intelligence, attention, immediate retention, learning, skill and problem solving abilities, concept formation, cognitive flexibility, priming, constructional ability, and retrograde memory was used. The patient's short-term memory and attention were well above average. He gave a number of examples of still intact skill and implicit memory abilities, but had no awareness of his severe anterograde and retrograde amnesia. The results from our patient confirm the dichotomy between declarative and non-declarative mnemonic functions and demonstrate that disconnecting portions of the medial and basolateral limbic circuits have devastating consequences on memory.

5.13

AMNESIA FOLLOWING ANTERIOR COMMUNICATING ARTERY ANEURYSM: PROPOSED CEREBRAL MECHANISMS. J. DeLuca, Kessler Institute for Rehabilitation, West Orange, NJ 07052.

Aneurysm of the anterior communicating artery (ACoA) in humans frequently results in a cluster of neurobehavioral symptoms often referred to as the "ACoA syndrome." These include a "Korsakoff-like" amnesia, confabulation and personality change. Two hypotheses concerning the neuropathologic mechanisms have been proposed: 1) A focal lesion hypothesis involving anterior cerebral structures, and 2) diffuse cerebral involvement. Two studies are presented addressing the issue of neurobehavioral mechanism, examining confabulation and amnesia.

Two groups were examined in both studies: patients with ACoA aneurysm and those with intracranial hemorrhages elsewhere in the brain. In study I, confabulation was observed during two naturally occurring conditions: disoriented and oriented periods. Confabulation was more frequent, severe, and persisted into the oriented phase in the ACoA group. In study II, neuropsychologic testing revealed no differences among groups on tests of immediate memory, but ACoA subjects were significantly more impaired on tests of delayed verbal recall. The ACoA group also performed significantly worse on tests of frontal lobe functioning. Results support a focal lesion hypothesis, and suggests both basal forebrain and frontal lobe involvement.

5.12

EFFECT OF SEPARATE VS COMBINED LESIONS OF AMYGDALA, HIPPOCAMPAL FORMATION AND BASAL FOREBRAIN ON HUMAN MEMORY. E.J. Eslinger, Neurology and Behavioral Science, Penn State University College of Medicine, Hershey, PA 17033.

Experimental animal studies indicate different effects of separate and combined lesions of medial temporal lobe structures on learning and memory. As a direct test of human brain function and related hypotheses derived from animal studies, standardized methods of anatomic localization and cognitive study were applied to 7 human cases with acquired, focal lesions of the amygdala (A), hippocampal formation (HF), and basal forebrain region (BF). Comparisons were made between lesion location within the left hemisphere and verbal learning and memory abilities. Anatomic study indicated cases of separate lesion to A, posterior HF, BF (n=3), and of combined lesion to A+HF and A+HF+BF. The combined lesions were also associated with anterior temporal cortex damage from herpes simplex encephalitis. The A+HF+BF lesion produced the most severe verbal amnesia, followed by A+HF. BF lesions alone produced moderate impairment and amnesia. Separate lesions to A and posterior HF (sparing rostral hippocampus and entorhinal cortex) produced only minor impairment and no verbal amnesia. Together with other human and animal studies, findings indicate that: (1) Combined lesions result in severe amnesia, (2) damage to A alone and to posterior HF alone produces only minor disturbance, (3) HF lesion probably requires strategic hippocampus or entorhinal cortex damage to produce amnesia, (4) BF lesions alone produce amnesia and have an additive effect on A+HF lesions.

5.14

DEFICITS IN RECALL, BUT NOT RECOGNITION FOLLOWING POSTERIOR COMMISSURECTOMY. E.A. Phelps¹, W. Hirst², M.S. Gazzaniga³. ¹Center for Neural Science, New York Univ., NY, N.Y. 10003, ²New School for Social Research, ³Dartmouth Medical School.

The role of the hippocampal commissure in memory functioning was examined in three studies. The first compared pre and post-operative performance on the logical memory and visual reproduction subtests of the Wechsler Memory Scale for patients receiving either anterior or posterior sectioning of the commissure. Posterior sectioning generally includes the hippocampal commissure while anterior sectioning does not. A deficit in both visual and verbal recall was found in patients with posterior sectioning, but not those receiving anterior sectioning. The second study examined pre and post-operative verbal memory performance in two anterior sectioned patients. Patients were given four lists of 20 words both pre and post-operatively. Each word was presented for 5 seconds followed by a retention interval of either 0 sec., 30 sec., 2 min., or 1 hour. Patients were then tested with free recall followed by forced-choice recognition. There was no deficit in either recall or recognition memory following sectioning of the anterior commissure at any of the retention intervals. The final experiment examined the nature of the memory deficit following complete commissurotomy, including the hippocampal commissure. Two split-brain patients and control subjects were presented 8 lists of 20 words. Each word was presented for 5 seconds followed by a 10 minute retention interval. Subjects were tested with free recall followed by forced-choice recognition. Patients with complete commissurotomies showed a deficit in recall, but not recognition in comparison to normal controls. This finding is consistent with the finding of relatively preserved recognition in amnesic patients and suggests that the mnemonic role of the hippocampal commissure may be more important for recall than recognition memory.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY I

6.1

SYSTEMIC ADMINISTRATION OF L-CYSTEINE (CYS) GREATLY ELEVATES CEREBRAL CYSTEINE SULFINATE (CSA) LEVELS AND PRODUCES HYPOGLYCEMIA-LIKE HIPPOCAMPAL PATHOLOGY. A. Lehmann, O. Orwar^{*} and M. Sandberg^{*}, Inst. of Neurobiol., Univ. of Göteborg, P.O. Box 33031, S-400 33 Göteborg, Sweden.

When administered systemically to infant animals, CYS produces a widespread brain damage mediated by NMDA receptors. It is not known if CYS is directly neurotoxic, or if its oxidation product CSA mediates the toxicity. In the present study, the effects of toxic doses of CYS on cortical CSA levels were determined in 4-days-old rats. Changes in the CYS metabolites alanine and taurine were also followed. Further, the distribution of CYS-induced damage was reinvestigated. S.c. injection of 1 mg/g CYS produced a 19-fold increase in cortical CYS levels after 1 h after which time they declined. There was a delayed increase in CSA and alanine amounting to 18 and 3 times of control levels, respectively, after 6 h. Taurine decreased after CYS injection, while most other amino acids increased. With the exception of CYS, CSA and alanine, CYS-induced alterations in other amino acids were prevented by the NMDA antagonist MK-801, suggesting that MK-801 does not interfere with cerebral uptake and metabolism of CYS, and that changes in other amino acids are caused by CYS neurotoxicity. The concentration of CSA was 0.1 µmol/g protein after 6h. Provided that this value chiefly reflects intracellular levels, it seems unlikely that CSA mediates CYS toxicity. At 0.5 mg/g, CYS inflicted a selective damage to the cingulate and medial parietal cortices. At 1.0 mg/g, CYS caused massive hemorrhages and a severe injury in many forebrain regions, especially in the cortex and hippocampus. In the latter region, damage was confined to neurons exposed to CSF indicating that the major route of uptake of CYS is across the choroid plexus. Although MK-801 (1.0 µg/g), but not the non-NMDA antagonist NBQX (15 µg/g), prevented CYS toxicity, the distribution of hippocampal injury did not correlate with the distribution of NMDA receptors previously reported by others.

6.2

GLUTAMATE MODULATES PHOSPHOLIPASE A₂ (PLA₂) ACTIVITY IN CULTURED CORTICAL NEURONS. G.Rordorf^{*}, W.J. Koroshetz, R.A. Nemenoff^{*} and J.V. Bonventre, Departments of Medicine and Neurology, Massachusetts Gen. Hosp., Harvard Med. Sch., Boston, MA 02114.

We have recently demonstrated that PLA₂ activity is stably enhanced in gerbil brain with ischemia and reperfusion. Using cultured rat cortical neurons we found that glutamate increases PLA₂ enzymatic activity. We have further characterized PLA₂ activity in cultured cortical neurons. PLA₂ activity was assayed in cell free extracts, by directly measuring release of arachidonic acid (AA) from exogenous [¹⁴C]AA-phospholipid. Two forms of the enzyme are present in the cell cytosolic extracts, a larger molecular weight form and a smaller form with a Mr of approximately 14 kDa. Glutamate enhances Ca²⁺ sensitivity and the activity of the smaller form. Both forms are Ca²⁺-dependent with optimal activities at pH 8.5. Phorbol 12,13-myristate acetate (PMA) (but not an inactive form of phorbol ester), and a calcium ionophore, stimulate PLA₂ activity. Downregulation of protein kinase C (PKC) activity by chronic exposure to PMA reduces the stable glutamate-induced PLA₂ activation by one-half. These results suggest that PKC plays an important role in the upregulation of PLA₂ activity seen with glutamate. The glutamate-induced stable enhancement of PLA₂ activity in cells occurs prior to cell death as determined by LDH release. These results suggest that PLA₂ may play a central role as a causative factor in glutamate-induced toxicity.

DOES PROTEIN KINASE C PLAY A ROLE IN THE DEVELOPMENT OF SLOWLY-TRIGGERED EXCITOTOXICITY IN CORTICAL CELL CULTURES? D.M. Hartley and D.W. Choi. Dept. of Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

The neuroprotective effect of gangliosides against glutamate-induced neurotoxicity has been proposed to be due to interference with protein kinase C (PKC) function (Manev et al., *FASEB J.* 4:2789, 1990). Murine cortical cell cultures exposed to 15 μ M NMDA or 35 μ M kainate + 10 μ M MK-801 for 24 hr developed submaximal neuronal degeneration. A two hour pretreatment with 200 μ M GT1b reduced NMDA-induced injury approximately 80-90%. This neuroprotection was specific to NMDA-induced cell death, as neither GT1b nor GM1 blocked kainate-induced cell death.

Does inhibition of PKC mimic this protective effect of gangliosides? A 24 hr pretreatment with 0.1 to 10 μ M phorbol 12-myristate 13-acetate down-regulated PKC activity in our cultures, approx. 90-95%, as measured by phosphorylation of the altered pseudosubstrate peptide, [(ser)25 PKC (19-31)]. However, sister cultures exposed to similar conditions showed little reduction in NMDA- or kainate-induced death. Furthermore, staurosporine at > 1.5 μ M blocked more than 90% of PKC activity, but concentrations up to 10 μ M did not reduce NMDA- or kainate-induced death. We speculate that the neuroprotective effect of GT1b on cortical neurons may be mediated at least in part by a mechanism other than reduction of PKC function (the alpha, beta, and gamma isoforms).

6.5

TWO MECHANISMS OF KAINATE NEUROTOXICITY IN RAT CORTICAL NEURONS *IN VITRO*. A.G. Knapp, C.J. Kirk* and T.J. Wolcott*. Cambridge NeuroScience, Inc., Cambridge, MA 02139.

To clarify the mechanisms by which excitatory amino acid agonists can cause neuronal damage, we have examined the time course and concentration dependence of kainic acid neurotoxicity in cultured rat cortical neurons. Neurons were enzymatically dissociated from neonatal rats, grown in 96-well tissue culture plates for 15-17 days and then exposed to kainate (1-1000 μ M) for varying durations (5 minutes to 24 hours). Cell death was measured by automated colorimetric assay of lactate dehydrogenase released into the culture medium 24 hours after the start of the exposure. In contrast to previous reports, we have found that exposures to kainate as brief as 5 minutes are sufficient to kill more than 90% of neurons. The concentration-response relationship for this rapid component of excitotoxicity was very steep (Hill slopes > 3), with a threshold near 100 μ M and half-maximal damage occurring at 200-300 μ M. Neuronal death caused by brief (5-30 minutes) exposures to kainate could be almost completely prevented by both competitive (APV) and non-competitive (MK-801) antagonists of NMDA receptors. With longer exposure durations, kainate damaged neurons at lower concentrations (EC_{50} = 40-60 μ M at 24 hours) and the concentration-response relationship became less steep (Hill slopes 1-2). This slower form of neurotoxicity was insensitive to NMDA antagonists, but the competitive non-NMDA receptor antagonist DNQX (1-10 μ M) shifted the concentration-response curve to the right in a dose-dependent manner. We propose that the rapid form of kainate neurotoxicity results from indirect activation of NMDA receptors by release of an endogenous NMDA agonist (e.g. glutamate) from the cultures or by potentiation of basal amounts of such an agonist. The slower form of toxicity likely reflects kainate's direct actions on non-NMDA receptors.

6.7

SERUM ALBUMIN STRONGLY POTENTIATES GLUTAMATE NEUROTOXICITY IN CULTURED RAT CEREBELLAR GRANULE CELLS. M. Schramm and S. Eimerl*, Department of Biological Chemistry, Institute of Life Sciences, Hebrew University of Jerusalem, Jerusalem 91904, Israel.

Addition of 1% serum to 14 day cultured granule cells in a Locke salt-glucose solution caused acute cell death. The glutamate in the serum, acting on the NMDA receptor, in conjunction with a putative potentiating factor, accounted for the acute toxicity (M. Schramm et al., *Proc. Natl. Acad. Sci. USA* 87, 1193-1197, 1990). Serum albumin appears to be the potentiating factor, showing no toxicity on its own, but boosting toxicity of glutamate 3-10 fold. Bovine serum albumin (BSA), regular or fatty acid-free, or human serum albumin, were all about equally effective, with maximal enhancement at 2 mg/ml. Casein was the only substance, among some other polymers tested, which produced enhancement of toxicity. Potentiation by BSA occurred in presence and absence of Mg^{++} , with glutamate or NMDA as agonist. BSA was only effective when present together with the NMDA receptor agonist. Potentiation by BSA required 1 mM Ca^{++} , with a maximum effect at 1.7 mM. It is suggested that serum albumin, by magnifying threshold toxic activation, of the NMDA receptor may play an important role in neuronal degeneration.

6.4

RAPID CA1 INJURY INDUCED BY NON-NMDA AGONISTS IN HIPPOCAMPAL SLICES. R.A. Wallis, K.L. Panizzon, J.M. Boring* and C.G. Wasterlain. Dept. of Neurology, Sepulveda VAMC and UCLA Sch. of Medicine, Sepulveda, CA 91343.

In dissociated cortical cultures, NMDA induces rapid neuronal injury while non-NMDA causes slow neuronal injury. We examined the non-NMDA excitotoxicity in the CA1 sector of hippocampal slices, using the CA1 population spike (PS) amplitude as a physiological end point. An 8 min. exposure to AMPA (50 μ M) induced 98.4% \pm 1.7 (SE) damage of the antidromically evoked CA1 PS. This damage was blocked by 100 μ M DNQX, provided DNQX was continued for 60 min. during recovery. Low calcium, dantrolene (20 μ M), MK-801 (32 μ M) and azelastine (15 μ M) offered little protection. Trans-ACPD (up to 200 μ M) for 35 min. failed to cause significant CA1 neuronal injury. An 8 min. exposure to kainic acid (65 μ M) caused severe CA1 neuronal damage (recovery 19.9% \pm 6.6) which was blocked by DNQX (100 μ M) but not by MK-801, dantrolene or azelastine. These data suggest that in the hippocampal slice, non-NMDA agonists can produce rapid neuronal injury through activation of AMPA and kainic receptors, while stimulation of "metabotropic" receptors alone is not excitotoxic.

CALCIUM ACCUMULATION IN EXCITOTOXIC BRAIN LESIONS: TIME COURSE AND CORRELATION WITH CELL DEATH. J.B.P. Gramsbergen and A.J. van der Sluijs-Gelling*, Erasmus Univ. Rotterdam Sch of Med and TNO Med Biol Lab, Rijswijk, Netherlands.

In order to examine the relationship between calcium overload and excitotoxic cell death, we investigated the time course of regional ^{45}Ca accumulation in the rat brain following intrastriatal quinolinic acid (QUIN) or systemic kainic acid (KA) administration using semi-quantitative $^{45}CaCl_2$ -autoradiography and radioactivity counting of dissected tissues. In addition, using different doses of QUIN, the ^{45}Ca contents in the basal ganglia were correlated with biochemical or histological markers of cell dysfunction or death in those areas. One week after QUIN striatal ^{45}Ca accumulation was highly correlated with reductions of striatal glutamic acid decarboxylase (GAD; $r=0.9$) and with histological damage of the same brain sections. Time course studies of 25 ug QUIN rats showed that, although GAD was maximally reduced (74%) at day 2, striatal ^{45}Ca continued to accumulate up to day 42 (67%), suggesting that ^{45}Ca was also trapped in extracellular calcium deposits. Several hours after KA (12 mg/kg) both CA3 and CA1 cells in the hippocampus were labeled, whereas at day 2 ^{45}Ca could not be detected in CA3 and was diminished in CA1. However, 1 and 2 weeks following KA ^{45}Ca accumulated again in CA1, but not in CA3. Thus, CA3 pyramidal cells seem to die quickly, whereas CA1 neurons die more slowly or can accumulate more ^{45}Ca before death.

AMANTADINE DERIVATIVES PREVENT NMDA RECEPTOR-MEDIATED NEUROTOXICITY. James W. Pellegrini*, H-S. Vincent Chen, Sizheng Z. Lei, Nikolaus J. Sucher and Stuart A. Lipton. Dept of Neurology, Children's Hospital & Progr. in Neurosci., Harvard Med Sch, Boston, MA.

Increasing evidence supports the hypothesis that escalating levels of excitatory amino acids are responsible for neuronal cell death in a variety of acute and chronic neurological conditions including hypoxia/ischemia, trauma, hypoglycemia, epilepsy, and degenerative diseases such as AIDS dementia. In some areas of the central nervous system, the predominant form of this neuronal injury is mediated by excessive stimulation of NMDA receptors. Recently, the antiviral and anti-Parkinsonian drug memantine, a derivative of amantadine, has been shown to antagonize NMDA-evoked electrical currents in neurons, probably by a mechanism similar to that of MK-801 (J. Bormann, *Eur. J. Pharm.* 1989;166:591-2). Unlike MK-801, however, memantine and other amantadine derivatives are clinically tested drugs with relatively few side-effects at micromolar levels. Here, we show that memantine (6 μ M) blocks NMDA-evoked electrical currents in primary cultures of central neurons, i.e., postnatal rat retinal ganglion cells. Also, we report that amantadine (200 μ M) or congener memantine (6 μ M) attenuates NMDA-induced increases in intracellular $[Ca^{2+}]$ and prevents NMDA receptor-mediated neurotoxicity.

PENTAMIDINE, A NOVEL NMDA RECEPTOR ANTAGONIST IS NEUROPROTECTIVE IN VITRO. L.J. Reynolds and E. Aizenman.

Depts. Pharmacol. and Physiol., U. Pittsburgh, Pittsburgh PA 15261. Dementia frequently accompanies acquired immunodeficiency syndrome (AIDS). This may arise from excessive stimulation of NMDA receptors by either quinolinate or a similar neurotoxin produced by HIV-infected macrophages (Giulian et al., *Science* 250:1593, 1991). A prediction of this hypothesis is that an NMDA antagonist may delay or prevent AIDS related dementia.

We have found that pentamidine, frequently used to treat *P. carinii* infections in AIDS patients, is an effective and potent NMDA antagonist. Pentamidine inhibits [³H] dizocilpine binding with an IC₅₀ of about 2 μM. It is non-competitive with glutamate, glycine and spermidine, and also slows the dissociation of [³H] dizocilpine. Pentamidine also inhibits NMDA- and glycine induced increases in [Ca²⁺]_i in cultured cortical neurons at similar concentrations. The inhibition of whole-cell voltage clamped responses is independent of membrane potential, and, with the protocol used, does not show use dependence.

Approximately 70% of cultured cortical neurons die within 24hr of being exposed to 200 μM NMDA for 30min. This excitotoxic action of NMDA was completely reversed by the addition of 5 μM pentamidine during the NMDA exposure. However, concentrations of pentamidine above 30 μM were directly neurotoxic when present for 24hr.

These findings suggest that pentamidine may be useful in treating AIDS-related dementia in addition to its antimicrobial activity.

IMPAIRMENT OF TRANSMITTER GLUTAMATE SYNTHESIS AND KCl-INDUCED RELEASE BY PHENYL SUCCINATE: A MICRODIALYSIS STUDY.

Diemer NH, Bruhn T, Berg M, Christensen T, Schouboe A
Cerebral Ischemia Research Group & PharmaBiotec Research Center
Institute of Neuropathology, University of Copenhagen and
Royal Danish School of Pharmacy, Copenhagen, Denmark

Excessive activation of the glutamate (glu) transmission seems to be involved in the neuron damage after cerebral ischemia and kainate induced seizures. Besides blockade of postsynaptic glutamate receptors another possibility for reduction of glutamatergic transmission would be to decrease the pool of transmitter glutamate. Studies on cultured cerebellar granule cells (Falkowski, Hertz, Schouboe 1988) have shown that phenylsuccinate (PS) is able to reduce KCl stimulated glutamate release by interfering with a ketodicarboxylate carrier in the mitochondrial membrane. We studied this in anesthetized rats by means of stereotactically placed microdialysis fibers in dorsal hippocampi. Both fibers were perfused with 5 μl/min Krebs buffer; to the right fiber was added 50 mM PS. Fifty mM KCl was periodically added to the perfusion fluid on both sides (10 min on, 20 min off). Sampling time was 5 min and the dialysates were analyzed for amino acids after OPA derivatization on a HPLC system with fluorescence detector. During the unstimulated period of sampling no side difference in glu concentration was observed. KCl induced distinct elevations of glu on the control side whereas the PS-treated side showed no release of glu. Thus also in vivo PS is able to reduce glu release; the significance of this is currently investigated in ischemia and kainate induced neurons damage.

6.10

HIV ENVELOPE PROTEIN gp120 AND THE NMDA RECEPTOR-CHANNEL COMPLEX. Stuart A. Lipton, Linda A. Wong, Maureen Oyola, Nikolaus J. Suchar, & Eyan B. Dreyer. Dept. of Neurology, Children's Hospital & Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Piconolar concentrations of the HIV coat protein gp120 increase [Ca²⁺]_i and produce neuronal injury in rat retinal cultures; within 24 hr of exposure to 20 pM gp120, 15-50% of the retinal ganglion cell neurons die compared to controls (Dreyer et al., *Science* 1990;248:364). Previously, we found that calcium channel antagonists ameliorate this form of neurotoxicity as do the NMDA antagonists APV and MK-801 (Lipton et al., *Neuron*, in press). Here we report that in preliminary experiments gp120-induced neurotoxicity was partially attenuated by an antagonist of the glycine co-agonist site, 7-Cl-kynurenate (50 μM). Nevertheless, whole-cell recordings with patch electrodes failed to demonstrate any conclusive action of gp120 (20-600 pM) in evoking NMDA-like electrical responses or in enhancing NMDA- or glutamate-activated currents. To assess effects requiring intracellular messengers, we also recorded from retinal ganglion cells using the 'perforated patch' technique (*n* = 30). However, gp120 still produced no consistent NMDA-like effects. Thus, at 20-600 pM, gp120 apparently lacks a direct excitatory effect on the NMDA receptor-channel complex, and other actions must be sought either upstream or downstream from this site.

NMDA RECEPTORS ON BRAIN CAPILLARIES MEDIATE COLD INJURY-INDUCED ACTIVATION OF POLYAMINE SYNTHESIS AND BLOOD-BRAIN BARRIER BREAKDOWN. H. Koenig*, A. Goldstone*, J.J. Trout*, C.Y. Lu* & Z. Iqbal. Neurol. Serv., VA Lakeside Med. Ctr. & Dept. of Neurol., Northwestern U. Med. Sch., Chicago, IL 60611

Focal cold injury (CI) induces blood-brain barrier breakdown (BBB) & brain edema linked to a biphasic increase in ornithine decarboxylase activity (ODC-A) & polyamine (PA) levels in rat brain capillaries (BC). A rapid increase appears at 1-2 min coincident with BBB, & lasts > 72 h (Koenig et al., *J. Neurochem.* 52:622-631, 1989). The ODC inhibitor DFMO, & verapamil, dexamethasone & aspirin block the CI-induced activation of the ODC/PA cascade & BBB, & putrescine (PUT) reverses these effects (Koenig et al., 1983, 1989). The NMDA receptor antagonist MK-801 (1-10 mg/kg) also blocks the early (2 min) increase in ODC/PA & BBB, monitored by fluorescein, [¹⁴C]AIB, & HRP transport. NMDA evokes a conc.-dep. increase in ODC-A, PUT & transport of ⁴⁵Ca²⁺, [³H]deoxyglucose & HRP in isolated BC. This response is Ca²⁺-dep., blocked by AP5, MK-801 & DFMO, & DFMO inhibition is reversed by PUT. BC membranes show NMDA-displaceable L-[³H]glutamate binding (K_d 50 nM, B_{max} 176 fmol/mg) & GLU + GLY stimutable [³H]MK-801 binding sensitive to AP5 & DFMO. These data suggest that NMDA-R are present on BC, are coupled to the ODC/PA cascade, upmodulate BC transport, & mediate BBB breakdown induced by CI.

VISUAL PSYCHOPHYSICS AND BEHAVIOR

WHEN POPULATION CODING SURPASSES SINGLE NEURON PERFORMANCE E. Zohary¹*, A.C. Sittig²*, and Shaul Hochstein¹, Neurobiology Dept., Life Sciences Inst., Hebrew University, Jerusalem, Israel¹, Delft University of Technology, The Netherlands²

We recorded the activity of V1 neurons in the awake macaque monkey. Neural responses to gratings of different orientations or spatial or temporal frequencies indicate that the reliability of the most selective neurons in signalling a difference between two stimuli differing in one dimension may be comparable with psychophysical performance. Also, the channel capacity of some neurons reached the perceptual limits reported in one-dimensional absolute judgement tasks (around 2.5 bits). Thus, there are cases where behavior may be governed by the performance of single units. However, neurons in the visual cortex are typically selective to a number of stimulus dimensions, resulting in an ambiguity in relating the response level of a single neuron to the stimulus values. We show that a multi-dimensional stimulus may be coded reliably by an ensemble of neurons, using a weighted average population coding model. We simulated neurons with physiological parameters, modelling a two-dimensional case of orientation and spatial frequency tuning, and found that 10³-10⁴ neurons are needed to reach psychophysical discrimination levels. Introduction of each additional dimension requires 1.7 times the number of neurons in the ensemble to reach the same level of accuracy. Since the number of neurons in the hypercolumn is less than 10⁵, only 3 to 5 dimensions could influence neuronal response. This provides another rationale for the existence of parallel processing pathways in vision.

DIRECTION DISCRIMINATION THRESHOLDS AND RESPONSE VARIANCE IN AREA V1 AND MT OF THE MONKEY Stefan Treue, Robert J. Snowden, & Richard A. Andersen
Dept. of Brain & Cognitive Sciences, M. I. T., Cambridge, MA 02139

The ability of a direction-tuned neuron to discriminate two super-threshold patterns moving in different directions depends not only on the neuron's tuning curve but also on the variability of its firing. We determined the tuning curves and the response variance of neurons in visual areas V1 and MT of the awake behaving monkey.

Response variance was about equal to the mean response rate in both areas. This suggests that the response variance of a MT cell arises from mechanisms inherent in the cell itself, rather than being inherited from its inputs since MT cells should otherwise achieve a lower variance by pooling the signals from many V1 cells.

From the above measurements we were able to derive a neuron's neurometric function for any firing level ('criterion rate'). This function plots the probability that the neuron fires above the criterion rate against the stimulus direction. From the neurometric functions derived for a range of criterion rates we calculated the cell's direction discrimination thresholds.

Discrimination thresholds followed a U-shape when plotted as a function of criterion rate. The best discriminations are achieved along the flanks of the neuron's tuning curve. This is in agreement with psychophysical adaptation studies which suggest that the channels involved in direction discrimination of super-threshold stimuli (rather than stimulus detection at threshold) are those with a preferred direction off the test directions. Our experiments further show that some MT neurons can discriminate differences as low as 1.5° similar to the ability of humans performing the same task.

LESIONS OF MT IMPAIR SPEED DISCRIMINATION PERFORMANCE IN THE JAPANESE MONKEYS (MACACA FUSCATA). E. Vandenbussche, R.C. Saunders and G.A. Orban. Laboratorium voor neuro- en psychofysiologie, K.U.Leuven, Belgium and NIMH, Washington D.C., U.S.A.

Monkeys (n=4) were trained to discriminate between two speeds (different or the same) of horizontally moving random dots presented in succession. By pressing on one of the two levers, the monkeys decided if they saw two bars with the same or a different speed. Although two stimuli were presented in each trial, control experiments showed that the monkeys based their discrimination solely on the second stimulus and thus used an absolute identification strategy.

The just noticeable differences (JNDs) in speed were measured using a staircase procedure over a range of reference speeds (2 to 128 deg/sec). JNDs in speed were minimal for intermediate reference speeds (of 16 to 64 deg/sec). Using the same stimulus set-up JNDs in speed were also measured in humans (n=2) and found to be very similar to those of the monkeys.

In three monkeys, area MT of both hemispheres was ablated by a combination of subpial aspiration (posterior bank of ST sulcus) and injections of ibotenic acid (floor of the sulcus). Animals were retested postoperatively for three months at the reference speeds of 8 or 32 deg/sec. In one animal JNDs increased from a Weber fraction of 15% obtained preoperatively to a Weber fraction of 40%. In two other animals the MT lesions had a more devastating effect. For these two animals no stimulus control was obtained for a difference in speed equal to 120%. Six months after the lesion stimulus control was obtained for one of the two animals, but not the other. The third monkey remained at the same level (40% Weber fraction) after six months. In control experiments these three monkeys were shown to perform postoperatively at a 73.5% level of correct responses in a Vernier acuity task for an offset of 1.5 minutes of arcs. In a second control experiment, area TE was ablated bilaterally in two monkeys without effect on speed discrimination.

7.5

GLOBAL MOTION PERCEPTION AFTER MT/MST LESIONS IN A MACAQUE. Tatiana Pasternak, John H.R. Maunsell, Vincent Ferrera, William H. Merigan, University of Rochester Medical School, Rochester NY 14642.

Dynamic random-dot stimuli were used to study the cortical mechanisms that underlie the integration of local direction information into a global motion percept. In such stimuli, each dot is displaced with a constant step size in a direction chosen at random from a distribution, and the stimulus appears to move in the direction of the mean of the distribution. We examined the perception of global motion in two monkeys with ibotenic acid lesions of areas MT and MST (see Merigan et al., Soc. Neurosci. 1991). We measured range thresholds for the discrimination of opposite directions as a function of the fraction of dots that moved in random directions. When no dots moved randomly, the postoperative decrease in range threshold was modest (from 330° to 250-280°). This deficit increased when the proportion of randomly moving dots increased, and beyond 50% the monkeys were unable to perform the task. This compares to preoperative thresholds of 96% of the dots in the target moving randomly. Thus, the discrimination of opposite directions of global motion in the presence of directional noise was severely disrupted. The lesions also produced a 2-4 fold loss in direction difference thresholds that was independent of both stimulus speed and the range of directions in the global motion stimulus. These deficits, like those described above, persisted throughout the 5 months of postlesion testing.

Our studies demonstrate two effects of MT/MST lesions on direction sensitivity in the absence of directional noise: direction difference thresholds were elevated, and the range of directions that could be integrated to judge opposite direction was decreased. The relatively modest size of these effects suggests some sparing of direction integration and direction difference sensitivity after MT/MST lesions. On the other hand, the addition of even small amounts of directional noise severely compromised direction sensitivity, suggesting that these extrastriate areas may be most critical for preserving motion visibility in the presence of motion noise.

REDUCTION IN DIRECTIONALLY SELECTIVE NEURONS EXTENDS SPATIAL LIMIT FOR GLOBAL MOTION. Kirsten K. Rudolph, Tatiana Pasternak, and Vincent Ferrera, Center for Visual Science, University of Rochester, Rochester, NY 14627.

Global motion, the perception of coherent flow, requires integration of many localized direction signals. We used dynamic random-dots to study the neural mechanisms underlying this process. In such displays, each dot is displaced with a constant step size in a direction chosen at random from a specified range. We've shown that cats with severely reduced proportions of directionally selective cortical neurons (reduced DS) discriminate opposite directions of global motion at normal levels, but are unable to make judgments of direction difference more refined than 20-30 deg. In this study, we manipulated step size to determine whether the same pattern of results would hold over a range of spatial displacements. Opposite direction discrimination was tested in humans, normal, and reduced DS cats. As step size increased, range thresholds decreased for all observers, but reduced DS animals were less affected than normals and could do the task at step sizes beyond those which limited performance for other observers. Discrimination of small direction differences revealed the same pattern of results. Whereas the accuracy of normal observers decreased sharply as a function of step size, at intermediate and especially large step sizes (2.4-3.8 deg), animals lacking the majority of their directionally responsive cells did as well, and often better than normals. The spatial displacement limit for these animals was extended relative to that of normals.

We used autocorrelation to compute the signal-to-noise in the stimuli, and used this ratio as input to a modified line-element model. By varying spatial weights used in computation of the signal, good fits could be achieved for all observers. This result, together with the finding of improved performance with reduction in dot density suggest that spatial scale change in residual directional mechanisms, along with a reorganization of sampling in the visual systems of reduced DS cats, may account for the superiority of their performance at large step sizes.

PERMANENT DEFICITS IN SPEED DISCRIMINATION AFTER MT/MST LESIONS IN MACAQUE MONKEYS. William H. Merigan, Tatiana Pasternak, Vincent Ferrera, John H.R. Maunsell, University of Rochester Medical Center, Rochester, NY 14642.

Anatomical and physiological evidence suggests a central role for cortical areas MT and MST in motion processing, and behavioral lesion results are generally consistent with such a role. This study examined motion related psychophysical thresholds in two macaque monkeys, before and after large bilateral lesions were made of cortical areas MT and MST. Lesions were placed by making a grid of ibotenic acid injections in the anterior and posterior banks of the dorsal 7 mm of the superior temporal sulci. Histological reconstruction, completed in one monkey, showed the damage was centered on areas MT and MST, which were severely damaged. Some cortex in the region of V3 in the lunate sulcus was also damaged. Contrast sensitivity for detecting 1 c/deg drifting gratings over a wide range of drift rates was unaffected by the lesion. Moreover, the monkeys discriminated the direction of motion at contrasts near or just below detection threshold (.5-1.3%). On the other hand, the lesion produced deficits in the discrimination of stimulus speed. Prelesion, thresholds were about 10-13% of the speed of a 1 c/deg grating. Postlesion, the speed threshold was elevated about 2-4 fold at all grating contrasts. This elevation was still present at the time of the last testing, about five months after the lesions were made, and therefore can be considered essentially permanent. These results show that the ability to discriminate speed is reduced, but not abolished, by extensive lesions of areas MT/MST. Thus, extrastriate areas MT and MST do not appear essential to either detection or opposite direction discrimination measured as contrast sensitivity with drifting gratings. On the other hand, these areas appear important for the computation of the speed of stimulus motion, although some discrimination ability survives their removal.

SPEED DISCRIMINATION AND GLOBAL MOTION PERCEPTION IN PATIENTS WITH UNILATERAL POSTERIOR BRAIN LESIONS. L.M. Vaina, M. LeMay, N. Stratton, and T. Kemper. ¹Intelligent Systems Laboratory and ²Neurology Department, Boston University, Boston, MA 02215; ³Division of Health Sciences and Technology, MIT, Cambridge, MA 02139; ⁴Harvard Medical School, Boston, MA 02115

Recent studies show that MT/MST lesions in the macaque produce severe deficits of speed discrimination and global motion perceptions. We have reported (1) that bilateral lesions involving the occipital-parietal-temporal junction in humans produce similar deficits. Here we show further examples of such deficits from patients with unilateral brain lesions. We will also show possible dissociations between impaired speed discrimination and global motion perception similar to that of our patient AMG reported at ARVO in 1991 (2). We will contrast both these results with the anatomical description of the lesions and with the performance on other motion psychophysical tasks.

INVARIANCE IN APPARENT MOTION STRENGTH WITH VIEWING DISTANCE IS DUE TO CANCELING OF SEPARATE 2-D SIZE AND PROXIMITY EFFECTS. Michael E. Rudd and Paola Bressan, Psychology Department, Johns Hopkins University, Baltimore, MD 21218 and Dipartimento di Psicologia Generale, Università di Padova, 35139 Padova, Italy

The separate modulating effects of stimulus element luminance and size on the variation of apparent motion strength with 2-D proximity were studied using the stimulus display and competition paradigm of Shechter and Hochstein (Vis. Res. 29:579, 1989). Luminance-proximity and size-proximity interactions were analyzed on the basis of trials run in blocks in which luminance and size were held constant while proximity varied. This method allowed us to quantitatively model the interaction effects in the absence of confounds introduced in earlier studies.

Our results reveal a significant size-proximity interaction, consistent with earlier findings. Furthermore, we show that this interaction obeys a quantitative law which accounts for the previously reported "scale invariance" of motion strength with viewing distance (Burt and Sperling, Psych. Rev. 88:171, 1981): Z-scores for motion in the reported direction vary in proportion to the element diameter. This finding cannot be explained as an artifact of the covariation of element size and element interedge distance. No effects of either luminance or luminance flux were observed. The results are related to a recent model of motion computation by the cortex (Rudd and Grossberg, Neurosci. Abst. 16, 962, 1990).

PERCEIVED VELOCITY OF GRATINGS VARIES WITH TARGET AND MOTION PATH TEMPORAL FREQUENCY. E. Katz, J. Victor and M. S. Gizzi. Department of Neurology and Neuroscience, Cornell University - Medical College, New York, and Department of Neurology, Mount Sinai School of Medicine, New York.

Last year we reported that the perceived velocity of an object is inversely related to the length of the motion path and thus positively related to the temporal frequency (TF) of the motion path (Katz et al. *Neurosci. Abstr.* 46.3, 1990). In the present study we measured perceived velocity of grating patches as a function of their true velocity, the TF of the grating and the TF of the motion profile. Vertical grating patches (2.2°x2.2°) moving at constant speed, back and forth for 1 cycle of a triangular motion profile were produced on a 608 Tektronix oscilloscope and viewed at 57 cm. Each trial consisted of randomly ordered sequential presentation of standard and test stimuli. Velocities were judged in a two-alternative forced-choice paradigm. The standard stimulus moved at 8.3°/s or 10.2°/s, along 4.0° or 4.8° motion path. The velocity of the test stimulus was 9.28°/s and its motion path varied from 0.55° to 4.4°. In addition, we manipulated the TF of both test and standard stimuli by presenting them at spatial frequencies of 0.91 cyc/° and 3.6 cyc/° in matched and mismatched conditions.

The data indicate that when standard and test stimuli were identical in grating TF and motion path TF, the 10% velocity difference was barely discriminable. When standard and test stimuli differed in grating TF but not in motion path TF, the stimulus with the higher grating TF was perceived as faster, independent of true velocity. Finally, when the stimuli differed in motion path TF, the stimulus with higher motion path TF was perceived as faster regardless of grating TF and true velocity.

COLOR SATURATION CONSTANCY

Richard O. Brown & Donald I. A. MacLeod
Dept. of Psychology, UCSD, La Jolla, CA 92093-0109

In color constancy, the perceived color of an area depends on the relationship between the light from that spot and the light from its surround. These effects have been widely studied for the color dimensions of lightness and hue. We report such surround effects occur also for color saturation.

Colors appeared more saturated in a low-saturation surround than in a high-saturation surround, even when the mean lightness and chromaticity of the two surrounds were identical. Similarly, achromatic colors appeared blacker or whiter in surrounds with low contrast variance than in high contrast surrounds.

These saturation effects may be analogous to the well-known phenomena of induction and constancy for lightness and hue, but they are neither predicted nor explained by the usual accounts and models of color constancy. Saturation constancy implies compensatory expansion or compression of the range of colors present in a scene, without necessarily shifting the centroid (or neutral grey point) of those colors.

Color constancy is commonly considered as a matter of "discounting the illuminant". Most changes in the illuminant primarily affect lightness and chromaticity, with relatively minor effects on saturation. Color constancy, including constancy for saturation, may be important for additional visual functions, such as vision through haze, transparency, depth, etc.

7.10

CROSS DIRECTIONAL INHIBITION IN HUMAN MOTION PROCESSING.

R. J. Snowden, University of Wales College Cardiff, Cardiff CF1 3YG, UK.

Selective adaptation experiments have led to the notion of 'visual channels'. For instance adaptation to a pattern moving upward increases the threshold for seeing patterns moving upward, the effect decreasing as the angle between the adapting and test pattern increases until no effect is seen (typically when the patterns differ by more than 120 deg). This suggests that there are independent directional specific channels in human vision.

To test this notion I have used a 'double adaptation' procedure. Subjects adapt to a random dot pattern which alternates between two directions (A & B). If directions A & B activate the same channel threshold elevation to direction A should be greater than adapting to A alone; if A & B activate independent channels then elevation should be the same as A alone; whereas if there is inhibition between channels A and B elevation will be less than A alone. The results show that a clear inhibitory effect between patterns which differ by more than 100 deg, with the greatest inhibition when the patterns differ by around 120 deg.

Patterns which differ by 120 deg do not affect each others threshold for detection, yet appear to be inhibitory in the 'double adaptation' procedure. This suggests a 'divisive' inhibition. This notion was further tested by measuring threshold elevation as a function of adapting contrast either in the presence of absence of such an inhibitory pattern. Again the results clearly show that the inhibitory effect is divisive in nature. These results bear great resemblance to those reported for individual cells of the extrastriate area MT (Snowden et al. *Soc. Neurosci. Abs.* 16: 7.5, 1990).

7.12

Surface representation vs features in visual search.

Z. He¹, K. Nakayama¹ and N. Tumosa². Dept. Psychology, Harvard Univ¹. Optometry Sch, Univ. Missouri-St. Louis²

Often implicit in the interpretation of visual search tasks is the assumption that the detection of targets is determined by the properties of early feature processing. In this report, we cast doubt on this view by manipulating binocular disparity so that supposed "features" can become parts of surfaces which render them less clearly distinguishable as targets and distractors. For example, an L next to a square (see figure beside) can appear to be part of an occluded surface particularly if its disparity is uncrossed with respect to the square. Similarly, an L in a slightly more complex display can appear as part of a transparent surface in front if the sign of binocular disparity is crossed and the luminance conditions are correct (Nakayama, et al., *Perception*, 1990). In a series of experiments manipulating binocular disparity, distractor number, and luminance ratios, we were able to show that the detection of a reversed L among other Ls was significantly impaired when the L formed part of a more complete surface. These results raise the possibility that visual search has little or no access to the level of feature extraction but must have as an input, a later process of surface representation.

Eye morphogenesis in the zebrafish. E.A. Schmitt*, C. Fulwiler, L.V. Goodrich* & J.E. Dowling. Biological Laboratories, Harvard University, Cambridge, MA 02138.

As a foundation for genetic analysis of retinal development in zebrafish, we examined eye morphogenesis in wild type and haploid embryos by scanning EM and light microscopy. Here we describe novel features of eye development observed in the course of these studies.

After evagination of the optic vesicles between the 6 and 10 somite (s) stages, the vesicles of the zebrafish flatten as they extend laterally. Then upon contact with ectoderm, they rotate downward along the long axis of the embryo. A central crevice appears separating the distal and proximal neuroepithelia and will later form the optic lumenae. Shortly afterwards, an antero-posterior furrow becomes visible on the surface of the vesicle (15s). Invagination commences with a central depression in the furrow, spreading symmetrically across the vesicles. At the anterior end of the furrow a shallow groove marks the first appearance of the choroid fissure (16s) which will increase in depth along with the optic cup between 16 and 20s.

Between 1 and 1.5 days, ventral flexure of the head results in rotation of the eye by 90°. This brings the choroid fissure into a ventral position. In haploids, the fissure is abnormally wide and fails to close. Subsequently, as the surrounding ventral retina differentiates, the organization of cellular layers in this region is disrupted.

Our observations indicate that the epithelium which becomes neural retina originates in the dorsal half of the vesicle prior to its downward rotation.

Pattern regulation in the retina of the zebrafish mutant cyclops. C. Fulwiler, E.A. Schmitt*, & J.E. Dowling. Prog. in Neuroscience, Harvard Medical School and Biological Laboratories, Harvard Univ.

We examined retinal development in the γ -ray induced zygotic lethal mutation *cyc-1(b16)*, obtained from Dr. C. Kimmel, U. of Oregon (Hotta, et al., *Nature* 350:339, 1991) in order to investigate how synophthalmia affects retinal pattern formation. Plastic sections from mutants between 1 & 3 d. were compared with sections from wild type siblings.

In the *cyclops* eye at 1.5-2d, a midline inner retinal pattern develops between two laterally placed inner retinas. Two eye fields appear to have fused and induced a third field. The cellular and plexiform layers in the midline are continuous with the layers on either side.

By 3d., three outer retinal layers are apparent, one midline and one on each side. The photoreceptor, outer plexiform and horizontal cell layers are continuous across the midline, there being a gradual transition in cell polarities between them. Abnormal cell death is seen, primarily medially where the two eye fields overlap. We have tentatively identified new germinal cells moving into this region, perhaps to contribute to the emerging midline pattern. The result is a ventral to dorsal gradient of retinal cells with the oldest ganglion cells across the ventral margin and the youngest photoreceptors across the dorsal margin.

The effect of the *cyclops* mutation on the retina is probably indirect, reflecting a regulative response of cells to abnormal positional relationships created by the fusion of two eye fields. Our observations suggest that in the retina, interactions between neighbors may be more important to the generation and maintenance of the laminar pattern than information about a cell's position within the eye field.

8.3

CORRESPONDING ORTHOGONAL GRADIENTS OF TOP MOLECULES IN THE DEVELOPING RETINA AND OPTIC TECTUM. D. Trisler, S. Gill*† and J. Joshi*. Lab. of Biochemical Genetics, NHLBI, NIH, Bethesda, MD 20892 and †George Washington Univ. School of Medicine, Washington, DC 20037.

The topographic map of cell position in the avian retina is conserved and inverted when retinal ganglion neurons synapse with neurons in the optic tectum. Developmental mechanisms based on molecular gradients that specify positional information have been postulated in the establishment of these topographic maps of cells in the retina and tectum. Two cell surface proteins in chicken retina, TOP_{DV} and TOP_{AP}, are distributed in dorsoventral and anteroposterior topographic gradients, respectively (Trisler, 1990, J. Exp. Biol. 153: 11-23). Corresponding gradients of TOP molecules, present in the tectum, are inverted with respect to the retinal gradients; TOP_{DV} is more abundant in dorsal retina and ventral tectum and TOP_{AP} is more abundant in posterior retina and anterior tectum. Both TOP_{DV} and TOP_{AP} are present at embryonic day 2 and persist throughout development and in the hatched chick. Regulation of TOP expression was studied *in vivo* and *in vitro* using the quail neuroretina cell line, QNR/D (Pessac, *et al.*, 1983, Nature 302: 616-617). Eye rotation and retinal sector ablation studies show that TOP_{DV} expression is determined before embryonic day 3. The level of TOP_{DV} expression throughout the retina is established by cell lineage. These orthogonal gradients of TOP_{DV} and TOP_{AP} molecules provide a possible Cartesian coordinate system for designation of cell position at all points in the retinotectal map.

8.5

A ROSTROCAUDAL GRADIENT OF TRANSGENE EXPRESSION IN ADULT MOUSE SKELETAL MUSCLE. Maria J. Donoghue*, John P. Merlie, and Joshua R. Sanes. Departments of Anatomy and Neurobiology and of Molecular Biology and Pharmacology, Washington University Medical School, St. Louis, MO 63110.

We previously generated transgenic mice in which a promoter and enhancer from a myosin light chain (MLC) 1/3 gene are linked to a chloramphenicol acetyltransferase (CAT) gene. CAT expression is muscle-specific and developmentally regulated in these mice. Analysis of 35 individual muscles now reveals that CAT and CAT mRNA expression are positionally graded along the rostral-caudal axis. The gradient spans the entire body, and has a >100-fold range from lowest levels in muscles innervated by cranial nerves to highest levels in muscles innervated by lumbar and sacral nerves. The relationship between rostral-caudal position and level of transgene expression is not due to the site of transgene integration into the chromosome or to sequences in CAT. A novel histochemical stain for CAT reveals that transgene expression is fiber type-dependent (Type IIB>IIX>IIA>I), but that levels of CAT are positionally graded among fibers of each type. However, there is no gradation in the expression of the endogenous MLC 1/3 gene. Our interpretation of these results is that MLC sequences, when taken out of their genomic context, respond to an endogenous regulator of transcription whose activity is positionally graded. The stability of this positional memory is demonstrable *in vitro*: myoblasts from individual muscles divide in culture and form myotubes that express levels of CAT characteristic of their muscle of origin. This pattern of transgene expression provides a molecular correlate of positional gradients of synaptic preference demonstrated electrophysiologically (e.g., Wigston and Sanes, J. Neurosci. 5:1208, 1985), and the transgene may be useful for investigating the endogenous determinants of this positional information. (Supported by NIH and MDA.)

NERVE GROWTH FACTOR INJECTIONS RESCUE CELLS, BUT NOT CNS WHISKER PATTERNS, AFTER INFRAORBITAL NERVE INJURY AT BIRTH. P.A. Osborne*, T.A. Henderson, E.M. Johnson, C.A. Bennett-Clarke, P.A. Young, R.W. Rhoades, & M.F. Jacquin. Dept. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104; Dept. Molec. Biol. & Pharm., Washington Univ. Sch. Med., St. Louis, MO 63110; Dept. Anat., Med. Coll. Ohio, Toledo, OH 43699.

Neonatal infraorbital nerve section rapidly kills large numbers of trigeminal first- and second-order cells, and interrupts pattern formation in brainstem, thalamus, and cortex. To determine whether rescue of axotomized ganglion cells by NGF prevents second-order cell death and permits development of whisker-related patterns, rats were given sub-Q injections of 5 mg/kg NGF prior to, and every day after, left infraorbital nerve section on the day of birth until sacrifice on postnatal day (P) 1, 3, 5, or 7. Unlike pups not given NGF (Henderson & Jacquin, *Neurosci. Abstr.* 16, '90), NGF-treated animals displayed no significant cell loss in the ganglion (P1: 97±4, P3: 103±12, P5: 103±15, P7: 95±11; % ± SD vs. control right side, N=5 each) or brainstem nucleus principalis (P1: 102±5, P3: 102±7, P5: 100±7, P7: 99±3; N=5 each). 5 other NGF-treated nerve cut pups from each age were processed to show whisker-related cytochrome patches in the brainstem and thalamus, and 5-HT patches in the cortex. Deterioration of brainstem patterns, and failure to develop higher-order patterns, proceeded as in cases not given NGF. These data are consistent with prior proposals that communication with the periphery is necessary for the normal development of CNS whisker patterns. They also suggest that rescuing primary afferents prevents second-order cell death, but this conclusion must be tempered by known direct effects of NGF on CNS cells. DE07734, DE07662, NS24679, NS28888.

8.4

MOLECULAR CLONING AND EXPRESSION OF TOP_{AP}; A GRADIENT MOLECULE IN THE CHICK RETINOTECTAL SYSTEM. J.M. Savitt*, D. Trisler and D.C. Hill. Dept. of Biochemistry and Neurology, Univ. of Maryland Sch. of Med., Baltimore, MD 21201. Laboratory of Biochemical Genetics, NHLBI, NIH, Bethesda, MD 20892.

TOP_{AP} is a 40 kD protein found in an exponential gradient in chick retina and tectum. Studies involving monoclonal antibodies have shown that the TOP_{AP} epitope is found preferentially in posterior retinal cells and their major projection area, anterior tectum. These studies and additional *in vivo* experiments suggest that TOP_{AP} may be involved in position-specific neural connections in the developing chick visual system. In order to better understand the structure and function of this molecule we constructed a cDNA expression library from posterior quadrant chick retina mRNA and screened 10⁶ clones using an anti-TOP_{AP} monoclonal antibody. A single positive clone was identified, and subsequently expressed as a 45 kD Lac Z fusion protein which was recognized by the monoclonal antibody on Western blots. Analysis of the cloned sequence demonstrated a near full-length cDNA of approximately 3.1kb with an open reading frame coding for 371 amino acids. The translated sequence showed limited similarity to known protein-coding regions found in the NBRF database. Further analysis has shown that a single mRNA species of approximately 3.5kb codes for TOP_{AP} and appears to be preferentially expressed in posterior quadrant chick retina.

8.6

FETAL INJECTIONS OF NERVE GROWTH FACTOR INTERRUPTS WHISKER-RELATED PATTERN FORMATION IN BRAINSTEM. T.A. Henderson, P.A. Osborne*, R. Srisumrid*, T.A. Woolsey, E.M. Johnson, & M.F. Jacquin. Dept. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104; Dept. Molec. Biol. & Pharm., Div. Exp. Neurol. & Neurosurg., Washington Univ. Sch. Med., St. Louis, MO 63110.

Mechanisms normally controlling pattern formation in the developing trigeminal (V) system are unknown. The only direct manipulation known to alter development of whisker-related CNS patterns is peripheral nerve injury. To test the role of naturally occurring ganglion cell death in this process, rat embryos were given transuterine, sub-Q injections of exogenous NGF (20 or 30 ug) on either embryonic day 15 (E15), E16, E18, or both E15 + E18. Control embryos received injections of matching volumes of antibodies to the NGF receptor or vehicle. Fetuses were brought to term (E21.5 ± .5; conception = E0), weighed, and perfused. Brainstems were processed for cytochrome oxidase (CO) histochemistry. Experimental and control pups had equivalent body weights that were on average 20% below normal. All controls, and pups given NGF on E16 or E18, exhibited distinct whisker-related CO patterns that did not differ from those in untreated pups at birth. E15 NGF cases had a less distinct pattern. Pups given NGF on E15 + E18 did not display whisker-related CO patterns in any portion of the V brainstem complex, despite dense CO staining where patterns normally appear. Other E15 + E18 NGF pups sustained for 24 or 72 hours postnatally, and given daily injections of 5 mg/kg NGF, also did not develop CO patterns. Here too, dense CO staining was seen in the V complex. Other than lacking a whisker pattern, V nuclei looked normal. Why patterns do not form is under study. NGF may alter projections to the face or rescue "interpatch-projecting" ganglion cells from a natural death. DE07734, DE07662, NS24679.

ACTIVITY-DEPENDENT COMPETITIVE INTERACTIONS IN THE DEVELOPING WHISKER-BARREL NEURAXIS. P.H. Lee*, W.R. Weaver*, T.A. Henderson, R.V. Sonty, T.A. Woolsey, & M.F. Jacquin. Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104; Exp. Neurol. & Neurosurg., Washington Univ. Sch. Med., St. Louis, MO 63110.

We (Henderson *et al.*, *Neurosci. Abstr.* 15, '89) have shown that postnatal blockade of infraorbital nerve impulses does not alter pattern formation or cytochrome oxidase (CO) staining in developing whisker-barrel pathways. Yet, others have documented reduced CO staining following neonatal deafferentation/deprivation or chronic whisker-trimming in adult rats (eg. Land & Simons, *Brain Res.* 341, '85). In an attempt to reconcile these data, additional whisker deprivation paradigms were studied. 5 rats had all of their left (L) whiskers trimmed daily for 2 wks from birth and CO staining patterns and intensities were evaluated. L and right (R) trigeminal nuclei, thalamus, and cortices were indistinguishable. Identical methods were used in 6 littermates to determine whether CO patches stain differentially when all of the whiskers, except those in the C-row, were trimmed daily. Again, L and R staining patterns and densities, as well as patch sizes, were equivalent in each station. In another litter, we found that cortical B+D row patch sizes were not altered by L C-row cautery at birth (vs control: 97±11%, N=4). In contrast, cortical B+D row patches were larger than normal when littermates were subjected to both C-row cautery at birth and daily whisker trimming (vs control: 117±17, N=4, p<.01). Taken together, the above data suggest that under normal conditions, postnatal ganglion cell activity does not control pattern formation or metabolic activity in the developing barrel neuraxis. However, subordinate activity-dependent competitive interactions can be revealed when a competitive advantage is conferred upon B+D row neuropil by C-row cautery at birth. NIH DE07734, DE07662, NS17763.

CORTICAL FIELD TRANSITIONS DO NOT FORM CELL LINEAGE BOUNDARIES IN RAT HIPPOCAMPUS. E.A. Grove and J. Price*, National Institute for Medical Research, Mill Hill, London NW7 1AA, U.K.

We employed the retroviral method for tracing cell lineage to ask whether clonal restriction boundaries define the borders between areas in a portion of the cerebral cortex: the hippocampus. A replication-incompetent retrovirus, carrying the *lac-Z* gene, was injected into the cerebral vesicles of embryonic rat brains at the peak of cortical neurogenesis, embryonic day 16. Pups were allowed to survive until the third postnatal week, when cortical area boundaries appear mature. Clones of neurons derived from infected progenitor cells were histochemically identified and their dispersion examined relative to area boundaries determined in the same tissue sections.

The spread of individual neuronal clones in the hippocampus appears limited compared with that seen in contiguous neocortex; pairs of clonally related neurons rarely lay more than 100-200µm apart. Nonetheless, clones freely crossed field boundaries among the CA fields of Ammon's horn and between CA1 and the subiculum. Statistical analysis of data from our sample of 49 hippocampi indicated that the dispersion of neuronal clones is not constrained by structural boundaries at all; rather clones distribute in an apparently random manner over the surface of the hippocampus. Cortical fields, at least in the hippocampus, therefore appear to differ from structural subdivisions in the hindbrain and diencephalon, whose borders form clonal restriction boundaries during neurogenesis.

EVOLUTION OF INSECT SEGMENTATION AND HOMEOTIC GENES AND THEIR FUNCTION DURING NEUROGENESIS.

E.E. Ball¹, E.J. Rehm^{2*} and N.H. Patel^{2*}, and C.S. Goodman¹.
¹Mol. Neuro., RSBS, Aust. Natl. Uni., PO Box 475, Canberra ACT 2601, Australia; ²HHMI, Dept of Mol. Cell Biol., Uni Calif., Berkeley CA 94720.

In *Drosophila*, segmentation and homeotic genes are expressed in the blastoderm and control the pattern and identity of segments. Many of these same genes are also expressed later during the development of the nervous system and several have been shown to control the differentiation of particular neurons. Previous studies on *engrailed* (*en*) indicate that this *Drosophila* segment polarity gene is utilized for both segmentation and neurogenesis in arthropods, but its only conserved function in chordates appears to be in neural development. To expand our knowledge of the evolution of genes involved in segmentation and neurogenesis, we have cloned the grasshopper homologs of the *Drosophila* pair-rule gene *even-skipped* (*eve*) and the homeotic gene *Antennapedia* (*Antp*), both of which encode homeodomain-containing proteins. In both insects, *eve* is expressed in a very similar subset of neurons and by muscles that are innervated by the motoneurons that express *eve*, suggesting a potential role for this gene in regulating neuromuscular connectivity. The grasshopper *eve* gene, however, is neither expressed in a pair-rule nor any other pattern during segmentation. In contrast, the grasshopper *Antp* gene is expressed during both segmentation and neurogenesis in a manner very similar to its *Drosophila* counterpart. These results suggest that the early pattern formation and neurogenic functions of homeotic (*Antp*) and segment polarity (*en*) genes have been largely conserved between grasshopper (a more primitive insect) and *Drosophila*, whereas only the neurogenic function of a pair-rule gene (*eve*) has been conserved between these two species.

8.13

REGULATION OF EARLY DORSAL ROOT GANGLION (DRG) SIZE DEPENDS UPON THE TYPE OF MESODERM ENCOUNTERED BY MIGRATING NEURAL CREST CELLS. C. Kalcheim, R.S. Goldstein and G. Gvirtzman, Dept. Anat. & Embryol., Hebrew Univ.-Hadassah Med. School, Jerusalem 91010, Israel.

The environment created by grafting rostral somitic halves in place of normal somites, leads to the formation of non segmented peripheral ganglia (Kalcheim & Teillet, Dev. 106, 85-103, 1989; Goldstein & Kalcheim, Dev., 1991, in press) and is mitogenic for neural crest (NC) cells that become DRG (Goldstein et al., PNA's., 87, 4476-80, 1990). We have now studied the effect of additional mesodermal tissues on DRG growth in chick embryos: a. unilateral deletion of epithelial somites (SD), similar deletions followed by grafting; b. a 3 - dimensional collagen matrix (CM), or c. fragments of quail lateral plate mesoderm (LPM). Neural structures were identified with the HNK-1 antibody and the graft of quail cells with hematoxylin counterstaining. NC cells migrated into the grafted LPM, and unsegmented DRG formed whose volume was increased by 68% (n=3, E4) compared to the contralateral ganglia. In contrast, NC cells did not penetrate the intermediate mesoderm that was apposed to the neural tube in SD embryos, or the CM invaded by loose mesenchyme. In SD and CM embryos, unsegmented ganglia formed whose volumes were decreased by 19% (n=5, E4) and 13% (n=5, E4), respectively, compared to controls. These results suggests that although DRG precursors do not require the sclerotome to begin migration and condensation processes, DRG size is largely regulated by the properties of the mesoderm. Permissiveness to migration is then correlated with an increase in DRG volume. This increase observed in LPM grafts presumably results from contribution of sympathetic precursors remaining in dorsal positions and/or by increased proliferation of NC cells as previously demonstrated for rostral somitic grafts.

8.10

RHOMBOMERIC ORGANIZATION IN THE EMBRYONIC VERTEBRATE HINDBRAIN. R. Baker, E. Gilland*, and D. Noden*, Dept. of Physiol. and Biophys. NYU Med. Ctr., New York, NY 10016 and Dept. of Anat., NY Coll. of Vet. Med., Cornell Univ., Ithaca, NY 14853.

Rhombomeres are metameric units in the hindbrain of vertebrates that may delineate compartments in which neurons develop at different times and project to specific peripheral and central targets. To better understand the phylogeny and ontogeny of rhombomeric organization we have examined embryonic motor nuclei in segmenting hindbrain neuroepithelium utilizing cationic lipophilic dyes applied to formaldehyde preserved and living skate, shark, turtle, bird, mouse, and ferret embryos. All species exhibited seven clear hindbrain rhombomeres, but boundaries of an eighth were less evident, especially in shark and skate. An alternating wedge-like segmental shape was prominent in r2-5, especially in the bird and ferret. Motoneurons of nerves V, VII, IX, and X originated in adjacent pairs of rhombomeres (r2-3, r4-5, r6-7, r7-8) and the sensory/motor fibers entered and exited at rhombomeres 2, 4/5 junction, 7 and 8, respectively. In the shark and skate, most Vth motoneurons originated from r3 and the nerve rootlet exited from that rhombomere. In mouse and ferret, V and VII motoneurons largely originated from r2 and r4, but in turtle and bird equal numbers were observed in r2-3 and r4-5. The VIth nerve emerged from the floor plate of r6 (skate and shark), r5 and r6 (turtle and bird), but only from r5 in ferret and mouse. Motoneurons of the VIth nerve were medial to those of VII and IX in r5 and r6. We conclude that the branchio-motor origins of V, VII, IX and X are similar in all species; however there is considerable interspecific disparity in the VIth nerve, some in V and less in VII. These data suggest that rhombomeric compartmentalization is a highly conserved template upon which species-typical developmental modifications are executed.

8.12

RETINOIC ACID DISRUPTS ANTEROPOSTERIOR PATTERNING AND NEURAL GENE EXPRESSION INSIDE AND OUTSIDE EMBRYONIC FROG BRAIN: EVIDENCE FOR POSTERIOR TRANSFORMATION? W.P. Hayes and Y.P. Loh. Lab. Dev. Neurobiol., NICHD, Bethesda, MD 20892.

Increasing evidence suggests all-trans retinoic acid (RA) is a morphogen during embryogenesis. A strong case exists for RA in anteroposterior (A-P) patterning of chick limb bud (Smith et al. 1989, *Development Supplement*). More recently, RA has been implicated in A-P patterning of the embryonic CNS in *Xenopus*. Like Sive et al. (1990, *Genes & Development* 4), we found a progressive and dose-dependent A-P deletion of the CNS by RA. Since the RA-sensitive period precedes neural induction, RA may be toxic to more anterior gastrulating mesodermal cells and thus block anterior neural induction. But since RA is present in gastrulae and neurulae, and since an apparent enlargement of the remaining posterior CNS was observed, it has been proposed that RA normally acts to transform anterior-specified neural tissue to more posterior CNS (Durstion et al. 1989, *Nature* 340). Regional homeobox (HB) gene expression also supports this, because RA only acts in concert with growth factors that have differentially induced anterior or posterior HB genes (Cho and De Robertis 1990, *Genes & Development* 4).

To test this hypothesis we are using neuropeptide genes to map regional neural differentiation after progressive A-P 'ablation' by RA. Our previous *in situ* hybridization studies showed that proopiomelanocortin (POMC) is the anteriormost embryonic marker of neural gene transcription (Hayes and Loh 1990, *Development* 110), whereas thyrotropin-releasing hormone (TRH) and proenkephalin label more posterior CNS. Interestingly, 10-7 and 5x10-8 but not 10-8 RA eliminated POMC expression in pituitary and CNS, although at 5x10-8 RA, forebrain areas which normally express POMC were still present. Nevertheless, at 10-7 RA, anterior brain did, as previously reported, resemble enlarged hindbrain tissue. We are now using proenkephalin and TRH probes to determine if as predicted this 'transformed' region exhibits a pattern of neural differentiation characteristic of hindbrain and spinal cord.

9.1

AN EYE-SPECIFIC PROTEIN KINASE C IS REQUIRED FOR MEDIATING EXTRACELLULAR CALCIUM DEPENDENT LIGHT ADAPTATION IN DROSOPHILA PHOTORECEPTORS. B. Ranganathan, D. P. Smith, C. E. Stevens, and C. S. Zuker. Howard Hughes Medical Institute, Depts. of Biology and Neuroscience, UC San Diego, La Jolla, CA 92093, and the Salk Institute, La Jolla, CA 92037.

With the goal of examining the role of calcium ions in invertebrate phototransduction, we have developed a novel preparation of isolated *Drosophila* photoreceptors suitable for an electrophysiological characterization of the light response using patch clamp techniques. Our general characterization of the *Drosophila* light activated conductance indicated that it is permeable to many monovalent cations, and is highly permeable to calcium ions. The responses to both brief flashes and longer pulses of light show a marked asymmetry about the reversal potential in which the kinetics of adaptation and inactivation are much faster during inward current flow. Our results indicate that this behavior is not directly voltage dependent, but is instead dependent on the direction of ion flow. Experiments in which we recorded from photoreceptors under varying $[Ca^{2+}]_{out}$ showed that extracellular calcium is both sufficient and necessary for mediating a rapid stimulus-dependent inactivation of the phototransduction cascade that underlies the observed asymmetries.

In order to understand the biological significance of this calcium-dependent inactivation process, we screened putative phototransduction mutants for those defective in this process. We show that mutations in a gene that encodes a photoreceptor-specific isoform of a protein kinase C (PKC) are specifically defective in this calcium-dependent inactivation mechanism and that the expression of the mutant phenotype completely requires extracellular calcium. These data suggest a model in which calcium mobilization as a result of channel activation modulates the phototransduction cascade largely through the activation of this protein kinase C, and that this mechanism may represent a molecular basis for light adaptation in *Drosophila*.

9.3

STRUCTURE OF THE HUMAN SAMPLING MOSAIC IN PERIPHERAL RETINA. J. Hirsch and M. Bianchi. Department of Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, CT 06510.

The structure and packing of retinal photoreceptors determines the spatial detail available to the visual system for subsequent neural processing. Although the sampling mosaic plays a fundamental role in vision, sampling strategies have not been explored beyond the foveal region. We compare the foveal mosaic^{1,2} with a region of the same retina between 9 and 11 degrees of eccentricity, and find that the cone center-to-center spacings exceed those in the fovea (factors of 4 to 5), rods are more numerous than cones (factor of 16), and the cone spacings exceed cone aperture diameters (factor of 1.8) all resulting in a substantial loss of sampled spatial detail. Further, measures of highest visual acuity in this region (8.6 to 11 c/deg)³ are below the resolution capacity (as estimated from cone spacings) of this peripheral cone mosaic (14 to 15 c/deg) suggesting that peripheral postreceptoral processes that mediate resolution may be compromised in comparison to the more central systems where the visual acuity coincides with the anatomical resolution.²

ROD OUTER SEGMENT LENGTH: A CASE OF STRUCTURE-FUNCTION RELATIONSHIPS. K. N. Leibovic and R. Moreno-Diaz Jr. Biophysics Department, Sch. of Med. SUNY/Buffalo, N.Y. 14214 and Computer Science, Universidad de Las Palmas, E-35016 Las Palmas, Spain.

There are numerous examples of structure subserving function in the literature, a case in point being diameter and spacing of photoreceptors with respect to acuity and the limits of diffraction. Photoreceptor length, on the other hand, has not received such attention. Vertebrate rods are exquisitely sensitive, being able to detect single photons in spite of the presence of noise due to the transduction machinery. Efficient absorption of photons favors a long outer segment (OS), while noise control requires a short one. These competing demands lead to an optimality criterion for rods operating in dim illumination. We have shown that this criterion predicts the correct OS length in *Bufo marinus*. Here we extend the optimality criterion to several other species including *Macaca fascicularis*. We show that our computed OS lengths are in close agreement with the experimental values. It supports the notion that these rods are designed to act as efficient photon detectors in the presence of noise. On the other hand, there is no such agreement for the rods of the skate. This is consistent with the fact that the latter rods operate over a range of light intensities covered by rods and cones in most other vertebrate eyes. Our results provide a rationale for rod OS length in a variety of vertebrate species and can be used as an aid in classifying functionally different photoreceptors.

Supported by a gift to K.N. Leibovic from the UB Medical School class of '39 and by a grant from the Cognitive Science Center SUNY/B.

LIGHT ADAPTATION OF HUMAN PHOTORECEPTORS. D. C. Hood and D. G. Birch. Columbia Univ., NY 10027 and Retina Foundation of the SW, Dallas, TX 75231

The role our photoreceptors play in our ability to adjust to steady ambient lights is incompletely understood. In this study, we measured human photoreceptor activity by examining the leading edge of the a-wave of the ERG.

We have recently shown that the leading edge of the a-wave provides a measure of the activity of human photoreceptors¹. In particular, the a-wave varies with time and flash energy in ways consistent with known computational models² of receptor responses. In separate experiments, we isolated the cone and rod a-wave by procedures previously described¹. The 600 μ s flashes were red (W26) or blue (W47B) and were presented upon 'white' adapting fields. Amplitude-intensity data for full-field ERGs were obtained in the dark and upon steady adapting fields ranging in intensity from 10 to 10,000 trolands for the cones and from 1 to 250 scot td for the rods. Plots of response amplitude at fixed times after the flash confirm that the data can be described by a class of models with a linear filter followed by a static nonlinearity^{1,2}. A computational model of adaptation was fitted to the data.

Both receptor types show adaptation but not until the adapting field is relatively intense, greater than 1.0 log scot td for the rods and 3.0 log td for the cones. Adaptation includes a gain change and some change in the time course. A similar computational model of adaptation fits both receptor types.

PHOTORECEPTOR TRANSPLANTATION: ANATOMIC, ELECTROPHYSIOLOGIC AND BEHAVIORAL EVIDENCE FOR THE FUNCTIONAL RECONSTRUCTION OF RETINAS LACKING PHOTORECEPTORS. M.S. Silverman, S.E. Hughes, and T.L. Valentino. Sensory Neuroscience Laboratory, Central Institute for the Deaf, and ¹Dept. of Biology, St. Louis University, St. Louis, MO 63110.

We have shown that sheets of photoreceptors can be transplanted to retina lacking photoreceptors (Silverman and Hughes, 1989, *IOVS* 30:1684). However we wished to determine whether these transplanted photoreceptors functionally integrate with the dystrophic retina and if so, whether such integration results in any degree of visual function. Sheets of neonatal photoreceptors were transplanted to the subretinal space of one eye of hosts (albino rats with severe photoreceptor loss induced by constant light exposure) using the photoreceptor isolation and transplantation procedures previously described. Two to 10 weeks post-transplantation cortical evoked potentials (VEP) were recorded from skull screws located over the visual cortex. Flash stimulation of the reconstructed eye resulted in a cortical potential comparable in waveform and up to 50% the amplitude of VEP recorded from normal rats. Little or no response was recorded by such stimulation of the fellow unreconstructed eye or sham operated eyes. The reconstructed eyes also show a conventional pupillary reflex to light, while fellow unreconstructed or sham-operated eyes show a much attenuated response that was aberrant in form (a small pupillary dilation to continuous light). Ultrastructural examination of the reconstructed retinas revealed a new outer plexiform-like layer (OPL) at the interface of the transplanted outer nuclear layer and the host inner nuclear layer (Hughes et al., 1990, *IOVS* 31:594). Ribbon synapses are evident within this OPL. These synapses are characteristic of those formed by rod photoreceptors, displaying an electron-dense ribbon surrounded by a cluster of vesicles. Ribbon synapses are found only rarely in control light-damaged retina. These results show that transplanted photoreceptors can functionally integrate with the dystrophic retina to reestablish evoked activity and behavioral responsiveness to light.

VISUALIZING SYNAPSES WITH CONFOCAL MICROSCOPY IN A LIVE RETINA. R.F. Miller, R.M. Wolfe, J.L. Eiesland, R.W. Fuller and C.B. Toris. Department of Physiology and Graduate Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN 55455.

We have labeled and visualized synaptic boutons in the amphibian and rabbit retina, using activity-dependent dyes (ADD) and optical, 3D reconstruction methods based on confocal microscopy. This approach was combined with electrophysiological experiments in which single neurons were identified and intracellularly labeled with a dye, such as lucifer yellow (LY). The combination of the two labelling techniques permitted visualization of presumed synaptic contacts between ADD filled terminals and the dendrites of single neurons. Several different types of dyes proved useful for labelling terminals, including highly polar dyes which are taken up endocytotically, dyes which label "active" mitochondria and voltage-sensitive dyes. LY filled processes could be separated from ADD filled profiles by switching barrier filters in the light pathway to the PMT. Localization of ADD dyes to nerve terminals was established by dissociating retinas which had been exposed to the dye and using a cooled CCD camera to obtain image data of the cell together with dye localization information. ADD fluorescence was detected in the terminals of photoreceptors, bipolar cell-like neurons and presumed amacrine cells. No ADD dye was observed in ganglion cells which had been back labeled. Single LY filled dendrites, surrounded by ADD filled terminals were optically reconstructed (Voxel View, Vital Images) to evaluate the proximity and density of contacts between these structures. Results with this approach suggest that only a small number of ADD profiles are sufficiently close to any single dendrite to be considered as a likely synaptic connection. These observations demonstrate the feasibility of labelling and studying synaptic terminals in the intact retina. Supported by NEI grants EY03014 and EY07376.

HORIZONTAL CELLS IN THE CONE-DOMINATED RETINA OF THE TREE SHREW. L. Peichl and B. Müller*. Max-Planck-Institut für Hirnforschung, Deutschordenstr. 46, W-6000 Frankfurt/M.71 Germany.

We have studied the morphology, distribution, and synaptic connections of tree shrew horizontal cells (first described by Mariani, J.C.N. 233:553, 1985) by intracellular injection and photoconversion of Lucifer Yellow, and by staining with a neurofilament antibody.

The larger (A-type) cells have sparsely branched dendrites; up to eight dendritic processes end in extensive bushy arborisations (not found in any other mammal). Along the dendrites and on the bushy arborisations, photoreceptor contacts are made through single spiny terminals and small terminal aggregates. Electron microscopy shows that all contacts are with cones, like in the A-type cells of other mammals. A-type densities decrease from 1220/mm² in central retina to 450/mm² in the periphery. Conversely, dendritic fields increase from 400 µm to 540 µm diameter.

The smaller (B-type) cells have a densely branched dendritic tree with 40-80 terminal aggregates, and a single axon with a few terminals that presumably contact rods. The terminal aggregates synapse with practically all cone pedicles in the dendritic field, i.e. there is no colour specificity. Dendritic tree sizes increase from central to peripheral retina (40-70 µm diameter).

Supported by the DFG (SPB 45/C7).

GABAERGIC TRANSMISSION IN DISTAL MAMMALIAN RETINA. T. E. Frumkes and R. Nelson. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, Md. 20892

Histological studies have provided conflicting findings regarding the role of GABA in mammalian outer plexiform layer. We studied the influence of GABAergic substances applied by means of ophthalmic artery perfusion upon intracellular responses of retinal horizontal cells (HCs) of the cat. GABA agonists depolarized HCs, decreased the amplitude and slowed the time course of the light response as reported for many cold-blooded vertebrates. However, such effects required long application of high drug concentrations (>20 mM GABA, >0.2 mM Muscimol). 1 mM Baclofen had negligible effects. Other GABAergic drugs produced more striking results. 1 minute exposure to 4 mM dAVA (delta amino valeric acid, which is reported to be a GABA_A agonist and a GABA_B antagonist) totally abolished the photic response and depolarized HCs by >20 mV; a smaller, similar effect could be obtained with 1 mM concentration. Nipecotic acid, a presumed GABA uptake blocker, produced effects similar to dAVA. Application of Bicuculline (BCC) greatly speeded up HC responses to light offset. The influences of dAVA and BCC did not antagonize each other and, hence, appear to act by independent mechanisms. Collectively, these results suggest that GABA plays some role in synaptic transmission in the outer plexiform layer of mammalian retina, a role not adhering to "conventional" GABA_A or GABA_B pharmacology.

9.11

Synaptic Connections of the Axon Terminal of a Cone Bipolar Cell in the Rabbit Retina. E. Strettoi*, R.E. Dacheux, and E. Raviola. Istituto di Neurofisiologia del CNR, Pisa, Italy and Dept. Anatomy and Cell. Biology, Harvard Medical School, Boston, MA 02115.

The synaptic connections of the axonal arborization of one cone bipolar cell of the rabbit were reconstructed at the electron microscope from continuous series of thin, radial sections. Its processes branched in the vitreal sublamina of the inner plexiform layer (S4) and established gap junctions with the All amacrine cell; thus, this bipolar was probably involved in the transfer of scotopic signals to ganglion cells. The processes of this cone bipolar were presynaptic at ribbon synapses and usually contacted a dyad of postsynaptic dendrites that belonged to amacrine and ganglion cells. The pattern of connections at the dyad synapse was not constant: about one third of the postsynaptic amacrine cell dendrites returned a reciprocal synapse onto the cone bipolar and the other two thirds did not; a small number of these nonreciprocal amacrine cells were in turn presynaptic to nearby rod bipolar axon terminals. The reciprocal synapses represented only a minor portion of the input to this cone bipolar terminal, for the majority of the presynaptic processes originated from a heterogeneous population of nonreciprocal amacrines. An important characteristic of this cone bipolar was the large number of synapses onto ganglion cell dendrites (30%) when compared to rod bipolars (.5%) and All amacrine cells (3%). This indicates that this cone bipolar mediates the access to ganglion cells of both rod and cone signals. EY01344 & EY03011.

COMPARISON OF THE EFFECTS OF STEADY AND FLICKERING LIGHT ON DOPAMINE-MEDIATED CHANGES IN HORIZONTAL CELL COUPLING IN MUDPUPPY RETINA. C.-J. Dong* and J.S. McReynolds, Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

We recently reported that in mudpuppy retina steady light (SL) causes a dopamine (DA)-mediated uncoupling of horizontal cells (HC), probably by an action through ON-center bipolar cells. However, reports that flickering light (FL) is a more effective stimulus for DA release in other species raises the possibility that FL may release additional DA via the OFF pathway. The effects of SL and FL on HC coupling in dark-adapted retinas were compared by measuring changes in HC responses to illumination of the center and surround portions of the receptive field. For a given period of adaptation, SL was more effective than FL of equal intensity with 1/10 the total on-time and 10 times the number of light-dark transitions. For SL and FL of equal on-time, FL had about the same effect as SL when the duty cycle of the FL was 1:10 (light on : light off), and was slightly more effective than SL when the duty cycle of the FL was increased to 1:1. The uncoupling effects of both SL and FL were blocked by DA antagonists and by APB. These results suggest that both FL and SL affect DA release and HC coupling via the ON pathway. The greater effectiveness of more rapidly changing illumination may be due to the initial transients of bipolar cell responses at the onset of each light flash.

DAPI LABELS THREE TYPES OF BIPOLAR CELL IN RABBIT RETINA. Stephen L. Mills*, M.L.J. Crawford, and Stephen C. Massey*. Sensory Sciences, Graduate School of Biomedical Science, University of Texas Health Science Center, Houston, TX.

The fluorescent dye DAPI has been shown to label starburst amacrine cells in rabbit retina a day or two after intraocular injection (Vaney, 1984, *Proc. R. Soc. Lond. B*, 220, 501; Tauchi and Masland 1984, *Proc. R. Soc. Lond. B*, 223, 101) and All amacrine cells following in vitro incubation (Mills and Massey 1991, *J. Comp. Neurol.*, 304, 491). We now show that 3 types of cone bipolar cell can be labeled by brief (< 15 min) exposures to DAPI in vitro. All 3 types ramify in sublamina a, suggesting they are "OFF" bipolar cells. The type most brightly labeled was characterized by a small field in both the OPL and IPL, with the axon branching rather narrowly in layer 1. A second type, appearing darker under DAPI fluorescence, branched more diffusely throughout the whole of sublamina a. The third and largest type branched very narrowly in layer 1 of sublamina a and was most notable for the large spatial extent of its processes in the IPL, which generally exceeded the area of the OPL processes by a factor of about 3.

PEPTIDERGIC MODULATION OF CALCIUM CURRENTS IN ISOLATED RETINAL BIPOLAR CELLS. George S Ayoub & Gary Matthews. Dept of Neurobiology, SUNY, Stony Brook, NY 11794

Retinal bipolar cells are non-spiking interneurons that relay information from photoreceptors to amacrine and ganglion cells. We have recorded the calcium currents of enzymatically isolated, rod-dominated depolarizing bipolar cells of the goldfish (type Mb1) using patch pipette/whole cell recording. These cells have a prominent synaptic Ca influx in response to depolarization which is carried by L-type Ca channels (Matthews & Heidelberger, 1990 Neurosci Abst). Application of peptides known to be present in amacrine cells presynaptic to the Mb1 cells modulated this calcium current. Specifically, application of nanomolar concentrations of substance P, somatostatin, or met-enkephalin increase the activation potential of the Ca current to more positive potentials, with the maximal Ca current suppression at membrane potentials of -30 to -20 mV. While 1 nM substance P suppresses approximately 20% of the Ca current, 10 nM suppresses about 40%. Higher concentrations are no more effective than 10 nM. The Ca current modulation by substance P requires GTP in the patch pipette, implicating G-protein mediation. Additionally, though the peptide effects sum with low drug concentrations, there is no summation with high concentrations, indicating a common mechanism of operation. The modulation we observe with these peptides appears similar to the effect of GABA on the Ca current of these cells (Matthews, Ayoub & Heidelberger, 1991 Neurosci Abst).

10.1

RAPID LAMININ-INDUCED CHANGES IN SYMPATHETIC GROWTH CONES D.W. Burneister, R. I. Rivas*, A.M. Coriano*, D.J. Goldberg Dept Pharm. & Cntr for Neurobiol. & Behavior, Columbia Univ., NY NY 10032

Adding laminin (ln) to cultures of sympathetic neurons growing on polylysine substrates induces a rapid change in growth cone (gc) morphology as a prelude to enhancing the rate of neurite elongation. Using video microscopy of living gcs, and subsequent immunocytochemistry, we find that the earliest and most pronounced effect of ln addition is an acceleration of the net movement of membranous organelles and microtubules into peripheral lamellipodia (Rivas & Goldberg, JCB 111: 490a). This movement is termed engorgement, and appears to be a necessary stage in the growth of neurites (Goldberg & Burneister, TINS 12: 503). The advance of the leading edge of the gc and the rate of engorgement on polylysine treated substrates was about 5 $\mu\text{m}/\text{h}$. After the addition of 25 $\mu\text{g}/\text{ml}$ ln the rate of engorgement increased more than 4-fold within 20 min, while advance of the leading edge continued at a slow pace. This initial, rapid effect on engorgement, but not other stages of neurite advancement, indicates 1. engorgement, in some circumstances, may be a rate limiting step in neurite elongation, 2. engorgement is particularly sensitive to ln, and 3. stimulation of engorgement could be a mechanism by which ln stimulates neurite growth. Ln-induced engorgement was blocked by antibodies to the $\beta 1$ subunit of integrin, but not by pre-immune serum, indicating that integrins probably mediate the engorgement response. However, interfering with the binding of ln to cell surface $\beta 1,4$ -galactosyltransferase with α -lactalbumin (which inhibits neurite outgrowth from PC12 cells), also blocked ln-induced engorgement in sympathetic gcs. These results are consistent with the idea that multiple surface receptors mediate the ln-induced changes in gcs.

10.3

THE FIBRONECTIN RECEPTOR ($\alpha 5 \beta 1$ INTEGRIN HETERODIMER) AND FIBRONECTIN ARE REGULATED DURING PERIPHERAL NERVE DEVELOPMENT AND REGENERATION. Frances Lefcort and Louis F. Reichardt, Dept. of Physiology and HHMI, University of California, San Francisco, San Francisco, CA, 94143-0724

Fibronectin, a major glycoprotein constituent of extracellular matrix (ECM), has been demonstrated to potently promote peripheral neurite outgrowth in vitro. Immunohistochemical studies have shown that fibronectin is present in the environment of the developing and regenerating peripheral nerve and that regenerating neurites are in close contact with the ECM. The Integrin family of ECM receptors has been identified as the primary class of ECM receptors for peripheral neurons in vitro, with the $\alpha 5 \beta 1$ subunit serving as a major fibronectin receptor. To understand the significance of $\alpha 5 \beta 1$ and fibronectin for actively growing neurites in vivo, we have examined the protein expression levels and distribution of the $\alpha 5 \beta 1$ integrin receptor and its ligand, fibronectin, in developing and regenerating chick peripheral nerve by quantitative analysis of western blots and immunocytochemistry. We have found that in vivo, 1) peripheral neurites express $\alpha 5 \beta 1$, 2) $\alpha 5 \beta 1$ is dramatically down regulated with peripheral nerve maturation on both axons and Schwann cells, 3) $\alpha 5 \beta 1$ is upregulated in adult nerve following nerve transection on both neurites and non-neuronal cells. Similarly, fibronectin is also down regulated in adult nerve and strongly upregulated during nerve regeneration. The expression patterns of $\alpha 5 \beta 1$ and fibronectin are overlapping and interestingly in regenerating peripheral nerve, fibronectin is most strongly expressed immediately in advance of the distal front of regenerating growth cones (a region where laminin expression is extremely low). Our results implicate a major role for the $\alpha 5 \beta 1$ integrin receptor and fibronectin in nerve regeneration and development and functional tests of this prediction are now in progress. (We thank Drs. J.A. MacDonald, R. Horwitz, J. Muschler for the anti- $\alpha 5 \beta 1$ antibodies and K. Venstrom for the anti-fibronectin).

10.5

LASER INACTIVATION OF FASCICLIN II INHIBITS AXONOGENESIS OF THE PIONEER NEURONS OF THE GRASSHOPPER LIMB BUD. James W. Booth*, Lisa Park* and Daniel G. Jay, Dept. of Cellular and Developmental Biology, Harvard University, Cambridge, MA.

Previously, we showed that fasciclin I plays a role in axon adhesion using chromophore assisted laser inactivation (CALI) (Nature 348:548, 1990). We now show that CALI directed against fasciclin II, the insect NCAM homolog, results in a perturbation of axonogenesis but not axon adhesion in the grasshopper PNS. Laser irradiation of 31% embryos injected with Malachite green-labeled anti-fasciclin II resulted in an inability of the T11 pioneer neurons of the metathoracic limb buds to extend axons even though their cell bodies appeared to differentiate (8 out of 10). This was visualized by anti-HRP immunostaining. Control embryos injected with dye-labeled BSA or not subjected to laser light showed normal axonogenesis (6 out of 6) and axon extension up to 100 μm . CALI against fasciclin II in later embryos (33%) showed no significant inhibition of axon growth nor defasciculation, a result of CALI using anti-fasciclin I.

These results suggest that fasciclin II functions in the initiation of axon outgrowth and that its role in neurodevelopment is distinct from fasciclin I. Its concurrent expression on the neighboring epithelial cells and its homology to NCAM suggest that it functions in the initial adhesive contacts of the growth cone to the epithelium.

The use of CALI to determine the functions of fasciclin I and II in the development of T11 neurons suggests that this technique will be useful in understanding molecular mechanisms in neurodevelopment.

10.2

EXPRESSION OF A CHIMERIC HUMAN/RAT $\alpha 5 \beta 1$ INTEGRIN HETERODIMER IN A RAT NEURONAL CELL LINE (PC12): EFFECTS ON ATTACHMENT AND NEURITE OUTGROWTH IN RESPONSE TO FIBRONECTIN. K. J. Tomaselli*, S. C. Bodary*, L. I. Rubin and L. F. Reichardt, Athena Neurosciences Inc., So. S.F., CA, 94080; Dept of Physiology and Howard Hughes Med. Inst., UCSF, S.F., CA, 94135.

Previous studies showed that rat PC12 cells attach well to laminin (LN) and several collagens (COL), but attach to fibronectin (FN) at levels only 10-20% of those achieved on LN or COL. The comparatively weak attachment to FN is inhibited by $\beta 1$ integrin antibodies or RGD peptides, indicating that attachment is mediated by either the $\alpha 5 \beta 1$ or $\alpha 3 \beta 1$ integrins. Immunoprecipitation studies demonstrated, however, that while PC12 cells express both $\alpha 3 \beta 1$ and $\alpha 1 \beta 1$, they do not express detectable amounts of $\alpha 5 \beta 1$ (Tomaselli *et al.*, J. Cell Biol., 107:1241-1252). We have attempted to enhance the responsiveness of PC12 cells to FN by transfection of the integrin $\alpha 5$ subunit cDNA. The human $\alpha 5$ cDNA (gift of L. Fitzgerald) was subcloned into the p β APr-1-*neo* expression vector and was transfected into PC12 cells. Of about 20 stably transfected clones that attached at high levels to FN, four were characterized in more detail. Each expressed the human $\alpha 5$ subunit in association with the endogenous rat $\beta 1$ subunit as assayed by immunoprecipitation of radiolabelled cells using a rat MAb (B262) that recognizes human, but not rat, $\alpha 5 \beta 1$ dimers. Attachment to FN was inhibited by the B262 MAb and also by an RGD peptide. In addition, $\alpha 5$ transfectants showed an increased ability to regenerate neurites on FN after priming with NGF. These results demonstrate the feasibility of manipulating the responses of neuronal cells to components of the ECM by expression of exogenous integrin subunits.

10.4

SINGLE CELL CHROMOPHORE ASSISTED LASER INACTIVATION (CALI) SHOWS THE SITE OF FASCICLIN I ACTIVITY IS AT THE GROWTH CONE.

Anne M. Sydor, Joel Bard*, Ancei Mallavarapu*, Timothy P. O'Connor, and Daniel G. Jay Dept. of Cell. and Dev. Biology, Harvard Univ., Cambridge, MA and Dept. of Molecular and Cell Biology, Univ. of CA, Berkeley, CA.

CALI inactivates specific protein function with laser light directed to the protein through a dye-labeled antibody (PNAS 85:5454, 1988). The dye moiety absorbs light at 620 nm, a wavelength which is not absorbed by cellular components. We have developed single cell CALI in which a laser beam is focused through a microscope to a 10 μm diameter such that protein function can be inactivated in single cells.

We tested single cell CALI by inactivating the enzyme HRP bound to the surface of a single *S2 Drosophila* cell. Single cell CALI was done on *S2* cells expressing fasciclin I, a neuronal membrane glycoprotein that causes these cells to aggregate. Inactivation of fasciclin I on a single cell caused that cell to separate from a cluster. This was not observed when laser light was directed at clusters incubated with dye-labeled BSA.

We have now used single cell CALI to localize the function of fasciclin I to the neuronal growth cone. The T11 neurons are a fasciclin I-expressing cell pair in the grasshopper limb bud which fasciculate together as they project to the CNS. Previously we have shown that fasciclin I functions in adhesion between these sister axons (Nature 338:548, 1990). To visualize the growth cones, T11 neurons were labeled with dil in an open limb bud preparation (J. Neurosci. 10:3935, 1990). Embryos were incubated with dye-labeled anti-fasciclin I. Laser light directed to the growth cones resulted in defasciculation in 3 out of 3 limbs while a control limb that was not subjected to laser light appeared normal.

Our results show that the adhesive function of fasciclin I is initiated at the growth cone. Single cell CALI is the molecular analog of cellular laser ablation and provides an unprecedented level of spatial and temporal resolution for studying neurodevelopment.

10.6

AN ENDOGENOUS GLIAL RECEPTOR FOR THE NEURONAL GLYCOPROTEIN THY-1: FURTHER BIOCHEMICAL CHARACTERIZATION. Evan B. Dreyer†, Paul Lucek*, Kristen Upchurch*, Dana Leifer, & Stuart A. Lipton, Program in Neuroscience, Harvard Medical School, Children's Hospital, & †Massachusetts Eye and Ear Infirmary, Boston, MA.

Previous work in our laboratory (Leifer, *et al.*, Science, 224:303, 1984) has demonstrated a role for Thy-1 in neurite outgrowth by central mammalian neurons. Thy-1 antibodies promote neurite outgrowth of cultured retinal ganglion cells. Using two monoclonal anti-idiotypic antibodies as probes, we have identified endogenous binding sites for Thy-1 that may represent part or all of an endogenous Thy-1 receptor. We have shown that this putative receptor has a similar effect in modulating neurite outgrowth to that seen with the Thy-1 antibodies. The proposed Thy-1 receptor has been identified in cultured astrocyte and whole brain preparations. Anti-idiotypic binding to the proposed receptor is competitively blocked by purified Thy-1.

Several Thy-1 binding proteins (MWs 90,175,180kD) have been identified in Western blots of whole rat brain and astrocyte preparations. Two dimensional blots have now been analyzed by similar techniques, and a partial protein sequence determined. This provides further information on the biochemistry of the proposed Thy-1 receptor. These data suggest that a receptor for the neuronal glycoprotein Thy-1 exists on glia, and that this receptor plays a role in modulating retinal ganglion cell neurite outgrowth.

10.7

IDENTIFICATION AND ANALYSIS OF THY-1 RECEPTOR cDNA CLONES FROM BRAIN AND MUSCLE. Dana Leifer, Evan B. Dreyer, Kelly S. Rothe*, John Heng*, Rachael L. Neve† and Stuart A. Lipton. Dept. of Neurology, Children's Hospital, Massachusetts General Hospital and Harvard Medical School, Boston, MA, and †Dept. of Psychobiology, Univ. of California, Irvine, CA.

We have previously used anti-idiotypic monoclonal antibodies against Thy-1 antibodies to identify putative Thy-1 receptor proteins that appear to modulate neurite outgrowth in culture. We screened a human fetal brain cDNA library with the anti-idiotypic antibodies and identified candidate receptor clones. An antiserum against a fusion protein derived from one of the clones binds to the same bands on Western blots of brain and astrocyte preparations that the anti-idiotypic antibodies identify. Moreover, purified Thy-1 blocks binding of the anti-idiotypic antibodies to these bands. The clones contain an open reading frame at least 1.34 kb in length. Searches of the GenBank and NBRF databases indicate that the sequence has not been reported previously. The sequence has several potential glycosylation sites. RNA blot analysis demonstrates that the putative receptor cDNA identifies specific bands in brain and muscle, but not in a variety of other tissues. The RNA blots and the sequence data indicate that the clones initially isolated were partial clones. We have therefore used one of them to re-screen brain and muscle libraries. We have isolated potentially full-length clones from both brain and muscle. Taken together, our results suggest that we have now identified Thy-1 receptor proteins and corresponding cDNA clones.

10.9

ULTRASTRUCTURE OF AN IDENTIFIED GROWTH CONE ARRAY IN EMBRYONIC LEECH REVEALS SPATIALLY DIVERSE CELL AND MATRIX INTERACTIONS DURING DIRECTED MIGRATION. D.M. Kopp, D. McCarthy*, and J. Jellies. Neurobiology Research Center and Dept. of Physiol. and Biophysics, Univ. of Alabama at Birmingham, Birmingham, AL, 35294.

Unique, transient muscle-organizing cells (Comb or C-cells) in the embryonic medicinal leech, *Hirudo medicinalis*, each extend about 70 parallel growth cones and establish a framework of processes used to collect myocytes into an oblique array sandwiched between circular and longitudinal muscle layers. It has been suggested that an interplay of spatio-temporally regulated cell-cell and cell-matrix events mediate the parallel alignment of growth cones followed by their rapid, directed extension through the body wall. A simple alternative is that direction is intrinsically limited by the cytoskeleton and that C-cell growth cones are mechanically constrained to grow between existing layers of circular and longitudinal muscle, perhaps even within pre-existing channels. Our initial ultrastructural examination of HRP-filled C-cells makes this simple scheme seem unlikely. C-cell growth cones in 11 day old embryos appear neuron-like with microfilaments, microtubules, and large and small vesicular elements. Filopodia and growth cones associate not only with the orthogonal grid of circular and longitudinal muscle, but also with basolateral epidermal surfaces, undifferentiated mesenchyme, the basement membranes associated with all of these developing cells, and diffuse matrix. C-cell growth cones occasionally enwrap and are themselves enveloped by cells in these layers, and filopodial insertions into muscle were observed. Close (<10 nm) growth cone-cell contacts are common, but not restricted to a particular cell type in the environment. Processes, in contrast to leading growth cones, appear to be more restricted in position, often being closely apposed to mesenchymal cells. Thus, at the developmental stage examined here, C-cell growth cones are capable of sampling a variety of cell surfaces and matrices, potentially extracting guidance cues from any, or all, of them. Overall, these observations are consistent with the idea that a range of cell/matrix interactions may mediate the emergence of order in C-cell growth cone navigation and the subsequent assembly of the oblique muscles, rather than a simple scheme of pre-existing anatomical pathways guiding C-cell growth cones inescapably along particular oblique trajectories. (Supported by NIH NS28603 to JJ).

10.11

DIFFERENTIAL REGULATION OF NEURITE GROWTH IN RAT SYMPATHETIC NEURONS BY PHOSPHORYLATION INHIBITORS AND NGF. R. B. Campenot and D. D. Draker*. Dept. of Anatomy and Cell Biology, Faculty of Medicine, Univ. of Alberta, Edmonton, Alta., Canada T6G 2H7.

Long-term application of phorbol 12-myristate 13-acetate (PMA) locally to distal neurites of NGF-supplied (200 ng 2.5S NGF/ml) rat sympathetic neurons in compartmented cultures caused a concentration-dependent reduction in neurite extension rate over a broad range (10 nM-10 μ M), but was without effect when applied to cell bodies and proximal neurites. PMA is a short-term activator, but long-term downregulator of protein kinase C (PKC). Similar results were obtained with staurosporine (range 100 nM - 1 μ M), a general inhibitor of phosphorylations specific for PKC in its low nM range. No other agents have been observed to modulate the rate of neurite extension in compartmented cultures, and NGF over a broad range (5-200 ng/ml 2.5S NGF) modulates neurite density without effect upon extension rate. Also, substantial neurite growth was observed with 2 μ M PMA, and 10 nM staurosporine had little or no effect on neurite growth. Thus, protein kinase C activity appears to be unnecessary for neurite growth or NGF signaling. Neurite growth in 2 μ M PMA was blocked by anti-NGF IgG. Thus, it is unlikely that long-term PMA treatment depressed neurite growth by interfering with NGF action. These results suggest the presence of phosphorylation-mediated signalling systems in sympathetic neurites that regulate their growth independently of NGF. What phosphorylations or ligands may be involved are presently unknown, but such systems may play major roles in regulating nerve growth and regeneration. Supported by the AHFMR, MRC, and NCE.

10.8

NCAM AND N-CADHERIN DIRECTLY PROMOTE MORPHOLOGICAL AND BIOCHEMICAL DIFFERENTIATION OF PC12 CELLS VIA A PERTUSSIS TOXIN SENSITIVE PATHWAY. P. Doherty, S.V. Ashton, F.S. Walsh. Dept. Experimental Pathology, UMDS, Guy's Hospital, London SE1 9RT, U.K.

Neurite length and specific cell surface glycoprotein expression have been measured for PC12 cells cultured on confluent monolayers of control 3T3 cells or 3T3 cells expressing either transfected human NCAM or chick N-cadherin. NCAM and N-cadherin in the monolayer directly induced a change in the morphology of PC12 cells from an adrenal to neuronal phenotype. This was accompanied by a transient increase in Thy-1 immunoreactivity, but not L1 or NGF-receptor immunoreactivity. The morphological responses could be specifically inhibited by antibodies to NCAM or N-cadherin but not by antibodies to NGF or FGF. The response differed from NGF induced morphological differentiation in that it did not depend on transcription. The NCAM and N-cadherin responses could also be fully inhibited by pertussis toxin and partially inhibited by the calcium channel antagonists verapamil and diltiazem. These data suggest that NCAM and N-cadherin can directly modulate cell phenotype and that they may do so via activation of similar second messenger pathways.

10.10

A CYTOPLASMIC GRADIENT OF CYCLIC AMP ACROSS THE XENOPUS GROWTH CONE IS SUFFICIENT TO INDUCE TURNING. A.M. Lohof, M. Quillan, Y. Dan, and M. Poo. Dept. of Biological Sciences, Columbia Univ. N.Y., N.Y. 10027.

We have studied the role of cAMP in growth cone guidance in cultured embryonic *Xenopus* spinal neurons. Stable microscopic gradients of membrane-permeable drugs known to alter intracellular cAMP activity were established extracellularly by repetitive pulsatile application of the drug from a micropipette. The behavior of the growth cone in the applied gradient was determined by measuring the angle of growth cone orientation and neurite extension from video records. We found that when a gradient of dibutyryl cAMP (20 mM pipette solution) was produced at a 45° angle across the growth cone, significant growth cone turning (average angle 29.1 \pm 4.9°, N = 20) toward the pipette was observed within 2 hr. Application of similar concentrations of sucrose, underivatized cAMP, or dibutyryl cGMP produced no significant turning. Gradients of drugs which perturb the endogenous level of cAMP were also tested. The phosphodiesterase inhibitor IBMX (1.5 mM) produced orientation similar to dibutyryl cAMP. The adenylyl cyclase activator forskolin (5 mM) produced a mean turning angle of 19.9 \pm 5.4° (N = 34) within 30 min. A cytoplasmic gradient of cAMP thus appears to be sufficient for inducing the turning response; whether such a gradient is necessary for growth cone turning induced by extracellular guidance cues remains to be determined. The consistency of the orientation response in the chemical gradient offers the opportunity to explore the sequence of cellular events leading to the reorientation response of the growth cone.

10.12

AXON RETRACTION IS MEDIATED BY ENHANCEMENT OF PROTEIN PHOSPHORYLATION. S. Finnegan Sloan, E. Koenig and Y. Lemmon. Dept. of Physiology, Univ. at Buffalo, Buffalo, NY 14214, and Center for Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106.

Videomicroscopic studies reveal that mAb 8A2 induces retraction in regenerating retinal ganglion cell axons of goldfish explants *in vitro* characterized by: 1) growth cone collapse, 2) collection of axoplasm into a mass, and 3) retrograde translocation of the mass leaving multiple strands distally (*Soc. Neurosci. Abstr.* Vol. 15, p. 1027, 1989). The mAb 8A2 retraction response may serve as a model for retraction associated with axon elimination during development. The response is arrested by cytochalasin D, but continues in the presence of nocodazole or taxol suggesting that microtubules are probably passive components and that the actin filament network plays an active role. (*Soc. Neurosci. Abstr.* Vol. 16, p. 314, 1990). Microtubules are translocated proximally out of the distal strands where only components of the membrane cytoskeleton such as spectrin and talin remain. Exposure of axons to phorbol 12-myristate 13-acetate (10 nM) triggers a similar retraction response while inactive phorbol ester analogs do not. In addition, okadaic acid, a phosphatase inhibitor, triggers axon retraction with very short latency. Both mAb 8A2 and phorbol ester stimulated retraction are blocked by kinase inhibitor staurosporine. Genistein, another kinase inhibitor, blocks mAb 8A2 induced retraction but was not tested with phorbol ester. These results indicate that the mAb 8A2 response may involve kinase activation and/or phosphatase inhibition. This strongly suggests that axon retraction is associated with an enhanced phosphorylation state of one or more axonal proteins.

GAP-43 IS A UNIQUE TYPE OF GUANINE NUCLEOTIDE RELEASE PROTEIN FOR G₀. S.M. Strittmatter*, D. Valenzuela*, Y. Sudo*, D. Platika and M.C. Fishman, Depts. of Neurology and Medicine, Harvard Medical School and Massachusetts General Hospital, Boston, MA

We previously showed that G₀ is a major protein in the growth cone membrane, suggesting that it may transduce some extracellular signals into second messenger changes which lead to directed neurite outgrowth. In addition, G₀ activity is susceptible to GAP-43. This is the first intracellular protein reported to regulate G proteins, an activity previously thought to be restricted to ligand-receptor complexes. Now we have studied the mechanism of G₀ and GAP-43 interaction, comparing it to that of receptors and G proteins. Like receptors, GAP-43 increases the rate of GDP release, the initial rate of GTPγS binding and the steady state GTPase activity of G₀, but does not affect the intrinsic turnover number for hydrolysis of bound GTP. GAP-43 can be distinguished from receptors in that its stimulation of G₀ is not blocked by pertussis toxin, is not dependent on the presence of βγ subunits, and occurs equally effectively in detergent solution and in phospholipid vesicles. These data demonstrate that GAP-43 is a guanine nucleotide release protein (GNRP) for G₀, but that it has some unique properties compared to other G protein stimulators. The GNRP activity of GAP-43 argues that it is an upstream positive regulator of G₀ *in vivo*, and that therefore G₀ may integrate extracellular and intracellular signals in the growth cone.

10.14

G-PROTEINS MODULATE GROWTH CONE FUNCTION IN SYMPATHETIC GANGLION CELLS. T. Vartanian*, S.M. Strittmatter*, J. Vanselow* and M.C. Fishman, Depts. of Neurology and Medicine, Mass. General Hospital and Harvard Medical School, Boston, MA 02114.

Previous work has demonstrated that G₀ is both a major component of the growth cone membrane and is regulated by the growth associated protein, GAP-43, thus leading to the speculation that growth cone G-proteins regulate neuronal morphogenesis. To examine this hypothesis we have perturbed G-protein function in cultured embryonic chick sympathetic neurons. We find that pertussis toxin-mediated uncoupling of G₀ and G_i from receptors causes an increase in both the length and the total number of neurites, and that this effect is modulated by the nature of the substratum. In contrast, direct stimulation of G-proteins with mastoparan or aluminum fluoride nearly abolishes neurite extension, in a reversible manner. These data provide support for the notion that G-proteins play a critical role in growth cone function.

TYROSINE PHOSPHORYLATION OF MAP KINASE INDUCED BY STIMULATION OF PI-LINKED GLUTAMATE RECEPTOR. J.M. Baraban, R.S. Fiore, and T.H. Murphy, Depts. of Neuroscience, Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Recent studies have identified a novel serine-threonine phosphorylating enzyme, referred to as MAP kinase, that is activated by tyrosine phosphorylation. In previous studies, we have demonstrated activation of this kinase in hippocampus by electroconvulsive treatment (*J. Neurochem.* 56, 147 (1991)). To study the regulation of this kinase by neurotransmitters, we have employed primary cortical cultures. We have found that phorbol 12,13 diacetate, an activator of PKC, produces a marked increase in tyrosine phosphorylation of a 42 kD protein that co-migrates with MAP kinase. Furthermore, trans-ACPD, a selective agonist of the PI-coupled glutamate receptor, produces a similar effect. These findings indicate that the tyrosine kinase signalling pathway can be activated by neurotransmitter stimulation of the PI-PKC system and that MAP kinase is regulated via this cascade.

11.2

SYNERGISTIC ACTIVATION OF PROTEIN KINASE C BY ARACHIDONIC ACID AND DIACYLGLYCEROLS IN HIPPOCAMPAL NEURONS. D.O. KEYSER AND B.E. ALGER, University of Maryland School of Medicine, Dept. of Physiology, Baltimore, MD 21201.

Activation of protein kinase C (PKC) influences neuronal activity through regulation of Ca²⁺ and other ion channels, enhancement of spontaneous synaptic activity and induction of LTP. Diacylglycerols (DAG) and arachidonic acid (AA) each can activate PKC but the high concentrations tested have raised questions about their actual role.

We tested the hypothesis that AA and DAG can synergistically activate PKC at low concentrations using two PKC-mediated responses as electrophysiological bioassays in hippocampal neurons: 1) We found a marked synergistic interaction between AA and DAG on PKC-mediated depression of whole-cell Ca²⁺ current. EC₅₀'s of the dose-response curves for AA or DAG alone shifted from ≥25 μM to ~2 μM when both were present. Enhanced responses were blocked by PKC inhibitors and were not seen with inactive compounds. Interestingly, synergy occurred over a limited dose range, suggesting a novel specificity, perhaps related to different PKC isoforms. 2) Spontaneous synaptic activity was increased by AA-plus-DAG in a PKC-dependent way, providing the first physiological evidence that the α and β PKC isoforms are susceptible to the synergistic interactions of AA and DAG and are, indeed, involved in synaptic transmission. In view of these data, a role of AA in PKC activation assumes an even more likely physiological significance.

11.3

Characterization of [3H]Phorbol 12,13-dibutyrate binding in the circumesophageal ganglion of *Hermisenda crassicornis*. Donna L. McPhie, David S. Lester, James L. Olds and Daniel L. Alkon, Neural Systems Section, NINDS, NIH, Bethesda MD 20892.

Hermisenda crassicornis exhibits a learning specific increase in [3H] Phorbol 12,13-dibutyrate binding that is localized to individual types of nerve cells as assessed by emulsion autoradiography of the circumesophageal ganglion (McPhie et al, 1990). In the present study saturation binding conditions, subcellular distribution and competition with binding of diacylglycerol were further characterized to demonstrate the specificity of [3H]PDBU binding to Protein Kinase C in *Hermisenda*. [3H]PDBU binding was shown to be saturable at 15-25nM. K_d was estimated (B_{max}/2) at 9±2nM, similar to that found in vertebrates and other invertebrates. Incubation of cytosol and detergent extracted membrane fractions at a saturating concentration of [3H]PDBU (25nM) showed *Hermisenda* CNS to bind 4.7±0.4 fmol [3H]PDBU/mg protein and 3.9±0.5 fmol [3H]PDBU/mg protein, giving a cytosol/membrane distribution of 55% and 45% respectively. *Hermisenda* CNS incubated in 2.5nM [3H]PDBU specifically bound 80 fmol [3H]PDBU/mg protein. In the presence of OAG, a cell permeable diacylglycerol analog, and (1 x 10⁻⁵ M) PDBU there was 17.7 fmol [3H] PDBU/mg protein bound, indicating that OAG displaced 78% of specific [3H] PDBU binding. The above results support the proposal that [3H] PDBU binds to PKC in *Hermisenda* CNS. Also to our knowledge this is the first demonstration of competition of OAG in an intact tissue system.

11.4

EFFECT OF ALCOHOL DEPENDENCE AND WITHDRAWAL ON PHOSPHO-INOSITIDE TURNOVER IN RAT BRAIN. S.C. Pandey*, M. Plano*, P.L. Reddy*, D. Schwartz*, J.M. Davis and G.N. Pandey, College of Medicine, University of Illinois at Chicago.

In order to examine if alcohol dependence or withdrawal are related to changes in receptor-mediated phosphoinositide signalling systems, we studied the effects of long- and short-term ethanol treatment and withdrawal on agonist-stimulated inositol phosphate formation in rat brain. Rats were maintained on either Lieber-decarll liquid diet containing ethanol (9% v/v) or control liquid diet for 2 month (chronic) or 15 days (subchronic). Rats were sacrificed after 0 and 24 hrs of withdrawal, and 5HT₂, α₁, adrenergic receptors, NE and 5HT stimulated inositol phosphates formation was determined in cerebral cortex. We observed that 5HT-stimulated [³H]-IP₁ formation was significantly decreased in chronically treated rats as compared to control rats. 5HT₂ receptors number, as measured by [³H]-Ketanserin binding tended to decrease but was not significantly changed in cortex of chronic ethanol treated rats compared to control rats. 5HT-stimulated [³H]-IP₁ formation was also decreased in subchronically treated rats before ethanol withdrawal and after 24 hours of ethanol withdrawal. Neither NE-stimulated [³H]-IP₁ formation nor B_{max} and K_d of [³H]-prazosin binding were significantly changed in chronic or subchronic ethanol treated rats. Our results thus indicate that chronic or subchronic treatment with ethanol decreases 5HT-induced but not NE-induced PI turnover. This decrease in 5HT-induced PI turnover may be due to decrease in coupling of 5HT₂ receptors to effector pathway of PI system after chronic exposure to ethanol.

11.5

MODULATION BY LITHIUM OF BASAL AND CHOLINERGIC-INDUCED PHOSPHOINOSITIDE SIGNALING IN THE BRAIN. K.M.Savolainen and M.-R.Hirvonen. Natl. Publ. Hlth Inst., Dept. Env. Hyg. & Toxicol., P.O.B. 95, SF-70701 Kuopio, Finland.

Effects of LiCl on basal and cholinergic-induced cerebral regional phosphoinositide (PI) signaling were studied in rats after a single (2.5-16 mEq/kg) and 14 repeated i.p. doses (2.5 mEq/kg) of LiCl. To study the effects of LiCl on cholinergic-induced PI signaling rats were pretreated with saline or LiCl (10 Meq/kg) 24 h prior to a convulsive dose of an indirect cholinergic agonist malyloxon (MO; 39.2 mg/kg i.p.). Changes in mass amounts of inositol and inositol-1-phosphate (Ins1P) were used as indices of changes in PI signaling. A single dose of LiCl decreased cerebral inositol dose-dependently with a threshold maximum at 10 mEq/kg and caused a reduction of inositol from about 20 to 12 mmol/kg (dry brain weight). Similarly, the threshold maximum of LiCl-induced increase of Ins1P was at 10 mEq/kg, but the increase of Ins1P was only 5 % of the decrease of inositol at this dose of LiCl. Inositol-4-phosphate levels remained stable. Repeated doses of LiCl caused a slight but transient increase of Ins1P, but inositol levels were unaffected. When rats were given 39.2 mg/kg of MO, 60 % of the rats had tonic-clonic convulsions, and a stimulation of PI signaling occurred in most brain regions during the 72 h observation period. Increased PI signaling correlated well with the occurrence of convulsions. LiCl pretreatment decreased the dose of MO which produced convulsions (26.2 mg/kg) but, at the same time, attenuated cholinergic-induced PI signaling. These results provide evidence that lithium may not work through the PI signaling system in cyclic affective disorders. Also, although LiCl increases the potential of a cholinergic agonist to produce convulsions it at the same time attenuates cholinergic-induced PI signaling. Supported by the Research Council of Environmental Sciences, The Academy of Finland.

11.7

TREATMENT OF CEREBELLAR GRANULE CELLS WITH CHOLERA TOXIN REDUCES CARBACHOL-INDUCED PHOSPHOINOSITIDE HYDROLYSIS. R. Raulli, E. Costa, and J.T. Wroblewski, Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, DC 20007.

Primary cultures of cerebellar granule cells express muscarinic receptors coupled to phosphoinositide (PI) hydrolysis. In these cells, the cholinergic muscarinic agonist carbachol induced a concentration-dependent increase in PI hydrolysis ($EC_{50} = 10 \mu M$). Overnight treatment of granule cells with cholera toxin (CTX), a potent endotoxin that causes ADP-ribosylation of G proteins, decreased the response to carbachol. The effect CTX was dose-dependent reaching a plateau at toxin concentration of 1.5 $\mu g/ml$. At maximal concentrations CTX inhibited the carbachol-induced PI hydrolysis by about 50%. The carbachol dose-response curves performed with and without CTX pretreatment indicated a noncompetitive character of CTX-induced inhibition. In order to investigate the ability of CTX to cause ADP-ribosylation of protein substrates in cerebellar granule cells the cell homogenates were incubated with increasing concentrations of CTX in the presence of [^{32}P]NAD. The results indicated a dose-dependent increase in ^{32}P incorporated into a 45 kDa protein band. The incorporation of label was reduced in the presence of snake venom phosphodiesterase, or when the labelled proteins were treated with NaOH or neutral hydroxylamine, indicating that the label is incorporated via covalent ADP-ribosylation. These data indicate that the G protein involved in the coupling of muscarinic receptors to phospholipase C can be inhibited by the ADP-ribosyltransferase activity of CTX.

11.9

INOSITOLTRISPHOSPHATE RECEPTOR: IDENTIFICATION OF PHOSPHORYLATION SITES AND CHARACTERIZATION OF THE RECONSTITUTED ION CHANNEL COMPLEX. Christopher D. Ferris, Andrew M. Cameron, David S. Bredt, Sonye K. Danoff, Christopher A. Ross, Richard L. Haganir and Solomon H. Snyder. Department of Neuroscience, Johns Hopkins School of Medicine, Baltimore, MD 21205.

The inositoltrisphosphate receptor has been biochemically isolated, molecularly cloned, and functionally reconstituted in lipid vesicles. In the published cDNA sequences of both the rat and mouse receptors two consensus sequences for PKA phosphorylation are observed. Recently we have isolated and sequenced tryptic fragments from the rat cerebellar receptor following PKA phosphorylation and directly demonstrated phosphoserine at amino acids 1589 and 1755. S-1755 is much more readily phosphorylated in the cerebellar form of the receptor. Also, we have found a 120 nucleotide insert between S-1589 and S-1755 which is removed by alternative splicing in non-neuronal forms of the receptor. We have used the purified rat *defersens* receptor to characterize this shorter form. In the shorter form the K_m for PKA phosphorylation is five fold higher (3nM) and serine 1589 is preferentially labeled. We have recently cloned the human cerebellar receptor and found that the phosphorylation sites are conserved. PKC and Cam kinase II have also been found to phosphorylate the receptor in reconstituted vesicles on serine. The sites which are labeled are being investigated. We are also investigating the functional regulation of the reconstituted receptor by calcium, nucleotides and phosphorylation.

11.6

A NOVEL INOSITOL PHOSPHATE ACTS AS A SELECTIVE NEUROPEPTIDE Y (NPY) ANTAGONIST. C. Wahlestedt, D.J. Reis and L. Edvinsson*. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021; Dept. of Internal Medicine, Lund Univ., S-221 85 Lund, Sweden.

The novel compound D-myo-inositol 1,2,6-triphosphate (Ins[1,2,6]P₃, PP56) is a synthetic isomer of the Ca²⁺ mobilizing second messenger, Ins[1,4,5]P₃. While the potent sympathetic vasoconstrictor, NPY, indeed is a Ca²⁺ mobilizing agonist in vascular smooth muscle cells (VSMC), the peptide does not elicit appreciable changes in Ins[1,4,5]P₃ levels. Since there exists an array of inositol phosphates, we hypothesized that (at least) one might be involved in and/or modulate the signal transduction of NPY. In several blood vessel segments, including guinea-pig basilar and human subcutaneous arteries, extracellularly applied Ins[1,2,6]P₃, in sub- to low micromolar concentrations, inhibited (by >80%) vasoconstriction elicited by NPY, but not by norepinephrine or a range of other vasoconstrictors. Parallel experiments in cultured VSMC from rat vena cava (RVC) revealed the ability of Ins[1,2,6]P₃ to selectively inhibit NPY-induced elevations of intracellular Ca²⁺. Ins[1,2,6]P₃ did not appear to act as a dihydropyridine Ca²⁺ channel antagonist nor did it show high affinity to previously characterized inositol phosphate binding sites. Moreover, binding studies using intact or homogenized VSMC from RVC (or rat brain homogenates) indicated that Ins[1,2,6]P₃ does not affect the binding characteristics of [^{125}I]NPY at its specific binding sites. We therefore conclude that the novel inositol phosphate acts as a selective (functional) NPY antagonist, presumably by inhibiting the pathway involved in NPY-induced Ca²⁺ mobilization.

11.8

IMAGING OF Ca²⁺ LIBERATED IN XENOPUS OOCYTES BY AGONISTS AND PHOTO-RELEASED INOSITOL TRISPHOSPHATE. Y. Yao and J. Parker, Lab. Cellular & Molecular Neurobiology, Dept. Psychobiology, University of California Irvine, CA 92717.

By the use of long-wavelength fluorescent indicator dyes we had recorded Ca²⁺ transients in *Xenopus* oocytes evoked by photo-released inositol 1,4,5-trisphosphate (InsP₃) (Parker & Ivorra, *Science* 250, 977-979; 1990). We have now extended these studies by using an intensified CCD camera to image intracellular Ca²⁺ transients evoked by agonists and by spatially defined photorelease of InsP₃.

Experiments were done on isolated, defolliculated oocytes of *Xenopus laevis*, obtained from albino frogs and injected 1 hr before recording with 1-5 nl of a solution containing 5 mM fluo-3 and 0.5 mM caged InsP₃. Following bath application of serum to activate the InsP₃ pathway, Ca²⁺-fluorescence signals began after a few tens of seconds, and appeared as discrete foci. Over several seconds these enlarged, and additional foci appeared, until the Ca²⁺ level was diffusely elevated over the whole oocyte. The fluorescence was then greater in the animal hemisphere as compared to the vegetal, and this polarity was maintained as the fluorescence subsided after washing out the serum. Flash-photolysis of caged InsP₃ by a slit of UV light oriented along the animal/vegetal axis evoked a fluorescence signal that began following a short (a few hundred ms) latency and was brighter near the animal pole. However, unlike the spreading wave of Ca²⁺ seen with agonist application, Ca²⁺ liberation remained confined to that region stimulated by the light. Supported by grant GM39831.

DISTINCT IP₃R FORMS DERIVED BY ALTERNATIVE SPLICING. S.K. Danoff, S.H. Snyder and C.A. Ross. Dept of Neuroscience, Johns Hopkins University Sch. of Med., Baltimore, MD 21205.

The inositol 1,4,5-trisphosphate receptor (IP₃R) mediates the release of calcium from intracellular stores. The IP₃R has been purified from rat cerebellum and is regulated by calcium concentration, ATP concentration and protein kinase A (PKA) phosphorylation. The receptor cDNA has recently been cloned from mouse, rat and human. We have identified a 120 nucleotide alternative splice site with tissue specific expression. The splice site is located between two PKA phosphorylation consensus sequences. IP₃R isolated from tissues expressing the short or long forms of the message display distinct phosphorylation patterns and kinetics with PKA. This splice site may represent a regulatory mechanism conferring different phosphorylation characteristics to receptors differing in the expression of the splice site. We have developed anti-peptide antibodies directed at the two splice forms which recognize the distinct proteins derived from the short and long messages. We are carrying out genomic cloning to determine the intron/exon structure.

11.11

INOSITOL 1,4,5-TRISPHOSPHATE RECEPTORS (IP₃R): CLONING OF THE HUMAN cDNA AND AN IP₃R-RELATED MOUSE cDNA INDICATING A FAMILY OF IP₃R-RELATED GENES. C.A. Ross, S.K. Danoff, C.D. Ferris, C. Donath, G.A. Fischer, S. Munemitsu, S.H. Snyder and A. Ullrich. Johns Hopkins University School of Medicine, Department of Neuroscience, Baltimore, MD 21205; Max Planck Institut für Biochemie, Department of Molecular Biology, 8033 Martinsried bei München, Germany.

IP₃ stimulation of the IP₃R mediates the mobilization of intracellular calcium in response to hormones or neurotransmitters. We are in the process of cloning a cDNA for the human IP₃R. In the 5 kb we have sequenced, there is over 90% identity with the mouse cDNA sequence. Northern blot analysis of human cerebellar RNA showed a single 10 kb band, and *in situ* hybridization showed dense label over cerebellar Purkinje neurons.

We have also identified cDNAs with sequences related to the IP₃R, using PCR and low stringency hybridization. One clone, M1, is homologous to a portion of the mouse IP₃R coding for part of the membrane spanning regions. It has 85% nucleotide identity with the IP₃R and about 60% identity with the ryanodine receptor. This is consistent with the hypothesis that the IP₃R is a member of a gene family.

11.12

INOSITOL TETRAKISPHOSPHATE AND HEXAKISPHOSPHATE RECEPTORS: ISOLATION AND PHOTOAFFINITY LABELING IN RAT BRAIN. A. Theibert, V. Estevez, R. Mourey, C. Ferris, R. Barrow, G. Prestwich* and S. Snyder. Dept. Neuroscience, Johns Hopkins School of Med, Baltimore, Md. 21205 and Dept. Chemistry, SUNY at Stony Brook, Stony Brook, N.Y.

Using an Inositol tetrakisphosphate (IP₄) affinity column (V. Estevez and G. Prestwich, *Tetrahedron Lett.* 32, 1623-1626, 1991) we have isolated high affinity IP₄ and inositol hexakisphosphate (IP₆) binding proteins from detergent solubilized rat cerebellar membranes. Three binding peaks can be eluted from the IP₄ column. An IP₆-selective site elutes first with a Kd for IP₆ of 10-20 nM. IP₄ and IP₅ bind with 2-3 fold lower affinity. By SDS-PAGE, three proteins of 115, 105, and 50 kDa coelute with the binding peak. Under native conditions, binding migrates as a 300-350 kDa complex. The 105 and 115 kDa subunits, but not the 50 kDa subunit is specifically photoaffinity labeled with [125I]1-O-[N-(4-azido-salicyloxy)-3-aminopropyl]-1-phospho myo-inositol 3,4,5 trisphosphate.

Two distinct IP₄-selective binding peaks can be eluted off the IP₄ column with high salt that have high affinity and selectivity for IP₄ (Kd = 2-6 nM) with IP₅, IP₆ and IP₃ only 10.5, and 1%, respectively, as potent as IP₄. By SDS-PAGE, binding corresponds to proteins of 182 kDa in the first peak and 174 and 84 kDa in the second peak. These proteins are specifically photolabeled with the [125I]ASA-IP₄. Photolabeled receptors have distinct pH optima, sensitivity to divalent cations, high affinity and selectivity for IP₄, and are enriched in the brain. The IP₄ receptor proteins are phosphorylated *in vitro* by protein kinases C and A. We are determining whether these are part of a single receptor if they are distinct receptors and examining their physiological function.

NERVE GROWTH FACTOR I

12.1

NERVE GROWTH FACTOR REGULATES MUSCARINIC RECEPTORS mRNA IN TELECEPHALIC NEURONAL CULTURES FROM NEONATAL RATS. Carola Eva, Mariella Fusco, Rossella Brusa*, Alessandra Obero*, Guido Vantini and Enrico Geazzani*. Istituto di Farmacologia e Terapia Sperimentale, University of Torino (1), and Fidia Research Laboratories, Abano Terme(2), Italy.

The effect of nerve growth factor (NGF) on muscarinic cholinergic receptors (mAChR) was investigated in a primary culture of telencephalic neurons prepared from newborn rats. The treatment with NGF (100 ng/ml), that elevates both choline acetyltransferase activity and intracellular ACh content, differentially regulates the expression of mAChR during cultivation. NGF induces a significant increase of mAChR number at the 3rd and the 5th day of *in vitro* (DIV), as measured by [³H]-quinuclidinyl benzylate binding to cell homogenate, that is followed by a dramatic decrease of the receptor density from the 9th day of culture. The decrease of mAChR induced by prolonged exposure of telencephalic neurons to NGF is associated with a comparable reduction of the relative content of the mRNA encoding m1 and m3 receptors at the 10th DIV, while the m4 mRNA is increased by the treatment. We suggest that the stimulation of cholinergic neurons by NGF induces a downregulation of postsynaptic muscarinic receptors (m1 and m3) in the cerebral cortex and the hippocampus, while it increases the synthesis of the m4 receptor that may be mainly presynaptically localized on striatal interneurons. The transient increase of the receptor number that occurs at the first days of culture, is not paralleled by changes in the relative content of mRNA encoding mAChR subtypes and might be associated with the trophic activity of NGF on cholinergic synapses during early development.

12.3

REGULATION OF GENE EXPRESSION IN MATURE SYMPATHETIC NEURONS BY TERMINALLY-DERIVED NGF. F.D. Miller, T.C. Mathew, and A. Spelman* Dept. of Anat. and Cell Biol., Univ. of Alberta, Edmonton, Alberta, CANADA.

We have previously demonstrated that systemic administration of NGF increases neuronal expression of mRNAs encoding the low-affinity NGF receptor (LNGFR), tyrosine hydroxylase (TH), and α -tubulin (α T) in neonatal rats (Miller et al., JCB, 112, 303, 1991). To determine whether terminally-derived NGF is capable of eliciting similar changes in mature neurons, we retrogradely labelled neurons that project from the SCG to the iris with fast blue, and labelled those that project from the SCG to the ear with fluorogold. For 7 days following labelling, 2.5S NGF was injected daily into the anterior chamber of one eye, and PBS or cytochrome C into the other. We subsequently performed *in situ* hybridization to compare levels of LNGFR, TH, and α T-tubulin mRNAs in fast blue-labelled neurons innervating the iris versus fluorogold-labelled neurons of the same ganglia innervating the ear. This analysis demonstrated that NGF delivered to nerve terminals in the iris caused hypertrophy of mature sympathetic neurons, increasing cross-sectional areas 25-35% relative to control neurons innervating the PBS injected eye. Grain-counting of fast blue and fluorogold-labelled neurons within the same ganglion (done to minimize intersection variability) indicated that LNGFR and TH mRNAs were at least two-fold higher in neurons whose terminals were treated with NGF. Preliminary results indicate a somewhat smaller increase in levels of α T mRNA. These results suggest that the availability of target-derived neurotrophins may regulate the synthesis of proteins important to neuronal growth and transmitter function in the mature nervous system.

12.2

TRANSYNAPTIC REGULATION OF THE NGF RECEPTOR (LNGFR) GENE AND OF VGF, AN NGF-INDUCIBLE GENE, FOLLOWING PARTIAL NEURAL LESIONS. G.A. Kuchel^{1,2}, S. Salton¹, R. Hellendall¹ and M. Blum¹, Fishberg Research Center in Neurobiology¹ and Dept. of Geriatrics², Mount Sinai School of Medicine, New York, NY 10029.

The rat pineal gland receives bilateral innervation from the two sympathetic superior cervical ganglia (SCG) through internal carotid nerves (ICN). Cutting the ICN on one side has been shown to remove one-half of the pineal innervation and to be followed by the development of collateral sprouting from the other SCG which can be detected by 3 days. We used a quantitative ribonuclease protection assay to measure NGF receptor (LNGFR) mRNA levels in individual SCG. LNGFR mRNA levels (pg/ μ g total RNA) were increased 25-30%, with no change in cyclophilin mRNA, in the "intact" SCG, contralateral to the lesion performed 1 or 3 days earlier, as compared to "intact" SCG in sham-operated animals (2-way Anova; p < .05). These results, combined with *in situ* hybridization studies, suggest that there is increased expression of the LNGFR gene in the SCG from which collateral sprouting takes place. We also measured levels of NGF mRNA in pooled pineal glands and VGF mRNA in SCG after this lesion. The latter gene is known to be rapidly and quite selectively induced by NGF in PC12 cells. A finding of elevated VGF mRNA levels in the SCG involved in collateral sprouting would support the hypothesis that LNGFR gene induction in collateral sprouting may be mediated through greater stimulation by target tissue-derived NGF. (supported by MRC of Canada, the Brookdale Foundation and the MacArthur Foundation Program on Successful Aging)

12.4

GENETICALLY ENGINEERED CELLS PRODUCING NGF REDUCE THE NEUROTOXICITY OF QUINOLINATE AND QUISQUALATE *IN VIVO*. J.M. Schumacher, W.S. Rosenberg, M.P. Short, S.B. Bossi*, X.O. Breakfield and Q. Isacson, Dept. Neurology and Neurosurgery, Harvard Med. Sch., McLean Hospital, Belmont MA 02178 and Neuroscience Center, Massachusetts General Hospital.

Trophic factors, such as NGF, may elevate the neuronal threshold towards excitotoxicity *in vivo*. In order to test this hypothesis (1) a genetically engineered NGF-producing rat fibroblast cell line (NGF+) was produced and then stereotactically implanted into the brain, providing a continuous supply of NGF prior to, during, and after the neuronal insults. A second group of rat received the same number of fibroblasts without the NGF gene inserted; (NGF-) (2) One week later, quinolinic acid (120 nmoles) or quisqualic acid (105 nmoles), was infused as a neurotoxin into the neostriatum in both groups. The animals with prior graft placement of NGF(-) fibroblasts, had quinolinic and quisqualic lesions of the neostriatum with sizes similar to those in animals without any implants. In contrast, the lesion area in the NGF(+) transplanted group was between 50-70% smaller than those in animals containing NGF(-) grafts. Relative sparing of cholinergic neurons was significantly increased within lesion zones in the NGF(+) groups, while NADPH diaphorase neuronal counts were not affected by this treatment. These results show that NGF released by genetically modified cells can reduce neurotoxicity produced by glutamate-receptor agonists *in vivo*.

12.5

7S-NGF PENETRATES FROM THE BLOOD TO THE CNS IN THE NEONATAL RAT. R.H. Fabian and C.E. Hulsebosch. Dept. of Neurol. and of Anat. and Neurosci. and the Marine Biomed. Inst., Univ. Tex. Med. Branch, Galveston, TX 77550.

Recent evidence indicates that NGF is present in significant amounts in the serum of neonatal rats. We postulate that blood borne NGF has a role in the development of the CNS as a humoral trophic factor. We began to investigate this possibility by determining the extent to which NGF can penetrate from the blood to the brain in neonatal rats.

Radiiodinated NGF was injected intraperitoneally into 1 or 2 day old rats. Following a survival of 2, 4, 6, 12, 24, and 48 hours, the rats were deeply anesthetized and perfused with saline and paraformaldehyde following sampling of blood. Blocks of brain tissue were prepared and gamma activity and weights of all tissue samples determined. Some blocks were prepared for autoradiography.

The results indicate that NGF penetrates from the blood to the CSF to bind to NGF receptors in nervous tissue. Levels of NGF in the brain reach levels of 3 to 5% of blood activity within 4 hours. This supports a role for blood-borne NGF as a humoral trophic factor for CNS development.

Supported by NS 11255 and 01217, the Amyotrophic Lateral Sclerosis Association, and Bristol-Myers Squibb.

POTENTIAL INVOLVEMENT OF NERVE GROWTH FACTOR (NGF) IN SPATIAL MEMORY FORMATION. J.E. Springer, B.J. Gwag, G. Woertwein, R. Stackman, R. Rogers, K. Opello, and T.J. Walsh, Dept. of Neurology, Hahnemann Univ, Phila, PA 19102 (JES and BJG), and Dept of Psychology, Rutgers Univ, New Brunswick, NJ 08903.

Molecular, biochemical and morphological data support the role of NGF as a neurotrophic molecule for basal forebrain cholinergic neurons. This population of cholinergic neurons appears to be critical in spatial memory formation in rats. Due to the close association of NGF with the basal forebrain cholinergic system, we have suggested that NGF may play a more dynamic role in memory formation. To test this, we determined the effects of NGF treatment on acquisition of a well-defined spatial task, the Morris water maze. Animals received daily infusions of NGF (3.0 µg) prior to exposure to the spatial task. We found that daily infusions of NGF, but not basic fibroblast growth factor, or control infusions disrupted the animals ability to learn the location of the escape platform. In addition, NGF treatment resulted in increased NGF receptor gene expression in cells of the medial septum and striatum, areas known to contain NGF-responsive neurons. In a second study, we analyzed levels of NGF messenger RNA (mRNA) in the hippocampus of animals following 20 trials in the spatial task. Using this single day testing paradigm, one population of animals showed excellent learning of the spatial task, while another group of animals exhibited difficulty in acquisition. A third group of animals was run as a yoked control group, which received exposure to the task but were not allowed escape the maze. Using the RNA protection assay procedure, we determined that animals exhibiting rapid learning in the spatial task had lower levels of NGF mRNA in the hippocampus when compared to animals exhibiting slow learning, or control animals. We suggest that in addition to its role as a neurotrophic factor, NGF may function as a modifier of memory formation in the hippocampal formation, and "flooding" the central nervous system with NGF may mask or disrupt stimulus-specific signals necessary for normal memory formation. PERINATAL CHOLINE TREATMENT INCREASES BASAL FOREBRAIN CELL SIZE AND HIPPOCAMPAL NGF. R. Loy, and Y.S. Choe*. Canandaigua VAMC and Department of Neurology, University of Rochester, 435 E. Henrietta Road, Rochester, NY 14620.

Perinatal choline treatment results in long-lasting facilitation of spatial memory (Meck *et al.*, 1988, *Devel. Psychobiol.* 21, 339). In rats treated *in utero* from ED12 (300 mg/kg/day, *p.o.* to the dam) and postnatally until day 30 (150 mg/kg/day, *s.c.*) with choline chloride the average area of diagonal band somata immunoreactive for NGF receptor (NGFRir) or ChAT is up to 30% larger than controls (Loy *et al.*, 1991, *The Basal Forebrain: Anatomy to Function*). To determine if choline treatment causes cells to grow larger throughout development or prevents the naturally occurring regression of cell size after PD15 (Koh and Loy, 1989, *J. Neurosci.* 9, 2999), we compared the area of NGFRir cells in the diagonal band on the day of birth in rat pups treated *in utero* from ED12-17 and found that choline-treated cells have nearly twice the area of controls. In addition, hippocampi were dissected from PD20 rats following choline treatment given between ED12 and PD19, tissues frozen, then homogenized and assayed by ELISA. NGF levels in choline-treated hippocampus were approximately 3-fold higher than controls. We conclude that the organizational effects of perinatal choline treatment on spatial memory may be based in part on an early increase in the size and presumably enhanced cholinergic function in the septohippocampal system, which in turn may be regulated by altered levels of NGF in the developing hippocampus.

We thank Dr. W. Mobley for assistance with the NGF ELISA, D. Heyer and J. Miller for technical assistance, and W. Meck and C. Williams for helpful discussions. Supported by AG09525.

NGF RECEPTORS, FGF RECEPTORS, AND CHOLINERGIC NEURONS IN THE DEVELOPING AVIAN CERULEUS COMPLEX. C.S. von Bartheld and M. Bothwell. Dept. of Physiology & Biophysics (SJ-40), University of Washington, Seattle, WA 98195.

The mesencephalic tegmentum and ceruleus complex contain neuronal populations with heterogeneous phenotypes. We used *in situ* hybridization in adjacent sections to determine FGF- and NGF receptor mRNA expression, and immunocytochemistry to visualize choline acetyltransferase in the developing chick brain (E6-P14).

As early as E6, about 2000 cholinergic neurons extend from the nucleus mesencephalicus profundus, pars ventralis (MPv) to the locus ceruleus. FGF-R expression begins at E13 in the same population of at least 1600 neurons and appears codistributed with the cholinergic phenotype. While FGF-R expression remains at high levels, NGF-R expression generally decreases during development, but not in a distinct population of about 700 neurons in the caudal ceruleus complex which retains high levels of NGF-R expression and may coincide with the noradrenergic population of the ceruleus complex.

Our results indicate that the MPv and part of the avian ceruleus complex are homologous to the cholinergic pontomesencephalotegmental complex of mammals (Woolf, N.J. & Butcher, L.L.: *Brain Res. Bull.* 16:603, 1986). Transmitter heterogeneity of the avian ceruleus neurons is reflected by a heterogeneity of growth factor receptors, with FGF-R expressed in the cholinergic subpopulation, and NGF-R in the presumptive noradrenergic population. These results are consistent with the hypothesis that transmitter phenotypes and target specificity may be regulated by neurotrophic factors.

NGF-LIKE AND NGFR IMMUNOREACTIVITY IN PITUITARY OF DEVELOPING MACAQUES. S. Borson*, G. Schatteman, P. Claude, M. Dubach, and M. Bothwell. Depts of Psychiatry and Physiology & Biophysics, Univ Wash Sch Med, Seattle WA 98195.

NGFR immunostaining of fibers in the median eminence has been observed in rat and primate, but neither NGF nor NGFR immunoreactivity (IR) has been well characterized in pituitary. We examined the pituitary and median eminence of macaques for the presence of NGF-like and NGFR IR. Nine animals, including fetal (≥ 100d), newborn, and adult specimens, were examined using NGFR5 (a monoclonal antibody to human NGFR) and an affinity-purified polyclonal antibody to mouse submandibular NGF. At all ages, NGF IR was associated with what appear to be adenohypophyseal secretory cells. Stained cells were most numerous in anterior pars distalis and in pars tuberalis, where they represented up to 50% of the cells. NGF-IR cells were arrayed singly, in groups along capillaries, or in duct-like or pseudoacinar structures. Sequential staining of adult glands with Abs to NGF and ACTH, GH, or PRL (gifts of the National Hormone and Pituitary Program) revealed few double-stained cells. The distribution of NGFR-IR contrasted markedly with that of NGF-IR. In pars distalis, NGFR-IR was limited to cell bodies and processes of folliculostellate cells. In fetal animals these processes formed an extensive network throughout the gland, becoming less prominent in the newborn and adult. In pars nervosa, intense NGFR-IR was seen adjacent to NGF-IR cells of pars tuberalis in fetal specimens, and on fibers and in the capillary network of the hypophyseal portal system at all ages. In the median eminence and proximal infundibulum, tanyocyte processes, capillary walls and the contractile loops of the portal circulation were NGFR-IR. These anatomic findings suggest that NGF may be a secretory product of a subset of adenohypophyseal cells present by midgestation. NGFR's are also well developed by day 100 of fetal life, but the pattern of NGFR-IR varies during development, perhaps reflecting differing functions of pituitary NGF.

BASAL FOREBRAIN NEURONS IMMUNOREACTIVE TO NERVE GROWTH FACTOR RECEPTOR INNERVATE THE RETICULAR THALAMIC NUCLEUS IN THE RAT.

Marina Bentivoglio, Sheng Chen

Institute of Anatomy, University of Verona, Italy

Recent observations have shown that the reticular thalamic nucleus (RTN) is richly innervated by nerve growth factor receptor (NGF-R) immunopositive fibers, whose staining is considerably enhanced by intracerebroventricular administration of NGF. We searched in the present study for the origin of this RTN innervation in the basal forebrain (BF), using retrograde tracing with immunohistochemistry. Preliminary findings based on fluorescent tracer injection in the anterior pole of RTN indicate that some (5-10%) retrogradely labeled BF cells were also immunostained with NGF-R. Immunohistochemistry performed on alternate sections revealed that 5-10% of the BF labeled neurons were choline acetyl transferase-positive, and 10-15% were parvalbumin-positive. These data indicate that RTN is one of the targets of BF neurons expressing NGF-R. Moreover, in agreement with previous findings, the present results suggest that BF neurons projecting to RTN are chemically heterogeneous. The study of the relationships among NGF-R immunopositive cells, GABAergic cell bodies, and neurons projecting to RTN in the BF, as well as triple labeling experiments aimed at investigating the colocalization of NGF-R with other neuroactive compounds in the BF cells innervating RTN, are in progress.

EFFECTS OF FIMBRIA-FORNIX AND ANGULAR BUNDLE TRANSECTION ON NGFR mRNA-EXPRESSING CELLS LOCATED IN THE MEDIAL SEPTUM AND DIAGONAL BAND OF BROCA. R.B. Gibbs¹, M.V. Chao², & D.W. Pfaff¹. ¹Laboratory of Neurobiology & Behavior, Rockefeller University, and ²Department of Cell Biology & Anatomy, Cornell University, N.Y., N.Y. 10021

Quantitative *in situ* hybridization techniques were used to examine the effects of lesions which sever hippocampal cholinergic and cortical afferents on nerve growth factor receptor (NGFR) mRNA-expressing cells located in the medial septum (MS), and the vertical (VDB) and horizontal (HDB) limbs of the diagonal band. Animals received either bilateral transection of the fimbria-fornix (FFX), unilateral transection of the angular bundle (ABX), or sham surgery (4 animals/group). Four days later, animals were sacrificed and sections through the MS, VDB, and HDB were processed for detection of NGFR mRNA using a ³H-labeled riboprobe and *in situ* hybridization techniques previously described (Gibbs et al., Mol. Brain Res. 6: 275-287, 1989).

In the MS and VDB, FFX resulted in a significant decrease in the size of NGFR-expressing cells (25.9% and 15.1% respectively) which was accompanied by a significant reduction (37.9% and 12.7% fewer grains/cell) in relative levels of NGFR mRNA. In the HDB, FFX had no significant effect on the average size of NGFR-expressing cells; however, a significant increase (49%) in the mean relative level of NGFR mRNA was observed. ABX resulted in small but significant increases (9.4% and 10.9%) in relative levels of NGFR mRNA in the MS and VDB, as well as an increase (19.6%) in the number of NGFR mRNA-expressing cells in the HDB, on the injured side. No increase in NGFR expression in the MS, VDB, or HDB contralateral to the lesion was observed; however, a decrease in the size (8.0%) and message content (19.4%) of NGFR-expressing cells was detected in the MS contralateral to the lesion.

These data are consistent with the effects of FFX and ABX on the subsequent survival and growth of cholinergic neurons located in the MS, VDB and HDB, and therefore provide evidence for a link between NGF-related effects and lesion-induced changes in the organization and sprouting of cholinergic projections in the adult CNS.

NERVE GROWTH FACTOR ENHANCES NEURONAL PLASTICITY IN THE AGING RAT NEOCORTEX: A QUANTITATIVE GOLGI STUDY. R.F. Mervis^{1,2}, R. Lewis^{1,2}, R.M. Dvorak^{1,2}, D. Pope², and L.W. Williams². ¹Neurocognitive Research Labs, Inc., Columbus, OH. 43212, ²Div. Neuropathol., Ohio State Univ. Med. Ctr., Columbus, OH., ³The Upjohn Co., Kalamazoo, MI.

The role of NGF on cortical neurons and circuitry is unknown. Here, we evaluated effects of chronic exogenous NGF treatment on extent of dendritic branching and dendritic spine density from the basilar tree of layer V frontal cortex pyramids in 3 groups of Fischer 344 rats: Young Controls (4 mo) [YC]; Old Controls (24 mo) [OC] and Old-NGF-Treated (24 mo) [O-NGF]. Old Ss were administered NGF (or control vehicle) unilaterally via osmotic minipump (1.2 ug/day) i.c.v. unilaterally for four weeks. Sholl Analysis of basilar dendritic branching showed that in 24 mo rats, the dendritic domain was larger than in 4 mo controls (compensatory hypertrophy). NGF treatment resulted in regression of dendritic branching. Dendritic spines were sampled on terminal tip and internal branch segments. Aging resulted in significant spine loss in both regions. However, NGF treatment caused a significant plastic response on the terminal tip segments: there was plumping of the segment and formation of new dendritic spines in old rats. Internal (non-plastic) segments showed no response. [Supported by Sigma Kappa Foundation, Roessler Foundation and the Upjohn Company]

HUMAN COGNITION

MODULATION OF EARLY SENSORY PROCESSING IN HUMAN AUDITORY CORTEX DURING AUDITORY SELECTIVE ATTENTION. R.G. Miodorff¹(1), C.G. Gallen², S.R. Hampson²(2), S.A. Willard¹, E. Pantev²(2), and E.E. Bloom². Dept. of Neurosciences, Univ. of Calif. at San Diego, La Jolla, CA 92093-0608 (1), Dept. of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla, CA, 92037 (2).

A dichotic listening experiment was conducted in which the stimulus and task conditions were optimized for the selective focusing of attention. Subjects (N=7) listened selectively to sequences of rapidly presented tone pips in one ear while ignoring tone pips of a different pitch in the opposite ear. Thirty-seven channels of event-related magnetic fields (ERPs) and three channels of event-related potentials (ERPs) were simultaneously recorded from over the left hemisphere. Previous ERP studies using this paradigm had revealed a small enhanced positivity between 20-50 msec (the "P20-50") in the ERPs to attended-channel tone pips, followed by a relative enhancement of several of the exogenous ERPs, including subcomponents of the central M1 and P2 waves and the temporal T-complex. The ERPs recorded in the present study confirmed the basic results of the previous studies. The magnetic counterpart to the electrical M1 wave, the "M1", also showed a strong effect of attention which, similar to the electrical M1 effect, closely overlapped the exogenous M1 in time. Moreover, the field patterns of the magnetic M1 and the attention effect on it were highly dipolar, inverting in polarity at anterior relative to posterior sensor locations. MRI scans were obtained from several subjects, and the anatomical locations of the neural generators of the attention-sensitive activity were determined by dipole source localization techniques. These calculations placed the sources of both the M1 and its enhancement with attention to be within Meschl's gyri on the supratemporal plane (primary and secondary auditory cortex). In addition, the earlier P20-50 attention effect also demonstrated a dipolar magnetic field distribution indicative of a source in Meschl's gyri.

PHYSIOLOGICAL AND ANATOMICAL EVIDENCE FOR A MAGNOCELLULAR DEFECT IN DEVELOPMENTAL DYSLEXIA — A.M. Galaburda, Depts. of Neurology and Neurobiology, Harvard Medical School, G.D. Rosen and F.W. Drislane*, Dept. of Neurology, and M.S. Livingstone, Dept. of Neurobiology, Boston, MA 02215.

Developmental dyslexics do poorly on tests of rapid visual information processing¹. In the primate, fast visual information is carried by the magnocellular subdivision of the visual pathway. We recorded visually evoked scalp potentials in dyslexics and found that they showed diminished potentials for rapid, low contrast stimuli but normal responses to slow or high contrast stimuli. The differences in the dyslexics' evoked responses were consistent with an abnormality in the magnocellular division at the level of Visual Area 1 or earlier. We therefore compared the lateral geniculate nuclei in 5 dyslexic and 5 non-dyslexic brains and found that the magnocellular neurons of the dyslexic brains were significantly smaller, on average 27% smaller, but the parvocellular neurons were the same size as in normals. Dyslexics often do poorly on tests of rapid auditory transitions as well,² and we hypothesize that auditory, and possibly other sensory and motor systems, are similarly divided into a fast and a slow subdivision and that dyslexics are specifically affected in the fast subdivisions.

Asymmetries of Probe Evoked Potentials and Intellectual performance in cognitively impaired children. D.W. Shucard and J.L. Shucard*, Department of Neurology, SUNY at Buffalo School of Medicine and Biomedical Sciences, 100 High Street (D-6), Buffalo, NY 14203.

In a series of investigations, we examined the relationship between electrocortical activity and specific patterns of cognitive abilities as measured by the Wechsler Intelligence Scale for Children-Revised (WISC-R). The subject groups included males and females with no known cognitive deficits, and two groups with cognitive deficits: males with reading disability (RD) and females with Turner Syndrome (TS). Subjects ranged in age from 8-15 years. Auditory evoked potentials (AEPs) to task-irrelevant tone stimuli (Probes) were obtained while subjects performed specific Verbal or Spatial tasks. These tasks were presented in both auditory and visual modalities. The probe tones were superimposed on the on-going visual or auditory information. AEPs to the probe tones were obtained from temporal scalp sites of the left and right cerebral hemispheres.

The findings indicated that significant differences were present in the patterns of AEP amplitude asymmetries among the groups studied. Further, significant relationships were found between AEP amplitude asymmetry and WISC-R verbal performance scores, regardless of the group. For example, the pattern of right - left temporal site amplitude asymmetry seen in TS girls paralleled the visual spatial deficits seen in this group. In addition, within the TS group, AEP amplitude asymmetry correlated significantly with the degree of discrepancy between verbal and performance WISC-R scores.

These findings, obtained across different populations, suggest that AEPs to probe stimuli may offer insight into the relationship between the functional organization of the brain and human abilities. Supported in part by NICHD grant HD11681 and Genentech, Inc.

ANATOMICAL SUBSTRATES OF EVENT-RELATED POTENTIALS ELICITED DURING MEMORY CHALLENGE: CLINICAL OBSERVATIONS. L. deToledo-Morrell, D. Charletta*, F. Morrell and T. McNally*. Dept. of Neurological Sci. and Dept. Diagnostic Radiology, Rush Med. Coll., Chicago, IL 60612.

The P300 component of long-latency evoked potentials generated during a mnemonic task considered to engage hippocampal circuits may provide an index of the anatomical integrity of the hippocampal formation. We studied four patients electrophysiologically and with a special high resolution MRI protocol. Two patients had low-grade glioma; in one, the tumor infiltrated the entorhinal cortex, perforant path and dentate gyrus while in the other it involved the amygdala and uncus, sparing the hippocampus entirely. Two patients with vascular disease had primarily neocortical atrophy, one with and one without associated hippocampal destruction. P300 potentials were recorded referentially during a modified Sternberg memory scanning task having different degrees of memory load. P300 amplitude was strikingly diminished with increasing memory load only over the involved hemisphere and only in the patients with hippocampal destruction. Neocortical involvement alone did not diminish P300 amplitude or render it sensitive to memory load. We conclude that the P300 component of event related potentials recorded in the context of mnemonic demand may provide a sensitive marker of hippocampal dysfunction.

PRACTICE-RELATED CHANGES IN HUMAN BRAIN FUNCTIONAL ANATOMY. M. E. Raichle, J. Fiez, T. O. Videan, P. T. Fox, J. V. Pardo, S. E. Petersen. Washington U. Sch. of Med., Box 8131, St. Louis, MO 63110.

A previous PET study (Nature 331:585, 1988) led to the hypothesis that two distinct pathways can be used for verbal response selection, and the use of these pathways reflects the degree to which a given response is automatic. As a test of this hypothesis, a PET study, using measurements of local blood flow in 11 normal humans, was conducted to determine the functional effects of practice on a verb generation task. For the generation task, subjects were instructed to say aloud an appropriate verb for each of 40 visually presented nouns. As a control state subjects were asked to repeat the seen noun. Subjects were scanned during performance of the generation task in three different states of practice: 1) NAIVE -- initial (unpracticed) performance of the verb generation task, 2) PRACTICED -- following 9 blocks of practice with the same set of nouns, and 3) NOVEL -- following practice with the task, but with a novel set of nouns as stimuli. Six regions of interest were selected for analysis. An ANOVA was performed for each region across the 3 conditions followed by post hoc t-tests. All 6 regions varied significantly. Regions most active during NAIVE performance (left prefrontal, left temporal, anterior cingulate cortices and right cerebellar hemisphere) were all less active during PRACTICED performance. These changes were accompanied by reciprocal changes in sylvian-insular cortex bilaterally. The functional changes were correlated behaviorally with a significant reduction in response times and the occurrence of stereotyped responses across practice blocks. The practice-related changes appear to be largely item-specific, since analysis of the NAIVE vs. NOVEL subtraction images only reveals a significant difference in left prefrontal cortex. Thus, subjects appear to change areas used during the verb generation task following less than 15 minutes of practice.

13.9

VARIETIES OF PROSOPAGNOSIA: NEUROBIOLOGICAL EVIDENCE. J. Sergent & J.-L. Signoret*. Cognitive Neuroscience Lab., Montreal Neurological Institute, Montreal, H3A 2B4, Canada, & Salpêtrière, Neurologie, Paris, France.

Studies of brain-damaged patients have revealed the existence of a selective impairment of face processing, prosopagnosia. Although the functional deficit is the same in all patients - an inability to experience a feeling of familiarity at the view of faces of known persons - the qualitative nature of the impairment varies considerably across patients. In this study, the patterns of successes and failures on various tasks of face and object processing by 4 prosopagnosic patients are considered in relation with radiological (MRI) and physiological (PET) data, in an attempt to determine what cortical areas are critically involved in the processing of faces, what functional aspects of face processing are served by these areas, and whether these areas are uniquely devoted to the processing of faces. This examination indicates that the locus of the lesion determines the functional locus of the cognitive impairment, and that damage in one of three cortical regions within the ventral occipito-temporal cortex of the right hemisphere may result in a break-down of facial information processing. The data from the patients are further compared to the results from a combined MRI and PET study in normal subjects.

13.6

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING OBJECT AND WORD NAMING. S.Y. Bookheimer, T.A. Zeffiro, C. Pelizzari, W. Theodore, W. Gaillard, P. Fedio and M. Hallett. Medical Neurology Branch, 10-5D49, NINDS, National Institutes of Health, Bethesda, MD, 20892.

Although lesions of the inferior frontal gyrus (IFG) can produce expressive aphasia, positron emission tomography (PET) studies have not consistently demonstrated rCBF changes associated with language in that region. In the present study, rCBF was measured using H_2O^{15} in normal volunteers while naming objects or words, viewing objects or words, or viewing meaningless designs. After global normalization, image pairs were subtracted to obtain task-specific changes in rCBF. The resulting difference images were aligned with corresponding MRI using a surface registration algorithm. rCBF values were then obtained for cortical regions identified on MRI and analyzed using a 2x2x2 ANOVA design (hemisphere x naming condition x stimulus).

We found a significant increase in rCBF in the left IFG during viewing of both pictures and words ($p < 0.001$), and decreased rCBF in the IFG during naming compared to viewing ($p < 0.01$). In contrast, orofacial regions in pre- and post-central gyri were bilaterally active during naming but not viewing ($p < 0.001$). In the medial superior frontal gyrus (supplementary speech area), rCBF was greater during naming than during viewing and greater on the left than on the right ($p < 0.01$). The location of task-related changes in the IFG varied markedly across subjects.

These results indicate a more complex set of region-task interactions in the IFG than previously assumed. Specifically, the higher IFG activation with viewing rather than naming suggests a role in receptive language processing. Our results may differ from previous studies that found no activation in the IFG after subject averaging of PET data, which may reduce apparent activity due to anatomical variation in functional localization.

13.8

CHANGES IN LOCATION OF BLOOD FLOW ACTIVATION IN EXTRASTRIATE CORTEX CORRELATE WITH PERFORMANCE DURING OBJECT AND SPATIAL VISUAL PROCESSING. C. Grady, B. Horwitz, J. Haxby*, S. Rapoport, M. Schapiro*. Lab. of Neurosciences, Nat. Inst. on Aging, Bethesda, MD 20892.

We measured cerebral blood flow (CBF) in 11 young subjects using [^{15}O]-water and positron emission tomography during 2 runs of 3 visual tasks- face and dot-location matching and a control task. Normalized difference images were computed by subtracting the first and second sets of control task images from the first and second sets of images obtained during the matching tasks, respectively. Areas of extrastriate cortex were identified based on our previous finding of occipitotemporal (OT) activation during face matching and superior parietal (SP) activation during dot-location matching. The centers of gravity (COG) of the CBF increases in OT and SP were determined from the difference images and compared between the 2 runs. The mean absolute change in the anterior/posterior location of the COG was 4.6 ± 1.1 mm (mean \pm s.e.) in OT during face matching and 5.9 ± 1.5 mm in SP during dot-location matching. Some subjects showed COG changes of 8 mm or more, which were twice as likely to occur in the left hemisphere; 85% were in the anterior direction. There were significant correlations between the size of the left hemisphere COG shift and reaction time in the first run during both face ($r=0.71$, $p < 0.01$) and dot-location matching ($r=0.74$, $p < 0.01$). Although the location of rCBF activation in extrastriate cortex is relatively stable during repeated visual testing, some large changes are found, suggesting that more anterior cortical areas may be recruited during subsequent performance of the task. The left hemisphere COG shift that follows slower performance may reflect a change in strategy.

13.10

CORTICAL STIMULATION EVIDENCE FOR TOPOGRAPHIC REORGANIZATION OF SPEECH IN BILINGUAL PATIENTS. D.F. Cawthon, G.A. Ojemann, and E. Lettich*, Department of Neurological Surgery, University of Washington, Seattle, WA 98195

During surgery for medically intractable epilepsy, performed in awake patients under local anesthesia, we have mapped speech cortex related to naming of line-drawn objects in 2 languages for each of 7 bilingual patients, based on errors characterized as naming arrest, substitution, or delay. A multinomial distribution and median absolute deviation methods were used in error analysis. Topographic analysis for 1st and 2nd languages in these patients usually showed partial overlap. We divided our patients into 2 groups, one more fluent in the 1st language and the other in the 2nd. Comparison of areas for 1st and 2nd languages within each group showed that the 2nd language territory on average was larger than the 1st for both groups, but with predominant fluency in the 2nd language, territories for both languages were smaller.

For pooled independent (single language) sites, the 1st language followed a diagonal from midfrontal to posterior temporal cortex, while the 2nd language appeared in parallel diagonals on either side of the 1st language. Independent 2nd language sites of lesser fluency could fall on the usual 1st language diagonal, though still independent from their 1st language sites in those patients. MENTALLY ROTATING THREE-DIMENSIONAL FIGURES AND LISTENING TO TEXT: AN EEG MAPPING STUDY ON COGNITIVE PROCESSES IN HEALTHY PERSONS AND SCHIZOPHRENICS

D. Lacroix, P. Rappelsberger*, K. Steinberger*, K. Thau*, H. Petsche*, B. Rescher*
Research Institute for Physiology and Anatomy of the Cortex, Academy of Sciences, Institute of Neurophysiology and Psychiatry Unit, University of Vienna
Währingerstraße 17, A-1090 Vienna, Austria

Recordings were obtained from 23 healthy and 11 schizophrenic males with eyes open and eyes closed and during two separate tasks: trying to determine if figures differently oriented in space were identical and listening to text with eyes closed. EEG was recorded with 19 electrodes placed on the scalp according to the international 10/20 system and against averaged signals picked up from both ear lobes (TC 0.3s, Filter 35 Hz). Topographic mapping was used to illustrate differences in spectral parameters such as amplitude (AM), local coherence (LC) and interhemispheric coherence (IHC).

In healthy males, during the rotation task, LC was increased mostly in parietal and central regions presumably related to spatial analysis and most pronounced in the beta3 range. LC was decreased mostly in frontal regions and in posterior areas known to process visual informations and was most pronounced in the alpha range. IHC was increased in posterior and decreased in frontal areas. When listening to text, main changes were present in local coherence (LC) between left temporal, central and parietal electrodes. In both tasks, regional changes involved both hemispheres and interhemispheric cognitive processing was increased.

In schizophrenics, important differences in LC and IHC were present suggesting altered language and visuo-spatial processing. When listening to text, changes in the left hemisphere were noticeably reduced although comprehension of the text was not altered. IHC results suggest significantly modified cognitive processing between both hemispheres.

13.12

ASSOCIATION OF ELECTROPHYSIOLOGIC BRAIN FUNCTION AND NUTRITIONAL STATUS IN HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) INFECTION. G. Shor-Posner, R.E. Ramsay*, R. Morgan*, J. Slater*, R.S. Beach*, E. Mantero-Aienza and M.K. Baum*
Biopsychosocial Center for Study of AIDS, University of Miami School of Medicine, Miami, FL 33101

There is evidence to suggest that abnormalities of vitamin B₁₂ (cobalamin) and vitamin B₆ (pyridoxine) may affect neurologic function. This is of particular interest in light of recent findings demonstrating that alterations in these specific nutrients occur early in HIV-1 infection, and may be related to cognitive changes. The association between electrophysiologic brain function, as measured by quantified cognitive evoked potentials (CEP), and nutritional vitamin B₆ and B₁₂ status was evaluated in 22 HIV-1 seropositive homosexual individuals (CDC Stages III, IV) over an eighteen month period. Our findings indicate that the overall level of vitamin B₁₂ was related to electrophysiologic function ($r = -0.56$ $p < 0.05$) and that a decrease in vitamin B₆ status (measured as an activity coefficient) was associated with more deviant cognitive evoked potentials ($r = 0.58$ $p < 0.01$). These results suggest that an indirect mechanism (i.e. alteration of CNS metabolism via vitamin B₆ and/or vitamin B₁₂ deficiency) may be one method by which an HIV-1 infection produces cerebral dysfunction and changes in the CEP.

ACETYLCHOLINE RECEPTORS: NICOTINIC

14.1

THYMOPOIETIN PREVENTS NICOTINE INDUCED ALTERATIONS IN MORPHOLOGY AND NICOTINIC RECEPTORS IN NEONATAL RAT MUSCLE CULTURES. M. Quik, J. Philie* and G. Goldstein. Dept. Pharmacol, McGill U., Montreal, Can. and Immunobiol. Res. Inst., NJ, USA.

The present results show that thymopoietin (TPO), a 49 amino acid polypeptide isolated from thymus, potentially inhibits α -BGT binding (IC₅₀ = 4 nM) to cultured neonatal muscle cells. Studies were done to evaluate the potential functional consequences of this interaction of TPO at the receptor. Long term exposure (3 days) of muscle cells in culture to nicotine (3x10⁻⁶ M) or carbachol (10⁻⁶ M) inhibited muscle cell branching and cell size. TPO (3-6 nM), as well as α -BGT, prevented the effects of the nicotinic agonists on muscle cell morphology; furthermore, the decline in α -BGT binding which occurred after exposure to nicotine or carbachol was prevented by TPO. Thus, the long term effects of TPO on cellular morphology and on the nicotinic receptors correlate well with its interaction at the α -BGT site. TPO also inhibited nicotinic receptor mediated ²²Na uptake in cultured muscle cells, but at higher concentrations (IC₅₀ = 20 nM). These studies suggest that TPO may modulate muscle cells characteristics during development through an interaction at the nicotinic receptor.

A 90 KD PROTEIN RECOGNIZED BY ANTI-SRC ANTIBODIES COLOCALIZES WITH THE nAChR. K.R. Wagner, S.L. Swope, R.L. Haganir. Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

The nicotinic acetylcholine receptor (nAChR) is a ligand gated ion channel that mediates signal transduction at the postsynaptic membrane of synapses including the neuromuscular junction and the electric organ of electric fish. The nAChR is known to be modulated by both serine and tyrosine phosphorylation. Although the kinases responsible for serine phosphorylation have been identified, the kinase responsible for tyrosine phosphorylation has been elusive. In an effort to identify this protein tyrosine kinase (PTK), antibodies were raised to a synthetic peptide based on the sequence of the autophosphorylation site of the src PTK. On Western blots of *Torpedo* electric organ, this antibody primarily recognizes a 90 kD protein which is most abundant in postsynaptic membranes rich in nAChR. Anti-phosphotyrosine antibodies also recognize a 90 kD protein with the identical subcellular distribution. Immunofluorescent double labeling with the anti-src antibody and rhodamine conjugated α -bungarotoxin suggest that the 90 kD protein colocalizes with the nAChR in the electric organ. These results suggest that the 90 kD protein may be a PTK that phosphorylates the nAChR or a substrate for a PTK. The anti-src antibodies are currently being used to screen expression libraries of the electric organ to isolate a cDNA clone encoding the 90 kD protein.

THE δ -SUBUNIT DETERMINES VOLTAGE DEPENDENT CLOSING OF TORPEDO AChR CHANNELS. M.D. Golino* and O.P. Hamill. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

Acetylcholine receptor (AChR) channels of *Torpedo californica* were expressed in *Xenopus laevis* oocytes by injecting different combinations of subunit-specific mRNA transcripts of the individual AChR subunits α , β , γ , δ . The order of efficacy in producing ACh induced oocyte depolarization for different subunit combinations was $\alpha_2 \beta \gamma \delta > \alpha_2 \beta \delta > \alpha_2 \beta \gamma > \alpha_2 \delta > \alpha_2 \gamma > \alpha_2 \beta$. These results indicate the efficacy of non- α subunits in substituting for one another is $\delta > \gamma > \beta$. Oocytes injected with $\alpha_2 \beta \gamma \delta$ displayed brief current events with a channel conductance of 100 pS (measured under symmetrical 100 mM K⁺ at 16°C) and an average burst duration of 0.35 ms at -100 mV which increased with hyperpolarization (e-fold per 120-140 mV). Single AChR channels formed from the subunit deficient combinations $\alpha_2 \beta \gamma$, $\alpha_2 \beta \delta$ and $\alpha_2 \gamma \delta$ also displayed a channel conductance of around 100 pS and a similar voltage-dependent burst duration kinetics, with the exception that the δ -less combination expressed channels with burst kinetics that were relatively voltage insensitive (i.e. e-fold charge per 600 mV). We hypothesize that a specific structural domain resides in the δ -subunit which influences the voltage dependent closing step of AChR channels.

This work was supported by a grant from the Cornell Biotechnology Program which is sponsored by the New York State Science and Technology Foundation, a consortium of industries, the U.S. Army Research Office and the National Science Foundation.

Agonist-sensitive Photolabeling of the M2 Region of the Nicotinic Acetylcholine Receptor (AChR) by a Hydrophobic Noncompetitive Antagonist (NCA). Benjamin H. White and Jonathan B. Cohen. Dept. of Anatomy and Neurobiology, Washington University Sch. of Med., St. Louis, MO 63110

To characterize agonist-induced changes of AChR structure, we have mapped the site of photoincorporation of a novel photoaffinity NCA, 3-(trifluoromethyl)-3-(m-[¹²⁵I]iodophenyl)diazirine ([¹²⁵I]TID). Although [¹²⁵I]TID binds to the AChR with similar affinity in the presence and absence of agonist, agonist inhibits labeling of all subunits by >75%. Sites on the β - and δ -subunits labeled in the absence of agonist were identified by N-terminal sequencing of tryptic fragments purified by SDS-PAGE followed by reverse phase HPLC. [¹²⁵I]TID specifically labels homologous aliphatic residues (β L-257, δ L-265, β V-261, and δ V-269) in the M2 region of both subunits. In the presence of agonist labeling of these residues is reduced ~90% and the distribution of labeled residues is broadened to include a homologous set of serine residues at the N-terminus of M2. In the β -subunit residues β S-250, β S-254, β L-257 and β V-261 are all labeled in the presence of carbamylcholine. This pattern of labeling supports an α -helical model for M2 with the labeled face forming the ion channel lumen. The observed redistribution of label provides the first evidence for an agonist-dependent rearrangement of the M2 helices.

THE ROLE OF ASPARTATE-200 IN LIGAND ACTIVATION OF TORPEDO ACETYLCHOLINE RECEPTORS. Michael E. O'Leary* and Michael M. White, Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

The requirement for a positive charge on nicotinic agonists and antagonists has led to the assumption that electrostatic interactions are important for ligand binding. Chemical modification studies have localized the binding site to a region containing residues 180-210 on the α subunit. Within this region is a conserved aspartate (α D200) that could function as the anionic subsite thought to be part of the binding site. We have examined the role of this residue in agonist-mediated activation of the *Torpedo* AChR by means of site-directed mutagenesis and expression in *Xenopus* oocytes. Wild-type (WT) receptors are half-maximally activated (K_{act}) by 20 μ M ACh with a Hill coefficient $n=1.8$. Replacement of aspartate-200 by asparagine (α D200>N) shifts K_{act} for ACh to 75 μ M with no change in n , suggesting that α D200 is not absolutely essential for ACh binding. To further investigate the role of α D200, we examined receptor activation by two partial agonists, phenyltrimethylammonium (PTMA) and tetramethylammonium (TMA), which interact with the alkylammonium binding subsite of AChRs. WT receptors are activated by PTMA and TMA with K_{act} of 75 μ M and 2 mM, respectively. In contrast, α D200>N receptors do not respond to either of these compounds; however, they do act as competitive inhibitors of the mutant receptors with K_i of 30 μ M and 1.5 mM for PTMA and TMA, respectively. The close agreement for the WT K_{act} and mutant K_i for the partial agonists suggests that the affinity for these two compounds is not markedly affected by the mutation, but it does abolish the ability to couple binding to activation. We suggest that α D200 is not involved in agonist binding *per se*, but rather serves as a structural element involved in coupling ligand binding to activation. EHRlich's MAGIC BULLET REVISITED: AROMATIC ARSENOXIDES AS SELECTIVE REAGENTS FOR NICOTINIC RECEPTORS.

R.H. Loring¹, W. Lane¹, Y. Dou¹, and K. Stevensen². ¹Dept. of Pharmacol. Sci., Northeastern Univ., Boston, MA 02115 and ²Dept. of Biol. Sci., Univ. of Calgary, Calgary, Alberta, Canada T2N 1N4

An unusual feature of nicotinic receptors is the presence of a disulfide between adjacent cysteine residues near the agonist binding site. Aromatic arsenoxides selectively form stable ring structures with vicinal (spatially close) sulfhydryls. We investigated the ability of aromatic arsenoxides to covalently bond to reduced nicotinic receptors in the intact chick retina. Reduction with dithiothreitol (DTT; 2 mM, 20 min) increases the concentration of agonist needed to activate nicotinic receptors while decreasing the concentration of NMDA needed to activate NMDA receptors. These effects are reversed by reoxidation with dithiobis(nitrobenzoic acid) (DTNB; 1mM, 5 min). Neither 4-aminophenylarsenoxide (APA) nor bromoacetyl-4-aminophenylarsenoxide (BAPA) change nicotinic responses by themselves. When either compound is applied (20 μ M, 20 min @) after reduction with DTT, nicotinic responses remain diminished even after attempted reoxidation with DTNB. Furthermore, concentrations of nicotinic agonists that would normally activate DTT-treated receptors are ineffective after APA or BAPA application. However, treatment with the anti-arsenical, 2,3-dimercaptopropane-sulfonic acid (2 mM, 20 min), allows reoxidation of nicotinic receptors (recovery 60-90%). APA and BAPA have no effect on reduced or oxidized NMDA receptors, suggesting no functionally important vicinal cysteines in those receptors. Preliminary binding assays suggest that APA protects DTT-reduced *Torpedo* receptors against alkylation by bromoacetylcholine (as detected by inhibition of ¹²⁵I- α -bungarotoxin binding) with an EC_{50} of 1-10 nM. These results suggest that aromatic arsenoxides may be the basis for novel covalent, yet reversible, probes for nicotinic receptors. Supported by NS22472, STRC, and NSERC (Canada).

ACHR GENE PRODUCTS IN CHICK CILIARY GANGLIA: TRANSCRIPTS, SUBUNITS, AND RECEPTOR SUBTYPES. A.B. Vernallis, W.G. Conroy, R.A. Corniveau, S.W. Halvorsen, and D.K. Berg. Dept. of Biology, Univ. of Calif., San Diego, La Jolla, CA 92093.

Chick ciliary ganglion neurons have at least two classes of nicotinic acetylcholine receptors (AChRs). One class binds the monoclonal antibody mAb 35, occurs predominantly in synaptic membrane, and generates nicotinic responses mediating synaptic transmission through the ganglion (mAb 35-AChRs). The other class binds α -bungarotoxin, occurs predominantly in non-synaptic membrane, and only recently has been shown to function as a receptor (α Bgt-AChRs). RNase protection experiments demonstrated that ciliary ganglia from 18 day chick embryos contain substantial amounts of AChR gene $\alpha 7$ mRNA, moderate amounts of $\alpha 3$, $\alpha 5$, $\beta 2$, and $\beta 4$ mRNAs, and traces of $\alpha 4$ mRNA. The subunit composition of ciliary ganglion AChRs was examined with mAbs raised against fusion proteins containing relatively unique portions of the $\alpha 3$, $\alpha 7$, and $\beta 4$ gene products. Anti- $\alpha 3$ and anti- $\beta 4$ mAbs immunoprecipitated mAb 35-AChRs solubilized from embryonic ciliary ganglia. When immunoblots of affinity purified mAb 35-AChRs were probed with the anti- $\alpha 3$ mAb, bands of about 58 and 55 kD were obtained, as previously seen with an anti- $\alpha 3$ antiserum. The smaller band is likely to be a degradation product of the larger. Probing the immunoblots with an anti- $\beta 4$ mAb revealed a band of about 54 kD. mAb 268, raised against AChRs purified from brain, detected a component in the vicinity of the $\beta 4$ band that has yet to be correlated with a known gene. α Bgt-AChRs were immunoprecipitated with an anti- $\alpha 7$ mAb but not with anti- $\alpha 3$ or anti- $\beta 4$ mAbs. Most if not all ciliary ganglion neurons express $\alpha 3$ mRNA and have mAb 35-AChRs and α Bgt-AChRs. The results suggest that $\alpha 3$ and $\beta 4$ gene products co-assemble with each other but not with the $\alpha 7$ gene product, though all are likely to be present in the same cell. The multiplicity of AChR transcripts also implies that either neuronal AChRs can have more than two types of subunits or ciliary ganglia contain more than two species of AChRs. MAPPING THE NEGATIVE SUBSITE OF THE NICOTINIC ACETYLCHOLINE RECEPTOR AGONIST BINDING SITE. C. Czajkowski and A. Karlin. Center for Molecular Recognition, Columbia University, New York, NY 10032.

Our model of the acetylcholine (ACh) binding site places a negative subsite about 1 nm from a readily reducible disulfide bond. Previously, α Cys192 and Cys193 were shown to form the binding site disulfide. We have now identified a region that may contribute to the negative subsite. Starting with mildly reduced ACh receptor from *Torpedo*, we attached the 0.9 nm long ³H-N-glycylcysteamine (³H-GC) to either a Cys192 or Cys193 via a disulfide bond. We added a carbodiimide to form an amide bond between the ³H-GC glycyl amino group and nearby receptor carboxyl group(s). We then reduced the disulfide between ³H-GC and α Cys 192/193 so that all ³H-GC retained by the receptor was linked via an amide bond. The major site of amide bond formation was on the δ subunit. This crosslinking reaction from α to δ was blocked in the presence of ACh. By CNBr cleavage, HPLC, SDS-PAGE, and N-terminal sequencing, we identified δ 164-257 as the region specifically and uniquely crosslinked to a Cys192/193. This region therefore may contain all or part of the negative subsite of one of the two ACh binding sites. Supported in part by NIH grants NS07065 and NS07258 and by MDA.

NEREISTOXIN: REDOX EFFECTS ON NEURONAL NICOTINIC RECEPTORS IN CHICK RETINA. Y.Xie and R.H. Loring. Dept. of Pharmaceutical Sciences, Northeastern University, Boston, MA 02115

Nereistoxin (NTX; 4-N,N-dimethylamino-1,2-dithiolane) is reported to block nicotinic acetylcholine receptors in both muscle and neurons, as well as reversibly inhibit the binding of [³H]-ACh and [¹²⁵I]- α -bungarotoxin to *Torpedo* nicotinic receptors. We studied the effects of NTX in intact chick retina by electrophysiological recordings, and by the binding of [¹²⁵I]-neuronal bungarotoxin (¹²⁵I-NBT) to retinal homogenates. NTX (100 μ M, 10 min) substantially and irreversibly blocked the retinal responses to the nicotinic agonist, dimethylphenylpiperazium (DMPP). The oxidizing compound, dithiobis-(nitro-benzoic acid) (DTNB, 1 mM), transiently and repetitively reversed the action of NTX in chick retina (85% \pm 6, N=7 experiments). However after the application of the alkylating agent bromoacetylcholine (BAC, 100 μ M, in the presence of 1-2 μ M neostigmine), DTNB can no longer restore the function of nicotinic receptors. Both the agonist DMPP (10-300 μ M) and the noncompetitive antagonist hexamethonium (1 mM) partially protected, 74% \pm 16 (N=3) and 78% \pm 15 (N=4), respectively, against the irreversible effects of NTX in chick retina preparations. NTX reversibly displaced the binding of ¹²⁵I-NBT to chick retina homogenates (IC_{50} = 10 μ M). ¹²⁵I-NBT binding was recovered by washing away NTX, and BAC treatment, followed by washing, did not inhibit ¹²⁵I-NBT binding to the chick retina homogenates preincubated with NTX. However, preliminary binding assays indicate that treatment of living retinas with NTX followed by BAC treatment irreversibly inhibits ¹²⁵I-NBT binding. We hypothesize that NTX (or a metabolite) covalently attacks neuronal nicotinic receptors, possibly in the channel or near the agonist binding site, and alters the conformation in such a way that the disulfide bond in the agonist binding site becomes unstable and susceptible to alkylation by BAC. NICOTINIC RECEPTORS THAT BIND α -BUNGAROTOXIN ON NEURONS RAISE INTRACELLULAR FREE CA⁺⁺. S. Vijayaraghavan, M.M. Rathouz, P.C. Pugh*, and D.K. Berg. Dept. of Biology, Univ. of Calif., San Diego, La Jolla, CA 92093.

Many vertebrate cholinergic neurons have a membrane component that binds α -bungarotoxin (α Bgt) with high affinity and has physical properties characteristic of nicotinic receptors. Gene cloning studies indicate that a presumed subunit of the component can function as a ligand-gated ion channel, but no function has yet been demonstrated for the native component *in situ*. We find that the component (α Bgt-AChRs) serves as a nicotinic receptor and increases intracellular free Ca⁺⁺.

Chick ciliary ganglion neurons have high levels of α Bgt-AChRs in addition to a lower level of receptors previously shown to generate nicotinic responses and to bind the monoclonal antibody mAb 35 (mAb 35-AChRs). A fluorescence assay for nicotinic responses was devised by loading cells in culture with fluo-3, a Ca⁺⁺-sensitive fluorescent dye, and relying on AChRs to permit Ca⁺⁺ flux. Nicotine at 0.1-1.0 μ M produced an increase in fluorescence that was blocked by 20 μ M d-tubocurarine and by EGTA, but not by 0.1 μ M atropine or 10 μ M tetrodotoxin. α Bgt blocked the signal with an EC_{50} of 1-2 nM which agreed well with its K_i of 0.7 nM for competition with ¹²⁵I- α Bgt for binding to the neurons. Similarly, methyllycaconitine (MLA) blocked the signal with an EC_{50} of 1-2 nM and had a K_i of 2.8 nM against ¹²⁵I- α Bgt for binding. Neither α Bgt nor MLA acted on mAb 35-AChRs at these concentrations, and neither blocked K⁺-induced fluorescence. Whole cell voltage clamp analysis confirmed that currents induced by low concentrations of nicotine could be blocked in part by α Bgt and that the blockade did not represent α Bgt acting on mAb 35-AChRs. Previous failures to detect α Bgt-AChR function *in situ* probably resulted from assay conditions that allowed other nicotinic receptors to dominate the response. The increase in intracellular free Ca⁺⁺ caused by activation of α Bgt-AChRs may involve more than one mechanism. (Supported by R01 NS12601 & PO1 NS25916)

TISSUE SPECIFIC ALTERNATIVE SPLICING OF THE NICOTINIC RECEPTOR β_4 SUBUNIT GENE. K. E. Isenberg, S. G. Holstad*. Dept. of Psychiatry, Washington University School of Medicine, St. Louis College of Pharmacy, St. Louis, MO 63110.

The neuronal nicotinic acetylcholine receptor (nAChR), a multi-subunit ligand-gated ion channel, is thought to be composed of two types of subunits, an α or acetylcholine binding subunit, and a β or structural subunit. Alternative splicing is a means of regulating gene expression, generating protein products whose functional characteristics may contribute to the specific cellular phenotype. β_4 is a recently described neuronal nAChR structural subunit whose primary transcript may be spliced to generate two different transcripts. These transcripts result in β_4 subunits with significantly different amino termini reinforcing the possibility that selective expression of a transcript product would be tissue specific. We utilized a PCR assay employing primers that would generate a PCR product from mRNA for each of the possible transcripts to measure expression of each transcript. PCR products specific for both β_4 transcripts were synthesized and judged to be the correct products by size and hybridization criteria. Rat brain RNA predominantly generates a larger (356 bp) transcript in the PCR assay while PC-12 cells express both transcripts, a smaller (287 bp) product predominating. The PCR products observed in our assay confirms the proposed complexity of β_4 subunit expression, presumably with functional consequences for the cells expressing the β_4 subunit.

14.12

THE PREDOMINANT HIGH AFFINITY NICOTINIC RECEPTOR IN RAT BRAIN IS COMPRISED OF $\alpha 4$ AND $\beta 2$ SUBUNITS AND IS UP-REGULATED BY NICOTINE. C.M. Flores¹, S.W. Rogers¹, L.A. Pabreza¹, B.B. Wolfe¹ and K.J. Kellar¹. ¹Department of Pharmacology, Georgetown University, Washington, DC 20007¹ and The Salk Institute for Biological Studies, San Diego, CA 92138².

Several different α and β subunit components of neuronal nicotinic receptors have been cloned from rat brain. Although the transcripts for these subunits are expressed throughout the rat CNS, at the protein level neither the precise subunit composition and stoichiometry nor the regional distribution are known. It has also yet to be determined which subtype(s) is up-regulated in response to chronic administration of nicotine. Polyclonal antisera directed against non-homologous regions of the $\alpha 2, 3, 4, 5$ and $\beta 2, 3, 4$ subunits were used in an immunoprecipitation (IMP) protocol to address these issues. Washed membrane homogenates from rat brain were bound with ³H-cytisine, solubilized with Triton X-100 and immunoprecipitated by sequential incubation with antibody and stripped Pansorbin. Non-specific IMP was determined with either pre-immune or normal rabbit sera. Specific IMP was obtained only with sera directed against the $\alpha 4$ and $\beta 2$ subunits. Moreover, pre-clearing solubilized receptor with any of the other antisera did not decrease specifically immunoprecipitable $\alpha 4$ and $\beta 2$. However, specific IMP of both subunits was almost completely abolished by pre-clearing with either anti- $\alpha 4$ or anti- $\beta 2$ sera. These data indicate that in rat brain the predominant if not only subtype of nicotinic receptor with high affinity for agonists is comprised of $\alpha 4$ and $\beta 2$ subunits in association with each other. Furthermore, these subunits exhibit the same regional distribution profile generated by conventional nicotinic agonist binding assays in rat brain homogenates. Additional experiments demonstrated that this $\alpha 4/\beta 2$ subtype is up-regulated in the cortex of rats injected for 10 days with nicotine bitartrate dihydrate (2.0 mg/kg).

EXPRESSION OF AP-1 PROTEINS IN THE RAT SUPRACHIASMATIC NUCLEI DURING THE LIGHT PHASE. W.J. Schwartz, E. Davis,* K. Chase,* & N. Aronin. Depts Neurology & Medicine, U. Massachusetts Med School, Worcester, MA 01655

We (PNAS 87:5959) and others (Exp Neurol 109:353; Neurosci Lett 120:105) have reported a daily rhythm of immunoreactive Fos protein(s) in the rat SCN, with high levels during the light phase of the light-dark (LD) cycle and low levels during the dark phase. This rhythm is not endogenous; both the number of cell nuclei and the intensity of their labeling are reduced to dark phase levels if lights are not turned on at expected dawn and the rats remain in darkness. We now show that expression of c-Fos protein *per se* and AP-1 DNA binding activity both occur in the rat SCN during the light phase of the LD cycle.

In male albino rats entrained to a 12 hr:12 hr LD cycle, SCN c-fos mRNA levels peak 30 min after lights-on (by *in situ* hybridization using a ³²P-labeled rat cDNA probe, gift of T. Curran) whereas levels of Fos protein(s) are greatest 2 hr after lights-on (by immunohistochemistry using an affinity-purified antibody to c-Fos(132-154), gift of S.M. Sagar & F.R. Sharp). Protein from nuclear-enriched SCN cell extracts was obtained during the light phase; Western blot analysis identified the c-Fos protein (~60 kD) as the predominant immunoreactive species, and gel retardation assay demonstrated specific binding to a ³²P-labeled oligonucleotide probe corresponding to the AP-1 consensus sequence. Since Fos binds to the AP-1 site only when complexed as a heterodimer to Jun, the latter results also imply that Jun protein(s) are present in the SCN during the light phase. In rats free-running in constant darkness, high levels of c-fos mRNA and Fos immunoreactivity are expressed after light pulses during subjective night but not subjective day.

Altogether, these data suggest that the immunostaining we see during the light phase probably reflects the occurrence of light at dawn; for animals with $\tau > 24$ hr, a daily phase advance at dawn is required for entrainment to the 24-hr LD cycle.

LIGHT INDUCES PROTO-ONCOGENE EXPRESSION IN GASTRIN RELEASING PEPTIDE NEURONS WITHIN THE SUPRACHIASMATIC NUCLEUS. D.J. Earnest, S.M. DiGiorgio, L.A. Trojanczyk and J.A. Olschowka. Dept. of Neurobiology & Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642

During photostimulation at specific circadian times, the induction of c-fos proto-oncogene expression occurs within the ventrolateral subdivision of the suprachiasmatic nucleus (SCN), coinciding with the terminal fields of fibers that provide the photoentrainable pacemaker in the SCN with light information. Close associations between photic inputs to the ventrolateral SCN and a number of neuronal perikarya containing gastrin releasing peptide (GRP) and vasoactive intestinal polypeptide (VIP) suggest that these SCN neurons may be involved in processing visual information. Consequently, the present study was conducted to determine whether the photostimulation of c-fos expression in the ventrolateral SCN occurs within these populations of peptidergic neurons.

Ten male rats were transferred from LD 12:12 to constant darkness for ~24h, exposed to light for 1h near the mid-subjective night and then perfused for immunocytochemistry. Analysis was conducted to double label Fos protein(s) along with either GRP or VIP in the SCN in brain sections (4 μ m).

In all light-treated animals, SCN cells with Fos-positive nuclei were mainly segregated within the ventrolateral subfield and approximately 25% of these cells also exhibited cytoplasmic immunoreactivity for GRP. In the converse comparison, not all of the GRP neurons in the SCN expressed Fos-immunoreactivity in response to light. No sign of light-induced Fos expression was observed in VIP-positive neurons in the SCN. These results demonstrate that light induces c-fos expression in at least a subpopulation of the GRP-containing neurons in the SCN, suggesting that these cells may be involved in processing entraining light signals. Analysis of the effect of light on c-jun expression in SCN neurons containing GRP or VIP is in progress to complement these observations. Supported by AFSC Grant #90-0182 (D.E.).

LIGHT AND CIRCADIAN PHASE REGULATE JUN-B AND AP-1 EXPRESSION IN THE HAMSTER SUPRACHIASMATIC NUCLEUS. J.M. Kornhauser, D.E. Nelson, K.E. Mayo*, and J.S. Takahashi*. ¹Dept. of Biochemistry, Molecular Biology, and Cell Biology, and ²Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

The suprachiasmatic nucleus (SCN) of the mammalian hypothalamus contains a circadian pacemaker that regulates many physiological and behavioral rhythms. Photic information entrains this pacemaker to the environmental light-dark cycle. A molecular correlate of circadian entrainment has been identified in the regulation of the immediate-early gene c-fos in the rodent SCN by light. Photic induction of c-fos mRNA expression exhibits a circadian phase-dependence and an irradiance threshold matching those of the behavioral effects of light. To determine if another AP-1 transcription factor component is regulated by light in the same manner, we examined the effects of light upon jun-B mRNA in the golden hamster using *in situ* hybridization techniques. Light pulses of 5 minute duration induce a dramatic increase in jun-B mRNA in the SCN; peak jun-B mRNA levels occur 30 minutes following light onset, corresponding to the time-course of c-fos mRNA induction by light. In addition, the ability of light to induce jun-B mRNA in the SCN is gated by the circadian pacemaker. Light pulses during the subjective night that cause phase shifting of activity also induce jun-B mRNA expression; light at circadian times when no behavioral phase shift occurs does not affect jun-B mRNA levels. Since light-induced jun-B and c-fos expression exhibit the same anatomical and temporal specificity, we investigated if light regulates levels of the dimeric AP-1 protein complex. A gel mobility-shift assay was performed on SCN tissue extracts to determine levels of specific binding to an AP-1 oligonucleotide. Light increases levels of AP-1 binding activity in the hamster SCN, and this induction is dependent upon circadian phase. Thus, light may be coupled to coordinated changes in gene transcription mediating circadian entrainment in the SCN.

15.4

THE PUTATIVE SUPRACHIASMATIC NUCLEUS OF BIRDS RESPONDS TO VISUAL MOTION. Josh Wallman, Elizabeth Teakle*, and Rae Silver*. Dept. of Biology, City College, CUNY, New York, NY 10031 and ²Barnard College, Columbia Univ., New York, NY 10027

The mammalian suprachiasmatic nucleus (SCN) is a necessary pacemaker for various physiological and behavioral daily rhythms, and its own circadian rhythms of neural and metabolic activity can be entrained by daily light cycles.

In birds, a nucleus in the lateral hypothalamus has been identified as the avian SCN because it receives retinal afferents and contains neurotransmitters similar to the mammalian SCN, although a non-retinorecipient nucleus more medial and rostral is also a candidate SCN. Recently Rusak, et al. (1990) has shown that the SCN of hamsters and rats expresses the gene c-fos when exposed to light during subjective night, but not during subjective day. To help identify the avian SCN, we have repeated this experiment in chickens.

Chicks with one eye covered by a translucent occluder from hatching were put in darkness. During either subjective night or day the occluder was switched to the other eye and they were exposed either to brightly illuminated surroundings moving vertically at 15 deg/sec or to 10 Hz strobe light for 90 min. Brain sections were reacted with polyclonal antibodies to the protein products of the fos family (provided by R. Bravo, Bristol-Myers Squibb Inst.).

Surprisingly, the lateral nucleus was strongly labeled contralateral to the eye seeing visual motion, but not to the other eye, which saw diffuse light. In stroboscopic illumination, neither lateral nucleus was labeled. The labeling seen was similar to c-fos label in nuclei of the accessory optic system and pretectum known to signal whole-field visual motion (Rojas, et al Soc. Neurosci, 1990). The sensitivity to motion, but not to light, suggests that this nucleus is not the SCN, but may be part of an undiscovered motion pathway.

15.5

IN VIVO ASSESSMENT OF 5-HT AND AMINO ACID METABOLISM IN THE SCN: CORRELATION WITH OVERT CIRCADIAN RHYTHMS. J.D. Glass, U.E. Hauser, J.L. Blank and M.A. Rea. Dept. Biological Sciences, Kent State Univ., Kent, OH 44242. U.S.A.F. School of Aerospace Med., Brooks A.F.B., TX 78235.

In vivo microdialysis was used to characterize serotonergic (5-HT) and amino acid activity in the SCN region of freely-behaving golden hamsters under L:D 14:10. Animals with a microdialysis probe in or near the SCN (n=5) exhibited an apparent circadian rhythm in release of 5-hydroxyindoleacetic acid (5-HIAA), with the peak (127±1.5% of the daily mean) occurring 2 h after lights-off. This peak occurred with the large initial bout of wheel-running activity and 1.2°C rise in core temperature. The increase in 5-HIAA may reflect enhanced 5-HT synaptic activity, since the suppressive effect of the 5-HT reuptake blocker, citalopram, on 5-HIAA was greater during the dark phase than light phase (52.9±2.1% vs 80.0±9.0% of baseline; p<0.05). Amino acid neurotransmitters glutamate (GLU) and aspartate (ASP) in SCN dialysates also exhibited apparent circadian fluctuations with peaks during the dark phase. The GLU peak (239±68% of the daily mean) occurred 5 h after lights-off and gradually declined to daytime levels by morning. This peak was not associated with motor activity. Release of ASP was elevated throughout the dark phase, and glutamine was linear throughout the experiment. The differences in activities of 5-HT, GLU and ASP is evidence for a diversity of function of these substances in the SCN. AFOSR 440785 (J.D.G.) & AFOSR 2312W6 (M.A.R.).

PROPERTIES OF CULTURED SUPRACHIASMATIC NEURONS. D. K. Welsh and S. M. Reppert. Laboratory of Developmental Chronobiology, Massachusetts General Hospital, and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

The suprachiasmatic nucleus (SCN), site of a circadian clock, contains a heterogeneous population of neurons and glia. Which cell types are essential for clock function is not known. Also unknown is whether the clock emerges from specific patterns of connections in a neuronal network, or whether it consists of a coupled population of independent cellular oscillators. As an initial approach to these questions, we are examining the properties of dissociated SCN neurons in long-term culture. Neurons were dissociated from newborn rat SCN using papain, and plated on poly-D-lysine and laminin in medium containing 5% rat serum. Approximately 2/3 of dissociated neurons attached to the substrate, 1/2 of these were viable at 2 days, and 90% of the remaining neurons were still alive after 3 weeks in culture. Survival was clearly inferior in serum-free medium. Insulin-like growth factors (IGF-I, IGF-II) were no more effective than insulin in promoting cell survival in serum-free medium. IGF-I (10 nM) was less effective than insulin (1 µM; p=.01), whereas IGF-II (10 nM) was just as effective. Addition of nerve growth factor (NGF) promoted neurite outgrowth and fasciculation but did not improve survival. Preliminary morphological and immunocytochemical findings are consistent with known *in vivo* properties of SCN neurons. Whole cell patch recordings indicate that some SCN neurons fire spontaneous action potentials in culture. We are therefore testing the feasibility of long-term, multi-electrode recording of spontaneous activity in cultured SCN neurons.

15.9

NEURONAL CIRCUITRY INVOLVED IN CIRCADIAN RHYTHM REGULATION CHARACTERIZED BY TRANSNEURONAL PASSAGE OF PSEUDORABIES VIRUS. R.Y. Moore, J.C. Speh, L.W. Enquist* and J.P. Card. Univ. of Pittsburgh, Pittsburgh, PA 15261 and DuPont Merck Pharmaceutical Co., Wilmington, DE 19880.

Intraocular injection of an attenuated pseudorabies virus strain (Bartha, PRV-Ba) results in infection of a distinct class of ganglion cells with subsequent transneuronal passage of virus to centers of the circadian timing system, the suprachiasmatic nucleus (SCN) and the intergeniculate leaflet (IGL) of the lateral geniculate complex (Card et al. Neuron, in press). PRV-Ba is not transported by ganglion cells projecting to the dorsal lateral geniculate nucleus or superior colliculus. In the present study we have extended the post-injection interval to further define the neuronal circuits labeled by transneuronal passage of virus through the SCN and IGL. Labeled neurons are found in a series of basal telencephalic, diencephalic and brainstem cell groups including the septal nuclei, organum vasculosum lamina terminalis, medial preoptic area, anterior hypothalamic area, lateral a area, retrochiasmatic area, ventromedial and dorsomedial nuclei, perifornical and dorsal hypothalamic areas, periaqueductal gray, reticular formation, raphe nuclei and laterodorsal and pedunculopontine tegmental nuclei. The pattern of labeling is complex but its continuing analysis should provide further insight into pathways by which the SCN regulates physiological and behavioral rhythms. (Supported in part by NIH grant NS-16304 and by DuPont Merck Pharmaceutical Co.)

ENCAPSULATED FETAL SCN GRAFTS SURVIVE TRANSPLANTATION TO THE VENTRICLE. R. Silver¹, J. Le Sauter¹, M.T. Romero¹, P. Aebischer³ and M.N. Lehman². ¹Barnard College of Columbia Univ., New York, NY 10027, ²Univ. Cincinnati Coll. Med., Cincinnati, OH 45267, ³Brown Univ., Providence, RI 02912.

In mammals, a circadian pacemaker has been identified in the suprachiasmatic nucleus (SCN) of the hypothalamus. Ablation of this nucleus results in the loss of circadian rhythms of locomotor activity, and this response is restored following placement of intraventricular grafts of fetal hypothalamic tissue containing the SCN. In order for transplanted tissue to restore activity rhythms, the grafted SCN presumably sends a signal to appropriate target brain regions. Tract-tracing for neural efferents from intraventricular SCN grafts reveals scant neural connections with host brain (Canbeyli et al., Br. Res. in press). To set the stage for analysis of a diffusible signal(s) from the SCN, we encapsulated fetal SCN tissue within permeable acrylic copolymer tubes with a nominal molecular weight cut-off of 50,000 daltons, allowing nutrients, growth factors and transmitters to diffuse freely. The tubes were sealed with bone wax and compatible polymer glue and implanted stereotactically in the third ventricle of SCN-X hamsters. Encapsulated E15 whole tissue grafts or cell suspension grafts of fetal SCN transplanted into the 3rd ventricle of adult hamsters survive and develop VIP-immunoreactivity. Immunostaining for 5HT reveals fibers in host brain that do not cross the capsule wall. In the next series of experiments, the capacity of encapsulated grafts to restore locomotor rhythms in SCN-lesioned hamsters will be examined. (Support: NIH NS 24292).

ULTRADIAN CALCIUM OSCILLATIONS IN SUPRACHIASMATIC NUCLEUS CELLS. A.N. van den Pol, A. Cornell-Bell, S. Finkbeiner. Sect. Neurosurgery, Cell Biol., Molec. Neurobiol., Yale University, New Haven, Ct. 06510.

To study cellular ultradian oscillators, which have been postulated to underlie circadian clocks, we used digital video microscopy to examine calcium fluctuations in cultured suprachiasmatic (SCN) cells with the Ca²⁺ indicator dye fluo-3. SCN neurons and astrocytes showed an intracellular Ca²⁺ increase in response to glutamate and serotonin. Expression of regular neuronal oscillations (periods about 15 sec) could be blocked by the inhibitory transmitter GABA. Astrocytes showed very regular rhythms of cytoplasmic Ca²⁺ concentrations with periods ranging from 7 to 20 seconds. These periodic Ca²⁺ oscillations could be initiated by *in vitro* application of glutamate, a putative retinohypothalamic transmitter. Cellular Ca²⁺ oscillations arose from intracellular Ca²⁺ stores, and could be induced by neurotransmitters in the absence of extracellular Ca²⁺. Communication between glial cells capable of increasing the period length of cellular Ca²⁺ oscillations to 45 to 70 sec, mediated via gap junctions, could be induced by SCN neurotransmitters. These results show that both neurons and glia in the SCN exhibit regular ultradian oscillations which can be influenced by SCN transmitters. The interaction of these ultradian oscillators may play a role in SCN function.

15.10

DOES THE FETAL CIRCADIAN CLOCK PLAY A ROLE IN THE TIMING OF BIRTH? N. Viswanathan and F.C. Davis. Department of Biology, Northeastern University, Boston, MA 02115.

In rodents, a circadian clock begins to oscillate prenatally and is entrained by maternal rhythm(s). A hypothesis for the function of such prenatal maternal entrainment is that the fetal clock plays a role in the circadian timing of birth; i.e., the entrainment by the mother makes the fetus aware of the time of day. Prenatal injections of melatonin to the mother hamster can predictably set the phases of her offspring's circadian rhythms. It is possible that the prenatal injections of melatonin to the mother would affect the timing of birth. We examined this possibility in two groups of SCN-lesioned, pregnant syrian hamsters which received daily subcutaneous injections of melatonin on days 9-15 of gestation. One group received melatonin injections in the morning and the other in the evening. Following the last set of injections, animals were observed every hour until birth. The timing of birth was *not* significantly different between the two groups although the pups' activity rhythms at weaning were found to be related to the timing of melatonin injection. The results indicate that the fetal clock entrained by the exogenous melatonin is unable to influence the timing of birth. Preliminary studies using mutant *tau* hamsters born to wild-type mother also suggest that the fetal clock has no role in the timing of birth. Supported by NIH grant HD 18686 to FCD.

USE OF SILICON-BASED MULTICHANNEL MICRO-ELECTRODES TO CHARACTERIZE SINGLE-UNIT ACTIVITY OF NEURONS IN THE RAT SUPRACHIASMATIC NUCLEUS. M.N. Ghazzi*, K.D. Wise*, D.J. Anderson, S.W. Newman and A.R. Miggley Jr*, Rep. Sci. & Bieng. Prog. Univ. Michigan, Ann Arbor, MI 48109.

The nature of neuronal interactions that generate oscillatory rhythms and light responsiveness of suprachiasmatic nucleus (SCN) neurons are not understood. For example, although some SCN neurons have been previously classified as light-inhibited, the bursting pattern of these neurons has not been characterized. This study attempts to characterize neuronal interactions and light response properties of monitored SCN neurons. Miniature solid state electrodes (15 μm by 35 μm by 15 mm) with five 36 μm^2 recording sites spaced 100 μm apart were used for recordings of up to 8h. Probes were inserted stereotaxically into the SCN of urethane-anesthetized, mature, male, Sprague Dawley rats (12h light:12h dark). The recorded signal was buffered, amplified, filtered, and connected to a custom-designed, computerized, data acquisition system for analysis. In response to 10 min of light exposure at 1500 lux, some SCN neurons showed a reduction in spike rate. Closer examination, however, revealed that the decrease in overall spike rate for some of these "light inhibited" SCN neurons was accompanied by an increase in average number of spikes per burst. Analysis of spontaneous firing of neurons not exposed to light indicated that both inhibitory and excitatory interactions exist between SCN neurons. In some of these neurons the latency period between the firing of the leading and the lagging neuron was observed to shift intermittently from 4.5 ms to 5.5 ms to 4.5 ms. This suggests that a multi-path interactive mechanism may be involved in oscillatory SCN behavior. Thus, multichannel single-unit recording electrodes coupled with computerized data analysis revealed neuronal interactions otherwise indecipherable by conventional techniques. (5K11 HD00828-04)

BRAIN METABOLISM AND BLOOD FLOW I

16.1

THE PHASIC INCREASE IN CBF BY ENDOTHELIN IS MEDIATED BY THE RELEASE OF NITRIC OXIDE THROUGH AN ACTIVATION OF NMDA RECEPTORS. K. Nakai, M. Nakai*, K. Kubo*, T. Okuno, T. Itakura*, S. Hayashi*, N. Komai* Dept. Neurol. Surg., Wakayama Med. Col., Wakayama Japan

We have demonstrated a several minutes-long phasic increase in the regional cerebral blood flow (rCBF) with remarkably dilated parenchymal blood vessels by the intracortical injection of endothelin (ET), in spite of its strong vasoconstrictive activity (Nakai et al., *Neurosci. Abst.* 1989). Similar study using NMDA instead of ET also showed the phasic increase in the rCBF and dilated parenchymal blood vessels as well (Nakai et al., *Neurosci. Abst.* 1990). Present study tried to elucidate the underlying mechanism to cause such phasic increase in the blood flow caused by these two particular chemicals. After the intraperitoneal injection of MK801 (2mg/kg) or an inhibitor of the nitric oxide (NO) formation (NO₂arginine, 5mg/kg), parietal cortices of S-D rats were injected with either ET (1x10⁻⁴-6.8M) or NMDA (1x10⁻³-4.9M) at a constant rate (1 μl /10 min) through a glass capillary. Throughout the course of experiment rCBF was monitored by laser flowmetry. Higher doses of each chemicals (ET 1x10⁻⁴-9M, NMDA 1x10⁻³-4M) injected intracortically caused the phasic increase in the rCBF for a few minutes. Pretreatment of MK801 suppressed the phasic increase caused by NMDA (1x10⁻³-4M). Interestingly, the phasic increase by ET was significantly suppressed by the pretreatment of MK801, when the blood vessels in the vicinity of injection site were not remarkably dilated any more. There was no phasic increase in rCBF in animals pretreated with NO₂arginine under all doses of ET and NMDA examined in this study. Above results suggest that the temporary vasodilatory action of ET on the brain blood vessels is primarily mediated by NMDA receptor activation leading to a release of NO either from the neurons, as was reported by Garthwaite (Nature 1988), or from the vascular endothelium in the brain parenchyma.

16.3

COUPLING OF REGIONAL CEREBRAL METABOLISM AND BLOOD FLOW IN THE CONSCIOUS RAT IS MAINTAINED AFTER TREATMENT WITH THE MUSCARINIC AGONIST ARECOLINE. K. Maiese, H.W. Holloway*, D.M. Larson*, D.J. Reis, and T.T. Soncrant, Div. of Neurobiol., Cornell Univ. Med. Coll., NY, NY 10021 and Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892.

The muscarinic cholinergic agonist arecoline (AREC) selectively increases local cerebral glucose utilization (LCGU) in the conscious rat (Soncrant, T.T. et al., *Brain Research*, 347:205-216, 1985). We sought to determine whether these focal increases in metabolism were coupled to, or independent of, local cerebral blood flow (LCBF). In groups of young Fisher-344 rats, LCGU and LCBF were determined in 60 brain regions by the ¹⁴C 2-deoxyglucose and the ¹⁴C iodoantipyrine autoradiographic methods at three minutes following administration of normal saline, AREC 1mg/kg, and AREC 15mg/kg i.p. Each rat was pretreated with methylatropine 4mg/kg s.c. to reduce systemic parasympathetic discharge. In saline treated rats, LCBF was correlated with LCGU ($r=0.838$, $p<0.01$). AREC 1mg/kg produced only small changes in blood flow and metabolism, but the two parameters remained closely related ($r=0.891$, $p<0.01$). In contrast, AREC 15mg/kg yielded widespread (mean 242%) but regionally heterogeneous (range 130%-361%) increases in LCBF, and LCBF remained coupled to LCGU ($r=0.803$, $p<0.01$). Maintenance of coupling between LCGU and LCBF indicates that changes in LCBF following arecoline administration reflect regional drug effects on brain function.

16.2

CEREBRAL HYPEREMIC RESPONSES TO HYPOGLYCEMIA (HG) VS HYPOXIA (HX): ROLE OF ADENOSINE (ADO). D.A. Pelligrino and A. Sharp, Dept. of Anesthesiol., Univ. of Ill./Humana-Michael Reese Hosp., Chicago, IL 60616.

In the present study, we sought to determine whether ADO receptor (R) blockade, via 8-phenyltheophylline (8-PT), could attenuate the regional cerebral blood flow (rCBF) increases that accompany HG in the rat. Previous work has established a significant role for ADO in the rCBF increases associated with HX. Thus, to confirm the efficacy of 8-PT in blocking ADO-R mediated rCBF responses in our experimental system, the influence of 8-PT on the cerebral hyperemic response to HX also was evaluated. For study, the rats were anesthetized (fentanyl/70% N₂O), paralyzed and mechanically ventilated. rCBF was measured in the cortex, subcortex, brainstem, and cerebellum using radiolabeled microspheres. One μl 8-PT (10 $\mu\text{g}/\text{kg}$) or vehicle (VEH) was administered into a lateral cerebral ventricle (icv). In HX, injections were given following an initial rCBF measurement. rCBF was then measured at 10 min post-injection (normoxia) and at 10 min HX (PaO₂=30-35 mmHg). In HG, rCBF was measured prior to iv insulin and when plasma glucose (G) reached 1.5 mM. 8-PT or VEH was given and rCBF evaluated after 15 min (with G clamped at 1.5 mM) and 30 min (G permitted to fall to 1 mM). During HX, 8-PT produced a 50-60% attenuation of the normal 3-5 fold rCBF increase in all regions, indicating the efficacy of our protocol to induce ADO-R blockade. On the other hand, in HG, 8-PT had no effect on the 2-4 fold rCBF increases seen in VEH-injected rats at G=1.5 mM, but was associated with a 40-60% attenuation of the 4-6 fold rCBF increase normally observed at G=1 mM. Thus ADO appears to play a role in mediating rCBF increases only during severe HG, when G approaches or exceeds coma threshold.

16.4

BASAL FOREBRAIN (BF) REGULATION OF CORTICAL CEREBRAL BLOOD FLOW (CBF): EFFECTS OF AGING AND CHRONIC NICOTINE TREATMENT. D.G. Limville, S. Williams*, M.J. Malchrzak, J.L. Raszklewicz* and S.P. Americ*, Neuroscience, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL 60064-3500, and Dept. of Pharmacology, Southern Illinois University School of Medicine, Springfield, IL 62702.

Microstimulation of BF elicits profound increases in cortical CBF (*Excerpta Int. Cong. Series* 869:381, 1989). This response is enhanced by acute (-)nicotine (NIC) (*Soc. for Neurosci.* 16:129.9, 1990). Conversely, it shows age-related impairments, but is largely preserved in the frontal cortex (*Neurobiol. Aging* 11:73, 1990). This study sought to determine: Is the enhancement in cortical CBF elicited by NIC preserved following subacute administration? If so, is it effective in aged rats? Sprague-Dawley (3 or 18 mo.) rats were implanted with pellets delivering either placebo or 1.2 mg NIC/day (Innovative Research). After 14 days rats were anesthetized (urethane), paralyzed, artificially ventilated and arterial blood gases controlled. Resting and BF-elicited increases in cortical CBF were assessed using laser-doppler flowmetry on the dural surface (1.5 mm rostr. & 3.3 mm lat. to bregma). Unilateral electrical stimulation (100 μA ; 10 sec.; 6.25-50 Hz) of BF resulted in graded increases in CBF (up to 240% of resting). Acute infusion of NIC (12.5-200 $\mu\text{g}/\text{kg}$, iv) to 3 mo. rats further enhanced the responses by 100-500%; greatest enhancement was at lower Hz ($N=7$; $p<0.05$). Subacute NIC showed a remarkable, although diminished effect to acute NIC administration (50-350% enhancement). In aged rats the enhancement by acute NIC was similar following placebo or subacute NIC treatment ($N=5$), although diminished with respect to 3 mo. rats (50-350% enhancement). **CONCLUSION:** Cortical CBF governed by the BF is facilitated by NIC following acute and, although somewhat diminished, subacute administration. Aged rats have a diminished response to acute NIC, but are not further diminished by subacute NIC. (Support: ABBOTT & NIA Grant P-30 AG0 8014-01A1)

16.5

BASAL FOREBRAIN (BF) REGULATION OF CORTICAL CEREBRAL BLOOD FLOW (CBF): MODULATION BY SUBTYPE-SELECTIVE NEURONAL NICOTINE RECEPTOR AGONISTS. S.P. Americ, D.G. Linville, S. Williams, and J. Raszklewicz. Neuroscience, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL 60064-3500, and Dept. of Pharmacology, Southern Illinois University School of Medicine, Springfield, IL 62702.

Chemical and electrical microstimulation of the BF elicits profound increases in cortical CBF (Americ, *Excerpta Int. Cong. Series* 869:381, 1989), an effect that is enhanced by nicotinic receptor activation (Linville & Americ, *Soc. for Neurosci.* 16:129.9, 1990). The existence of multiple neuronal nicotinic receptors (nAChRs) in brain is supported by molecular biological and pharmacological evidence. Recently, Luetjé & Patrick (*J. Neurosci.* 11:837, 1991) have shown that nAChRs containing beta4 subunits are remarkably more sensitive to (-)cytisine (CYT) than (-)nicotine (NIC). This study sought to determine: Is the enhancement in cortical CBF elicited by nicotinic agonists linked to beta2 or beta4 containing nAChRs? Resting and BF-elicited increases in cortical CBF were assessed using laser-Doppler flowmetry. Sprague-Dawley rats (3-5 months) were anesthetized (urethane), paralyzed, artificially ventilated and arterial blood gases controlled. Flow probes were stereotaxically positioned on the dorsal surface (2.5 mm rostral & 2.6 mm lateral to Bregma). Unilateral electrical stimulation (100 uA; 10 sec.; 6.25-50 Hz) of BF resulted in graded, stimulus-locked increases in CBF (up to 271% above resting control). Infusion of NIC (50-200 ug/kg, iv) further enhanced the responses by another 100-300%; greatest enhancement was at lower Hz. CYT had a biphasic effect, with modest enhancement (30-40 %) at low doses (0.2-3 ug/kg), while the response was inhibited by 50% at 200 ug/kg. These data indicate that control of the cortical cerebral circulation by the BF is facilitated by nicotinic receptor agonists similar to NIC, not CYT. These data also suggest this response is mediated predominantly by nAChRs containing beta2, not beta4, subunits. (Support: ABBOTT & NIA Grant P-30 AGO 8014-01A1)

16.7

THREE-DIMENSIONAL RECONSTRUCTION OF DORSAL RAPHE NUCLEUS CEREBROVASCULAR REGULATORY SUBREGIONS IN RAT. M.D. Underwood, M.J. Bakalian, V. Arango, R.W. Smith and J.J. Mann. Labs. of Neuropharmacology, Univ. of Pittsburgh, Pittsburgh, PA 15213.

We have previously reported that electrical stimulation of the dorsal raphe nucleus (DRN) in rat elicits either decreased or increased local cortical blood flow (CrtBF) as measured by laser Doppler flowmeter (*Soc. Neurosci. Abstr.* 16: 290, 1990). We sought to determine whether the different effects on CrtBF could be explained by activation of different subregions of the DRN.

Animals were anesthetized (chloralose), paralyzed and ventilated. Arterial pressure (AP), heart rate and arterial blood gases were continuously monitored and controlled. The DRN was stimulated electrically (10 min; 1 sec on/1 sec off; 100 uA; 200 Hz) and CrtBF was measured with a laser-Doppler flowmeter. Marker lesions (200 uA, 10 sec) were made in all animals. A composite of electrode placements in DRN was reconstructed in 3-dimensions using a PC-based system based on data from Nissl-stained serial sections (25 um).

A marked difference in cerebrovascular response was observed depending on the rostrocaudal placement within the DRN. Stimulation within rostral portions of DRN elicited a slow onset sustained decrease in CrtBF (85 ± 4% of baseline; p < 0.05; n = 9). In contrast, stimulation in caudal DRN with identical stimulus parameters resulted in increased CrtBF (126 ± 6% of baseline; p < 0.05; n = 5). The different cerebrovascular responses could not be attributed to differences in arterial pressure, blood gases or hematocrit between groups.

We conclude that electrical stimulation of the DRN can evoke either increases or decreases in CrtBF depending on the anatomical sublocalization and is evidence for a functional topographical organization of the DRN. (Supported by PHS grant MH46745)

EDRF PARTICIPATES IN THE NEOCORTICAL VASODILATION ELICITED BY STIMULATION OF THE FASTIGIAL NUCLEUS. C. Iadecola, Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Electrical stimulation of the cerebellar fastigial nucleus (FN) increases cerebral blood flow (CBF) globally and maximally in neocortex, wherein the vasodilation is dependent on local release of acetylcholine (ACh). In brain as in other organs ACh probably mediates vasodilation through an endothelium-derived relaxing factor (EDRF), a substance, thought to be nitric oxide (NO), which induces smooth muscle relaxation by stimulating guanylyl cyclase (GC). We used the specific inhibitor of EDRF/NO synthesis N^G-nitro-L-arginine (NA) and the GC inhibitor methylene blue (MB) to determine whether EDRF/NO participates in the cortical vasodilation elicited by FN stimulation. Rats were anesthetized (halothane: 1-3%) and ventilated. FN or pontine reticular formation (PRF) were stimulated through microelectrodes. Hypertension was prevented by spinal cord transection with arterial pressure maintained by i.v. phenylephrine. Aerated Ringer (37°C) with and without MB or NA was superfused on the parietal cortex wherein CBF was monitored by laser-Doppler flowmetry. With normal Ringer superfusion FN stimulation (100uA; 50Hz) increased CBF by 86±7% (n=26; p<0.01, ANOVA) and PRF stimulation (100uA; 100Hz) by 128±18% (n=9; p<0.01). Superfusion with MB (10⁻³ M) did not change resting CBF but attenuated the CBF increase elicited by FN stimulation by 80±4% (n=15; p<0.01). MB did not affect the CBF increase elicited by PRF stimulation (+98±18%; n=9; p>0.05) or hypercapnia (+97±16%; pCO₂: 54±4; n=11). Similarly, NA attenuated the CBF increase elicited by FN stimulation (-67±5%; n=11; p<0.01 from Ringer) but not PRF stimulation (+104±14%; n=9; p>0.05). Thus, the neocortical vasodilation elicited by FN stimulation is substantially attenuated by inhibition of NO synthesis or action. Such attenuation is not a consequence of impaired vascular reactivity as the vasodilation evoked from the PRF or hypercapnia is not affected. The results strongly suggest that the vasodilation elicited by FN stimulation is mediated by EDRF/NO and raise the possibility that EDRF/NO may also be important in the regulation of the cerebral microcirculation.

16.6

CLOMIPRAMINE, A TRYCYCLIC ANTIDEPRESSANT, DOSE-DEPENDENTLY REDUCES LOCAL CEREBRAL GLUCOSE METABOLISM IN AWAKE RATS. U. Freo, M. Dam*, G. Pizzolato*, G. Chinaglia*, S. Ruggiero*, P. Pietrini#, and L. Battistin*. Neurology Department of Padova University, 35100 Padova, and #Psychiatric Department of Pisa University, 56100 Pisa, ITALY.

The relation of dose to regional cerebral metabolic rates for glucose (rCMRglc) were measured in awake male 3-month-old Fisher-344 rats after administration of clomipramine (CMI), a 5-HT uptake inhibitor used as an antidepressant and antiobsessive drug. Using the quantitative autoradiographic [¹⁴C]2-deoxyglucose technique, rCMRglc was determined in 47 brain regions 2 hours after intraperitoneal administration of 2, 10 or 50 mg/kg of CMI.

At the lower doses (2 and 10 mg/kg), CMI reduced rCMRglc in 12 (29%) and 14 (32%) brain regions, respectively. These areas belong to limbic (hippocampus, amygdala basolateral) and visual (superficial layer of superior colliculus, lateral geniculate, visual cortex) regions, locus coeruleus and raphe (dorsal and median) nuclei. Limbic regions as well as raphe nuclei and locus coeruleus are involved in mood regulation and possess high concentrations of 5-HT uptake sites. High dose CMI (50 mg/kg) produced a more widespread rCMRglc reduction (28 brain regions; 59%). Most of these latter regions were diencephalic and telencephalic projection areas of serotonin fibers arising from raphe nuclei system. Therefore, CMI affects areas associated with regulation of mood and control of behavior.

16.8

EXCITATION OF NEURONS OF DISCRETE REGION OF VENTROLATERAL MEDULLA MODIFY CEREBRAL BLOOD FLOW, BUT NOT METABOLISM, DEPENDENT UPON PROSTAGLANDIN(S) AND NO. E.V. Golanov*, M. Springston, S.B. Berger, D.A. Ruggiero, R. Blasberg, M. Itkis and D.J. Reis, Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Stimulation within areas of ventrolateral medulla (VLM) modifies arterial pressure, respiration and, conceivably, cerebral blood flow (Underwood et al., 1990). To assess the topographic organization of the cerebrovascular response, we examined the effects of excitation of the VLM on regional cerebral blood flow (rCBF) in frontal cortex of anesthetized, spinalized rats. Site-specific electrical stimulation of VLM increased rCBF, measured with a laser Doppler flowmeter, up to 260±40% of control (n=12). With a 10 sec stimulus (60Hz, 3x threshold current), the onset was between 5 and 10 sec and maximum responses were reached at 30-40 sec, persisting for >5 min. rCBF was comparably elevated by microinjection of glutamate (20nl, 15ug) or kainic acid (20nl, 0.4ug). The active zone was caudal to and distinct from the cardiovascular zone of rostral VLM. The evoked rCBF response was reduced by 57% with indomethacin (10mg/kg, i.v.; n=7) and 70% by blockade of NO synthesis with NMMA (30mg/kg, i.v.; n=5). Autoradiographic analysis of rCBF in cortex and glucose utilization by [¹⁴C]-2-deoxyglucose (n=6) demonstrated a significant (p<0.01) increase in rCBF unassociated with changes in glucose utilization. Neurons in VLM distinct from those regulating AP may regulate rCBF independently from metabolism by mechanisms largely dependent upon release of prostaglandins and NO.

BLOOD FLOW INCREASES IN RAT BARREL CORTEX DURING WHISKER STIMULATION. S.B. Cox*, T.A. Woolsey and C.M. Royvainen. Depts. Neurosurgery and Cell Biology, Washington Univ. Sch. of Med., St. Louis, MO 63110

We used videomicroscopy of the rat barrel cortex and natural stimulation of the whiskers to test the hypothesis that functional groups of neurons are linked to discrete groups of cortical vessels. These experiments extend previous studies by Winn *et al.* (1991). Our model is that one of a few penetrating pial arterioles supply each barrel, a group of cells that is activated by a vibrissa. Adult female rats were fitted with a closed cranial window over the barrel cortex. Vessels were imaged using a fluorescence microscope with a SIT or ICCD camera, and analyzed by computer. This provided an *in vivo*, instantaneous and continuous, record of vascular changes during stimulation. Following intravascular injection of fluorescent dextrans and 3um latex beads, changes in vessel diameter, arterial-venous transit time, and bead velocity were used to measure changes in blood flow. The row C whiskers were stimulated at 5 Hz for 1 min by stroking. All measured parameters for blood flow gave similar results: blood flow increases with whisker stimulation. The vessels in which flow increased supplied the appropriate barrels which were identified histologically. Increases in blood flow were not observed in vessels that supplied other cortex. Apnea increased blood flow more dramatically than whisker stimulation. The increases occurred throughout the arterial tree and independent of barrel location. Increases in local cerebral blood flow with whisker stimulation demonstrate a functional link between cerebral vascular units and corresponding cortical modules. This provides a basis for focal regulation of cerebral blood flow.

CUTANEOUS STIMULATION REGULATES REGIONAL CEREBRAL BLOOD FLOW IN ANESTHETIZED RATS.

O.Inanami¹*, K.Ohno²* and A.Sato¹. ¹Dept. of Autonomic Nervous System, Tokyo Metropolitan Institute of Gerontology, Tokyo 173. ²Dept. of Neurosug., Tokyo Dent. Med. Univ., Tokyo 113. Japan.

In previous study¹, the effects of pinching of a forepaw on cerebral blood flow (CBF) in the cortex were examined using laser Doppler flowmetry in halothane anesthetized, spinalized rats (transection at the first thoracic (T1) level) after eliminating pressor responses to pinching. It was demonstrated that the pinching of the forepaw produced a significant increase in CBF in the cortex irrespective of responses of systemic blood pressure (BP). The present experiment further evaluated whether pinching of the forepaw for one min influences regional CBF (rCBF) in various other brain regions in the anesthetized, spinalized rats. Bilateral rCBFs in a total of 27 brain regions on the one side were examined with autoradiography using [¹⁴C]iodoantipyrine. There were remarkable increased responses of rCBF in the bilateral cerebral cortex, caudate nucleus, hippocampus, thalamus and midbrain, but there were no regions to show the decrease. These results indicate that pinching stimulation of the forepaw produces widespread increases in rCBF bilaterally, but not decreases, irrespective of BP.

SPINAL CORD BLOOD FLOW FOLLOWING A COMPLETE LOW THORACIC TRANSECTION. O.U.Scremin, D.Heuser*, E.Romero* and E.Duran*. V.A.Medical Center and University of New Mexico School of Medicine, Albuquerque, NM 87108.

Profound alterations in functional activity of the spinal cord are observed below a complete transection (SCT). All reflexes are depressed within 24 hrs after SCT while enhanced reflex activity and new reflex modalities are present 4 weeks later. The status of spinal cord blood flow (SCBF) was investigated with the autoradiographic Iodo-¹⁴C-antipyrine technique, above and below a Th9 level SCT in 3 groups of 6 rats: non-transected controls, 24 hrs and 4 weeks after SCT. SCBF was measured in ventral (VC), lateral (LC) and dorsal (DC) column, ventral horn (VH) and dorsal horn (DH) at cervical (C), thoracic above SCT (Th) and lumbar (L) levels. SCBF of untreated controls were (ml*g⁻¹*min⁻¹, Mean±S.E.) CVC= .35±.07, CLC= .31±.03, CDC=.22±.04, CVH= 1.14±.18, CDH= 1.06±.19, ThVC= .29±.06, ThLC= .22±.05, ThDC= .19±.04, ThVH=.83±.15, ThDH=.84±.14, LVC= .41±.08, LLC= .44±.11, LDC= .33±.09, LVH= 1.38±.21, LDH= 1.25±.20. Statistical differences were assessed by ANOVA followed by Tukey's protected t. No significant differences with regard to controls were observed for any of the regions 24 hrs after SCT. At 4 weeks post-SCT, white matter regions of cervical (CLC= .64±.1, p<.025) and thoracic cord (ThLC= .58±.08, p<.01; ThDC= .52±.07, p<.01) showed higher SCBF than untreated controls. In conclusion, no variations in SCBF of white or gray matter were observed below SCT at 24 hrs or 4 weeks post-SCT in spite of large differences in reflex patterns. White matter columns above the level of SCT demonstrated about 100% increase in SCBF. It is hypothesized that this phenomenon may be related to degeneration/regeneration processes in white matter columns.

MISMATCH OF ELECTRICAL AND ACOUSTIC TUNING IN COCHLEAR HAIR CELLS OF THE ALLIGATOR LIZARD. R.A. Eatock and M. Saeki. Department of Physiology, University of Rochester, Rochester, NY 14642-8642.

In the "free-standing" region of the alligator lizard's cochlea, hair cells are tuned to sound frequencies between 1 and 4 kHz. It has been proposed that the acoustic tuning of these cells derives largely from micromechanical resonances of their hair bundles (Weiss and Leong, *Hearing Res.* 20:157,1985). In cochlear hair cells of turtles and some other species, acoustic tuning may instead arise from electrically resonant properties of the cell membrane (e.g., Fettiplace, *Trends Neurosci.* 10:421, 1987). Such electrical resonance has been documented only in hair cells tuned to frequencies below 500 Hz. To probe a higher frequency range and to look for potential interactions between micromechanical and electrical tuning mechanisms, we have examined electrical resonance in hair cells isolated from the free-standing region of the lizard's cochlea. Using conventional and perforated-patch whole-cell recording, we find that depolarizing current steps evoke lightly damped voltage oscillations at frequencies well below the acoustic characteristic frequencies of the free-standing region. Unlike turtle cochlear hair cells, the lizard's cells do not exhibit voltage oscillations spontaneously but only in response to injected currents $\geq +50$ pA. For 8 free-standing hair cells the mean electrical quality factor (Q) was 8 ± 2.4 (SEM) and the mean electrical resonant frequency was 134 ± 19.2 Hz (range 36-205). (For all cochlear hair cells, some of which may not be free-standing, the mean Q was 14 ± 4.8 (n=21), and the mean resonant frequency was 141 ± 11.3 (range 27-224).) Thus the electrical resonance of isolated free-standing hair cells is not congruent with their *in vivo* acoustic tuning, indirectly supporting the proposal that micromechanical mechanisms determine acoustic tuning in these cells. *Supported by NIH.*

A STOCHASTIC MOTOR THEORY OF COCHLEAR OUTER HAIR CELL MOTILITY. B.N. Evans, R. Hallworth and P. Dallos. Auditory Physiology Lab. (The Hugh Knowles Center) and Dept. Neurobiol. & Physiol., Northwestern Univ., Evanston, IL 60208.

The nature of the mechanism that generates electrically-induced length changes in isolated cochlear hair cells is unknown. Using the microchamber method, we have previously described the relationship between the applied voltage command and the length change (Evans et al., *Hear. Res.* 52, 288-304, 1991). The function is nonlinear over its entire range and saturates in both the contraction and extension directions. The length change function may be described by a second-order Boltzmann equation, although in many cells a first-order equation is a good approximation.

By varying the partitioning of the cell in the microchamber, we have demonstrated that the cell segments contract or extend independently as a function of the local membrane potential (Hallworth et al., *Soc. Neuro. Mtg.*, 1990). This suggests the existence of a large number of independently-acting motor elements. Considering this concept, together with the saturation property of the mechanism and its characterization, we propose a stochastic model of outer hair cell motility. By analogy with voltage-dependent ion channels, we suggest that the mechanism consists of a large number of molecular motors which fluctuate between two states, "long" and "short". The constants governing the rates of transition between the states are modulated by the membrane potential. The observed length change is therefore the statistical sum of the motor states.

Our previous studies also suggested a motor mechanism that generates the length change by axial deformation rather than radial constriction. Nevertheless, diameter changes, in opposite phase to the length change of the corresponding segment, are also observed. The diameter change amplitudes as a function of cell segment extrusion indicate that they are actively driven. They also exhibit the same nonlinearities as the length changes, demonstrating that the nonlinearity is the property of the molecular motor itself. We therefore propose that axial and radial changes are vector components driven by motors aligned at an angle with the cell's axis.

MEMBRANE PROPERTIES OF SOLITARY TALL COCHLEAR HAIR CELLS ISOLATED FROM THE ADULT PIGEON. M. J. Correia, D. G. Lang* and P. A. Fuchs. Departments of Otolaryngology and Physiology and Biophysics, UTMB, Galveston TX

Using dissociation and recording procedures detailed elsewhere (Correia et al., *J. Neurophysiol.* 62 924 1989), tall hair cells (17-20 μ m) were isolated from basal, central and apical regions of the auditory papillae and studied using whole cell patch clamp techniques. Recordings were made in 20° C pigeon Ringers solution containing 10mM HEPES and buffered to a pH of 7.4. The recording electrodes contained potassium or cesium as the major cation and 11 mM EGTA. The mean (\pm SEM) zero current potential (during voltage clamp) of 35 hair cells was -47.7 ± 1.8 mV. Mean input resistances, at rest, for apical, central and basal hair cells were 1.30 ± 0.13 G Ω (n=13), 2.39 ± 0.27 G Ω (n=7) and 0.97 ± 0.84 G Ω (n=3), respectively. Ten hair cells, (studied during voltage clamp), produced at least three putative types of ionic currents: an inward, calcium current; an outward calcium-dependent current (suggested by N-shaped I(V) curve) and an outward calcium-insensitive current (suggested by linear I(V) curves). Electrical resonance was observed in some cells. In general, the resonant frequency increased as the cells were depolarized. The resonant frequencies and the voltage dependency of the resonant frequencies of 9 apical, 6 central and 4 basal hair cells were compared and were the same, suggesting that electrical resonance in adult pigeon tall hair cells may not be tonotopically arranged. This work was supported in part by grants, NAG-2-293 and N00014-91-J-1027.

THE DISTRIBUTION OF VIBRATION-SENSITIVE FIBERS IN THE FROG INNER EAR. J. Christensen-Dalsgaard, D.D. Simmons and P.M. Narins. Dept. of Biology, UCLA, Los Angeles, CA 90024-1606.

We studied the responses of inner ear afferents in *Rana pipiens* to substrate-borne vibrations. We also injected fibers in the saccular nerve with biocytin and traced the course of the fibers in VIIIth nerve and brainstem. Recordings were made from the VIIIth nerve using a dorsal approach and from the anterior branch of the VIIIth nerve and the saccular nerve using a ventral approach. Nearly all fibers in the saccular nerve were vibration-sensitive with BF's ranging from 10 to 40 Hz, and clear responses were seen to levels of 0.01 cm/s². Vibration-sensitive fibers were also found in the anterior branch of the VIIIth nerve (lateral to its merge with the saccular branchlet) and in the dorsal part of the VIIIth nerve. Therefore, vibrational sensitivity is distributed among several inner ear organs. The saccular fibers form a homogeneous population with low-pass frequency characteristics.

Comparative data on the distribution of vibration-sensitive VIIIth nerve fibers in the Puerto Rican frog *Leptodactylus albilabris* will also be presented. DNSRC 11-7765 (JCD), Sloan Foundation (DDS) and NIH #DC00222 (PMN).

CENTRAL AND PERIPHERAL GENERATORS OF SHORT LATENCY VESTIBULAR RESPONSES. A.M. Nazareth* and T.A. Jones. Department of Oral Biology, College of Dentistry, Univ. of Nebraska Med. Ctr., Lincoln, NE 68583-0740.

Vestibular compound action potentials are elicited by linear acceleration pulses and appear as a series of four to seven waves in far-field recordings in the bird (*Gallus domesticus*). These responses occur within 8msec following the stimulus, exhibit peak-to-peak amplitudes ranging from 0.3 to 20 μ v, and have been shown to be dependent upon the activation of vestibular neurons bilaterally (Jones and Pederson 1969; Jones 1991). The exact neuroanatomical origins of vestibular responses have yet to be determined. The purpose of the current study was to distinguish response components generated by the vestibular periphery from those arising from central neuronal relays.

To accomplish this, responses were recorded before and after unilateral surgical interruption of the vestibulocochlear nerve near its exit at the internal acoustic meatus. Prior to sectioning, a contralateral intralabyrinthine injection of tetrodotoxin (TTX) was used to abolish all activity from that side. The effectiveness of the contralateral TTX blockade was confirmed ultimately by a second ipsilateral TTX application. Each animal (n=18) was anesthetized and tracheotomized. The cranium was embedded in plaster for delivery of vertical acceleration stimuli. Responses were recorded using traditional computer averaging techniques. Electrophysiological activity from the skull (vertex-mastoid) was amplified (gain=100,000), filtered (LF=300Hz, HF=3KHz), and directed to an analog to digital converter for processing. Following each study, heads were fixed, decalcified and blocked in preparation for histological sectioning. Histological sections were used to characterize the precise limits of surgical manipulations.

Sectioning of the eighth nerve abolished or substantially reduced response peaks beyond P2 (vertex positive, peaks numbered sequentially). P1 and N1 were consistently the least affected by sections. In two animals sections produced little or no effect indicating that vestibular relays were spared. These findings are consistent with the hypothesis that P1 and N1 represent components of the eighth nerve compound action potential and therefore reflect peripheral neural activity. We conclude that peaks arising later than P2 are generated by vestibular brainstem relays. This research was supported by NASA NAGW 1275, (TAJ) NIH IRISDC00474-01, (TAJ) NIH, Grad Res. Asst. COD (AMN).

CYTOCHEMICAL LOCALIZATION OF ADENYLATE CYCLASE IN THE TROUT SACCCLE. R.C. Kern¹, M.J. Drescher^{1,2}, K.M. Khan^{1,2}, S.F. Myers¹, and D.G. Drescher^{1,2}. ¹Dept. of Otolaryngology, ²Lab. of Biology, Wayne State University, Detroit, MI 48201.

The trout saccular sensory epithelium contains a large population of receptor cells (hair cells) and serves as a model system for octavolateralis end organ function in higher vertebrates. Adenylate cyclase, the enzyme of synthesis of cAMP, an important second-messenger regulator of cell function, has been cytochemically localized in the trout saccular epithelium by a modification of the histochemical method of Mees (1984). Pyrophosphate released from the artificial substrate AMP-PNP was precipitated by strontium ion and converted to a lead reaction product, visible in the electron microscope. Dithiothreitol and theophylline were added to inhibit nonspecific activity. Parallel control incubations were performed with substrate deleted.

In tissues incubated with the complete reaction mixture, precipitate was found to be associated with the stereocilia and apical membranes of the hair cells. Reaction product was also observed on lateral membrane specializations of mitochondria-rich cells in the region of transitional epithelium and noted in vesiculated, presumed efferent, nerve terminals on receptor cells. Little nonspecific precipitate was observed for control incubations.

Adenylate cyclase activity in the apical portion of hair cells could play a role in modulation of mechanotransduction processes. Activity on lateral membrane specializations in presumed ion-transporting cells may have a correlate in the stria vascularis and dark cells of higher vertebrates. Adenylate cyclase activity in presynaptic efferent neurons may subserve regulation of the synthesis and release of efferent neurotransmitter(s).

COMPUTER-AIDED ANATOMICAL RECONSTRUCTION OF THE SHAPE AND THE ORIENTATION OF HUMAN UTRICULAR AND SACCCULAR MACULAE.

U.J. Bucher*, M.A. Maier*, C.F. Ramos, R.K. Dismukes. Department of Psychology, Bionmathematical Section, University of Zurich, CH-8032 Zurich, Switzerland.

To understand functional aspects of the vestibular organs in spatial orientation, one is critically dependent on information about their shape and orientation in the head. Most of the available material up to date allows only poor visualization or measurement of the three-dimensional properties.

The present study presents a technique to reconstruct the macular epithelia in a three-dimensional virtual space, based on histological sections of one human left and right temporal bone. In this approach it is not necessary to previously mark the sections. Once the sections are digitized each can be aligned to its neighbor section by translation and rotation using the semicircular canal system as a frame of reference.

As a result, the maculae utriculi and sacculi cannot only be displayed graphically as stereopicture, but, furthermore, their shape and position relative to the Reid stereotactic system can be analytically defined with a polynomial function. Such data may conveniently be used in computer simulations as shown e.g. in a functional simulation of the otoliths' response to varying gravitational forces.

ONTOGENESIS OF F-ACTIN IN HAIR CELLS OF RAT'S COCHLEA. A. Zine, A. Hafidi, and R. Romand*.

Lab. de Neurobiologie, Université Blaise Pascal, 63177 Aubière Cedex, France.

Actin is the main component of stereocilia of the stato-acoustic receptors. Phalloidin is a specific marker for the polymerized form of actin, F-actin. This property was used with rhodamine-labelled phalloidin in order to follow the ontogenesis of this cytoskeletal protein in hair cells of the cochlea.

This study was performed in the rat from the 16th day of gestation (16 DG) up to adulthood on surface preparations and cryostat cross-sections of the organ of Corti. At 16 DG, no specific phalloidin labelling is visible on the apex of hair cells, except close to the plasmic membrane outlining the shape of cells. At 18 DG, specific labelling is present on the cuticular plate and very faint labelling on stereocilia of the inner hair cells, while in the outer hair cells (OHCs) the labelling on the cuticular plate is only visible at 20 DG and on stereocilia at birth. At this stage of development, the cuticular plate and stereocilia of both types of hair cells are clearly visible, although the W shaped stereocilia of OHCs appear later during the first postnatal week.

From these observations it can be concluded that F-actin follows the known pattern of lateral gradient of development between both types of hair cells and shows an adult distribution well before the onset of cochlear function in the rat.

NEUROGENESIS

18.1

CELL OUTPUT OF THE VENTRICULAR ZONE OF THE E14 MOUSE NEOCORTEX. T. Takahashi¹, R.S. Nowakowski², M. Jacobson¹

and V.S. Caviness, Jr.¹ ¹Dept. of Neurology, Mass. General Hospital, Boston MA 02114 and ²Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

The fraction of cells quitting (Q) and persisting (P, where P+Q = 1) in the proliferative cycle following cell division was determined by a ³H-thymidine (³H-TdR) and bromodeoxyuridine (BUDR) double labeling strategy for the E14 murine neocortical ventricular zone (VZ). In principle, the Q fraction should increase from 0 at E10, before neurogenesis begins, to 1.0 by E17, when the VZ becomes exhausted (Nowakowski, Soc. Neurosci. Abstr. 17: 1991). E14 is a time when the length of the overall cell cycle and S-phase are changing dramatically (Caviness et al., Soc. Neurosci. Abstr. 17: 1991).

A pulse of ³H-TdR was given 2 hr before the initiation of the cumulative labeling schedule with BUDR. This sequence labels those cells which leave the S-phase during the two hour period after the ³H-TdR pulse only with ³H-TdR; cells which leave the S-phase subsequent to the initiation of the BUDR labeling will be labeled with both markers or with BUDR alone. From a prior analysis of cytokinetic parameters at E14 (Takahashi et al., Soc. Neurosci. Abstr. 16:1147, 1990) it is known that 5.5 hr after ³H-TdR injection, cells singly labeled with ³H-TdR will have completed mitosis. Thus at 5.5 hr the number of singly labeled cells corresponds to the total number of daughter cells produced within the two hour period (N_p+N_o). At 14.5 hr after the ³H-TdR pulse the singly labeled cells will correspond to the Q fraction, that is cells which complete the full cycle without reentering S-phase. The ratio of the numbers of cells in these two populations, i.e. N_o/(N_p+N_o), determined at E14, is significantly less than 0.5. This means that at E14, the proliferating population is not in a "steady-state" and that most daughter cells return to S phase following M-phase. Therefore, at E14 the size of the proliferating population of the VZ is increasing.

18.2

CYTOKINETIC PARAMETERS OF THE VENTRICULAR ZONE IN DEVELOPING MOUSE NEOCORTEX. V.S. Caviness, Jr.¹, T. Takahashi¹

M. Jacobson¹ and R.S. Nowakowski² ¹Dept. of Neurology, Mass. General Hospital, Boston MA 02114 and ²Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

Cytokinetic parameters of the ventricular zone (VZ) in the neocortex of mice of the CD1 strain were determined by an analysis based upon cumulative S-phase labeling with bromodeoxyuridine (BUDR, Nowakowski et al., J. Neurocytol., 18:311-318, 1989; Takahashi et al., Soc. Neurosci. Abstr., 16:1147, 1990). The analysis spanned embryonic days 12 (E12) through E17 (E0 = day of conception), when the majority of infragranular and granular and all the supragranular neurons are generated (Caviness, Dev. Brain Res. 4:293-302, 1982).

The growth fraction (GF, the proportion of the total population that is proliferating) of the VZ is maintained at 1.0 between E12 and E15 and is only slightly less than 1.0 at E16. On E17, because the VZ is rapidly disappearing, the lengths of the cell cycle (T_c) and S-phase (T_s) and GF could not be reliably estimated. At every age considered here, the overall VZ population behaves as a homogeneous population with respect to T_c and T_s (single population model). T_c lengths from 10.4 to 19.1 hr between E12 and E16. T_s declines from values above 5 hr before E14 to values less than 5 hr afterwards. The ratio T_s/T_c falls sharply between E13 and E14.

These changes in the cytokinetic parameters of the VZ occurring around E14 are coincident with the appearance of the cortical plate within the primitive plexiform zone and of the subventricular zone. They may accompany an augmentation in the fraction of cells which leave the VZ (Takahashi et al., Soc. Neurosci. Abstr., 17: 1991). Supported by NIH 2 R01 NS 12005

	T _s (hr)	T _c (hr)	T _s /T _c	GF
E12	51	10.4	0.49	1.0
E13	63	14.7	0.43	1.0
E14	30	13.6	0.22	1.0
E15	40	18.3	0.22	1.0
E16	45	19.1	0.24	0.94

18.3

THE CONTRIBUTION OF COMPETITION DURING G1 AND REENTRY INTO THE PROLIFERATIVE POPULATION TO VARIATION IN CLONE SIZE. R.S. Nowakowski, Dept. of Neuroscience and Cell Biology, UMDNJ-RWJMS, Piscataway, NJ 08854.

The behavior of the cells in proliferative populations can be studied in a variety of ways. Using S-phase markers (e.g., ³H-TdR or BUdR), the average behavior of the cells comprising the population can be analyzed. Using retroviral or other single cell marking techniques, the behavior of the progeny of a single cell can be determined. For this study, data from both approaches have been analyzed in order to determine when during the cell cycle the decision to reenter S-phase is made by the two daughter cells which result from a single mitotic division. At each pass through the cell cycle, a proportion of the cells "decide" to continue to proliferate. The remainder of the cells leave the cell cycle to become permanently post-mitotic or quiescent. If the decision for each daughter cell to reenter the S-phase is made by competitive interaction with constituents of its environment, then the average behavior of the population can be described probabilistically. The range in variation in size of single clones as reported by retroviral experiments can be accounted for only if those competitive interactions are independent for each of the two daughter cells. Since the only time that independent decisions can be made by two daughter cells is after mitosis and during the early part of G1 (i.e., before the restriction checkpoint), it is concluded that the decision to reenter the proliferative population or to leave the proliferative population is made during G1.

STABILITY OF TIMING OF NEUROGENESIS IN RODENTS, MARSUPIALS, CARNIVORES AND PRIMATES AND ITS CONSEQUENCES FOR CELL PROLIFERATION. K.A. Jordan*, A. Baemstein*, L. Hinds* and B.L. Finlay Dept. of Psychol. Cornell Univ., Ithaca NY 14853

How schedules of neurogenesis in mammals are adjusted to conform to maturational periods that may differ in length by an order of magnitude, and the consequences of these neurogenetic schedules for cell proliferation is the subject of this study. Tritiated thymidine birthdating studies from five rodents (rat, mouse, gerbil, hamster and spiny mouse), two marsupials (possum and quokka), and in the cat and rhesus monkey were reviewed to determine the duration and peak day of neurogenesis for as many neural structures or cell classes as possible. All pairs of species were compared to determine the regression equation best relating the set of common neurogenetic events in one species to the other. In every case, the relationship was fit well by a linear equation, with correlation coefficients ranging from 0.66 to 0.93.

A test case of the consequences of extended cell proliferation for cell number was examined. The gerbil retina has twice the retinal ganglion cells of the hamster, and its retinal neurogenesis is about twice as long. Total retinal neuron number in early development was quantified to determine if extended duration of neurogenesis alone accounts for the greater number of retinal neurons in the gerbil, or if rate of neuron production also differed. The rates of cell proliferation were close to identical. Comparison of the slopes of increase of cell number over days showed no significant difference ($t=1.785$, $df=16$, $p<.20$) with the trend favoring faster proliferation in the hamster. Thus, duration of neurogenesis accounts for the species difference in neuron number. Supported by NIH RO1 NS19245.

IN VITRO NEUROGENESIS BY VENTRICULAR ZONE EXPLANTS OF THE ADULT SONGBIRD FOREBRAIN. S.A. Goldman and A. Zaremba*, Dept. of Neurology, Cornell Univ. Medical College., N.Y., N.Y. 10021.

The vocal control nucleus, HVC, of the songbird forebrain exhibits neurogenesis in adulthood, with the production of new neurons from local ventricular zone precursor cells. Ventricular zone explants derived from the adult canary HVC can be maintained *in vitro*, with the continued migration and differentiation of newborn neurons (J. Neurosci. 10:2931-39, 1990). Neuronal mitogenesis, however, has only rarely been observed in these cultures when raised in high-serum media (25% total). In the present study, we tested the possibility that serum-borne factors might suppress the mitosis of adult-derived neuronal precursor cells *in vitro*. When HVC ventricular zone explants derived from the adult zebra finch were raised in high concentrations of charcoal-pretreated fetal bovine serum (FBS, 25%), neuronal DNA replication, and inferentially precursor cell mitosis, was minimal: Only 4.4% of those neurons counted after 8 days *in vitro* ($n=1418$) were labelled by a sustained exposure to ³H-thymidine begun at 24 hrs *in vitro*. In contrast, 19.3% of neurons ($n=1972$) raised in low-serum medium (5% FBS) incorporated ³H-thymidine by the eighth day *in vitro*. Neuroblastic ³H-thymidine uptake continued through the first 96 hours in culture, with a decline thereafter in the neuronal labelling index. Immunolocalization of MAP-2 followed by autoradiography confirmed the neuronal identity of the ³H-thymidine labelled cells. This facilitation of neurogenesis by serum depletion suggests that serum-borne factors may inhibit the *in vitro* division of adult-derived neuronal precursors, either directly or by agents released by serum-stimulated glial or ependymal cells. (Supported by the Mathers Charitable Foundation, Mr. and Mrs. F. Merle-Smith, and NIH NS01316.)

18.4

REGULATION OF NEURON NUMBER BY THE PROLIFERATIVE POPULATION IN THE DENTATE GYRUS OF MICE. N.L. Hayes and R.S. Nowakowski, Dept. of Neuroscience and Cell Biology, UMDNJ-RWJMS, Piscataway, NJ 08854.

During development of the mouse the neurons of the dentate gyrus are produced over a period of time extending from approximately embryonic day 10 (E10) through the third postnatal week. We have compared the characteristics of the proliferative population of mice of the C58/J inbred strain, which have approximately 250,000 granule cells in the dentate gyrus, to that of the LG/J inbred strain, which have approximately 400,000 granule cells. Our data indicate that on the day of birth (P0) the length of the cell cycle (T_c) and of the S-phase (T_s) in the two inbred strains are approximately equal. However, the number of cells which comprise the proliferative population (i.e., the growth fraction GF) differs by a factor of approximately 2. These data indicate that the difference in the size of the adult population of neurons in the dentate gyrus of these two inbred strains of mice arises as a consequence of events which occur during the embryonic period at a time which precedes the generation of most of the granule cells. These events affect specifically the number of cells in the proliferative population but not other major aspects of the cell cycle.

CELL PROLIFERATION IN THE VENTRICULAR ZONE OF RING DOVES. C. Ling & M.-F. Cheng, Institute of Animal Behavior, Rutgers University, Newark, NJ 07102

Recent studies in adult canaries have identified areas within the VZ of the lateral ventricle (hot spots) in which new cells proliferate. In this study, we examined patterns of cell proliferation in the VZ of the ring dove, a non-song learner. Sixteen young doves (about three months old, adult body weight) received a single intramuscular injection of [³H] thymidine (4 μ Ci/g), a marker for DNA synthesis and therefore for cell replication. Birds were sacrificed under deep anesthesia after various survival times: 1h, 8h, 24h, and 48h. Brains were removed, sectioned, processed and scanned for silver grain as described by Alvarez-Buylla et al. (1990). There are 3 salient findings: (1) Most of labeled cells were found along the lateral wall of the VZ of the lateral ventricle, (2) concentration of labeled cells in the VZ increased gradually from anterior sections, reaching a peak at the level where the lobus parolfactory (LPO, avian basal ganglion) reaches its caudal edge and declining sharply in sections thereafter, (3) there are consistent sex differences in the pattern of cell proliferation in the VZ. Supported by Johnson and Johnson Discovery Award.

DEVELOPMENTAL PATTERNS OF NEUROGENESIS IN THE CNS OF THE CANARY. Alvarez-Buylla, A. and Ling, C.-Y Rockefeller University, New York, N.Y. 10021.

Many new neurons are produced in the brain of adult canaries (*serinus canaria*). These cells are born in the lateral ventricle and differentiate only within the telencephalon. Other regions of the brain receive no new neurons in adulthood. We have now investigated the time of neuronal birth in different canary brain structures. [³H]-thymidine was injected at the following ages: before hatching: E5, E9, E10, E12; and after hatching: P1-5, P6-10, P11-20, P21-30, P31-40, P41-50, P91-100, P120-129. All birds were killed at 10-13 months of age. Labeled neurons were identified in sagittal sections stained with cresyl violet. The positions of labeled neurons were mapped in the telencephalon, diencephalon and hind brain (except cerebellum) with the aid of a computer-microscope. With the exception of neurons of the dorsomedial thalamus, most of the neurons in regions caudal to the telencephalon were born before E9. Neurons in the dorsomedial thalamus were produced through E12 with very few if any born after hatching. The addition of new neurons throughout the brain decreased drastically after hatching, but continued in the telencephalon, where it was particularly high in lobus parolfactorius. Very few neurons outside the telencephalon were labeled after hatching and non after P50. Neurogenesis restricted to the telencephalon is therefore established very early, suggesting that both developmental and adult neurogenesis, may allow epigenetic and environmental factors to constantly sculpt telencephalic circuits.

ACCURATE DETERMINATION OF TIME OF NEURONAL BIRTH USING SEQUENTIAL LABELING WITH ³H-THYMIDINE AND BUdR.

A. Repka*, E. Adler-Graschinsky and R. Adler. Wilmer Inst., Hopkins Univer. Sch. of Med., Baltimore, MD.

Accurate data about the "birthdate" of neuronal precursors is of crucial importance for understanding its relationship with phenotypic commitment. Pulse and cumulative labeling methods using either ³H-Thymidine (³H TdR) or bromodeoxyuridine (BUdR) are useful, but only allow an approximate determination of the day of neuronal birth. We have developed a "window-labeling" technique to precisely determine the time of cell birth by labeling retinal precursor cell cultures first with ³H TdR and, after a specified time interval, with BUdR. Precursors that are already postmitotic prior to ³H TdR labeling are ³H TdR(-)/BUdR(-), while those that continue to divide after BUdR labeling are ³H TdR(+)/BUdR(+). Window-labeled cells, ³H TdR(+)/BUdR(-), are those that undergo the last round of DNA synthesis during the brief time interval between ³H TdR and BUdR treatments and can be easily and accurately identified in preparations processed for autoradiography and BUdR immunocytochemistry. This technique has no detectable deleterious effects upon precursor proliferation, survival or differentiation, and allows accurate determination of the time of terminal mitosis. Supported by USPHS EY04859 and EY07047-13.

CG-4, A NEW BIPOTENTIAL GLIAL CELL LINE FROM RAT BRAIN, CAPABLE OF DIFFERENTIATING INTO EITHER OLIGODENDROCYTES OR TYPE-2 ASTROCYTES. J.C. Louis, E. Magal, D. Muir, M. Manthorpe and S. Varon. Dept. of Biology 0601, Univ. Calif. San Diego, La Jolla, CA 92093.

Primary cultures of oligodendrocyte-type-2 astrocyte (O-2 A) progenitor cells from brain can be induced to differentiate into either oligodendrocytes or type-2 astrocytes under defined conditions. The O-2A cells are characterized by the presence of the A2B5 surface marker and the absence of potential differentiation markers for oligodendrocytes (galactocerebroside and myelin basic protein) or type-2 astrocytes (GFAP). From these cultures, we have established a permanent cell line, designated CG-4 (Central Glia-4). In contrast to primary O-2A cells, which proliferate for only a limited number of passages, the CG-4 cells can be propagated in serum-free culture medium (DME, with N1 supplement and biotin) supplemented with medium conditioned by the neuronal cell line B104 (B104-CM) for unrestricted periods of time as undifferentiated precursor cells. The CG-4 cells have a normal karyotype and display the same phenotype and differentiation potentials as normal O-2A cells. The proliferating CG-4 cells can display two interconvertible morphologies, bipolar or multipolar, depending on cell density. The multipolar morphology (perhaps a step towards oligodendrocyte differentiation) is favored in high density cultures and has a slower proliferation rate. Similar to normal O-2A cells, the CG-4 cell line can be induced to differentiate into either oligodendrocytes or type-2 astrocytes. Differentiation into oligodendrocytes is observed when proliferating CG-4 cells are transferred to serum-free medium in the absence of the B104-CM. Alternatively, CG-4 cells are induced to differentiate into type-2 astrocytes by medium supplemented with 20% fetal calf serum. Following differentiation, pure cultures of oligodendrocytes or type-2 astrocytes can be obtained in virtually unlimited numbers and maintained for several weeks in medium containing 5% fetal calf serum. In summary, we have established a line that shares all the characteristics with normal brain O-2A cells, except the limitation in proliferative capacity. Support: NINCDS NS16349; NSF BSN-88-08285.

DEVELOPMENTAL EXPRESSION AND MODULATION OF INTERMEDIATE FILAMENTS (IF) IN HUMAN FETAL ASTROGLIAL (HFA) STRAINS. J.J. Chao and W.P. Parks. Departments of Pediatrics and Microbiology, New York University School of Medicine, New York, NY 10016.

During astroglial development, expression of IF switches from vimentin, a pre-astrocytic form, to glial fibrillary acidic protein (GFAP), the specific marker of mature astrocytes. All mammalian systems studied thus far demonstrate this developmentally linked expression of IF suggesting a fundamental event in astrocyte differentiation. Little is known, however, about the mechanism governing differential expression of the IF gene family. Previous work in this lab has demonstrated the ability to grow purified human fetal astrocytes for prolonged periods in vitro and multiply passage them without obvious changes in differentiated cell characteristics. We now report that these HFA cultures have differential expression of GFAP and vimentin and that their IF expression can be modulated with certain cytokines. As previously described, human cell strains consisting predominantly of GFAP-positive astrocytes were established from abortuses of 8 - 18 weeks gestation. Growth requirements and characteristics were established over a 24 month period and greater than 45 passages. Two (2) HFA strains (HFA-1 and HFA-2), derived from the same fetal tissue, were further characterized. IF and cell surface and cytoplasmic markers were examined by immunocytochemistry, western blot analysis, and mRNA analysis by northern blotting. HFA-1 strains uniformly (>93% of cells) expressed high levels of GFAP and demonstrated minimal degrees of positivity for vimentin, MHC class II antigens, and A2B5. Interestingly, HFA-2 cells expressed GFAP at low or undetectable levels while vimentin and A2B5 are expressed at high levels, suggesting an astrocytic progenitor cell type. Neurofilament and galactose cerebroside were not detectable in either strains. In addition, HFA-1 and HFA-2 cultures were exposed to various cytokines (i.e. PDGF, TNF, FGF) to determine whether IF expression could be modulated or switched from one type to the other. The data suggests that HFA-1 represent a population of cells that are typical of Type I Astrocytes, while HFA-2 represents an progenitor cell type similar to the previously described O2A bipotential cell.

19.2

EXPRESSION OF OLIGODENDROCYTE AND O2A PROGENITOR CELL CHARACTERISTICS IN A HUMAN-HUMAN NEURAL HYBRID CELL LINE

G.C. Trudel, I. Shaw*, J.P. Antel, N.R. Cashman. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B4.

One of the barriers to understanding the cell biology of oligodendrocytes (OL) and OL precursors is the difficulty in obtaining primary neural cells in sufficient yield and purity. We have developed a series of immortal human-human hybrid cell lines which express many phenotypic characteristics of OLs and O2A progenitors. A thioguanine-resistant mutant of the human rhabdomyosarcoma (TE671-TR6) was fused with primary human OLs (cultured from surgical specimens) by a lectin-enhanced polyethylene-glycol procedure, and hybrids were selected in aminopterin-containing medium. In contrast to TE671-TR6, the hybrid line MO3-13 expressed surface immunoreactivity for A2B5, galactocerebroside (GalC), and myelin associated glycoprotein (MAG), and intracellular immunoreactivity for myelin basic protein (MBP) and glial fibrillary acidic protein (GFAP). By fluorescence cytometry, MBP, GalC, and MAG were upregulated by treatment of MO3-13 with phorbol esters, which was corroborated by northern analysis for MBP mRNA. Preliminary data suggest that serum-starved MO3-13 proliferate on exposure to PDGF, and that expression of MBP, GFAP, and A2B5 are regulated by serum concentration in a similar fashion to that described in cultured O2A progenitor cells. MO3-13 cells may provide a model to investigate OL differentiation in an immortalized clonal system.

RT4: NEW INSIGHTS INTO IN VIVO COUNTERPARTS. L.M. Donahue* and N. Sueoka*. Dept. of Cell Biol. and Anat., Texas Tech Univ. H.S.C. Lubbock, TX 79430; *Dept. of Mol., Cell. and Dev. Biology, University of Colorado, Boulder, CO 80309.

The RT4 cell line family was derived from an ENU-induced rat peripheral neurotumor and consists of a stem cell line which spontaneously and stably converts in culture to three derivative cell types in a process called cell type conversion. The stem cell expresses properties of both neurons and glia (Schwann cells) and upon cell type conversion the neuronal and glial properties segregate appropriately. We are studying transcriptional regulation of Na⁺-channel gene expression in the RT4 system with the idea that understanding cell type-specific gene regulation may lead to an understanding of how a cell becomes committed to a particular fate. We have shown that (1) upon cell type conversion, Na⁺-channel mRNA expression segregates primarily with the RT4 neuronal derivatives and (2) the SkM2 Na⁺-channel gene, which was originally isolated from rat muscle cDNA libraries, is the predominant Na⁺-channel gene expressed by the RT4 neuronal derivatives. Since the RT4 cell lines were derived from a peripheral neurotumor, our results present the possibility that the SkM2 Na⁺-channel gene may be important *in vivo* in the rat PNS. In addition our findings suggest that the RT4 system may derive from dorsal root ganglia (DRG) since neurons from rat DRG have tetrodotoxin (TTX) resistant Na⁺-current and the only known Na⁺-channel gene thought to encode a TTX-resistant channel is the SkM2 gene.

19.5

A CENTRAL NEURONAL-LIKE CELL LINE IMMORTALIZED WITH A RETROVIRUS ENCODING THE TEMPERATURE-SENSITIVE SV40 LARGE T ANTIGEN. K. Hisanaga, D.E. Bredesen and F.R. Sharp. Dept. of Neurology, UCSF and VA Medical Center, San Francisco, CA 94121 and Dept. of Neurology, UCLA, Los Angeles, CA 90024-1769.

A temperature-sensitive immortalized neuron-like cell line has been obtained from a primary fetal rat (E17) hippocampal cell culture using a retroviral vector encoding SV 40 large T antigen and neomycin phosphotransferase (generously provided by K. Frederiksen and R. McKay). The clonal cells, selected by the neomycin analogue G418 resistance, exhibit flat shape, and SV 40 large T antigen and vimentin-like immunoreactivity (IR) at the permissive temperature (33°C). At the non-permissive temperature (39°C), the cells exhibit fibrous morphology, and the rate of cell division is significantly reduced. The removal of fetal calf serum (FCS) from DME medium induces neuronal morphological changes in the cells at 39°C, but not 37°C, although most of cells die within 3 days. The addition of dibutyl-cyclic AMP to 10% FCS containing DME induces marked morphological changes in most of cells to bipolar- or tripolar-shaped neuron-like cells at 39°C, but not 33°C, and most of cells can survive for at least 5 days at 37°C. The cells exhibit NFP, VIP, and GAD-like IR, while GFAP is negative. These cells should be useful to investigate the neuronal differentiation *in vitro* and possibly *in vivo* (transplantation to the CNS).

EXPRESSION OF BASIC FIBROBLAST GROWTH FACTOR IN HUMAN NEUROBLASTOMA CELLS REGULATES IN A NEGATIVE MANNER AROMATIC L-AMINO ACID DECARBOXYLASE GENE TRANSCRIPTION. M.J. Weber, P. Barrailly, A. LeVanThai, Lab. Pharmacologie Toxicologie Fondamentales, CNRS, 31077 Toulouse France, B. Couderc, F. Amalric, H. Prats, Centre Recherche Biol. Génét. Cell., CNRS, Toulouse.

Human bFGF mRNA is translated from 3 alternative initiation codons, the usage of which determines the cellular localization of the protein products. Initiation at 2 CUG generates the 22.5 and 21 kD nuclear forms, whereas the initiation at a AUG generates the 18 kD cytoplasmic form (1,2).

To study the effects of intraneuronal bFGFs, human neuroblastoma cells SK-N-BE and SK-N-BE K2 have been transfected with a retroviral vector expressing the 3 forms of bFGF. The clonogenic capability of the resulting clones in soft agar was reduced compared to the parental cell lines. Moreover, neurofilaments immunoreactivity and aromatic L-amino acid decarboxylase (AADC) activity were suppressed. The suppression of AADC activity was also observed in the rat pancreatic exocrine cells AR4-2J. Exogenous bFGF had no effect on AADC activity in SK-N-BE cells.

A construct containing 9 kb of the presumptive promoter of human AADC gene linked to LacZ gene was transiently expressed in SK-N-BE and in its retrovirally transfected derivative. Whereas a strong β -gal activity was measured in the parental line, the corresponding promoter activity was strikingly reduced by the expression of the bFGFs, in agreement with the suppression of AADC activity. Therefore intraneuronal bFGF might regulate the transcription of AADC gene in a negative manner.

Experiments are in progress to determine the effects of the expression of individual forms of bFGF. These experiments might help understanding how intraneuronal bFGF affects the neurotransmitter phenotype of neurons.

ROLE OF ADRENERGIC AUTORECEPTORS IN THE DESIPRAMINE (DMI)-MEDIATED INHIBITION OF ADRENERGIC EXPRESSION BY NEURAL CREST CELLS. J.-M. Zhang¹, A. D. Strosberg², and M. Sieber-Blum¹.

¹Dept. of Cellular Biology and Anatomy, Med. Col. of Wisconsin, Milwaukee, WI 53226, and ²Institut Cochin de Génétique Moléculaire, 75014 Paris, France.

Norepinephrine (NE)-uptake inhibitors, such as DMI, block expression of the adrenergic phenotype in clonal neural crest cell cultures (Sieber-Blum, Dev. Biol. **136**, 372, 1989). We have investigated the possibility that this inhibition is caused by a down-regulation of adrenergic autoreceptors. Phentolamine (10 μ M), which blocks α -receptors (α -R; major type of adrenergic autoreceptors in the peripheral sympathetic nervous system), did not affect adrenergic expression by neural crest cells in clonal culture. By contrast, propranolol (10 μ M; β 1- and β 2- blocker; also known to directly inactivate tyrosine hydroxylase), caused a 59% decrease. Indirect immunofluorescence using antibodies against dopamine- β -hydroxylase and Mab against either β 1-R (B120; Chapot *et al.*, Hybridoma **8**, 535, 1987) or β 2-R (BRK-1; Kaveri *et al.*, Eur. J. Biochem., **167**, 449, 1987) indicated that some adrenergic neural crest cells express β 1- and β 2-autoreceptors. DMI caused a >6-fold decrease in the proportion of β 1-R⁺/DBH⁺ cells, while the number of adrenergic cells expressing β 2 autoreceptors did not seem to be affected. We have shown previously that while DMI causes a decrease, added NE causes an increase in adrenergic expression. If DMI acts via adrenergic autoreceptors, NE-agonists would be expected to also cause an increase in adrenergic expression. However, this was observed neither with clonidine (10 μ M; α 1-, α 2-agonist), nor with isoproterenol (10 μ M; β 1-, β 2-agonist). In summary, the data indicate that DMI-treatment is accompanied by a decrease of adrenergic β 1-, but not α - or β 2-, autoreceptors. Whether this effect has a causative relationship to the observed inhibition of adrenergic differentiation remains to be determined. However, the fact that isoproterenol did not increase phenotypic expression supports the notion that by increasing adrenergic expression NE acts upon an intracellular target that remains to be identified. Supported by USPHS grant HD21423 (M. S-B.) and by CNRS (A.D.S.).

EARLY AND LATE TRANSDIFFERENTIATING EFFECTS OF NGF ON CULTURED ADRENAL CHROMAFFIN CELLS MAY BE MEDIATED BY TWO DIFFERENT MECHANISMS. M.A. Herman¹, C.A. Schulz* and P. Claude². Wisconsin Regional Primate Research Center, ¹Department of Physiology and ²Neuroscience Training Program, University of Wisconsin, Madison, WI 53715.

During the first week in nerve growth factor (NGF), cultured rat adrenal chromaffin cells increase their rate of mitosis and extend neurites. Following the first week, as cells transdifferentiate into sympathetic neurons, a dense neuritic network forms, cell bodies enlarge, and cells become post-mitotic and dependent upon NGF for survival.

Recently we found that early effects of NGF may be mediated by protein kinase C (PKC), since chronic exposure to the PKC activator, phorbol myristate acetate (PMA; 30 ng/ml) closely mimics the early proliferative and differentiating effects of NGF (Devel. Biol., in press). However, cells grown in PMA remain in an arrested state of development and fail to transdifferentiate into sympathetic neurons. Even after 4 weeks in PMA, cells continue to incorporate ³H-thymidine and fail to develop the dense neuritic network and somatic hypertrophy of sympathetic neurons. This suggests that modulation of PKC is insufficient to complete transdifferentiation and that another biochemical pathway might be involved, perhaps one that uses cAMP.

Forskolin (FS; 50 μ M) an activator of adenylate cyclase (AC), inhibits both the proliferative and differentiating effects of either NGF or PMA during the first week in culture. However, at later times, FS does not inhibit the effects of either NGF or PMA. If FS is added to cultures grown for 2 weeks in PMA, a dense neuritic network develops and cells appear similar to those in sister cultures grown in NGF. FS also supports the neurites of NGF-dependent cells. Thus, the later phases of transdifferentiation may involve the activation of AC. [Supported by NSF BNS-8616958, NICDH HD-07118 and NIH RR00167]

REGULATION OF THE TYROSINE HYDROXYLASE IN QUAIL IMMORTALIZED NEURAL CREST CELLS. M. FAUQUET*, E. DUPIN* and A. PROCHIANITZ. CNRS URA 1414, Ecole Normale Supérieure 75005 Paris and Institut d'Embryologie, CNRS UMR 0009,94130 Nogent sur Marne France

The catecholaminergic differentiation of avian sympathoadrenal precursors, cultured *in vitro*, is highly dependant of the presence of chick embryonic extract (CEE) in the culture medium. We isolated a 1.5Kb 5' flanking region of the quail tyrosine hydroxylase (TH) gene. Constructs in which the 5' flanking sequences of the quail gene directed the expression of the bacterial chloramphenicol acetyltransferase (CAT) were transfected into cell lines and assayed for transient CAT expression. The CAT activity was 2% in the mouse fibroblast line LTK- but reached 15% in the TH-positive rat pheochromocytoma line PC12 and 20% in the quail immortalized neural crest cells (Fauquet *et al.*, 1990). To test the possibility that CEE acts on the TH promoter we added CEE to the culture medium of the immortalized crest cells and proceeded to the transient expression assay. We found a 60% increase of the promoter expression in the presence of 10% CEE. We showed that a region of 70 nucleotides including the TATA box and the cyclic AMP responsive element (CRE) is sufficient for the response to the CEE. Furthermore, forskolin was able to stimulate the adrenergic expression of the primary neural crest cells *in vitro*. These findings strongly suggest that CEE could act on the catecholaminergic metabolism via the cAMP pathway.

A CATECHOLAMINERGIC SENSORY PHENOTYPE IN CRANIAL DERIVATIVES OF THE NEURAL CREST: EVIDENCE FOR REGULATION BY CELL AGGREGATION. D.M. Katz and M.J. Erb.* Depts. of Neuroscience and Medicine, CWRU Sch. of Med., Cleveland, OH 44106.

Tyrosine hydroxylase (TH) is transiently detectable in cells of the root (crest-derived) sensory ganglia of most cranial nerves between embryonic day (E) 13.5-15.5; TH cells are only rarely found, however, in older ganglia (Jonakait, *et al.* 1983; Katz & Erb, 1990). To examine the possibility that the loss of TH after E16.5 was due to modulation by the ganglionic microenvironment, the jugular-superior ganglion (JSG) of nerves IX-X was used as a model system of TH development. E16.5 and older ganglia were grown for 24 h in explant and dissociate culture and monitored for TH by immunocytochemical staining. In contrast to explant cultures and the ganglion *in situ*, 20% of neurons in dissociate cultures of E16.5 JSG were TH+, suggesting that TH expression might be regulated by the state of cell aggregation. In support of this hypothesis, we found that a 4-fold increase in cell density, accompanied by an increase in aggregation, resulted in a 30% decrease in the percentage of TH neurons in dissociate cultures. This decrease was accompanied by changes in neuronal morphology characteristic of ganglion cell maturation *in vivo*. Our data indicate that factors associated with cell aggregation may play a role in regulating neuronal differentiation and transmitter phenotype during cranial sensory gangliogenesis. HL-42131 and Dysautonomia Fndtn.

MULTIPLE bFGF FORMS EXPRESSED IN AVIAN EMBRYOS PROMOTE NEURAL CREST CELL COMMITMENT. L. Sherman*, K. Stocker*, R. Morrison, and G. Ciment. Dept. Cell Biology & Anatomy, Oregon Health Sciences University, Portland, OR 97201.

The neural crest (NC) is a transient embryonic structure whose cells differentiate into a variety of phenotypes including sympathetic and sensory neurons, Schwann cells, and melanocytes. In previous studies, we demonstrated that cultured embryonic avian dorsal root ganglia (DRG) and peripheral nerves (PN), which do not normally give rise to melanocytes, become committed to the melanocyte lineage following treatment with basic fibroblast growth factor (bFGF). We also showed that the cells becoming melanocytes probably belonged to the Schwann cell lineage, and that bFGF appeared to be necessary for melanocyte commitment to occur *in vitro*.

In this study, we assayed avian embryo tissue extracts from NC migratory pathways and NC derivatives for their patterns of bFGF expression using protein immunoblots. Embryo extracts were shown to contain 17, 20, 23, 28 and 32 kDa forms of bFGF, each with unique patterns of expression dependent on embryonic age. We have partially purified these forms and compared their abilities to cause melanogenesis in avian embryonic DRG and PN cultures. Preliminary data suggest that the 17 and 23 kDa forms have similar activities. In addition, antibodies which neutralize these bFGF forms have been introduced into the wing buds of quail embryos. Embryos treated with these antibodies appear to demonstrate localized hypopigmentation in treated wings. These data suggest that bFGF may play an important role in melanocyte commitment, and that different forms for bFGF may have different activities during NC development.

CELL SHAPE AND DIFFERENTIATION I

20.1

DISTRIBUTION OF SECRETORY PROTEINS IN CULTURED NEURONAL CELLS. G. Terenghi, A.M. Suburo, S.C. Wheatley*, D. Horn*, D.S. Latchman*, J.M. Polak. Dept. Histochemistry, RPMS, Hammersmith Hospital and * Medical Molecular Biology Unit, University College & Middlesex School of Medicine, London, UK.

To obtain morphological information concerning cellular mechanisms regulating both the shape of nerve processes, and compartmentalisation and release of neurosubstances, we have used the mouse neuroblastoma N18T2 cell line and several clones of hybrid ND cells (ND7, ND9 and ND21) derived from the fusion of rat sensory neurones with neuroblastoma. These cell lines can be induced to differentiate *in vitro* and were studied using immunocytochemical methods to detect various neuronal markers, neuropeptides and proteins associated with secretion mechanisms. In all cell lines there was immunostaining for protein gene product 9.5, neuropeptide Y, C-flanking peptide of NPY (CPON), tyrosine hydroxylase and chromogranin. Synaptophysin could only be detected in ND cells. Immunoreactivities to substance P, calcitonin gene-related peptide, galanin and somatostatin were not detected in any of these cell lines. *In vitro* differentiation of N18T2 and ND7 cells induced appearance of cell processes of various length. With differentiation, immunostaining for NPY, CPON and chromogranin was found in the tips of the processes, whereas synaptophysin immunoreactivity was seen mainly in cell bodies. Thus the regulated secretory pathway associated with chromogranin was segregated into nerve processes at an early stage of differentiation, when synaptophysin-associated pathway is not yet completely expressed. As NPY, CPON and chromogranin are found in secretory granules, and synaptophysin is a marker for small synaptic-like vesicles, the results of this study are consistent with the view that these markers are associated with different subcellular structures. ND7 cells thus provide a useful model system to study changes in the distribution of neuropeptides, cytoskeletal elements and proteins associated with cell secretion during neuronal differentiation.

ETHANOL PROMOTES NEURITE ELONGATION IN RAT CEREBELLAR MACRONEURONS IN VITRO. JY Zou*, RA Rabin*, RJ Pentney. Depts. of Anatomical Sciences and Pharmacology and Therapeutics, State University of NY at Buffalo, Buffalo, NY 14214.

Ethanol reportedly inhibits neurite growth in chick DRG (Dow and Riopelle, Science 228:951, 1985) but accelerates neurite extension in PC12 cells (White and Wooten, FASEB J 5:A457, 1991). In the study reported here, cerebellar macro-neurons were grown *in vitro* on poly-L-lysine-coated coverslips (1000-1500 cells/mm²) from E17. The cells were stained with antibody against MAP2 for morphometric analysis. Ethanol (75mM), added to the cultures immediately after plating, did not affect neuronal survival or attachment to the substrate. Between 8 and 24 hrs *in vitro*, neurites in ethanol-treated neurons grew by 56% compared with 31% in the control cells. Between 24 and 48 hrs, they grew by 16% compared with 6% in the control cells. The ethanol-induced increases in total length resulted from linear extension of neurites and from increased branching of neurites. The observed changes were independent of the tissue culture medium employed. (Supported by NIAAA Grants AA05592 and AA06207)

20.2

GLYCOCONJUGATE CHANGES DURING SYNAPSE FORMATION. V.V.T.S. Prasad*, S. Fitzgerald*, P. Nelson, and J.R. Moskal. Chicago Institute for Neurosurgery and Neuroresearch, Chicago, IL 60614 and Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20814.

The role that cell-surface glycoconjugates play in the formation of appropriate, stable synapses remains to be determined. We have begun to address this question using 2 model systems; 1) the murine neuroblastoma x rat glioma hybrid cell line, NG108-15, in co-culture with rat myotubes under synapse forming conditions and 2) primary cultures of murine spinal cord (SC) in co-culture with dorsal root ganglia (DRG) also under synapse forming conditions. Gangliosides were purified from cultured cells and subjected to high-performance thin layer chromatography. Immunautoradiography experiments were then performed using A2B5, a monoclonal antibody that recognizes a family of gangliosides present in both neuronal and non-neuronal tissues. It was found that a ganglioside was expressed in the NG108-15 co-cultures that was not expressed in controls (i.e., N18T2-2 x muscle co-cultures or muscle cultured alone). This ganglioside migrates between GM1 and GM2 and may be the O-acetylated form of GD3. The ganglioside patterns observed with A2B5 in DRG x SC co-cultures were distinct from either NG108-15 x muscle co-cultures or DRG or SC cultured alone. These results demonstrate that cell-cell interactions between synapse forming cells and their targets induces significant changes in ganglioside expression; some of which may be important for appropriate synapse formation. This work was supported in part by NINDS grant NS 26186.

20.4

DIFFERENTIAL CONTROL OF MOTILITY, SHAPE AND DIFFERENTIATION OF OLIGODENDROCYTE PROGENITOR CELLS BY bFGF AND PDGF. B.D. McKinnon*¹, C.L. Smith², T.N. Behar³, T.G. Smith³, and M. Dubois-Dalq¹. Lab. of Viral and Molecular Pathogenesis¹, Neural Control² and Neurophysiology³, NINDS, NIH, Bethesda, MD 20892.

We examined the role of two CNS-derived mitogens, basic fibroblast (bFGF) and platelet-derived (PDGF) growth factors, on the proliferation, migration, and differentiation of perinatal rat cerebral oligodendrocyte progenitor cells *in vitro*. In the continued presence of bFGF, progenitors were stellate, non-migratory, divided, and remained undifferentiated expressing high levels of PDGF α -receptor and a POU-homeodomain protein (Oct-6/Scip) transcripts in absence of myelin gene expression. On addition of PDGF, FGF-treated progenitors quickly became bipolar and actively migratory while dividing. The complexity of the cells borders was quantitated by fractal analysis. When PDGF was removed, the cells reverted to their characteristic bFGF stellate shape and stopped migrating, demonstrating the plasticity of the cells response to PDGF. Finally, when bFGF was removed the progenitor cells quickly differentiated into highly branched, non-motile and non-dividing oligodendrocytes, acquired myelin gene transcripts (MBP, PLP, MAG), and down-regulated PDGF α -receptor and Oct-6 transcripts. In the presence of PDGF alone, in contrast, progenitor cells slowly differentiated into oligodendrocytes. Thus, bFGF and PDGF have distinct influences on shape, motility, and differentiation of oligodendrocyte progenitor cells.

TERMINAL DIFFERENTIATION OF A HUMAN NEUROBLASTOMA CELL LINE. P. LoPresti*, W. Poluha*, D. Poluha*, H. Piwnica-Worms* and A.H. Ross, Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, MA 01545.

Human neuroblastoma cell line SHSY5Y expresses both the 75 kDa low-affinity nerve growth factor (NGF) receptor and the *trk* protooncogene and is responsive to NGF. Treatment of these cells with NGF resulted in neurite extension, but not in cessation of cell growth. SHSY5Y cells were treated with NGF and the DNA polymerase inhibitor aphidicolin. The concentration of aphidicolin was varied to optimize differentiation and to minimize the cell death associated with aphidicolin treatment. There were few differentiated cells immediately following the aphidicolin-NGF treatment, but treatment of the cells with NGF in the ensuing week, resulted in extension of long neurites (>400 μ m). If maintained in NGF, the differentiated cells were stable for at least a month and were mitotically inactive. The protooncogene *c-myc* was downregulated. The mRNA for MAP 1B, a microtubule-associated protein associated with neurite extension, was upregulated in the differentiated cells, but there was little or no induction of synaptic vesicle antigens. To elucidate the relation between neuronal differentiation and cell cycle regulation, we are analyzing the expression of cell cycle-related proteins. The p34^{cdc2} kinase is expressed by the differentiated cells, and we are testing whether it is active. Supported by NIH grant NS21716.

NGF AND SATELLITE CELLS EFFECT ON DEVELOPMENT OF DENDRITES BY RAT NODOSE SENSORY NEURONS IN CULTURE. P. De Koninck*, S. Carbonetto* & E. Cooper*, Dept. of Biol., *Neurol. & *Physiol., McGill Univ., Montréal, Québec, H3G 1Y6.

Nodose neurons are pseudo-unipolar sensory neurons whose somas are devoid of synaptic contacts and lack conventional dendrites. Previously, it was shown that nodose neurons were capable of expressing high density nAChRs and forming cholinergic synapses among each other when they develop in culture in the absence of other cell types and with NGF. Therefore, we have asked whether these sensory neurons develop dendrites under these conditions. To distinguish dendrites from axons, we have used immunostaining with an antibody to MAP2, together with an antibody to phosphorylated neurofilaments (SMI31). Our results indicate that after 3 weeks in culture with NGF and without satellite cells, 24% (350/1450) of the neurons had MAP2 positive (SMI31 negative) processes which we have classified as dendrites. Of these neurons, 65% had 2 to 5 primary dendrites. In contrast, less than 5% (47/999) of neurons had dendrites in sister cultures without NGF. In addition, dendrites were two fold longer (155 μ m \pm 9) after 3 weeks in cultures with NGF than without NGF (75 μ m \pm 8). These results indicate that some neonatal sensory neurons are capable of developing dendrites and that NGF plays an important role in this process.

It was previously shown that nodose neurons do not form functional synapses when co-cultured with their ganglionic satellite cells and NGF. Our preliminary results suggest that few nodose neurons develop dendrites under these conditions. Our results, taken together, suggest that the expression of dendrites correlates with synapse formation in this system. Funded by NSERC, FRSQ and MRC.

THE RELATIONSHIP OF GLIAL CELLS TO SYNAPTIC REMODELLING VIEWED IN LIVING MICE. S.L. Pomeroy, Department of Neurology, Children's Hospital, Harvard Medical School, Boston MA 02115.

Synaptic boutons and satellite cells associated with autonomic ganglion neurons have been observed to change in position and number when viewed over time in living mice (Purves et al. 1987, *Science* 238:1122-6; Pomeroy and Purves 1988, *J Cell Biol* 103:1167-75). Since synapses are made preferentially near satellite nuclei, I have assessed whether synaptic remodelling is related to concurrent changes of these glia.

Salivary ganglion neurons were viewed in anesthetized adult male CF-1 mice using *in vivo* video microscopy. The positions of synaptic boutons (stained with the styryl pyridinium dye 4-di-1-ASP) and satellite cell nuclei were recorded initially and again 2-3 months later.

My results show that synaptic remodelling may occur without coincident change of glial cell nuclei, although a strong preference is retained for synaptic boutons to remain associated with nuclei during remodelling. Although changes of satellite nuclei are not necessary for synaptic remodelling, the persistence of their association suggests an important role of glial cells in the maintenance of these synaptic contacts.

AGE-RELATED EFFECTS OF NERVE GROWTH FACTOR ON THE MORPHOLOGY OF DEVELOPING SENSORY NEURONS. S.A. Scott and A. M. Davies, Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794 and Dept. of Anatomy, St. George's Hospital Medical School, London UK SW17 0RE.

Studies on neonatal mammals have shown that neuronal morphology is regulated by the availability of target-derived neurotrophic factor (Purves et al., 1988. *Nature* 336:123). We tested whether the same is true for embryonic neurons, which are critically dependent on target-derived neurotrophic factors for survival. We grew trigeminal sensory neurons from avian embryos of different ages (E6-E16) *in vitro* in different concentrations of nerve growth factor (NGF) (0.025-20 ng/ml) for 15 or 48 hr, and measured the size and complexity of the resulting arborizations; these levels of NGF supported 4-70% of neurons for at least 72 hr. As expected, the size and complexity of arborizations increased with embryonic age (up to E14), regardless of NGF concentration. Surprisingly, however, for embryos younger than E14 neuronal morphology at a given age was similar in all levels of NGF. By contrast, at E14 and E16, when trigeminal neurons begin to lose their absolute dependence on NGF, neurons established significantly larger and more complex arborizations in higher concentrations of NGF. Thus, in young embryos the extent of neurite outgrowth appears to be independent of neurotrophic factor levels; apparently all neurons that receive enough NGF to survive elaborate full-size arbors. As neurons mature and lose their absolute requirement for NGF, neurite growth becomes dependent on the availability of neurotrophic factor, as in neonates.

TARGET INTERACTIONS INFLUENCE MORPHOLOGY OF SV-2 POSITIVE CONTACTS IN CO-CULTURES OF CHICK EDINGER WESTPHAL NEURONS WITH APPROPRIATE AND INAPPROPRIATE TARGETS. J.T. Fujii, Dept. of Anatomy and Cell Biology, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

In vivo a subset of Edinger Westphal neurons forms large hand-like synaptic terminals known as calyces or calyciform terminals on a subset of ciliary ganglion neurons. Previous work (Fujii and Berg, 1987) has shown that Edinger Westphal neurons in culture, identified by their enkephalin immunoreactivity, form calyx-like contacts preferentially on ciliary ganglion neurons. These contacts have now been examined for the presence of synaptic structures using a monoclonal antibody raised against the synaptic vesicle protein SV-2.

EW nuclei were specifically dissected from 400 μ m thick embryonic brainstem slices, dissociated, and cultured with ciliary ganglion or sympathetic ganglion neurons. Double label immunohistochemistry experiments found that greater than 90% of the enkephalin-positive calyx-like contacts in these co-cultures were also positive for SV-2 immunoreactivity. Furthermore, the proportion of SV-2 positive contacts with calyx-like morphology was three times greater in co-cultures with ciliary ganglion neurons than in co-cultures with sympathetic neurons. The finding that calyx-like contacts are immunoreactive for SV-2 and that interaction with an appropriate target, ciliary ganglion neurons, favors their formation *in vitro* suggests that direct surface interactions with the target neuron may be important in determining the morphology of synaptic terminals *in vivo*.

LIMITED EFFECT OF AFFERENT INPUT ON OLFACTORY BULB DEVELOPMENT. J.H. McLean and A. Darby-King*, Basic Medical Sci., Memorial University of Nfld, St. John's, Newfoundland, Canada A1B 3V6

Cholinergic and noradrenergic (NE) axons have been suggested to be essential for providing synaptic plasticity during critical periods of cortical development (Bear & Singer '86). Recently, cholinergic inputs to the cortex have been shown to produce cytoarchitectural changes suggesting that the input influences cell migration (Hohmann et al. '88). In this study, Nissl, immunocytochemistry (ICC) of intrinsic dopaminergic neurons and glia, acetylcholinesterase histochemistry, and Golgi studies have been used to elucidate the pretransmission role of cholinergic inputs to the developing rat olfactory bulb (OB).

On the day of birth, an electrolytic lesion was made in the diagonal band (source of cholinergic input to the OB) and 6-OHDA was injected subcutaneously to deplete the locus coeruleus (NE) input to the OB. Following survival of 10 or 35 days the animals were sacrificed by perfusion. At PND 11, the main effect of the depletions was that the OB was smaller and fewer cells appeared to be present in the proliferative region (subependymal zone). In some cases there was also disruption of cytoarchitecture in the OB. ICC staining of intrinsic dopaminergic cells indicated that some of these cells had migration problems on the side ipsilateral to the diagonal band depletion. The distribution of glia appeared normal. Results at 35 day survival was similar to the 11 day survival. Golgi impregnation of the OB at different ages revealed normal cellular differentiation of intrinsic mitral, granule and periglomerular cells. Thus, the major change in the OB following depletions was fewer migrating cells. We interpret the results to indicate that the cholinergic/NE input has a role in cell migration or the electrolytic lesions directly interrupted migration of cells destined to reach the OB. Supported by MRC of Canada MT-10931.

CELL-CELL INFLUENCES ON THE MORPHOLOGICAL DEVELOPMENT OF AN IDENTIFIED MOTOR NEURON IN THE MOTH *MANDUCA SEXTA*. Karla S. Kent, Dept. Anat., Sch. Dent., Oregon Health Sciences University, Portland, OR 97201

During metamorphosis of the moth *Manduca sexta*, thoracic leg motor neurons (MNs) undergo substantial morphological changes, including dendritic loss and dendritic growth. In order to determine if these dendritic changes are influenced by cell-cell interactions, sensory and interneuronal inputs to one identified leg MN, the metathoracic femoral extensor MN, have been manipulated using surgical and chemical ablation techniques. Although ablation of one or both metathoracic legs does not substantially alter the course or magnitude of dendritic loss and growth, the overall morphology of the MN dendritic arbor is affected such that a characteristic dorsomedial process is much more extensive in preparations deprived of metathoracic legs during adult development. The extensive growth of this process occurs even when all three pairs of thoracic legs are absent suggesting that its elaboration is not induced by sensory inputs from other legs. In addition, elimination of postembryonically generated interneurons by use of an inhibitor of DNA synthesis (hydroxyurea) does not alter the overall extent of MN dendritic reorganization nor does it affect growth of the dorsomedial process. Current studies are aimed at identifying specific cell-cell interactions that influence MN dendritic growth and distinguishing between influences of specific leg sensory inputs and contact with specific leg muscles.

THE UNIQUE AND BIZARRE MORPHOLOGY OF LATE-APPEARING, PERIPHERALLY INDUCED CENTRAL NEURONS OF THE LEECH. Eduardo R. Macagno and Timothy Robin Gershon*, Dept. of Biological Sciences, Fairchild Center, Columbia University, NY, NY 10027

The peripherally induced central (PIC) neurons are found only in the segmental ganglia (SG) of the 5th and 6th body segments, the only segmental ganglia that innervate the reproductive organs. These neurons, of which there are approximately 350 per SG, are born later in embryogenesis than the other central neurons, in response to a signal generated by the male genitalia and conveyed along nerves to the sex SG (Baptista, C.A., et al, *Nature* 6287 855-858; 1990). PIC cells do not express their neuronal phenotype, however, until several months after the end of embryogenesis. After their delayed differentiation, the PIC neurons must incorporate themselves into the already formed and functioning CNS. We are endeavoring to shed light on the mechanisms controlling the timing of PIC neuron differentiation and the growth of PIC neuronal projections through existing circuitry.

We have found that the number of mature PIC neurons increases gradually during the animal's first year of life, but that it increases dramatically with body weight following episodic feeding. The arborization of PIC cells was studied using intracellular dye injection. Each PIC neuron was found to have a single long axon with short secondary branches. Individual axons followed different courses; some travelled in nerve roots to the periphery; others ran in the interganglionic connective nerve to adjacent SG. Most completed at least one, and often several 360° turns. The wide variation in PIC neuron morphology and the presence of multiple loops in their axons suggests that there may be a stochastic element in the guidance of their growing processes. We have proposed that the PIC neurons may be neurosecretory cells (Baptista, C.A. & Macagno, E.R. *J. Neurobiol.* 19 707-726, 1988), and if so, precise pathways and connections within the neuropil might not be required.

MOSSY FIBER OUTGROWTH PRECEDES DENDRITIC MATURATION IN DEVELOPING DENTATE GRANULE CELLS. B.J. Claiborne, M.P. O'Boyle* and S.P. Jones*, Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249.

Previous studies of early granule cell development in the dentate gyrus have not addressed the relationship between axonal outgrowth and dendritic maturation. In this study, Dil was used to retrogradely label developing granule cells whose axons had reached the CA3 region of the hippocampus. Crystals of Dil were placed in field CA3c of fixed hippocampal slices from rat pups between the ages of 2 and 9 days and the dye was allowed to diffuse for 18 to 36 hours.

Labeled granule cells at various stages of maturity were visible in all slices, reflecting the long period of granule cell neurogenesis in the rat. In general, labeled neurons from the youngest animals had very immature dendritic trees with thick primary dendrites and short stubby branches. Dendrites exhibited growth cones and numerous large varicosities, but had few or no spines. Basal dendrites were present on most cells. As the animals matured, dendritic branches elongated and spines began to appear. Varicosities, growth cones and basal dendrites decreased in number, but were still present on many labeled cells. In the adult rat, granule cells do not display dendritic varicosities, nor do they have basal dendrites. The present results indicate that the mossy fibers of at least some granule cells reach the CA3c region of the hippocampus long before the adult form of the dendritic tree has been established. DEVELOPMENTAL REMODELLING OF IDENTIFIED LEECH MOTOR NEURON PERIPHERAL ARBORIZATIONS. J. Jellies and D.M. Kopp, Neurobiology Research Center and Dept. Physiol. and Biophysics, Univ. of Alabama at Birmingham, Birmingham, AL, 35294.

Many neurons employ a developmental strategy whereby their final form and target innervation is sculpted by selective modification of "appropriate" versus "inappropriate" projections (Macagno *et al.*, *J. Neurobiol.*, 21:107, 1990), yet the mechanisms driving this process *in vivo* are somewhat obscure. We have recently discovered a particularly robust example of such plasticity in the medicinal leech, *Hirudo medicinalis*. The muscular heart tubes in this animal are peripheral targets for a pair of excitatory motor neurons, the HE's (Maranto & Calabrese, *J. Comp. Physiol.*, 154:367, 1984). We used intracellular dye-filling and immunostaining to compare embryonic to mature HE's. During early embryogenesis, all HE's project into multiple territories, including the primordial heart tubes and the ventro-lateral body wall. The body wall projections are extensive, often showing tertiary and quaternary branches. However, they are transient - being absent in the mature leech. Also, while there are no physiologically identified HE's in the first 2 or last 2-3 midbody segments in adults (Thompson & Stent, *J. Comp. Physiol.*, 111:261, 1976), we propose that there are, in fact, HE homologs in these segments. Our identification of these homologs is based upon comparisons of cell position and size, ipsilateral projection out the anterior nerve root, early dendritic morphology, and peripheral arborization (in early embryos these cells also project to the nascent heart tubes and ventro-lateral body wall). Additionally, the definitive HE's (segs. 3-18) and these homologs (segs. 1,2 & 19-21) have another feature in common, all being labelled by a mAb directed against human fibronectin. We further discovered that these anterior and posterior homologs probably persist, but as predicted, they are not driven by the central circuitry that generates the rhythmic heartbeat. Instead they exhibit primarily tonic discharge. We are examining the possibility that the HE homologs also remodel their peripheral arborizations, but perhaps do so in a fashion opposite to the definitive HE's, losing heart tube projections while elaborating the body wall arborization, ultimately being incorporated into different circuits. Whether HE remodelling is causally related to target contact or initial assembly of the heartbeat central pattern generator remains to be determined. (Supported by NIH NS28603 to JJ).

DEVELOPMENT OF ROSTROCAUDAL DENDRITES OF RAT PREGANGLIONIC SYMPATHETIC NEURONS E.B. Ezerman and C.J. Forehand, Dept. of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405

The longitudinal organization of preganglionic sympathetic neurons in the adult mammalian spinal cord takes the general form of a ladder (Barber *et al.* *J. Comp. Neurol.* 229: 329, '84). Dispersed clusters of neurons in the intermediolateral cell column (IML) and intercalated area form the rungs of the ladder. In the rat, preganglionic neurons of the IML have extensive dendritic arborizations in both rostrocaudal and mediolateral directions (Forehand, *J. Comp. Neurol.* 298:334, '90). We have investigated the development of the dendritic arborization of preganglionic sympathetic neurons. By embryonic day (E) 15, an extensive mediolateral arborization is present; however, development of the rostrocaudal arborization is largely postnatal and occurs in two spurts. Rostrocaudally oriented dendrites were first seen at E20 when the average rostrocaudal dendritic extension was 35µ. At postnatal days (P) 1, 3, and 5, the average rostrocaudal extension was 130µ; at P7 and 9, it was 250µ. Growth spurts occurred between E20 and P1 and between P5 and P7. These correlate with similar spurts in the distances between the developing ladder rungs. However, by P3, the rate of rostrocaudal dendritic extension exceeds the development of the spacing between the rungs of the ladder. By P7 the extent of the rostrocaudal arborization is almost double the distance between the rungs. The signal for this postnatal growth of a subpopulation of the dendrites of preganglionic neurons is unknown.

20.16

ELEVATED GM2 GANGLIOSIDE IS ASSOCIATED WITH THE PROLIFERATION OF DENDRITES ON PYRAMIDAL NEURONS IN DEVELOPING NEOCORTEX. L.A. Goodman, P.O. Livingston* and S.U. Walkley, Dept. Neuroscience, Rose F. Kennedy Center, Albert Einstein College of Medicine, Bronx, NY, 10461.

Recent studies of cats with the neuronal storage disease, α -mannosidosis, established that elevated GM2 ganglioside in mature cortical pyramidal neurons is associated with proliferation of new dendrites, suggesting that GM2 may stimulate dendritic growth (Goodman *et al.*, *Soc. Neurosci. Abstr.* 16:315). To determine whether the association between GM2 ganglioside and dendritic growth occurs under normal conditions, we used a monoclonal antibody to localize GM2 in cerebral cortex of developing cats. The present study shows that neurons contain GM2-like immunoreactivity (GM2-LIR) throughout the period when pyramidal cells elaborate their normal dendritic arbors. Whereas neurons in adult cats contained no GM2-LIR, pyramidal-like neurons in cats at late gestation through 2.5 weeks of age contained diffuse GM2-LIR that filled the soma and proximal portions of basilar and apical dendrites. Densely-stained cells were located in cortical layer V and in undifferentiated cortical plate above layer V. Some of the older (i.e., deep) neurons contained dark dots of GM2-LIR; in the electron microscope, the dots looked like lysosomes, suggesting that these cells were degrading excess GM2 ganglioside. At 3 and 4 weeks of age, only younger (i.e., superficial) cells contained GM2-LIR. By 6 weeks of age, when pyramidal neurons were morphologically mature, reactivity was no longer evident. Studies of developing rat cortex produced similar results; viz., neurons contained GM2-LIR from postnatal day 5 through day 21, once again coinciding with normal dendritogenesis. Thus, GM2 ganglioside appears to regulate dendritic growth on pyramidal neurons during normal development as well as on mature pyramidal neurons in a disease state. (NS18804 and NS07098)

20.17

A DEVELOPMENTAL GOLGI STUDY OF PURKINJE CELL DENDRITIC MORPHOLOGY IN LURCHER CHIMERIC MICE. J. M. Soha and K. Herrup. E.K. Shriver Center, Waltham, MA 02254.

Previous studies have shown that wild type cerebellar Purkinje cells (PCs) in mature lurcher mouse chimeras (+/Lc \leftrightarrow +/+) exhibit aberrant and atrophic morphologies that may reflect developmental deafferentation and an altered trophic environment. The present study analyzes PC morphology in lurcher chimeras and wild type chimeras (+/+ \leftrightarrow +/+) at postnatal day 20 to determine if the aberrant phenotype arises through regression after normal growth, or instead via a failure in development.

Mutant (+/Lc) PCs that remained in P20 lurcher chimeras were easily recognized by their immature morphology (typical of P7), indicating that the stunted morphological phenotype of lurcher PCs is a cell intrinsic effect of the lurcher gene. Several features of wild type PC dendrites, including height, width, and areal extent, were measured in sagittal sections of Golgi-Cox material. At P20, preliminary analysis suggests that wild type PCs in lurcher chimeras and wild type chimeras are similar with respect to these measures. Comparison to the same features in adult chimeras suggests the phenomenon is regressive; e.g., dendritic extent (area in the sagittal plane) in both lurcher and wild type chimeras at P20 closely resembled average extent in adult wild type chimeras, but was roughly twice that of adult lurcher chimeras. The same comparison also suggests that the phenotype is not widely expressed at P20. Supporting this conclusion, 1 μ m plastic sections of a P20 lurcher chimera stained with toluidine blue do not exhibit the distinctive abnormal staining of primary dendrites previously reported in adult lurcher chimeras. Supported by NIH grants NS18381 and NS20591 (KH), NS08896 (JS), and by March of Dimes 1-1175 (KH).

DEVELOPMENT OF COMMISSURAL NEURONS IN MAMMALIAN SPINAL CORD. I. Silos-Santiago and W.D. Snider. Department of Neurology, Washington University, School of Medicine, St. Louis, MO 63110.

Little is known about the development of interneurons in the mammalian spinal cord. We have studied the migration and dendritic arborization of spinal neurons with an axon in the ventral commissure in embryonic rats. Crystals of the lipid soluble tracer, Dil, were placed in various locations in the thoracic spinal cord in order to label commissural neurons within the intermediate zone and ventral horn at E13.5, E15, E17, and E19.

Dil revealed the morphology of these neurons with the detail of intracellular staining. At E13.5 we observed seven groups of neurons sending their axons to the ventral commissure. These groups appear to have originated in different places along the neuroepithelium adjacent to their position within the gray matter. By E15, a surprisingly early stage, commissural cells are near their final locations and exhibit characteristic morphologies. On the basis of dendritic arborization and position we can identify at least 15 different groups. Groups in the most dorsal location within the intermediate zone are widely separated and have the most characteristic morphologies with dendrites primarily orientated in the dorso-ventral axis. In more ventral regions cells with oblique, radial or horizontal dendritic trees are intermingled. Near the midline two types of cells are present, one with short radially distributed dendrites, and another with a long straight dendritic stem projecting toward the dorsal horn. How the differing dendritic arbors of commissural neurons relate to their target projection and the innervation they receive is currently under investigation.

We conclude that, in mammals, a large number of neuronal classes send an axon to the ventral commissure. Some of these can be classified on the basis of dendritic morphology and location. Characterization of the morphology of intrinsic spinal neurons is the first step in understanding how the complex circuitry of the spinal cord is generated.

20.18

EARLY DENDRITE DEVELOPMENT DESCRIBED BY FRACTAL DIMENSION. E.A. Neale, L.M. Bowers*, and T.J. Smith Jr. Lab. Develop. Neurobiol., NICHD and Lab. Neurophysiol., NINDS, NIH, Bethesda, MD 20892

The early development of neurons in cell culture was studied using fractal dimension (D) as a quantitative descriptor of the morphologic complexity of cellular borders. Dissociated fetal murine spinal cord cells, plated at low density onto a glial substrate, were stained using tetanus toxin Fragment C immunohistochemistry at intervals from shortly after plating until one week in vitro. Fluorescent images were captured and processed to obtain estimates of the value of D for individual neurons (Smith et al., J. Neurosci. Meth. 27: 173, 1989). D was consistent with perceived morphologic complexity and, after one week in culture, ranged from 1.28 to 1.46. The sample of neurons was subdivided into four groups on the basis of the number of primary processes emerging from the soma. Differences were significant among the groups in the plateau value and time-course of development of D. Neurons with 3 or 4 primary processes were analyzed additionally, over 7 days in vitro, for total dendrite length, area occupied by the arbor, number of interbranch segments, and number of intersections with a superimposed pattern of concentric circles. The mean value of D increased from 1.0, the value for a circle, to 1.34. Half of this increase occurred during the first 9 hr in culture. Increases in the other measures occurred over a different time-course, with half-maximum values attained after 4 days. The early rise in D occurred before the formation of interneuronal contacts, suggesting intrinsic control. The observation that growth of the dendrite arbor, during the first week in culture, was associated with a continued increase in D indicates that, over this interval, the arbor does not exhibit "fractal growth"; i.e., increase in size with constant D. Fractal analysis provides an objective quantitative measure of branching complexity for studies of the effects of extrinsic developmental factors, including physiologic activity, on dendrite morphology.

DELIVERY OF DOCOSAHEXAENOIC ACID (22:6) TO MEMBRANE PHOSPHOLIPIDS DURING SYNAPTOGENESIS. R.E. Martin and N.G. Bazan. LSU Eye Center and Neuroscience Center, New Orleans, LA 70112.

In vivo experiments were designed to investigate 22:6 delivery to the central nervous system and to follow its incorporation into growth cones and synaptosomal membranes. Instead of using [¹⁴C]18:3 (PNAS 86:2903;1989), in this study mice were injected with [³H]22:6 at 5 days postnatal and were later killed to follow the metabolism of 22:6 and its trafficking in the plasma from liver to brain and retina. Free 22:6 was rapidly esterified into phospholipids, triacylglycerols (TG), and cholesterol esters for transport in the plasma. Peak labeling of liver occurred 2 h after injection and decreased biphasically over 72 h. Enrichment of label in plasma was highest 2 h post-injection and decreased steadily over the next 70 h. Uptake of [³H]22:6 in retina and brain occurred later than incorporation in liver and increased with time. Label acquired by retina and brain paralleled loss of label from liver. When synaptosomes and less mature nerve endings (growth cones) were assayed for [³H]22:6 content 5 days after injection, growth cones were more enriched with [³H]22:6 than synaptosomes or the crude homogenate. The distribution of [³H]22:6 in growth cone and synaptosomes was similar. Phospholipids were most heavily labeled, followed by TG and free fatty acid. The data indicate that during development, 22:6 is transported from the liver in the plasma to the retina and brain as a fatty acid esterified in phospholipids, cholesterol ester, and TG. Upon arrival to the brain, [³H]22:6 is preferentially transferred to growth cones rather than to more mature synaptic endings. Supported by NEI EY04428.

21.2

HISTOCHEMICAL INCREASE OF CHICK CREATINE KINASE ACTIVITY DURING MATURATION OF INTERNEURONAL CONNECTIONS IN VITRO. O. Ramirez, V. Alemán, E. Jiménez* and B. Osorio*. Departamento de Bioquímica y de Fisiología, Biofísica & Neurociencias, Centro de Investigación y de Estudios Avanzados del I.P.N. México, D. F. 07000.

Formation of synapses have high energy requirements not completely covered by anaerobic and aerobic glycolysis. ATP must be produced by transphosphorylation. To study neuronal maturation, chick embryo brain neurons from stage 30 were cultured for 11 days on polylysine coated dishes. At 2 day intervals, representative samples were utilized for phase contrast observation, electron microscopy, and histochemical formazan-localization of creatine kinase (CK). An increase in the number of long processes between nerve cell clusters was followed by a 123% increase of cytosolic BB-CK specific activity from the 5th to the 7th day of culture. The intensity of catalytically active CK staining paralleled the cytosolic BB-CK specific activity increase in developing processes and nerve cells clusters. Formazan granules along neurites and in clusters clearly appeared from 5 day. Coinciding with the CK burst, synapses (\geq 200 nm long) showed, in the electron micrographs, a progressive increase in complexity as they matured from the fifth day. These findings support the view that, as a molecular marker, CK activity can be utilized during the establishment of interneuronal connections and synapse maturation.

21.3

PC12 CELL DIFFERENTIATION IS ALTERED BY ADENOVIRUS-5 E1A PRODUCTS. Kim E. Bouloukos* and Edward B. Ziff. Howard Hughes Medical Institute, Dept. of Biochemistry, NYU Medical Center, N.Y., N.Y., 10016.

The rat pheochromocytoma-derived PC12 cell line is a useful system for studying growth arrest and neuronal differentiation in the presence of neurotrophic factors such as nerve growth factor (NGF) or fibroblast growth factor (FGF). We have used viral transforming proteins to disrupt neuronal differentiation of PC12 cells to understand how regulation of PC12 cell growth contributes to neuronal differentiation. Since the human adenovirus E1a proteins are capable of altering cell growth properties, genomic E1a sequences were stably introduced into PC12 cells by electroporation and neomycin selection. The E1a transformed PC12 cells (PC-E1a cells) are flattened, irregular in shape and divide rapidly compared to parental PC12 cells. Gene expression is also modified such that mRNAs encoding the intermediate filament protein peripherin as well as other neuronal markers abundant in non-treated or NGF-treated PC12 cells are not expressed in PC-E1a cells. Effects of NGF and FGF treatment of PC-E1a cells were investigated by measuring DNA synthesis, morphological differences and changes in gene expression. We find that PC-E1a cells fail to respond to both NGF and FGF. Stimulation of parental PC12 cells with these ligands via their respective receptors transduces signals which eventually result in PC12 cells exiting the cell cycle and extending neurites. It appears that E1a products disrupt the expression of the receptor for NGF and possibly FGF, thereby abolishing the potential for signal transduction at the beginning of the differentiation pathway.

Since PC-E1a cells proliferate rapidly, we next investigated whether epidermal growth factor (EGF), which induces a proliferative response in PC12 cells, could still elicit such a response in PC-E1a cells. Thymidine labelling experiments indicate that EGF does not augment the proliferation of PC-E1a cells suggesting that some other mechanism(s) is responsible for inducing growth. Since the effects of E1a proteins are pleiotropic, we are currently investigating how E1a products alter gene expression and what role these genes play in growth arrest and neuronal outgrowth.

INDUCTION OF RAPID DIFFERENTIATION IN IMMORTALIZED RAT SEPTAL CELL LINES. E.M.Eves¹, J. Kwon¹, and B.H.Wainer^{1,2,3}. Depts. ¹Pharm. & Phys. Sci., ²Path. and ³Comm. on Neurobiol., The University of Chicago, Chicago, IL 60637.

Temperature sensitive alleles of the SV40 large T antigen were employed to immortalize rat embryonic (E14-15) septal cells. The resultant cell lines proliferate at 33° and cease or greatly slow proliferation at 39°. Seven of thirteen lines tested demonstrated a dramatic response to a cocktail of differentiation agents composed of 0.5mM 1-isobutyl-3-methyl xanthine, 0.5mM dibutyryl cAMP, and 25ng/ml NGF (XAN) (Ronnelt et al., 1990, Science 248, 603). The undifferentiated cells had a flat, epithelioid appearance. Within one hour following the addition of XAN the cells became refractile and had begun to produce long, multibranched processes. This morphological differentiation reached a maximum at approximately 4 hours. Neurofilament protein was detectable by immunocytochemistry in the differentiated cells; glial fibrillary acidic protein was not detectable. The effect of XAN on proliferating cells (33°, 10% FCS) was transient with many of the cells regaining epithelioid morphology within 24 hours. In non-proliferating or slowly proliferating cells (39°, 1% FCS) XAN treatment was lethal for the majority of the cells. (Supported by NS 25787 and The Alzheimer's Disease and Related Diseases Assn.)

MORPHOLOGICAL AND ELECTROPHYSIOLOGICAL DE-DIFFERENTIATION OF N1E-115 CELLS BY SERUM BORNE FACTOR(S). L.M.Ireland¹, C.Marr¹, R.H.Rech¹, & P.Cobbett¹. Dept. Pharmacol./Toxicol. & Neuroscience Program, Michigan State University, East Lansing, MI 48824-1317.

Murine neuroblastoma derived N1E-115 cells may be morphologically and electrophysiologically differentiated by various stimuli including removal of serum from the culture medium (Cobbett et al., Soc. Neurosci. Abstr. 16, 990, 1990). We have examined whether this differentiated state is maintained when the stimulus for differentiation is removed. N1E-115 cells were first maintained in serum free medium (SFM) for 12 days: cells were process bearing and generated large amplitude, short duration, Na⁺-dependent action potentials. SFM was then replaced with medium containing 10% new born calf serum: cells rapidly altered morphologically and electrophysiologically. Process withdrawal occurred with a variable latency but was rapid once initiated: after 24 hours, mean process length was not changed but the occurrence of process bearing cells decreased significantly (from 100.4 ± 0.4% to 37.0 ± 6.6%). Within 48 hours, <20% of cells were process bearing. Morphologically de-differentiated cells had significantly decreased resting membrane potentials, and action potential amplitudes but had increased input resistances and action potential durations. The data clearly show that differentiation of N1E-115 cells may easily be reversed by as yet unknown factor(s) in the serum. Morphological and electrophysiological de-differentiation are closely associated temporally suggesting the possible dependence of one on the other. (Supported by the Pharmaceutical Manufacturers Association Foundation.)

21.4

REGULATION OF PROTEIN KINASE C IN HUMAN AND MURINE NEUROBLASTOMA CELL DIFFERENTIATION.

F. Battaini¹, S. Bergamaschi¹, S. Govoni¹, L. M. Vicentini¹, M. Parenti¹ and M. Trabucchi¹. Dept. Exptl. Med. Bioch. Sci. Iud Univ. Rome, ¹Dept. Med. Pharmacol. Toxicol. and Chemother. Univ. Milan, ²Pharmacobiol. Dept., Univ. Bari, Italy.

The induction of neurite outgrowth in neuroblastoma cells is a useful model for the analysis of the neurochemical parameters related to neuronal differentiation. Protein kinase C (PKC) is one of the key enzymes involved in cell growth and differentiation; its inhibition, in fact, induces neuroblastoma cells to differentiate. In this study we have investigated PKC in human (SK-N-BE) and murine (NG108-15) neuroblastoma cells. In both cell lines the differentiation is associated with neurite formation and with a decrease in PKC. In SK-N-BE differentiated (D) cells (Retinoic acid 2 μM for 10 days) there is almost a 40% decrease in 3H-Phorbol 12,13 dibutyrate total binding. In NG108-15 D cells (dibutyryl cAMP 1 mM for 4 days) phorbol ester binding is 50% of that in non D cells. The analysis of PKC function (histone-directed) indicates that the differentiation elicits a decrement in soluble (sol) and membrane-bound (mem) activity in both SK-N-BE (sol -41%, mem -22%) and in NG108-15 cells (sol -50%, mem -62%). The phosphorylating activity in both cell lines appears to be due to the α isoform of PKC. In fact Northern blot analysis reveals the presence of α, but not β or γ isozymes mRNA. The data indicate that PKC is modified when processes controlling neurite (SK-N-BE) and synapse formation (NG108-15 cells) are activated.

21.6

INTERACTION OF ACIDIC FIBROBLAST GROWTH FACTOR AND TRANSFORMING GROWTH FACTOR BETA IN FETAL RAT ASTROCYTES IN VITRO. T.C. Ryken¹, R.K. Osenbach¹, V.C. Traynelis¹ and R. Lim¹. Divisions of Neurosurgery and Neurochemistry, University of Iowa College of Medicine, Iowa City, Iowa 52242.

The mitogenic and morphologic effects of acidic fibroblast growth factor (aFGF) and transforming growth factor beta (TGF-β) were assayed on fetal rat astrocytes in the presence and absence of serum using growth curves, phase contrast, and scanning electron microscopy. Astrocytes incubated with aFGF underwent a characteristic morphological change involving extensive process formation and rounding of cell bodies, accompanied by an increase in mitotic activity. Astrocytes incubated with TGF-β underwent a slight decrease in mitotic activity and remained morphologically unchanged. The cells incubated in a combination of aFGF and TGF-β demonstrated an attenuation of both the mitogenic and morphological changes observed in the presence of aFGF alone. These results suggest that in normal fetal rat astrocytes, TGF-β is capable of attenuating the mitogenic and morphological changes induced by aFGF *in vitro* and may have a regulatory role in astrocyte growth and differentiation.

21.8

NEURONAL CELLS DERIVED FROM THE CELL LINE N-TERA 2 EXHIBIT A CHOLINERGIC PHENOTYPE S.R. Kleppner, S.J. Pleasure, V.M. Y. Lee¹. Inst. of Neurosci., Dept. of Path., Univ. of PA Sch. of Med., Phila., PA 19104.

We have previously developed a culture system which yields nearly pure post-mitotic neuronal cultures from N-Tera 2 (NT2) cells treated with retinoic acid (RA). In this study, we sought to determine the neurotransmitter phenotype of these cells. Our initial work focussed on cholinergic properties as measured by choline acetyl transferase (ChAT), an enzyme responsible for acetyl choline production. ChAT levels were assayed using a modification of the radiochemical method described by Fonnum (J. Neurochem. 24: 1975). Measurements of ChAT using this method established that neuronal cells derived from the NT2 cell line with RA treatment exhibited cholinergic activity. Antibodies directed against ChAT confirmed its presence in these pure cultures. We also characterized the onset and time course of cholinergic activity following exposure of the cells to RA as well as the effects of various concentrations of RA on ChAT activity. ChAT first appeared at low levels in mixed cultures one week after initial exposure to RA, and activity increased dramatically over the following two weeks. To determine whether various concentrations of RA yielded cells committed to different phenotypes, pure neuronal cultures induced with RA concentrations between 10⁻⁵ and 10⁻⁸ M were examined. These experiments yielded pure cultures with cells exhibiting ChAT activity. Finally, we attempted to correlate the onset of ChAT activity to other cellular events occurring during the first three weeks following RA treatment. Preliminary results indicate that ChAT activity accompanies the terminal commitment to a neuronal phenotype. Thus, RA treatment of NT2 cells leads to a cholinergic phenotype of resulting neuronal cells. Expression of this activity follows a specific time course which seems to match the appearance of other neuronal markers. We are now working to define more precisely the relative levels and timing of ChAT expression in these cells.

21.9

IN VITRO CYTOSKELETAL DIFFERENTIATION OF NEURONAL CELLS INDUCED BY RETINOIC ACID IN NTERA 2 CELLS. S.J. Pleasure and V.M.-Y. Lee*. Dept. of Path., Univ. of PA Sch. of Med., Phila., PA 19104.

NTERA 2 (NT2) cells are a human teratocarcinoma cell line which differentiates into neuronal cells in response to retinoic acid (RA). We have shown previously that it is possible to isolate large numbers of neuronal cells (NT2-N cells) in pure cultures from RA treated cells. We have now examined the changes in cytoskeletal phenotype from undifferentiated stem cells to nearly pure neuronal cultures. Before treatment, NT2 cells are flat, epithelioid cells that express nestin, keratins 8 and 18, vimentin and small amounts of NF-L, NF-M and NF66. P+++ NF-M begins to appear in clusters 3 days following the first RA treatment and by 1 week there is extensive expression of P+++ NF-M. At 2 weeks, the cultures contain two distinct populations of cells; the first resembles the original stem cells and the second elaborates rudimentary processes and no longer expresses nestin or keratins. The latter also express P+++ NF-M, MAP2 and tau. By 3 weeks, the second group of cells have extended long processes. Following purification of the NT2-N cells there is a period of extensive neurite outgrowth during which MAP2 and P+++ NF-M are ubiquitously expressed throughout the cell. At 3-4 weeks, as the neuritic network stratifies, segregation of these antigens begins to appear. By 5 weeks, the NT2-N cells have established a more differentiated neuronal phenotype with readily recognizable dendrites and axons. The dendritic processes and cell bodies of these cells contain MAP2 and P. NF-M while the axonal processes have P+++ NF-M.

In summary, RA induces a complete conversion of NT2 cells from a cell line with neuroepithelial stem cell characteristics into post-mitotic neurons that eventually develop the polarized morphology of neurons. Thus, NT2 cells are an excellent system for studying both the regulation of polarity in neurons and factors controlling the commitment of neuroepithelial stem cells to neurogenesis.

21.11

PHENYLETHANOLAMINE N-METHYLTRANSFERASE-EXPRESSING ADRENAL CHROMAFFIN CELL LINES DERIVED FROM PNMT-SV40 TRANSGENIC MICE. A. Messing, E.E. Baetge and J.P. Hammang. School of Veterinary Medicine, University of Wisconsin-Madison, Madison, WI 53706; Bristol-Myers Squibb Co., Wallingford, CT 06402.

Clonal lines of phenylethanolamine N-methyltransferase (PNMT)-expressing (adrenergic) chromaffin cells have been derived from adrenal medullary tumors in PNMT-SV40 transgenic mice. When cultured in the presence of glucocorticoid, two immortalized lines (designated AT-1 and AT-2) express the nuclear SV40 large T antigen (Tag), maintain a characteristic chromaffin cell morphology, are catecholaminergic, and continue to divide. The AT cell lines are unique in that the cells express both TH (tyrosine hydroxylase) and PNMT protein and PNMT mRNA, and consequently produce both norepinephrine and epinephrine. When the AT cell lines are grown in the absence of glucocorticoid, Tag levels fall and most of the cells slow or stop dividing. After 1-2 weeks in the absence of glucocorticoid a number of the cells then increase their expression of the neurofilament proteins and extend neurite processes. Unlike PC12 cells, the AT cells do not express cytokeratin, the epithelial cell-specific intermediate filament. These AT cell lines represent an improved system for studying the biochemistry and development of the PNMT-expressing adrenal chromaffin cell.

21.13

CEREBELLAR GRANULE NEURONS PROMOTE PURKINJE CELL SURVIVAL AND DIFFERENTIATION IN VITRO. C.A. Baptista, D.H. Baird, W.-Q. Gao, M.E. Hatten and C.A. Mason. Dept. Pathology, Columbia Univ., Coll. Physicians and Surgeons, New York, N.Y. 10032.

To analyze afferent-target cell interactions *in vitro*, we have been co-culturing purified target cells with specific afferents, taken from the developing rodent cerebellum. We have improved our purification method for Purkinje cells (Baptista et al., Soc. Neurosci. 16:1150, 1990) to obtain more than 80% purity, by a combination of density gradients and immunoadsorption (panning). At this level of purity, Purkinje cells plated alone did not survive for more than 3 days. When plated on monolayers of purified cerebellar astroglia, Purkinje cells survived for longer periods but their morphological differentiation was impaired.

To test the influence of one of the principal Purkinje cell afferents, the parallel fibers, on Purkinje cell survival and morphogenesis, highly purified Purkinje cells were co-cultured with small reagggregates of purified granule cells that extended numerous neurites. Purkinje cells contacting these neurites survived, extended dendrites, and developed profuse spines by 2-3 weeks *in vitro*. Moreover, the extent of dendritic development appeared to depend on the density of granule cell axons contacting Purkinje cells. Thus, interactions with one appropriate set of afferents are necessary for the long term survival and differentiation of characteristic morphology by Purkinje cells. We will next determine the effect of contact with the other Purkinje cell afferents, the climbing fibers, as well as inappropriate afferents, on Purkinje cell survival and differentiation. These experiments suggest that specific afferent connections promote CNS target cell survival and differentiation.

21.10

INDUCTION OF PROTEIN KINASE C- β AND PHOSPHORYLATED NEUROFILAMENT-IMMUNOREACTIVITY IN CULTURED ADRENAL CHROMAFFIN CELLS AND PINEALOCYTES. R. Roivainen and J. Koistinaho. Department of Public Health, University of Tampere, P.O. Box 607, SF-33101 Tampere, Finland.

Adrenal chromaffin (AC) cells of the newborn rat and human fetuses were cultured with and without nerve growth factor (NGF) for 3-7 days. Pinealocytes of the newborn rat were cultured without NGF for 14 days. The cultures were immunostained with antibodies to phosphorylated M- and H-subunits of neurofilaments (PNF) and protein kinase C- β (PKC- β). Noncultured human and rat AC cells as well as AC cells maintained in culture without NGF showed no immunoreactivity, whereas strong PKC- β and PNF-staining was seen when the cells were supported with NGF for 3-7 days. Likewise intact rat pinealocytes contained no PKC- β or PNF-LI, but when they were cultured for two weeks a proportion of them started to express PKC- β and PNF-immunoreactivity. Both in the pinealocyte and AC cell cultures the immunopositive cells had developed neuron-like characteristics and they grew out processes of varying length. The results indicate that PKC- β may contribute to the phosphorylation of neurofilaments, which is induced in certain endocrine cells cultured in conditions favouring the transformation to a neuronal phenotype.

IN VITRO DEVELOPMENT OF TYROSINE HYDROXYLASE-IMMUNOREACTIVE NEURONS FROM THE EMBRYONIC CHICK HYPOTHALAMUS. A.A. Romero*, J.K. Lobner*, A.M. Gabaldon*, R.L. Lopez* and J.A. Wallace. Dept. of Anatomy, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131.

Unlike dopaminergic (DA) neurons in the mammalian hypothalamus, the majority of tyrosine hydroxylase-immunoreactive (TH+) neurons in the chick diencephalon do not synthesize dopamine (Romero et al., SON abs 16:646, '90). Here we have examined whether chick hypothalamic TH+ neurons develop similarly *in vitro* as they do *in vivo* with respect to the expression of the DA phenotype. Dissociated cell cultures of the diencephalon were developed from embryos at ages 5-7 or 10-12 days of incubation, times at which the TH+ cell groups first appear embryologically or are already well established. From either embryonic age, the number of TH+ neurons observed in the cultures was less than that anticipated from the incidence of these cells *in vivo*. Nonetheless, as in the intact animal, only a small proportion of the hypothalamic TH+ neurons appear to synthesize DA, detected immunocytochemically. This contrasts markedly with the large ratio of DA to TH-immunoreactive cells found in sister cultures of the chick midbrain. Therefore, the characteristics expressed in culture by developing hypothalamic TH+ neurons is consistent with that observed *in vivo* by these diencephalic cells in the chick embryo. Supported by NIH grants GM08222 and RR08139.

PATTERNS OF ANTIGEN EXPRESSION IN THE DEVELOPING RAT THALAMIC RETICULAR NUCLEUS. J. Mitrofanis* and R.W. Guillery. Department of Human Anatomy, South Parks Road, University of Oxford, OX1 3QX, UK.

The thalamic reticular nucleus (TRN) is a sheet of cells covering most of the dorsal thalamus (dT). Its major afferents are collaterals from passing corticothalamic and thalamocortical fibres and the majority of its efferents go to the dT. We have examined the postnatal development of the TRN in rats with antibodies to gamma-aminobutyric acid (GABA), parvalbumin (PV) and pro-alpha-thyrotropin-releasing hormone (TRH). Each of these antibodies labels most, if not all TRN cells in adults. PV- and TRH-immunoreactive (IR) cells during early development (P0 to P10) were apparent along the lateral border and rostral pole of the TRN only. Labelled cells extended laterally to the TRN into the internal capsule (IC) and into the globus pallidus (GP) and entopeduncular nucleus (EPN). Later in development (P10 to P24), some PV-IR cells were still in the GP and EPN but all the PV- and TRH-IR cells in the IC and rostral TRN had disappeared. The fate of these cells is unclear: they could either have been migratory, died, or transiently expressed these antigens. During this period (P10 to P24), a second wave, or pattern of PV- and TRH-IR expression was apparent: labelled cells emerged first in central TRN and with increasing maturity, labelled cells appeared in caudal and then in rostral TRN. GABA-immunoreactivity in the developing TRN was similar to the second pattern of PV- and TRH-immunoreactivity, but it began much earlier (P0). For example, GABA-IR cells appeared first in central TRN and then subsequently in caudal and rostral TRN. Thus, different immunocytochemical markers of TRN cells show distinct patterns of development. It remains to be determined how these patterns of antigen expression relate to, firstly, patterns of TRN cell birth and secondly, to the maturation of the connections of different sensory modalities related to distinct TRN sectors.

21.15

THE NUMBER AND BIRTHDATE OF NEUROPEPTIDE NEURONS IN DEVELOPING CHICK GUT. Miles L. Epstein and Kristian T. Poulsen*. Dept of Anatomy, University of Wisconsin, Madison, WI 53706.

A diverse array of neurotransmitters is found within enteric ganglia. We have investigated the number, coexistence, and birthdate of myenteric neurons expressing vasoactive intestinal peptide (VIP), somatostatin (SOM) and substance P (SP) in the developing proventriculus of the chick gut. The number of neurons expressing a particular peptide was counted in immunostained whole mounts obtained from E4-E21 embryos. Coexistence was examined by double labeling techniques. Birthdate was determined by applying ^3H -thymidine to eggs and preparing sections of immunostained gut for radioautography. We found that VIP appeared first at E5.5, SOM at E6.5, and SP at E10.5. At hatching the largest number of neurons contained VIP and about one-half that number each expressed SOM and SP. After double-staining we found a large percentage of cells showed the coexistence of VIP and SOM at E8.5, but a very small percentage at E15.5 and E21. No coexistence was found for VIP and SOM or for SP and SOM. The majority of the myenteric neurons were born between E4 and E11, although a small number were born even at E16.5. Our results suggest that decisions about transmitter phenotype occur concurrently in different cells. Supported by NSF BNS 8820658.

CLONED CEREBRAL ENDOTHELIAL CELLS: AN *IN VITRO* MODEL FOR BRAIN VASCULARIZATION?

A. Amberger*, U. Tontsch*, G. Gabbiani¹* and H.C. Bauer
Inst. f. Molekularbiologie OAW, Salzburg, Austria
1 University of Geneva, 1 rue Michel-Servet, Switzerland.

We have recently shown that cloned cerebral endothelial cells (cEC) of porcine and murine origin differentiated reversibly into two distinct phenotypes depending on the presence of endothelial cell growth factor and heparin in the culture medium. Factor enriched medium produced cobblestone like cEC (type I) which responded to glial and neuronal stimulation of blood brain barrier (bbb) related enzyme activities (Tontsch U. and Bauer H.C., 1991, Brain Res. 539, 247). Depletion of factors resulted in a phenotypic switch producing spindle shaped cells (type II) which did not respond to neural membrane stimulation. This phenotype expressed different proteins, such as smooth muscle α -actin as shown by immunofluorescence, Immunoblots and Northernblots. In addition, the cells showed enhanced migratory behaviour and different protease activities depending on the cell substrate. The data support the hypothesis that type II cEC are involved in neovascularization and that type I cEC are related to bbb function.

AXON GUIDANCE MECHANISMS AND PATHWAYS I

22.1

THE RELATIONSHIP OF OPTIC GROWTH CONES TO THE TRACT OF THE POSTOPTIC COMMISSURE IN THE DEVELOPING ZEBRAFISH BRAIN. J. D. Burrill and S. S. Easter, Jr., Department of Biology, University of Michigan, Ann Arbor MI, 48109.

Previous work has suggested that the pial basal lamina and/or the axons in the tract of the postoptic commissure (TPOC) may provide local guidance cues for optic axons to reach the tectum. We have examined what structures are contacted by optic growth cones *en route* to the tectum.

The optic axons of fixed embryos (34-48h) were labelled by intraocular injection of DiI, and then photoconverted. The embryos were then embedded and sectioned for electron microscopy.

The first retinal ganglion cell axons leave the eye between 32-34h, and reach the tectum about 46-48h. In most cases 1-3 axons had advanced farther up the diencephalon than a larger group of axons (5-20). The leading optic growth cones are separated from the basal lamina 1-3 μm by neuroepithelial endfeet. The leading optic growth cones do not extensively contact TPOC axons; in fact, only occasional filopodial contact with other axons was observed. At the midline of 33-36h embryos the optic axons are separated from the TPOC by neuroepithelial processes. These processes are smaller at 48h, causing the optic axons to appear adjacent to the TPOC axons.

Our work indicates that the neuroepithelial endfeet rather than either the basal lamina or other axons probably provide the local guidance cues for the optic axons. Supported by R01-EY-00168 and T32-EY-007022.

BRAIN EXPANSION IN THE CHICK EMBRYO REQUIRES Na^+/K^+ -ATPASE PUMPS FOR FLUID TRANSPORT. X.Y. Li* and M.E. Desmond. Department of Biology, Villanova University, Villanova, PA. 19085.

The brain region of the embryonic central nervous system expands markedly once the tube is sealed at both ends as a result of closure of the rostral neuropore and occlusion of the spinal cord. This growth is rapid and directly controlled by intra-luminal pressure (ILP) generated by neural tube fluid. How does the fluid cross the neuroepithelium into the brain cavity during this period of rapid enlargement? This study reports on experiments designed to test the hypothesis that fluid transport via the Na^+/K^+ -ATPase pump is essential for normal brain expansion. Over 25 dozen chick embryos (stages 11-25) were treated with ouabain, a specific inhibitor of the Na^+/K^+ -ATPase pump, at various concentrations (5-1000 μM) for 24 hrs while in shell-less culture at 38 $^\circ\text{C}$. Embryos were critically staged, photographed atop the yolk and fixed in Carnoy's for serial sectioning and volume measurements. Preliminary results show that stage 18 embryos treated 24 hrs with 50 μM ouabain exhibited extensive folding of the neuroepithelium similar to previously reported studies in which the ILP was decreased, thus suggesting a significant decrease in the cavity size after ouabain treatment. Volume measurements are in progress to determine the actual amount of reduction. The younger embryos (stage 11-14) were less sensitive to ouabain than the older embryos (14-25) suggesting that either Na^+/K^+ -ATPase pumps were not present in the younger embryos or, if present, were inactive. Autoradiography is being done in order to confirm the first appearance of the pumps. Supported by NIH RO1 HD24710-01A2.

22.2

THE MIDLINE OF THE MOUSE OPTIC CHIASM: CELLULAR COMPOSITION AND ANTIGEN EXPRESSION DURING RETINAL AXON GROWTH. C.A. Mason, B. Blazeski, J. Dodd, and P. Godement. Depts. of Pathology, and Physiology and Cellular Biophysics, Columbia Univ., Coll. of Physicians and Surgeons, New York, N.Y. 10032, and Inst. Neurosciences, CNRS, Univ. P. M. Curie, Paris 75005.

Our previous studies on retinal axon guidance suggest that a region spanning the midline of the optic chiasm inhibits the advance of uncrossed retinal fibers, while it is permissive for the growth of crossed fibers. The inhibitory zone on either side of the midline is occupied by a palisade of radial glia, recognized in the mouse by the MAb RC2 (Mason et al., Soc. Neurosci. 16:1125, 1990). The palisade is present from the time the earliest retinal axons arrive in the diencephalon at E13, and loses RC2 immunoreactivity in late fetal periods. The midline glial cells were further characterized by immunostaining for the presence of antigens expressed by the floor plate of the spinal cord, another midline structure important for axon guidance. Among the antigens expressed by both structures is SSEA I, a stage-specific embryonic antigen expressed on embryonic stem cells. This antigen is expressed on some fibers of the glial palisade, and at the midline seam of the chiasm. In addition, with the Pan-Macrophage monoclonal (Serotec), we have identified cells of the macrophage/monocyte lineage. These cells form a carpet of cells subpially, where recently arrived axons grow and turn. Immunopositive cells are also found in the subventricular zone of the third ventricle.

Characterization of the resident cells of the chiasm should reveal properties of the chiasm midline important for guidance of retinal axons, and will allow the cells used *in vitro* assays of retinal axon growth (Guillaume et al., this volume) to be identified unambiguously.

22.3

RETINAL AXON-OPTIC CHIASM CELLULAR INTERACTIONS *IN VITRO*. P. Guillaume*, L.-C. Wang, C.A. Mason and P. Godement. Inst. Neurosciences, CNRS, Univ. P. M. Curie, Paris 75005 and Dept. Pathology, Coll. Physicians and Surgeons, Columbia Univ., New York, N.Y., 10032.

Our previous studies suggest that the midline of the optic chiasm inhibits the advance of uncrossed retinal fibers, while it is permissive for the growth of crossed fibers. To investigate the cellular interactions that underly retinal axon guidance to both sides of the brain, we are developing an *in vitro* model system, in which retina is co-cultured with dissociated cells from the optic chiasm, both taken from mouse embryos at E15-16.

The majority of cells in these cultures are glial, showing both RC2 immunoreactivity, as does the midline glial palisade, and GFAP immunoreactivity. After 2-3 days in culture, RC2 immunoreactivity diminishes, and GFAP immunoreactivity is retained. In these cultures, other cells, in greater numbers in serum-free conditions, appear to be neurons, based on reactivity with antibodies against neurofilaments and alpha internexin, a new neuronal intermediate filament expressed early in the CNS (gift of Dr Liem, Columbia University). A striking cellular interaction is the formation of "islands" of such neuronal cells settled around "spokes" of RC-2 positive elongated processes, partially mimicking the glial palisade *in vivo*.

Retinal fibers from regions of retina giving rise to crossed fibers readily grow on optic chiasm cells as unfasciculated axons, suggesting that these cells are very supportive to their elongation. Fibers from inferior temporal retina grow as fascicles among optic chiasm cells, or stop next to the fields of chiasm cells. Some growth cones appear to turn back, in a fashion that is reminiscent of what is observed for uncrossed retinal fibers *in vivo*.

These observations suggest that divergence of crossed and uncrossed retinal fibers involves contact interactions with optic chiasm cells.

22.5

EVIDENCE OF A TRANSFORMATION OF AXONAL ORDER AT THE OPTIC NERVE HEAD IN THE DEVELOPING CHICK. Cheri Y. Williams and S.C. McLoon, Department of Cell Biology, University of Minnesota, Minneapolis, MN 55455.

The retina projects to the tectum in a topographic manner such that neighboring retinal ganglion cells project to neighboring regions of the tectum. However, there is a mirror-reversal in this projection between retinal ganglion cells and their terminals in the tectum. This reversal requires a transformation of axon order at some point along the pathway. There is conflicting evidence as to where such a transformation might occur. Previous work with monoclonal antibodies that recognize axons from specific retinal regions suggested that there is a decussation of axons from the two sides of the retina at the optic nerve head. The present study analyzed the course of axons from various retinal regions through the optic nerve head. DiI was used to label groups of axons in the retina. Labeled axons were then followed from the retina into the optic nerve. Axons from dorsal retina entered directly into the optic nerve with no detectable crossing of axons. Many axons from both the nasal and temporal sides of the retina appeared to cross within the nerve head to the opposite side of the nerve. However, some axons from both sides entered the nerve without decussating. These results suggest that there is a partial decussation of axons in the optic nerve head of the chick. Other sites of axonal reorganization have been reported in the visual pathway. It seems likely that the mirror-reversal of axons between the retina and the visual centers is the result of several reorganizations along the pathway beginning at the optic nerve head.

22.7

RETINOTOPIC REFINEMENT OF INDIVIDUAL AXONAL ARBORS DURING OPTIC NERVE REGENERATION IN GOLDFISH WITH AND WITHOUT OPTIC ACTIVITY. Z.R. Wang* and R.L. Meyer, Developmental Biology Center, Univ. California, Irvine CA 92717 and Biology Dept., Lanzhou Univ., China.

The retinotopy of axon arbors was analyzed by making small injections of DiI into retina to label a small number of optic fibers. These fibers were visualized in tectal wholemounts using conventional and confocal fluorescence microscopy. In normals, small largely overlapping arbors were observed in the appropriate retinotopic position of tectum. Contrary to previous HRP studies, regenerating fibers at early times after nerve crush had few branches, and these were small and distributed near the distal segment. With time, fibers formed small arbors which initially had little overlap with each other but became progressively coextensive. Elimination of impulse activity by repeated intraocular injections of TTX did not prevent the formation of restricted terminal arbors but did prevent them from becoming overlapped.

The results suggest that the development of arborization is an activity independent process while retinotopic localization of the arbor requires activity. It is also noteworthy that arborization develops in a progressive fashion during regeneration like that reported for development even though the target cells are already differentiated.

Supported by NIH grant RO1-EY06746.

THE ORIGIN AND COURSE OF UNCROSSED RETINAL GANGLION CELL AXONS IN XENOPUS. Jeremy S.H. Taylor* (SPON: Brain Research Association).

Department of Human Anatomy, University of Oxford, South Parks Road, Oxford. OX1 3QX, U.K.

To investigate the location of possible cues which guide ipsilaterally projecting axons, HRP was injected into the optic tracts post-metamorphic frogs. Labelled axons were then traced through the optic tract and nerve to their cells of origin in the ipsilateral retina.

The largest ipsilateral retinal ganglion cells form a mosaic array. They have somata approximately 20µm diameter, and dendritic arbors which are sparsely branched but extend over a wide area (radius 250µm). Smaller cells cannot be designated to any particular class.

In the optic nerve ipsilateral axons are intermixed with the contralateral axons from adjacent retinal regions as they pass through the zone of reorganisation and become distributed around the periphery of the nerve. As the nerve nears the diencephalon the ipsilateral axons gather at the posterior nerve margin, with axons lying in the anterior periphery of the nerve abruptly traversing the width of the nerve. The turning of axons into the ipsilateral optic tract coincides with the alteration in glial environment at the nerve/tract junction. The fibres turn directly into the optic tract as they enter the diencephalon and occupy the rostral-most edge of the tract. The decision to project ipsilaterally is made before the fibres reach the mid-line and encounter axons from the other eye suggesting that the ipsilateral decision is independent of the other eye.

In animals with embryonic monocular enucleation, the course and distribution of the ipsilateral projection in the post-metamorphic frog is shown to be unaffected.

It is concluded that the largest ipsilateral cells are of a specific sub-class. All ipsilateral axons have a predilection for the anterior edge of the ipsilateral optic tract. This behaviour is manifest as the fibres reach the cellular environment of the diencephalon. The ipsilateral projection is independent of inter-action with contralateral projection of the other eye.

OUTGROWTH OF TRANSPLANT-DERIVED RETINAL AXONS IN CEREBRAL CORTEX OF NEONATAL RATS. A.J. Sefton*, K. Rao, M.H. Hankin and B.D. Lund. Univ. of Pittsburgh, Pittsburgh, PA 15261 and *Univ. of Sydney, Sydney, NSW 2006, Australia.

Embryonic (E13) mouse retinae were transplanted to cortical locations in newborn (P1) rats to determine if optic axons could grow in regions of the brain not normally encountered during development. Transplant-derived retinal axon outgrowth was examined immunohistochemically using mouse-specific monoclonal antibodies, and peroxidase-coupled secondary antibodies.

Retinal transplants were located at various depths in the cortex, ranging from superficial (subpial) to deep (in cortical plate and/or white matter). Two projection patterns could be detected during the first week post-transplantation (PT): (1) locally along the edges of the implantation lesion created by the introduction of the grafted tissue with a glass pipette, and (2) for distances of several mm along cortical layer 1 (not associated with obvious surgical damage). Layer 1 projections were usually confined to one or two directions along the cortical margin (they did not extend radially as they might in a culture dish), although there was no preference outgrowth in any one particular direction or cortical area. Such projections were not seen after the first week PT, but they could be sustained for long periods if they contacted co-grafted target tissue, even if the co-graft was located several mm from the retina.

These results suggest that retinal axons can use outgrowth-promoting substrates present along the subpial margin of the developing cortex, and are consistent with the idea of target-derived maintenance. In addition, lesions in early postnatal animals appear not to represent an impediment to axonal outgrowth, and may, in fact, produce outgrowth-promoting substances.

A SPECIFIC BRAIN TRACT GUIDES FOLLOWER GROWTH CONES IN TWO REGIONS OF THE ZEBRAFISH BRAIN. A.B. CHITNIS, C.K. PATEL, and J.Y. KUWADA. Neuroscience Prog., Dept. of Biology, University of Michigan, Ann Arbor, MI 48109.

Neurons of the nucPC, an identifiable cluster of neurons in the embryonic zebrafish brain, project growth cones ventrally along the posterior commissure (PC) to an intersection in the anterior tegmentum where the commissure crosses two longitudinal tracts, the TPOC and the MLF. Once at the intersection nucPC growth cones turn posteriorly onto the TPOC in the dorsolateral tegmentum and follow it to the hindbrain. Previously we showed that in the absence of the TPOC, nucPC growth cones often extend along aberrant paths suggesting that fasciculation with axons in the TPOC helps to guide the growth cones along their normal pathway. However, many nucPC growth cones also continue to extend along the dorsolateral tegmentum in the absence of the TPOC suggesting that cues associated with the dorsolateral tegmentum, independent of the TPOC, also help to guide the nucPC growth cones.

We have now confirmed using electron microscopy, that nucPC growth cones normally first fasciculate with axons in the PC and then with axons in the TPOC. In the absence of the TPOC the growth cones extend along the dorsolateral tegmentum in contact with the endfeet of dorsolateral neuroepithelial cells suggesting that cues associated with these cells guide the nucPC growth cones in the absence of the TPOC axons. We also show that in the absence of the TPOC, significantly more nucPC growth cones turn aberrantly at the midbrain/hindbrain border. This suggests that fasciculation with TPOC axons may also help the nucPC growth cones to cross this border in the brain. Supported by grants from N.I.H. and M.O.D.

Subplate cells in medial cortex send the first axons across the corpus callosum.

S. E. Koester and D. D. M. O'Leary. Neural Sciences Prog., Washington Univ., St. Louis, MO 63110 and Molecular Neurobiology Lab, The Salk Institute, La Jolla, CA 92037.

Subplate (SP) cells extend the first axons out of cortex through the internal capsule (McConnell et al Science 245 '89; DeCarlos & O'Leary Soc NS Abs '90). Here, we report that in rats SP cells extend the first axons through another major cortical pathway, the corpus callosum (CC). Anterograde Dil labeling in fixed tissue shows that the first growth cones reach the midline of the nascent CC at E17 - 1.5 days earlier than previously reported. By E18, many axons cross the midline and extend dorsolaterally in the intermediate zone (IZ). To determine the origin of these earliest crossing axons, we injected Dil into the medial IZ of fetuses fixed at E18. In the cortex contralateral to the injection, retrogradely labeled neurons are seen only in presumptive cingulate cortex, an area adjacent to the midline. Axons emerge from the labeled cells, descend into the IZ, turn abruptly, and can be followed into the nascent CC. Where the SP layer is distinct from the emerging cortical plate (CP), the labeled cells are clearly in the SP. Nearest the midline, where cortex is less differentiated, the labeled cells have morphologies characteristic of SP cells, and distinct from CP neurons, at this stage of development. In utero injections of Rhodamine beads label a similarly arrayed population at E18.5. Further evidence that these neurons are SP cells comes from birthing them. ³H-Thy was injected on E12 to label SP or on E15 to label CP; pups were fixed at E18, and Dil was injected into the IZ of medial cortex. Most Dil labeled cells in contralateral cortex are co-labeled with ³H-Thy injected at E12, but are rarely co-labeled with E15 injections, as would be predicted for SP cells. Neurons in more dorsal and lateral parts of cortex can be first labeled from contralateral cortex on E19 and are found in both CP and SP. We conclude that in the rat a population of SP cells in medial (cingulate) cortex send the first axons across the corpus callosum. This population of SP cells is distinct from that which extends the first cortical axons through the internal capsule, which may indicate that these are specialized populations of cells with unique roles in cortical development. HIPPOCAMPAL CA3 AFFINITY IS MAINTAINED BY NEONATAL GRANULE CELL MOSSY FIBERS IN VITRO. A. Hussein, S. Trikha, N. Ortiz, S. Springfield and P. Sajovic.

In the developing hippocampus, granule cells of the dentate gyrus project mossy fiber axons to the CA3 subfield of the hippocampus proper. Mossy fiber growth cones form synaptic contacts with the apical dendrites of pyramidal cells in this region. In the present study we sought to determine if neonatal granule cell projections maintain CA3 affinity in coculture with hippocampal explants varying in age.

Under sterile conditions the granule cells from P1-3 Sprague-Dawley rats were trypsinized and plated out at low density on poly-D-lysine treated coverslips in DMEM. Hippocampal explants obtained from: 1) adult, 2) 1 month old, and 3) P1-3 rats were cocultured with granule cells in a sandwich arrangement.

The addition of the explants significantly increased the degree of arborization and projection lengths of granule cells. Granule cells grown in the presence of explants exhibited mean projection lengths of 470 μ whereas the control cells had mean projection lengths of 75 μ . The viability of granule cells was increased in the presence of an explant. In all three types of cocultures CA3 affinity was maintained, however, granule cells cocultured with 1 month old rats demonstrated the greatest affinity for the CA3 region. Possible explanations for this affinity are that the pyramidal cells of the CA3 region may be involved in the secretion of a diffusible factor that may serve as a target for mossy fiber growth cones or that the cell surfaces of the granule cells may interact with surface molecules along the pathway to the target cells.

ONTOGENESIS OF DESCENDING PATHWAYS FROM VARIOUS BRAINSTEM NUCLEI TO THE SPINAL CORD IN THE RAT. E. Auclair, M.-C. Bélanger and R. Marchand. Centre de recherche en neurobiologie, Hôpital de l'Enfant-Jésus, Québec, Qc, Canada, G1J 1Z4

In order to gain better understanding of the development of the descending pathways from the brainstem to the spinal cord in the rat, we implanted a crystal of Dil, a retrograde and anterograde plasma membrane fluorescent tracer, into the neural tube of young embryos. The tracer was allowed to diffuse in plasma membranes for a period of 2 to 4 months. After implantation in both the ventral and lateral funiculi in the cervical spinal cord of 14 and 15 day embryos, we encountered somas in the bulbar reticular formation which were retrogradely labeled by the marker. This group of neurons extended along the whole length of the ventral medulla oblongata. Their axons coursed into the ventral marginal zone at bulbar levels and entered the ventral funiculus when reaching the cervical spinal cord. In another set of experiments, we placed a crystal of Dil in the region of the interstitial nucleus of Cajal in embryos of 12.0 to 14.5 days (E12.0 to E14.5) to determine when the projections from that nucleus reached the cervical spinal cord. Fibers from that nucleus reached the rostral pons by E12.0 and arrived to the first segments of the cervical spinal cord by E13.5. As expected, these fibers coursed into the primordium of the medial longitudinal fasciculus. Finally, we placed a crystal of the same tracer into the vestibular complex of E14.5 and E19.0 embryos. Fibers from these nuclei in the E14.5 embryo could be followed as far as lower cervical segments while at E19.0 they reached at least the lower thoracic segments and in both cases, these fibers coursed into the ventral and ventrolateral funiculi. At E19.0, some fibers entered the ventral horn of the spinal cord at all levels mentioned above. These results among others suggest that the supraspinal control on spinal cord neurons is initiated early during the development of the rat. Supported by MRC of Canada, FRSQ and FCAR.

MANIPULATION OF CEREBRAL CORTICAL PHENOTYPE IN TRANSPLANTS SPECIFIES THALAMIC AFFERENT PROJECTION PATTERNS. M. F. Barbe and P. Levitt. Dept. of Physical Therapy, Temple Univ., Philadelphia, PA 19140 and Dept of Anatomy and Neurobiology, Med. Coll. of Pennsylvania, Philadelphia, PA 19129.

Previous studies using a molecular marker of limbic phenotype (limbic system associated membrane protein, LAMP), in combination with brain tissue transplants, have shown that there is an early critical period for the commitment of the fate of developing cortical neurons (Barbe and Levitt, J. Neurosci., 11: 519-533). The present study has taken advantage of the ability to manipulate cortical phenotype of the grafts to determine whether LAMP expression by the transplanted tissue correlates with the organization of limbic and nonlimbic thalamic afferent projections to the grafts. Slabs of presumptive perirhinal and sensorimotor cortex were obtained from fetal rats at 12 and 14 days of gestation, times before and after the commitment to the limbic molecular phenotype, respectively, and were transplanted into perirhinal (PR) or sensorimotor (SM) cortex of newborn rats. Fixed brains from hosts were harvested 2 weeks after grafting and Dil-coated glass micropipettes were inserted into the transplant for retrograde labeling. Control homotopic transplants at both ages received appropriate SM or limbic thalamic projections. E12 heterotopic transplants of both presumptive limbic and SM cortex, in which the molecular phenotype is regulated by the host environment, receives thalamic afferents that reflect the grafts' new identities. Thus, LAMP-positive presumptive SM tissue placed in PR cortex of the host receives limbic projections from the thalamus, while LAMP-negative presumptive PR tissue placed in SM cortex of the host receives ventrobasal nuclear projections. E14 heterotopic transplants, in which the molecular phenotype is specified irrespective of the environment, receive thalamic afferents that correspond to the grafts' original fate. The data suggest that developing thalamic afferents respond to alteration of target phenotype by specifying their limbic and sensorimotor projections in correspondence to LAMP expression. GUIDANCE IN CULTURE OF NEURITIC PROCESSES OF IDENTIFIED RAT BRAIN STEM MOTONEURONS. J.P. Ternaux, P. Portallier*, P. Clark* and A. Curtis* - Unité de Neurocybernétique Cellulaire - UPR 418 CNRS, Marseille, France. Department of Cell Biology. University of Glasgow, Scotland.

Dissociated cells from the hypoglossal nucleus of 18 day old rat foetuses or 1 to 16 day old new born rats were cultured on poly-L-Lysine coated petri dishes for several weeks in a DMEM/F12 medium supplemented with additives and 3% FCS. Neurons, motoneurons and glial cells were identified using immunohistochemical staining with specific antibodies respectively raised against enolase, choline acetyl transferase and glial fibrillary acidic protein. Motoneurons were also identified by using retrograde transport of both fluorescent latex microspheres and carbocyanines (Dil and DiO) previously injected in the tongue. Cells were cultured on topographical microstructures (glass and quartz) with engraved grooves of various width and depth. Guidance of the neuritic tree was observed with grooves of 3 μ m deep and wide, and was related to the size of cell bodies and to the angular position of the neurite outgrowth in function of the orientation of the groove. Microphotolithographic method combined with silanes chemical treatment allows to obtain controlled routes of adhesive proteins, such as laminine, on which dissociated cells can be cultured. In these conditions, we can arranged that the cells have 1, 2, 3 or 5 final neurites, 0,1 or 2 levels of bifurcation in each neurite and simple architecture of neuritic tree can be drawn. This method would be helpful to study the processing of information and its relationship with the shape of the dendritic tree.

COMMISSURAL PROJECTIONS OF THE HOFMANN KÖHLICHER NUCLEI CELLS IN EMBRYONIC CHICKEN SPINAL CORD.

A.L. Eide, Institute of Basic Medical Sciences, Univ. of Oslo, Norway

The Hofmann-Köhlicher (HK) nuclei are segmentally iterated clusters of large cells found on the ventrolateral surface of the avian spinal cord at lumbosacral levels. Little is known about the anatomy and function of the cells in these nuclei.

The purpose of this study was to follow the embryonic development of the axonal projections of the HK cells. Chicken embryos were fixed at successive developmental stages and the lipophilic tracer Dil was applied in the HK nuclei for anterograde tracing and in the ventral funiculus or the ventral midline for retrograde tracing. The typical HK cell extends an axon that crosses the ventral midline in the segment of origin without branching on the ipsilateral side. The axon bifurcates in the contralateral ventral funiculus near the midline, one branch extends rostrally and the other extends caudally. By embryonic day (E)9 collaterals that extend towards the medial MN pool are established in the transverse plane. At E10 tertiary branching appears. By E16 the longitudinally running axons from the HK nucleus lying between lumbar segments 4 and 5 project 4 segments rostrally and 4 segments caudally, giving off collaterals all along their length. The HK cells at one segmental level may innervate the ventral horn of the entire lumbosacral extent of the spinal cord.

The HK nuclei may provide an accessible model system for studying the development of commissural axon projections in the spinal cord.

CYCLOPAMINE INDUCES A SPECIFIC PATTERN OF NEURAL DEFECTS IN EMBRYONIC ZEBRAFISH. Scott E. Stachel and Paul Z. Myers. Dept. of Human Genetics & Dept. of Biology, U. of Utah, Salt Lake City, UT.

Cyclopamine is a teratogenic alkaloid produced by several Western range grasses. Zebrafish embryos exposed to cyclopamine exhibit abnormalities that mimic many of the defects caused by the *cyc-1* mutation in zebrafish. The most prominent defects caused by both the drug and the mutation are cyclopia and a failure of the trunk myotomes to properly differentiate. However, unlike *cyc-1* animals which lack a floorplate, cyclopamine-treated animals show no disorganization in the neural midline and have a normal floorplate. Our analysis suggests that one effect of cyclopamine is to suppress formation of the cartilaginous branchial arches, allowing the eyes to slump together ventrally. Cyclopia can therefore develop in the absence of any defect in the neural midline.

The earliest trunk defect in cyclopamine-treated animals can be traced to the failure to differentiate a specific longitudinal array of early muscle fibers, termed muscle pioneers, that express the *engrailed* protein. We thereafter see that a longitudinal furrow called the horizontal septum does not form and that the myotomes retain an immature organization. These myotomal defects lead to aberrant pathfinding by a peripheral sensory structure, the lateral line. In normal animals, axons of the lateral line extend longitudinally, following a migrating primordium. In animals exposed to cyclopamine at high concentrations, the primordium fails to migrate and axons accumulate in a tangled knot just caudal to their somata. At lower concentrations, the primordium migrates, but fails to find its normal cues and instead wanders aberrantly. The lateral line nerve follows the path of the errant primordium, and neuromast organs form in abnormal locations. We suggest that the aberrant migration of the lateral line primordium is a consequence of the disruption of the horizontal septum by the cyclopamine treatment.

THE ORGANIZATION OF PRECOCIOUS NEURONS IN THE RAT EMBRYO REPRESENTS A BLUEPRINT FOR THE ORDERLY GROWTH OF AXONS. M.-C. Bédaride, F. Auclair*, L. Bertrand* and R. Marchand. C.R. Neurobiologie, Hôpital de l'Enfant-Jésus, 1401, 18e rue, Québec (Qc), Canada, G1J 1Z4

During embryogenesis, the fiber tracts grow in a highly stereotyped pattern. Katz and Lasek (1980) have elaborated the concept of substrate pathways, defined as (...) a set of similar guidance cues which are aligned in a continuous discrete pathway (...). How are such guidance cues settled in pathways? In other words, what is the origin of substrate pathways? We had previously observed that the precocious neurons displayed a very peculiar arrangement that predicted the pattern of some CNS axonal tracts. To determine if the first neurons play a role in the guidance of early nerve fibers, they were mapped in the brain of an E12.5 embryo (embryonic day 12 and 15 hours) after injection of tritiated thymidine to gestating rats at E11.5. In the embryo, early-generated neurons were organized in longitudinal columns throughout the entire length of the brain. In the prosencephalon, they formed a complex and ramified basal prosencephalic column. In the brainstem, two columns were seen: a medial one, including members of the somatomotor column, and a more lateral one, in the reticular formation. All these columns were associated with well-differentiated regions in the marginal zone, characterized by open spaces, progressively filled by growing fibers. These regions represented the prospective accessory olfactory tract, medial forebrain bundle, optic tract, medial longitudinal fasciculus and central tegmental tract. To further verify the relation between the columns and the growth of axons, nerve fibers were traced with DII in the brain of young embryos. Fasciculi were seen to travel in close proximity to regions of early-generated neuronal columns. It is proposed that the primitive pattern of precocious neurons is responsible for the orderly growth of longitudinal axonal tracts.

BRACHIAL PLEXUS FORMATION IN CHICK EMBRYOS WITH DISTURBED SEGMENTATION OF THE VENTRAL ROOTS AND SENSORY GANGLIA.

R.S. Goldstein and C. Kalcheim, Dept. Anat. and Embryol. Hebrew Univ.-Hadassah Medical School, Jerusalem, Israel.

A possible role for the segmented pattern of the peripheral nervous system (PNS) is the carrying of positional information necessary for the sorting out and establishment of axonal bundles and plexuses. To test this possibility, we have studied embryos with unilateral disruption of normal segmentation of paraxial PNS structures. Replacing somites at the prospective brachial level of the neural tube in chick embryos with rostral half-somites from quail donors, prevents the segmentation of the sensory ganglia, ventral roots and sympathetic trunk. Three-dimensional reconstructions were made of 6 and 9 day embryos, in which neural tissues were distinguished with an antibody to HNK-1 and grafted quail cells with hematoxylin.

In normal embryos, three major (14,15,16) and one smaller (13,17) spinal nerves participate in the formation of the brachial plexus. These nerves merge and then separate into two trunks, as well as giving off smaller nerves. In spite of the lack of individual ventral roots and spinal nerves corresponding to each segment, the axons on the operated side of chimeric embryos converge and then diverge to produce trunks and nerves very similar to their counterparts in normal embryos and in the control plexuses of chimeric embryos.

The zone proximal to the plexus contains environmental cues that cause axons to selectively gather into groups that become individual peripheral nerves. Our results demonstrate that segmentally-repeating cues present in this proximal zone are distinct from the cues responsible for 1) the convergence of axons into a plexus and 2) the normal formation of trunks and nerves arising from the plexus.

DOES PERIPHERAL NERVE REPAIR INCREASE THE ACCURACY OF AXONAL REGENERATION? R.D. Madison^{1,2,3}, C. Harsh¹, and S.J. Archibald¹.

¹Department of Surgery (Neurosurgery) and ² Department of Neurobiology, Duke University Medical, and ³ Research Service, VA Hospital, Durham, NC 27710.

We have recently refined a model of nerve regeneration to allow the anatomical accuracy of nerve regeneration at the single neuron level (Madison et al., *Soc. Neurosci. Abstr.*, 16: 336.2, 1990). We applied this model to answer the question: Does direct suture repair of the rat femoral nerve increase the accuracy of regeneration? Control experiments showed that the primary sensory neurons which project into the saphenous nerve (a purely sensory terminal branch of the femoral nerve) can be reliably prelabeled by exposure of the saphenous nerve to DII, and two weeks later approximately 99% of the same population of neurons can be labeled with Fluorogold application to the same nerve. Following prelabeling of the sensory projection to the saphenous nerve in 20 adult rats, the parent femoral nerve was cut and either simply repositioned (N=10) or repaired by direct suture (N=10). Two weeks later the percentage of returning sensory neurons from the L4 DRG was quantified by Fluorogold application to the saphenous nerve; 27 ± 12% and 8 ± 11% (respectively) of the neurons correctly regenerated an axon into the saphenous branch (p < .05, t-test). Thus although the rodent PNS demonstrates spontaneous regeneration, accuracy can be significantly improved by nerve repair techniques. This double labeling technique provides a powerful and accurate mechanism to evaluate the effectiveness of various nerve repair techniques and prostheses. Supported by NS 22404-06 (RDM).

GROWTH FACTORS AND TROPHIC AGENTS I

THE EFFECTS OF bFGF ON THE DEVELOPMENT OF DOPAMINE NEURONS FOLLOWING EXPOSURE TO MPP⁺: COMPARISON WITH THE EFFECTS OF EGF. T. Bak and C. Mytilineou. Dept. of Neurology, Mt. Sinai Sch. of Med. New York, N.Y. 10029

bFGF has been shown to increase dopamine (DA) neuron survival and stimulate ³H-DA uptake in mesencephalic cultures (Ferrari et al., 1988) and to induce regrowth of damaged DA neurons in vivo (Otto and Unsicker, 1990). We examined whether bFGF could protect cultured DA neurons from the neurotoxin MPP⁺, or affect the recovery of MPP⁺-damaged neurons. We also examined whether bFGF effects on DA neurons are direct or mediated by other cell populations. Mesencephalic cultures were established from E16 rats and maintained in defined medium. bFGF was added to the appropriate groups and was present throughout the experiment. Cultures were exposed to 10 μM MPP⁺ for 24 hrs on 4 DIV and analyzed at various times for ³H-DA uptake and TH immunocytochemistry. Following removal of MPP⁺, a similar reduction of DA uptake (~60%) was observed in control and bFGF treated cultures, suggesting a lack of a protective effect of bFGF against MPP⁺-induced damage. However bFGF promoted long term survival of DA neurons and increased DA uptake in both control and MPP⁺-treated cultures. Similar effects were observed with EGF on parallel cultures. Treatment with FUDR along with EGF resulted in a reduction of >90% in DA uptake as well as a decrease in TH+ neurons, suggesting that the EGF effects are mediated by proliferating glia. In cultures treated with FUDR and bFGF, there was a reduction of ~50% in DA uptake, and no loss of TH+ neurons, suggesting that the bFGF effects are only partially dependent on the presence of glial cells. Our results indicate that EGF and bFGF do not prevent MPP⁺ neurotoxicity but support the survival and neurite outgrowth of remaining DA neurons in a similar manner, but by different mechanisms.

23.2

MULTIPLE FORMS OF bFGF ARE DEVELOPMENTALLY EXPRESSED IN THE RAT CNS. Suzanne Giordano, Larry Sherman*, and Richard Morrison. R.S. Dow Neurological Sciences Institute and Department of Cell Biology & Anatomy Oregon Health Sciences University, Portland, OR.

Recently multiple molecular weight forms of the bFGF protein have been identified. Some of these molecular weight forms appear to be amino terminal extensions of the 18Kd bFGF protein that are translated from a single mRNA species.

Here we demonstrate changes in the expression of different bFGF protein forms during the development of the rat CNS. In the adult rat brain western blots demonstrated the presence of four bFGF protein forms with approximate molecular weights of 18, 21, 22 and 34Kd using a previously characterized monoclonal antibody. All four bFGF protein forms bound to heparin and their staining on blots was eliminated in the presence of the 18 Kd human recombinant bFGF.

The expression pattern of these protein forms changed during CNS development. Proteins were extracted from whole rat brains at age E15, E18, P1, P7, P14, and adult. Embryonic brain contained three bFGF forms at 18, 21 and 34Kd, but lacked the 22Kd bFGF form present in the adult. The expression of the 22Kd form was first observed in brain following birth and then steadily increased to adult levels. bFGF protein forms appeared to be regulated differently in different regions of the developing rat CNS. Although the spinal cord and cortex showed the same pattern of bFGF expression as observed in whole brain, the adult cerebellum lacked the 21 and 22Kd forms.

These alterations in the expression of bFGF during CNS development suggest that individual forms may have discrete functions and that these changes may underlie specific developmental events. Research support (to RM) from NIH Grant NS 26125-01 and a grant from the M.J. Murdock Charitable Trust.

PROLIFERATION OF NEURAL PRECURSORS REGULATED BY ENDOGENOUS PRODUCTION OF FIBROBLAST AND INSULIN-LIKE GROWTH FACTORS. P.F. Bartlett, J. Drago* and M. Murphy*. The Walter and Eliza Hall Institute of Medical Research, Parkville, Victoria, Australia 3054.

The first stage of CNS formation is the rapid expansion of neuroepithelial cells within the neural tube. It has been shown *in vitro* that fibroblast growth factor (FGF; both acidic and basic) is capable of stimulating this proliferation. (Murphy et al. *J. Neurosci. Res.* 25:463, 1990). This response has been found recently to be dependent on the presence of insulin-like growth factors (IGF), especially the truncated form of IGF-1. (Drago et al. *Proc. Nat. Acad. Sci., USA.* 88:2199, 1991).

As the requirement for these exogenous factors can be overcome *in vitro* by plating neuroepithelial cells at high cell density, we investigated whether this resulted from the production of endogenous FGF and IGF. This was examined by using antibodies that neutralised either IGF-1 or bFGF activity. Pure populations of neuroepithelial cells obtained from embryonic day 10 CBA mouse mesencephalon and telencephalon were plated at 10^4 cells/well (Terasaki wells containing a final volume of 15 μ l) in insulin- and serum-free medium in the presence of varying dilutions of a monoclonal anti-IGF-1 (SM-1.2) or a polyclonal anti-bFGF (Gift of D. Gospodarowicz). The anti-IGF-1 completely inhibited growth whereas the anti-bFGF only partially inhibited this response.

This finding coupled with our demonstration that neuroepithelium also contains mRNA for both IGF-1 and bFGF supports the concept that early neuroepithelial growth may be regulated in an autocrine/paracrine manner and indicates that both IGF and FGF may be important in this regulation.

EXPRESSION OF BIOLOGICALLY ACTIVE BASIC FIBROBLAST GROWTH FACTOR (bFGF) IN PRIMARY FIBROBLASTS. Jasodhara Ray*, Mitsuhiro Kakihana*, Malcolm Schinstine*, Andrew Baird# and Fred H. Gage*. * Dept. of Neurosci., Univ. of Calif. San Diego, La Jolla, CA 92093, # Dept. of Mol. & Cell Growth Biology, Whitier Institute, La Jolla, CA 92037

Basic fibroblast growth factor (bFGF) is a potent growth and mitogenic factor and possesses both trophic and neurite-promoting activity for a variety of central (CNS) and peripheral nervous system (PNS) neurons. Expression and characterization of bFGF producing primary fibroblasts will be reported.

The cDNA encoding for the entire 18 kd coding region for bFGF was cloned into an expression vector under the control of Rous sarcoma virus long terminal repeat (RSV-LTR) promoter. The recombinant plasmid was introduced into primary fibroblasts and stable transformants were selected by growing cells in medium containing G418.

The success of expression of bFGF was confirmed by measurement of bFGF in the cell lysate by radioimmunoassay. Fibroblasts (FF) endogenously express bFGF at a low level (0.1 μ g/mg protein). Genetically modified fibroblasts (FF/FGF) produced bFGF 18 times higher than control fibroblasts (1.8 μ g/mg protein). Basic FGF was not secreted into the medium but was expressed on the cell membrane. Treatment with 0.1% Triton X-100 removed the immunoreactivity. Soft agar assay showed that the cells were not transformed. To determine if these cells have any of the biological effects of purified soluble bFGF, hippocampal (HC) neurons were co-cultured with either control FF or FF/FGF cells and the neurite lengths and survival of neurons were measured. Results showed that 93% of HC neurons survived in the presence of FF/FGF cells after 7 days in culture compared to 73% in the presence of FF cells. At day 2, the number of neurons bearing neurites (that were >50 μ m) was significantly higher in presence of FF/FGF (61%) than control cells (39%). Additional studies, including the growth and expression of bFGF during different stages of cell growth, will be presented.

ACIDIC FGF PROMOTION OF NEURITE OUTGROWTH IN SYMPATHETIC NEURONS IS MEDIATED BY NON-NEURONAL CELLS. M. Deschuyteneer, K.W. Roche*, W.D. Matthew and J.N. Davis, Neurology Research, Veterans Adm. Med. Ctr., Durham NC 27705 and Dept. of Neurobiology, Duke Univ. Med. Ctr., Durham NC 27710.

Fibroblast growth factors (FGF) appear to influence the kinetics and morphology of neuronal outgrowth in a variety of *in vitro* models. We studied the ability of human recombinant acidic FGF and basic FGF to elicit neurite outgrowth from whole explants and dissociated neurons of the neonatal mouse superior cervical ganglion. In explants, aFGF consistently promoted neurite outgrowth and was 25 times more potent than bFGF (ED_{50} = 0.06 nM and 1.5 nM, respectively). In a pure population of dissociated sympathetic neurons, aFGF and bFGF elicited little neurite outgrowth. By contrast, in mixed populations of dissociated ganglia cells that combined both the neurons and non-neuronal cells, aFGF and bFGF promoted significant neurite outgrowth in individual neurons and aFGF was more potent than bFGF. In addition, aFGF significantly enhanced neurite outgrowth in dissociated neurons co-cultured with a line of immortalized mouse Schwann cells or with Balb/c 3T3 mouse fibroblasts. The Schwann cell line was more efficient in eliciting neurite outgrowth than the fibroblast one. These results show that non-neuronal cells mediate the potent aFGF neurite outgrowth promotion in sympathetic neurons and suggest that Schwann cells are the primary intermediate in this process. β -AMYLOID (1-42) ENHANCES THE RELEASE OF FIBROBLAST GROWTH FACTOR (FGF) AND INTERLEUKIN-1 (IL-1) FROM GLIAL CELLS. A. J. Walencewicz, D. M. Araujo, and C. W. Cotman, Dept. Psychobiol., Univ. California, Irvine, CA, 92717 USA.

Microglia and astrocytes surrounding plaques in Alzheimer's disease (AD) appear to play a significant role in the neurodegenerative changes observed in the disease. However, it is not yet clear whether alterations in the function of these cells contribute to the β -amyloid-induced neurodegenerative changes, nor is it evident whether the proliferation of these cells around neuritic plaques is caused by the peptide. Therefore, the main objective of the present study was to determine the effects of β -amyloid (1-42) on glial cells *in vitro*. The results show that β -amyloid (1-42) (10 and 100 μ g/ml) enhances 3 H-thymidine uptake by microglia (by 49 and 75%, respectively) and astrocytes (by 10 and 20%, respectively) *in vitro*. Moreover, β -amyloid (1-42) appears to increase glial cell activity. First, the release of basic FGF-like immunoreactive material from astrocytes and microglia was augmented by the peptide (by 58-98%). Second, the release of IL-1 from microglia and astrocytes was also increased (by 51-97%) by β -amyloid (1-42). In addition, exogenous application of either basic FGF or IL-1 (10-100 ng/ml) appears to enhance the neurotoxic effects of β -amyloid (1-42) on hippocampal neurons *in vitro*, an effect that is apparent by 24h in culture. Thus, it is possible that β -amyloid stimulates the release of various GFs and lymphokines from glial cells that may contribute to the neurotoxic properties of the peptide observed in AD.

23.6

NGF, FGF AND EGF RAPIDLY STIMULATE $p21^{ras}$ GTP BINDING IN PC12 CELLS BY SEPARATE, CONVERGENT MECHANISMS. M.-S. Qiu, and S.H. Green, Dept. of Biology, Univ. of Iowa, Iowa City, IA 52242

NGF and basic FGF (bFGF) are trophic factors for PC12 cells and induce neuronal differentiation. Treatment with EGF, by contrast, does not produce these effects. Since the receptors for these factors all appear to be tyrosine kinases, the differences in the responses presumably derive from differences in intracellular signal mechanisms activated by these receptors. By immunoblotting with antiphosphotyrosine, we have observed only small differences between substrates of EGF- and NGF-activated tyrosine kinases but bFGF-induced tyrosine phosphorylations have a very different pattern. $p21^{ras}$ has been implicated as a signal transducer for NGF induction of neuronal differentiation in PC12 cells. Here we show directly that NGF, bFGF and EGF all transiently activate $p21^{ras}$ to a similar extent. $p21^{ras}$ was immunoprecipitated from [32 P]-labeled-PC12 cells and $p21^{ras}$ -associated nucleotide phosphates were chromatographically separated. Activation of $p21^{ras}$ by growth factor was detected as a $\approx 20\%$ increase in $p21^{ras}$ -associated GTP — maximal within 3 min but decaying nearly to prestimulus levels within 30 min. The timecourse was similar for the three factors, although somewhat prolonged in bFGF-treated cells. $p21^{ras}$ activation appears to require tyrosine phosphorylation as it is inhibited by genistein, although low genistein concentrations which block most tyrosine phosphorylation inhibit only EGF and not NGF or FGF responses. PC12 mutants that lack *trk* respond to EGF but not to NGF. Methylation inhibitors block $p21^{ras}$ activation by NGF and bFGF but not by EGF. K-252a (a general kinase inhibitor) blocks only $p21^{ras}$ activation by NGF; other kinase inhibitors (H-7, sphingosine, 6-thioguanine, 2-aminopurine) do not block at all. Effects of NGF and EGF are not additive, implying a common pathway downstream of these receptors. These results imply that activation of $p21^{ras}$ is not sufficient for neuronal differentiation but reveal differences in the mechanism of $p21^{ras}$ activation by the three factors that may be exploited for the identification of signals specific to neurotrophic effects.

23.8

THE ROLE OF BASIC FIBROBLAST GROWTH FACTOR IN THE HYPOGLOSSAL SYSTEM. C. Grothe and K. Unsicker, Dept. of Anatomy and Cell Biology, Univ. of Marburg, D-3550 Marburg, F.R.G.

We found bFGF-like immunoreactivity (bFGF-IR) in the hypoglossal nucleus (HN), localized in cell bodies and fibers of a neuronal subpopulation. Transection of the hypoglossal nerve led to a nearly complete reduction of bFGF-IR in the ipsilateral HN after 48 h. Cresyl violet-stained consecutive sections revealed no signs of chromatolysis. Injection of 125 I bFGF into the tongue resulted in a prominent labeling of neuronal perikarya in the HN. No labeling was found in animals that received heat-denatured 125 I bFGF or an excess of unlabeled bFGF in addition to 125 I bFGF. These results suggest a specific retrograde axonal transport of bFGF in the hypoglossal system.

In vitro bFGF stimulated the survival of hypoglossal neurons of 7 day old rats in a dose-dependent manner (ED_{50} 2 ng/ml). *In vivo* administration of bFGF did not prevent lesion-induced (i) neuron death in the HN of 7 day old rats and (ii) decrease of choline acetyltransferase in the HN of adult rats. We suggest that, *in vivo*, bFGF may have a non-neurotrophic role in the hypoglossal system or act as a co-neurotrophic factor with a hitherto unknown protein.

23.9

TRANSIENT LESION-INDUCED EXPRESSION OF bFGF AND ITS RECEPTOR IN LAYER VIB (SUBPLATE CELLS) OF THE ADULT RAT CEREBRAL CORTEX. F. Gómez-Pinilla, J. Won-Kyun Lee* and C. W. Cotman. Dept. of Psychobiology, University of California, Irvine, CA 92717.

bFGF is a potent trophic factor with a wide spectrum of activity which appears to play a role in various stages of neuronal development. Cortical layer VIB of adult rats seems to be homologous with the transient subplate cell population of embryonic cerebral cortex of cats and primates. Since cells of cortical layer VIB survive into adulthood in rats, it is possible that these cells could possess special trophic capabilities. Accordingly, we examined the effect of brain injury on the expression of bFGF and its receptor (bFGFR) by the subplate cell population of the adult rat. Male Sprague-Dawley rats three to six months old, were deeply anesthetized and received unilateral electrolytic entorhinal cortex ablation, fimbria-fornix transection or partial aspiration of the dorsal cortex (2 x 2 mm). Rats were sacrificed 2, 7 or 14 days after lesion and processed for bFGF immunohistochemistry by the ABC method. We used an affinity purified monoclonal antibody that recognizes the configuration of bFGF related to its biological activity. In normal rats, layer VIB did not show bFGF/bFGFR immunoreactivity. After each of the lesions, there was a transient lesion-induced expression of bFGF/bFGFR immunoreactivity in the layer VIB of the cerebral cortex. This induction of bFGF appeared by postlesion day 2 and had already disappeared by day 7. Our findings suggest that, endogenous bFGF may have a neuroprotective role after insult/trauma and thus may help to maintain subplate cells throughout life.

23.11

ENDOGENOUS EXPRESSION OF ACIDIC AND BASIC FIBROBLAST GROWTH FACTORS IN 1-METHYL-4-PHENYL-1,2,3,5-TETRAHYDROPYRIDINE (MPTP) LESIONED MOUSE BRAIN. J. Logel, D. Luthman*, J. Luthman, M. Hall*, B. Hoffer and S. Leonard. Department of Pharmacology, University of Colorado Health Sciences Center, Denver, Colorado, 80262.

Substantial evidence suggests that fibroblast growth factor may influence the survival of dopaminergic neurons both *in vitro* and *in vivo*, but endogenous response of the FGFs to chemical lesion in dopaminergic systems has not been measured. The fibroblast growth factor family comprises at least five unique gene sequences. To study endogenous gene expression in dopaminergic neurons, we have treated Swiss-Webster mice with 3 X 30 mg/kg of the neurotoxin 1-methyl-4-phenyl-1,2,3,5-tetrahydropyridine (MPTD) on successive days. After one week and five weeks, animals were sacrificed and the brains were removed for dissection of the substantia nigra and striatum. RNA was isolated from a pool of each of these tissues for each time point and mRNA quantitated by multiplex PCR for acidic and basic fibroblast growth factors. Results suggest that the endogenous expression of both acidic and basic fibroblast growth factor increases at one week post-MPTP-lesion.

23.13

IMMUNOHISTOCHEMICAL LOCALIZATION OF bFGF IN THE CNS. W.R. Woodward, C.K. Meshul, R. Nishi, T.E. Williams* and F.P. Eckenstein. Depts. of Neurology and Cell Biology and Anatomy, Oregon Health Sciences Univ. and VA Medical Center, Portland, OR 97201.

Basic fibroblast growth factor (bFGF) is present in relatively high levels in the brain where it may play an important role in the development and maintenance of the tissue. We used a mouse monoclonal anti-bFGF to examine the immunocytochemical distribution of bFGF in frozen sections of rat brain. We found bFGF-immunoreactivity to be predominantly associated with GFAP-positive astrocytes throughout all regions of the CNS. Only a few neuronal populations were found to contain bFGF-immunoreactivity: prominent among them were neurons in the CA2 area of hippocampus and small neurons in the retrosplenial cortex. The bFGF-immunoreactivity in these cells appeared to be present in both the nucleus and the cytoplasm. The nuclear localization of bFGF-immunoreactivity was confirmed by EM analysis for both astrocytes and CA2 neurons. In CA2 bFGF-immunoreactivity was only observed in a subpopulation of pyramidal neurons with irregular-shaped nuclei. The only other cells in the CNS showing bFGF-immunoreactivity were ventricular ependymal cells. These data suggest that bFGF might be involved in mediating astrocytic influences on late postnatal maturation and plasticity in the CNS. The nuclear localization suggests that bFGF may be important for the differentiation of astrocytes and specific neuronal populations.

LIMBIC SEIZURES INCREASE BASIC FIBROBLAST GROWTH FACTOR (bFGF) GENE EXPRESSION IN HIPPOCAMPUS AND ENTORHINAL CORTEX. M.A. Riva*, K. Gale*, J. Graham*, A. Pazos* and I. Mocchetti. Departments of *Anatomy and Cell Biology and *Pharmacology, Georgetown University Medical Center, Washington, D.C. 20007.

bFGF, an important growth factor for maintenance of neurons, has been postulated to serve a protective role in degenerative processes. Using an RNase protection assay, we investigated the regulation of bFGF gene expression in selected limbic regions of rats following convulsive seizures evoked focally from area tempestas (AT), an epileptogenic site in the deep prepiriform cortex.

Following infusion of bicuculline methiodide (118 pmol in 120 nl) into the AT, limbic motor seizures, characterized by rearing with facial and forelimb clonus, recurred over a 45 min period. At 5 and 10 hr following initiation of seizures from AT, the levels of bFGF mRNA in entorhinal cortex and hippocampus were significantly increased (by more than twofold). An increase in bFGF mRNA was also detected in substantia nigra, but no increases occurred in striatum or hypothalamus. Infusions of saline into AT, or infusions of bicuculline adjacent to AT (which did not induce seizures) were without effect on bFGF mRNA levels. Moreover, infusions of bicuculline into the inferior colliculus, which evoked characteristic brain stem seizures (explosive running and bouncing convulsions), did not increase bFGF mRNA in any of the forebrain regions investigated.

These data suggest that the regional expression of bFGF mRNA selectively changes in response to the propagation of seizure discharge through limbic circuits and raises the possibility that bFGF may participate in adaptive changes occurring following limbic seizure activity.

INJURY-INDUCED INCREASE IN BASIC FIBROBLAST GROWTH FACTOR IN THE RAT BRAIN. C. Wolak*, S. Webb*, L. Hjelmlund* and V. Vijayan. Dept. of Cell Biol. & Human Anat. and Dept. of Med. Ophthalmol., University of California, Davis, CA 95616.

Basic fibroblast growth factor (bFGF) has been localized to neurons and astrocytes in the C. N. S. bFGF level increases following brain injury and this may contribute to repair and neurotrophic support of injured neurons. We undertook immunohistochemical studies to examine the loci of bFGF increase following injury in a previously characterized model of neural trauma in the rat (Topp et al., 1989; Vijayan et al., 1990).

We observed bFGF immunoreactivity in many neurons, in ependymal cells and in subpopulations of gray and white matter astrocytes throughout the rat brain in the absence of injury. Two to 15 days following injury, the wound area demonstrated acid phosphatase- and OX 42-positive macrophages in the cavity and adjacent neuropil, and intensely GFAP-reactive hypertrophied astrocytes in the border zone. bFGF staining appeared in the extracellular space near the wound and in the nuclei and cytoplasm of macrophages. In addition, reactive astrocytes demonstrated an increase in nuclear bFGF immunoreactivity.

Our observations suggest that bFGF released into the extracellular space and produced by brain macrophages and reactive astrocytes are potential sources for the growth factor following a traumatic injury to the rat brain. Supported by NIH grant AG06159.

BASIC FIBROBLAST GROWTH FACTOR (bFGF) SUPPRESSES AN INITIAL PHASE OF NEURONAL DIFFERENTIATION IN CULTURE IN CHICK NEURAL TUBE DEVELOPMENT. Y. Kinoshita, C. Kinoshita*, and M. Bothwell. Dept. of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195.

Neurotrophic activities of bFGF have been demonstrated for a variety of developing neuronal populations. Here we report that bFGF instead suppresses neuronal differentiation in culture when it is applied to cells at a very early stage of neuronal differentiation. Dissociated neural tube cells obtained from a thoracic region of -E2.5 (26-30 somites) chick embryos were cultured on polyornithine-coated substrate in Keratinocyte Serum-Free Medium (Gibco) + 1 % FBS with or without bFGF (10 ng/mL), in which little cell proliferation occurs. bFGF reduces the number of neurons, as identified after 2 days of culture using an anti-neurofilament antibody, down to ~40% for well-differentiated neurons (neurite > 2 cell body size) and to ~55% for the total neuronal count, with a half-maximal effective concentration below 0.1 ng/mL. This adverse effect of bFGF is seen only when cells are exposed to bFGF within 12 hrs following cell plating (roughly corresponding to E3), and later exposures to bFGF result in a weak neurotrophic action. During development *in ovo*, the suppressive effect of bFGF becomes largely unnoticeable by E3.5 for well-differentiated neurons that are thought to be born earlier, although poorly-differentiated neurons are still susceptible to bFGF. bFGF also suppresses neuronal differentiation of cells cultured on collagen substrate in F12 + 10% FBS medium.

These results indicate that in an initial phase of neuronal development there is a critical period during which bFGF can act suppressively on neuronal differentiation and support the hypothesis that FGFs may exert different functions at two discrete phases of neuronal differentiation (Heuer et al., Neuron 5:283, 1990).

23.15

CHARACTERIZATION OF A PC12 VARIANT UNRESPONSIVE TO FIBROBLAST GROWTH FACTOR. M. E. Zuber, D. J. Marshall* and B. B. Olwin*. Department of Biochemistry, University of Wisconsin, Madison, WI 53706.

The rat pheochromocytoma cell line PC12 has been used as a model system in the study of neurite outgrowth. PC12 cells differentiate reversibly when treated with nerve growth factor (NGF), acidic or basic fibroblast growth factor (aFGF and bFGF respectively). We have isolated a PC12 variant (PC12-) that is not responsive to either aFGF or bFGF yet retains the ability to extend neurites in the presence of NGF. We have examined FGF receptors in PC12- cells to determine if an alteration in FGF receptors is responsible for the loss of FGF-dependent neurite outgrowth in these cells. ¹²⁵I-aFGF cell surface binding studies indicated that PC12- cells bind less than 25% of the aFGF bound to control PC12+ (FGF-responsive) cells. Chemical cross-linking of ¹²⁵I-aFGF to intact PC12- and PC12+ cells revealed that PC12+ cells express a ~160 kDa cell surface FGF binding protein not present in PC12- cells. Northern blot (mRNA) analysis demonstrated that PC12+ cells express a transcript(s) that hybridizes to a member of the tyrosine kinase FGF receptor (TK FGFR) family. PC12- cells lack detectable levels of this transcript. The simplest interpretation of these results is that PC12- cells lack a TK FGFR and therefore cannot respond to FGF as a factor that stimulates neurite outgrowth. Experiments are in progress to test this hypothesis.

EFFECTS OF bFGF ANTISENSE OLIGONUCLEOTIDES ON ASTROCYTES AND HIPPOCAMPAL CELL CULTURES. W. Gerdes, W. Brysch, K.H. Schlingensiefen, W. Seifert Dept. Neurobiology, Max-Planck-Inst. biophys. Chem. 3400 Göttingen, Germany

Basic fibroblast growth factor (bFGF) has been recognized as a neurotrophic growth factor for CNS neurons in recent years. We have used a stable synthetic bFGF antisense oligodeoxynucleotide in order to block the bFGF gene expression in astrocyte cultures from rat cortex and in neuronal cultures from rat hippocampus (E18).

Astrocytes from 8-10 days old cultures of newborn rats grown in DMEM plus 10% calf serum were trypsinized and replated in 24- or 96-multiwell plates, either in serumfree DMEM or in hormone-supplemented DMEM. After addition of the antisense oligo, growth factors (10% serum / FGF / EGF) were added and cell proliferation was tested at 24 hrs and 48 hrs by ³H-thymidine incorporation into DNA and by the FDA assay in a cytofluorimeter. In cultures stimulated by these factors a significant inhibition of DNA synthesis and cell proliferation was observed. In hippocampal neuronal cultures (E18, 3 days in serumfree cult) the antisense oligodeoxynucleotide had no effect on survival after 24 hrs.

23.19

Increase in immunoreactivity and mRNA level of basic fibroblast growth factor in rat brain after transient forebrain ischemia. K. Takami, Y. Kiyota, M. Iwane*, M. Miyamoto, A. Nagaoka*, A. Shino* and R. Tsukuda*. Biology Res. Lab. & Biotechnology Res. Lab., Res. and Dev. Div., Takeda Chemical Ind. Ltd., Osaka 532, Japan.

Using immunohistochemistry and *in situ* hybridization, we examined whether basic fibroblast growth factor (bFGF) is generated as one of the 'self-repair' responses in rat brain following 20 min of forebrain ischemia. We used monoclonal anti-human bFGF antibody for immunostaining and synthesized oligonucleotide probe complementary to bFGF mRNA. In ischemic rats, remarkable neuronal degeneration and necrosis were observed in the CA1 subfield of the hippocampus and the caudate putamen. In these areas, intense bFGF immunoreactivity was observed while slight in normal rats. Marked immunoreactivity was also evident in the temporal cortex, corpus callosum and CA4 subfield of the hippocampus. In addition, transient forebrain ischemia markedly increased the levels of mRNA for bFGF in the hippocampus, especially in the CA1 subfield. These results suggest that induction of bFGF may be related to the healing which follows brain ischemia.

23.16

EVIDENCE FOR A PERTUSSIS TOXIN-SENSITIVE G-BINDING PROTEIN COUPLED TO THE CLONED HUMAN ACIDIC FIBROBLAST GROWTH FACTOR (aFGF) RECEPTOR. Michael F. Jarvis and George Gessner, Rhône-Poulenc Rorer Central Research, King of Prussia, PA 19406.

Acidic fibroblast growth factor (aFGF) is a neurotrophic agent that mediates neuronal differentiation via a specific cell surface receptor. The cloned human aFGF receptor possesses a single membrane spanning region and is functionally linked to the activation of tyrosine kinase. [¹²⁵I]aFGF binds to NIH 3T3 murine fibroblast cell membranes containing the recombinant and overexpressed human aFGF receptor with high affinity (K_d = 300 pM) and limited capacity (B_{max} = 19 pmol/mg protein). Preincubation of the membranes with pertussis toxin resulted in a concentration-dependent decrease in ligand affinity (K_d = 800 pM) with no significant change in apparent B_{max}. Experiments with cholera toxin failed to produce binding parameters different from control values. Under appropriate experimental conditions, the binding of [¹²⁵I]aFGF was also reduced by GTP, GTP-γ-S, and Gpp(NH)p. These results provide direct evidence that the aFGF receptor is coupled to a G (possibly G_i)-binding protein and that functional receptor activation involves the formation of a ternary (agonist/receptor/G-protein) complex.

DEVELOPMENTAL CHANGES IN PDGF AND FGF mRNA LEVELS IN CAT CORTEX AND CEREBELLUM. MA McCormack, P. Tolentino, K.M. Rosen, G.D. Mower and L. Villa-Komaroff. Department of Neurology and Program in Neuroscience, Children's Hospital and Harvard Medical School, Boston, MA 02115

Northern/slot blot analysis was used to describe the postnatal developmental expression of mRNAs encoding the two chains of Platelet-Derived Growth Factor (PDGF) and the two forms of Fibroblast Growth Factor (FGF). For the PDGF family, the developmental pattern of expression was different in different structures. In visual cortex, RNA encoding PDGF-B showed a peak of expression at 5 weeks of age, mirroring the postnatal critical period in this structure. By contrast, levels of this RNA were highest at 1 week and showed a steady 2-3 fold decline to adulthood in frontal cortex and cerebellum. Levels of PDGF-A mRNA declined 6-8 fold in frontal and visual cortex but remained constant in cerebellum. RNA encoding bFGF rose sharply over the first 10 weeks, then declined 2-3 fold to adult levels in all three structures, correlating with the time course of synaptogenesis and gliogenesis. Levels of aFGF mRNA were essentially constant in all three structures. To investigate the effect of environmental input on the expression of these RNAs, we are examining the effect of dark rearing and exposure to light after dark rearing in young (5 week) and older (20+ week) cats. Preliminary results suggest that there is no striking effect of these conditions on mRNAs encoding these growth factors in either visual or frontal cortex. These results indicate that the two members of each of these growth factor families have different patterns of expression during postnatal life. The consequence of these patterns is that the relative amounts of the two forms of FGF and the homodimers and heterodimers of PDGF change over the course of normal brain development.

CYTOKINE GENE EXPRESSION IN THE DEVELOPING BRAIN T.M. Burns*, J.A. Clough*, M. De * N.E.J. Berman, R.M. Klein, G.W. Wood*. Departments of Pathology and Oncology and Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS, 66103.

Cytokines have been shown to have profound effects on the proliferation and differentiation of numerous cell types, but little is known about their potential role in brain development. To determine whether cytokines are expressed in the developing brain, we extracted total RNA from fetal and early postnatal mouse brains (E12-P39) and performed Northern blots using formaldehyde gel electrophoresis. IL-1α, a potent mitogen, was expressed at all time periods examined, and the mRNA was present as more than one transcript. TNF-α, which is known to be cytostatic and cytotoxic, increased during fetal and neonatal development, but decreased dramatically after postnatal day 36. IL-6, which is known to be induced by IL-1 and TNF-α, was also present at all time periods. TGF-β₁, which regulates extracellular matrix deposition, increased from E12 to P6, and increased again between P12 and P39. These results show that cytokine genes are expressed at different times during CNS development. The differential expression of cytokine genes may reflect regional differences in brain development and/or involvement of cytokines in distinct developmental processes. REGIONAL DIFFERENCES IN OPIATE-DEPENDENT ASTROCYTE GROWTH IN ORGANOTYPIC CULTURES OF THE MOUSE CEREBELLUM, HIPPOCAMPUS AND CEREBRAL CORTEX. **K.F. Hauser**. Dept. of Anat. and Neurobiol., Univ. Kentucky Sch. Med., Lexington, KY 40536

To determine whether opiates directly modulate neural growth, opiate-dependent growth was examined in organotypic explant cultures derived from rat cerebellum, hippocampus, and cerebral cortex. Each of these brain regions was taken from a total of 36 male, Swiss (ICR) mice on postnatal days 1 or 7, and dissected into 6 symmetrical (right vs left) explant pairs. One explant from each pair was continuously exposed to 10^{-5} M morphine, 10^{-5} M morphine plus 3×10^{-5} M naloxone, or 3×10^{-5} M naloxone alone for 7-10 days *in vitro*, while the other explant served as a control. In general, maximum growth occurred in hippocampal and cerebral cortical explants derived from PD 1 mice, and in cerebellar tissue from PD 7 mice. Moreover, initial observations of opiate-dependent growth in living explants demonstrated that cells with astrocytic morphology were highly responsive. To better explore differences in astrocyte growth, glial fibrillary acidic protein (GFAP) immunoreactivity was assessed in whole-mount explants derived from tissue at the above ages. In cerebellar cultures, the outgrowth area of GFAP-immunoreactive cells was significantly reduced by morphine treatment (prevented by concomitant naloxone treatment), while the total number of GFAP-immunoreactive cells per μm^2 of outgrowth was unaffected. The growth of hippocampal explants was unaffected by opiates, whereas cerebral cortical cultures displayed variable growth responsiveness - perhaps due to differing responsiveness within the cortex itself. Collectively, the results indicate that opiates can inhibit the growth of astrocytes in organotypic neural cultures, but that intrinsic regional differences in the astrocytes themselves or associated neural cells mediate the responsiveness of astrocytes to opiates. Supported by NIDA grant DA 06204.

OLIGODENDROCYTE SURVIVAL SELECTIVELY DETERMINED BY A SOLUBLE ASTROCYTE-DERIVED FACTOR. **A.L. Gard and S.E. Pfeiffer**. Dept. of Microbiology, Univ. of Connecticut Med. Sch., Farmington, CT 06032 and Dept. of Structural & Cellular Biology, Univ. of South Alabama Med. Sch., Mobile, AL 36688.

Oligodendrocyte (OL) survival and its trophic regulation have received considerably less attention experimentally than neuronal growth in this regard. However, when OL progenitors bearing the $\text{O4}^+\text{GalC}^-$ antigenic surface phenotype are purified directly from their normal germinal environment in the postnatal rat telencephalon by immunoselection, >95% of the cells are viable initially but die thereafter in a basal defined culture medium (BDM) which otherwise promotes differentiation of the remaining population (Gard and Pfeiffer, Development 106:119, 1989). Death of ~75% of the cells occurs between days 1 and 3 in culture just before, or soon after, their maturation into OL expressing galatocerebroside (GalC). Hypothesizing that a specific trophic factor is deprived from the system, supplemental BDM conditioned individually by meningeal cells, astroglia, cerebellar interneurons, macrophages were screened for survival-enhancing activity in low-density progenitor cultures. Only astrocyte-conditioned medium (ACM) was effective. Acting in a dose-dependent manner, 33% (v/v) ACM maximally increased the OL progenitor plating efficiency 9-10 fold. The size and purity (>96% O4^+ cells) of the population was sustained through 21 days of study. ACM was neither mitogenic for progenitors nor did it impair differentiation as determined by the ordered expression of galatocerebroside and myelin basic protein into myelinic membrane. These data support the concept of an interval during OL development when survival is regulated independently of proliferation and differentiation by a soluble astroglial factor. Supported by NIH grant NS10861.

THE ROLE OF bFGF IN NEURAL CONTROL OF ADRENOCORTICAL CELL PROLIFERATION. **D.P. Basile¹ and M.A. Holzwarth**. Department Physiology & Biophysics, Univ. Illinois, Urbana, IL 61801

We are investigating the role of bFGF as an autocrine mitogen in compensatory adrenocortical growth (CAG), a neurally mediated cell proliferation which occurs in the remaining adrenal in response to unilateral adrenalectomy. Isolated rat capsule-glomerulosa (CG) preps incubated *in vitro* 24 hrs after unilateral adrenalectomy demonstrate a $33 \pm 13\%$ increase in ^3H -thymidine uptake. Basic FGF (3ng/ml) stimulates a $68 \pm 14\%$ increase in DNA synthesis rate in rat CG preps *in vitro* and has been localized immunocytochemically (anti- M1-26 bFGF) in glomerulosa and outer fasciculata cells and in some medullary cells, but not in adrenocortical nerves. Molecular forms of rat adrenal bFGF are being identified by SDS-PAGE and Western blot. Suramin (1mM), which blocks bFGF-receptor interaction, inhibited the effect of bFGF (3ng/ml) on CG preps *in vitro*. Suramin was then used to test the role of bFGF in CAG *in vivo*; a high dose ($5\text{mg}/100\text{gBW}$) enhanced the baseline DNA synthesis rate within 24 hrs. A low dose ($0.2\text{mg}/100\text{gBW}$, 1 wk prior) did not affect basal DNA synthesis but surprisingly enhanced rather than blocked the CAG response. Presumably this is the result of bFGF receptor up-regulation because CG preps from suramin-pretreated rats showed an enhanced response to exogenous bFGF *in vitro*. These data suggest that bFGF participates in the mediation of CAG.

DEVELOPMENTAL APPEARANCE OF PROENKEPHALIN IMMUNOREACTIVITY IN PRIMARY EXPLANT CULTURES OF RAT CEREBELLUM. **J.G. Osborne¹, B.A. Spruce², and K.F. Hauser¹**. ¹Dept. of Anat. and Neurobiol., Univ. of Kentucky Sch. of Med., Lexington, KY 40536 and ²Dept. of Biochem., Med. Sci. Inst., The University, Dundee DD1 4HN, UK.

Enkephalin immunoreactivity is reported to transiently appear within the germinative cells of the cerebellar external granule layer (EGL) *in vivo* and *in vitro*. Moreover, endogenous opioids are reported to modify the rate of EGL cell proliferation *in vivo*. To better understand the regulation of opioid expression in the neuronal progenitor cells of the EGL, proenkephalin immunoreactivity (PE-IR) was examined in primary explant cultures using a novel monoclonal antibody (PE-25) specific for the intact/partially processed proenkephalin peptide. Cerebella from 8 male, neonatal Sprague-Dawley rats were dissected into 6 symmetrical explant pairs (i.e., comparable right vs left portions were compared) per cerebellum, and maintained as organotypic cultures for 7, 14, or 21 days. In whole-mount explants, PE-IR was detected in a portion of the EGL cells and their granule cell progeny, as well as in Golgi cells and some immature glia. When EGL cells and their derivatives were quantitatively compared in explant pair homologues at different times *in vitro*, the number of cells displaying PE-IR increased with progressive development - an interesting observation in light of previous reports of decreasing numbers of EGL cells possessing enkephalin immunoreactivity (ENK-IR) with increased maturation. Collectively, the increases in the number of cells with PE-IR appear to be developmentally regulated by local factors intrinsic to the cerebellum. Furthermore, differences between the patterns of PE-IR and those previously reported for ENK-IR suggest significant modulation of proenkephalin posttranslational processing by cerebellar neurons and their progenitors during maturation. Supported by NIDA grant DA 06204 and NIH grant RR-05374.

THE EFFECTS OF EPIDERMAL GROWTH FACTOR (EGF) ON SEPTAL CHOLINERGIC NEURONAL DIFFERENTIATION. **I.E. Mazzoni^{*} and R.L. Kenigsberg**. Centre de Recherche Pédriatrique, Hôpital Ste-Justine, Montreal, Quebec, Canada, H3T 1C5.

We found that 7 days of exposure to EGF decreases choline acetyltransferase (ChAT) activity in primary dissociated fetal rat medial septal cultures indirectly via proliferating glia. The decrease in ChAT enzymatic activity was accompanied by a comparable decrease in the number of acetylcholinesterase (AChE) positive neurons. In order to clearly determine whether EGF was affecting the survival of a subset of the cholinergic neurons in our cultures, 7 days of EGF treatment was followed by 2 days of exposure to nerve growth factor (NGF). In these cultures, ChAT activity levels returned to or surpassed control values, while the number of AChE positive cells returned to control levels. This suggests that EGF is not affecting cholinergic cell survival but acting as a de-differentiating factor on a subset of cholinergic neurons in our cultures which are responsive to NGF. In addition, we found that the proliferative response of the glia in our cultures to EGF as assessed by ^3H -thymidine incorporation, preceded the decrease in ChAT enzymatic activity by 48 h. Furthermore, the EGF-induced increases in thymidine uptake, like the decreases in ChAT were dose-dependent. At the moment the response of potential proliferating glial cells in our culture (i.e. astroglia, oligodendrocytes and microglia) to EGF are being assessed in order to identify which glial cell types and in turn which glial-derived molecules are implicated in the cholinergic cell response to EGF.

REGENERATION CONTRIBUTES TO THE FUNCTIONAL REPAIR OF SPINAL CORD INJURIES IN EMBRYONIC CHICKEN. S.J. Hasan, H.S. Keirstead and J.D. Steeves. Departments of Anatomy and Zoology, University of British Columbia, Vancouver, B.C., V6T 1Z4.

Previous results have demonstrated complete anatomical and functional repair of descending brainstem-spinal projections in chicken embryos that underwent thoracic cord transection prior to embryonic day (E)13. To determine to what extent regeneration is contributing to this repair process, we have conducted experiments using a double retrograde tract-tracing protocol. On E8-12, the upper lumbar spinal cord was injected with the first fluorescent tracing dye to label the existing brainstem-spinal neurons. One to two days later (on E10-14), the mid-thoracic spinal cord was completely transected. After an additional 5-7 days, the second fluorescent tracing dye was injected into the lumbar cord, caudal to the site of transection. Two days later (on E17-20), the CNS was fixed, sectioned, and the brainstem and spinal cord tissue sections were then viewed with epifluorescence microscopy. Our findings indicate that there are double labelled brainstem-spinal neurons after a transection prior to E13 and the number of double labelled brainstem-spinal neurons decreases after an E13-14 transection. In addition, at each subsequent stage of development (between E9-13), a higher ratio of double labelled brainstem-spinal neurons (indicating regeneration of previously severed axons) to the number of cell bodies labelled with the second fluorescent tracer alone (indicating possible subsequent development) was observed. This would suggest that regeneration of previously axotomized fibers increasingly contributes to the observed anatomical and functional recovery after thoracic cord transections prior to E13. (Supported by the MRC and NSERC of Canada.)

24.3

PROTEIN CHANGES ASSOCIATED WITH THE PERMISSIVE AND RESTRICTIVE PERIODS FOR EMBRYONIC SPINAL CORD REPAIR IN THE CHICK. D.W. Ethell and J.D. Steeves. Departments of Anatomy and Zoology, University of British Columbia (UBC), Vancouver, B.C., V6T 1Z4

Recent experiments in our lab have established both a permissive and restrictive period for axonal repair/regeneration, following an upper thoracic spinal cord transection. The transition from permissive to restrictive environments occurs around embryonic day (E) 13 of chick development. Major protein changes accompanying the transition in regenerative capacity have been investigated. Upper thoracic spinal cord segments were micro-dissected from chick embryos aged E6 to E20. Proteins were purified from the spinal cords and run on 2D gels. Protein spots were visualized using either a high resolution silver stain protocol or autoradiography.

Two sets of proteins have been sought in comparing these 2D gels: 1) proteins present exclusively after E13 (possibly contributing to inhibition of repair), termed late neural proteins (LNPs) and, 2) proteins present exclusively before E13 (possibly supporting axonal repair), termed early neural proteins (ENPs). At least seven potential LNPs and eight ENPs have been identified as conforming to these criteria. Since the functions of these proteins cannot be determined from 2D gels alone, LNPs and ENPs are currently being purified for micro-sequencing. Subsequent cloning of cDNAs for LNPs and ENPs is a long term strategy. (Supported by MRC).

ACUTE SPINAL CORD COMPRESSION INJURY RESULTS IN REGENERATION-ASSOCIATED GENE EXPRESSION IN ADULT RAT RUBROSPINAL NEURONS. E. Theriault¹, K.M. Mearow², W. Tetzlaff² and C.H. Tator¹. Univ. of Toronto¹, McMaster Univ.², and Univ. of Calgary³, Canada.

The recent application of *in situ* hybridization techniques to experimental spinal cord injury has allowed the study of the expression of specific genes in lesioned CNS neurons. Since the mechanism of injury in the majority of human traumatic spinal cord injuries involves rapid cord compression due to bone displacement, accompanying fracture-dislocation, or burst fracture (Tator, 1983), we have used the rat model of clip compression injury to examine this question in identified populations of adult rubrospinal neurons. We have used *in situ* hybridization techniques with both radioactive and non-radioactive labelled probes to examine the mRNA levels for GAP-43, tubulin, actin, ChAT, GAD and glutaminase (GLU). Our preliminary results reveal a population of magnocellular red nucleus (RN) neurons with elevated expression of GAP-43 mRNA at 1-2 but not at 4 weeks post-lesion. Changes in neurotransmitter-related mRNA for GAD and ChAT were not detected, however transcription of GLU mRNA appeared to decrease in large magnocellular RN neurons. We are currently using fluorescent retrograde labelling techniques to more clearly identify the responding populations of RN neurons. These and other findings suggest that contusion injuries of the spinal cord can result in regeneration-associated gene expression in intrinsic CNS neurons and raise the question of how to sustain and manipulate this 'new growth' mode of gene expression in the adult nervous system.

DEVELOPMENTAL TRANSITION IN THE EMBRYONIC CHICK SPINAL CORD FROM PERMISSIVE TO NONPERMISSIVE SUBSTRATES FOR NEURONAL DIFFERENTIATION. K.W. Cheng, D.W. Ethell¹, L.M. Jordan and J.D. Steeves¹, Dept. of Physiology, Univ. of Manitoba, Winnipeg, MB, Canada, and ²Dept. of Zoology, Univ. of British Columbia, Vancouver, BC, Canada.

Recent studies of spinal cord development and plasticity, in embryonic chick, have demonstrated a loss in regenerative ability correlated with a developmental stage. This report describes effects of plasma membranes from embryonic chick spinal cords on cultures of neuroblastoma X glioma hybrid NG108-15 cells, as an *in vitro* neurite outgrowth assay for permissive and nonpermissive substrates. Thoracic spinal cord segments were isolated from embryonic chicks at different stages of development (E10-E21), homogenized in isotonic buffer, and fractionated by differential centrifugation to obtain plasma membranes for coating dishes as substrate for cultures of NG108-15 cells. Upon coatings of E10 or E12 membranes, NG108-15 cells adhered strongly to the substrate, began to differentiate after 1-2 h, and became highly differentiated with neurites longer than 2-3 times cell diameter after 24 h in culture. The permissive effect of E10 membranes was observed to be slightly higher than that of the E12 cords. In contrast, pre-coating with E18 membranes prevented adhesion and differentiation of NG108-15 cells, which remained undifferentiated as clumps with round morphology even after 24 h in culture. These results indicate that the embryonic chick spinal cord undergoes a developmental transition from permissive to nonpermissive substrates for neurite outgrowth, correlating with our previous observation that, upon transection of the thoracic spinal cord prior to, but not after, embryonic day 13, chicks can repair to a complete functional recovery.

24.4

DEVELOPMENTAL EXPRESSION AND THE EFFECT OF SPINAL CORD TRANSECTION ON BRAINSTEM GAP 43 AND α -TUBULIN mRNA LEVELS IN THE CHICK EMBRYO. D.M. Pataky, S.J. Hasan and J.D. Steeves. Dept. of Zoology, UBC, Vancouver, Canada V6T 1Z4.

Previous work in our lab has determined there is a permissive (before E13) and restrictive (E13 or older) period for functional repair after a complete thoracic spinal cord transection. This study examines GAP 43 and α -tubulin mRNA levels during development, and after spinal cord transection during both the permissive and restrictive periods for repair. Cytoplasmic RNA was isolated from the pons/medulla of E4-E21 chick embryos, some of which received complete spinal cord transections at E11 (permissive) or E14 (restrictive), with 1,3,5 and 7 days survival post-transection (PT). Northern blotting was performed using cRNA probes generated from a chicken GAP 43 cDNA (kind gift of Dr. L. Baizer) and a rat α -tubulin cDNA (kind gift of Dr. F. Miller).

Developmentally, α -tubulin mRNA levels are very low at E4, with a large increase at E6, and a smaller increase to peak at E8. Levels then decrease gradually to E17-E19, and drop to just above E4 levels by E21. Transection on E11 results in little change, until 7 days PT when there is a decrease below control α -tubulin mRNA levels. Transection on E14 results in increased α -tubulin mRNA levels 1 day PT, followed by a subsequent decrease below control levels by 5 days PT, returning to control levels by 7 days PT. GAP 43 mRNA is almost undetectable at E4, with a considerable increase at E7.5, and a smaller increase to peak at E10. Levels decrease at E14, then drop to almost undetectable amounts through E17-21. Transection on E11 results in decreased levels 1 day PT, rising above control levels at 3 days PT, then decreasing below control levels by 7 days PT. Transection on E14 results in increased levels peaking 5 days PT, followed by a decrease, though still above control levels, by 7 days PT. Future experiments will include *in situ* hybridization histochemistry. (Supported by Rick Hansen Man in Motion Legacy Fund and British Columbia Health Research Foundation)

CHANGES IN mRNA LEVELS FOR GAP43, TUBULIN AND NEUROFILAMENT-M IN RAT SPINAL MOTONEURONS AFTER PROXIMAL VERSUS DISTAL AXOTOMY. B.J. Tsui, S.L. Cassar and W. Tetzlaff. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada, T2N 4N1.

We have examined whether spinal motor neurons display distance-dependence in their expression of mRNA for GAP43, α -tubulin and the medium neurofilament subunit, NFM, following axotomy. For a proximal lesion the L5 spinal nerve was transected 5 mm distal to the DRG. For a distal lesion the common peroneal nerve was transected at the entry into the muscle. The cells were retrogradely filled with either Fast Blue or Fluorogold to restrict the analysis to axotomized (labelled) neurons only. *In situ* hybridization was performed on frozen sections of the spinal cords. At 7, 14 and 21 days post lesion, there was an increase in both GAP43 and α -tubulin mRNA expression. The increase in GAP43 mRNA expression following distal lesion was not different than that observed after proximal lesion. The increases in α -tubulin mRNA were greater after proximal lesion than after distal lesion. The mRNA levels for NFM decreased following both proximal and distal axotomy, and were not different after 14 days. The differing extent of the changes in mRNA expression in response to distal versus proximal lesions suggests that different molecular signals are involved in the regulation of these regeneration associated genes.

RAP-14: A PROTEIN ASSOCIATED WITH THE TIME COURSE OF THE ABILITY OF RAT SPINAL CORD TO RECOVER FUNCTION FOLLOWING INJURY W. E. Edmonston, Jr., Colgate University, Hamilton, NY 13346

Electrophoretic analysis of the polypeptide composition of fetal, neonatal and adult rat spinal cord tissue reveals a 14kD protein which is present in the younger tissue (Fetal 19 through Neonatal 15 to 18 days), but absent in older tissue. The disappearance of the protein (RAP-14 -- Regeneration Associated Protein) coincides with the cessation of the ability of rat spinal cord to reorganize and re-establish function following injury. Adult frog CNS also contains RAP-14. Immunoblot analysis established that RAP-14 is neither Myelin Basic Protein nor Nerve Growth Factor. Differential centrifugation of 3-6-, 10-, 12-, 16-, and 23-day old rat tissue revealed a progressive disappearance from specific cell fractions with age in accord with expectations regarding its manufacture and storage within the cell.

LOCALIZATION OF THROMBOSPONDIN FOLLOWING OPTIC NERVE CRUSH IN THE MOUSE AND GOLDFISH.

J.R. Hoffman, K.S. O'Shea, and Y.M. Dixit*
Univ. of Michigan, Ann Arbor, MI 48109

Thrombospondin (TSP) is a 420 kDa component of the extracellular matrix present at high levels during development and in regeneration of the peripheral nervous system. In the current study, adult male CD-1 mice or 5-10 cm goldfish were anesthetized and the optic nerve was crushed within 2-3 mm of exiting the eye. After 1-60 d, frozen sections were cut and processed to localize TSP. Control mouse optic nerve showed low levels of TSP associated with glial cells, while the goldfish optic nerve had much higher levels of TSP in a fasciculated pattern. Following nerve crush in the mouse, TSP levels increased in regions of gliosis and cellular infiltration near the crush site. In the goldfish optic nerve, TSP levels rapidly increased throughout the nerve forming distinct tracts of TSP running from the retina past the crush site. Following nerve crush, TSP levels in mouse optic nerve increased somewhat randomly in association with gliosis. TSP levels in the goldfish optic nerve were much higher and very organized.

ROLE OF EXTRACELLULAR MATRIX MOLECULES AND MICROGLIAL CELLS IN REGENERATION OF LEECH CNS L. Masuda-Nakagawa*, C. Wiedemann*, A. Walz*, D. Neely* and J.G. Nicholls Dept. Pharmacology, Biocenter, 4056 Basel, Switzerland

The aim of these experiments is to analyze how protein molecules in extracellular matrix (ECM) of leech CNS influence the shapes of neurons and of microglial cells that accumulate at sites of injury. An interesting paradox is that microglial cells *in situ* become closely associated with laminin and regenerating axons as they grow through a lesion; by contrast in co-cultures of microglia and identified neurons, they produce contact inhibition of neurite outgrowth. The pattern of neuronal outgrowth depends critically upon the molecular composition of the substrate. For example on laminin the processes of a Retzius cell are slender, straight and unbranched; on the plant lectin Con A they are thick, curved and branched. Another molecule, tenascin, has now been purified by gradient centrifugation of high pH extracts of ECM surrounding leech CNS. On highly enriched tenascin fractions the pattern of neurite outgrowth resembles that on Con A. Substrate molecules also influence the shapes of cultured microglial cells. On Con A they are rounded and resemble fried eggs; on ECM they are thin and spindle-shaped. Tests are now being made to determine whether microglial cells secrete growth promoting molecules and whether their functions are influenced by the substrates that they come into contact with.

THE GROWTH-ASSOCIATED PROTEIN GAP43 IS EXPRESSED IN DEGENERATING PERIPHERAL NERVE AFTER AXOTOMY. M.A. Bisby¹, K.C. Harrington^{2*} and W. Tetzlaff². ¹Dept. of Physiology, Queen's University, Kingston, Ontario, Canada and ²Depts. of Anatomy and Pathology, University of Calgary, Calgary, Alberta, T2N 4N1, Canada.

We reported that GAP43 immunoreactivity was associated not only with regenerating axons in rat sciatic nerve, but also with Schwann cells (Tetzlaff *et al.*, *J. Neurosci.*, 9:1303, 1989). Further, GAP43 immunoreactivity was detected surrounding unmyelinated axon bundles in normal nerve. These findings raise the possibility that GAP43 is synthesized by cells within peripheral nerve. Northern blot analysis showed that an appropriate size signal (1.4 kb) was recognized by a GAP43 cDNA probe (Basi *et al.*, *Cell*; 49:785, 1987) in degenerating rat facial nerve samples. No signal was detectable in normal nerve. Now, using the more sensitive technique of reverse transcription followed by polymerase chain reaction amplification with primers spanning the entire coding region, we have detected amplified products of the expected size in normal samples, and higher levels in degenerating samples. GAP43, once thought to be exclusively neuronal, may also be expressed by cells within peripheral nerve. Increased expression in degenerating peripheral nerve suggests a site of action for GAP43 additional to its implied role within the growing axon.

24.10

MATRIX REMODELLING AND INTERSTITIAL CELLS AT DENERVATED FROG NEUROMUSCULAR JUNCTIONS. E. A. Connor and H. A. Martin* Univ. of Massachusetts, Amherst, MA.

When a motor nerve is damaged, the connective tissue in junctional regions of skeletal muscle undergoes striking changes. Interstitial cells and several matrix molecules including fibronectin and tenascin are concentrated near denervated neuromuscular junctions. These interstitial cells may be responsible for remodelling the extracellular matrix and thereby may influence synapse regeneration. Previously, we identified two monoclonal antibodies (mAbs), 2G3 and 7B11, that stain muscle connective tissue and whose staining patterns are altered by denervation; both antigens are concentrated in junctional regions of denervated muscle. To determine if the mAb 2G3 and 7B11 antigens were produced by interstitial cells, muscles were dissociated enzymatically and the freed interstitial cells were maintained *in vitro*. By 1 week in culture, interstitial cells produced mAb 2G3 and 7B11 antigens as well as tenascin and fibronectin. The mAb 2G3 and 7B11 antigens were found to be extracellular and bound to glass coverslips. MAb 2G3 stain was distributed in a filamentous pattern coincident with that of fibronectin. In Western blots, mAb 2G3 recognized a protein of 235kD molecular weight. MAb 7B11 stain was distributed in a punctate pattern and in young cultures was excluded from substrate areas apposed to stress fibers. In older cultures, the substrate was uniformly stained. These data suggest that the interstitial cells remodel the extracellular matrix in junctional regions of muscle after denervation and are consistent with findings in rat muscle (Gatchalian *et al.*, 1989). The mAb 2G3 and 7B11 antigens may be previously uncharacterized matrix molecules whose distribution is altered by denervation.

EFFECTS OF AXOTOMY ON PROTEIN SYNTHESIS AND DEGRADATION IN THE RAT HYPOGLOSSAL NUCLEUS Y. Sun¹, L. Sokoloff² and C. Beebe² Smith, Laboratory of Cerebral Metabolism, NIMH, Bethesda, MD 20892

In previous studies we found that unilateral XIPⁿ n. axotomy results in an apparent increase in the rate of protein synthesis in the ipsilateral hypoglossal nucleus (Smith *et al.* *J. Neurosci.* 4:2489, 1984). This effect is seen as early as 48 h postaxotomy and returns to normal by postaxotomy Day 35. Local rates of protein synthesis were determined with the quantitative autoradiographic [¹⁴C]leucine method with the assumption that there was no recycling of unlabeled leucine derived from protein degradation back into the precursor amino acid pool for protein synthesis. We recently determined that there is such recycling and that in the brain as a whole 42% of leucine in the precursor pool is derived from protein degradation (Smith *et al.* *PNAS* 85:9341, 1988). The rates of protein synthesis determined in our previous study were, therefore, underestimated. In the present study we have examined the degree of recycling in the regenerating nucleus. In order to determine the degree of recycling in whole brain we measured the ratio of specific activity of leucine in the precursor pool (tRNA-bound leucine) to that in plasma in rats with the brain in a steady state for both labeled and unlabeled leucine. The concentration of leucyl-tRNA in brain is too low to measure in individual brain regions, however; instead we measured the steady state specific activity of leucine in the total acid-soluble pool as an index of the tRNA-bound pool in the ipsilateral and contralateral hypoglossal nuclei of nine adult, male rats five days after unilateral hypoglossal axotomy. The steady state ratios of specific activities were significantly (6%) lower in the axotomized as compared with the control side (P < .05, paired t-Test). These results confirm our earlier finding that protein synthesis is increased in the regenerating hypoglossal nucleus, but indicate that protein degradation is also increased under these conditions.

24.13

PURIFICATION AND CHARACTERIZATION OF p68/70 FROM GOLDFISH BRAIN. M.L. Leski*, M. Moos*, K. Seamon* and B.W. Agranoff. Dept. of Biological Chemistry and Neuroscience Lab, Univ. of Michigan, Ann Arbor, MI 48104-1687; Div. of Biochemistry and Biophysics, Center for Biological Evaluation and Research, FDA, Bethesda, MD 20892.

Comparison of autoradiographs of two-dimensional polyacrylamide gels following incorporation of radioactivity from labeled amino acids into goldfish (*Carassius auratus*) retinal proteins in controls and in retinas in which the optic nerve had been previously lesioned, reveals a number of differences. One such difference is a dramatic increase of labeling of two acidic proteins of apparent molecular weights 68 and 70 kDa (p68/70). We have purified this protein doublet to homogeneity from goldfish brain homogenates. This was accomplished by sequential chromatography of the 100,000 x g supernatant on DEAE-Sephacel, copper (II)-charged iminodiacetic acid agarose and TSK-3000. Initial attempts to sequence p68/70 indicated that it is N-terminal blocked. Chemical and enzymatic treatment of p68/70 has yielded several sequenceable stretches. One thirteen amino acid segment has identity with a synaptic vesicle protein from the *Torpedo*, VAT-1 (Linial, M., Miller, K. and Scheller, R.H., *Neuron* 2:1265-73, 1989). However, a polyclonal antibody against p68/70 does not recognize VAT-1. While p68/70 is not associated with synaptic vesicles, much of it appears to be membrane-bound. In extraction studies neither 1 M NaCl, 1 M neutral hydroxylamine, 5 M urea nor 200 mM sodium carbonate buffer, pH 11 completely released p68/70 from the membrane, while 1% Triton X-100 did, a result that suggests that the doublet is integral to the membrane. In phase partitioning experiments using Triton X-114, both cytosolic and membrane-bound p68/70 partitioned into the aqueous phase, indicating that the membrane association is not likely attributable to covalently-bound lipid. (Supported by NIH grant EY 05947.)

IN SITU HYBRIDIZATION STUDIES OF J1/TENASCIN REAPPEARANCE FOLLOWING TRAUMATIC BRAIN INJURY IN MOUSE AND HUMAN. E.D. Laywell*, T.F. O'Brien, K. Harrington*, D.A. Steindler, M. Schachner, and U. Dorries*. Univ. of Tenn., Memphis and ETH, Zurich.

J1/tenascin is an extracellular matrix (ECM) molecule with a prominent distribution during development. In the brain, J1/tenascin is associated during late embryonic and early postnatal development with boundaries that outline many functional units such as cortical barrels, neostriatal striosomes, and various nuclei. After functional brain patterns have been stabilized, J1/tenascin expression is greatly reduced, or disappears altogether as seen immunocytochemically or biochemically.

Recently, our labs have presented immunocytochemical evidence for enhanced J1/tenascin expression following lesions of the adult mouse cerebellum and cerebral cortex. In immunocytochemical studies of developing and lesioned adult brains, astrocytes appear to be the primary source of tenascin; however, because other cell types have been identified as sources of J1/tenascin (eg. fibroblasts), a more precise approach was needed to unequivocally assign enhanced J1/tenascin expression to a particular cell type. Here, we use a J1/tenascin riboprobe to identify and localize the cell type responsible for this reappearance. *In situ* hybridization, using a digoxigenin labeled riboprobe to J1/tenascin, was performed on sections of lesioned adult mouse brain and postmortem human brain tissue following traumatic head injury. In all cases the J1/tenascin probe proved to be an extremely sensitive marker of some of the earliest cellular changes following brain lesion. In double labeling studies, the J1/tenascin probe identifies a population of glial fibrillary acidic protein positive astrocytes. In particular, Golgi epithelial cells of the cerebellum and astrocytes of the cortex exhibit a discretely localized distribution around lesion sites.

In conclusion, *in situ* hybridization with this newly developed riboprobe to J1/tenascin appears to be a very reliable indicator of early astrocyte response to brain injury. The functional relevance of injury-induced, enhanced expression of such ECM molecules is not yet known. However, it is possible that these molecules may adversely affect neurite regeneration in and around brain wounds. Supported by NSF and NIH grants BNS-8911514 and NS 20856.

STUDY OF GLYCOSAMINOGLYCANS DERIVED FROM AXONALLY TRANSPORTED PROTEOGLYCANS IN REGENERATING GOLDFISH OPTIC NERVE. Jean E. Challacombe* and J.S. Elam, Department of Biological Science, Florida State University, Tallahassee, Florida 32306

Sulfated proteoglycans (PGs) present in brain contain heparan sulfate (HS) and chondroitin sulfate (CS) GAGs, both of which have been implicated in control of neuronal growth. Previous work in our lab has shown that regenerating goldfish optic nerves axonally transport 60% of ^{35}S O₄-labelled GAG in CS and 40% in HS, while unoperated control nerves transport 26% in CS and 74% in HS (Coughlin and Elam, *Br. Res.* 493, 326(89)). To see if there are additional regeneration-related differences in the structure or distribution of transported GAGs, fish were administered unilateral optic nerve crushes and were stored for 21 days at 21 C. Eight hours following intraocular injection of ^{35}S O₄, optic tracts were removed and processed for isolation of axonally transported GAGs. Results of gel filtration on Sepharose CL-6B show that CS and HS from regenerating tracts are of similar size to those from unoperated control tracts, while paper chromatographic analysis shows that sulfation of CS in regenerating tract remains in the C-4 position of GalNAc. In contrast, a regeneration-correlated increase in ionic strength required for elution is seen during DEAE ion exchange chromatography of CS. Sequential homogenization of tracts with neutral buffer (to extract soluble proteoglycans) followed by buffer containing 1M NaCl-1% Triton X-100 (to extract membranous proteoglycans) showed that regeneration is correlated with a shift in transported ^{35}S O₄ (from 49% to 72%) affiliated with the membranous compartment. Taken together, these results indicate that the regeneration-related shift in the proportion of GAGs is accompanied by changes in charge density and in subcellular localization. (Supported by NS 20502)

EXPRESSION OF p68/70 IN REGENERATING GOLDFISH VISUAL SYSTEM. G.R. Wilmut, P.R. Raymond and B.W. Agranoff. Mental Health Research Inst. and Dept. Anat. and Cell Biol., University of Michigan, Ann Arbor, MI 48104.

We previously described increased amino acid incorporation into a nominally 68-70 kDa protein doublet in the goldfish retina following optic nerve crush. This doublet (p68/70) is slowly transported via the optic nerve to the tectum, indicating that it is present in retinal ganglion cells (RGC's). We have developed an affinity-purified polyclonal antibody (α -p68/70) which specifically recognizes p68/70, and have utilized α -p68/70 to characterize the expression of p68/70 in normal and regenerating goldfish visual system. The cellular distribution of p68/70 was examined in cryostat sections of fixed tissue using avidin-fluorescein or avidin-biotin-peroxidase. In the central retina, immunoreactivity was highest in RGC dendrites, somata and axons. During regeneration the immunoreactivity of RGC somata increased markedly. Occasional immunolabeled cells were also observed throughout the retina. Most of these scattered cells were also recognized by the monoclonal antibody NN1, which recognizes phagocytic cells of presumed monocytic origin. The remaining α -p68/70 positive cells that were NN1 negative were located in the outer nuclear layer and appear to be rod precursors and/or recently born rods. In peripheral retina adjacent to the germinal epithelium, which contains recently differentiated retinal neurons, α -p68/70 immunoreactivity was observed in all layers. Immunostaining was also observed in the germinal epithelial cells, which give rise to new retinal neurons. In tectum, young neuronal cell bodies adjacent to the tectal germinal zone were prominently labeled. Immunolabeling of the remainder of the tectum was restricted to fiber layers and was most prominent in the *s. marginale*, which receives input from the *torus longitudinalis*. RGC fibers terminating within the *s. griseum et griseum superficiale* were lightly labeled in normal tectum but were intensely immunoreactive during regeneration. Immunofluorescent labeling of retinal explants revealed that p68/70 is present in growth cones, filopodia and intracellular membranous organelles of regenerating RGC neurites. The expression of p68/70 thus suggests that this protein plays a role in axonal growth and possibly in cellular differentiation as well. (Supported by NIH grant EY 05947.)

IMMUNOCYTOCHEMICAL DETECTION OF TENASCIN IN THE TRANSECTED ADULT RAT OPTIC NERVE. A. Ajemian* and S. David, Centre for Research in Neuroscience, Montreal Gen.Hosp.Res.Inst. and McGill Univ., 1650 Cedar Ave. Montreal, Quebec, Canada.

Growth promoting and growth inhibitory molecules are both likely to play a role in controlling axonal regeneration in the adult mammalian CNS. The presence of an inhibitory molecule associated with mammalian oligodendrocytes and CNS myelin has been reported (Schwab, *TINS* 13: 452). The ECM molecule tenascin (TEN) which is produced by astrocytes in the CNS, was also recently reported to be inhibitory for cell attachment and neurite growth of CNS neurons (Faissner & Kruse, *Neuron* 5: 627).

In this study we have examined the distribution of TEN in the lesioned adult rat optic nerve. Longitudinal cryostat sections of fixed rat optic nerve, obtained 5 days to several weeks after transection were double labeled by indirect immunofluorescence with anti-TEN and anti-GFAP antibodies. Intense tenascin-like immunoreactivity was seen in a narrow region at the site of transection, at 5 and 10 days after transection, but not after 3 weeks. In some areas the TEN⁺ labeling showed correspondence with GFAP⁺ astrocytes. It is possible that tenascin which delineates the edge of the lesion, might serve to limit the growth of axons across the lesion site. (Supported by the Canadian MRC).

ACCUMULATION OF NEUROFILAMENT PROTEINS IN THE REGENERATING FACIAL NERVE. L.T. Wang-Bennett, A. de Jong* and D.J. Liebl*. Dept. of Otorhinolaryngology and Communicative Sci., Baylor College of Med., Houston, TX 77030.

The accumulation of the neurofilament (NF) proteins in the regenerating facial nerve of adult New Zealand rabbits was compared in two surgical models. The animals were operated on bilaterally, with a chamber model placed on one side and a cable graft model inserted on the contralateral side. Normal nerve from unoperated animals or nerve removed during nerve repair surgery served as controls. Using immunoblot techniques and densitometric measurement, we examined specific changes in the individual NF [High (H), Medium (M), and Low (L) molecular weight] at regeneration time of 3 and 7 wk. Linearity of the densitometric system was established by separation and immunostaining of serial dilutions of known NF.

The amount of all three NF's decreased during the regeneration, but did not behave similarly. The NFH in the distal segment of the chamber repaired nerve at 7 wk was 60% - 70% of the preoperative state, which correlated with a previous morphological study of axonal caliber during regeneration. The NFH contents showed a regeneration time-dependent change and an interaction effect from time x repair models. Accumulation of NFL displayed a site-dependent change. The result was discussed in relation to the progress of axonal sprouting and the differential appearance of NF proteins in the developmental stage. (Supported by Texas Advanced Technology Program #1165 and Coker Memorial Research Foundation.)

CHANGE IN EXPRESSION OF ACETYLCHOLINESTERASE IN TERMINAL FIELDS OF GUSTATORY PRIMARY AFFERENTS FOLLOWING PERIPHERAL NERVE DAMAGE, REGENERATION, AND REINNERVATION OF TASTE BUDS. M.A. Barry, R.G. Wehby*, L.D. Savoy*, and M.E. Frank. Dept. of Biostructure and Function, Univ. Conn. Health Ctr., Farmington, CT 06030.

Damage to the peripheral processes of primary sensory afferents generally has subtle morphological but often profound physiological effects in adult mammals. Little is known about these effects for the gustatory system. Previous studies (Barry et al. 1991, J. Elect. Microsc. Tech., In Press) have shown that the terminal fields of the chorda tympani branch of the facial nerve and lingual branch of the glossopharyngeal nerve in the nucleus of the solitary tract (NST) are characterized by intense staining with acetylcholinesterase (AChE) in hamsters. We examined AChE staining in the NST after cutting or crushing these nerves unilaterally in adult male golden hamsters (*Mesocricetus auratus*). At 1 week following nerve damage there was a decrease in AChE staining limited to the area corresponding to the terminal fields. By 2 weeks, the terminal fields could not be easily distinguished from surrounding regions. There was a concomitant loss of foliate taste buds on the affected side of the tongue. At 4-5 weeks, the nerves had apparently regenerated since foliate taste buds reappeared, but there was little or no recovery of AChE staining in the NST. The recovery of AChE activity may correlate with the complete return of gustatory function. NIH-DC00168-10.

POSTTRANSLATIONAL ARGINYLYATION OF PROTEINS IN EXPLANTS OF CRUSHED SCIATIC NERVES OF RATS. N-S Xu, G. Chakraborty* and N. Ingoglia. Dep't of Physiology, N. J. Med. Sch, Newark, N.J. 07103.

Posttranslational arginylation of proteins has been demonstrated in fractions of high speed supernatants of sciatic nerves but not in intact tissue. In the present experiments we have utilized the finding that Arg is added at the N-terminus of the target protein to demonstrate posttranslational modification of endogenous proteins in sciatic nerve explants. Sciatic nerves were crushed *in vivo* and 2 hrs later segments of nerve, including the site of the crush, were removed and incubated in media containing ³H-Arg. Incorporation of ³H-Arg into proteins was analyzed by acid precipitation and the presence of label at the N-terminus by micro Edman degradation. 20% of the protein bound ³H-Arg was released by the Edman reaction indicating that it was added posttranslationally rather than through protein synthesis. Nerves not crushed prior to explant and incubation showed no evidence of N-terminal labeling. These results support previous *in vitro* evidence for increases in N-terminal arginylation of proteins following injury to rat peripheral nerves. (Supported by the Foundation of UMDNJ)

APOLIPOPROTEIN-E ACCUMULATION IN THE RAT LIMBIC SYSTEM FOLLOWING SYSTEMIC ADMINISTRATION OF KAINIC ACID. G.E. Handelman and D.H. Lowenstein. Gladstone Foundation Labs. and Dept. of Neurology, Univ. of California, San Francisco, CA 94140.

Apolipoprotein (apo)-E, a lipid transport protein, is synthesized by astrocytes in the rat brain. One of the responses of astrocytes to brain injury is the increased secretion of factors which may aid processes of tissue repair. We therefore examined the distribution of apo-E in the brain by immunocytochemistry at various times after systemic administration of kainic acid (KA; 10 mg/kg). We also examined the production of apo-E mRNA in the hippocampus by Northern blots. The KA produced extensive tissue damage in the hippocampus, amygdala, and entorhinal cortex. Within 7 days, astrocytes in these regions demonstrated increased apo-E immunoreactivity and there was considerable extracellular accumulation of apo-E. Apo-E positive macrophages were also present within the meninges and the third ventricle. After 28 days, all three brain regions still contained large amounts of extracellular apo-E, although the immunoreactivity within the astrocytes was decreased. At this time, apo-E-positive macrophages were present in the neuropil of the amygdala and entorhinal cortex, but not the hippocampus. The Northern blots indicated that apo-E mRNA increased in the hippocampus around 14 days after KA treatment, although there was considerable variability among rats in the timing of the increase. In summary, apo-E accumulates in injured portions of the limbic system following KA treatment. At first, apo-E is probably contributed by astrocytes. Later, apo-E may also be derived from invading macrophages. The production of apo-E mRNA does not appear to be associated with the immediate effects of KA, but instead may be related to the repair or remodeling of nervous tissue.

24.22

A LOW MOLECULAR WEIGHT FACTOR CAN INHIBIT THE ARGINYLYATION OF tRNA AND THE POSTTRANSLATIONAL ARGINYLYATION OF PROTEINS IN RAT BRAIN. M. Yu and N. Ingoglia. Dep't of Physiology, New Jersey Medical School, Newark, NJ 07103.

The tRNA mediated N-end arginylation of proteins can only be demonstrated *in vitro* if low molecular weight molecules are removed by gel filtration chromatography. We have proposed that an endogenous peptide is responsible for the regulation of these reactions. In the present experiments we have isolated and attempted to purify this peptide. Rat brains were extracted with acidic methanol and the 20k xg supernatant was used as the source of the putative regulator. Fractionation on a Sephadex G-50 column demonstrated inhibitory activity (I.A.) eluting at < 4kDa. When purified by Sep-Pak C18 cartridges (Waters, I.A.) was found in a 30% but not an 80% acetonitrile/TFA fraction and eluted at approx. 34 ml when purified further by reverse phase HPLC. This fraction was able to block the arginylation of rabbit liver tRNA suggesting that the regulator prevents protein arginylation by inhibiting the charging of tRNA. We suggest that this factor is an endogenous regulator of the arginylation of RNA and proteins.

TRANSPLANTATION: CORTEX

25.1

SURVIVAL AND DIFFERENTIATION OF FETAL RAT CORTICAL CELL SUSPENSION AFTER TRANSPLANTATION INTO AN ADULT RAT CEREBRAL CORTICAL LESION CAVITY. B.W. Chopko, R.L. Berry, T.J. Voneida. Dept. of Neurobiology, N.E. Ohio Univ. College of Medicine, Rootstown, Ohio 44272, U.S.A.

The anatomical characteristics of a fetal cell suspension graft transplanted into an adult cerebral cortical lesion cavity are largely unknown. A suspension of frontal cerebral cortical tissue, obtained from rats on embryonic day 15, was prepared by sequential trypsinization and centrifugation. Immediately before transplantation, a sample of suspension was used to establish cell cultures. Cortical suspensions were grafted into 3 adult rat hosts; the transplantation site consisted of a transcortical cavity in the rostral motor cortex, which was produced by aspiration 45 minutes before grafting. After survival periods of 2, 12 and 12 weeks, grafts were studied using Nissl, myelin and axonal stains. All grafts were viable and attached to the lesion cavity, but only 1 completely filled the cavity. Grafts consisted of a dense, nonlamina mixture of neuronal, glial, inflammatory and spindle cells. Axons were short and sparse at 2 weeks. At 12 weeks, axons were abundant and arranged into a dense tangle of single axons and fascicles; focally, graft axons entered the host brain for distances of greater than 500 μ m. Myelin was present only at 12 weeks. Cultures contained cells arranged in both monolayers and multicellular spherical aggregates; filamentous cellular processes were also present. Suspension grafts of fetal cortical tissue survived and differentiated when transplanted into cerebral cortical lesion cavities. Graft success in this paradigm is further testimony to the resilience and plasticity of fetal brain tissue.

25.2

MIGRATION OF TRANSPLANTED EMBRYONIC NEOCORTICAL NEURONS INTO SELECTIVELY NEURON-DEFICIENT CORTEX OF EARLY POSTNATAL MICE. J.D. Macklis. Dept. of Neurology, Prog. in Neuroscience, Harvard Medical School, Children's Hospital, Boston, MA, 02115

The central purpose of this work is the study of neuronal migration and cellular integration following transplantation of immature neocortex into a "custom-generated" pyramidal neuron-deficient host, as both a developmental and transplantation model. Unfocused, noninvasive laser illumination, at long wavelengths that penetrate through nervous system tissue without major absorption, can cause extremely selective, noninvasive, cell-specific damage to desired subpopulations of neurons, targeted by retrograde incorporation of latex nanospheres containing the cytolytic, photoactive chromophore chlorin *a*.

Postnatal day 1-5 mouse pups (n=54) served as hosts for transplants into control (n=49) and experimental lesioned cortices (n=5). Lesions were effected to pups following retrograde neuronal labeling *in vivo* with photoactive nanospheres. Embryonic day 17 neurons were labeled *in vitro* with nanoparticles that allowed identification of host and graft cells at both the fluorescence and EM levels. After survival times of 6 days to 12 weeks, serial sections were cut and processed for nanosphere intracellular fluorescence and routine histology; 6 were studied by EM. Camera lucida drawings and higher magnification fluorescence microscopy were used to identify and assess donor neuron migration and cellular integration; EM was used to confirm identities of migrated neurons. Neurons placed near host zones of neuron deficiency within lamina II/III migrated to and integrated within them; control grafts revealed only local spread without laminar preference. Donor neurons within the lesioned zones largely assumed a pyramidal phenotype. These results suggest that transplanted neocortex may seek to restore normal cytoarchitecture, using developmentally age-specific cues to guide migration and integration. Supported by HD00859, Alzheimer's Association, and Hearst Fund.

HETEROTOPIC AND HOMOTOPIC FETAL CORTICAL TRANSPLANTS TO THE DEVELOPING ROSTRAL CORTEX OF RATS PRODUCE DIFFERENT BEHAVIORAL EFFECTS. T. M. Barth and B. B. Stanfield, Dept. of Psychology, Texas Christian University, Fort Worth, Texas 76129 and Lab. Neurophysiol., NIMH, NIH Animal Center, Poolesville, MD 20837.

Fetal occipital cortical neurons transplanted to the rostral cortex of newborn rat pups (i.e. heterotopic transplants), behave like the host neurons of the recipient cortical region in terms of their eventual projections. Specifically, the transplanted occipital cortical neurons maintain a corticospinal projection even though this projection is eliminated when these neurons develop in their original occipital locale. As expected, homotopic transplants (i.e. fetal rostral transplant to rostral cortex) also maintain a corticospinal projection. These anatomical findings suggest that the behavioral effects of homotopic and heterotopic transplants should be similar. The present experiment was designed to compare the functional capacity of heterotopic and homotopic transplants.

Newborn (P0) rats received small unilateral lesions of the rostral cortex and pieces of 5-bromo-2'-deoxyuridine labeled fetal cortex (E17) from either the rostral or occipital region was placed in the cavity. The rats were tested for somatosensory asymmetries (as measured by bilateral-tactile stimulation tests) and forelimb placing on P45. Previous behavioral experiments have shown that rats with large unilateral neonatal cortical lesions exhibit an enduring ipsilateral somatosensory asymmetry, but no impairments in forelimb placing. The principal finding of the present experiment is that rats with heterotopic transplants showed a marked somatosensory asymmetry and contralateral impairments on forelimb placing tasks while rats with homotopic transplants failed to show significant impairments on any of the behavioral tests used. Bromodeoxyuridine-immunohistochemistry was utilized for positive identification of the transplants in both groups. These data suggest that while homotopic fetal cortical transplants may help ameliorate behavioral deficits following neonatal lesions of the rostral cortex, heterotopic transplants do not, and may indeed exacerbate the deficits, despite their seemingly appropriate projections.

25.5

FETAL NEOCORTICAL TRANSPLANT PROJECTIONS DEMONSTRATED BY PHA-L AXONAL TRACING. J.C. Sørensen*, B. Klausen*, J. Zimmer, and A.J. Castro. Inst. of Neurobiology, Aarhus Univ., DK-8000 Aarhus C, Denmark and Dept. of Cell Biol., Neurobiol. and Anatomy, Loyola Sch. Med., Maywood, IL 60153.

Fetal neocortical grafts placed into newborn recipients receive extensive inputs from the host brain. In the present study, PHA-L was used to examine graft efferents from fetal (E14-16) neocortical transplants placed homotopically into frontal cortical lesions made immediately prior to grafting in newborn rats. At maturity, PHA-L was injected into the grafts and the animals were sacrificed two weeks later.

In four animals showing injections confined to the transplants, efferent projections were traced into the cortex adjacent to the graft, and other fibers traversed the subcortical white matter to the ipsilateral parietal cortex or traversed the callosum to the contralateral forelimb area. Descending fibers projected through the striatum and internal capsule giving terminal branches to the caudate-putamen, the thalamic ventrobasal and posterior nuclei, claustrum and pontine gray. In one animal, fibers were seen approaching the red nucleus. These projections resembled normal connectivity.

BIOCHEMICAL AND BEHAVIORAL ANALYSIS OF NEUROTOXIN LESIONS AND MONOAMINERGIC NEURAL TRANSPLANTS IN THE RAT FRONTAL NEOCORTEX C.E. Sortwell and J. Sagen. Dept. Anat. and Cell Biol., Univ. IL at Chicago, Chicago, IL 60612.

Monoaminergic neural transplants into the rat frontal cortex have been demonstrated in our laboratory to reduce immobility in the Forced Swimming Test (FST), an animal model where reduced immobility time is regarded to reflect increased antidepressant activity. Our past findings suggest that neural transplants may provide a long-term source of monoamines that may correct the central imbalance of noradrenergic and serotonergic function believed to cause depression. This study investigates the effect of injections of monoaminergic neurotoxins to the frontal neocortex of rats on FST immobility time and the ability of monoaminergic neural grafts to reverse this depletion. Either serotonergic neurotoxin 5,6-DHT, adrenergic neurotoxin 6-OHDA or an equal volume of saline vehicle were stereotaxically injected into the frontal neocortex of rats. One week after injecting, 5,6-DHT lesions were found to produce a marked increase in immobility times when compared to saline injected and naive controls. In contrast, 6-OHDA lesions produced a reduction in immobility time when compared to saline lesioned and naive controls. Most 5,6-DHT lesioned rats were then transplanted with either serotonin (5-HT) containing pineal gland tissue or equal volumes of sciatic nerve tissue to the lesion site. Six weeks following transplantation FST immobility times were assessed once again. While all three 5,6-DHT lesioned groups displayed reduced immobility times, the pineal grafted group displayed significantly further reduced immobility times when compared to the 5,6-DHT sciatic group and 5,6-DHT nontransplanted group. Biochemical analysis using HPLC revealed that 5,6-DHT lesioned frontal neocortex contained lower levels of 5-HT than vehicle injected and control frontal cortex. Pineal grafted neocortex contained higher levels of 5-HT than sciatic nerve grafted or nongrafted controls. There were decreased levels of both norepinephrine and dopamine in the 6-OHDA lesioned frontal neocortex. These results provide further evidence to suggest an important role for neocortical 5-HT transmission in antidepressant activity and that transplants of 5-HT containing tissue may eliminate biochemical deficits in depression.

NOREPINEPHRINE (NE) AND DOPAMINE (DA) INNERVATION OF EMBRYONIC CORTEX GRAFTS IN ADULT RATS WITH CATECHOLAMINE (CA) LESIONS OF THE MEDIAL FOREBRAIN BUNDLE (MFB). A. Dunn-Meynell & B.E. Levin, Neurol.Svc., DVA Med. Ctr., E.Orange, NJ 07019, Depart. Neurosci., NJ Med.Sch., Newark NJ 07103.

The study was performed to determine the nature of CA innervation of grafts placed in the adult rat mfb. 6-hydroxydopamine was injected into the mfb to lesion CA fibers followed after 2 wk by E15-16 frontal cortex grafts, or sham grafts, to the lesion site. NE and DA innervation were distinguished using dopamine- β -hydroxylase and tyrosine hydroxylase immunoreactivity (DBH-IR and TH-IR) or high affinity ³H desmethylimipramine (DMI) or mazindol uptake. Lesions produced massive depletion of these parameters in distal host structures, regardless of graft presence. However, DA fibers grew into grafts as reflected by patches of high mazindol binding (up to 803 fM/mg) and TH-IR. NE graft innervation was much more sparse with few DBH-IR fibers and no significant DMI binding. Conversely, in additional rats with grafts and no mfb lesions DBH-IR fiber ingrowth was much more extensive. Thus, following CA lesions of the mfb which, in the absence of grafts, allow little or no regenerative sprouting, grafts promote mainly DA fiber sprouting. Supported by DVA Med. Res. Svc. and Foundation of UMDNJ.

25.6

PHARMACOLOGIC SPECIFICITY OF REDUCED IMMOBILITY IN A RODENT DEPRESSION MODEL BY MONOAMINERGIC NEURAL TRANSPLANTS D. Dougherty, C.E. Sortwell, and J. Sagen. Dept. Anat. and Cell Biol., Univ. IL at Chicago, Chicago, IL 60612.

Previous findings in our laboratory have indicated that the transplantation of monoaminergic tissue into the frontal neocortex of rats can reduce behavioral deficits in rodent depression models. The purpose of the present study was to pharmacologically characterize the effects of these transplants using specific antagonists. After transplantation of serotonin (5-HT) containing pineal gland tissue, norepinephrine (NE) containing adrenal medullary tissue, a combination of both pineal and adrenal medullary tissue, or sciatic nerve (control) into the rat frontal neocortex, the animals' behavior was assessed using the behavioral despair model. The behavioral despair model measures immobility time while swimming in a clear cylinder as a correlate to antidepressant activity. As in previous studies, monoaminergic transplants but not control transplants produced marked decreases in immobility time. After establishing these baselines, the transplants were assessed pharmacologically with norepinephrine antagonists phentolamine (α -adrenergic) and propranolol (β -adrenergic) and serotonin antagonists metergoline (5-HT₁) and pirlperone (5-HT₂). If the reduction in behavioral deficits by the transplants is due to the release of monoamines, it should be blocked by specific monoaminergic antagonists. Both serotonergic antagonists blocked the decreased immobility produced by the pineal transplants and the pineal-adrenal cogsrafts, but had no effect on either adrenal or control transplanted animals. Interestingly, α - and β -adrenergic antagonists not only blocked, but overcompensated for the adrenal transplants, producing a large increase in immobility and blocked decreased immobility produced in cogsrafted animals. The α - and β -antagonists had no effect on pineal or control transplanted animals. Immunocytochemical analysis of the transplants revealed that both the adrenal medullary and pineal transplants survived well and continued to produce high levels of monoamines. The results of this study suggest that the transplantation of monoaminergic tissue into the CNS may reduce depressive symptoms by increasing CNS levels of NE or 5-HT.

Expression of amyloid in cortical transplants of trisomy 16 mouse. C.F. Hohmann, G.T. Capone, A.M. Diggs and J.T. Coyle. Dept. of Psychiatry, Johns Hopkins University and The Kennedy Institute, Baltimore, Maryland.

Trisomy of murine chromosome 16 [Ts16] shares phenotypic and genotypic similarities with human trisomy 21, Down Syndrome [DS], thus providing a suitable model to study the effects of triplication of these genes on brain development. Since Ts16 does not survive to birth, we devised a transplantation paradigm to examine cortical development. We here investigate the expression of APP protein and mRNA in grafts of late embryonic Ts16 and euploid litter mate cortex transplanted to the neocortex of neonatal euploid hosts.

Immunocytochemistry was performed using an antiserum (F5) to amino acid 687-695 of the APP molecule and *in situ* hybridization using a RNA probe (AB1) coding for the carboxyterminus and A4 region (both courtesy of Dr. R. L. Neve). Compared to euploid (N=4), immunoreactivity [IR] to APP was elevated diffusely in the neuropil of Ts16 grafts (N=4) and the surrounding host tissue at 2 weeks following transplantation. Furthermore, IR was seen in neurons and other, to be identified, cellular elements, predominantly in the border regions between host and transplants. Such stained cells were not found as frequently in euploid grafts and the immediate host environment. Transplants of both euploid (N=4) and Ts16 (N=4) tissue, 4-6 weeks following grafting, did not display similar elevations of diffuse or cell associated APP IR. *In situ* hybridization displayed a pattern similar to IR. Experiments are currently underway to study in greater detail the time course of APP expression between 1 week and 6 month post-grafting. In agreement with previous studies on GAP43 and SOM, these data indicate that host and graft tissue interact with each other in the regulation of the expression of genes located on chromosome 16.

25.9

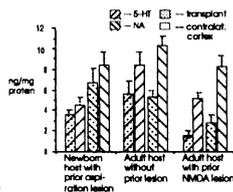

INTRACEREBRAL NEOCORTICAL TRANSPLANTS CONTAIN MEASURABLE AMOUNTS OF NEUROTRANSMITTERS NOREPINEPHRINE AND SEROTONIN. M.K. Schulz, J.A. McNulty, T.P. Hogan*, J. Zimmer and A.J. Castro. Dept. of Cell Biol., Neurobiol. and Anatomy, Loyola Sch. Med., Maywood, IL 60153 and Instit. of Anatomy, Aarhus Univ., DK-8000 Aarhus C, Denmark.

Fetal neocortical grafts placed homotopically into newborn recipients receive extensive input from the host brain including afferents from the locus coeruleus and midline raphe. To measure these latter inputs, the present study examined noradrenaline (NA) and serotonin (5HT) content in fetal (E14-15) neocortical grafts placed into cortical aspiration cavities made immediately before grafting in newborn rats or into NMDA-induced cortical lesions made one week earlier in adult rats. Unablated adults were also used.

At three months postgrafting and using high performance liquid chromatography with electrochemical detection, tissue levels of NA and 5-HT were measured in dissected samples of the transplants and the contralateral cortex.

As indicated in the accompanying figure, NA and 5HT levels reached control, i.e., contralateral cortex, levels in newborn recipients whereas grafts placed into adult hosts were significantly below control values.

25.10

FETAL NEOCORTICAL TRANSPLANTS INTO FOCAL ISCHEMIC LESIONS IN ADULT RATS. G.L. Tillotson, M.K. Schulz, T.P. Hogan*, P.L. Shaw* and A.J. Castro. Dept. of Neurology and Dept. of Cell Biol., Neurobiol. and Anatomy, Loyola Sch. of Med., Maywood, IL 60153 USA.

The present study was undertaken to investigate the viability of embryonic cortical tissue transplanted into adult ischemic cortical lesions.

Adult rats received focal ischemic lesions by permanent occlusion of the left middle cerebral artery at the level of the rhinal fissure. Seven days later, rat embryonic neocortical graft tissue (E14-15) was transplanted into the cortical ischemic zone. After a 20 day survival period, animals were sacrificed and brains processed for acetylcholinesterase and routine Nissl stain. Upon histological inspection, ischemic infarctions were localized to the left cerebral cortex, primarily involving the sensorimotor area, with relative sparing of subcortical structures. Surviving transplants were found integrated into host tissue in cortical areas surrounding the infarct as well as deep to the infarct in the striatum. Acetylcholinesterase positive fibers were found within the transplant; although less dense than in the surrounding host tissue, these fibers appeared to be derived from the host brain.

(Supported by NIH Grant 13230).

25.11

SUPERIOR CERVICAL GANGLION REGENERATING AXONS BRIDGED BY AUTOLOGOUS NERVE GRAFTS INNERVATE DISCRETE BRAIN REGIONS. E. Fernandez, R. Pallini*, L. Lauretti*, V. Bozzini* and E. Dell'Anna* (#). Institutes of Neurosurgery and Neurology (#), Catholic University, Rome, Italy.

Transplantation studies in animal models have shown that intracerebral superior cervical ganglion (SCG) grafts may survive and sprout catecholaminergic (CA) fibers. However, the number of surviving CA cells rapidly decreases after grafting. The present work explored the possibility to innervate selected brain areas by SCG derived axons circumventing the ganglion cell loss seen after the direct SCG grafting procedure. In adult rats the SCG was microsurgically exposed. The post-ganglionic branch was cut and a segment of autologous sciatic nerve 35 mm long was grafted between the SCG and a surgically created cortical cavity in the parietal region. After 15-20 weeks of survival, axonal regeneration was evaluated by horseradish peroxidase (Sigma VI, 8-10% solution) injected into the graft and tyrosine hydroxylase immunocytochemistry. SCG derived axons do regenerate into the graft, penetrate the glial scar, and extend into the cortex.

DIFFERENTIAL EXPRESSION OF $\beta A4$ PRECURSOR PROTEIN mRNA TRANSCRIPTS DURING HIPPOCAMPAL NEURON DEVELOPMENT *IN VITRO*. M.J. Strong and D.M. Jakowec*. Dept. of Clin. Neurological Sciences, UWO, London, Ont., Canada, N6A 5A5.

We have confirmed and extended our previous qualitative observations of a developmentally-specific pattern of $\beta A4$ precursor protein (APP) mRNA hybridization during neuronal maturation *in vitro* (Exp Neurol 1990;109:171). using synthetic junctional oligonucleotide probes (Kitaguchi et al., Nature 1988;331:530). Hippocampal neurons from fetal New Zealand white rabbits were grown in chemically-defined medium and at intervals of 6, 12, 18, 24 and 30 days postplating, the total cellular RNA isolated using guanidine isothiocyanate isolation on CsCl gradients. Prior to hybridization, RNA samples were normalized by slot-blot analysis with a [32 P]-labelled TTP probe synthesized on poly A⁺ oligo dt₁₂₋₁₈ with M-MLV reverse transcriptase. The oligonucleotide probes were 3'-labelled with terminal deoxynucleotide transferase and [32 P]-dCTP (10 μ Ci/ μ mole) and the hybridization carried out at 52°C (42°C for APP₇₇₀ probe) in 5x SCC, 1x Denhardt's, 1% SDS, 100 μ g/ml ssDNA on Nytran membrane following RNA separation on 1.0% formaldehyde-agarose gels. Hybridization patterns to a β -tubulin oligoprobe (Dupont) and a cDNA probe encoding the NF-L protein served as controls. The following patterns of APP mRNA transcript expression were observed: peak levels of APP₆₉₅ mRNA at d18-24 and thereafter declining; progressively increasing levels of APP₇₅₁ mRNA to d30; peak levels of APP₇₇₀ mRNA at d18-24 with a marked decline thereafter. Current experiments are attempting to determine if an intrinsic neuronal signal linked to the acquisition of synaptic polarity mediates this temporal profile of APP mRNA transcript expression.

26.2

ISOLATION AND CHARACTERIZATION OF THE NEURONAL PHOSPHOPROTEINS B-50/GAP-43 AND BICKS/NEUROGRANIN FROM HUMAN BRAIN. M. R. Martzen¹, A. Nagy², P. D. Coleman¹ and H. Zwierni². Dept. of Neurobiol. and Anatomy¹, Univ. of Rochester Med. Center, Rochester, NY 14642 and Depts. of Med. Physiol. and Med. Biochem.², Univ. of Calgary, Calgary, Alberta, Canada T2N 4N1.

The neuronal phosphoproteins B-50 and BICKS share a highly conserved amino acid sequence which includes a PKC phosphorylation site and calmodulin binding domain. The B-50 molecule has at least one proteolysis product (B-60) whose cleavage is inhibited by thiol protease inhibitors. B-50 has been associated with neuronal development, axonal regeneration, polyphosphoinositol metabolism and synaptic plasticity. The function of BICKS, immunohistologically localized to perikarya and dendrites, is less clear but may ultimately share some functional homology with B-50 through their common domains. In normally aging brain neurons mount a plastic compensatory response resulting in a net increase in dendritic extent. This response may be defective in certain pathological states. Neuronal proteins associated with plasticity, therefore, may provide some insight into these events. B-50 and BICKS were isolated from normal and Alzheimer's disease post-mortem human brains and separated into membrane and cytoplasmic fractions, followed by C18 reverse phase HPLC in TFA and CH₃CN. Isolated proteins from superior temporal gyrus, visual cortex and cerebral spinal fluid were then analyzed by gel scanning, Western blotting and analytical C4 reverse phase HPLC. B-50 and BICKS were found present in both cytoplasmic and membrane fractions. In addition, a series of immunoreactive bands were found concentrated in the cytoplasmic fractions with apparent molecular weights ranging from 43-15 kDa. A similar pattern was not seen with BICKS. These results suggest a series of B-50 immunoreactive molecules potentially resulting from proteolytic processing of native B-50 in its PEST regions. Implications of these results and their correlation with aging and Alzheimer's disease will be discussed. Supported by grants AG 01121 and by a LEAD award (PDC) and by the MRC of Canada (HZ).

CALCIUM BINDING PROTEINS IN THE SEPTO-HIPPOCAMPAL SYSTEM OF YOUNG AND AGED RATS. M.L. Smith and R.M. Booze
Dept Pharmacology, U.K. Medical Center, Lexington, KY 40536

Altered calcium homeostasis has been proposed as a mechanism of neuronal cell death in aging and Alzheimer's disease. In this study we examined the localization of calcium binding proteins within the septo-hippocampal system, a brain region affected by age-related cell loss and atrophy. We investigated 1) the distribution of calmodulin and calbindin D_{28k} within the septal nucleus and the hippocampus and 2) the age-related differences in calmodulin and calbindin D_{28k} immunoreactivity.

Pairs of young (4-5 month) and aged (24-25 month) Fischer-344 male rats were perfused and the brains sectioned on a Vibratome (40 μ m). Serial sections from each pair were collected through the septal nucleus and dorsal hippocampal formation. Adjacent sections were processed simultaneously for calmodulin (1:1000; Chemicon), calbindin D_{28k} (1:500; Sigma), ChAT (1:1000; Chemicon) and GAD (1:300; Chemicon) using standard ABC immunocytochemical techniques.

Both young and aged rats showed extensive calmodulin immunoreactivity which was not confined to a specific region or cell population. No clear age-related differences were detected in the intensity of calmodulin binding. Calbindin D_{28k} immunoreactivity was highly localized in the neocortex, striatum, septal nucleus and hippocampus. Within the hippocampus, CA1 and CA2 pyramidal cells were immunoreactive. Lower reactivity was present in dentate gyrus granule cells. No calbindin D_{28k} was observed in the CA3 pyramidal cell layer. There was an age-related decrease in calbindin D_{28k} staining intensity within the hippocampus; however, there were no detectable decreases in the cortical and striatal areas. Within the septum the calbindin D_{28k} was localized to the medial septal nucleus, as well as in the lateral septum. The localization of calbindin D_{28k} within the septum and CA1/CA2 pyramidal cells suggests that calbindin D_{28k} may be an important factor in calcium-dependent mechanisms of age-related cell loss.

AGE-RELATED CHANGES IN ASTROCYTE mRNAs IN FIVE REGIONS OF MOUSE BRAIN. J.R. Goss & D.G. Morgan, Gerontology Center & Dept. of Biol. Sci., Univ. of Southern California; Los Angeles, CA 90089-0191.

In previous studies we found a 40-80% increase in the message level for glial fibrillary acidic protein (GFAP) in aged mouse cortex, cerebellum, and hippocampus. In these same studies we found no change in glutamine synthetase (GS), another astrocyte message, in the cortex (Goss, Finch and Morgan; *Neurobiol. Aging* 12:165-170). In this study we have expanded on these findings by examining GFAP, GS, and three other astrocyte messages: sulfated glycoprotein-2 (SGP-2), apolipoprotein-E (APO-E), and amyloid precursor protein (APP; also found in neurons), in five brain regions from four ages of mice.

Male C57BL/6Nia mice of ages 4, 12, 20, and 28 months were used. Brains were removed from six animals per age group and dissected into five regions: cortex; cerebellum; brainstem (medulla, pons, and midbrain); a region containing hippocampus, and diencephalon; and a region containing basal ganglia and basal forebrain. Northern blot hybridization was performed using 3 μ g of total RNA per lane and single strand [32 P]labelled cRNA probes.

Results confirm a 20-100% increase in GFAP RNA between 4 and 28 months over the five brain regions. All other RNA markers changed less than 20% except for a 60% increase in the cerebellum for GS, a 45% increase in the cerebellum for APO-E, and a 30% decrease for APP in the cortex. These results suggest that the increase in GFAP RNA with age may be specific for GFAP, and not due to general astrocyte hypertrophy or hyperplasia in most areas of the brain; although the increases in APO-E and GS found in the cerebellum may indicate some increase in astrocyte size or number. S-100 RNA is presently being investigated with these same samples. Supported by AG-07892, AG-00093, AHA-GIA 891079, and AHA-EIA 890173.

SENESCENCE OF VIRALLY STIMULATED NEURORETINAL CELLS INVOLVES ALTERED EXPRESSION OF c-Fos AND v-Src ONCOPROTEINS G.M. Seigel and M.F.D. Notter, Department of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642.

Embryonic day 7 chick neuroretinal cell cultures were mitotically stimulated *in vitro* with the transforming v-Src oncogene of Rous Sarcoma virus. The result was a transformed cell population (LA29NR) with an extended mitotic lifespan in culture. Interestingly, over the course of 5 months in culture, these cells reached a state of senescence which we have characterized with regard to cell growth, morphology, as well as c-Fos and v-Src protein expression.

At one month in culture, "early" LA29 NR cells were 85% to 95% mitotic, as shown by tritiated thymidine incorporation. These "early" cells expressed significant levels of c-Fos and v-Src oncogene proteins as seen by Western blot analysis. As LA29NR cells aged in culture, a precipitous decline in mitotic index was accompanied by unusual morphological changes and decreases in oncogene expression. By 5 months in culture, "late" LA29NR cells exhibited a three-fold decrease in v-Src expression and a six-fold decrease in c-Fos expression compared with their "early" counterparts. In addition, the level of tyrosine phosphorylation of a 41 kilodalton phosphoprotein was significantly decreased by 5 months in culture. Therefore, specific modulations in gene expression were associated with senescence of LA29NR cells and their ability to overcome the mitogenic effects of Rous Sarcoma virus. These studies may prove useful in the characterization of cellular events accompanying senescence, as well as tumor regression. This work was supported, in part, by training grant T32AG00107 (G.M.S.) and EY 05262 from the National Eye Institute.

INCREASED GFAP EXPRESSION IN THE AGED RAT BRAIN DOES NOT RESULT FROM INCREASED ASTROCYTE DENSITY. M.N. Gordon and D.G. Morgan, Division of Neurogerontology, Univ. of Southern California, Los Angeles, CA 90089-0191.

Brain sections from Wistar or Fisher 344/Brown-Norway F1 hybrids were stained for GFAP or S100 using a direct coupling technique in which the secondary antibody is conjugated to peroxidase. We previously demonstrated that such sections may be analyzed by image analysis to yield quantitative measurements of area occupied by reaction product (Gordon et al, Soc. for Neuroscience Abst. 16:347, 1990). Rats from 5 to 28 mo. of age were examined. Area occupied by GFAP or S100 reaction product was measured in two brain regions, the caudate nucleus containing a low astrocyte density, and the hilus of the dentate gyrus containing a high astrocyte density. Sections stained for S100 were also used to measure astrocyte density (cells / mm²) and the cross-sectional area of S100 positive cells containing visible nuclei.

Astrocytes stained for GFAP possess reaction product restricted to cellular processes; in contrast, S100 staining is largely confined to the cell soma. Area occupied by GFAP reaction product increased with age by 100% in caudate nucleus and 40% in the hilus. With aging, S100 staining revealed no increase in the area occupied by reaction product, astrocyte cell soma area or astrocyte density (cells/mm²). Similar results were observed in both brain regions of both rat strains. These findings demonstrate that the age-related increase in GFAP expression is specific for this protein, and does not result from increased astrocyte cell density accompanying aging. Technical assistance was provided by D.G. Berg, X. Ou, C.M. Flores and C.S. Young.

SPECTRIN BREAKDOWN PRODUCT AND CHANGES IN N-CAM INCREASE WITH AGE IN SPECIFIC BRAIN AREAS. L.T. Ha*, B.A. Bahr, P. Vanderklish*, M.T. Tin*, B. Murray* & G. Lynch, Ctr. Neurobio. Learning/Memory and Dept. Devmntl. & Cell Biol., Univ. of Calif., Irvine, CA 92717

It has been suggested that many neurodegenerative conditions are, at least in part, a consequence of the normal aging process. It is of interest, therefore, to ask whether components of cytoskeletal and adhesive structures which contribute to neuronal shapes and properties are modified as part of normal aging. The membrane cytoskeletal protein spectrin is present throughout neurons and is a preferred substrate for the calcium dependent protease calpain. Proteolysis of spectrin produces characteristic breakdown products (BDPs of 155 and 150 kDa) together which are a biochemical marker that correlates with the onset of many instances of brain pathology. This study indicates that a highly significant linear correlation (r) exists between age (3 to 30 months) and the level of spectrin BDPs (5 to 16% of the anti-spectrin immunoreactivity) in the telencephalon (slope= 0.29, $r = 0.91$, $p < 0.01$) but not in the hindbrain (slope= -0.10, $r = 0.53$, $p > 0.1$) of Balb/c mice. BDPs in the mesencephalon also exhibited a linear increase across life-span, but was weakly correlated with age (slope= 0.12, $r = 0.76$, $p > 0.05$). These data suggest that the spectrin breakdown process associated with pathogenesis increases with age in some but not all brain regions. Second, N-CAM adhesion molecules whose presence in brain membranes has recently been shown to be sensitive to calpain (Sheppard, Wu, Bahr, Lynch, *Synapse* 1991, in press) were tested across mouse age. A highly significant linear correlation between age and percent loss of immunoreactivity toward NCAM-140 was found in the mesencephalon (slope= 2.1, $r = 0.90$, $p < 0.01$) but not in other brain areas. NCAM-180, however, was unchanged across life-span in all brain areas tested even though it was similarly concentrated as NCAM-140 in synaptic plasma membranes vs homogenates in the mesencephalon as well as the telencephalon. Note, the N-CAMs in hind brain material did not exhibit such localization. This suggests that normal aging involves the loss of distinct adhesion molecules from specific brain areas. (Supported by NIA grant #AG00538 and the Pew Foundation.)

26.8

LOSS OF MUSCARINIC RESPONSIVENESS IN SENESCENCE MAY BE THE RESULT OF DECREASED MEMBRANE FLUIDITY. J.A. Joseph, K. Yamagami, and G.S. Roth*, Gerontology Res. Ctr./NIA, Baltimore, MD 21224.

Previous research has indicated that reductions in muscarinic (m) agonist enhancement of K⁺-evoked dopamine release (K⁺ERDA) and decreased IP₃ release upon m receptor (mAChR) agonist stimulation are partially the result of deficits in signal transduction (ST). The present experiments were carried out in order to test the hypothesis that these putative ST deficits may occur as a result of alterations in the ligand-mAChR-G protein complex produced by age-related decreases in membrane fluidity. Oxotremorine (oxo) enhancement of K⁺ERDA was examined in perfused striatal slices from mature (6 mo) and old (24 mo) Wistar rats incubated (30 min, 37° C) with S-adenosyl-L-methionine (SAM, 0, 0.2, 0.5, 1.0 mM) in a modified Krebs medium containing 2.5 mM KCl. Tissue was then aliquoted into a perfusion apparatus and washed (10 min) with the low KCl medium, followed by a switch to a hi KCl (30 mM) medium containing 0, 0.1, or 0.5 mM oxo and 5 min samples collected for HPLC analysis. Results indicated that SAM treatment significantly reduced the age deficit in oxo enhancement of K⁺ERDA (e.g. no SAM treatment, 0.5 mM oxo peak DA release diff. from 0.0 mM oxo, Mature 69.22 ± 5.00 Old, 44.71 ± 9.59 p moles/mg protein; t (6) = 3.74; p < 0.02; 0.5 mM SAM treatment Mature 122.73 ± 24.62, Old 126.18 ± 17.11 pmoles/mg protein; t (8) < 1). Direct measurements of fluidity are being carried out, but these preliminary results suggest that loss of m-agonist responsiveness in senescence may be explained partially by decreases in membrane fluidity.

26.9

THE EFFECT OF AGING AND DIETARY RESTRICTION ON INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) BINDING SITES IN THE BRAIN. A. D'Costa, C.R. Breese, and W.E. Sonntag, Department of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27103.

IGF-1 is a peptide hormone which demonstrates mitogenic activity in many tissues and has been reported to show decreased plasma levels with age and in animals that are dietary restricted. This study was undertaken to examine IGF-1 receptor binding sites in the brain and examine the modification of these receptors with aging (7, 17 and 28 months) and dietary restriction. Autoradiography was performed on slide mounted sections, incubated with 125 I-IGF-1, and apposed to Hyperfilm- 3 H. Non-specific binding was estimated by the addition of 2 μ g of IGF-1. Receptor binding was observed in the s. oriens and s. lucidum of CA3 and the dentate gyrus of the hippocampus. Laminar binding was seen in the cortex with high levels of binding in layer VI of the frontal cortex and layer II of the parietal and temporal cortex. Moderate binding was seen in the cerebellum (molecular layer). Quantitative autoradiographic analysis revealed an increase in IGF-1 binding in layer II and VI of the cortex with increasing age ($p < 0.02$). CA3, dentate gyrus, and cerebellum showed no changes in binding with age. Receptor binding assays were performed by incubation of isolated membranes (50 μ g) from dissected cortex, cerebellum, and hippocampus of rats with varying concentrations of cold IGF-1. Scatchard analysis showed no significant changes in K_D values in all the tissues examined. Receptor number increased in the cortex ($p < 0.05$) with age and in response to dietary restriction. B_{max} values for the cerebellum and the hippocampus were not significantly different. These results suggest that changes observed in IGF-1 receptor density with age may have an important role in maintenance of cortical function in the aging animal (supported by NIH grant AG07752 to WES)

26.11

MODULATION OF BRAIN TRANSDUCING MECHANISMS BY L-ACETYL CARNITINE (LAC) IN YOUNG AND AGED RATS. T. Florio, O. Meucci, M. Grimaldi, A. Scorziello, O. Ghirardi, A. Marino, G. Schettini, Dept. Pharmacology, II School of Medicine, University of Naples, and *Inst. for Research on Senescence, Rome ITALY.

In the present study, we evaluated the effect of LAC on frontal cortex adenylate cyclase (AC) activity, inositol phosphate (IP) production and free intrasynaptosomal calcium levels ($[Ca^{++}]_i$), in young and aged rats. Both acute and subchronic treatments with LAC were carried on and we observed that: 1) Acute administration of LAC did not significantly modify basal and stimulated AC, IP production, $[Ca^{++}]_i$; 2) The subchronic treatment with LAC (250 mg/kg, 30 days) potentiated AC activity under carbamylcholine (CCh), norepinephrine (NE) and dopamine (DA)-stimulated conditions, in young as well as in aged animals, whereas it did not affect basal enzyme activity. 3) In synaptosomes from old rat cortex, LAC increased CCh-stimulated inositol phosphate production while in young rats also basal IP production was enhanced. 4) The subchronic administration of LAC neither affected basal $[Ca^{++}]_i$ levels in hippocampal synaptosomes from young and aged rats, nor modified $[Ca^{++}]_i$ rise induced by K^+ -depolarization or maitotoxin.

26.10

AGE RELATED DECREASES IN NEOSTRIAL HIGH AFFINITY [125 I] RECOMBINANT HUMAN NERVE GROWTH FACTOR (NGF) BINDING AND CHOLINE ACETYLTRANSFERASE (ChAT).

R. H. Soriano, M. Dugich-Djordjevic, C. A. Altar, Endocrine Research Department, Genentech, Inc., South San Francisco, CA 94080.

Numerous reports have shown decreases in rat cholinergic neuronal cell number, density, size, biosynthetic capacity and acetylcholine release during aging. We examined aging effects on the high affinity binding of NGF to rat neostriatum using quantitative receptor autoradiography (Altar, C.A. *et al.*, *PNAS* 88, 281, 1991). ChAT activity was measured in the contralateral neostriatum, olfactory tubercle, hippocampus and neocortex from 1-24 month old male Sprague Dawley rats (6 per group) using a radioenzymatic assay.

Saturable neostriatal binding of NGF was decreased in 6, 7, 8, and 12 month compared to 1 and 2 month rats ($p < 0.05$). The B_{max} decreased 42% from 9.52 ± 0.96 fmol/mg in 1 month to 5.54 ± 0.49 fmol/mg in 24 month rats ($p < 0.001$). ChAT activity decreased from 1 to 24 months in the neostriatum, olfactory tubercle and neocortex by 58, 33, and 42%, respectively ($p < 0.05$). ChAT did not change in the hippocampus at any age. This loss of NGF receptor number and reduction in cholinergic activity may be related to the recognized cell loss in these forebrain regions during aging.

26.12

Free Radicals, glutamate and 5-HT after reperfusion in aging gerbil brain.

G. Delbarre, B. Delbarre and F. Calinon*, Faculté de Médecine, 37032, Tours, France.

Levels of neuromediators are low at birth, reach a plateau, then decrease with aging. In gerbil brain, there is no indication of stroke index (SI) and levels of these amines and OH° in aging after ischemia reperfusion insult (IRI). We have determined the SI and the levels of glutamate (Xu, X., *J. Liquid Chromatog.*, 9, 2253, 1986), 5-HT (Rips, R., *Progress in HPLC*, Vol. 2 : 375-94, 1986) and OH° (Floyd R.A., *J. Free Radic. Biol. & Med.*, 2 : 13, 1986) in the gerbil brain (3, 9 and 15 months old) after IRI. Carotid artery was occluded during 60 min; the SI (Delbarre G., *Stroke*, 19 : 26, 1988) was determined 4, 24, 48 and 72 h after release of the clip and for levels determination of amines and OH° , the brain was dissected 30 min after release of the clip (Delbarre G., *Stroke*, 19 : 26, 1988). After IRI, the SI and glutamate, 5-HT and OH° were significantly increased in 9 and 15 months old gerbil compared with 3 months old one. These results demonstrate that after IRI, the SI, glutamate, 5-HT and OH° are more important in old brain gerbils.

	Percentage of increase versus 3 months old		
	OH°	Glutamate	5-HT
9 months	146.37***	216.55***	407.60**
15 months	418.10***	478.05***	487.56*

Unpaired Student t test, $p < 0.05^*$, $p < 0.001^{***}$

REGULATION OF CARBOXYPEPTIDASE E SECRETION AND SYNTHESIS IN CULTURED ASTROCYTES. R. S. Klein, B. Das, L. D. Fricke, Depts. Molecular Pharmacology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Cultured astrocytes have been shown to produce neuropeptides and neuropeptide processing enzymes. In this study, we used the neuropeptide processing enzyme carboxypeptidase E (CPE) as a marker for neuropeptide biosynthesis and to examine the secretory pathway in cultured astrocytes. In pulse/chase and metabolic labeling experiments cultured astrocytes were labeled with 35 S-methionine and CPE was isolated from media and cells using substrate affinity columns. Results from the pulse/chase studies showed that the secretion of labeled CPE from the astrocytes occurred after a 30 minute lag time and was complete by 120 minutes, indicating that all newly synthesized CPE is rapidly secreted. In metabolic labeling experiments, the secretion of CPE protein from cultured astrocytes was increased 2-3 fold by prolonged treatment (3-48 hours) with the phorbol ester 12-O-tetradecanoyl phorbol 13-acetate (TPA). This increase occurred after 3 hours of TPA treatment in hypothalamic and frontal cortical astrocytes, with no further increase upon longer TPA exposure, and after 24 hours of treatment in astrocytes cultured from the striatum and cerebellum. In addition, Northern blot analysis of expression of CPE mRNA by cultured cerebellar astrocytes showed a slight (1.3-fold) increase after 24 hours of exposure to TPA but not after 3 hours of exposure. These results indicate that the neuropeptide secretory pathway in astrocytes does not include a storage step, and that the secretion of neuropeptides and the synthesis of CPE may be regulated through a TPA-inducible second messenger system.

27.2

HYPEROSMOTIC EXPOSURE ALTERS GLUTAMATE TRANSPORT AND GLUTAMINE SYNTHETASE ACTIVITY OF CEREBRAL ASTROCYTES. J. E. Olson, Dept Emerg Med, Wright State Univ, Dayton, OH 45401

The content of glutamine, glutamate, and other amino acids increases in astrocytes following prolonged exposure to hyperosmotic conditions *in vitro* (*J Neurosci Res* 27: 241, 1990). To understand the mechanisms which produce these changes in amino acid content, we measured glutamate transport and the activity of glutamine synthetase (GS) in hyperosmotic-treated and normal astrocyte cultures.

Cells obtained from 2-4 day-old rat pups were grown for 2 weeks in normal medium. Thereafter, the osmolality of the culture medium was increased 50 mOsm at each feeding (3 time/week) by adding NaCl. Astrocytes were used after 4 weeks *in vitro* when the culture medium was 600 mOsm. Transport was determined in intact cells using glutamate concentrations ranging from 10-1000 μ M and osmolalities matched to that of the final culture medium. GS was determined after lysing the cells in a hypoosmotic solution.

GS activity was 4.30 ± 0.44 μ Mole/(mg protein hr) in hyperosmotic-treated astrocytes compared with 3.06 ± 0.49 μ Mole/(mg protein hr) in control cells (N=8, $p < 0.02$). Hyperosmotic treatment decreased the V_{max} for glutamate transport by approximately 50% while K_m was unchanged.

The increased glutamine content of hyperosmotic-treated cells may be due in part to increased GS activity. The increase in glutamate content is not due to an increase in inward glutamate transport. Supported by NINDS (NS23218).

27.3

EICOSANOID-INDUCED INHIBITION OF GLUTAMATE UPTAKE INTO CORTICAL ASTROCYTES. D.M. Vaughn, R.C. Rossmannith* and N.R. Cox*. Scott-Ritchey Research Program, College of Veterinary Medicine, Auburn University, Auburn, AL 36849.

Elevated concentrations of arachidonic acid (AA) metabolites in brain are known to occur in association with trauma, ischemia & enhanced neuroimmune reactivity. We investigated the capabilities of AA, the cyclooxygenase metabolites PGE₂ & carbacyclin-TXA₂, & the lipoxygenase metabolites LTB₄ & LTD₄ to inhibit [¹⁴C]-glutamate uptake into cultured rat cortical astrocytes. All eicosanoids were incubated at 50, 25, 12.5 μM for 90 min prior to a 5 min glutamate uptake. All cpds, except LTD₄, induced a 95-45% dose-dependent inhibition of glutamate uptake with the following rank order of potency PGE₂ > AA > TXA₂ > LTB₄. Both arachidonic acid (20:0) & palmitic acid (16:0) stimulated glutamate uptake into astrocytes by approximately 100% at 50 μM. Therefore, both polyunsaturated lipoxygenase and cyclooxygenase metabolites may contribute to the neurotoxic effects of glutamate by increasing extracellular glutamate concentrations.

27.5

IONOTROPIC GLUTAMATE RECEPTOR mRNA EXPRESSION IN CULTURED RAT BRAIN ASTROCYTES AND RAT OPTIC NERVE. Abbie Jensen* and S.Y. Chiu. Neuroscience Training Program & Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

Northern blot analysis of poly (A)⁺ RNA obtained from cultures of neonatal cortical astrocytes was performed to test for the presence of ionotropic glutamate receptors, GluR1-GluR5. The cultures were ~2 months old, and contained ~ 60% type-1 astrocytes, 30% type-2 astrocytes, as determined by double GFAP and A2B5 antibody labeling of a sister culture, and the remaining percentage consisted of O-2A progenitor cells, oligodendrocytes and meningeal cells. Partial-length probes (~1.4 kb, 5' end through first membrane spanning region) were generated using the random prime method. Prehybridization, hybridization, and washes were done using high stringency conditions. After overnight exposure substantial signals were observed in the GluR1 and GluR2 lanes (3 μg mRNA/lane). Even after several days of exposure no signal was observed in the GluR3, GluR4, and GluR5 lanes. The GluR1 probe recognized a transcript of 5.5 kb; GluR2 probe recognized two major transcripts of 6 kb and 3.8 kb, and a minor transcript of 4.8 kb.

In Situ hybridization of postnatal day 7 rat optic nerve was performed using full length sense and antisense ³⁵S-riboprobes generated from GluR2 cDNA. Prehybridization, hybridization (approximately same probe cpm of sense and antisense added) and stringency conditions were identical for both probes. Slides were dipped in emulsion and exposed for 14 days. Silver grains were counted overlying optic nerve sections in both the sense and antisense cases. The grain density was 4-10 times higher in the antisense hybridized sections as compared to sense.

27.7

Potential second messengers mediating proliferation of rat glial cells in culture. L. H. Fossom and G. H. DeVries, Medical College of VA, Richmond, VA 23298.

In the peripheral nervous system, Schwann cells (SC) proliferate and subsequently differentiate in response to neurons. Although a signal for proliferation apparently resides in the neuronal plasma membrane (since axolemma (AEF) can induce rat SC to divide in cell culture), the identity of the axolemmal mitogen(s) remains unresolved and the associated signal transduction system(s) remains to be elucidated. Although several agents that elevate cAMP levels in cultured SC also stimulate SC to divide (Raff et al., 1978), cAMP levels in rat primary SC are unaffected by 3-9 hr treatment with mitogenic concentrations of AEF (Meador-Woodruff et al., 1984). In the current study we measured protein kinase A (PKA), the unique mediator of cAMP responses in eukaryotes, as an index of cAMP involvement in the interaction of AEF with SC. Transformed SC (TSC)(Tennekoon et al., 1987) were maintained in serum-free defined medium; PKA was measured in cell supernatant as the transfer of ³²P from ATP to histone IIA substrate. PKA in TSC was maximally activated *in vitro* by 1 μM 8-Br-cAMP (EC₅₀=0.1 μM) and maximally inhibited by 10 μM synthetic peptide of the Walsh inhibitor (IC₅₀=0.3 μM). Under control culture conditions approximately 20% of PKA in TSC was activated; 30 min treatment of TSC with AEF did not alter this activity, although treatment with 0.5 mM 8-Br-cAMP completely activated the kinase. This data corroborates the earlier data on cAMP levels suggesting that the axolemmal mitogen does not work directly through cAMP. [Supported by NIH Grants H207110 and NS15408]

27.4

SERUM EFFECTS AND REGIONAL DIFFERENCES IN ASTROCYTIC SEROTONIN AND GLUTAMATE UPTAKE

Kimelberg, H.K., *Goderie, S.K. and *Amundson, R.

Div. Neurosurgery A-60, Albany Medical College, Albany, New York 12208

Na⁺-dependent, fluoxetine-sensitive high-affinity uptake of serotonin and Na⁺-dependent uptake of glutamate were studied in primary astrocyte cultures from 1-day-old rat neocortex. High-affinity serotonin uptake was decreased when cells were grown in horse serum as compared to fetal bovine serum and was almost absent when cells were grown in chemically defined medium. In contrast glutamate uptake was unaffected by the composition of the medium in which the cultures were grown. For cultures prepared from different brain regions grown in fetal bovine serum, Na⁺-dependent [³H] L-glutamate and fluoxetine-sensitive [³H] 5HT uptake varied markedly. For astrocytes the relative order of uptake for [³H] L-glutamate was HP (hippocampus) > CC (cerebral cortex) > BG + DI (basal ganglia + diencephalon) ≥ MS (mesencephalon) ≥ BS (brain stem) > CB (cerebellum) and for [³H] 5HT was MS > CS > HP > BS > CB. For [³H] 5HT this essentially corresponds to the order of binding of the [³H] 5HT specific uptake ligand [³H] citalopram *in situ*. For [³H] glutamate regional variation of the uptake from the different cultures exactly corresponds to the regional uptake by rat brain. Uptake was also analyzed at the single cell level by simultaneous autoradiography (ARG) and GFAP staining and for different morphological, GFAP(+) cells. Flat cells, with or without processes and comprising 65-98% of the cultures, represented most of the uptake. These differences in transmitter uptake by GFAP(+) astrocytes in primary culture which are dependent on the region of origin or morphological type, suggests that such uptake *in vitro* is an expression of differences shown by astrocytes *in situ*. (Supported by grant NS 19491 to H.K.K.)

27.6

GLUTAMATE-INDUCED INCREASE IN ASTROCYTE GLYCOGEN IS MEDIATED BY CELL VOLUME CHANGES. R.S. Dombro*, A.S. Bender, L. Machado*, J. Blicharska*, D.G. Hutson* and M.D. Norenberg. VAMC, Miami, FL 33125 and Depts of Surgery and Pathol., Univ. Miami School of Medicine, Miami, FL 33101.

Elevated glycogen content is a common response of astroglial cells following exposure to a variety of agents associated with conditions leading to astroglial swelling. Glutamate increases the glycogen content in cultured astrocytes (Swanson et al., J. Neurochem. 54, 490, 1990), and also induces astrocytic swelling (Chan et al., J. Neurosci. Res. 25, 87, 1990). We tested the possibility that the glutamate-induced increase in astrocyte glycogen levels is mediated by changes in cell volume. Glycogen levels were measured using the method of Lust et al., (Anal. Biochem. 68, 328, 1975), and cell volume was determined as described by Kletzien et al., (Anal. Biochem. 86, 537, 1975). When astrocytes were incubated with 1 mM glutamate in isotonic Krebs-Ringer bicarbonate medium for 90 min, glycogen levels increased by 60% and cell volume increased by 123%. Treatment of these cells with hypertonic medium (216 mM NaCl) blocked the swelling and also inhibited the glutamate-induced increase in glycogen. These results suggest that glutamate-induced glycogen accumulation in astrocytes is mediated by a signal that is generated by an increase in cell volume. (Supported by VA Medical Research Service and NIH grant AM 38153).

27.8

ROLE OF CALCIUM IN ATP-STIMULATED EICOSANOID PRODUCTION IN ASTROCYTES G. Bruner and S. Murphy Dept. of Pharmacology, College of Medicine, Univ. of Iowa, Iowa City, IA 52242

Stimulation of rat cortical astrocytes with ATP can elicit eicosanoid production via activation of a P₂Y-purineric receptor. ATP does not alter the sensitivity of phospholipase A₂ (PLA₂) to Ca²⁺. Activation of PLA₂ could occur secondary to a rise in [Ca²⁺]_i. Alternatively, physiologic increases in [Ca²⁺]_i alone may not be sufficient to elicit production of eicosanoids. In fura-loaded cells, [Ca²⁺]_i rose from 106±18 nM to 321±42 nM (n=8) within 6 sec upon stimulation with 500 μM ATP. In Ca²⁺-free buffer (plus 0.5mM EGTA) basal [Ca²⁺]_i was decreased (50±8 nM), as was peak [Ca²⁺]_i (105±25 nM) (n=7) and the time to peak was slower (20 sec), suggesting that much of the initial rapid increase in [Ca²⁺]_i is due to influx.

Previously we have demonstrated that pertussis toxin (PTx) pretreatment inhibits ATP-stimulated eicosanoid production in a concentration-dependent manner. However, PTx did not alter ATP-stimulated increases in [Ca²⁺]_i either in the absence or presence of extracellular Ca²⁺. Furthermore, PTx did not completely inhibit inositol trisphosphate formation, suggesting that mobilization of Ca²⁺ from intracellular stores is not the stimulus for PLA₂ activation. These data indicate that an increase in [Ca²⁺]_i alone is an insufficient stimulus for PLA₂ activation.

ENHANCEMENT OF Ca^{2+} SIGNALS IN ACUTELY ISOLATED ASTROCYTES BY β -ADRENERGIC AGONISTS AND cAMP. S. Duffy and B.A. MacVicar. Neuroscience Research Group, University of Calgary, Alberta, Canada T2N-4N1.

Neurotransmitters acting through specific membrane receptors have been shown to modulate ionic channels in cultured glial cells. For example, β -adrenergic agonists and cAMP analogues increase Ca currents in cultured astrocytes (MacVicar and Tse, *Glia* 1: 359, 1988). However, it is not known if astrocyte Ca channel modulation occurs *in vivo*. We have previously shown that astrocytes acutely isolated from mature rat hippocampus possess functional high-threshold voltage-gated Ca channels (Duffy et al *Soc Neurosci Abstr* 16: 279.12, 1990). To investigate the possibility that these channels are modulated by neurotransmitters, acutely isolated astrocytes were loaded with the Ca-sensitive dye Indo-1, and changes in $[Ca^{2+}]_i$ monitored in response to application of neurotransmitters and second messenger analogues. It was found that the β -adrenergic agonist isoproterenol and the cell permeant cAMP analogues dibutyryl-cAMP and 8-bromo-cAMP can increase both resting $[Ca^{2+}]_i$ and depolarization-evoked $[Ca^{2+}]_i$ signals by enhancing the activity of these channels. Cell autofluorescence at 485 nm, which is correlated with intracellular NADH levels, decreased upon Ca^{2+} influx. This is indicative of an increase in cell metabolic turnover. It is proposed that increases in $[K^+]_o$ associated with neuronal activity triggers Ca^{2+} influx into astrocytes and that this can be regulated by neurotransmitters. One possible function of astrocyte Ca^{2+} signals is to trigger the release of metabolic substrates during brain activity. The control of astrocyte Ca^{2+} signals by K^+ and transmitters released from neurons may constitute an important form of neuron-glia signalling.

EFFECT OF HYPOTONIC STRESS ON Ca^{2+} /CALMODULIN-DEPENDENT PROTEIN KINASE ACTIVITY IN ASTROCYTES. A.S. Bender, J.T. Neary, J. Blicharska* and M.D. Norenberg. Laboratory of Neuropathology, University of Miami School of Medicine & Veterans Administration Medical Center, Miami, FL 33101.

When astrocytes are exposed to hypotonic stress, they immediately swell and then subsequently return to almost their normal volume. These events are associated with an increased Ca^{2+} uptake (Bender et al., 1991, *J. Neurochem.*, in press). This effect on Ca^{2+} uptake could affect the enzymatic activity of Ca^{2+} -dependent protein kinases. Because calmodulin antagonists were shown to block volume regulation, we investigated the effect of hypotonic stress on Ca^{2+} /calmodulin (CaM) protein kinase. Cells were exposed to hypotonic stress (105 mOsm) for various time periods ranging from 0.5 to 30 min, and CaM kinase activity was assayed as described by Babcock-Atkinson et al. (*Glia* 2: 112-118, 1989). CaM kinase activity was increased three-fold in the supernatant fraction, reaching maximal activity at 5 min, whereas it was concomitantly decreased in particulate fraction by 65%, reaching its lowest activity at 2 min. Thus, hypotonic stress activates CaM kinase, and appears to induce its translocation from the particulate to the supernatant fraction. These changes in CaM kinase may mediate the ionic changes which are involved in volume regulation. (Supported by M.R.C. of Canada and the Veterans Administration).

NEURONAL ACTIVITY ELICITS ASTROCYTE Ca^{2+} WAVES AND OSCILLATIONS WITHIN HIPPOCAMPAL SLICES. John W. Dani, Alex Cherniavsky*, JoAnn Buchanan*, & Stephen J Smith*. *Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA 94305.*

Using laser confocal microscopy and the Ca^{2+} indicator dye fluo-3, we have imaged intracellular Ca^{2+} concentrations in organotypic hippocampal slices following electrical stimulation of the dentate gyrus. Specific cells within the slice were identified as astrocytes on the basis of correlative GFAP immunocytochemistry and electron microscopy. Both neurons and astrocytes located within area CA3 exhibited elevated intracellular Ca^{2+} levels with electrical stimulation. These responses were mediated through a TTX-sensitive fiber pathway. Astrocyte Ca^{2+} responses were delayed by 1-2 seconds when compared with the neuronal Ca^{2+} response, which appeared within milliseconds following the onset of stimulation. In addition, the astrocytes displayed both propagating waves of intracellular Ca^{2+} and Ca^{2+} oscillations, whereas the neurons exhibited only sustained Ca^{2+} rises. Kynurenic acid, a glutamate antagonist, completely blocked astrocyte responses to electrical stimulation, suggesting that neuronal glutamate release may mediate this aspect of the response. Astrocyte Ca^{2+} waves and oscillations were observed with stimulus frequencies as low as 2 Hz. At room temperature, wave velocities ranged from 7 to 15 μ m/s, and the periods for oscillations averaged 20 seconds. These findings indicate that a prompt form of neuronal-to-glia communication and a long-distance glial signalling system exists within the brain. If one supposes that glial Ca^{2+} signals in some way feed-back to influence neuronal excitability or synaptic transmission, these findings suggest that astrocytes may be partners with neurons in the brain's information processing functions. 27.10

HETEROGENEITY OF RECEPTOR MEDIATED RESPONSES WITHIN CLONES OF TYPE 1 ASTROGLIA Y. Shao and K. McCarthy, Dept. of Pharmacology, Univ. of North Carolina at Chapel Hill, NC 27599

Previous studies from this laboratory indicated that type 1 astroglia are pharmacologically heterogeneous. Experiments were designed to determine if astroglia within a given clone were pharmacologically identical and if the ability of individual astroglia to respond to a neuroligand was stable over time in culture. Astroglia derived from neonatal rat cerebral cortical tissue were plated at low density such that the development of clones from individual cells could be monitored via time lapse microscopy. A video-based imaging system and the Ca^{2+} indicator dye fura-2 were used to measure changes in Ca^{2+} . Interestingly, only a fraction of the cells within a given clone responded to carbachol or histamine with an increase in Ca^{2+} , whereas treatment with a P_{2U} purinergic receptor agonist generally increased Ca^{2+} in 100% of the cells within the clone. To examine the stability of the receptor signalling, individual astroglia within a number of clones were tested on different days for their ability to respond to neuroligands. The results of these experiments indicated that the ability of an astroglial cell to respond to ligands changes with time in culture. For example, certain cells responded to carbachol but not NE in the first week, lost the carbachol response during the second week and became responsive to NE. These results suggest that intrinsic mechanisms must operate in these cells. Whether the pharmacological heterogeneity reflects a change in receptor expression or other subcellular events remains to be determined. (NS20212)

27.12

EFFECT OF CALCIUM ON ASTROCYTE VOLUME REGULATION, ION AND AMINO-ACID RELEASE.

E.R. O'Connor and H.K. Kimelberg.

Dept. of Pharmacology and Toxicology, and Div. of Neurosurgery, Albany Medical College, Albany, NY 12208.

Swelling of astrocytes in hypotonic media causes regulatory volume decrease (RVD) and release of ions and amino-acids. Using a dynamic method to measure cell volume in attached cells, which measures extracellular electrical impedance, volume regulation in astrocytes exposed to hypotonic media without calcium is abolished. The addition of 1 mM $CaCl_2$ to swollen astrocytes in hypotonic media without calcium causes an almost immediate initiation of volume regulation. The removal of extracellular calcium also abolishes swelling-induced K^+ (^{86}Rb) and ^{36}Cl efflux, but does not affect swelling-induced aspartate or taurine release. The addition of 1 mM quinine \cdot HCl, which is known to block Ca^{2+} -activated K^+ channels, abolishes volume regulation and K^+ efflux in hypotonic-induced swollen astrocytes in the presence of calcium. Measuring intracellular free calcium with Fura-2, swollen astrocytes show a rapid increase in $[Ca^{2+}]_i$, followed by a decrease to an elevated plateau that mirrors the time course of volume regulation. These results suggest that an increase in free $[Ca^{2+}]_i$ triggers activation of Ca^{2+} -dependent ion channels, releasing intracellular ions and osmotically obligated water, leading to a return to near normal cell volume (RVD). (Supported by grant NS 23750 to H.K.K.).

CALCIUM-MEDIATED RESPONSES IN CULTURED CORTICAL ASTROCYTES: COMPARISONS BETWEEN cAMP INDUCED AND NON-INDUCED CELLS. J. Holliday, Y. Aizenman, D. Maciejewski-Lenoir, D.L. Grisol, and R.J. Milner. Department of Neuropharmacology, Scripps Clinic and Research Foundation, La Jolla, CA 92037.

Previous studies have shown that astrocytes become more rounded, express a larger voltage-dependent calcium current and produce increased GFAP mRNA when treated with cAMP. Calcium and cAMP can act together to produce changes in mRNA abundance. Many stimuli may converge upon the calcium messenger system to regulate astrocyte function and the calcium response may depend upon the state of the astrocyte. Here we investigate the effects of various stimuli on calcium levels in cultured cortical astrocytes.

This astrocyte culture system has been developed to minimize contamination by cell types, such as microglia. We have observed changes in calcium levels induced by a variety of stimuli in cultured astrocytes using fura-2 imaging. Depolarization causes large calcium elevations only in forskolin treated astrocytes. In contrast, quisqualate induced elevations are unaffected by treatment. These results suggest that some aspects of calcium regulation depend upon the state of the astrocyte.

Stimulation with any of several cytokines, including IL-1 β , IFN γ , and TNF α , produce small elevations similar to those observed with quisqualate stimulation. Responses to cytokines, such as IL-1 β , are unaltered in forskolin differentiated cells while some differences may be observed in response to cytokines such as IFN. Few interactive effects have been observed with combined cytokine stimulation.

The effects of cytokines on the abundance of a variety of transcripts is being investigated using northern blotting techniques. The transcripts include those coding for GFAP, cytokines, and their receptors. Preliminary results indicate that changes in the amount of some transcripts can be detected in response to cytokines and that forskolin treatment may further alter some mRNA abundancies. The role of calcium in receptor mediated changes is being determined.

Na/Ca EXCHANGE: A MAJOR DETERMINANT OF ASTROCYTE RESPONSIVENESS TO NEUROTRANSMITTERS AND EXCITOTOXINS. M.P. Blaustein, B.K. Krueger, P.J. Yarowsky, & W.F. Goldman. Depts. of Physiol. & Pharmacol., U. MD Sch. Med., Baltimore, MD 21201

The influence of the Na^+ gradient on resting intracellular Ca^{2+} , $[\text{Ca}^{2+}]_i$, and on evoked increases in $[\text{Ca}^{2+}]_i$ was measured in cultured rat brain astrocytes. The cells were loaded with fura-2, introduced as the acetoxymethyl ester; the apparent free intracellular Ca^{2+} , $[\text{Ca}^{2+}]_{app}$ was determined by digital imaging. In unstimulated cells, $[\text{Ca}^{2+}]_{app}$ was heterogeneously distributed; in most cytoplasmic areas $[\text{Ca}^{2+}]_{app}$ was 50-100 nM, but much higher levels were seen in some areas. Glutamate, 100 μM , or 40-100 mM K^+ evoked transient, non-uniform increases in $[\text{Ca}^{2+}]_{app}$ as high as 1 μM . Replacement of 135 mM Na^+ by isosmolar N-methylglucamine, or 15 min exposure to ouabain, induced a small increase in $[\text{Ca}^{2+}]_{app}$ in most cells, but substantially potentiated the amplitude and duration of glutamate- and K^+ -evoked Ca^{2+} increases. After exposure to ouabain, reduction of $[\text{Na}^+]_o$ induced a dramatic, external Ca^{2+} -dependent rise in $[\text{Ca}^{2+}]_{app}$. Thus, reduction of the plasmalemmal Na^+ gradient not only increases $[\text{Ca}^{2+}]_i$ in resting astrocytes, but also augments the Ca^{2+} transients evoked by depolarizing agents. The latter may be due to increased intracellular Ca^{2+} storage as well as to inhibition of Ca^{2+} extrusion via Na/Ca exchange: the exchanger may not only play an important role in regulating $[\text{Ca}^{2+}]_i$ in astrocytes, but it may also be a major determinant of the responsiveness of these cells to neurotransmitters and excitotoxins by regulating Ca^{2+} in intracellular stores.

TRANSIENT PERIOD OF ELECTROGENESIS DURING THE DEVELOPMENT OF RAT SPINAL CORD ASTROCYTES *IN VITRO*.

H. Sontheimer, J.A. Black, B.B. Ransom, and S.G. Waxman. Dept. Neurology, Yale University, New Haven, CT 06510 and VA Hospital, West Haven, CT 06516.

The expression of voltage-activated Na^+ and K^+ currents was studied in astrocytes cultured from P0 rat spinal cord using whole-cell patch-clamp recordings. As with optic nerve cultures, two antigenically distinct astrocyte populations (GFAP+/A2B5⁻ and GFAP+/A2B5⁺) can be identified. Both astrocyte types express 4-AP-sensitive, voltage-activated outward K^+ currents at high densities (100-200 pA/pF) immediately after dissociation. However, at such early times *in vitro*, voltage-activated Na^+ currents are only expressed in A2B5⁺ astrocytes. A2B5⁺ astrocytes begin to show robust Na^+ currents after 5-6 DIV; in fact, Na^+ currents are so large (up to 18 nA; I-dens. 100-300 pA/pF) that channel densities are 10-50fold higher (~ 3/ μm^2) than in optic nerve or hippocampal astrocytes. Outward K^+ currents are almost lost in A2B5⁺ astrocytes at the time that these large Na^+ currents are expressed. At 5-10 DIV A2B5⁺ astrocytes exhibit action-potential-like responses in response to hyperpolarizing current injections ("anode break spikes"), without pharmacological blockage of outward currents. These responses overshoot 0 mV and return to resting potential with a time-constant of ~ 6 msec. Trains of such responses can be elicited by repetitive stimulation. Hyperpolarization in excess of -150 mV is required to overcome Na^+ channel inactivation since even at potentials as negative as -130 mV Na^+ current inactivation is not always removed (h_{∞} -curves of A2B5⁺ astrocytes show midpoints around -90 mV whereas A2B5⁻ astrocytes typically have midpoints around -60 mV). Action-potential-like responses could not be recorded in A2B5⁺ astrocytes since these cells continue to express large outward K^+ currents that exceed Na^+ current amplitudes by 2-10fold and stabilize the cells resting-potential. Since ion channel densities appear to be modulated by extrajugal factors *in situ* and by *in vitro* culture conditions, it is not clear whether astrocytes *in situ* display regenerative responses. L 644,711 INHIBITS K^+ - STIMULATED CHLORIDE ION UPTAKE AND CELLULAR INJURY IN CORTICAL ASTROCYTES. P. Thakran, M.P. Leuschen, A. Chatterjee. Div. Newborn Med., Univ. Nebraska Med. Ctr., Omaha NE 68198.

Cytotoxic edema of astrocytes is the major hypoxic-ischemic lesion in the brain of premature infants and has been attributed to a high extracellular K^+ - stimulated, chloride mediated process. The effect of the anion transport inhibitor L 644,711 (5,6-Dichloro-2,3,9,9a-Tetrahydro-3-oxo-9a-propyl-1H-fluoren-7yl) oxyacetic acid was investigated in an *in vitro* model consisting of primary cultures dissociated with dispase from cerebral cortices of neonatal guinea pigs, plated on Vitrogen™, maintained in modified DMEM with 10% FCS and characterized as >90% astrocytes by immunohistochemistry with antiserum to GFAP. The extracellular milieu of 18-day, confluent astrocytes was manipulated by incubation in either a basal buffer (BB) with an ionic composition similar to DMEM or one with 60 mM K^+ (HiK). Cellular injury was quantitated by three parameters, uptake of ^{36}Cl , efflux of lactate dehydrogenase (LDH) and the MTT viability assay. Incubation in HiK (vs. BB) resulted in an increase in ^{36}Cl uptake within 10 minutes, a time-dependent increase in LDH efflux (30 min. - 4 hours), and significantly reduced cell viability ($p < 0.05$). L 644,711 significantly inhibited HiK-stimulated ^{36}Cl uptake and reduced LDH efflux in a dose dependent manner. The MTT assay revealed 10^{11} M L 644,711 as the peak effective dose for preventing injury when administered simultaneously with the HiK paradigm in a 1-hour incubation. The same dose was effective in reversing injury when administered 10 min. after exposing the cells to HiK. These findings indicate the potential usefulness of agents which modify ion transport processes in hypoxic-ischemic cerebral injury.

27.16

THE EXPRESSION OF SODIUM CHANNELS IN ASTROCYTES FROM NEONATAL RAT SPINAL CORD *IN VITRO*. J.A. Black, H. Sontheimer, B.R. Ransom and S.G. Waxman. Dept. of Neurology, Yale University School of Medicine, New Haven, CT 06510 and Neuroscience Research Center, VA Medical Center, West Haven, CT 06516.

Astrocytes derived from optic nerve, hippocampus, and cerebral cortex have been shown to express voltage-sensitive sodium channels *in vitro*. However, it has become clear that neither the pattern of expression nor the physiological properties of sodium channels are invariable for astrocytes derived from differing CNS regions. Thus, we have begun to examine the expression of sodium channels in astrocytes derived from neonatal rat spinal cords.

Cells from P-0 rat spinal cords were dissociated and plated at a density of $10^5/\text{ml}$ on poly-ornithine/laminin-coated glass slides; cells were maintained in Earle's MEM containing 10% fetal calf serum. At 1 day *in vitro* (DIV), many cells exhibited GFAP and/or vimentin staining; in addition, A2B5 and O4 immunoreactivity was present on some cells. Sodium channel immunostaining with antibody 7493 was present but weak at 1 DIV. At 7 DIV, sodium channel staining was robust on GFAP⁺ cells. Many of the GFAP⁺ cells exhibited A2B5 or O4 staining. By 14 DIV, sodium channel immunostaining was reduced, and by 28 days in culture it was not detectable; A2B5 staining was greatly attenuated at 14 DIV and completely absent by 28 DIV. In contrast, GFAP⁺/O4⁺ cells continued to be present at 28 DIV.

These observations demonstrate that astrocytes derived from neonatal rat spinal cord exhibit a different pattern of sodium channel expression than astrocytes derived from several other CNS regions, and suggest a regional difference of sodium channel expression in astrocytes.

POTASSIUM AND ANION CHANNELS OPENED BY OSMOTIC GRADIENTS ACROSS ASTROCYTE PLASMA MEMBRANES

*T. Jalonen, A.J. Popp and H.K. Kimelberg

Dept. of Biomedical Sciences, *Univ. of Tampere, SF-33101 Tampere, Finland and Div. of Neurosurgery, Albany Medical College, Albany, N.Y. 12208 USA.

Astrocytic swelling can be induced *in vitro* by osmotic gradients and high extracellular K^+ . After a fast initial volume increase in hypoosmotic solutions astrocytes undergo a regulatory volume decrease (RVD), but usually remain swollen in high K^+ . Activation of "stretch-sensitive" channels has been proposed to contribute to this RVD. We have found increased occurrence of large-conductance, potential-dependent anion (A^-) channels in isolated astrocyte membrane patches when hypoosmotic solutions were present in the bath and isosmotic solutions were present in the pipette. Currently about half (12 of 26) of such recordings have clearly shown a large-conductance Cl^- channel, as determined by the reversal potential for the current. High K^+ in bath, both in inside-out and cell attached recording configurations, induced K^+ channel activity while A^- channels were only rarely detected. With gluconate present on the extracellular side only K^+ channels have been detected, suggesting that gluconate is inhibiting the A^- channel. This anion channel is also blocked by L-644,711, an anion transport inhibitor that has been shown to be useful in recovery from experimental stroke and head injury. Supported by NS 23750 (H.K.K.) and the H. Schaffer Foundation (A.J.P.).

27.20

APPLICATION OF POTASSIUM CHLORIDE TO THE CORTICAL SURFACE DRAMATICALLY UPREGULATES LEVELS OF MESSENGER RNA FOR GLIAL FIBRILLARY ACIDIC PROTEIN IN CORTEX AND HIPPOCAMPUS.

D.J. Bonthuis, J.L. Stringer, E.W. Lothman and O. Steward. Departments of Neuroscience, Pediatrics and Neurology, University of Virginia, Charlottesville, Virginia 22908.

It has previously been shown that electrically-induced seizures lead to increased levels of mRNA for GFAP in the hippocampus (Steward et al., P.N.A.S., in press). The present study investigates whether the signal for this increased expression might include elevated extracellular potassium.

Adult male rats underwent unilateral parietal craniotomy, and pledgets soaked in KCl (3M) were applied to the exposed parietal cortex for ten minutes. Previous studies have shown that this treatment can induce cortical spreading depression. K^+ -sensitive microelectrode recording revealed a negative shift in DC potential and a sharp increase in extracellular K^+ , conditions characteristic of spreading depression. The animals were killed 24 hours following KCl application and levels of GFAP mRNA were assessed by *in situ* and dot blot hybridization.

In situ hybridization revealed increased labelling throughout the ipsilateral cortex and throughout the hippocampus bilaterally. Dot blot hybridization revealed a greater than 10-fold increase in GFAP mRNA in the hippocampus, relative to saline-treated controls. In a time-course study, animals were killed 1.5, 3, 6, 12 and 24 hours post KCl application, and *in situ* hybridization was used to evaluate levels of GFAP mRNA. Increases in GFAP mRNA first became detectable at 6 hours, and levels continued to increase up to 24 hours. These results suggest that elevated extracellular K^+ can upregulate GFAP gene expression and that this effect can be seen over widespread areas, possibly as a result of spreading depression. (Supported by NIH Grant NS12333 to O.S.)

28.1

DIFFUSIVE TRANSPORT OF MACROMOLECULES IN DEVELOPING NERVE PROCESSES. S. Popov and M-m. Poo, Dept. of Biological Sciences, Columbia Univ. N.Y., N.Y. 10027.

Passive transport of macromolecules in growing nerve processes was analyzed quantitatively by measuring the rate of diffusional spread of fluorescently-labeled molecules injected into the soma of cultured *Xenopus* neurons, using digital fluorescence imaging techniques. The diffusion coefficient (D) of a typical globular protein bovine serum albumin (BSA) was found to be $12.5 \pm 2.3 \times 10^{-8} \text{ cm}^2/\text{s}$ (s.e., N=6), a value 10-fold higher than the previously reported values for BSA diffusion in fibroblast cytoplasm. The relatively high D value of soluble macromolecules in developing neurons suggests that passive diffusion could serve as an effective transport mechanism. When the diffusion of dextrans of various sizes was examined, we found that the dependence of D on the molecular size deviates considerably from that expected for diffusion in a viscous aqueous medium. Treatment of the neuron with microfilament-disrupting agent cytochalasin B, or pre-loading the neuron with dephospho-synapsin I, a molecule that induces bundling of actin filaments, significantly increased the diffusion rate for large dextrans, but had little effect on the diffusion of small dextrans. This finding suggests that the microfilament meshwork imposes a selective constraint on the diffusion of large macromolecular components within the neuronal cytoplasm.

UNC-116, A MUTANT IN THE *C. ELEGANS* KINESIN HOMOLOG HAS SPECIFIC NERVOUS SYSTEM DEFECTS G. de Feo*, N. Patel, and J.R. Mancillas. UCLA, Los Angeles, CA. 90024

Unc-116, the *C. elegans* kinesin homolog (N. Patel et al., Society for Neuroscience abstract, 1991), was identified as a new genetic locus in a screen for mutants in abnormal backward locomotion (J. R. Mancillas, *Neuroscience* 22:S236, 1987). We are characterizing the neuroanatomical defects of two alleles of this gene. The first, e2281, is a weak hypomorph which has a restricted set of defects in the nervous system. By using a variety of antibody stains that mark specific subsets of neurons, we have detected neuronal defects such as abnormal varicosities in the Alm (anterior lateral microtubule cell, a touch receptor neuron), an abnormal posterior projection in the Alm, and dorsally misplaced Alm axons. These defects seem to be variable from individual to individual which may explain the variable behavioral phenotype of these animals. The second allele we are investigating is rh24 (provided by J. Plenefisch and E. Hedgecock), a much stronger allele which is 80% embryonic lethal (J. Plenefisch, personal communication). This allele has more severe neuroanatomical defects, which correlates with more severe locomotor defects in these animals. These studies indicate that a disruption in kinesin has consequences for both early development, and nervous system development.

28.5

SUPPRESSION OF KINESIN EXPRESSION USING ANTISENSE OLIGONUCLEOTIDES IN CULTURED HIPPOCAMPAL NEURONS. A. Ferreira*, J. Niclas*, K. Kosik, R. Vale*, and G. Banker, Univ. of Virginia, Charlottesville, Virginia; Harvard Medical School, Boston, MA; UCSF, San Francisco, CA.

As one approach to examine the functional role of kinesin in living nerve cells, we used antisense oligonucleotides to inhibit kinesin expression in dissociated-cell cultures prepared from embryonic rat hippocampus. Based upon the sequence of the human kinesin gene, a 25-mer oligonucleotide in the antisense orientation was prepared against a region of the heavy chain that spanned the initiator methionine. Subsequent analysis has revealed only two discrepant nucleotides in the corresponding region of the rat gene. Antisense oligonucleotide was added to cultures every 12 hours, beginning 4 hours after plating. After 48 hours kinesin levels were assessed using a monoclonal antibody directed against the heavy chain (SUK-4, J. Scholey). In comparison to untreated or sense-treated controls, kinesin immunostaining was abolished under antisense conditions and the content of immunoreactive kinesin was reduced by more than 90% based on dot immunobinding. Analysis of neurite length revealed that elongation was inhibited by almost 50% in the presence of the antisense oligonucleotide, axons and minor processes being equally affected. As one measure of the transport of vesicle-associated proteins, we examined the distribution of synapsin I and GAP-43. Under antisense conditions, immunostaining for both proteins was largely confined to the cell body, whereas in control cultures immunoreactivity extended into the neurites and was concentrated at their distal tips. These results are consistent with the suggestion that kinesin mediates vesicle transport toward the plus ends of microtubules in vivo, and that interference with this transport interferes with process outgrowth.

28.2

UNC-116 ENCODES *C. ELEGANS* KINESIN. N. Patel, G. de Feo*, J.R. Mancillas. UCLA, Los Angeles, CA. 90024

During a screen for genes involved in axonal guidance, a single hypomorphic allele, e2281, representing a new locus, unc-116, was identified. (J.R. Mancillas, *Neuroscience* 22:S236, 1987). We have cloned unc-116 using a combination of the transposon tagged allele and the physical map. Analysis of putative full length cDNA and predicted amino acid (aa) sequence reveals that unc-116 encodes the heavy chain of kinesin. At the aa level, unc-116 is 55% identical to *Drosophila* kinesin (Yang et al., *Cell* 1989) and to squid kinesin (Kosik et al., *Journal of Biological Chemistry*, 1990). The three major domains of kinesin (Yang et al.) are present in unc-116: the motor domain is 71% identical to *Drosophila* and contains the consensus ATP binding sequence; the stalk region is 150 aa shorter than in *Drosophila* but has the heptad repeat characteristic of coiled-coil α -helices; and the tail is 60% identical. The transposon insertion in e2281 occurred near the stalk-tail junction; the resulting alteration in kinesin may affect transport of specific membrane-bound organelles and thus account for the specific axon misplacements observed in this allele (de Feo et al., SNS abstract 1991). Embryonic lethality in a second, independently isolated allele (J. Plenefisch and E. Hedgecock, unpublished data), suggests a function for kinesin in early development, in addition to its neuronal function.

28.4

Distribution of kinesin in squid axoplasm by rapid freeze immunocytochemistry. J. E. Moreira*, A. Klodakis* and T. S. Reese, Laboratory of Neurobiology, NIH, Bethesda MD 20892.

Axoplasmic kinesin was originally thought to be the source of the transport motor for moving organelles, but recent work shows that the anterograde organelle motor appears to be very tightly attached to the organelle surface (Schnapp et al.). It now becomes essential to distinguish cytoplasmic kinesin that might bind to the organelle surfaces during fixation from kinesin originally on organelle surfaces. In order to prevent displacement of kinesin during preparation, squid axoplasm was extruded and immediately frozen on a liquid helium cooled copper block, freeze-substituted in 0.1% uranyl acetate in acetone at -80°C , infiltrated with Lowicryl K11M at -60°C , and warmed up from -70°C during ten days of UV polymerization. This protocol avoids contact with water, cross-linking fixatives, and stabilizes the tissue prior to cutting. Electron microscopic immunolabeling of thin sections with rabbit polyclonal anti-kinesin and protein A-gold showed gold grains on both organelles and cytosol. Specific labeling by a polyclonal antibody against squid neurofilament was used along with the anti-kinesin to compare the localization of both proteins. Backgrounds were very low and controls, incubated with rabbit non-immune IgG or whole serum, showed only a few gold particles. Our results suggest that the antigens reacting with the kinesin polyclonal antibody are widely distributed in cytoplasm. Though organelles showed labeling density slightly above cytoplasmic levels it remains unclear whether this organelle staining corresponds to the motors that move the organelles.

28.6

AXONAL TRANSPORT IN TRANSECTED NERVES: FURTHER EVIDENCE FOR BIDIRECTIONAL TRANSPORT OF NEUROFILAMENTS. J.D. Glass, P.N. Hoffman and J.W. Griffin. Departments of Pathology, Neurology, and Ophthalmology and the Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, Maryland 21205.

Peripheral nerves of C57BL/6J mice degenerate very slowly following separation from their nerve cell bodies. Previously, we have described the massive accumulation of neurofilaments (NF) at both proximal and distal cut sites of doubly transected sciatic nerves, suggesting the bidirectional transport of NF. In the present study, the axonal transport of pulse-labeled NF proteins was analyzed in axons isolated from their cell bodies. At either 7 or 14 days after [^{35}S] methionine was injected into the L5 dorsal root ganglion (DRG) of C57BL/6J mice, DRG were removed (ganglionectomized) and the distribution of labeled proteins in the isolated sciatic nerve was analyzed 7 or 14 days later, respectively (i.e., 21 days after labeling). Comparison of these transport profiles with those from corresponding intact nerves demonstrated that NF proteins were located more proximally in ganglionectomized nerves. These findings support the hypothesis that NF proteins are transported in a retrograde direction in isolated nerve segments.

BLOCKAGE OF FAST AXOPLASMIC TRANSPORT BY MECHANICAL COMPRESSION. Paul E. Gallant, Laboratory of Neurobiology, NINDS, NIH, Bethesda MD 20892

Fast axoplasmic transport is often studied by collecting material that accumulates focally after crushing or tying off an axon. These procedures might block fast transport indirectly by cutting off the blood supply or more directly by damaging axonal structures necessary for fast transport. The direct effects of mechanical compression on fast axoplasmic transport were studied by video-enhanced differential interference microscopy of isolated squid giant axons that were compressed with 0.5, 5.0, 20, or 100 g weights over a 1 mm length of axon. Compressions with 0.5 g/mm momentarily deformed the axon but produced no change in fast axoplasmic transport. Compressing the axon with 5-20 g/mm broke and separated the axoplasm at the site of the crush. Though the axoplasm usually returned to the crush site after the weight was removed, organelles failed to cross this rejoined crush site, instead they accumulated over time at the crush site. This block was not due to an influx of harmful extracellular ions into the axon at the crush site, since replacing the normal external ions with an internal-type media had no effect on the blockage or accumulation of organelles produced by a 5-20 g/mm crush. Compression with 100 g/mm led to a rapid ion dependent liquefaction of axoplasm at the site of the crush. Replacing the harmful external media with internal-type media prevented the axoplasmic liquefaction, but the internal media did not prevent the breakage of the axoplasm or the blockage of transport in the axons compressed with 100 g/mm. Moderate pressures thus appear to block transport mostly by breaking the axoplasm, while higher pressures break both the axoplasm and the plasma membrane.

TRANSPORT AND TURNOVER OF AXOPLASMIC PROTEINS IN CONTROL AND ANUCLEATE MAUTNER AXONS OF GOLDFISH
J. W. Mochlenbruck, J. A. Cummings*, and G. D. Bitner
Dept. of Zoology, Univ. of Texas, Austin, Tx. 78712

After severance, the distal segments of giant Mauthner axons (anucleate M-axons) in goldfish remain morphologically and physiologically intact for months at 10-30°C, but eventually degenerate in a proximal-to-distal (P-D) direction at a temperature-dependent rate (Blundon et al., 1990). Long term survival (LTS) of anucleate M-axons could be due to a very slow turnover of axoplasmic proteins. In goldfish maintained at 15°C, the turnover of 80 kD and 130 kD neurofilament proteins in single anucleate M-axons was analyzed using 1D SDS/PAGE, silver staining for total protein, and/or Bodian's silver stain for neurofilaments. The neurofilament bands, and other axoplasmic protein bands, were intensely stained in gels from anucleate M-axons severed 70 days previously (or from intact M-axons), but not in samples from anucleate M-axons severed for over 80 days.

We have also analyzed the transport of neurofilament proteins within control M-axons. In goldfish maintained at 15°C and 25°C, axoplasmic proteins were radiolabeled at the Mauthner cell body in the medulla. At postinjection intervals of 10-60 days, consecutive 3 mm segments of single M-axons were isolated and labeled M-axon proteins visualized using SDS-PAGE and fluorography. Slow transport of neurofilaments within intact M-axons occurred at rates of 0.1-0.2 mm/day at 15°C and 0.4-1.3 mm/day at 25°C. These rates are similar to observed rates of P-D degeneration in anucleate M-axons. We are now measuring slow transport rates in anucleate M-axons. Our results are consistent with a very slow turnover of axoplasmic proteins during LTS of anucleate M-axons and during slow transport in intact M-axons. Supported by NSF and TATP grants to GDB.

RETROGRADE AXONAL TRANSPORT OF PHOSPHATIDYLCHOLINE AFTER INTRANEURAL INJECTION OF [³H]CHOLINE INTO THE RAT SCIATIC NERVE. S. Padilla*, E.H. Bennett*¹, P. Tandon². Neurotox. Div. (MD-74B), US E.P.A. and ¹METI, Res. Tri.Pk., NC 27711; and ²Center for Environmental Medicine, Univ. of NC, Chapel Hill, NC 27514.

Retrograde axonal transport of phosphatidylcholine (PC) in the sciatic nerve has only been demonstrated after injection of lipid precursor into the cell body regions. When [³H]choline was injected locally into the sciatic nerve the majority of the label was incorporated into myelin phospholipids (Gould et al., 1987 *J. Neurochem.* 48; 1121). We now report, however, that after microinjection (1 µl) of [methyl-³H]choline chloride (87.6 Ci/mmol; 15 µCi) into the rat sciatic nerve (45-50 mm distal to L₄ and L₅ dorsal root ganglia; DRGs), time-dependent accumulation of [³H]labeled lipid occurred only in DRGs ipsilateral to the injection site. The dpm present in the contralateral DRGs remained constant at 140-193 dpm between 2 and 72 hrs after injection; the labeling in the ipsilateral ganglia was minimal at 2 hrs (96 dpm) and increased thereafter: 7 hrs=272 dpm (median); 24 hrs=1590 dpm; 48 hrs=748 dpm and 72 hrs= 1055 dpm (n=3 to 5 per time point). One dimensional TLC separation of the ipsilateral DRG lipid extract revealed that ≥90% of the label was present in PC at all time points. Because colchicine injection into the sciatic nerve prevented the accumulation of radiolabel in the ipsilateral ganglia, the presence of this delayed radiolabeling of the ipsilateral DRGs is probably due to retrograde axonal transport of PC.

28.8

BREFELDIN A INHIBITS FAST AXONAL PROTEIN TRANSPORT AND DISASSEMBLES GOLGI APPARATUS BUT DOES NOT DIMINISH ANTEROGRADE AXONAL VESICLE TRANSPORT R.S. Smith, H. Chan* and R. E. Snyder, Department of Anatomy and Cell Biology and Department of Applied Sciences in Medicine, University of Alberta, Edmonton, Canada T6G 2H7

Newly synthesized proteins that undergo rapid axonal transport are carried by vesicles and tubulovesicular organelles, but whether the transport of these organelles is dependent on the recent synthesis of protein is not known. To investigate this relationship we have prevented the export of newly synthesized protein from the cell body using brefeldin A, a drug that has been shown to disassemble the cis and medial Golgi in non-neuronal cells and have determined the effect of this agent on the rapid axonal transport of proteins and vesicles.

The sciatic nerves and dorsal root ganglia (DRG) with or without the spinal cord were isolated from the amphibian *Xenopus laevis* and maintained for periods up to 27 h in a physiological saline. Newly synthesized protein was metabolically labeled in DRG with ³⁵S-methionine or ³H-leucine. The DRG were exposed to brefeldin A (10 µg/ml), and for comparison to cycloheximide (125 µg/ml), or puromycin (500 µg/ml). Rapidly transported protein was assayed in the sciatic axons by liquid scintillation analysis. The status of the Golgi apparatus was determined by transmission electron microscopy. Organelle transport was studied in isolated sciatic axons using video microscopy.

Brefeldin A did not affect the synthesis of proteins in the DRG but rapidly (<1 h) inhibited the amount of axonal transport of protein undergoing axonal transport to less than 1 % of control values. The inhibition of axonal transport was concomitant with the ultrastructural disappearance of Golgi stacks, and was similar in time course and in magnitude to the inhibition achieved with cycloheximide or puromycin. In contrast, the anterograde flux of vesicles as determined by video microscopy remained at control values for times up to 24 h in the presence of each of the inhibitors. We conclude that newly synthesized proteins are not required for the formation or transport of vesicles from the neuronal cell body. (Supported by MRC, Canada)

CYCLIC AMP INCREASES THE QUANTITY OF ELH-CONTAINING PROTEINS IN THE NEURITES OF APLYSIA BAG CELL NEURONS. E. Azhdarian*, C.-H. Lin, D. Hefner*, P. Forscher and L. K. Kaczmarek, Yale University, New Haven, CT. 06510

Brief synaptic stimulation of the bag cell neurons triggers an afterdischarge during which cAMP levels are elevated. During the discharge, the neuropeptide ELH is released from the terminals of the bag cell processes. Previous work has shown elevations in cAMP increase the synthesis of ELH and accelerate processing of the initial ELH prohormone. We now report that cAMP increases the transport of ELH-immunoreactive proteins from the bag cell somata towards the terminals. Bag cell clusters in intact abdominal ganglia were labeled with ³H leucine and then incubated with TTX to inhibit afterdischarges. Experimental ganglia were exposed to a cAMP analog CPTcAMP(500 µM) after which the bag cell somata and the neurite-containing sheath were dissected away from the rest of the ganglion. After a 10 min treatment with CPTcAMP we found that the amount of ELH-containing proteins in the neurite-containing sheath increased several fold over control. We also analyzed the distribution of ELH immunofluorescence in the processes of cultured bag cell neurons incubated with the adenylate cyclase activator forskolin in the presence of 10 µM anisomycin and 50 µM TTX. ELH immunoreactivity was found to extend relatively uniformly along the length of the neurites in control cells while forskolin treatment resulted in an increased concentration of ELH immunoreactivity toward the distal end of the neurites. These findings are consistent with the hypothesis that an elevation of cAMP increases the transport of ELH-containing secretory granules into and along the neurites. We are presently using video-enhanced microscopy to determine whether the rates of granule movement and the density of granules on microtubule tracks are modulated by cAMP.

28.12

THE THIOL-PROTEASE INHIBITOR E64 INHIBITS THE REVERSAL OF ACETYLCHOLINESTERASE AT A NERVE SECTION. G. Filliatreau*, B. Tavitian, R. Hässiq*, L. Di Giamberardino, INSERM U.334, Service Hospitalier Frédéric Joliot, CEA, F-91406 Orsay, France.

Axonal acetylcholinesterase (AChE) carried by rapid anterograde axonal transport "turns around" at a nerve section and is carried back to the cell body. This mechanism is probably identical to the "anterograde to retrograde (A-R) conversion mechanism" occurring at the nerve endings, which was reported to be blocked by protease inhibitors (Sahenk and Lasek, 1988).

We analyzed the effect of E64 and leupeptin, two thiol-protease inhibitors, on the turnaround of AChE in transected sciatic nerves of young Leghorn chickens.

When the tip of the cut nerve was dipped *in vivo* for 30 min to 5 hours into a solution of E64 (10 mg/ml) immediately after the section, the turnaround of AChE was inhibited up to 50%. However, no inhibition was observed if the application of E64 was delayed for one hour or more after the section. On the contrary, leupeptin had no effect on the turnaround of AChE.

These observations suggest that cysteine proteases could be implicated in the events leading to the establishment of the A-R conversion mechanism at the tip of a cut nerve.

TISSUE IMMUNOLocalIZATION OF A 60KD PROTEIN ORIGINALLY ISOLATED FROM CNS PRESYNAPTIC TERMINALS. J.A. Garner and M. J. Cullen, Dept. of Anatomy and Cell Biology, USC School of Medicine, Los Angeles, CA 90033.

Previously, a 60KD protein was shown by axonal transport studies to be a major constituent of guinea pig retinal ganglion cell (RGC) collicular terminals. It is a major slow component b protein (6.9% of total cpm), the group of proteins thought to convey the cytoplasmic matrix. The unusual solubility characteristics of this 60KD presynaptic protein (when exposed to micromolar levels of calcium) has allowed its ultimate purification from whole guinea pig cortex. A polyclonal antibody was generated in chickens against the purified protein and has been used in the present study to investigate the tissue immunolocalization of the antigen. Immunoblots of a number of central nervous system and other guinea pig tissues (including superior colliculus, spinal cord, cerebellum, cerebrum, retina, lung, liver, adrenal gland, kidney, small intestine, striated muscle, and cardiac muscle) revealed the presence of a 60KD antigen within all tissues except lung and liver, with some enrichment in CNS tissues, and substantial enrichment in retina, striated muscle, and cardiac muscle. Tissues stained with primary and fluorescently-derivatized secondary antibody reveal cytoplasmic staining specifically in pyramidal type neurons in cerebral cortex, in alpha motoneurone and radial glia in spinal cord, punctate staining in outer plexiform layer and generalized RGC staining in retina, punctate cytoplasmic staining in adrenal medulla, and a distinct striated pattern of staining in striated and cardiac muscles. TRANSYNAPTIC AND NON-TRANSYNAPTIC FORMS OF WGA-HRP. Michael J. Russell, Hong Liu*, Richard J. Nunes*, and Vijaya Vijayan. Dept. Anesthesiology, Univ. of Calif. Davis, Med. Sch., Sacramento, CA 95817.

The mechanisms of intraneuronal transport are reasonably well understood. However, why some materials cross a synaptic barrier while others do not is still largely a unknown. It is essential for the study of transynaptic carriers to develop the ability to control when a material will cross the synapse, and when it will not. In collaboration with E-Y Labs of San Mateo, CA we have developed two closely related forms of WGA-HRP. Both of these were tested by placing them into the right naris of rats to determine if they would be taken up and carried through the olfactory system into the brain. We found that one form WGA-aminocaproic-HRP ($H_2N(CH_2)_5COOH$) was taken up by the olfactory receptor neurons, but stopped at the first synapse. The other form WGA-HRP (coupled directly) was taken up and also carried across the synapse into the olfactory bulb. The coupling of HRP to WGA with aminocaproic acid results in a charge difference in the molecule as well as some conformational change. This modification is apparently not enough to prevent the material from being taken up by olfactory receptor neurons, but it does prevent the material from being transported to the next cell. This work is an important step in developing tools for the study of transynaptic transport mechanisms.

ALTERATIONS IN THE PATTERN OF NUCLEAR PROTEINS IN *Aedes albopictus* CELLS INFECTED WITH *MAYARO VIRUS*. Andrade, A. and Carvalho, M.G.C. Dept. de Biofisica Molecular, IBCCF, UFRJ, Rio de Janeiro, RJ 21941, Brazil.

Comparative studies on the replication of *Sindbis* virus (Alpha-virus) in cultured vertebrate and invertebrate cells revealed that enucleated mosquito cells, unlike enucleated vertebrate cells, are incapable of producing significant amounts of viral particules. This suggested that some host function was required for efficient virus replication in invertebrate cells. In the present work, we isolated *Aedes albopictus* nucleus in an attempt to characterize the pattern of nuclear protein of infected cells. We compared isolated nucleus obtained from infected cells maintained at 28°C (normal temperature of growth) and at 37°C (induces inhibition of cellular growth and viral replication). We observed the presence of a viral structural protein (34 Kd) and a high molecular weight group of proteins in nucleus from infected cells incubated at 28°C. In contrast, at 37°C, a modification in the pattern of this group could be detected. The molecular weight of these proteins corresponded to that of the nonstructural proteins of *Sindbis*. The above results were reinforced by electron microscopy studies. Our data suggested that viral infection can alter the pattern of nuclear proteins through the transport of viral proteins to nucleus and/or induction of cellular proteins. The viral proteins translocation could be associated to the dependence of the virus upon the nuclear function of invertebrate cells. Support: FINEP, FAPERJ and CNPq.

IS THE SMALL GTP-BINDING PROTEIN RAB6 INVOLVED IN THE VECTORIAL DELIVERY OF SYNAPTIC PROTEINS ? B.J. Jasmin, B. Goud*, G. Camus* and J. Cartaud*. Institut Jacques Monod and Institut Pasteur, Paris, France.

Recently, the Rab genes have been cloned and sequenced in mammals, and their products represent good candidates for small GTP-binding proteins involved in the intracellular transport of vesicles in higher eukaryotes. Remarkably, each of the Rab proteins appears associated with a distinct step of either the exocytic or endocytic pathway. In particular, Rab6p has been localized to the outermost Golgi cisternae in NRK cells where its function remains unclear (Goud et al., *Nature* 345: 125, 1990). In this work, we carried out immunocytochemical analyses of the distribution of Rab6p in a polarized cell, the electrocyte of *Torpedo marmorata*, to gain insights into the role of this small GTP-binding protein in exocytic events. We report that the bulk of Rab6p associates selectively with clusters of distinctive post-Golgi vesicles: only those located at the cytoplasmic face of the innervated membrane of the electrocyte. Thus, Rab6p presents a polarized distribution in this cell. Also, we show that this distribution is dependent on the integrity of the microtubule network of the electrocyte. These data are coherent with the notion that Rab6p is involved in the regulation of membrane traffic from the trans-Golgi network to specialized domains of the plasma membrane. As such, Rab6p may represent a key element involved in the sorting and targeting of synaptic proteins.

28.16

THE ALZHEIMER'S AMYLOID PRECURSOR PROTEIN (APP) IS CLEAVED INTRACELLULARLY IN A POST-GOLGI COMPARTMENT. K. Sambamurti*, J. Shioi, and N. K. Robakis. Dept. of Psychiatry, Box # 1229, The Mount Sinai Medical Center, New York, N.Y. 10029.

APP is secreted from many different cell lines as a part of its normal metabolism. The cleavage site resulting in the secreted form of APP (nexin II) is located within the amyloid peptide sequence and is inconsistent with amyloid formation. To identify the enzyme responsible for this cleavage, we have characterized the subcellular location of the cleavage event. Using PC12 cells as a model, we found that nexin II was also present in freshly prepared cell extracts. Furthermore, nexin II was detected in sedimentable vesicles and was released after permeabilization by digitonin. Pulse-chase analysis demonstrated that APP had a short half-life and was cleaved intracellularly at a late stage in the secretory pathway. Inhibition of protein-transport at the trans-golgi network (TGN) by conducting the chase reaction at 20°C resulted in the inhibition of APP cleavage suggesting that the cleavage event occurs after the APP molecule crosses the TGN. Nexin II secretion was not significantly affected at 23°C and therefore, it is unlikely that the cleavage inhibition was due to the lack of activity of the secretase at this temperature. Cell-surface labelling did not detect any APP on the surface of PC12 cells. These results indicate that APP is cleaved intracellularly in a post-golgi compartment, presumably the constitutive transport vesicles. Such a cleavage reaction has been reported earlier for certain viral proteins such as the Semliki forest virus surface glycoprotein P62.

29.1

NOREPINEPHRINE-INDUCED CALCIUM CURRENT INHIBITION IN ADULT RAT SYMPATHETIC NEURONS DOES NOT REQUIRE PROTEIN KINASE C ACTIVATION. G.G. Schofield and T.P. Abrahams, Dept. Physiology, Tulane University Medical School, New Orleans, LA 70112.

The α_2 -adrenoceptor-mediated inhibition of the Ca^{2+} current of adult rat superior cervical ganglion (SCG) neurons is transduced via a pertussis toxin sensitive G-protein. In dorsal root ganglion neurons norepinephrine-induced inhibition of the Ca^{2+} current is also transduced via a G-protein but requires activation of protein kinase C. Experiments were performed to investigate if protein kinase C is involved in the norepinephrine-induced inhibition of the Ca^{2+} current in adult rat SCG neurons. Ca^{2+} currents were recorded from dispersed SCG neurons, acutely isolated from adult rats using the whole-cell patch-clamp technique. The Ca^{2+} current induced by step depolarizations to +10 mV from a holding potential of -80 mV was decreased by both norepinephrine and by the protein kinase C activator 1,2-dioctanoyl-sn-glycerol (diC8). The Ca^{2+} current rising phase became double exponential in the presence of norepinephrine whereas in the presence of diC8 the rising phase remained mono exponential and the current displayed a prominent decay. Intracellular application of three protein kinase C inhibitors; PKC 19-36, staurosporine and H7, from the patch pipette, had no effect on the norepinephrine-induced Ca^{2+} current inhibition. Moreover, these inhibitors did not decrease the Ca^{2+} current inhibition induced by diC8. Thus, it appears that the α_2 -adrenoceptor-mediated inhibition of the Ca^{2+} current of adult rat superior cervical ganglion neurons is not transduced by protein kinase C activation, and that diC8 can inhibit Ca^{2+} currents by a protein kinase C independent mechanism. Supported by PHS grant HL 43656.

29.3

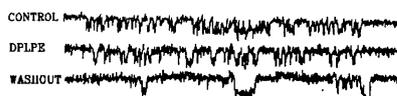

NEUROPEPTIDE Y DECREASES THE CALCIUM CURRENT IN NEURONS ACUTELY DISSOCIATED FROM THE RAT SUPERIOR CERVICAL GANGLION. S. Foucart, D. Bleakman and R.J. Miller, Dept. of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637.

The calcium current (I_{Ca}) and the intracellular calcium signal [Ca^{2+}]_i were measured in acutely dissociated neurons from the adult rat superior cervical ganglion (SCG). The neurons were prepared according to the method of Schofield and Ikeda (Pflüger Arch. 411:481, 1988). In these neurons, simultaneous whole cell patch clamp and [Ca^{2+}]_i measurements showed that somatostatin (SMS) and noradrenaline (NA) reduced the I_{Ca} and the [Ca^{2+}]_i. In the whole cell patch clamp configuration, neuropeptide Y (NPY) also inhibited the I_{Ca} in these cells. While the effects of NA and SMS were observed in most neurons, it was observed that NPY inhibited I_{Ca} mainly in cells with smaller diameter. Overall (n=50), 75% of neurons smaller than 22 μ m responded to NPY whereas only 23% of the neurons larger than 22 μ m were affected by NPY. The maximum current inhibition was 32.4% at a concentration of 1 μ M NPY (n=8) and the IC_{50} value was 143nM. Pretreatment of cells with pertussis toxin (200 ng/ml, 16 hrs) abolished the effect of NPY, NA and SMS. It is concluded that NPY inhibits Ca^{2+} current in a specific population of SCG neurons.

29.5

OPIOID INCREASES MEAN OPEN TIME OF SINGLE L-TYPE CALCIUM CHANNELS IN N1E-115 NEUROBLASTOMA CELLS. E. Reuveny and T. Narahashi, Dept. of Pharmacol. Northwestern Univ. Med. School, Chicago, IL 60611.

The activation of δ -opioid receptors specifically reduces L-type calcium channel currents in NG108-15 neuroblastoma cells (Tsunoo *et al.* PNAS, 83 9832, 1986). We have previously found that during prolonged application of δ receptor agonist, Ca^{2+} channel currents are gradually restored (desensitization). Upon washout of the agonist, currents increase in amplitude by $\approx 40\%$ above the control levels (rebound). We have now studied this modulation at the single-channel level. Cell-attached patches were held at -30 mV and step depolarized to 0 mV for 160 msec. The δ -opioid receptor agonist, DPLPE (1 μ M, applied to the bath) did not change the peak amplitude. In control, during DPLPE application and after washout, the peak amplitudes were 0.96 ± 0.078 , 0.92 ± 0.014 and 0.91 ± 0.12 pA (n=2), respectively. Mean open time histograms for control and in DPLPE were best fitted by single exponential curve to $\tau = 166 \pm 14$ and $\tau = 159 \pm 1$ μ sec, respectively. In contrast, upon washout, the mean open time histogram was best fitted by double exponential curve with $\tau_1 = 93 \pm 33$ and $\tau_2 = 880 \pm 263$ μ sec. The inability of DPLPE to inhibit single Ca^{2+} channel currents suggests direct G-protein interaction. The increase in open time upon washout suggests the involvement of second messengers. Supported by NIH grant NS14144.

29.2

MUSCARINIC MODULATION OF N- AND L-TYPE CALCIUM CHANNELS IN RAT SYMPATHETIC NEURONS. L. Bernheim, A. Mathie and B. Hille, University of Washington, School of Medicine, Seattle WA 98195.

Our previous work on freshly isolated neurons from adult rat superior cervical ganglion showed that muscarinic receptor activation suppresses more than 80% of the whole-cell calcium current. This occurs through parallel pathways, one of which uses a diffusible second messenger. To study modulation at the single channel level, we recorded barium currents from cell-attached patches with pipettes containing 110 mM BaCl₂. The membrane potential of the rest of the cell was zeroed with a bath solution containing 140 mM K-aspartate and 5 mM EGTA. L-type calcium channels were recorded in the presence of 10 μ M ω -conotoxin in the pipette; their activity was greatly enhanced by the dihydropyridine agonist (+)202791 and was not inactivated by holding the patch at -30 mV for several minutes. N-type calcium channel activity recorded without ω -conotoxin was not enhanced by (+)202791 and could be inactivated by holding the patch at -30 mV. Application of 10 μ M oxotremorine-M (a specific muscarinic agonist) by bath perfusion reduced the averaged current through L-type channels by $67 \pm 19\%$ (n=4) and the averaged current through N-type channels by $81 \pm 15\%$ (n=4). The suppression of L-type activity was confirmed using whole-cell voltage-clamp. (+)202791-enhanced calcium tail-currents could be reduced by the muscarinic agonist. Interestingly, noradrenaline (10 μ M in presence of 1 μ M propranolol), which reduces calcium current by about 50% without using the second messenger pathway, failed to act on the (+)202791-enhanced calcium tail-current. This work shows that neuronal L-type calcium channel activity can be decreased by activation of muscarinic receptors but not by activation of α -adrenergic receptors whereas both agonists decrease N-type activity. (NIH NS08174, McKnight Research Award, Fondation Suisse de Bourses en Médecine et Biologie, Fogarty Fellowship F05 TW04457)

CHARACTERIZATION OF INTRACELLULAR CALCIUM INCREASE INDUCED BY M1 AND M3 RECEPTOR SUBTYPE STIMULATION IN LAN-1 HUMAN NEUROBLASTOMA CELLS. A. Patatis, A. Bassi, L.M.T. Canzoniero, G.F. Di Renzo* and L. Annunziato. Section of Pharmacology, Department of Human Communication Sciences II School of Medicine - University of Naples "Federico II" Via Pansini 5 80131 Naples, ITALY.

In LAN-1 human neuroblastoma cells, Carbachol (CCh) in a dose dependent manner (1-1000 nM) caused an increase of [Ca^{2+}]_i, detected on single cell using Fura-2. This increase was characterized by a "peak phase" (10'') and a "plateau phase" that lasted 5-10 minutes in presence of CCh. If the extracellular Ca^{++} was removed, the "peak phase" was still present even if reduced of about 40%, whereas the "plateau phase" was completely abolished, suggesting an involvement of an extracellular calcium influx. This Ca^{++} entrance was Nimodipine insensitive and Verapamil and Gadolinium sensitive. Furthermore, Tetrodotoxin did not prevent CCh-induced [Ca^{++}]_i increase. Pirenzepine and 4-DAMP, two M1 and M3 receptor antagonists respectively, reduced of about 80% the [Ca^{++}]_i increase after CCh treatment, whereas Atropine completely abolished CCh induced calcium influx. Moreover, Pertussis Toxin and Staurosporine did not show any inhibitory activity on CCh induced [Ca^{++}]_i increase, whereas the two intracellular Ca^{++} blockers Phytic acid and Thaps-8 did interfere with cch induced Ca^{++} increase. (Supported by C.N.R. 883416 grant to L.A.)

NICOTINE ACTIVATES A WHOLE-CELL CALCIUM CURRENT IN CULTURED RAT NEOCORTICAL NEURONS. Sam A. Deadwyler, Robert E. Hampson, Jian Mu*, Barbara A. Bennett, Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine, Pat Lippicello, and Eric Fluhler, Div. of Pharmacology, R.J. Reynolds Tobacco Co., Winston-Salem, NC.

Previous studies from these laboratories have demonstrated the presence of nicotinic cholinergic receptors on neurons cultured from fetal rat neocortex (Lippicello *et al.*, JPET 246:409-416, 1988). Experiments utilizing Fura-2 probe demonstrated increases in intracellular calcium levels following nicotine application (Fluhler *et al.*, SN Abstr. 15:679, 1989). These techniques, however, did not demonstrate how nicotine effected calcium entry into these neurons.

The studies to be presented include whole-cell patch clamp recordings of alterations in voltage-clamp currents in cultured cortical neurons following application of nicotine to the bath (20-100 μ M) or via pressure pipette (1mM). At membrane potentials between -50 and -90 mV, a voltage-sensitive potassium current was evoked by depolarizing voltage steps. Following nicotine application, the magnitude and duration of the potassium current was enhanced. The potassium current was also enhanced by barium and blocked by cadmium, indicative of a calcium-mediated potassium (I_{KCa}) current. The nicotine enhancement of I_{KCa} was blocked by d-tubocurarine (60 μ M). Brief application of nicotine to cortical neurons in culture produced a depolarizing current, which reversed at +20 mV. Substitution of choline for sodium in the bath resulted in a 50-75% decrease in nicotine-gated current. This residual current was blocked by cadmium, and by nicotinic receptor blockers d-tubocurarine and hexamethonium.

Nicotinic receptor activation in cortical neurons resulted in calcium entry simultaneous with sodium entry into cells. Similar experiments in cultured hippocampal neurons did not result in nicotine-gated sodium and calcium currents. [Supported by NIDA grant DA05073 (B.A.B.) and a gift from the R.J.Reynolds Tobacco Co. (S.A.D.)]

MULTIPLE WAYS TO REGULATE HIGH THRESHOLD Ca^{++} CURRENTS BY OPIOIDS AND PRIOR ELECTRICAL ACTIVITY. M.D. Womack and E.W. McCleskey. Dept. of Cell Biology and Physiology, Washington Univ. Med. Sch., St. Louis, MO 63110.

What is the physical change in neuronal Ca^{++} channels when they are inhibited by μ opioids? As reported for other neurotransmitters (Bean, 1989; Elmslie et al., 1990), we find that μ opioids often cause Ca^{++} currents in rat dorsal root ganglion neurons to shift their range of gating to more positive voltages. Depolarizing prepulses to potentials greater than +10 mV recruit Ca^{++} channels both in the presence and absence of opioids, but the recruited current is consistently larger in the presence of opioids. These results suggest that μ opioids suppress activity of a population of Ca^{++} channels by shifting their activation range to more depolarized potentials, while electrical activity enhances activity of the same population of channels by shifting the activation curve to more hyperpolarized potentials. Consistent with this hypothesis is the finding that the current recruited by positive prepulses has the same properties as the opioid-sensitive current: it activates at around -40 mV in 3 mM Ba^{++} , it is transient, it inactivates at negative voltages (-90 to -60 mV), and it is blocked by both ω -conotoxin and nifedipine. Opioids also suppress Ca^{++} currents in a voltage-independent manner. In some neurons current amplitude is decreased without a shift of the activation curve. Furthermore, extremely positive prepulses rarely recover all the opioid-sensitive current. Thus, μ opioids regulate Ca^{++} currents through both voltage-dependent and voltage-independent pathways.

Bean, B.P. Nature 340, 153-156 (1989).

SELECTIVE ADENOSINE RECEPTOR ACTIVATION POTENTIATES Ca CURRENT IN ACUTELY ISOLATED HIPPOCAMPAL CA3 PYRAMIDAL NEURONS. D. J. Mogul and A. P. Fox. Dept. of Pharmacol./Physiol., Univ. of Chicago, Chicago, IL 60614.

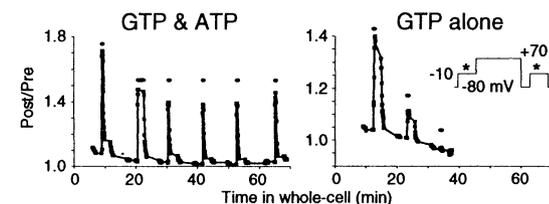

Previously published reports have shown that the exposure of cardiac muscle cells, DRG neurons, and hippocampal pyramidal neurons to adenosine or its analogues elicit a decrement in Ca current (I_{Ca}), possibly by blocking the N-type channel. We have found that the effect of adenosine receptor agonists on I_{Ca} in acutely isolated guinea pig hippocampal pyramidal neurons from the CA3 region depended upon which type of adenosine receptor was activated. We have previously shown that these neurons contain T-, N-, and L-type Ca currents and a whole cell current component not blocked by typical N- and L-type channel blockers. Exposure to the adenosine analogue 2-chloroadenosine (2-CA; 5 μ M) decreased I_{Ca} in most neurons studied. However, in some cells, 2-CA caused an increase in I_{Ca} . If the adenosine A_1 receptor was blocked by the A_1 antagonist, cyclopentyl-theophylline (CPT; 500 μ M), from a holding potential of -100 mV adenosine (50 μ M) potentiated I_{Ca} at test potentials more negative than -30 mV but blocked I_{Ca} at more positive test potentials in the same cell. This potentiation was not blocked by the N-type channel blocker ω -conotoxin but was blocked by Ni^{2+} (100 μ M). Potentiation of I_{Ca} was also observed with the A_2 agonist DPMA (50 nM) but was not seen with the selective A_2 agonist CGS 21680 (50 nM - 1000 nM) suggesting that potentiation of I_{Ca} with adenosine receptor activation does not occur through A_1 or A_2 receptors. In addition, when the holding potential was -60 mV, neither CPT and adenosine nor DPMA produced potentiation of I_{Ca} at any test potential suggesting that the L-type Ca channel was not responsible for the potentiation of I_{Ca} .

29.11

WHOLE-CELL DIALYSIS WITH ATP AND GTP PRESERVES MODULATION OF CALCIUM CURRENT BY NOREPINEPHRINE. Keith S. Elmslie, Jeffrey L. Overholt*, and Stephen W. Jones. Dept. of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH 44106.

Norepinephrine (NE) inhibits whole-cell calcium current in bullfrog sympathetic neurons via a pertussis-sensitive G protein, but it is not clear whether second messengers or protein phosphorylation are also involved. We have examined the effects of internally applied ATP (5 mM) and GTP (0.3 mM) on the NE response. Initially, 10 μ M NE inhibited 25 - 60% of the current regardless of added nucleotides, but over tens of minutes the effect disappeared unless both ATP and GTP were added. The NE response decreased at a similar rate with GTP only, ATP only, and with no added nucleotide. Thus, both ATP and GTP appear to be necessary for maintenance of receptor-channel coupling.

Figure: NE selectively reduces the current during a prepulse to -10 mV (protocol shown at the right), increasing the postpulse/prepulse ratio. This measurement compensates for rundown, which is generally faster without ATP. The short horizontal bars mark applications of 10 μ M NE.

29.8

PHARMACOLOGICAL CHARACTERIZATION OF HIGH VOLTAGE ACTIVATED (HVA) CALCIUM CURRENTS IN DORSAL ROOT GANGLION NEURONS AND THEIR MODULATION BY NOREPINEPHRINE AND GABA. D.H. Cox* and K. Dunlap. Physiology Dept., Tufts Med. Sch., Boston, MA 02111

Norepinephrine (NE) and GABA reversibly inhibit HVA calcium channels in embryonic chick dorsal root ganglion neurons via pharmacologically distinct receptors. Since the HVA calcium current is likely composed of more than a single component, we have first characterized these currents using specific pharmacological agents--omega-conotoxin (ω -CgTx) and a dihydropyridine (DHP) agonist, (+)-(s)-202-791, and antagonist, nimodipine. ω -CgTx (9 μ M) irreversibly blocked ca. 85% of the HVA current. The ω -CgTx-resistant component was reversibly augmented by (+)-(s)-202-791 and inhibited completely by nimodipine. The slow tail current produced by (+)-(s)-202-791 was not inhibited by ω -CgTx, indicating that the DHP-sensitive (L-type) calcium current was not blocked by the toxin. GABA and NE inhibited the HVA calcium current by 30-50%. Pretreatment of the neurons with ω -CgTx eliminated the transmitter-induced inhibition suggesting that NE and GABA target the ω -CgTx-sensitive (N-type) component of the HVA current. This was further demonstrated in experiments with (+)-(s)-202-791. The current during the test pulse was inhibited by GABA while the (+)-(s)-202-791-prolonged tail was unaffected.

SINGLE CALCIUM CHANNEL CURRENTS IN INSULIN-SECRETING HIT-T15 CELLS AND THEIR MODULATION BY GLUCOSE AND BETHANECHOL. J.A. Love, N. Richards*, C. Qwyang*, and D. Dawson*. Depts. of Internal Medicine and Physiology, Univ. of Michigan Med. Center, Ann Arbor, MI 48109

The influx of extracellular Ca^{++} through voltage-dependent channels secondary to membrane depolarization is essential for glucose-stimulated insulin release and its potentiation by cholinergic agonists. To determine whether these secretagogues also modulate Ca^{++} channels independent of changes in membrane potential single-channel (Ba^{++}) currents were recorded from cell-attached patches of HIT-T15 cells. Cells were depolarized to near 0mV by a high K^+ (143 mM) bath solution and depolarizing steps (45-65mV) applied from a holding potential of -70mV. Channel openings with a mean conductance of 30 pS were evoked at patch potentials positive to -40mV and showed little inactivation during prolonged depolarizing steps. BAY K 8644 (1 μ M) prolonged channel openings and patch excision rapidly abolished activity. Increasing bath glucose concentration from 0mM to 20mM (10-30 minutes) resulted in a 257% increase in the frequency of channel opening (n=5). Mean open times were increased 159% (0.39 vs 0.62 msec) in 3 of 5 cells and unchanged in 2 others. Exposure (5-30 min) of cells (n=6) to glucose-free bath solutions containing bethanechol (100 μ M) increased the opening frequency by 218%. Mean open time increased from 0.53 to 0.95 msec (179%) in all 6 cells. Thus, L-type Ca^{++} channels predominate in HIT-T15 cells and channel activity is increased by both nutrient and neural stimulants of insulin secretion independent of effects on membrane potential. CALCIUM CHANNEL CURRENTS IN CULTURED CEREBELLAR GRANULE NEURONES: EFFECTS OF PERTUSSIS TOXIN. H.A. Pearson*, E. Huston*, A.C. Dolphin, Department of Pharmacology, Royal Free Hospital, London NW3 2PF, UK.

Studies of Ca^{2+} -dependent glutamate release from cultured rat cerebellar granule neurones have shown that the $GABA_B$ agonist (-)baclofen inhibits K^+ -evoked release of glutamate, this action being blocked by 16h pretreatment with pertussis toxin (PTX)(1). 16h PTX also increased the amount of glutamate released following K^+ -depolarisation, suggesting a tonic G-protein regulation of Ca^{2+} channels. We have therefore investigated the whole cell Ca^{2+} channel currents (I_{Ba}) in these cells with 10 μ M Ba^{2+} as the charge carrier.

I_{Ba} recorded from the cell body was found to be small and sustained. The threshold for activation of I_{Ba} was typically -40mV from a holding potential of -80mV and the maximal current, 61.0±4.8 pA occurred at -6.9±1.4mV (n=23). The reversal potential for I_{Ba} was 43.7±2.6mV (n=23). The dihydropyridine agonist (+)-202-791 (1 μ M) significantly (p<0.05) increased the current by 36.1±11.5% (n=4) whereas ω -conotoxin GIVA (1 μ M) perfused into cells in 10 μ M Ba^{2+} solution had no effect (n=3). In agreement with this 1 μ M ω -conotoxin did not inhibit K^+ -stimulated glutamate release.

I_{Ba} recorded in cells pretreated with PTX (16h, 150ng/ml) was not significantly different from controls. 16h PTX did, however, attenuate the effect of 100 μ M (-)baclofen on I_{Ba} in these cells (52.8±6.6% inhibition in controls, n=7, 6.2±1.8% inhibition in treated cells, n=3, p<0.005).

These data suggest that I_{Ba} in these cells is carried predominantly by 'L-type' calcium channels which are coupled to $GABA_B$ receptors. The lack of action of PTX on I_{Ba} indicates that there is no tonic G-protein regulation of I_{Ba} at the cell body.

NEUROSTEROIDS BLOCK CALCIUM CURRENT IN FRESHLY ISOLATED GUINEA-PIG HIPPOCAMPAL CA1 NEURONS. K. T. Spence and J. M. H. French-Mullen. Dept. of Pharmacology, ICI Pharmaceuticals Group, ICI Americas Inc., Wilmington, DE 19897.

Neurosteroid block of Ca^{2+} channel current in enzymatically dissociated CA1 neurons from adult guinea-pig hippocampi was examined using the whole-cell patch clamp technique in solutions containing 3 mM external Ba^{2+} and internal NMG-Cl, Cs⁺-BAPTA and Mg²⁺-ATP. I_{Ca} was examined with 5 ms to 1 s depolarizing command steps from a holding potential of -80 mV to a test potential of -10 mV. The steroids Allotetrahydrocorticosterone (THCC), Allotetrahydrodeoxycorticosterone (DHCC), Dehydroepiandrosterone sulfate (DHEAS), Pregnanolone, Allopregnanolone (3 α -OH-DHP), Alfaxalone and Progesterone were applied by rapid superfusion. THCC, 3 α -OH-DHP, THCC, DHEAS and Pregnanolone depressed peak Ca^{2+} current (0.01-100 μ M) with maximal block at 100 μ M of 40, 42, 61, 74 and 78% respectively. The Ca^{2+} current was reversibly blocked through 10 μ M with partial (60-85%) >100 μ M. Alfaxalone showed a 29% block at 100 μ M; progesterone had no effect. Picrotoxin (10 μ M), had no effect on the Ca^{2+} current and/or the blocking action of these steroids. THCC and Pregnanolone showed no change in the peak I-V relationship or deactivation kinetics. THCC, 0.1-10 μ M, selectively depressed the inactivating (N-type) portion of the current. In the presence of 10 μ M omega-conotoxin (fraction GVIA: CTX), THCC (10 & 100 μ M) had no effect. Conversely, in the presence of THCC (10 & 100 μ M), CTX had no effect. In contrast, pregnanolone continued to block. These results demonstrate a novel action of certain neurosteroids: blockade of voltage-gated calcium channels in mammalian hippocampal neurons. Secondly, an endogenous compound, THCC, appears to act at a separate site to selectively depress the CTX sensitive, inactivating or (N-type) channel. Thus, in addition to the GABA-gated Cl⁻ current, the data suggest an additional site at which the steroids exert their pharmacological actions to modulate brain excitability.

USE-DEPENDENT BLOCK OF CALCIUM CURRENT BY PHENCYCLIDINE IN ACUTELY DISSOCIATED HIPPOCAMPAL NEURONS. J.M.H. French-Mullen¹ and M.A. Rogawski². ¹ICI Americas, Wilmington, DE 19897 and ²Neuronal Excitability Section, Bethesda, MD 20892.

Phencyclidine (PCP) is well known to block a variety of ion channels in excitable cells. However, voltage-dependent Ca^{2+} channels in most tissues are relatively resistant to the drug. One exception is the Ca^{2+} channel in acutely dissociated adult guinea-pig CA1 hippocampal neurons activated by step depolarization from -80 to -10 mV which is reversibly depressed by PCP in a voltage-dependent manner by low concentrations of PCP (IC_{50} , 7 μ M; *Soc. Neurosci. Abstr.* 16: 510, 1990). We now report that the PCP block occurs in a use-dependent fashion with trapping of the drug by the resting channel. Ca^{2+} channel currents were recorded with patch electrodes containing an ATP regenerating system to minimize rundown and with 3 mM Ba^{2+} in the extracellular solution as charge carrier. PCP (5 μ M) was equilibrated with the cells and trains of repetitive 10 ms duration depolarizing stimuli were applied at various rates. Negligible block of the peak current was observed with the first stimulus in the trains. Steady-state block was achieved with subsequent steps according to an exponential course. The use-dependent development of block was analyzed according to the guarded receptor model of Starmer *et al.* (*J. theor. Biol.* 124: 335, 1987). The uptake rate (k^*) was dependent upon stimulation interval (0.5 - 15 s) with an apparent unbinding rate (k_u) of 0.1 s⁻¹. However, there was no rate-dependent increase in steady state block and upon termination of the stimulus trains, no recovery of the current occurred even with recovery intervals of up to 5 min. Upon perfusion with drug-free solution, complete recovery was always obtained upon the presentation of 3 to 6 stimuli. We conclude that PCP block of Ca^{2+} current in CA1 neurons occurs in a strongly use-dependent fashion with an apparent unbinding rate that is distinct from the negligible true unbinding rate suggesting a novel blocking mechanism.

DM-9384, A NEW COGNITION-ENHANCING AGENT, IS A POTENT FACILITATOR OF NEURONAL Ca CHANNEL ACTIVITY AS COMPARED WITH OTHER PYRROLIDONE DERIVATIVES. S. Watabe¹, M. Yoshii², H. Yamaguchi^{1*} and S. Ashida^{1*}. ¹Explor. Res. Lab. II, Daiichi Pharmaceutical Co., Ltd., Tokyo 134, Japan and ²Dept. Neurophysiol., Psychiatric Res. Inst. Tokyo, Tokyo 156, Japan.

Recent neurochemical studies have reported that DM-9384 (N-(2,6-dimethylphenyl)-2-(2-oxo-1-pyrrolidinyl)acetamide) increases transmitter release from GABAergic and cholinergic neurons in the rat cortex (Watabe *et al.*, *Soc. Neurosci. Abstr.* 15, 601, 1989; 16, 137, 1990). One possible way to explain this effect is that the drug may potentiate Ca channel opening that regulates transmitter release. This possibility has been supported by our recent whole-cell patch-clamp study in neuroblastoma x glioma hybrid (NG108-15) cells, in which long-lasting (type II) Ca channel currents were markedly increased by DM-9384 (Yoshii and Watabe, *Biophys. J.* 59, 82a, 1991). In the present study, we have compared the potency of four different pyrrolidone derivatives in the Ca channel facilitation at a constant concentration of 1 μ M. Type II channel currents were increased in the following sequence: DM-9384 (by more than 100%) > aniracetam (by 50-70%) > oxiracetam (by 10-25%) >> piracetam (no significant increase). The present results were consistent with the previous reports that GABA and ACh releases were both potentiated by DM-9384 whereas they were not increased remarkably by either aniracetam or oxiracetam.

GLUCOCORTICOID ENHANCE DIHYDROPYRIDINE BINDING TO SYNAPTOSOMAL PLASMA MEMBRANE FROM RAT BRAIN. Paul Y. Sze and Zafar Iqbal. Dept. of Pharmacol. & Mol. Biol., The Chicago Medical School, North Chicago, IL 60064, and Dept. of Neurology, Northwestern Univ. Medical School, Chicago, IL 60611.

The effects of glucocorticoids on the uptake of $^{45}Ca^{2+}$ were determined in intact synaptosomes from rat cerebral cortex following depolarization of the membrane by high K^+ (70 mM). Preincubation of the synaptosomes with corticosterone (50 nM-1 μ M) at 37 °C for 15 min. resulted in an increase of the depolarization stimulated uptake of $^{45}Ca^{2+}$ (70-80% above the control at 1 μ M). Cortisol, dexamethasone and triamcinolone were similarly effective, whereas 17 β -estradiol and progesterone produced only small and insignificant increases.

To examine the effects of glucocorticoids on Ca^{2+} channels, specific binding of [³H]PN-200-110 was determined following the disruption of the synaptosomes by sonication. Preincubation of the membrane preparation with corticosterone (1 μ M) had no effect on the radiolabeled dihydropyridine binding. However, when intact synaptosomes were preincubated with the steroid and then disrupted, the membrane binding of [³H]PN-200-110 was markedly increased. Scatchard analysis indicates that the increase of radioligand binding was due to an increase of the binding sites. It appears that a cytosolic factor(s) was required in the steroid action which led to an increase of the active dihydropyridine binding sites on the synaptosomal membrane.

Our results support the notion that glucocorticoids act on synaptosomal plasma membrane and one of such membrane actions is the modulation of L-subtype Ca^{2+} channels.

EFFECTS OF ANESTHETICS ON INTRACELLULAR Ca^{2+} LEVELS OF MAMMALIAN NEURONS. M.E. Morris, S.K. Nsonwah* and D. Shnier*. Department of Pharmacology, University of Ottawa, Ottawa, Canada K1H 8M5.

Neurons were isolated from brains of 11-13 day-old mouse embryos, incubated with fura-2 AM, and prepared in a 4 x 10⁶ cells/ml suspension for fluorimetric cuvette analysis of Ca_i (Morris *et al.* 1987 *Exp. Brain Res.* 65: 520). Effects of ketamine (5-200 μ M), hexanol (1-800 mM) and ethanol (10-800 mM) were observed on resting Ca_i levels in normal, Ca-free and low-Na Ringer solutions and on responses evoked by 10-100 mM KCl. Ketamine produced only small and variable change in resting Ca_i and had no effect on voltage-dependent Ca^{2+} entry. Hexanol evoked dose-dependent \uparrow 's in Ca_i in the presence of Ca_o and decreases in its absence; \geq 30 mM hexanol caused progressively greater Ca^{2+} membrane permeability. In contrast, single/sequential additions of ethanol evoked graded \uparrow 's in Ca_i in normal, Ca-free and low-Na Ringer. Increasing concentrations of ethanol progressively attenuated and reversed the Ca_i \uparrow 's evoked by \uparrow K_o . It is concluded that an intracellular release of Ca^{2+} significantly contributes to the accumulation of Ca_i evoked by ethanol, and that with the presence/production of high Ca_o /depolarization mechanisms of uptake/outward transport may also be enhanced/activated.

ROLE OF GTP-BINDING PROTEINS IN ETHANOL-INDUCED SUPPRESSION OF L-TYPE CALCIUM CHANNELS IN NEURONS OF LONG- AND SHORT-SLEEP MICE. G.-J. Huang & J.J. McArdle, Dept. Pharmacology & Toxicology, New Jersey Medical School (UMDNJ), Newark, NJ 07103-2714.

In previous reports, we noted that ethanol produces a dose-dependent biphasic alteration of the calcium currents (I_{Ca}) mediated by L-type calcium channels of neurons in cultured dorsal root ganglia; i.e., 25 mg% enhances while 200 mg% depresses I_{Ca} . While single channel recording indicates that these effects of ethanol are secondary to an increase and decrease, respectively, of the probability of single channel opening the underlying mechanism remains unknown. In order to explore this mechanism, we have used the whole cell recording technique to dialyze cells of long (LS) and short (SS) sleep mice with intracellular solutions containing 100 μ M GTP- γ -S or GDP- β -S. The latter compound did not alter the effect of 25 and 200 mg% ethanol on I_{Ca} for both strains of mice. In contrast, GTP- γ -S produced an interesting change in the influence of ethanol on I_{Ca} . Specifically, the voltage-sensitivity of I_{Ca} for LS neurons was shifted to the right in a time dependent manner. That is, control I_{Ca} was maximal in response to a voltage-clamp command to 8 mV while the same amplitude of I_{Ca} was elicited in response to a step to 35 mV at 10 min after exposure to 200 mg% ethanol. Our findings extend Bean's (Nature 340:152) suggestion that chemicals can suppress I_{Ca} by changing its voltage dependence. This shift of the voltage sensitivity was less for the neurons of SS mice. Supported by NIAAA grant R01 AA08025.

CHRONIC ETHANOL FEEDING INCREASES RAT CARDIAC BUT NOT NEURONAL CALCIUM CHANNEL DENSITY. M.H. Hawthorn and R. Bangalore. Dept. of Biochemical Pharmacology, School of Pharmacy, SUNY at Buffalo, Buffalo, NY 14260.

The recent observation that tolerance to ethanol is associated with an increase in L-type calcium channel density in the cortex led us to examine if this occurred in other brain areas and with other VDCC subtypes. Rats (220-260g) were chronically fed an alcohol containing diet (4.5%) according to the method of Miller (1980). This diet induced tolerance to ethanol as indicated by the length of time animals could stay on a rotor rod at 60 rpm. An i.p. injection of ethanol (1g/kg) caused a fall of $71.5 \pm 5.9\%$ in the time control animals stayed on the rotor rod but only a $26.8 \pm 11\%$ fall in the alcohol treated animals. However, unlike previously reported observations, L-type calcium channel density as assessed by [3 H]PN200-110 binding was not altered in the cortex of tolerant rats with B_{max} values being 398 ± 29.2 and 313 ± 76.3 fmol/mg in control and treated animals respectively. There was also no change in density in the striatum (200 ± 16.8 fmol/mg control and 194 ± 29 fmol/mg treated) or hippocampus (304 ± 23 fmol/mg control and 308 ± 33 fmol/mg treated). Ethanol had no effect on the K_D in any of the brain regions studied. Ethanol treatment was also without effect on N channel density as assessed by [125 I] ω -conotoxin in the brain areas examined. B_{max} values in control animals were 2180 ± 260 fmol/mg, 1109 ± 40 fmol/mg and 937 ± 95 fmol/mg for the cortex, striatum and hippocampus respectively and 2940 ± 330 fmol/mg, 942 ± 103 fmol/mg and 989 ± 117 fmol/mg in treated animals.

In contrast to neuronal tissue, density of L-type calcium channels in the heart was increased 30% after chronic ethanol treatment, with the B_{max} for [3 H]PN200-110 increasing from 402 ± 38.6 fmol/mg in control animals to 520 ± 31.2 fmol/mg in treated animals with no change in K_D .

ELECTROPHYSIOLOGICAL EFFECTS OF LOW DOSE ETHANOL ON CALCIUM CURRENTS IN DENTATE GRANULE NEURONS AT PHYSIOLOGICAL TEMPERATURE.

S.S. Jahromi and P.L. Carlen. Playfair Neuroscience Unit, Addiction Research Foundation, Departments of Physiology and Medicine (Neurology), Toronto Western Hospital, University of Toronto, Toronto, Ontario, M5T 2S8.

Ethanol has been shown to affect several Ca^{2+} -related processes in different neuronal preparations (Carlen and Wu, Int. Rev. Neurobiol., 22, 161-189, 1988). The purpose of this study is to examine the effects of low dose (20 mM) ethanol on Ca^{2+} currents at physiological temperature (36°C) in a central mammalian neuron. Adult Wistar rat hippocampal dentate granule neurons were perfused with a medium containing K^+ and Na^+ channel blockers as per Blaxter et al. (J. Physiol., 412, 93-112, 1989). Single electrode voltage clamp recordings of Ca^{2+} currents were obtained with 3M CsCl electrodes. Voltage clamp pulses of over 500 ms were delivered at different holding potentials. At hyperpolarized holding potentials, there was little effect on the early peak (unclamped) current, but some depression of the later slowly inactivating inward current was observed. The most consistent effect of ethanol was partial suppression of the L-type current elicited from depolarized holding potentials. In the majority of cells, this effect was reversible after wash.

It is hypothesized that ethanol enhances Ca^{2+} -mediated inactivation of Ca^{2+} currents at physiological temperature.

POTASSIUM CHANNELS: PHYSIOLOGY AND REGULATION I

30.1

INHIBITION BY CARBACHOL OF M-CURRENT AND POTASSIUM LEAK CONDUCTANCE IN NEURONS OF THE BASOLATERAL AMYGDALA. M.D. Womble and H.C. Moises. Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

Stimulation of cholinergic pathways or application of muscarinic agonists depolarizes neurons of the basolateral amygdala (BLA) and increases their input resistance (Washburn & Moises, Neurosci. Abstr. 15:193, 1989). These effects have been examined in rat BLA cells *in vitro* with the single-electrode voltage-clamp. Hyperpolarizing commands from a holding potential (V_H) of -40 mV identify the muscarinic-sensitive M-current (I_M) as a slow, inward current relaxation. Total M-conductance rises steeply with depolarization from -70 mV, the lower limit for I_M activation. At $V_H = -40$ mV, the application of carbachol produces an inward current shift and decreases membrane chord conductance. These effects represent inhibition of both the voltage-dependent M-current, and a voltage-independent K^+ leak current (I_{leak}). At potentials negative to -70 mV, only inhibition of I_{leak} is seen. Both currents are inhibited by carbachol in a dose-dependent and atropine-sensitive manner, indicating activation of muscarinic receptors. In control saline (3.5 mM K^+), I_M and I_{leak} show reversal potentials of -84 and -108 mV, respectively, and these are shifted in the positive direction by elevation of $[K^+]_{out}$. In a minority of cells, the instantaneous I-V curves at $V_H = -70$ mV (\pm carbachol) do not cross, possibly indicating the activation by carbachol of a non-specific dendritic conductance. We conclude that muscarinic activation produces inhibition of both M-current and a nonvoltage-dependent potassium leak conductance. (Supported by NIDA grant DA03365).

30.3

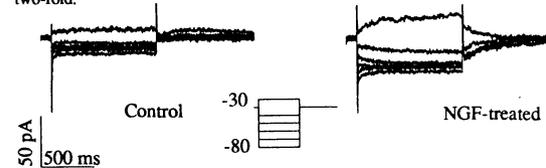

MULTIPLE TYPES OF GLUCOSE-SENSITIVE K^+ CHANNELS IN HIPPOCAMPAL AND CORTICAL NEURONS C. Tromba, A. Salvaggio, P. Cassutti, G. Racagni & A. Volterra. Ctr. Neuropharmacology & Inst. Pharmacol. Sci., Univ. Milan, Farmitalia Carlo Erba, Milan, Italy.

Glucose-sensitive K^+ channels (K_{ATP}) have been described in central neurons. They may participate in the control of cell excitability and neurotransmitter release and their activity may be altered in hypoglycemic/ischemic conditions. Using the cell-attached mode of the patch-clamp technique we are trying to identify K_{ATP} channels on rat hippocampal and cortical neurons in primary culture. Cells are patched with pipettes containing in mM: KCl 130, $CaCl_2$ 1, $MgCl_2$ 1, Hepes-KOH 10, and superfused with Tyrode's solution with or without 20 mM glucose. Not all the recorded channels show sensitivity to changes in glucose concentration. However, at least 3 different types have their activity reversibly decreased by glucose: a "big" channel of 5 pA, an "intermediate" one of 2 pA, both open at rest ($V_p = 0$ mV), and a "small" channel of 0.8 pA, seen on hyperpolarization ($V_p = +40$ mV). Different glucose-sensitive channels sometimes coexist in the same patch. In conclusion, glucose-sensitivity is not a property of a specific type of K^+ channels in brain, but of a discrete "family".

30.2

NGF Induced Expression of M-Current in PC 12 Cells. N.V. Marrion, N.E. Kremer, S. Halegoua* & P.R. Adams*. Dept. of Neurobiology & Behavior & HHMI, SUNY at Stony Brook, NY 11794.

NGF induces PC 12 cells to develop a sympathetic neuron-like phenotype. Sympathetic neurons characteristically show a non-inactivating potassium current called the M-current. The presence of M-current in PC 12 cells before and after treatment with NGF was determined. PC 12 cells were whole-cell voltage clamped at -30 mV and the presence of M-current was tested by stepping the voltage depolarized or hyperpolarized for 1 second. M-current was absent from cells not treated with NGF. However, time- and voltage-dependent current relaxations characteristic of M-current were apparent within 24 hours after addition of NGF (30 ng/ml). NGF treatment increased cell capacity less than two-fold.

A channel density of $0.3 \mu m^{-2}$ and a unitary current of 0.2 pA ($\gamma = 4$ pS) were estimated using nonstationary noise analysis.

To determine the signal transduction pathway for NGF's action we have initiated study of M-current expression in a PC 12 subline expressing a temperature sensitive v-src tyrosine kinase. When these cells were grown at the non-permissive temperature (41°C) the M-current was absent. A shift to the permissive temperature (35°C) caused appearance of M-current at a channel density similar to that seen with NGF. These results suggest that the expression of M-channels is induced by NGF, an effect which may be mediated via src activation.

30.4

MAJOR DIFFERENCES IN CNS K_{ATP} CHANNEL DISTRIBUTION BETWEEN RAT (NEWBORN, ADULT) AND TURTLE. Y. Xia and G. G. Haddad. Dept. of Pediatrics, Section of Respiratory Medicine, Yale University School of Medicine, CT 06510.

Using electrophysiological techniques, we have previously shown that 1) K_{ATP} channels are key regulators of K^+ homeostasis and neuronal responsiveness in the rat brain during hypoxia and 2) their role is quantitatively more important in the adult than in the newborn. The purpose of this present study was to examine the distribution of K_{ATP} channels using labelled glibenclamide, a potent sulfonylurea ligand which targets K_{ATP} channels, in the adult and newborn rat CNS. Since the adult turtle is resistant to anoxia, we also compared rat to turtle brain K_{ATP} channel distribution. In all animals, specific glibenclamide binding was saturable. Scatchard plots suggested that glibenclamide was bound to two types of sites in the rat and one type in the turtle. Autoradiographic images shows that distribution of glibenclamide sites was heterogeneous in the adult rat CNS with a higher density in rostral than in caudal regions. The highest binding densities were seen in the cortex, hippocampus, cerebellum, substantia nigra and a few thalamic nuclei. There were intermediate densities in the basal ganglia, septum, and hypoglossal nucleus and low density in most nuclei of the hypothalamus, midbrain, brainstem and spinal cord. The newborn rat (5 day) had a homogeneous distribution throughout the CNS but 5-10 X lower density than the adult CNS. The binding density was even lower in the turtle than in the newborn rat. Our results suggest that the mature mammalian brain is rich in glibenclamide sites and the immature mammalian or reptile brain is not. We suggest that K_{ATP} channels are expressed postnatally with maturation and speculate that they may be new phylogenetic receptors in the CNS.

GLIBENCLAMIDE ANTAGONIZES PREJUNCTIONAL EFFECTS OF DIAZOXIDE AT FROG NEUROMUSCULAR JUNCTION. Delanhi Salgado and Karim A. Alkadhi, Department of Pharmacology, University of Houston, Houston, TX 77204-5515

The K^+ channel openers cromakalim and diazoxide have been shown to decrease evoked (endplate potentials, EPPs) without affecting spontaneous transmitter release (miniature EPP, MEPPs) at the frog neuromuscular junction (Salgado et. al., *FASEB J.* 5:A1598, 1991). In order to determine whether the observed action is related to opening of the ATP-regulated K^+ channels (K_{ATP}) the effects of diazoxide in the absence and presence of a selective channel blocker were investigated. Glibenclamide (10 μ M), a selective K_{ATP} blocker, caused an immediate and significant depolarization of the muscle membrane (control RMP: -82 ± 1 mV; 20 min after glibenclamide: -73 ± 4 mV; $p > 0.05$, $n=3$). However, the resting potential of the membrane gradually recovered. Other than this depolarization of the membrane potential, glibenclamide by itself had no significant effect on the parameters of transmitter release. Furthermore, glibenclamide had no significant effect on MEPP frequency. In the presence of glibenclamide, diazoxide failed to decrease the EPP amplitude and there was no significant effect on the quantal content. These results indicate that the inhibition of evoked release by diazoxide involves K_{ATP} channels that exist prejunctionally.

CROMAKALIM-INDUCED HYPERPOLARIZATION IMAGED IN SINGLE RAT CULTURED NEURONS IS GLYBURIDE-INHIBITABLE AND CORRELATED WITH INHIBITION OF ELEVATED $[Ca^{2+}]_i$ DURING DEPOLARIZATION. J. Chisholm, J. Davis* and E. Hühnicutt, Miles Inst. Preclin. Pharm., West Haven, CT 06516

The localization of a specific subset of K^+ channels (K_{ATP}), defined pharmacologically by sulfonylurea inhibitors such as glyburide (GLB), and by K-channel agonists including cromakalim (CRK), has recently been extended to the mammalian CNS. We now report that CRK dose-dependently inhibits elevated $[Ca^{2+}]_i$ during sustained depolarization, measured in single fura2-loaded neurons, and dose-dependently hyperpolarizes single neurons during sustained depolarization measured with bisoxonol. Hyperpolarizing responses to CRK are completely inhibited by 1 μ M GLB (block by GLB pretreatment is not mimicked by GLB treatment after CRK.) These data are consistent with a physiological relevance of these channels to intracellular calcium ($[Ca^{2+}]_i$) metabolism in neurons.

DEPRESSION BY VOLTAGE-DEPENDENT INACTIVATION OR BY BARIUM OF THE DELAYED RECTIFIER OF RAT HIPPOCAMPAL NEURONES. A. Nistri¹ and E. Cherubini², INSERM U29, 123 Bd de Port-Royal, 75014 Paris, France.

Responses from CA3 pyramidal neurones of the adult rat hippocampal slice preparation were recorded under single electrode voltage clamp at 33°C. A TEA (20 mM) sensitive slow outward K^+ current was identified as the delayed rectifier (I_K) after suppression of other voltage-dependent conductances with tetrodotoxin (1 μ M), 4-aminopyridine (2 mM), Co^{2+} (2 mM), Cs^+ (2 mM), and carbachol (50 μ M) in a Ca^{2+} -free superfusing solution. Voltage-dependent inactivation of I_K was shown with hyperpolarizing prepulses (from -55 to -100 mV) which enhanced the steady state amplitude of I_K elicited by steps positive to -50 mV. Half inactivation was reached at -80 mV, and was dependent on the interval between prepulse and test pulse (τ 211 ms). Low concentrations of barium (0.1-0.3 mM) reduced, in a voltage independent fashion, the amplitude of I_K by up to 50% without affecting its inactivation properties. These data suggest that membrane hyper-polarization enhances the ability of I_K to inhibit neuronal excitability. Furthermore, the barium-induced depression of I_K may contribute to the bursting behaviour elicited by this cation.

CHARACTERIZATION OF [³H]GLIBENCLAMIDE BINDING TO RAT CEREBRAL CORTEX AND HEART MEMBRANE PREPARATIONS. C.E. Stidsen, Dept. of Molecular Pharmacology, Bioscience, Novo Nordisk A/S, DK-2880 Bagsvaerd, Denmark.

Binding of [³H]glibenclamide, a sulfonylurea, to rat cerebral cortex, heart and pancreatic β -cells is highly specific with only small differences in binding constants. The sulfonylureas are supposed to label ATP-dependent potassium channels due to their ability to inhibit potassium currents in ATP-depleted preparations measured electrophysiologically or using ⁸⁶Rb. It was recently shown that a radioiodinated analogue of glibenclamide labeled three distinct proteins, the one (140 kDa) with high affinity, the others (65 kDa and 43 kDa) with low affinity. It is still uncertain whether the action of glibenclamide on ATP-dependent potassium channels is due to a direct interaction with the channel protein or is exerted via a modulatory subunit.

Exercising strict control of buffer ionic composition, the biochemical and pharmacological characteristics of [³H]glibenclamide binding to rat cerebral cortex and heart *in vitro* will be discussed, especially evaluating the question of direct or indirect potassium channel modulation.

EFFECTS OF CALCIUM AND ADRENALINE ON POTASSIUM CURRENT IN TONIC SKELETAL MUSCLE FIBERS OF THE FROG. J. Lomeli*, C. Vázquez*, X. Trujillo*, M. Huerta and J. Muñoz*, Centro Universitario de Investigaciones Biomédicas, Universidad de Colima, Apdo. Postal 199, 28000 Colima, Col., México.

We investigated the presence of a calcium-activated potassium (K^+) current in tonic skeletal muscle fibers. Experiments were done on cruralis muscle of *Rana pipiens*, using three-microelectrode voltage-clamp technique (Adrian, Chandler & Hodgkin, 1970). The normal solution contained (mM): Na-CH₃SO₃, 117.5; K-CH₃SO₃, 2.5; Ca(CH₃SO₃)₂, 1.8 and sucrose 350. Muscle fibers were identified according to their passive electrical properties. Control outward K^+ currents were recorded in the normal solution. When the external calcium was omitted from the solution, the amplitude of the K^+ currents were reduced c.a. 250% ($n=3$). In contrast, if external calcium was increased to 11.8 mM, the K^+ current was incremented 200% from the previous control currents ($n=5$). In this same experimental condition, with high calcium, we added adrenaline (5 μ M), which augmented the $[Ca^{2+}]_i$, and a new increase of potassium current was observed until 50% ($n=5$). These results suggest the presence of calcium-activated K^+ channels in the membranes of tonic skeletal muscle fibers of the frog. + CONACyT fellowship.

VOLTAGE-GATED POTASSIUM CURRENTS IN ACUTELY-DISSOCIATED RAT NEOCORTICAL NEURONS. R.C. Foehring and D.J. Surmeier, Department of Anatomy and Neurobiology, University of Tennessee, Memphis, Memphis, TN 38103-4901.

There is controversy in the literature concerning the number, kinetics and pharmacology of voltage-gated K^+ currents in neocortical neurons. We tested the hypothesis that three such currents were present in acutely-dissociated neocortical neurons: a traditional A current (I_{AF}), a transient current with slower kinetics (I_{AS}), and a delayed rectifier (I_K). Cells were dissociated using pronase E treatment followed by mechanical trituration. An attempt was made to select for cells with pyramidal-shaped somas and small processes. TTX (1 μ M) and CdCl₂ (400 μ M) were present in the bath to block Na- and Ca-dependent currents.

We found evidence for all three voltage-gated (non-Ca-gated) K^+ currents in adult neocortical neurons. All cells displayed a large outward current at voltages above -40 to -30 mV which inactivated relatively slowly. Kinetic analysis of deactivation tails suggest that at least two conductances contribute to this current: I_{AS} and I_K . Some neurons displayed a distinct early current which peaked in 6-10 ms (as expected for I_{AF}), while others did not. The currents were differentiated in several other ways including their sensitivity to the pharmacological blockers 4AP, TEA, and dendrotoxin. Supported by NINDS grant NS27180.

POTASSIUM CHANNELS OPEN AT RESTING MEMBRANE POTENTIAL IN CULTURED GUINEA PIG ADRENAL GLOMERULOSA CELLS. M.N. Satyanarayan & D.P. Lotshaw, Depts. of Physiol. and Biol. Sci., Univ. of Kentucky, Lexington, KY 40506

Angiotensin II (AII)-induced depolarization of the adrenal glomerulosa cell contributes to the mechanism of AII stimulation of aldosterone secretion. AII-induced depolarization is thought to be mediated by a decrease in resting K^+ conductance (Quinn et al., *Endocrinology* 120:1581). In order to elucidate AII regulation of plasma membrane ion channels and mechanisms regulating steroidogenesis, we initiated a characterization of K^+ channels involved in the glomerulosa cell resting membrane potential. Guinea pig adrenal capsules were dissociated by collagenase treatment and dispersed glomerulosa cells maintained in primary cell culture. Cultured glomerulosa cells were identified by a nearly circular shape and diameter less than 15 microns. For cell-attached patch clamp recordings, cells were bathed in Krebs's Ringer and patch pipettes were filled with a K^+ -rich solution (in mM: 150-KCl, 1.25-CaCl₂, 1.2-MgCl₂) to select for K^+ channel currents. At the resting membrane potential, multiple current amplitudes and open time kinetics were observed for both inward and outward currents. Outward currents appeared to represent anion channels, usually reversing direction of current flow in response to positive polarization of the pipette by 10 to 20 mV (hyperpolarization of the patch membrane potential). Inward currents behaved like K^+ channels, increasing in amplitude with patch membrane hyperpolarization and decreasing with depolarization. Inward currents were also observed to reverse with depolarization of the patch membrane by 70 to 80 mV, consistent with the estimated reversal potential for K^+ in these cells. These results indicated that multiple species of K^+ channels open at the resting potential and may be involved in determination of membrane potential. TETRANDRINE BLOCKS Ca^{2+} -ACTIVATED K^+ CHANNELS BESIDES INHIBITING A Ca^{2+} -CURRENT IN RAT NEUROHYPOPHYSIAL NERVE TERMINALS. G. Wang and J.R. Lemos, Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, MA 01545.

(+)-Tetrandrine (Tet), an alkaloid with a bis-benzylisoquinoline structure isolated from the Chinese medicinal plant *Stephania tetrandra*, has been widely used in China for the treatment of hypertension. The mechanism for its hypotensive action is considered to be related to its negative inotropic effect by blocking L-type Ca channels in myocardium and arteries.

In the present study, the effects of Tet on the Ca^{2+} -current (I_{Ca}) and the Ca^{2+} -activated K^+ current ($I_{K,Ca}$) of isolated rat neurohypophysial nerve terminals (containing either vasopressin or oxytocin) were investigated using whole-cell and outside-out patch-clamp techniques. I_{Ca} was elicited with either 10 mM Ca^{2+} or Ba^{2+} in the bath solution. There are two components to the neurohypophysial I_{Ca} . Low concentrations of Tet (3-15 μ M) inhibit the long-lasting component in a dose-dependent manner. The I_{Ca} is 13.5 μ M. However, no effect by low doses of Tet on the transient component was observed. Higher doses (100 μ M) of Tet significantly inhibit both I_{Ca} components. Furthermore, Tet (7-30 μ M) also markedly inhibits, in a voltage-dependent manner, the $I_{K,Ca}$ of the terminals which is activated by 10 μ M Ca^{2+} in the pipette solution. At the single channel level, in the presence of 7 μ M Tet, the open time duration of the large-conductance K^+ channel was greatly decreased when depolarizing from -50 mV to +40 mV. Tet, however, did not affect the I_{Na} or I_A of the terminals at such a low concentration.

The results that Tet, at nearly the same doses, blocked only I_{Ca} and $I_{K,Ca}$ in the isolated nerve terminals suggests the possibility that in these two channels there are receptor sites with similar structure for binding Tet. In addition, by inhibiting I_{Ca} , Tet possibly interferes with the release of vasopressin, which would contribute to its hypotensive action.

CALCIUM-ACTIVATED POTASSIUM CHANNELS IN SMOOTH MUSCLE CELLS OF RAT CEREBRAL ARTERY. Y.Wang and D.A.Mathers, Department of Physiology, University of British Columbia, Vancouver B.C., Canada V6T 1W5.

This experiments were performed to study the nature of calcium-dependent potassium, K(Ca) channels in smooth muscle cells (SMCs) derived from cerebral arteries of adult Wistar rats. Enzyme dissociated SMCs were maintained in a solution containing (mM): NaCl 130, KCl 5, CaCl₂ 0.8, MgCl₂ 1.3, glucose 5 and HEPES 10 at 4°C for 1-3 days prior to use. Inside-out patch clamp recordings were made at 21-23°C using a List EPC-5 amplifier (bandwidth DC-2 KHz).

Two populations of K(Ca) channels were identified, these having single-channel conductances of about 200pS and 90pS respectively in symmetrical 140 mM K^+ solutions. Both channel types were activated by membrane depolarization when the cytoplasmic membrane face was bathed in low calcium solutions. The probability of either channel type being open increased when the concentration of calcium ions bathing the cytoplasmic membrane face was raised, especially over the range of 0.1-10 μ M. Both channel types showed negligible permeability to Na^+ or Cs^+ and both were blocked by application of tetraethylammonium (TEA, 5 mM) to the cytoplasmic membrane face.

Dendrotoxin and mast cell degranulating peptide block a voltage-activated potassium current in acutely isolated chick ciliary ganglion neurons. M.E. Wcislo and S.E. Dryer, Program in Psychobiology and Neuroscience, Dept. of Biological Science, Florida State University, Tallahassee, FL 32306.

Voltage-activated K^+ currents were studied using whole-cell recordings from ciliary ganglion neurons obtained from E10-E14 chick embryos. Recordings were made in Ca^{2+} -free salines to minimize activation of Ca^{2+} -dependent K^+ currents. Ciliary neurons express two types of voltage-activated K^+ currents based on differences in kinetics and sensitivity to blockade by TEA. The delayed rectifier current (I_{DR}) is blocked by TEA, activates slowly, and shows a subsequent slow inactivation. The inactivation time constant shows considerable variation from cell to cell, but is always greater than 180ms at +30mV. I_{DR} shows half-maximal activation close to 0mV, and half-maximal steady-state inactivation at -40mV. In contrast, I_A is resistant to TEA, activates rapidly, and becomes inactivated rapidly (time constant of 14-25ms at +30mV). Half-maximal activation of I_A is at -20mV, while steady-state inactivation is half maximal at -80mV. Application of 2mM 4-AP partially blocks both currents. Dendrotoxin (280nM) and mast cell degranulating peptide (200nM) had very similar effects, each producing a partial but selective blockade of I_{DR} . Blockade produced by both peptide neurotoxins was best seen when I_{DR} was evoked by depolarizing steps positive to 0 mV. Neither toxin produced detectable blockade of I_A .

LARGE CONDUCTANCE, CALCIUM ACTIVATED K^+ CHANNEL IN CEREBELLAR GRANULE CELLS. S.-P. Olesen*, E.Ø. Nielsen and J. Drejer*, NeuroSearch A/S, Smedeland 26, DK-2600 Glostrup, Denmark.

Cerebellar granule cells represent the only excitatory neurons in the cerebellar cortex. Neuronal cultures obtained from 7-day-old mouse cerebellum are well characterized and consist of around 95% cerebellar granule cells. Patch-clamp studies on excitatory amino acid activated cation channels and on GABA activated chloride channels have been performed on cerebellar granule cells. Here we report single channel studies demonstrating the presence of a large conductance, calcium activated (BK_{Ca}) channel in cerebellar granule cells.

Single BK_{Ca} channels were found in about 10% of all inside-out patches. The single channel conductance is 154 pS (SD = 17 pS, n = 9) in symmetric 146 mM K^+ and 76 pS (SD = 5 pS, n = 12) in 4 mM external K^+ . The channel is highly K^+ selective, i.e. reducing the internal K^+ concentration from 146 to 73 mM shifts the reversal potential by +16 mV.

The open probability is significantly increased by depolarizations, and the channel does not inactivate. Furthermore, rising the free calcium concentration on the cytosolic side from 100 to 1000 nM increases the open probability by 8-60x at $V_m = 0$ mV. Pinacidil (10 μ M) does not activate the channel. In outside-out patches charybotoxin (20 nM) blocks the channel by inducing long silent periods, and TEA (0.5 mM) inhibits channel activity by a very fast block.

In conclusion, the large K^+ selective channel identified in the cerebellar granule cells exhibits all the characteristics of a BK_{Ca} channel.

TRANSIENT POTASSIUM CURRENTS IN NEURONS ACUTELY DISSOCIATED FROM THE ADULT RAT SUPRAOPTIC NUCLEUS: ARE THEY CALCIUM DEPENDENT? M.H.O'Regan & P.Cobbett, Dept. Pharmacol./Toxicol. & Neuroscience Program, Michigan State University, East Lansing, MI 48824-1317.

Magnocellular neurosecretory cells of the mammalian supraoptic nucleus (SON) release the hormones vasopressin and oxytocin into the systemic circulation. In these SON neurons, transient and/or Ca^{2+} dependent K^+ currents may determine interspike intervals and have been implicated in generation of the intrinsic firing patterns exhibited by the two types of cell. Voltage gated K^+ currents were examined in acutely dissociated neurosecretory SON cells using the whole cell configuration of the patch clamp technique. Three separate K^+ currents were distinguished by their voltage dependence, kinetics and pharmacology. A sustained current, present in all neurons, corresponded to the delayed rectifier current (I_K). In addition, two Ca^{2+} independent transient currents, $I_{K(fast)}$ and $I_{K(slow)}$ having significantly different kinetics of inactivation, were recorded in separate populations of SON neurons. I_K was selectively blocked by tetraethylammonium whereas $I_{K(fast)}$ and $I_{K(slow)}$ were blocked by 4-aminopyridine. The kinetics and Ca^{2+} independence of K^+ currents in magnocellular supraoptic neurons may reflect the role of these currents in modulating firing activity of the neurons and thus hypothalamo-neurohypophysial function. (Supported by NIH NS28206.)

WHY USE INTRACELLULAR CITRATE FOR RECORDING CALCIUM ACTIVATED POTASSIUM CURRENTS: A POSSIBLE ROLE OF MAGNESIUM. R. Cloues, J. Robbins*, and D.A. Brown, Dept. of Pharmacology, University College London, Gower Street, London WC1E 6BT, England.

Inositol 1,4,5 trisphosphate (IP3) raises intracellular calcium levels and activates an outward Ca-dependent potassium current in NG108-15 cells. This current, evoked by intracellular ionophoresis of IP3, has previously been studied in cells impaled with sharp electrodes (Brown and Higashida, *J. Physiol.* 397:185-207; 1988). In experiments using the whole cell patch clamp technique we have found the ability to record this current depends on the anion used in the pipette solution. Recordings with acetate, aspartate, gluconate, or methylsulphate showed no currents; with fluoride or chloride, a low percentage of cells showed the response: currents were small and ran down. However, with citrate as the dominant anion, the IP3-induced current could be evoked in over 75% of the cells. In addition, bradykinin, which causes IP3 release through a G protein linked receptor, evoked an outward current only when citrate was used in the recording solution. Since citrate buffers magnesium (Mg²⁺) to a greater degree than acetate (0.1 mM vs 1.9 mM free Mg²⁺), we lowered the Mg²⁺ concentration in the acetate solution. This now enabled us to record the IP3 activated current. As intracellular injections of Ca²⁺ also activated the outward current only in low Mg²⁺ solutions, it is suggested that intracellular Mg²⁺ blocks Ca-activated K channels in these cells. Supported by Wellcome Trust and MRC.

THE ROLE OF CALCIUM INFLUX AND CALCIUM INDUCED CALCIUM RELEASE IN ACTIVATING POTASSIUM CURRENTS IN GUINEA PIG AND RAT VAGAL NEURONS. P. Sah and E.M. McLachlan, Dept. of Physiology and Pharmacology, University of Queensland, Qld 4072, Australia.

In neurons, influx of calcium via voltage gated channels which open during an action potential can activate several types of potassium currents. We have studied the kinetics of potassium currents underlying the afterhyperpolarization (ahp) in vagal preganglionic neurones. Intracellular recordings were made from cells in the dorsal motor nucleus of the vagus (dmv) in transverse slices of brainstem maintained in vitro. Neurons had resting potentials of -60 to -70mV and input resistances of 100 to 600MΩ. In both rats and guinea pigs single action potentials were followed by prolonged ahp's. Under voltage clamp, the tail current underlying the ahp in rat dmv cells was maximal after the action potential, decayed exponentially with a time constant of 150ms and was blocked by apamin. In guinea pigs the tail current had two phases: an early fast phase (GkCa₁) which decayed exponentially and a slower phase (GkCa₂) which had a slow rising phase and then decayed exponentially with a time constant of 1.4s. GkCa₁ had properties identical to the tail current in rat dmv neurons. GkCa₂ was unaffected by apamin but was selectively blocked by noradrenaline. GkCa₂ was selectively blocked by compounds which interfere with release of intracellular calcium stores. We conclude that in guinea pig dmv neurons influx of calcium (i) directly activates one class of potassium channels and (ii) leads to release of intracellular calcium which activates a second class of potassium channel. In rat dmv neurons this second type of channel is not expressed.

ION CHANNELS: MODULATION AND REGULATION I

31.1

EFFECTS OF MUSCARINIC RECEPTOR SUBTYPES ON AN INWARD POTASSIUM CONDUCTANCE AND ON EXOCYTOSIS. S.V.P. Jones, Neuroscience Research Unit, Department of Psychiatry, University of Vermont, Burlington, VT 05405.

The effects of activation of two of the five muscarinic receptor subtypes were investigated in RBL 2H3 cells. These cells were transfected with the m1 and m2 muscarinic receptor genes. Electrophysiological effects were monitored using the whole-cell patch clamp technique. RBL 2H3 cells express an inwardly rectifying potassium conductance which is active at potentials more hyperpolarized than -60 mV. The current was sensitive to 5 mM barium and 1 mM cesium. The RBL cell showed little evidence of other conductances. Application of 10 μM acetylcholine (ACh) to m2-transformed RBL cells increased the amplitude of the inward rectifier current. Whole-cell conductance was increased from ~2.5 nS in control to ~5 nS on application of ACh. This action was completely inhibited by 1 μM atropine. Application of 10 μM ACh to m1-transformed RBL cells did not appear to affect the inward rectifier, but resulted in a time-dependent change in morphology, indicative of exocytosis. This effect was abolished on application of 1 μM atropine. An accompanying activation of calcium-dependent conductances was noted on application of ACh to the m1-transformed cells, similar to those observed on antigen-induced exocytosis in these cells.

31.3

ROLE OF TARGET ORGAN IN THE MAINTENANCE OF CALCIUM CURRENTS IN BULLFROG SYMPATHETIC NEURONES. B.S. Jassar and P.A. Smith, Dept. of Pharmacology, University of Alberta, Edmonton, Canada.

Axotomy of bullfrog sympathetic ganglion neurones results in an increase in spike width and a decrease in the amplitude and duration of the action potential afterhyperpolarization (Gordon *et al.*, *J. Physiol.*, 392, 213, 1987). These changes, which are partially reversed following re-innervation of the target organ (Kelly *et al.*, *J. Neurobiol.*, 19, 357, 1988), have been attributed to functional loss of Ca²⁺-sensitive K⁺ conductances (G_{KCa}; Kelly *et al.*, *Neurosci. Letts.*, 67, 163, 1986). Since Ca²⁺ influx is required for the activation of G_{KCa} during the action potential (Lancaster & Pennefather, *J. Physiol.*, 387, 519, 1987), it is possible that the changes in the afterhyperpolarization and action potential which accompany axotomy and re-innervation result from changes in Ca²⁺ currents. We therefore used the whole-cell patch-clamp technique to compare control Ba²⁺ currents with those recorded from neurones 14-15 days and 28-30 days after *in vivo* axotomy. Axotomy caused peak Ba²⁺ current to decrease to about 53% of control whilst the voltage-dependence of activation was unaffected. τ for activation/deactivation was reduced after axotomy and this was especially apparent for activation at -20mV and for deactivation at -30mV (P<0.005). Although the extent and rate of development of inactivation was increased, τ for recovery from inactivation was unchanged. These changes were partially reversed 28-30 days after axotomy (when some reinnervation had probably occurred). These results show that contact of neurones with target organs is somehow responsible for the maintenance of Ca²⁺ currents in the cell body and that the properties of the individual channels expressed in axotomized cells differ from those seen in normal cells. (Supported by the MRC of Canada).

31.2

EFFECT OF ARACHIDONIC ACID PATHWAY INHIBITORS ON CALCIUM REGULATED M CURRENT ENHANCEMENT. S.P. Yu, P.R. Adams and A.D. Rosen* Howard Hughes Med. Inst., Department of Neurobiol. & Behavior, *Department of Neurology, SUNY at Stony Brook, Stony Brook, NY, 11794

We previously reported (Biophysical J. 59:78a, 1991; Neuron 6:533-545, 1991) that intracellular Ca²⁺ can modulate the M current (I_M) in bullfrog sympathetic ganglion neurons. Increasing free [Ca²⁺]_i from zero to 80 nM by intracellular perfusion doubled the size of M current. The effect was reversible. High free [Ca²⁺]_i (>300 nM) reduced normal I_M.

Possible Ca²⁺-dependent transduction pathways involved in M channel regulation were tested in dissociated bullfrog ganglion B cells using whole cell voltage clamp and intracellular perfusion. External solutions contained 0.5 mM EGTA, 2.0 mM MnCl₂ and no Ca²⁺. Internal solutions had, *inter alia*, 20 mM BAPTA and 1.5 mM ATP. I_M was measured by 1 sec, -20 mV jumps from a holding potential of -30 mV.

The lipoxygenase inhibitor NDGA (1 μM) blocked 80% of I_M at 80 nM free [Ca²⁺]_i within 15 min, while it had smaller effect when free [Ca²⁺]_i was zero. The current remaining in 1 μM NDGA was still normally sensitive to 1 - 10 μM muscarine but the overrecovery, which usually occurs at 80 nM free [Ca²⁺]_i with 20 mM BAPTA when washing out muscarine, disappeared. Overrecovery also disappeared when muscarine was tested at zero [Ca²⁺]_i, even if NDGA was not present. The IC₅₀ of NDGA for I_M inhibition at 80 nM free [Ca²⁺]_i was 0.3 μM. NDGA (1 μM), applied either in the bath or intracellularly, completely blocked the I_M enhancement normally seen upon raising intracellular free Ca²⁺ from zero to 80 nM. The cyclooxygenase inhibitor indomethacin (10 μM) had no effect on such I_M augmentation. Two phospholipase A₂ inhibitors 4-BPB (4 μM) and quinacrine (10 μM) partially blocked the Ca²⁺-induced I_M enhancement. In preliminary tests, arachidonic acid (AA) itself increased I_M by 30-50% and this effect could be blocked by NDGA. The data indicate that AA metabolite(s), together with Ca²⁺, may act to modulate M channels. The involvement of any particular AA metabolite(s) or other unsaturated fatty acids remains to be probed.

31.4

SEROTONIN MODULATION OF A TRANSIENT OUTWARD POTASSIUM CURRENT IN CEREBELLAR PURKINJE CELLS. Y. Wang*, J.C. Strahlendorf and H.K. Strahlendorf, Neurology and Physiology, Texas Tech Univ. Hlth. Sci. Ctr. Lubbock, TX. 79430

Under voltage clamp Purkinje cells (PCs) demonstrate a rapidly inactivating transient outward current (I_{TO}) similar to the A-current found in many neurons. A-current may participate in frequency encoding of firing rate in response to graded depolarizations, may modulate excitatory synaptic input and in some cases contribute to spike repolarization. Current and voltage clamp recordings of rat PCs were made from slices. In voltage clamp I_{TO} was elicited with depolarizing steps following a hyperpolarizing prepulse. 5-HT (10nM - 10μM) caused a dose-dependent decrease in I_{TO} amplitude ranging from 13 to 89%. In current clamp 5-HT (5μM) shortened the delay to the first action potential and increased the slope of the electrotonic membrane response elicited by depolarizing current injection. Suprathreshold depolarizations elicited a higher spike firing frequency compared to control conditions. Resting membrane potential and input resistance were unaffected by these doses of 5-HT. Our results suggest that one mechanism by which 5-HT can enhance PC excitability is via a reduction in I_{TO}. Supported by the Tx. Adv. Res. Prog., 010674-020 and NS 19296.

31.5

INTRACELLULAR GUANOSINE-5'-O-(2-THIODIPHOSPHATE) ALTERS THE KINETICS OF THE RESPONSES TO AGONISTS IN BULLFROG SYMPATHETIC NEURONS. Mark A. Simmons and Robert J. Mather*. The Neuropharmacology Lab., Dept. Pharmacol., Marshall University, Huntington, WV, 25755-9310.

Chicken II-luteinizing hormone releasing hormone (cII-LHRH), muscarine, and substance P (SP) inhibit a K^+ current, the M current, in bullfrog sympathetic neurons. The effects of intracellularly applied guanosine-5'-O-(2-thiodiphosphate) (GDP β S) on the responses to these agonists were examined. Whole cell recordings were made from single neurons dissociated from bullfrog sympathetic ganglia. GDP β S was added to the pipette solution with fixed amounts of GTP. At maximal concentrations of agonist, neither the response to the first application of agonist nor the proportion of cells which responded to any of the agonists was altered by GDP β S. With repeated agonist applications, successive responses were decreased in amplitude and increased in time course in the presence of GDP β S. Intracellular GDP β S did not accelerate the rate or magnitude of desensitization to SP. A model of receptor-G protein coupling predicts that a decrease in the available G protein pool should decrease both the magnitude and the time course of the build up of active G proteins. The results are consistent with the hypothesis that GDP β S binds tightly to G proteins in competition with GTP, thereby effectively decreasing the available G protein pool with repeated agonist applications.

31.7

MODULATION OF VOLTAGE-DEPENDENT IONIC CURRENTS BY DOPAMINE: EVIDENCE FOR THE INVOLVEMENT OF DIFFERENT G PROTEIN TYPES.

Lledo P-M*, Homburger V*, Israel J M*, Bockaert J* and Vincent J-D. INSERM, unité 176, rue C. St Saëns, 33077 Bordeaux and (H. V. and B. J.) CCIPE, rue de la Cardonille, 34094 Montpellier Cedex 2, France.

Dopamine (DA), acting on D2 receptors, reversibly reduces two voltage-dependent Ca^{2+} currents (the T- and the L-type), and increases two voltage-dependent K^+ currents (IA and IK) in rat pituitary lactotroph cells and thereby decreases prolactin secretion. These effects were potentiated by intracellular application of the nonhydrolyzable GTP analog, GTP- γ -S, and blocked by the GDP analog, GDP- β -S. Pretreatment of the cells with pertussis toxin (PTX) abolishes the DA effect, suggesting that PTX-sensitive GTP-binding regulatory proteins (G-proteins) are involved in the signal transduction mechanism which links D2 receptor activation to the modulation of the four types of ionic channel.

To identify the G-proteins involved, we made intracellular injections of affinity-purified polyclonal antibodies raised against the carboxy-terminal sequence of the α -subunit of either G_0 , G_{i3} or G_{i1} and G_{i2} . Ionic currents were recorded using the whole-cell configuration of the patch-clamp technique. Currents were measured 10 min after patch membrane had been broken in the absence or presence of 10 nM-dopamine. The pipette solution contained 180 μ g/ml of antibody, heat-inactivated antibody (as control) or antiserum against G_0 , G_{i3} or G_{i1} and G_{i2} . Loading of cells with antibody was demonstrated by immunohistochemistry.

Only cells dialysed with antiserum G_0 significantly reduced the inhibition of Ca^{2+} currents induced by DA application whereas the response to DA on K^+ currents was markedly attenuated by the injection of antiserum G_{i3} . We therefore conclude that in lactotroph cells, Ca^{2+} and K^+ currents are both modulated by G proteins with a different type of G protein for channels specific for each ion.

CLONING OF G PROTEIN cDNAS FROM HELISOMA CENTRAL GANGLIA. S. Durgerian*, P. G. Haydon and D. D. Larson*. Dept. of Zoology and Genetics, Iowa State Univ., Ames, IA 50011.

The tetrapeptide neuromodulator FMRFamide regulates synaptic transmission by inhibiting the release of acetylcholine (ACh) from nerve terminals in the pond snail *Helisoma*. FMRFamide acts through pertussis toxin-sensitive G proteins to reduce calcium influx into the nerve terminal and to reduce the sensitivity of the secretory machinery to calcium. Some effects of FMRFamide are mimicked by microinjection of GTP γ S-activated α subunit of purified bovine G_{o2} (Man-Son-Hing et al. '90). In order to study the endogenous G proteins responsible for these effects, we have isolated two unique sets of clones from a *Helisoma* cDNA library which are similar to other invertebrate G_{o2} sequences.

ANALYSIS OF G PROTEIN-GATED K^+ CURRENTS ACTIVATED BY 7-HELIX RECEPTORS. A. Karschin, B.Y. Ho*, N. Davidson, and H.A. Lester. Caltech, Division of Biology 156-29, Pasadena, CA 91125.

We have described vaccinia virus-mediated high-efficiency expression of human 5-HT $_{1A}$ receptors in primary cultures of neonatal rat atrial cells. The expressed receptors coupled to endogenous G protein-gated K^+ channels normally activated by mACh receptors (Karschin et al. *Soc. Neurosci. Abstr.* 16:462, 1990). Here we report about the kinetic analysis of the currents activated by ACh and 5-HT and suggest a model for direct K^+ channel activation by G protein subunits.

The inwardly rectifying K^+ current $I_{K(ACh)}$ evoked by ACh (5 μ M) activated with a time constant of $\tau_{act} = 317 \pm 12$ ms (mean \pm SEM; n=32) and deactivated with $\tau_{deact} = 965 \pm 75$ ms (n=23) upon removal of the agonist. Responses mediated by the expressed 5-HT $_{1A}$ Rs (5 μ M 5-HT) showed similar deactivation with $\tau_{deact} = 924 \pm 39$ ms (n=16), but slower activation time constants $\tau_{act} = 1682 \pm 180$ ms (n=12) and smaller current amplitudes. Internal perfusion with GTP γ S, performed to investigate this difference, caused the persistent activation of $I_{K(ACh)}$ within several minutes. In addition, GTP γ S stimulated an increase in the rate of current activation and a decrease in deactivation rate, and especially for 5-HT, an increase in current amplitude. Thus, irreversible G protein activation by GTP γ S enhances the efficiency of transduction by a subsequent pulse of agonist, possibly changing the number or nature of rate-limiting steps for activation/deactivation. These effects could be interpreted in a straightforward fashion if the channel was much more likely to be activated by several (n) G protein α -subunits than by a single one. 31.8

BIOCHEMICAL EVIDENCE THAT DIHYDROPYRIDINE AND $GABA_B$ RECEPTORS INTERACT WITH G_0 AND G_i RESPECTIVELY. M.I. Sweeney, A.C. Dolphin, Department of Pharmacology, Royal Free Hospital School of Medicine, London, NW3 2PF, England.

Recent studies have suggested that the interaction of dihydropyridines (DHPs) with Ca^{2+} -channels is modulated by G-proteins. Here, we have examined a direct interaction by studying the effect of DHPs on GTPase activity. Membranes were prepared from the frontal cortex of male Wistar rats and GTPase was quantitated by liberation of $^{32}P_i$ following hydrolysis of γ - ^{32}P -GTP at 37°C for 10 minutes. The $GABA_B$ receptor agonist (-)-baclofen (1-30 μ M), and the DHP agonist (+)-202-791 and antagonist (-)-202-791 (0.33-10 μ M) stimulated a high affinity GTPase in a dose-dependent manner. (-)-202-791 was one order of magnitude less potent than the (+)-enantiomer. When data were expressed as a Lineweaver-Burk relationship, 10 μ M baclofen increased the maximal rate of GTP hydrolysis (V_{max}) from 227 \pm 32 to 322 \pm 57 pmol/mg protein/min, but had no effect on the affinity of the enzyme (K_M). 1 μ M (+)-202-791 increased V_{max} by 48% also with no effect on K_M (control, 0.65 \pm 0.16 μ M; DHP, 0.71 \pm 0.15 μ M, n=12). The effects of sub-maximal concentrations of baclofen and DHPs were additive. In membranes pretreated at 30°C for 60 minutes with antiserum (OCL, 1:50) against G_0 , the effect of DHP on GTPase was completely attenuated while that of baclofen was reduced by 20%. In contrast, pretreatment with the antisera AS7 and SGL (1:50), which interact with G_i , reduced the effect of baclofen by 83-88% while not affecting stimulation by either DHP. These data indicate that DHP binding produces an increase in GTP hydrolysis, possibly representing a direct coupling between DHP-sensitive Ca^{2+} -channels and G_0 . $GABA_B$ receptors may be coupled to a proportion of these G_0 proteins, although they also interact with G_i in cortical membranes.

Supported by the MRC (UK and Canada) and Wellcome Trust. We thank Dr G Milligan, Glasgow University for anti-G protein antibodies.

31.10

GLUCOCORTICOID INCREASES THE EXPRESSION OF VOLTAGE-DEPENDENT Ca^{2+} CHANNELS OF HUMAN MUSCLE IN CULTURE. S. Braun*, V. Askanas, W.K. Engel. USC Neuromuscular Center, Univ. of Southern Calif. Sch. of Med., Los Angeles, CA 90017.

Glucocorticoid increases the accumulation of non-junctional acetylcholine receptors (AChRs) on aneurally cultured human muscle (Askanas et al., 1986) and of junctional-AChRs on cultured human muscle, that has been innervated by fetal rat spinal cord (Braun et al., 1991). The increased accumulation of AChRs is due to both increased synthesis and decreased degradation. Since activation of Ca^{2+} channels was shown to slow degradation of AChRs in rat muscle culture (Rotzler et al., 1991), we investigated whether glucocorticoid modulates the Ca^{2+} channels in cultured human muscle.

Hydrocortisone (HC) treatment was initiated on 8-day-old aneurally cultured human muscle and continued for up to 14 days. The Ca^{2+} channels were measured by binding of the dihydropyridine derivative [3H]PN200-110, a potent Ca^{2+} channel antagonist. HC significantly increased the specific PN200-110 binding 2.4 times, $p < 0.05$ (18 cultures). The effect was time-related (maximum after 10 to 14 days of treatment) and concentration-dependent. There was a correlation between HC-promoted increase of PN binding and increase of AChR accumulation.

Our study provides the first demonstration that glucocorticoid influences Ca^{2+} channels in cultured human muscle and raises the possibility that its influence on AChR metabolism may be through a Ca^{2+} channel effect.

ARACHIDONIC ACID HAS DOSE-DEPENDENT EFFECTS ON THE MEMBRANE POTENTIAL OF ACUTELY DISSOCIATED EMBRYONIC CHICK SPINAL CORD CELLS. K.S. Madden, A. Prasad, S.V. Smith, G.D. Lange and J.L. Barker, LNP and ICS, NINDS, NIH, Bethesda, MD 20892

Arachidonic acid (AA) metabolism has been implicated in the events of signal transduction in response to various electrical, chemical and mechanical stimuli. These responses are superimposed on the basal metabolic state of cells which is commonly modified by exposure to cold or radiolabeled AA. To assess the effects of this treatment, alone, acutely suspended embryonic chick spinal cord cells (E5-8) were exposed to increasing doses of AA (3 nM to 3 mM). Flow cytometry was used to measure effects on individual cells (20,000/trial) in preparations that were untreated or stained by a fluorescent indicator dye such as oxonol (voltage-sensitive) or fluo-3 (calcium-sensitive). The data revealed four dose-dependent effects on the oxonol signal intensity. 1) Low doses (3 nM-6 μ M) decreased the signal intensity of most, if not all, cells without affecting either the autofluorescent (AF) or fluo-3 signals. 2) Transition doses (9 μ M-45 μ M) decreased, did not change, or increased the signal intensity. 3) Higher doses (ca. 45-90 μ M) increased the intensities of oxonol, AF and fluo-3 signals without increasing cell mortality. 4) High doses (>100 μ M) killed cells. The low dose effects (1) are consistent with a hyperpolarization caused by the activation of potassium channels. Higher doses (3) probably depolarize cells owing to increases in the intracellular concentrations of calcium ions. Transition effects (2) are likely to result from simultaneous, dual antagonistic effects. This could help to explain some diversity in the reported effects of these concentrations in other preparations.

EFFECTS OF ADENOSINE ON VOLTAGE-DEPENDENT CALCIUM CURRENTS IN IDENTIFIED MOUSE MOTONEURONS. M. Mynlieff and K.G. Beam, Dept. of Physiology, Colorado State University, Fort Collins, CO 80523

Endogenous and exogenous adenosine have been shown to reduce both electrically-evoked and potassium-evoked release of acetylcholine from the neuromuscular junction. This effect is calcium-dependent, blocked by xanthines and exhibits an A1 adenosine receptor antagonist profile. Unlike most A1 receptor mediated effects, the inhibition of neuromuscular transmission by adenosine is not due to the inhibition of adenylate cyclase. The inhibitory effect of adenosine on mammalian motor nerve endings is abolished by pertussis toxin treatment suggesting that activation of the A1 adenosine receptor produces second messengers which alter the conductance of the voltage-dependent calcium channels.

We have used voltage clamp whole-cell patch recording from embryonic mouse motoneurons to study the effects of adenosine on voltage-dependent calcium channels. The motoneurons from 14 day old embryos were identified by retrograde labeling with the carbocyanine dye "dil" prior to dissociation of the cells. Adenosine (40 μ M) decreased the transient high-voltage activated (HVA) calcium current (10 mM external Ca^{2+} , $29.1 \pm 4.3\%$, $n=10$) without affecting the sustained HVA calcium current ($8.2 \pm 7.2\%$) and T-current ($6.3 \pm 9.5\%$). This decrease in transient HVA current might explain the depressant effect of adenosine on release of acetylcholine at the neuromuscular junction.

CHARACTERIZATION OF A PARTICULATE PROTEIN PHOSPHATASE IN NEURONS OF APLYSIA. S. Endo, S. Shenolikar, and J.H. Byrne, Departments of Neurobiology and Anatomy, and Pharmacology, University of Texas Medical School, Houston, TX 77225.

The phosphorylation state of a given protein reflects the activities of both protein kinases and protein phosphatases (PrPs). Recent studies indicate that PrPs in *Aplysia* are similar to those of mammalian in many of their biochemical properties including substrate specificity and sensitivity to a variety of inhibitors, such as the mammalian inhibitor I-2 (a specific inhibitor of PrP-1), okadaic acid (OA) and Microcystin-LR (specific inhibitors of PrP-1 and -2A) (Endo et al., 1989, 1990). Moreover, OA and Microcystin-LR alter 5-HT- and cAMP-dependent membrane currents in voltage clamped pleural sensory neurons (Ichinose et al. 1990; Byrne et al. 1990). To characterize the PrPs which may be involved in the regulation of membrane proteins, we analyzed PrPs in a crude membrane fraction from *Aplysia* neurons.

Homogenate of the central nervous system was centrifuged at 1,000 xg and the resulting supernatant was again centrifuged at 100,000 xg to yield a particulate fraction. More than 70% of PrP activity, measured using ^{32}P -phosphorylase α as substrate, was extracted from the particulate fraction by repeated washings with the buffer containing 0.5 M NaCl. Greater than 80% of that PrP activity was PrP-1 as defined by its inhibition by I-2. Furthermore, over 75% of PrP activities in membrane "ghosts" of R2 cells and PL1 cells was PrP-1. Salt-extracts of neural membrane were subjected to gel filtration on Superose-6, yielding multiple high molecular weight peaks of PrP activity. All the PrP activities in these peaks were completely inhibited by OA (1 μ M), but one was only partially inhibited by I-2, suggesting the presence of multiple forms of PrP-1. These PrP-1 complexes retained the ability to reassociate with membranes and suggest the presence of additional components which confer membrane binding to PrP-1. In summary, these data confirmed that the major PrP activity associated with membrane from *Aplysia* neural tissue is PrP-1, and suggest that PrP-1 may be a candidate for the regulation of phosphorylation-dependent membrane processes.

31.12

INVOLVEMENT OF ATP-SENSITIVE K^{+} CHANNELS IN SOMATOSTATIN (SRIF)-INDUCED CYTOSOLIC CALCIUM REDUCTION, MEMBRANE HYPERPOLARIZATION BUT NOT INHIBITION OF ADENYLATE CYCLASE ACTIVITY IN MMQ CELLS. O. Meucci, A. Scorziello*, E. Landolfi*, T. Florio, C. Ventra, G. Schettini Dept. Pharmacology, II School of Medicine, University of Naples ITALY.

In MMQ cells, a PRL-secreting rat cell line, which naturally expresses functional SRIF receptor, SRIF dose-dependently reduced intracellular calcium levels ($[Ca^{++}]_i$) and induced a membrane hyperpolarization in basal conditions. SRIF also inhibited the membrane depolarization caused by high extracellular K^{+} , whereas it did not affect the K^{+} depolarization-induced $[Ca^{++}]_i$ rise. The sulfonylurea glibenclamide (Glib), a blocker of K^{+} (ATP)-channels, depolarized the cells, increased $[Ca^{++}]_i$, and markedly reduced SRIF inhibition of basal $[Ca^{++}]_i$. Furthermore, Glib inhibited SRIF reduction of K^{+} -induced depolarization. SRIF inhibited forskolin-stimulated PRL secretion from single cell without affecting basal hormone release, an effect modulated by Glib pretreatment. SRIF reduced adenylate cyclase (AC) activity in basal and forskolin-stimulated conditions in a dose dependent manner (100nM-100uM). Glib did not modify SRIF inhibition of the AC enzyme.

31.14

ATP-ACTIVATED ION CHANNELS IN RAT NODOSE GANGLION NEURONS. Chaoying Li*, Sergio Visentin* and Forrest F. Wight, Section of Electrophysiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

The ion currents induced by externally applied ATP were investigated by means of whole-cell patch-clamp method in single neurons freshly isolated from adult rat nodose ganglion. At a holding potential of -60 mV, rapid application of ATP (0.5-250 μ M) induced a dose dependent inward current with a $K_d=9.3$ μ M. The current exhibited fast activation and deactivation kinetics. Under normal external conditions, the reversal potential was near 0 mV. In Na^{+} -free or Na^{+} -free/ Ca^{++} -free external medium (NMG replacement), the ATP-activated current was decreased in amplitude by 85% and 95%, and the reversal potential was shifted to -38 mV and -52 mV, respectively. α,β -Methylene ATP (50 μ M) and ADP (200 μ M) also activated an inward current, but were much less potent than ATP. Adenosine (100 μ M), AMP (200 μ M) and GTP (200 μ M) had no effect. These observations suggest that interaction of ATP with a P2 type of purinergic receptor can activate a ligand-gated ion channel in rat nodose neurons. The inward current of this ATP-activated channel appears to be carried mainly by Na^{+} , but Ca^{++} may also contribute.

31.16

PROTEIN PHOSPHATASE-1 INHIBITORS ATTENUATE 5-HT MODULATED K^{+} CURRENTS IN APLYSIA SENSORY NEURONS. S.D. Critz, S. Endo, S. Shenolikar, and J.H. Byrne, Depts. of Neurobiology and Anatomy and Pharmacology, Univ. of Texas Medical School, Houston, TX 77225.

We previously reported that okadaic acid and microcystin-LR (MCYST) reduced serotonin (5-HT) and cAMP responses in sensory neurons of *Aplysia* (Ichinose et al. 1990a,b). These compounds, however, which potentially inhibit both protein phosphatase-1 (PrP-1) and -2A, did not define the regulatory roles of the individual phosphatases. To address this issue, we have used the purified vertebrate inhibitor proteins, I-1 and I-2, which selectively inhibit PrP-1, to determine the physiological role of PrP-1 in the modulation of 5-HT responses.

Isolated clusters of sensory neurons from the pleural ganglion were perfused (0.5 ml/min) with 20 mM Tris-buffered artificial sea water (pH 7.4). Sensory cells were two-electrode voltage-clamped at a holding potential of -25 mV using 0.5 M KCl-filled electrodes. The current passing electrode also contained either I-1, I-2 or vehicle, which passively diffused into the impaled cell. Responses were produced by "puffing" 5-HT (3.0 s, 5-20 p.s.i., 100 μ M) from a third electrode every 6 min. Puffs of 5-HT produced transient inward shifts of the holding current that correspond to the cAMP-dependent protein kinase mediated suppression of the $S-K^{+}$ current (e.g., Siegelbaum et al. 1982, Ichinose et al. 1990a,b). Both thiophosphorylated I-1 (activated form, 20 units/ μ L, $n=6$) and I-2 (16 units/ μ L, $n=5$) gradually attenuated the responses to 5-HT. The kinetics of recovery from 5-HT puffs were unchanged and there was little change in baseline input conductance. In contrast, both okadaic acid and MCYST prolonged the recovery phase and gradually reduced baseline input conductance. These results suggest that PrP-1 dephosphorylates substrate proteins involved in the control of K^{+} currents in *Aplysia* neurons. Since MCYST effects were not completely reproduced by either activated I-1 or I-2, PrP-2A may also participate in the regulation of K^{+} currents.

32.1

WIDESPREAD DEGENERATION INDUCED IN THE DEVELOPING RODENT CNS BY D,L-2-AMINO-3-PHOSPHONOPROPIONATE (AP3). *L.P. Tizzano, D. D. Schoepp, M. T. Price and J. W. Olney*. Eli Lilly and Company, Greenfield, IN 46140 and Washington University Medical School, St. Louis, MO 63110.

AP3 is an aspartate analog known to cause acute gliotoxic changes in circumventricular organ (CVO) regions of infant rodent brain (Olney et al., 1971). Recently, AP3 was shown to inhibit the function of a unique phosphoinositide (PIn) hydrolysis-coupled glutamate (Glu) receptor subtype, the quisqualate metabotropic receptor. In rat brain, activation of this receptor by specific agonists (quisqualate or ACPD) stimulates PIn hydrolysis, and AP3 inhibits agonist-stimulated PIn hydrolysis (Schoepp & Johnson, 1989). Metabotropic receptor-coupled PIn hydrolysis is markedly enhanced in the neonatal rat CNS, suggesting a role for this receptor in CNS development. Tizzano et al. (NS Abstr., 1990) found that daily AP3 treatment of rats from postnatal days 3-12 inhibited ACPD-stimulated PIn hydrolysis and also caused developmental behavioral deficits, plus degeneration and/or dysplasia of the retina and optic nerve. We now report results of a more detailed histopathological analysis of the latter effect. A single i.p. treatment of infant mice with AP3 (500 mg/kg) caused rapid (within 2 hrs) edematous changes limited to gliopendymal elements in CVO brain regions and slightly more delayed (within 6-8 hrs) edematous degeneration of small numbers of retinal neurons. Giving the same dose daily from postnatal days 4-8 consistently caused degeneration of the entire retina and in some animals induced degeneration of both glial and neural elements in scattered distribution over many brain regions, including CVO, cerebral cortex, caudate nucleus, hippocampus, thalamus, superior colliculus, cerebellum and cochlear nucleus. Thus, sub-chronic AP3 treatment of infant rodents can cause both inhibition of metabotropic receptor function and widespread neurodegenerative changes throughout the developing CNS. By several criteria, the neurotoxic action of AP3 appears different from that of Glu and related excitotoxins. Whether any relationship exists between the gliotoxic and neurotoxic actions of AP3 remains to be determined.

32.3

STEREOSELECTIVE EX VIVO INHIBITION OF PHOSPHOINOSITIDE-COUPLED EXCITATORY AMINO ACID RECEPTORS BY L-2-AMINO-3-PHOSPHONOPROPIONIC ACID (L-AP3). *B.G. Johnson, E.C.R. Smith, L.A. McQuaid, and D.D. Schoepp*, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

During early postnatal ages in the rat, there is enhanced *in vitro* coupling of the metabotropic (phosphoinositide-coupled) excitatory amino acid receptor. Recently, we showed that i.p. administration of AP3 to neonatal rats produced long-lasting selective inhibition of excitatory amino acid-coupled phosphoinositide hydrolysis in the *ex vivo* brain slice (Neurochem. International 18: 411, 1991). This study further examined the stereoselectivity and pharmacology of *ex vivo* AP3 inhibition of the metabotropic receptors in the neonatal rat. When given to neonatal rats at doses of 125, 250, or 500 mg/kg i.p. for 3 consecutive days (6 days old at first dose), L-AP3 produced dose-related inhibition of trans-ACPD (100 μ M)-stimulated phosphoinositide hydrolysis in hippocampal slices. *In vivo* L-AP3 treatment significantly reduced the maximal trans-ACPD (100 μ M) stimulation (2148 \pm 196 % of basal in saline group, and 1110 \pm 134 % of basal following 250mg/kg x3 L-AP3), while having little effect on the trans-ACPD EC₅₀ (saline control = 34.56 \pm 6.18 μ M; 250 mg/kg x3 L-AP3 = 28.93 \pm 3.72 μ M). *In vivo* treatment with the metabotropic agonist trans-ACPD (50 mg/kg i.p. x 3) or the inactive AP3 isomer, D-AP3, (500 mg/kg i.p. x3) produced no effect on *in vitro* trans-ACPD (100 μ M)-stimulated phosphoinositide hydrolysis. These studies show that the stereoselectivity and pharmacology of *ex vivo* L-AP3 inhibition is similar to that observed *in vitro*. *In vivo* L-AP3 administration to neonatal rats provides a selective pharmacological approach to prevent metabotropic excitatory amino acid receptor coupling in the neonatal rat brain.

32.5

L-AP3 INHIBITS RECEPTORS ACTIVATED BY (\pm)TRANS-ACPD AND 1S,3R-ACPD IN XENOPUS OOCYTES EXPRESSING CEREBELLAR METABOTROPIC GLUTAMATE RECEPTORS. *B.L. Berry, P.C. May, L. McQuaid, E.C.R. Smith, M.J. Valli, J.A. Monn, and L.K. Simmons*. Eli Lilly and Co., Indianapolis, IN 46285.

The metabotropic glutamate receptor (mGluR) increases cellular calcium levels by activating phosphoinositide metabolism. Recently, increasing research has focused on the mGluR, prompted in part by the possible role of this receptor in the mechanisms underlying neuronal plasticity. Using the Ca²⁺-dependent chloride current as an assay of mGluR activity, we have pharmacologically characterized the activities of enantiomers of the selective mGluR agonist (\pm)trans-ACPD in *Xenopus* oocytes injected with rat cerebellar mRNA. Oocytes were exposed to increasing concentrations (30 μ M-1 mM) of the racemate (\pm)trans-ACPD and its enantiomers--1S,3R-ACPD and 1R,3S-ACPD. For any given concentration, the largest amplitude current was elicited with 1S,3R-ACPD, the racemate elicited an intermediate response, and 1R,3S-ACPD was virtually inactive.

We subsequently tested the ability of the antagonist L-AP3 to block the actions of (\pm)trans-ACPD and 1S,3R-ACPD. Three mM L-AP3 reversibly inhibited the responses to (\pm)trans-ACPD in all oocytes tested, but blocked responses to 1S,3R-ACPD only 58% of the time. These experiments show that cerebellar mGluRs expressed in *Xenopus* oocytes are qualitatively similar to mGluRs that have been described in other systems-- 1S,3R-ACPD is the active isomer of (\pm)trans-ACPD and L-AP3 inhibits the racemate. We are currently investigating possible explanations for L-AP3's inability to consistently block 1S,3R-ACPD at concentrations that significantly block the racemate.

32.2

EXPOSURE TO trans-1-AMINO-1,3-CYCLOPENTANEDICARBOXYLIC ACID (trans-ACPD) INCREASES INTRACELLULAR FREE CALCIUM IN CULTURED TYPE I ASTROCYTES.

E.R. Whittemore, R.J. Bridges and C.W. Cotman, Dept. of Psychobiology and Neurology, Univ. of Calif., Irvine, CA 92717

Biochemical studies have shown that trans-ACPD is the most selective known agonist at the G-protein-coupled excitatory amino acid receptor linked to the hydrolysis of inositol phospholipids. Although calcium imaging techniques have shown that activation of this receptor by other compounds induces increases in intracellular free calcium in cultured neurons and astrocytes, these studies have utilized less selective agonists such as quisqualate, which has known activity at a variety of other sites. To investigate whether activation of this receptor by the selective agonist trans-ACPD also induces increases in intracellular free calcium, we assayed cultured rat cortical astrocytes for responses to trans-ACPD using the calcium dye Fura-2 and digital fluorescence imaging microscopy. Type I astrocytes were prepared from the cortices of 4 day old rat pups. Oligodendrocytes and type II astrocytes were removed by shaking, and the purified type I astrocytes were plated onto polylysine-coated glass coverslips and allowed to reach confluency (14-21 days). Individual coverslips were incubated with 2 μ M Fura-2 AM for 30-40 min at room temperature and transferred to the stage of an inverted fluorescence microscope. Drugs were applied at room temperature for 2-4 min. using a flow-through chamber, and the ratio of fluorescence at 340 and 380nm was observed. Clear increases in intracellular free calcium were observed in response to 200 μ M trans-ACPD, which were characterized by a large initial spike, and subsequent smaller oscillations. In other experiments, 1 mM DL-2-amino-3-phosphonopropionic acid (AP3) was applied before and during exposure to 200 μ M trans-ACPD. In accordance with biochemical studies, this compound was a weak antagonist in some cells, and had no effect in others. These results suggest that astrocytes express functional trans-ACPD receptors, which mediate calcium responses, and that DL-AP3 is a weak or ineffective antagonist at this site.

32.4

EFFECTS OF EXCITATORY AMINO ACID ANTAGONISTS AT THE STRIATAL METABOTROPIC GLUTAMATE RECEPTOR IN VITRO. *B.P. Symons and S. Weiss*, Neuroscience Research Group, University of Calgary, Calgary, AB, Canada

The putative actions of the excitatory amino acid (EAA) antagonists 2-amino-3-phosphonopropionate (AP3), 2-amino-4-phosphonobutyrate (AP4) and 2-amino-5-phosphonovalerate (APV) in blocking EAA agonist-induced [³H]-inositol phosphate (InsP) accumulation were examined in mouse striatal neurons in primary culture. The agonists quisqualate (Quis), ibotenate (Ibo) and 1-amino-trans-1,3-cyclopentylidicarboxylate (ACPD) all induced dose-dependent increases in [³H]-InsP accumulation with EC₅₀ values of 0.5, 5, and 35 μ M, respectively. At saturating concentrations, Quis induced a 4-fold increase over the basal [³H]-InsP accumulation, whereas Ibo and ACPD evoked a 3.5-fold increase. AP3 and AP4 (1mM) were partial agonists, inducing a 1.5 to 2-fold increase over the basal [³H]-InsP accumulation. AP3 and AP4 stimulation was not additive, however, with the three other agonists tested and AP3 actually significantly attenuated 1 μ M Quis-induced [³H]-InsP accumulation (IC₅₀, 500 μ M). APV (ineffective alone) significantly attenuated Ibo- and ACPD-induced [³H]-InsP accumulation in a dose-dependent manner (IC₅₀, 40 μ M); Quis actions were unaffected. These results suggest that agonist/antagonist interactions can distinguish multiple mechanisms mediating EAA-induced [³H]-InsP accumulation in striatal neurons.

Supported by the Medical Research Council of Canada.

EVIDENCE FOR METABOTROPIC EXCITATORY AMINO ACID RECEPTOR HETEROGENEITY: DEVELOPMENTAL AND BRAIN REGIONAL STUDIES. *G.G. Vecil*, P.P. Li and J.J. Warsh*. Clarke Institute of Psychiatry, University of Toronto, Canada, M5T 1R8.

To investigate whether multiple subtypes of the excitatory amino acid (EAA) receptor-linked to polyphosphoinositide (PPI) hydrolysis exist, we have pharmacologically characterized the metabotropic EAA receptor response in rat neonatal and adult hippocampus and cerebellum. Activation of PPI hydrolysis was determined by the accumulation of [³H]inositol monophosphate (InsP) in brain slices prelabelled with [³H]inositol. In neonatal hippocampal slices D,L-2-amino-3-phosphonopropionic acid (AP3; 1 mM) inhibited the *cis*-1-aminocyclopentane-1,3-dicarboxylic acid (IUPAC, ACPD)- and quisqualate (Quis)-stimulated PPI hydrolysis by 73% and 66%, respectively, but did not affect ACPD- or Quis-stimulated [³H]InsP accumulation in neonatal cerebellar slices. In adult hippocampus, AP3 stimulated PPI hydrolysis with comparable potency and efficacy to ACPD and Quis, and completely masked the Quis concentration-response curve. In adult cerebellum, Quis behaved as a full agonist, whereas ACPD and AP3 appeared to be weak or partial agonists. The Quis concentration-response curve was shifted to the right with a 4-fold increase in the EC₅₀ value in the presence of a maximally effective concentration of ACPD. In contrast, the resultant accumulation of [³H]InsP when AP3 (5 mM) and Quis (500 μ M) were co-incubated was nearly additive with the response produced by either drug alone. Taken together, our data reveal significant developmental and brain regional differences in metabotropic EAA receptor responses and support the notion that the metabotropic EAA receptor is heterogeneous, both in a regionally specific and developmentally dependent manner.

EXCITATORY AMINO ACID STIMULATED IP₃ FORMATION IN RAT FOREBRAIN SYNAPTONEUROSONES. **A.K. Chaudhary***, **I.M. Tucek*** and **D.D. Johnson**. Dept. of Pharmacology, College of Medicine, Univ. of Saskatchewan, Saskatoon, SK S7N 0W0.

A considerable amount of work has been reported on the effect of excitatory amino acids (EAA) on phosphoinositide (PI) turnover. The majority of the studies have estimated PI turnover on the basis of accumulation of total inositol phosphates during lengthy incubations of brain preparations with an EAA agonist and LiCl. While the total accumulated inositol phosphates are mainly IP and IP₂, it is assumed that the source of these inositol phosphates is IP₃. Hence, it is believed that an increased accumulation of IP and IP₂ reflects increased amount of IP₃ formation as well. However, it is also known that IP and IP₂ can be formed from the hydrolysis of PI and PIP respectively. In this report, we have examined the effect of various EAA agonists on the PI system by quantifying the amount of IP₃ formed using a radioreceptor assay kit (NEN). Rat forebrain synaptoneurosome preparations were preincubated at 37°C for 5 min in a buffer consisting of 110 mM NaCl, 5 mM KCl, 1.3 mM MgCl₂, 1.3 mM CaCl₂, 10 mM glucose, 1 mM pyruvate, 0.25 mM DTT and 50 mM imidazole pH 7.4. After preincubation, various EAA agonists were added and the samples were further incubated for 2 min. The hydrolysis was terminated by the addition of TCA (5% final) and the precipitate was pelleted by centrifugation. The supernatant was extracted with trichlorofluoroethane/trioctylamine and assayed for IP₃. Using this method, concentration-effect curves for various EAA agonists including glutamate, quisqualate, t-ACPD and domoate can be demonstrated even when synaptoneurosones from adult rats are used. DELAYED QUISQUALATE NEUROTOXICITY IN RAT CORTICAL CULTURES. **W. C. Zinkand, P. A. DeFeo† Carolann Thompson*** and **J. Patel**, ICI Pharmaceuticals Group, ICI Americas, Wilmington, DE 19897.

The excitatory amino acid quisqualate (quis) displays a type of neurotoxicity that is quite different from other excitatory amino acids. The ionotropic quis antagonists DNQX and NBQX are potent quis toxicity blockers when administered following quis washout but are ineffective when co-incubated with quis. Similarly, removal of the cell culture media 30 min. after quis washout is neuroprotective, and that media, when transferred to naive cells, is toxic. Quis is not toxic to the non-neuronal cells in our cell culture; however, those cells are able to reproduce this "transfer toxicity" phenomenon. We believe that quis is taken up by both neuronal and non-neuronal cells in rat cortical cell cultures and that a neurotoxic factor (likely quisqualate or slightly modified quisqualate) is then re-released to cause neurotoxicity by persistent activation of the ionotropic quis receptor. The time course of this neurotoxicity is similar to that of AMPA, which is toxic via the ionotropic quis receptor but has none of the peculiar properties of quis. The possible role of a neurotransmitter uptake site is implicated by the observation that quis is not toxic if incubated with neuronal cells in sodium-free buffer.

32.11

CHARACTERIZATION OF L-AP4 ACTION FOLLOWING PRIMING BY QUISQUALATE IN HIPPOCAMPAL SLICE CULTURES OF RAT **Serge Charpak, Urs Gerber, & Beat Gähwiler**, Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland

Several studies have shown that an enhanced excitatory action of L-2-amino-4-phosphonobutyric acid (L-AP4) at various CNS pathways is only observed following preexposure of tissue to quisqualate. However, the mechanism for this "priming" effect remains unclear. We have studied quisqualate priming of L-AP4 effects in voltage-clamped CA3 pyramidal cells using hippocampal slice cultures in TTX. Prior to quisqualate exposure, CA3 cells showed no response to L-AP4 (50–200 μM). Following exposure to quisqualate (500 nM for 30 sec) L-AP4 induced a complex response. At hyperpolarized membrane potentials an ionotropic inward current associated with a conductance increase was observed. This response was in part sensitive to CNQX and in part sensitive to L-APV and Mg²⁺ ions. At depolarized potentials in the presence of CNQX and D-APV, L-AP4 induced a metabotropic excitation resulting from depression of K⁺ currents. This indicates that the action of L-AP4 is mediated by three different receptor types: the NMDA receptor, the AMPA receptor, and a glutamatergic metabotropic receptor. The L-AP4 response appears to be calcium insensitive as it persists in low Ca²⁺ high Mg²⁺ medium with 200 μM Cd²⁺.

The L-AP4 response was markedly decreased or abolished by short applications of the endogenous excitatory amino acids glutamate, aspartate and homocysteate at concentrations of 10–100 μM. The response to L-AP4 following priming might be explained by two mechanisms: a presynaptic action involving (Ca²⁺ insensitive) release of endogenous EAA by L-AP4 from presynaptic or glial sites, or a postsynaptic action whereby quisqualate would sensitize NMDA, AMPA and metabotropic receptors to L-AP4.

BEHAVIORAL EFFECTS OF INTRATHECALLY ADMINISTERED ACPD AND AP4, AGONISTS FOR NOVEL EAA RECEPTORS. **Kelley Kito* and George Wilcox**, Department of Pharmacology, University of Minnesota, Minneapolis, MN 55455.

The involvement of traditional excitatory amino acid (EAA) receptors (NMDA and non-NMDA) in nociceptive neurotransmission in mouse spinal cord has been well documented. In particular, both NMDA and AMPA elicit caudally directed biting behavior in mice and excite nociceptive dorsal horn neurons in rats. We have observed a qualitative difference in the behavior elicited by quisqualate and AMPA. This result suggested the participation of receptors other than the AMPA-gated cation channel in quisqualate's action. Therefore, we chose to examine the participation of the G-protein-coupled (metabotropic) receptor activated by quisqualate and glutamate using (+/-)-1-amino-1,3-cyclopentane-*trans*-dicarboxylic acid (*trans*-ACPD) as an agonist. We observed that ACPD elicited behavior more similar to that elicited by substance P (SP) than to that elicited by NMDA. This result is consistent with the similarity of the intracellular events evoked by both ACPD and SP (i.e., mobilization of IP₃ and Ca²⁺). Biting and scratching behaviors similar to SP behaviors were elicited in a dose dependent manner (0.03, 0.1, 0.3, 1.0 μg/5μL). We tested whether ACPD-elicited behavior or tail flick responses would be inhibited by AP4. For comparison, we tested agents which inhibit SP-elicited behavior, α₂ adrenergic and δ or μ opioid agonists. ACPD-elicited behavior was inhibited by the α₂ adrenergic agonist UK-14304-18 (0.1 μg) and by the δ and μ opioid agonists DPDPE (1 μg) and DAMGO (0.5 ng) but not by AP4 (1 μg). (Supported by NIDA grants R01-DA-04274 and R01-DA-01933)

32.10

RETENTION OF QUISQUALIC ACID BY HIPPOCAMPAL SLICES FOLLOWING QUISQUALIC ACID INDUCED SENSITIZATION TO L-AP4. **M.K. Schulte and J.E. Koerner**, Dept. of Biochem. and Neurosci. Grad. Program, Univ. of Minnesota, Minneapolis, MN 55455

Previous work performed in our laboratory demonstrated that a brief exposure of pyramidal and granule cell neurons of the rat hippocampus to the excitatory amino acid agonist L-quisqualic acid results in a 30-100 fold increase in sensitivity to depolarization by L-AP4 (The QUIS effect). We have also reported that pre-exposure of slices to L-homocysteine sulfinic acid, L-serine-O-sulfate and L-α-amino adipic acid can block induction of this effect and reverse it once it has been induced. The pharmacological profile of the induction site and sensitized L-AP4 site have been extensively investigated, however, the molecular mechanisms involved are unknown. It has been proposed that a first step might involve neuronal uptake of quisqualic acid. Due to the unavailability of radiolabeled quisqualic acid, no direct uptake studies have been performed. We have, therefore, developed a sensitive assay system utilizing HPLC separation of o-phthalaldehyde (OPA) derivatives of quisqualic acid which enables us to detect quisqualic acid retention by hippocampal slices. Slices were monitored via extracellular recording in the regio superior of the stratum radiatum and exposed to quisqualic acid. Following extensive washing with QUIS-free media, quisqualic acid was extracted from the tissue and samples were derivatized with OPA. Derivatized amino acids were separated via HPLC. Our experiments demonstrate a retention by hippocampal slices of 10 pMoles quisqualic acid per mg of tissue. This level of quisqualic acid remains throughout a 2 hour wash with QUIS-free medium. Treatment of slices with "pre-blocker" or "reverser" compounds had no observed effect upon levels of quisqualic acid within the slice. These results are consistent with the hypothesis that a sequestration step is involved in the induction of the QUIS effect.

32.12

ROLE OF NITRIC OXIDE IN N-METHYL-D-ASPARTATE-STIMULATED NEUROTRANSMITTER RELEASE. **A.K. Stout* and J.L. Woodward**, Dept. of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298.

N-methyl-D-aspartate (NMDA) stimulated the release of tritiated norepinephrine from hippocampal slices of adult Sprague-Dawley rats. N-nitro-L-arginine, a competitive inhibitor of nitric oxide (NO) synthase, had no apparent effect on NMDA-stimulated neurotransmitter release at concentrations between 0.1 and 100 μM. Hemoglobin, an iron-containing protein which binds NO, also had no significant effect on NMDA-stimulated transmitter release at concentrations of 0.001-1 μM. However, sodium nitroprusside (SNP), a vasodilator which generates NO upon reacting with sulfhydryl groups, inhibited transmitter release with an IC₅₀ of approximately 100 μM. The inhibitory effect of SNP was not blocked by 1 μM hemoglobin and was not due to the formation of cyanide ions, since equivalent concentrations of potassium cyanide (10-300 μM) actually enhanced NMDA-stimulated release. Pretreatment of the slices with the sulfhydryl reducing agent dithiothreitol (5 mM) more than doubled NMDA-stimulated release and shifted the SNP inhibition curve upward. Pretreatment of the slices with the sulfhydryl oxidizing agent 5,5'-dithio-bis(2-nitrobenzoic acid) (0.5 mM) had no effect on NMDA-stimulated release by itself, but blocked the inhibitory effects of SNP. These results suggest that NO, either directly or indirectly, could feedback to inhibit NMDA-stimulated processes. Supported by NIAAA AA08089 and a grant from the Alcoholic Beverage Medical Research Foundation.

NMDA INCREASES PHOSPHATIDYLINOSITOL HYDROLYSIS VIA THE NOVEL SECOND MESSENGER NITRIC OXIDE IN NEONATAL RAT CEREBELLUM. J. Li¹, M.C. Kennedy and S.S. Smith. Dept. of Anatomy, Inst. for Neurosci., Hahnemann Univ., Philadelphia, PA 19102.

NMDA receptor stimulation has been associated with development and plasticity of the CNS. Recent reports indicate that activation of this excitatory amino acid receptor subtype produces nitric oxide (NO) from arginine substrates (Garthwaite et al, 1989) and results in subsequent increases in cGMP. In the present study, the ability of NMDA to stimulate hydrolysis of phosphatidylinositol (PI) via production of NO was studied in neonatal cerebellar tissue, as sequelae of PI hydrolysis have also been linked with developmental processes in the CNS. Previous results from this lab indicate that the GABA_B agonist baclofen (1 μ M) exerts potent permissive effects on the ability of NMDA (100 μ M) to stimulate PI hydrolysis 70% above basal values (P < 0.001), an 80% increase above NMDA-stimulated levels of this parameter observed under control conditions. PI turnover was assessed using tritiated inositol in 160 μ m cross-chopped slices of cerebellar tissue from 7-9 d.o. female rats. Following a 20 min incubation with agonists and chloroform extraction, total inositol phosphates were separated using anion exchange chromatography. Addition of 30 μ M l-arginine to the incubation mixture produced NMDA-stimulated values of PI turnover which were 50% above basal levels (P < 0.01), an effect similar to that seen in the presence of 1 μ M baclofen. In contrast, administration of 100 μ M L-N^G-monomethyl arginine or N^G-nitro-l-arginine, blockers of nitric oxide production, completely prevented the permissive effect of baclofen on the ability of NMDA to enhance PI hydrolysis. This blockade was reversed by addition of 200 μ M l-arginine. In contrast, incubation with methylene blue (10 μ M), which prevents formation of cGMP, did not alter NMDA-stimulated levels of this parameter, suggesting that stimulation of PI hydrolysis via NMDA-induced production of NO is not mediated by cGMP. Further, it is proposed by the results from this study that the ability of NMDA to produce NO and enhance PI hydrolysis is regulated by the degree of gabaergic tone via the GABA_B receptor, actions which may be relevant for developmental processes in the cerebellum. NITRIC OXIDE (NO) MODULATES NMDA-INDUCED INCREASES IN INTRACELLULAR Ca²⁺ IN CULTURED FOREBRAIN NEURONS. K.R. Gilbert, E. Aizenman¹ and J.J. Reynolds. Departments of Pharmacology and ¹Physiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

N-methyl-D-aspartate (NMDA) receptor responses are potentiated by chemical reduction and are inhibited by oxidation. In our search for potential endogenous redox agents which might physiologically modulate this receptor we tested NO, an oxidizing agent, for its effects on NMDA receptors. We recorded NMDA-induced changes in [Ca²⁺]_i in single cultured rat forebrain neurons using fura-2. Pretreatment with NO (1 μ M-300 μ M) for 200s followed by washing results in significant inhibition of NMDA-elicited calcium fluxes (63.8 \pm 5.6% of control at 100 μ M; mean \pm SEM, p < 0.05 Student's t test, n = 16). Pretreatment with NO (100 μ M) also causes a small, but significant inhibition of [Ca²⁺]_i fluxes in response to 50mM KCl or 50 μ M kainate. Additionally, sodium nitroprusside (1-300 μ M), which releases NO, mimics these effects of NO. Finally, this effect of NO probably is not a consequence of NMDA receptor oxidation because the effects of NO spontaneously reverse upon washing, which is in contrast to the actions of agents that oxidize the NMDA receptor. Because NO release is stimulated by NMDA receptor activation in neurons, this modulation of NMDA receptors by NO may represent a novel feedback mechanism for controlling synaptic NMDA responses.

STIMULATION OF NEURONAL N-METHYL-D-ASPARTATE RECEPTORS BY GLUTATHIONE. L.M. Brown, R.D. Trent¹, Y.H. Lee¹, P.K. Randall, S.S. Lau¹, T.J. Monks¹, and S.W. Leslie. Inst. for Neuroscience and College of Pharmacy, Univ. of Texas, Austin, TX 78712.

Reduced glutathione (GSH, γ -glutamylcysteinylglycine) contains three amino acids which have been demonstrated to interact individually with the NMDA receptor complex. Oxidized glutathione (GSSG) is composed of two molecules of GSH connected by a disulfide bond. This study examined the effects of GSH and GSSG on NMDA receptor function and binding. Dissociated brain cells were isolated from newborn rats and loaded with fura-2 (Dildy and Leslie, *Br. Res.* 492 (1989) 383-387). Concentration-dependent increases in free intracellular Ca²⁺ concentrations ([Ca²⁺]_i) were observed upon the addition of GSH (10-3000 μ M) or GSSG (16-8000 μ M). Concentration effect curves were analyzed by the computer program ALLFIT (DeLean, et al., *Am. J. Physiol.* 235 (1978) E97-E102). The EC₅₀'s for GSH (980.6 \pm 151.9 μ M) and GSSG (908.4 \pm 49.7 μ M) were not significantly different. Maximum responses, expressed as percent change in [Ca²⁺]_i compared to resting levels, for GSH (24.4 \pm 2.4 %) and GSSG (72.8 \pm 1.6 %) were different (p < 0.01). The response produced by 2 mM GSH or GSSG was significantly prevented or reversed by the NMDA antagonists Mg²⁺ (1.0 mM), APV (100 μ M), MK-801 (400 nM), and DGG (250 μ M).

The interaction of GSH and GSSG with the NMDA binding site was also examined. These assays were performed according to the method of Sills et al. (*Eur. J. Pharmacol.* 192 (1991) 19-24) using the high affinity NMDA antagonist [³H]CGP-39653. Saturation curves for [³H]CGP-39653 (0.47-60 nM) generated a K_d of 9 \pm 0.71 nM with a B_{max} of 1265 \pm 69 fmol/mg protein. When these experiments were performed in the presence of 1 μ M GSH the K_d was significantly elevated to 13.3 \pm 1.1 nM and the B_{max} was significantly decreased to 907 \pm 62 fmol/mg protein. Competition curves using 30 nM [³H]CGP-39653 demonstrated that GSH and GSSG inhibited binding with IC₅₀'s of 0.977 \pm 0.18 and 11.2 \pm 1.37 μ M respectively. These results suggest the potential for modulation of the NMDA receptor site by GSH and GSSG. Supported by NIAAA grants AA05809 and AA08104.

NITRIC OXIDE (NO) SELECTIVELY INHIBITS NMDA RECEPTOR ACTIVATION VIA A cGMP-INDEPENDENT PATHWAY. Q.J. Manzoni¹, J. Fagni¹, P. Marin¹, I. Prazeau¹, A. Sahuquet¹, F. Sladeczek and J. Beckaert (spon: F. Sladeczek) C.C.I.P.E. Rue de la Cardonille, 34094 Montpellier Cedex 5 France.

We examined the effects of NO-producing drugs on N-methyl-D-Aspartate (NMDA) receptor activation, measured by Fura-2 ratio imaging and whole cell patch clamp recording in striatal and cerebellar granule neurons in primary culture. Sodium Nitroprusside (SNP), a compound that spontaneously released NO, inhibited in a non competitive manner NMDA-induced [Ca²⁺]_i. This effect was slow to develop (a 5 min preincubation was necessary) and reversible after a 10-15 min washout. NO inhibitory effect was inhibited by haemoglobin that strongly binds NO, and reproduced by glycerol trinitrate, showing that SNP effects were specifically due to NO production. Neither (RS) α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA)- nor 56 mM K⁺-induced [Ca²⁺]_i increase were affected, suggesting that NO effect was specific to NMDA receptors. Both SNP and NMDA were able to induce cGMP formation in striatal neurons, but NO effects were not reproduced by application of cyclic GMP (cGMP) in the recording patch-pipette or by bath perfusion of 8-bromo-cGMP, showing that NO inhibitory action did not depend on cGMP accumulation. Interestingly, we found that NO inhibitory effects were not obtained when the NMDA receptor was already occupied by NMDA or by competitive antagonists (CPP or AP5). Furthermore, the specific binding of [³H]-CGS 17955 at the NMDA binding site was displaced by SNP pretreatment, strongly suggesting that NO could directly act at the NMDA binding site. Since NMDA receptor activation is known to induce NO synthesis, a feedback inhibition of NMDA receptor action is likely. NO could play a role in heterosynaptic depression and neuroprotection.

32.16

AGONIST ACTION OF L-PROLINE AT GLUTAMATE AND GLYCINE RECEPTORS. V. Henzi and A.B. MacDermott. Dept. of Physiology and Center for Neurobiology and Behavior, Columbia University, New York City, NY 10032.

The capability of brain tissue for high-affinity reuptake and K⁺-evoked release of L-proline (PRO) have implicated it as a potential neurotransmitter. However, to date it has remained unclear which neuronal receptors are sensitive to PRO. We have found that millimolar concentrations of PRO evoke an inward current in voltage-clamped rat embryonic spinal cord neurons in culture that is partially blocked by APV (30 μ M) and CNQX (10 μ M), the selective glutamate receptor antagonists (Helm et al, 1990). We now report that the remaining portion of the PRO-activated current is blocked by the selective glycine receptor antagonist strychnine (5 μ M). Furthermore, using combinations of the selective antagonists, we isolated APV-, CNQX-, and strychnine-sensitive components of the PRO-evoked whole-cell currents and found that these had identical characteristics (reversal potential, desensitization, and other criteria) to those evoked by the selective agonists NMDA, kainate, and glycine respectively. This establishes an agonist action of PRO at strychnine-sensitive glycine receptors and at NMDA and non-NMDA glutamate receptors. No evidence was obtained for the proposal that PRO can act as an antagonist at these receptors or as an agonist at the strychnine-insensitive glycine site of the NMDA receptor. We went on to evaluate the agonist potency of PRO at each of these receptor subtypes. Detectable strychnine-sensitive currents were observed with [PRO] > 100 μ M, while APV- and CNQX-sensitive currents were first observed with [PRO] > 300 μ M. In each case, the responses did not saturate even at [PRO] = 50 mM. At 10 mM PRO, the APV-, CNQX-, and strychnine-sensitive currents were comparable to currents elicited by 15 μ M NMDA, 5 μ M kainate, and 35 μ M glycine respectively. These actions may be physiologically significant if PRO functions as a neurotransmitter as well as in cases of hyperprolinemia, a metabolic disorder in which the [PRO] in cerebrospinal fluid reaches high micromolar concentrations.

PREGNENOLONE SULFATE: A POSITIVE MODULATOR OF THE NMDA-INDUCED CURRENT IN CULTURED NEURONS. F.-S. Wu, T.T. Gibbs, and D.H. Farb. Dept. of Pharmacology and Experimental Therapeutics, Boston Univ. Sch. of Med., Boston, MA 02118.

We have shown previously that the neurosteroid pregnenolone sulfate (PS) is a negative modulator of both GABA and glycine responses. Here we examine the effects of this steroid on currents induced by N-methyl-D-aspartate (NMDA), kainate, and α -amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA) in cultures of chick spinal cord neurons. Using whole-cell recording methods, cells were voltage-clamped at -70 mV. Drug solutions were applied to single neurons by pressure ejection from 7-barrel pipets. PS (100 μ M) rapidly and reversibly potentiated the response to 30 μ M NMDA (by 197%) and slightly inhibited responses to 50 μ M kainate (by 25%) and 25 μ M AMPA (by 29%). Potentiation of the NMDA response by PS in the presence of a maximal concentration (10 μ M) of glycine did not differ significantly from that measured without added glycine, indicating that glycine contamination cannot account for the observed effect. Similarly, potentiation of the NMDA response by 10 μ M glycine was still observable in the presence of a near-maximal concentration (100 μ M) of PS, indicating that enhancement of the NMDA response by PS is not mediated by the glycine modulatory site of the NMDA receptor. The effects of PS on NMDA and GABA were dose-dependent, with EC₅₀ values of 57 and 7 μ M and maxima of +256 and -100%, respectively. These results are consistent with the hypothesis that neurosteroids such as PS are involved in regulating the balance between excitation and inhibition in the central nervous system.

32.19

N-ACETYL-ASPARTYL GLUTAMATE (NAAG) AND ACTIVATORS OF THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR/CHANNEL COMPLEX AS REGULATORS OF [³H]NOREPINEPHRINE ([³H]NE) RELEASE FROM RAT HIPPOCAMPAL SLICES. L.L. Werling, D. Montgomery, J.T. Coyle and P.S. Puttfarcken. Dept. Pharmacology, The GWU Med. Ctr., Washington, DC 20037 and Dept. Psychiatry, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

NMDA and other agonists at the NMDA receptor/channel complex have previously been reported to stimulate the release of NE from rat hippocampus. NAAG and NE are colocalized in cell bodies of the locus coeruleus, the origin of noradrenergic projections to the hippocampus. We have studied the interaction between NAAG and activators of the NMDA receptor/channel complex.

Hippocampi of rats were dissected, chopped into strips, washed in modified Krebs-HEPES buffer (MKB), and incubated with 15 nM [³H]NE. Tissue was washed with MKB, resuspended in MKB containing 1 μM concentrations of desipramine and yohimbine to prevent reuptake of and feedback inhibition by released [³H]NE, and loaded into superfusion chambers. After establishment of a low, stable baseline release, tissue was stimulated by 2 min exposures to excitatory amino acid.

Under conditions in which activity of NAALadase, the enzyme responsible for the degradation of NAAG to N-acetyl aspartate (NAA) and glutamate, was inhibited, NAAG (1 mM) had no effect on release of [³H]NE. NAA (1 mM) also had no effect on release. However, the other degradation product glutamate (50 μM-1 mM), as well as NMDA (25 μM) stimulated release of [³H]NE. This release was sensitive to the non-competitive NMDA antagonist MK-801. The presence of 50 or 100 μM NAAG significantly reduced glutamate- and NMDA-stimulated release. This suggests a potential neuromodulatory role for NAAG in the release of NE from hippocampus. (Supported by an NRSA from NIMH to PSP and a PMAF grant to LLW).

EXCITATORY AMINO ACIDS: RECEPTORS I

33.1

CLONING OF, GLUR6, A GLUTAMATE RECEPTOR SUBUNIT ACTIVATED BY KAINATE BUT NOT AMPA. J. Egebjerg*, B. Bettler*, J. Hermans-Borgmeyer* and S. Heinemann. Molecular Neurobiology Laboratory, The Salk Institute for Biological Studies, La Jolla, CA 92037

We have cloned a glutamate receptor subunit, GluR6, using GluR5 as probe in a low stringency hybridization screening approach. Sequence homology between cDNA clones encoding GluR1-GluR6 receptor subunits reveals the existence of two subunit classes: the GluR1 to GluR4 class, and the GluR5 and GluR6 class. Receptors generated from the GluR1-GluR4 class have a high apparent affinity for AMPA whereas the GluR6 subunit has the highest apparent affinity for kainate. Upon expression in *Xenopus* oocytes the homomeric GluR6 receptor is activated by kainate, quisqualate and L-glutamate but not by AMPA. The order of EC₅₀'s is kainate < quisqualate < glutamate. Desensitization of the receptor was observed in continuous application of agonist. The homomeric GluR6 glutamate receptor exhibits an outwardly rectifying current-voltage relationship. Finally, in situ hybridization reveals a pattern of GluR6 gene expression reminiscent of the binding pattern obtained with [³H]kainate, showing high levels of transcript in regions which are most sensitive to kainate induced cell death.

33.3

MOLECULAR CLONING OF NEURONAL AND MUSCLE SPECIFIC GLUTAMATE RECEPTOR SUBUNITS OF *DROSOPHILA*. C. M. Schuster*, A. Ullsch*, P. Schloss*, B. Schmitt* and H. Betz. (SPON: European Neuroscience Association). Zentrum für Molekulare Biologie, Universität Heidelberg, Im Neuenheimer Feld 282, D-6900 Heidelberg, FRG, and Max-Planck-Institut für Hirnforschung, Abteilung Neurochemie, Deutschordenstraße 46, D-6000 Frankfurt 71, FRG.

Insects and other invertebrates use glutamate as a neurotransmitter both in the central nervous system and at the neuromuscular junction. We have isolated cDNAs from *Drosophila melanogaster*, which encode two distinct glutamate receptor (GluR) subtypes, designated DGluR-I and DGluR-II. Primary structure analysis indicates a close evolutionary relationship between DGluR-I and the family of rat brain kainate/AMPA-sensitive GluR subunits, whereas DGluR-II represents a distant homolog of these proteins. Whole mount *in situ* hybridisation and Northern blot analysis disclosed a differential expression regulation for DGluR-I and DGluR-II mRNA: DGluR-I transcripts accumulate during major periods of neuronal differentiation and are localized in the developing central nervous system, whereas the embryonic DGluR-II gene expression seems to be restricted to somatic muscle tissue. Functional expression in *Xenopus* oocytes revealed that DGluR-II proteins form L-glutamate and L-aspartate gated cation channels of low agonist affinity. Our data indicate that this muscle-type GluR subunit shares structural and functional features with both the *Drosophila* neuronal DGluR-I and different excitatory amino acid receptor subtypes from mammalian brain. This suggests that the DGluR-II protein represents a distinct GluR subtype, and that all subtypes of the ionotropic glutamate receptor superfamily exhibit a common structural design. Supported by DFG (Leibniz Prog.), BMFT (BCT 365/1) and Fonds der Chemischen Industrie.

FUNCTIONAL CHARACTERIZATION OF A THIRD ISOFORM OF RAT GLUR4. C.A. Winters*, V. Gallo, A. Buonanno, L. Vyklicky*, M.L. Mayer, J.T. Russell. Section of Neurophysiology and Biophysics, Unit on Molecular Neurobiology, Section of Neuronal Secretory Systems, LDN, NICHD, NIH, Bethesda, MD 20892.

Glutamate receptor subunits activated by kainate and AMPA have been shown to exist in flip and flop isoforms generated by alternative splicing, (Sommer, 1990). An additional isoform of the flop version of the GluR-4, differing in sequence for 36 amino acids located at the C-terminus, was isolated by screening a rat cerebellar cDNA library, (see Gallo, Neurosci. Abstr., 1991).

Xenopus levis oocytes were injected with 10 ng of RNA synthesized from GluR-4c cDNA. Experiments were performed under two-electrode voltage-clamp 4-6 days after injection. Agonists were applied rapidly using a small chamber with a volume of ~ 3 μl. AMPA-kainate receptor agonists but not N-methyl-D-aspartic acid induced inward currents. Dose response curves exhibited the following EC₅₀ values and Hill coefficients: Kainate 44 ± 9 μM, 1.3 ± 0.1; domoate 6.1 ± 2.8 μM, 0.9 ± 0.1; quisqualate 0.36 ± 0.07 μM, 0.6 ± 0.02 and glutamate 1.8 ± 1.4 μM, 0.7 ± 0.1. Responses to kainate were blocked by 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) with a Ki = 0.43 ± 0.26 μM. These values are similar to those reported for the GluR-1 flop clone (Dawson et al, 1990). No potentiation of the kainate response was observed with coapplication of zinc, however inhibition occurred with zinc concentrations greater than 30 μM. Coapplication of 0.3 μM to 30 μM quisqualate reduced the current evoked by 100 μM kainate with an IC₅₀ of 3.5 ± 2.7 μM. The I/V relationship, recorded using 100 μM kainate, showed inward rectification: The slope was linear between -100 mV and -60 mV but decreased with further depolarization. No inward current was detectable above 0 mV.

Further studies characterizing the functional properties of this clone compared to those for other glutamate receptor subunits and the native receptor will be presented.

PURIFICATION, PHARMACOLOGICAL CHARACTERIZATION AND CLONING OF NMDA RECEPTOR. K.N. Kumar, N.T. Tilakaratne, P.S. Johnson, K.T. Eggeman, E.K. Michaelis. Departments of Pharmacology & Toxicology, Biochemistry and the Center for Biomedical Research, University of Kansas, Lawrence, Kansas 66045.

Our laboratory has recently purified a complex of four proteins with molecular weights of 70, 59, 47 and 36 kDa from rat brain synaptic membranes. The purification was carried out on a glutamate derivation affinity matrix and specifically eluted with NMDA. This complex of proteins had the ligand binding sites for the agonists glutamate and NMDA, the antagonists CPP and AP-7, the modulator glycine and the ion channel blockers TCP, PCP AND MK-801 that act on NMDA receptor. The same complex of proteins did not bind AMPA, kainate or quisqualate. The ligand binding constants for L-glutamate, NMDA and TCP were equivalent to those determined in synaptic membrane preparations. The 70 kDa subunit of this complex was recognized by antibodies raised against the previously purified 70 kDa glutamate-binding protein (Eaton et al., *J. Biol. Chem.* 265:16195, 1990). These antibodies were used to screen cDNA libraries from the rat brain hippocampus and a 2.3 kb cDNA for the 70 kDa subunit of the complex was cloned and sequenced. 33.5

ION CHANNEL CHARACTERIZATION OF A RECONSTITUTED GLUTAMATE/NMDA SENSITIVE RECEPTOR COMPLEX. Katy Eggeman, Gary Aistrup, K.N. Kumar, E.K. Michaelis, R. L. Schowen*. Departments of Biochemistry, Pharmacology and Toxicology, Chemistry, and the Center for Biomedical Research, University of Kansas, Lawrence, KS 66045.

In attempts to demonstrate ion channel function of an isolated protein complex that represents the NMDA receptor (K.N. Kumar, et. al., this meeting), planar lipid bilayer membrane (PLM) reconstitution studies were undertaken in our laboratory. These studies involved the identification of channel conductances, effector ligand concentration dependence, and kinetic analyses of the corresponding closed and opened states of the reconstituted channel. At present, much of the evaluation has been restricted to those responses evoked by L-glutamate, but agonist/antagonist studies have been initiated. Initial results indicate multiple conductance levels of 20-25 pS, 40-50 pS, and 60-80 pS for single-channel responses activated by 8-10 μ M L-glu. Mean open/closed state lifetime distribution analysis shows fast, intermediate, and slow components of the time constant for each level. A simple three entity, two state model has been proposed to explain the fractional dwell time in each conductance state, and possibly the transition rates between them. (Supported by grants AA04732 and DAAL-03-88-K0017)

33.7

A CHIMERIC AMPA RECEPTOR SUBUNIT: DISCRETE SEQUENCE CHANGES TRANSFORM GLUR1 INTO GLUR2. P.Bochet*, A.Dutriaux*, B.Lambolez*, E.Nalivaiko*, J.Rossier and L.Prado de Carvalho*. Laboratoire de Physiologie Neveuse. Centre National de la Recherche Scientifique. 91198 Gif sur Yvette Cedex. France.

GluR1, GluR2 and GluR3 are three highly homologous subunits of the glutamate AMPA receptor but with different functional properties. In ligand gated channels the second transmembrane domain is thought to form the wall of the ionic channel and determine its electrical properties. A chimeric AMPA receptor subunit was constructed by replacing the region comprising the putative first and second transmembrane domains in GluR1 by the corresponding region of GluR2. The functional properties of the resulting chimera, which is essentially GluR1 with a stretch of 143 amino-acids from GluR2, were studied in the *Xenopus laevis* oocyte expression system. Similar to GluR2, the chimera did not respond to agonists but greatly enhanced the response when coexpressed with GluR1, indicating the formation of heteromers. Furthermore, the current-voltage relationship of GluR1 + chimera was linear like that of GluR1 + GluR2 and did not display the strong inward rectification characteristic of GluR1 alone. Sequence comparisons suggest that the presence of an arginine in the chimera in the place of glutamine at position 600 in GluR1 and GluR3 is responsible for these properties.

33.9

PARTIAL PURIFICATION AND SPECIFIC IMMUNOREACTIVITY OF THE AMPA-TYPE GLUTAMATE RECEPTOR FROM RAT BRAIN. R. Hall*, B.A. Bahr, M. Kessler, K. Sumikawa & G. Lynch*. Ctr. Neurobio. of Learning/Memory, and Dept. of Psychobio, Univ. of Calif., Irvine, CA 92717

The subclass of glutamate receptors specifically activated by AMPA (α -amino-3-hydroxy-5-methylisoxazole-4-propionic acid) appears to mediate most of the excitatory synaptic transmission in the brain and a recent study by Staubli et al. (*Psychobio*, 18377, 1990) has shown that a change in this receptor most likely accounts for the expression of long-term potentiation, a lasting increase in synaptic strength presumably involved in memory encoding. The present study is aimed at methods which may lead to the purification of this receptor. More than 50% of the [3 H]AMPA binding sites were solubilized from rat forebrain membranes (1 mg protein/ml) with 1% Triton X-100. Each of the following procedures produced a significant increase in specific AMPA binding (shown in parenthesis): (a) DEAE anion-exchange chromatography (up to 10 fold); (b) wheat-germ lectin affinity chromatography (10-15 fold); (c) heparin affinity chromatography (5-10 fold); and (d) hydroxyapatite adsorptive chromatography (up to 5 fold). Sequential application of these procedures produced as much as 40-fold purification. The partially purified AMPA receptor chromatographed on an HPLC size exclusion column with an apparent particle molecular mass (including bound detergent) of approximately 425,000 daltons, whereas on silver-stained polyacrylamide gels a single band was enriched with each purification step which had an electrophoretic mobility corresponding to 102 kDa. Using fusion techniques, rabbit antibodies (anti-AR) were developed toward a 19 amino acid sequence located in the large extracellular N-terminal domain of the 'Glu 1' receptor (based on the cloned sequence and nomenclature of Hollmann et al. *Nature* 342:643, 1989). Through consecutive chromatographic steps, [3 H]AMPA binding and the immunolabeling of a 102 kDa band by anti-AR were comparably enhanced. The data suggest that anti-AR recognizes the AMPA-type glutamate receptor present in the central nervous system and that this receptor is a tetramer consisting of four subunits of about equal mass. (Supported by grants AFOSR #89-0383 and NIH #21860)

33.6

NMDA RECEPTOR PROTEIN IN CULTURED HIPPOCAMPAL NEURONS: DEVELOPMENTAL EXPRESSION, RELATION TO EXCITOTOXICITY, AND REGULATION BY BASIC FGF. E.K. Michaelis, H. Wang*, M.P. Mattison*. Dept. Pharmacology and Toxicology, Univ. of Kansas, Lawrence, KS 66045. Center on Aging and Anatomy & Neurobiol., Univ. of Kentucky, Lexington, KY 40536.

We recently isolated, characterized and cloned a 71 kDa subunit of the NMDA receptor protein (NMDARP) from rat brain (Kumar, et al., this meeting). We now report on the localization, function, and regulation by growth factors of this NMDARP in cultured embryonic rat hippocampal neurons. Immunocytochemistry and Western blots using monoclonal antibodies to the NMDARP demonstrated an increase in its expression in neurons with time in culture. NMDARP was localized to the somata and dendrites of pyramidal-like neurons and was sparse or absent in the axons. The developmental expression of NMDARP immunoreactivity closely paralleled the development of sensitivity to NMDA neurotoxicity, and neurons with high levels of NMDARP immunoreactivity were the most vulnerable to NMDA. A polyclonal NMDARP antiserum reduced NMDA neurotoxicity selectively. We previously found that FGF protected neurons against glutamate toxicity (*J. Neurosci.* 9:3728). Here we show that bFGF (but not NGF or EGF) causes a marked reduction in NMDARP levels in the cultured hippocampal neurons. We are currently examining the expression of mRNA for the NMDARP. This first demonstration of regulation of the expression of a glutamate receptor protein by a growth factor suggests that growth factors may play roles in modifying both adaptive and pathological actions of excitatory amino acids. Supported by AA04732, ARO DAAL-03-88-K0017 (E.K.M.); and NS 29001, AG05144, Alzheimer's Association (M.P.M.).

ANALYSIS OF SIGNAL TRANSDUCTION AND LIGAND-BINDING OF CHIMERIC cDNAs WITH KBP AND GLUR1. K. Doi*, N. Yokotani*, R.J. Wenthold and K. Wada*. Lab. of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892

cDNAs encoding a kainate-binding protein (KBP) and glutamate receptor subunits (GluR1-5) were isolated from frog, chick and rat brain, respectively (Wada et al., *Nature*, 342, 684, 1989; Gregor et al., *Nature*, 342, 689, 1989; Bettler et al., *Neuron*, 5, 583, 1990). We constructed four chimeric cDNAs with KBP and GluR1 to examine a possibility that KBP is a part of a kainate receptor-ionophore complex and to identify molecular regions that are responsible for the kainate-binding activity of KBP. Chimeric cDNAs are: 1) GluR-KBP had N-terminal half of GluR1 and transmembrane domains and C-terminal extracellular domain of KBP. 2) KBP-GluR had N-terminal extracellular domain of KBP and C-terminal half of GluR1. 3) short KBP had a truncation of N-terminal extracellular domain of KBP. 4) KBP-GluR-KBP had N-terminal extracellular domain, transmembrane domains of GluR1 and C-terminal extracellular domain of KBP. Two-microelectrode voltage clamp of the oocytes injected with chimeric cRNAs and receptor ligand-binding of the transfected cells with chimeric cDNAs revealed that: 1) GluR-KBP might form a channel that was weakly activated only by L-glutamate. 2) KBP-GluR did not form a functional glutamate receptor. 3) GluR-KBP had kainate-binding activity as much as KBP while KBP-GluR did not have any. 4) short KBP did not have any kainate-binding activity. The results suggest that KBP might require additional factors to be assembled into a receptor-ionophore complex and that multiple regions of KBP are required for its kainate-binding activity.

SERINE AND TYROSINE PHOSPHORYLATION OF RECOMBINANT NON-NMDA GLUTAMATE RECEPTORS. S.J. Moss*, C.D. Blackstone, L. Raymond and R.L. Huganir*. Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

To examine the role of protein phosphorylation in the regulation of glutamate receptor function, we have been studying phosphorylation of recombinant non-NMDA glutamate receptor subunits transiently expressed in human embryonic kidney 293 cells. Using polyclonal anti-peptide antisera raised against the GluR1 subunit, we have immunoprecipitated a 106 kD phosphoprotein corresponding to the GluR1 subunit. The GluR1 subunit in this system is basally phosphorylated predominantly on serine residues. Treatment of the 293 cells with TPA, an activator of protein kinase C, increases phosphorylation of the GluR1 protein on serine residues. Phosphopeptide map analysis suggests that a single site is phosphorylated under both basal conditions and TPA stimulated conditions. Co-expression of the GluR1 subunit with v-src in 293 cells results in tyrosine phosphorylation of GluR1. These results suggest that the GluR1 protein is a substrate for protein kinase C and for protein tyrosine kinases. We are currently mapping these phosphorylation sites of the GluR1 subunit by site-specific mutagenesis. Comparisons between mutant nonphosphorylated receptors and the wild-type phosphorylated receptors will allow precise investigation of the effects of phosphorylation on ion channel function.

33.11

NMDA RECEPTOR PLASTICITY: SELECTIVE REGULATION OF RECEPTOR SUBTYPES BY KINDLING. D. W. Bonhaus, G. C. Yeh, J. V. Nadler and J. O. McNamara, Duke & V.A. Medical Centers, Durham, NC 27710

Kindling has been shown to upregulate hippocampal NMDA receptors. To characterize this receptor plasticity we examined the effects of kindling on the binding of NMDA receptor ligands ($[^3H]CPP$, $[^3H]CGS-19755$, $[^3H]L$ -glutamate) and on the agonist-dependent binding of an NMDA channel blocker ($[^3H]TCP$). Binding was measured in hippocampal membranes of amygdala kindled rats sacrificed 28 days after the last kindling stimulation. Kindling produced a 40-46% increase in the number of hippocampal $[^3H]CPP$ and NMDA-sensitive $[^3H]L$ -glutamate binding sites but did not significantly modify the number of $[^3H]CGS-19755$ binding sites. The binding affinity for $[^3H]CPP$ was decreased while that for $[^3H]L$ -glutamate and $[^3H]CGS-19755$ was unaltered. In parallel, kindling decreased the potency of CPP in inhibiting glutamate-stimulated $[^3H]TCP$ binding but had no effect on the potency of CGS-19755. In contrast to the diminished potency of CPP, kindling markedly increased the potency of the NMDA antagonist APV in this paradigm. Thus, kindling upregulated hippocampal NMDA receptors in a manner detected by $[^3H]L$ -glutamate and $[^3H]CPP$ but not $[^3H]CGS-19755$. These data strongly suggest that kindling selectively upregulates specific NMDA receptor subtypes. The differing effects of kindling on the potency of CPP and APV indicates that the upregulation does not correspond to a change in the so called agonist or antagonist preferring conformational state of the receptor. These changes probably explain the enhanced ability of NMDA to depolarize CA3 pyramidal cells in kindled rats and may contribute to the maintenance of the kindled state.

33.13

ZINC POTENTIATES DESENSITIZED KAINATE CURRENTS OF A GLUTAMATE RECEPTOR CLONE (GluR3). J.C. Dreixler and J.P. Leonard, Dept. of Biol. Sciences, Univ. of Illinois at Chicago, Chicago, IL 60680.

Endogenous zinc may take part in modifications that may contribute to synaptic plasticity. It has been shown that low concentrations of zinc do potentiate non-NMDA currents in *Xenopus* oocytes expressing total rat brain RNA [Rassendren, F-A et al. *Neuron*, 4, 733-740]. We used *Xenopus* oocytes to express mRNA of a glutamate receptor clone (GluR3) [Boulter, J. et al. *Science*, 249, 1033-1037]. Using a two electrode voltage clamp technique, desensitized currents were obtained upon application of 100 μ M kainate for 5 minutes. One minute later, during constant kainate perfusion, a solution of 5 μ M ZnSO₄ plus 100 μ M kainate was applied. We confirmed the effects of zinc on currents in oocytes expressing total rat brain RNA. We also found that zinc enhanced the currents expressed from GluR3 mRNA by 70 \pm 12% (s.e.m.) at -120 mV and by 82 \pm 10% at -80 mV. Here we show that the receptor-channel formed by GluR3 alone may be responsible for this effect. The domain responsible for zinc potentiation and the role of other subunits is under investigation. (Supported by NIH NS26432)

CHARACTERIZATION AND DISTRIBUTION OF GLUTATHIONE RECEPTORS AND GLUTATHIONE UPTAKE IN VISUAL CORTEX
S. Bowsby and C. Shaw, Depts. of Ophthalmology and Physiology, University of British Columbia, Vancouver, B.C., Canada V6T 1W5

Glutathione (GSH) has been suggested to be an excitatory-amino-acid (EAA) neurotransmitter candidate in the CNS (Ogita and Yoneda, 1987). We have attempted to characterize GSH receptors and examine their distribution in rat and cat primary visual cortex using *in-vitro* radioligand methods on 20- μ m-thick sections. Saturation binding of radiolabeled GSH in rat primary occipital cortex sections revealed a high-affinity site ($K_d = 5.4 \pm 0.8$ nM; $B_{max} = 235 \pm 16$ fmol/mg) and a much denser low-affinity site ($K_d = 1.25 \pm 0.3$ μ M; $B_{max} = 1.26 \pm 0.7$ pmol/mg), the latter in the affinity range for EAAs. Kinetic experiments yielded similar K_d s. Displacement studies of the EAA-range GSH binding showed a separate GSH site as well as binding with affinity for the EAA-neurotransmitter candidates cysteine, aspartate, and glutamate. The only EAA-subtype specificity shown was for AMPA. Radiolabeled GSH binding in adult rat visual cortex showed relatively uniform distribution across all cortical layers. Characterization and distribution studies in cat gave similar results with the exception that radiolabeled GSH binding was densest in layer 4 at 13 and 32 days of age. *In-vivo* microinjection of radiolabeled GSH and of its primary metabolites into area 17 of rat and cat produced uptake to visual-system thalamic nuclei. The presence of GSH receptors in visual cortex and GSH uptake to the LGN may suggest a role for GSH as a geniculate-occipital neurotransmitter.

33.12

Pharmacologically-Distinct NMDA Receptor Subtypes. D.T. Monaghan & J.A. Beaton*, Dept. Pharm., UNMC, Omaha, NE, 68198. Since the N-methyl-D-aspartate (NMDA) class of excitatory amino acid receptor plays a critical role in both normal and pathological processes throughout the vertebrate CNS, the identification of pharmacologically-distinct NMDA receptor subtypes is likely to be important for the therapeutic use of compounds active at the NMDA receptor. To evaluate possible subpopulations of NMDA receptors, several compounds were tested as inhibitors of L- $[^3H]$ glutamate binding to NMDA receptors in various regions of rat brain by quantitative autoradiography (*Eur. J. Pharm.* 194:123). In addition to differing regional distributions in the potencies of agonists and antagonists, agonists displayed two patterns of regional variation; antagonists displayed three patterns of regional variation. While all agonists displayed higher affinities in the medial striatum than in the lateral thalamus, only two agonists, quinolinate and homoquinolinate, displayed markedly lower affinities in the cerebellar granule cell layer. Curve-fitting analysis indicated that quinolinate and homoquinolinate each displayed two affinity components (24 μ M & 275 μ M and 0.26 μ M & 49 μ M, respectively). While all antagonists displayed higher affinities in the lateral thalamus than in the medial striatum, certain antagonists, such as CPP (3-(+)-2-carboxy-piperazin-4-yl-propyl-1-phosphonate), displayed a significantly lower affinity in the cerebellum than in other brain regions that was described by two affinity components. NMDA receptors of the medial thalamus also displayed relatively lower affinities specifically for homoquinolinate and CPP, but these binding sites were not pharmacologically identical to those found in the cerebellum and thus appear to represent a third class of pharmacologically-distinct NMDA receptor. (Support: NS 28966 & Eli Lilly Co.)

33.14

L-BOAA (β -N-OXALYLAMINO-L-ALANINE) EXHIBITS AMPA-LIKE AGONIST PROPERTIES AT NON-NMDA EXCITATORY AMINO ACID RECEPTORS EXPRESSED IN *XENOPUS* OOCYTES. D. Bednar, C. Maciver and W. Karbon, Nova Pharmaceutical Corporation, Baltimore, MD, 21224-2788.

The plant excitotoxin β -N-oxalylamino-L-alanine (L-BOAA) has been implicated as a causative agent in human lathyrism. In the present study electrophysiological responses to L-BOAA ($EC_{50} = 23$ μ M), AMPA ($EC_{50} = 5$ μ M) and kainic acid KA, ($EC_{50} = 90$ μ M) were characterized in *Xenopus laevis* oocytes injected with rat brain poly (A⁺) RNA. Although L-BOAA and AMPA produced inward currents having similar maximal amplitudes, they were substantially smaller than currents elicited by KA. In addition, L-BOAA, AMPA and KA demonstrated similar reversal potentials. The competitive non-NMDA antagonists DNQX ($K_i = 411$ nM) and NBQX ($K_i = 118$ nM) potently inhibited L-BOAA, with similar values being obtained for inhibition of AMPA. L-BOAA (100 μ M) reduced the response to KA (100 μ M) by 50% regardless of whether oocytes were pre-exposed to L-BOAA or simultaneously exposed to L-BOAA and KA. Similarly, AMPA (30 μ M) inhibited the response to KA by 30%. Simultaneous exposure of oocytes to saturating concentrations of AMPA (30 μ M) and L-BOAA (100 μ M) produced a response no greater than those obtained with either agent alone. These findings are evidence that L-BOAA, AMPA and KA interact with a common non-NMDA excitatory amino acid receptor in *Xenopus* oocytes and that AMPA and L-BOAA are partial or desensitizing agonists at these sites.

33.16

RELEASE OF GLUTATHIONE UPON DEPOLARIZATION OF RAT BRAIN SLICES. L. Zängerle*¹, M. Cuénod¹, K. Winterhalter*² and K.Q. Do¹. ¹Brain Res. Inst., Univ. of Zürich, CH-8029 Zürich; ²Laboratory for Biochemistry I, ETH-Zentrum, CH-8092 Zürich, Switzerland

The functional roles of the abundant tripeptide glutathione (γ -glutamyl-cysteinyl-glycine) are still undefined in CNS. It has been shown to inhibit the binding of glutamate to the NMDA recognition sites (Yoneda et al., 1990). Moreover, the NMDA responses were sensitive to redox agents (Aizeman et al. 1989). We investigated the release of reduced and total (reduced + oxidized) glutathione from brain slices upon 50mM K⁺-depolarization. Superfusates were derivatized with iodoacetic acid and o-phthaldehyde and analyzed by HPLC. The stimulated efflux of total glutathione was most prominent in cortex (3.9 pmol/mg protein/min; 3.0 x increase compared with resting efflux) and mesodiencephalon (4.0; 2.8 x), followed by striatum (2.6; 2.7 x) and hippocampus (2.6; 2.5 x), and lowest in medullas (2.0; 2.4 x) and cerebellum (2.2; 1.8 x). The Ca²⁺-dependency of these increases varied from 90% to 60%. A large part of the endogenous glutathione released was detected in the reduced form (85-100%). Taken together, our results suggest a role for glutathione in synaptic transmission, possibly in the redox modulation of receptors and channels.

33.17

CONANTOKINS, LIGANDS FOR THE NMDA RECEPTOR. L. J. Cruz, R. A. Myers*, J-F. Hernandez*, J. Torres*, J. Rivier* and B. M. Olivera. Dept. of Biology, Univ. Utah, Salt Lake City, UT 84112; Marine Science Inst., Univ. Philippines, Diliman, Q. C. 1101; Salk Inst., La Jolla, CA 92057.

Conantokins, the first neuroactive peptides found to contain γ -carboxyglutamate (Gla), specifically inhibit glutamate receptors of the NMDA receptor subtype in several higher vertebrate systems. The conantokins isolated so far do not contain the multiple disulfide bonds characteristic of most *Conus* peptides; instead they have 4 conserved residues of Gla. An analysis of the natural peptides, as well as various analogs and derivatives suggest at least three structural motifs for full conantokin activity: the Gly-Glu residues at the amino end, an α -helical region stabilized by Gla residues, and the presence of positive charge(s) in the carboxyl terminal region.

One striking feature of these peptides is that they induce sleeping in 2-week old mice and cause hyperactivity in older mice. In the systems tested so far, such as *Xenopus* oocytes (Hammerland et al., *Neurosci. Abstr.*, 16: 540, 1990), rat cerebellar slices (Mena et al., *Neurosci Letters* 118:241, 1990), and rat cerebellar granule cells in culture (Haack et al., *J. Biol. Chem.* 265: 6025, 1990), conantokins act as antagonists of the NMDA receptor. However, the hyperactivity induced in older mice suggests that the peptides may also have some agonist effects in other systems. (Supported by NIH grants GM22737 and NS 27219.)

33.19

NOVEL KAINATE DERIVATIVES: THEIR CHARACTERISTIC POTENT EXCITATORY ACTIONS IN THE RAT. M. Ishida and H. Shinozaki. The Tokyo Metro. Inst. Med. Sci., Tokyo 113, Japan.

Some kainate agonists have been available for pharmacological examinations. Recently we have found another kainoid, acromelic acid A, which is a more potent kainate-type agonist than kainic acid or domoic acid. Systemic administration of acromelate shows quite different behavioral signs and distribution of neuron damage from that of kainate in the rat. This finding prompted us to search for new powerful kainoids, and we obtained several new compounds. Among them, a methoxyphenyl kainate derivative (MFPA) showed a higher depolarizing activity than acromelic acid in the newborn rat spinal motoneuron, and depolarized isolated dorsal root fibers more significantly than kainate. In addition, the MFPA-induced depolarization was reduced by CNQX in a dose dependent manner, and MFPA and kainate induced cross desensitization of receptors on the isolated dorsal root fiber, suggesting that MFPA is a kainate-type agonist. This compound demonstrated behavioral signs in common with both kainate and acromelate in the rat. The discovery of potent kainoid compounds that are capable of producing marked depolarization in the CNS would provide a variety of new opportunities for neurobiologists, for example, classification of supposed subtypes of kainate receptors.

33.18

CONANTOKINS AND THEIR INTERACTION WITH THE NMDA RECEPTOR R. A. Myers*, J. Haack, J. S. Imperial*, T. Parks and B. M. Olivera. Depts. of Biology and Anatomy, University of Utah, Salt Lake City, UT 84112.

The conantokins, peptides from *Conus* venoms (McIntosh et al. (1984) *J. Biol. Chem.* 259: 14343) reported to target the N-methyl-D-aspartate (NMDA)-subtype of glutamate receptor (Olivera et al. (1990) *Science* 249: 217-332), undergo a Ca^{++} -dependent transition to a tight α -helix, which binds phospholipid membranes. The conantokins apparently interact with the receptor's NMDA agonist site as evidenced by displacement binding of [3H]CGP-39653 (apparent $K_i=3 \mu M$) of postsynaptic densities (PSD). A similar interaction with the NMDA site has been demonstrated by monitoring NMDA-induced Ca^{++} entry into cerebellar granule cells by fura-2 fluorescence. Using this assay, no conantokin inhibition is observed on the co-agonist effects of glycine, nor do conantokins modulate the inhibitory effects of 7-chlorokynurenic acid. Saturating levels of conantokin do not completely abolish NMDA-induced Ca^{++} influx suggesting that conantokin induces an altered, but incompletely closed state of the receptor.

Photoaffinity and divalent crosslinking of synthetic radioiodinated conantokin analogs to PSDs consistently label electrophoretic bands with M_r of 50-60 kd; size-exclusion HPLC suggests that these are part of a much larger complex. We are attempting purification of the putative complex using affinity chromatography and other methods. (Supported by GM22737. We thank Natural Product Sciences, Salt Lake City, UT, for use of the fura-2 assay system.)

GABA RECEPTORS: STRUCTURE

34.1

USE OF SUBUNIT SPECIFIC ANTIBODIES TO DEFINE GABA_A RECEPTOR SUBTYPE STRUCTURE AND PHARMACOLOGY P. Whiting, K. Quirk*, N. Gillard*, P. Cox*, R. Prince*, C.I. Ragan* and R.M. McKernan*. Biochemistry Department, Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Eastwick Road, Harlow, Essex, CM20 2QR, U.K.

The GABA_A receptor gene family consists of multiple forms of homologous subunits which are proposed to co-assemble to form multiple receptor subtypes in the brain. The subunits have high levels of sequence identity apart from the putative cytoplasmic loop domain between hydrophobic domains M3 and M4. These putative cytoplasmic loop domains have been expressed in bacteria and the recombinant protein used as immunogen to produce subunit specific antisera. Using these antisera as biochemical probes we have been able to define the benzodiazepine pharmacology of immunopurified native receptor subtypes. Additionally, we have immunopurified GABA_A receptors using these antibodies and by western blot analysis we have begun to define which subunits co-assemble to form receptor subtypes.

34.2

GABA C RECEPTORS?: UNUSUAL PHARMACOLOGIC PROFILE AND HOMO-OLIGOMERIC EXPRESSION OF RETINA-ENRICHED RECEPTOR GABA RHO 1. G.R. Uhl, G.R. Cutting*#, S. Shimada, B. O'Hara, D. Donovan, and S. Kitayama*. Lab. Mol. Neurobiol., NIDA/ARC, Depts. of Neurol., Nsci. & #Peds., Ctr. Med. Gen., JHU Sch Med, Box 5180, Balto., MD 21224.

GABA A receptors are defined as GABA and bicuculline-sensitive ligand-gated chloride channels that are formed from combinations of alpha, beta, gamma, delta, and perhaps other subunits. Recently, we have used polymerase chain reaction techniques to identify a novel GABA receptor, GABA RHO 1, which is expressed at high levels in retina, and which displays more sequence divergence from the other receptor subunits than they display from each other.

This receptor robustly expresses GABA-gated chloride conductance when synthetic mRNA transcribed from the cDNA clone is injected into *Xenopus* oocytes. This conductance is potently blocked by picrotoxin. Neither bicuculline, pentobarbital, baclofen, nor benzodiazepines influence GABA-mediated current flows. Johnston and co-workers have suggested that bicuculline/baclofen-insensitive GABA receptors should be called "GABA C." We discussed the advantages and disadvantages of describing the cDNA as a GABA A receptor subtype, or as a prototype of a new class of GABA receptors. Inability to modify bicuculline insensitivity with co-expression of alpha and beta subunits underscores these points.

ULTRASTRUCTURAL IMMUNOLocalIZATION OF GABA_A RECEPTOR COMPLEX IN THE RAT THALAMUS. R. Spreafico¹, A. Amadeo^{1*}, S. De Biasi², A.L. de Bias³
¹ Dept Neurophysiology, Neurological Institute, Milano Italy; ² Dept Gen Physiol & Biochem, University of Milano, Italy; ³ Div Mol Biol & Biochem, UMKC, Kansas City, MO 64110 USA

The subcellular localization of the GABA_A receptor/benzodiazepine receptor/chloride channel complex (GABA_AR) was investigated in the rat thalamus by means of pre-embedding immunocytochemistry using the monoclonal antibody 62-3G1 (de Bias et al, 1988) directed to the β₂ and β₃ subunits of the GABA_AR. LM observation of vibratome sections showed that the immunoreactivity (IR) for GABA_AR is expressed by neuronal processes throughout the dorsal thalamus, with regional differences. The EM investigation was performed on the anteroventral, central lateral, paraventricular nuclei and ventrobasal complex. In all the nuclei examined, GABA_AR IR was observed along the membranes of a neuronal somata and dendrites, both at synaptic and non-synaptic sites. Labelling was intense close to synaptic junctions with terminals containing flattened vesicles, but absent from synapses made by large size terminals. The IR was also present in few endoplasmic reticulum cisternae and along the nuclear envelope of thalamic neurons. Myelinated fibers and the membrane of glial cells were always unlabeled. The results are in agreement with the subcellular distribution of GABA_AR observed in the cat lateral geniculate nucleus using a different antiserum (Soltész et al, 1990) and correlate with the intense GABAergic innervation of the investigated nuclei.

IMMUNOAFFINITY PURIFICATION OF GABA_A RECEPTOR α SUBUNIT ISO-OLIGOMERS. M.J. Duggan*, S. Pollard* and F.A. Stephenson, School of Pharmacy, University of London, 29/39 Brunswick Square, London WC1N 1AX, UK.

Characterisation of cloned GABA_A receptors has shown that the type of α subunit present in (αβγ₂) expressed proteins confers the subtype of benzodiazepine receptor pharmacology (D B Pritchett et al., 1989, *Science*, 45, 1389). In agreement with this, we have previously shown by quantitative immunoprecipitation assays using antibodies specific for the α1, α2 and α3 subunits of the GABA_A receptor, evidence for the existence of native α variant iso-oligomers (Duggan and Stephenson, 1990, *J. Biol. Chem.* 265, 3831). The sensitivity of these studies however was such that we could not exclude the possibility that in a minor population of receptors, the α1, α2 and α3 subunits may coexist. We have now addressed this question by the development of GABA_A receptor α subunit immunoaffinity chromatography purification procedures. Thus GABA_A receptors were purified from Na⁺ deoxycholate extracts of bovine cerebral cortex by either anti-α1 324-341; anti-Cys α2 414-424 or anti-Cys α3 454-467 antibody affinity chromatography. The respective purified receptors were characterised by their ligand binding properties and by immunoblotting where each was compared to benzodiazepine affinity chromatography purified GABA_A receptors. It was found that whereas the type of α subunit used for purification was enriched in the respective immunoaffinity purified material reactivity with the other subunit antibodies was also obtained. The use of two different specificity antibody affinity columns in series further substantiated these findings of co-existence. Thus we propose that although the predominant forms of native GABA_A receptors contain one type of α subunit only, some classes are heterogeneous with respect to their α subunit complements.

DISTRIBUTION, RELATIVE ABUNDANCE AND CO-LOCALIZATION OF GENE TRANSCRIPTS FOR DIVERSE GABA_A RECEPTOR SUBUNITS IN NEURONS OF RAT SPINAL CORD AND SPINAL GANGLION. E. Persohn*, P. Malherbe*, J.R. Martin and J.G. Richards, Pharma Division, Preclinical Research, F. Hoffmann-La Roche Ltd, CH-4002 Basel, Switzerland

Gene transcripts of diverse rat GABA_A receptor subunits (α1-6; β1-3; γ1,2; δ) were localized by *in situ* hybridization histochemistry using 35S-labelled 60mer oligonucleotide probes. The γ2 mRNA was the most ubiquitous and abundant; α6, β1 and δ were not detected. The labelling of motoneurons in layer IX was particularly strong for α2, moderate for β3 and γ2 and weak for α1,3 and 5. In layers VII, VIII and X the β3 and γ2 transcripts were moderately expressed whereas the α1 and β2 transcripts levels differed markedly among the cells of these layers. Although the mRNAs of all subunit variants could be detected in layers IV-VI, only α3, α5, β3 and γ2 hybridization signals were observed in layers II and III. In spinal ganglia, α2 transcripts were abundant in most large sensory neurons and to a much lower degree in the small diameter cells, whereas γ1,2 transcripts were confined to a subpopulation of large and small neurons. β2 and α1 transcripts were even more restricted in their distribution. Although the subunit composition and stoichiometry of the native receptor protein(s) are not known, the cellular colocalization of α2 β3 γ2 subunits suggests one likely combination. The findings provide a basis for the mediation of synaptic inhibition in the spinal cord by diverse GABA_A receptors and further strong evidence that presynaptic inhibition of inter- and motoneurons, via axo-axonic synapses between GABAergic interneurons and primary afferent terminals, is mediated by GABA_A receptors.

BINDING OF [³H]RO 15-4513 TO CEREBELLAR MEMBRANES: ONTOGENY AND SUBSTRATE SPECIFICITY. M. Uusi-Oukari, E.F. Korpi, J. Kaivola, K. Wegelius. Res. Labs, Alko Ltd., POB 350, SF-00101 Helsinki, and Dept. of Biomed. Sci., Univ. of Tampere, Tampere, Finland.

Cerebellar granule cells express a new GABA_A receptor subtype that has poor affinity to classical benzodiazepine agonists. Its preferred ligand is an imidazobenzodiazepine, [³H]RO 15-4513 (sapmazenil), a partial inverse agonist.

Micromolar concentrations of diazepam displaced all bound [³H]RO 15-4513 from cerebellar membranes prepared from 1-to-2-day-old rats, whereas about 30% of the bound ligand was not displaced in 14-day-old and adult rats. Correspondingly, the saturable binding of [³H]RO 15-4513 in the presence of 10 μM diazepam was greatest to membranes from adult rats.

Binding studies with cerebellar membranes from alcohol-sensitive (which have enhanced diazepam affinity) and alcohol-insensitive rats, using benzodiazepine receptor ligands of various chemical structure and agonist, partial agonist, antagonist, and inverse agonist properties, indicated that most of the ligands with high affinity to the "diazepam-insensitive" [³H]RO 15-4513 site belonged to inverse agonists and antagonists. Only some of the partial agonists had equal affinity in both rat lines.

The results suggest that the expression of diazepam-insensitive [³H]RO 15-4513 binding sites begins after the cerebellar granule cells have moved to the internal granule cell layer. Further work is needed to establish the behavioral correlates of this GABA_A receptor-associated binding site with unique substrate specificity.

CORRELATION OF GABA_A RECEPTOR mRNA SUBUNIT EXPRESSION AND SINGLE CHANNEL KINETICS IN THE DEVELOPING RAT CENTRAL NERVOUS SYSTEM. Poulter M.O.^{1,3}, A.-M. O'Carroll², L.C. Mahan², S.J. Lolait² and Barker J.L.¹ 1) Laboratory of Neurophysiology NINDS 2) Laboratory of Cell Biology, NIMH, NIH Bethesda, Maryland 20892. 3) McGill University, Montreal, Canada, H3G 1Y6.

Using *in situ* hybridization histochemistry the distribution of GABA_A receptor subunit mRNAs was studied in the developing rat CNS. DNA oligonucleotide probes were utilized which hybridize to the mRNA sequences coding for the proposed cytoplasmic loop domains of the α_{1-4 and 6}, β₁₋₃, γ₂ and δ subunits. In particular, at embryonic day 15 in the cervical spinal cord region (myelencephalon) only α₁, β_{2,3} and γ₂ subunit mRNAs could be detected. Based on these results we characterized the single channel kinetics of GABA_A receptor coupled ion channels containing this relatively constrained subunit composition. Using acutely dissociated neurons from this region and on-cell patch clamp recording technique, ion channel activity could be detected in approximately 70-80% patches containing GABA. This activity could first be recorded at a threshold dose of 200 nM GABA. No apparent desensitization was observed in patches containing up to 5 μM GABA. Channel currents were inward at patch pipette potentials less negative than -20 to -30 mV. Channel open and closed time duration frequency distributions could be fitted with up to 3 time constants. Brief (τ < 1.0 ms) channel openings predominated at all GABA concentrations whereas the frequency of opening increased with GABA concentration. This approach may therefore be an useful strategy for the correlation of GABA_A receptor subunit composition and its ion channel properties.

EXPRESSION OF GABA_A RECEPTOR SUBUNIT mRNAs IN ETHANOL WITHDRAWAL SEIZURE PRONE (WSP) AND RESISTANT (WSR) MICE: ANALYSIS BY POLYMERASE CHAIN REACTION (PCR). K.J. Buck, L.D. Hahner, J.M. Sikela and R.A. Harris. University of Colorado Health Sciences Center, Denver, CO 80262, USA.

Molecular cloning has revealed that the GABA_A receptor complex is composed of multiple subunits, and that the drug sensitivity of the complex depends upon its subunit composition (FASEB J. 4: 1469, 1990). Our recent studies indicate that modulation of the GABA_A complex by benzodiazepine inverse agonists may be related to genetic differences in ethanol withdrawal severity (*J. Neurochem.*, in press). In the present studies, levels of GABA_A receptor subunit mRNAs were determined using the polymerase chain reaction. WSP and WSR mice were fed a liquid diet containing ethanol, or an equicaloric diet with sucrose substituted for ethanol, for 10 days. Poly(A)⁺ mRNA was then isolated from mouse whole brain. Relative differences in accumulated mRNA levels of GABA_A receptor subunits were analyzed by a reverse transcriptase-polymerase chain reaction (RT-PCR) assay using degenerate oligonucleotide primers recognizing conserved domains, and Southern hybridization with subunit-specific [³²P]oligonucleotide probes. In pair-fed controls, levels of α₁ and α₂ were 50% lower in WSP than in WSR mice. Chronic ethanol administration decreased α₁ mRNA levels by 40% in WSP mice, but did not significantly decrease α₂ mRNA levels in WSR mice. In contrast, α₂ mRNA levels were decreased by 50% in WSR, but not WSP mice. Chronic ethanol exposure increased expression of γ₂ mRNA by 100% in both WSP and WSR mice, but levels of γ₁, γ₂S and α₃ mRNA were not changed. These results indicate that genetic differences in the regulation of α₁ subunit expression by chronic ethanol exposure may affect withdrawal severity. (Supported by the VA and AA06399 and AA03527.)

THE COMPLEMENT OF GABA-A RECEPTOR mRNAs IN RAT PITUITARY
J. Berman*, Andrea Gore, J. L. Roberts and Dolan Pritchett**
 Fishberg Center for Neurobiology, Mount Sinai School of Medicine,
 NY, NY 10029 and **Depts. of Pharmacology and Pediatrics,
 University of Pennsylvania School of Medicine, Phila., PA 19104

We have defined the complement of GABA-A receptor mRNAs in the anterior and intermediate lobes of the rat pituitary. In the anterior lobe, GABA receptors are composed of $\alpha 1$, $\alpha 2$, $\alpha 5$, $\beta 1$, and $\beta 3$, subunits as demonstrated by ribonuclease protection assays, and $\beta 2$, $\gamma 1$, and $\gamma 2$ as shown by PCR. In the intermediate lobe, we find $\alpha 2$, $\alpha 3$, $\alpha 5$, $\beta 1$, and $\beta 3$ subunits by protection assay, and have found $\beta 2$, $\gamma 1$, $\gamma 2$, and δ by PCR. $\alpha 6$ was not found in either lobe, in keeping with its presumed cerebellar localization. Both α and β subunit mRNAs are present at fairly low levels. The $\alpha 1$ mRNA in anterior lobe is of considerably higher abundance than the others; this finding parallels results obtained in the brain where $\alpha 1$ is typically seen to be the most abundant of these mRNAs. It is of interest that anterior lobe cells which receive only a diffuse GABAergic innervation contain subunits associated with high affinity BZD Type I pharmacology, while melanotrophs receiving direct but non-synaptic innervation express BZD Type II associated subunits. The $\alpha 5$ subunit may account for spontaneous chloride currents previously observed in melanotrophs. (Taleb et al. *Pflügers Arch*, 409) The occurrence of both γ and δ subunits in melanotrophs implies that these cells may have a dual population of GABA receptors, consisting of BZD responsive and BZD non-responsive subsets. Studies are underway to test these predicted properties.

DEVELOPMENTAL EXPRESSION AND MODULATION OF GABA_A RECEPTOR SUBUNIT mRNAs IN RAT CEREBELLAR CELL CULTURES. C.E. Beattie and R.E. Siegel, Dept. of Pharmacology, Case Western Reserve University, Cleveland, OH 44106.

Since the isolation of multiple GABA_A receptor subunit mRNAs, much has been learned about receptor composition and function. In contrast, very little is known about the regulation of the expression of these subunit mRNAs in the mammalian CNS. Earlier studies in our laboratory have raised the possibility that cell-cell interactions may regulate subunit mRNA expression in the developing cerebellum. To test this possibility we established cultures of cerebellar granule and Purkinje neurons prepared from embryonic day 19 rats. GABA_A receptor subunit mRNA levels were analyzed by the polymerase chain reaction with subunit specific primers. In granule cell cultures the $\alpha 1$ subunit mRNA was not detected at 4 hours but was present after 1 day *in vitro* (DIV). The $\gamma 2$ subunit mRNA, however, was detected at 4 hours and was expressed at a similar level at 1 DIV. Both subunit mRNA levels remained constant from 1-21 DIV with $\gamma 2$ being 4-6-fold more abundant than $\alpha 1$ at all times. To determine if activity could alter subunit mRNA expression in culture, granule cells were grown in depolarizing conditions (25mM KCl) for 14 days. Under these conditions $\alpha 1$ subunit mRNA expression was not significantly altered. Our findings *in vitro* differed from previously characterized patterns of expression *in vivo* where $\alpha 1$ and $\gamma 2$ subunit mRNA levels increased 5-fold during the second postnatal week. These results are consistent with the hypothesis that interactions which normally regulate subunit expression have been disrupted in the culture system. Studies to analyze other cell-cell interactions which may influence GABA_A receptor mRNA expression are underway.

CEREBELLAR GRANULE CELL AND GLIAL CELL CULTURES EXPRESS DIFFERENT PATTERNS OF GABA_A RECEPTOR SUBUNIT mRNAs. M.R. Santi, P. Bovolin, E. Costa, and D.R. Grayson, FGIN and Dept. of Biology, Georgetown Univ., Wash., DC 20007

The GABA_A receptor is a heteropolymeric integral membrane protein that includes an anionic channel. Four different classes of subunits have been defined: α , β , γ , and δ and multiple mRNA variants of each class exist. To determine the mRNA levels of GABA_A receptor subunits expressed in cerebellar granule cell and glial cell cultures, we used a variation of the polymerase chain reaction (PCR). Subunit specific oligonucleotides were used to amplify reverse transcribed mRNA isolated from each culture. In cerebellar granule cells maintained in culture for 8 days, the amount of the $\alpha 1$ mRNA subunit appears to be 5 times higher than that present in cerebellar glial cells prepared from the same rats and kept in culture until they reached confluence. The $\alpha 3$ and $\beta 3$ subunit mRNAs are 10 fold more abundant in granule cell cultures, also the $\alpha 4$, $\beta 1$, and δ subunit mRNAs content is from 15 to 20 times higher in granule cells than in glial cells. The $\alpha 2$ and $\beta 2$ mRNA abundances in cerebellar cells are about 2 to 3 times that of glial cells. Comparable amounts of the $\gamma 1$ subunit mRNA are expressed in both cultures; in contrast, in cerebellar glial cells the $\alpha 6$ and $\gamma 2$ subunit mRNAs are not detectable for up to 40 PCR cycles, using from 0.5 to 1.5 μ g glial cells total RNA.

Presently we are employing quantitative PCR, with the use of internal standards to determine the absolute amounts of different subunits in each culture type. Our results suggest that both cerebellar granule cells and cerebellar glial cells can express different GABA_A receptor subunits, these differences support the inference that each cell type may include different GABA_A receptor assemblies.

GABA_A RECEPTOR SUBUNIT mRNA EXPRESSION IN THE DEEP CEREBELLAR NUCLEI OF THE PURKINJE CELL DEGENERATION MUTANT (Pcd) IS UNALTERED BY PURKINJE CELL LOSS. C. Gambarana, C. J. Loria, G. Guidry, B. Kovacs, and R.E. Siegel, Dept. of Pharmacology, Case Western Reserve Univ., Cleveland, OH 44106.

The GABA_A receptor complex mediates the actions of GABA, the major inhibitory neurotransmitter in the mammalian CNS, as well as the actions of the benzodiazepines and barbiturates. The receptor is composed of multiple subunits and appears to exist in distinct compositions in different brain regions. While the signals regulating receptor expression are unknown, recent developmental studies have raised the possibility that synaptic interactions influence subunit mRNA levels in the cerebellum. To address this possibility, we have examined GABA_A receptor subunit mRNA expression in the Pcd mutant. In these animals innervation to cells in the deep cerebellar nuclei is lost following the postnatal degeneration of Purkinje neurons. Our studies using hybridization histochemistry demonstrate that the mRNAs encoding the $\alpha 1$, $\beta 2$, and $\gamma 2$ subunit mRNAs of the GABA_A receptor are present in the deep cerebellar nuclei of both the Pcd mutant and littermate controls. A 50% decrease in the level of $\alpha 1$ subunit mRNA is observed in the mutant soon after Purkinje cell loss (P24), but it returns to control levels at later stages (P50-90). In contrast, $\beta 2$ and $\gamma 2$ mRNA levels are similar in mutants and controls at all ages. These studies suggest that the maintenance of synaptic interactions is not required for GABA_A receptor subunit mRNA expression in cells of the deep cerebellar nuclei.

34.12

PCR QUANTITATION OF GABA_A RECEPTOR SUBUNIT mRNA CONTENTS IN RAT BRAIN AND IN CEREBELLAR GRANULE CELL CULTURES. P. Bovolin, M.R. Santi, E. Costa, and D.R. Grayson, FGIN and Biology Dept., Georgetown Univ., Washington, D.C. 20007.

The GABA_A receptor is a heteropolymeric protein complex including a variable combination of different subunits (α , β , γ , δ). In order to compare the expression of GABA_A receptor subunit mRNAs in selected brain regions or cultured cells, we performed PCR in the presence of appropriate internal standards to provide a quantitation of the amplified signal. Total RNA was reverse transcribed and co-amplified with the internal standard which utilizes the same primers and has virtually the same sequence as the natural template, except for an internal restriction site created by site directed mutagenesis. We found that the amounts of $\alpha 1$ mRNA present in the cortex and cerebellum of adult rat are very similar (2.6 versus 2.1 fmoles/ μ g RNA). In cortex, the $\alpha 4$ mRNA abundance is about 1/10 and in cerebellum is less than 1/100 that of $\alpha 1$. In cerebellum we also monitored the changes in $\alpha 1$, $\alpha 4$ and $\gamma 2$ (both the long, $\gamma 2L$, and the short, $\gamma 2S$, forms) mRNA contents during postnatal development. Their abundance changes with development and appear related to the changes occurring in granule cells developing in culture. Both the *in vitro* and *in vivo* expression of the $\alpha 1$, $\gamma 2L$ and $\gamma 2S$ mRNAs are similar in their temporal profiles and absolute amounts ($\alpha 1$ increases from about 0.1 to 2.5 fmoles/ μ g RNA). Postnatally, in cerebellum $\alpha 4$ mRNA continually decreases (from about 0.085 to 0.013 fmoles/ μ g RNA), while in cerebellar granule cells the change is biphasic: an initial increase is followed by a decrease. GABA_A receptor subunits and, presumably, subtypes appear to be developmentally regulated in their abundance in brain structures and single neuronal cells.

34.14

A QUANTITATIVE PCR ASSAY FOR GABA_A RECEPTOR SUBUNITS. L.G. Miller and J. Kang, Division of Clinical Pharmacology, Depts. of Pharmacology and Psychiatry, Tufts Univ. School of Medicine, Boston, MA 02111

Northern hybridization has been widely used to assess mRNA concentrations, but it is difficult to quantify messages present in low abundance or of high molecular weights using this technique. We have developed a quantitative RNA-based polymerase chain reaction (PCR) assay to evaluate a number of GABA_A receptor subunit mRNAs. Primer sequences were chosen from nonhomologous regions of 7 rat subunit cDNA sequences ($\alpha 1$ -2, $\beta 1$ -3, $\gamma 1$ -2). Each primer set was demonstrated to produce correct size amplified fragments. For internal standards, synthetic RNA of differential length for individual subunit were prepared from plasmid constructs that contain each primer set plus poly A sequences. Total RNA of different regions of mouse brain were mixed with synthetic RNAs and complementary first strand DNAs were synthesized by reverse transcriptase. Amplification was performed in the presence of 5'-end-³²P labeled primers followed by gel electrophoresis, and bands of appropriate amplified fragments were excised and counted. Using 5 μ g of total RNA and 5, 15, 25 pg of synthetic RNA, amplification was demonstrated to be exponential up to 30 cycles for all subunits. Using the slopes of the log-linear function of internal standards and of sample RNA (amplification efficiency), absolute amount of each subunit can be calculated. This technique offers a quantitative method to evaluate mRNA concentrations for GABA_A receptor subunits.

34.15

PHARMACOLOGICAL CHARACTERIZATION OF THE GABA_A RECEPTOR-CHANNEL COMPLEX COMPOSED OF RAT BRAIN α_1 AND β_2 SUBUNITS.

R.A. Cruciani¹, A.Y. Valeyev¹, L.C. Mahan², G.D. Lange³ and J.L. Barker¹.

¹Lab. of Neurophysiology, ²Lab. of Cell Biology (NIMH), ³Instrumentation and Computer Section, NINDS, NIH, Bethesda, MD; 20892, U.S.A.

The cloned rat brain α_1 and β_2 subunits of the GABA_A receptor-channel complex were co-expressed in cultured fibroblasts and characterized utilizing whole-cell recording techniques with patch electrodes. The current-voltage curves of the passive membrane properties were linear and the baseline current fluctuations were fit by a 1/f function. The reversal potential of the current activated by the application of GABA corresponded to the reversal potential for Cl⁻ ions, and depended on the [Cl⁻] across the membrane. The GABA-activated currents had a K_d of 7x10⁻⁶ M, and were blocked by bicuculline and potentiated by (-)pentobarbital. Surprisingly, (-)pentobarbital didn't exert an effect of its own at 100 μ M. Alfaxalone was relatively ineffective at 10-100 μ M and GABA-activated currents were not modulated by 10 μ M diazepam. The open times of the channels activated by either GABA, muscimol or alfaxalone were complex, but similar when evaluated using spectral techniques.

34.17

GABA_A RECEPTOR SUBUNIT mRNA EXPRESSION: DIFFERENTIAL REGULATION BY CHRONIC FG 7142 AND DIAZEPAM EXPOSURE IN RAT. R.J. Primus and D.W. Gallager. Dept. of Psychiatry, Yale Univ., New Haven, CT 06508.

Levels of mRNA for the α_1 , γ_2 and β_1 subunits of the GABA_A receptor complex were examined in rats maintained on a chronic, continuous schedule of exposure to the benzodiazepine inverse agonist FG 7142. Recent evidence indicates that chronic diazepam (DZ) exposure downregulates GABA_A α_1 subunit mRNA, but does not change β_1 subunit mRNA, in rat cortex. The present study was undertaken in order to determine if chronic FG 7142 exposure also influences levels of GABA_A subunit mRNA. The effect of chronic DZ exposure on γ_2 subunit mRNA was also examined.

FG 7142 (2 mg/ml of 100% DMSO) was administered continuously for eight days in the right lateral ventricular via an osmotic minipump (Alzet). At the end of the eighth day of exposure, cortex (CX), cerebellum (CB) and hippocampus (HP) were dissected and stored at -70°C until extraction of RNA. GABA_A α_1 and γ_2 subunit mRNA was examined by Northern blot analysis with cDNA probes specific for these subunits. A significant increase in α_1 subunit mRNA was measured in both CX and HP, but not in CB, of rats chronically exposed to FG 7142 relative to vehicle-treated rats. Likewise, a significant increase in γ_2 subunit mRNA in CX was also evident in drug-treated rats; however, no change in γ_2 subunit mRNA was observed in either the HP or CB. Examination of GABA_A β_1 subunit mRNA using a β_1 riboprobe revealed no effect of chronic FG 7142 treatment on this subunit in either CX, CB or HP. In rats chronically exposed to DZ (21 days via silastic implants), levels of γ_2 subunit mRNA were significantly decreased in CX, but not changed in either CB or HP.

The findings demonstrate that GABA_A α_1 and γ_2 subunit mRNA is differentially regulated by chronic FG 7142 and DZ exposure. These two chronic treatments result in opposite functional effects on GABA sensitivity in some brain regions (sensitivity following DZ, supersensitivity following FG 7142). Thus, the increase and decrease in subunit mRNA by FG 7142 and DZ, respectively, may underlie or at least reflect a compensatory response of the GABA_A receptor complex to chronic occupation by these ligands.

MULTIPLE CONDUCTANCE STATES OF RECOMBINANT GABA_A RECEPTORS. T. Ryan-Jastrov, T.P. Angelotti and R.L. Macdonald#. Depts. of Neurology, Physiology#, and Pharmacology@ Univ. of Michigan, Ann Arbor, MI 48109.

The conductance levels of GABA activated single channel chloride currents differ among species and brain regions. Multiple subunits and subunit variants of the GABA_A receptor have been identified. Different combinations of these subunits may underlie the diverse conductance properties observed. We have examined the conductance properties of single channel chloride currents activated by GABA in mammalian cells expressing recombinant GABA_A receptors.

COS or CV-1 cells were acutely transfected with GABA_A receptor bovine α_1 or α_3 subunit cDNA in combination with bovine β_1 and human γ_2 (short form) subunit cDNA. Subunit cDNAs were subcloned individually into the vectors pSVL and pCMVNeo. Transfections were done according to the method of Chen and Okayama. Single channel recordings were made from excised outside-out patches. Cells expressing the $\alpha_3\beta_1\gamma_2$ receptor responded to GABA with single channel currents which opened to conductance levels of 11, 19 and 27 pS. Substituting the α_1 subunit for the α_3 subunit resulted in GABA activated single channel currents which opened to the same conductance levels and an additional 33 pS level. The 27 pS conductance state was predominant for both recombinant receptors. Single channel kinetic properties were similar between the recombinant receptors for the 19 pS level but differed for the 27 pS level. These results suggest that the α subunit confers different conductance properties on the receptor. These differences in conductance properties may be due to structural differences between the individual α subunits. Alternatively, the α subunit could affect the stoichiometry of assembly of the receptor.

34.16

DEVELOPMENTAL CHANGES IN POLYADENYLATED VS TOTAL mRNA FOR THE GABA_A RECEPTOR β_1 , α_1 AND γ_2 SUBUNITS IN RAT. D.W. Gallager and R.J. Primus. Dept. of Psychiatry, Yale University, New Haven, CT 06508.

The ratio of polyadenylated (poly(A⁺)) to non-polyadenylated mRNA for the β_1 , α_1 and γ_2 subunits of the GABA_A receptor complex was examined in rats as a function of age. While others have reported that levels of poly(A⁺) mRNA for the GABA_A β_1 subunit decrease with increasing age, preliminary evidence from this laboratory suggested that levels of total mRNA for this subunit did not change as a function of age. Therefore, a comparison of total vs poly(A⁺) mRNA for the GABA_A receptor β_1 , α_1 and γ_2 subunits was made in rat brain membranes as a function of age.

RNA was extracted from whole brain of rats that were either 0, 1, 3, 5 or over 60 days of age. Poly(A⁺) RNA was purified by oligo(dT)-cellulose chromatography. Total and poly(A⁺) mRNA for the β_1 , α_1 and γ_2 subunits were examined by Northern blot analysis using cDNA probes specific for these subunits. Levels of β_1 subunit mRNA were also examined by solution hybridization with a β_1 riboprobe. Analysis of Northern blots revealed that levels of poly(A⁺) β_1 subunit mRNA were highest at 0 days of age, but decreased and reached adult levels by 5 days of age. In contrast, levels of total mRNA for the β_1 subunit were not significantly different at any of the ages examined, suggesting the existence of a population of β_1 subunit mRNA that is not polyadenylated. This discrepancy between total and poly(A⁺) β_1 subunit mRNA expression was also observed using solution hybridization analysis. In contrast, levels of both poly(A⁺) and total α_1 subunit mRNA increased by nearly 95% from 0 days of age to adulthood. Similarly, levels of both poly(A⁺) and total γ_2 subunit mRNA increased by approximately 25% from 0 days of age to adulthood.

These findings demonstrate that 1) polyadenylation of RNA for the GABA_A receptor β_1 , α_1 and γ_2 subunits is developmentally regulated, and 2) polyadenylated RNA for the β_1 subunit is not representative of the entire RNA population for this subunit, as reflected by the lack of developmental change in levels of total mRNA for the β_1 subunit. While the significance of a non-polyadenylated population of β_1 subunit mRNA remains unknown, it is clear that both total and poly(A⁺) RNA should be examined when evaluating developmental changes in receptor subunit expression.

34.18

MODULATION OF CLONED GABA_A RECEPTOR CURRENTS BY CHRONIC EXPOSURE TO ELEVATED LEVELS OF THE FREE CATALYTIC SUBUNIT OF PROTEIN KINASE A. T.P. Angelotti, M.D. Uhler@ and R.L. Macdonald#. Depts. of Pharmacology, Biochemistry@, Neurology#, and Physiology#, Univ. of Michigan, Ann Arbor, MI 48109.

cDNAs encoding the bovine α_1 , β_1 , and human γ_2 (short form) GABA_A receptor subunits were subcloned separately into the vector pCMVNeo, which utilizes the cytomegalovirus promoter to drive expression in mammalian cells. These constructs were co-transfected (1:1:1 ratio by weight) using the Chen-Okayama modified calcium phosphate technique into wild type L929 cells and the stable L cell clone Ca12. The Ca12 cell line produces free Ca catalytic subunit of protein kinase A (PKA) at a level five times higher than that found in wild type L929 cells.

GABA-evoked currents were recorded in L929 and Ca12 cells at 48 hrs. post-transfection. In both cell types, peak whole cell GABA (0.3-100 μ M) concentration-response curves produced Hill slopes averaging 1.5-2.0 with maximal current amplitudes occurring at 30 or 100 μ M GABA. 10 μ M GABA currents were enhanced 40-60% by 50 nM diazepam. Two different types of currents were observed, based upon current-voltage relationships. One group exhibited current amplitudes that did not differ at -50 and +50 mV, while the other was larger at +50 mV than -50 mV. The presence of these two currents was independent of cell type. One difference between cell types was the overall magnitude of the GABA-evoked currents; GABA receptor currents expressed in Ca12 cells were 2-3 times larger than those expressed in wild type L929 cells. This finding suggests that chronic exposure to elevated levels of PKA in Ca12 cells may modulate the assembly or functional expression of the GABA_A receptor complex.

GABA-A RECEPTOR SUBTYPES: COMPARISON OF REGIONAL VARIATION IN BINDING HETEROGENEITY WITH SUBUNIT SUBTYPE POLYPEPTIDES AND mRNAs. R.W. Olsen, M. Bureau*, S. Endo, G. Smith, D. Sapp, & A.J. Tobin. Brain Research Institute, UCLA, L.A., CA 90024.

Heterogeneity was observed for 15 ligands of the GABA-A/benzodiazepine receptor across regions of rat brain measured by autoradiography of [³H]muscimol, [³⁵S]TBPS and [³H]flunitrazepam binding. Regional variation was seen in the effects of allosteric modulators and competitive inhibitors. The same ligands showed differential interactions with [³H]flu or [³H]mus photolabeled polypeptides in purified receptors on SDS-PAGE. Barbiturates and steroids selectively enhanced binding to 51 and 55 compared to 53 and 58 kDa polypeptides; GABA selectively enhanced [³H]flu binding in 53 vs. 51 kDa band; THIP and taurine selectively inhibited [³H]mus labeling of 58 and 55 kDa bands respectively. Partial sequencing and subunit subtype-selective antibodies identified polypeptides as $\alpha_1(51)$, $\alpha_2(53)$, $\beta_2(55)$ and $\beta_3(58)$ gene products. In agreement with photolabeling specificity, areas rich in α_1 plus β_2 mRNAs are more sensitive to allosteric modulators, as shown by autoradiography; areas rich in α_2 show good GABA-BZ coupling, areas rich in β_2 or β_3 are more sensitive to taurine or THIP. Thus pharmacological subtypes based on binding heterogeneity exist in the brain, apparently corresponding to the nature of the α and β subunits present.

CYCLIC AMP-DEPENDENT PROTEIN KINASE PHOSPHORYLATES THE β_3 SUBUNIT OF THE RAT GABA-A RECEPTOR. G.B. Smith¹, M.D. Browning², S. Endo¹ & R.W. Olsen¹. Department of Pharmacology, UCLA School of Medicine,¹ Los Angeles, CA 90024 & Department of Pharmacology, University of Colorado Health Sciences Center,² Denver, CO 80602.

Cyclic AMP-dependent protein kinase A (PKA) and protein kinase C (PKC) phosphorylate two subunits of the GABA-A receptor with Mr of 58 and 56 kDa, respectively, comigrating with muscimol-binding β subunits (Browning *et al.*, *PNAS* 87:1315 (1990)). Here we report that a major substrate polypeptide phosphorylated with PKA is the rat β_3 gene product. Purified rat receptor was phosphorylated with purified PKA catalytic subunit and [³²P]ATP as described. The labeled protein was concentrated and digested sequentially with *S. aureus* V8 protease and TLCK-chymotrypsin for a total of 48 hrs. Peptides were separated on a 16.5% SDS gel and transferred to PVDF membrane. Autoradiography revealed two major labeled peptides of 11 and 9 kDa. N-terminal sequence analysis of the 11 kDa band gave a 16 residue partial sequence beginning at Met₃₅₃ of the rat β_3 clone. This peptide contains a consensus sequence for PKA phosphorylation, although the sequence does not extend that far. Supported by NS26377 (MDB) and NS22071, NS28772 (RWO).

STRESSOR-INDUCED CHANGES IN GABA RECEPTOR FUNCTION: ROLE OF HYPOTHALAMIC NOREPINEPHRINE PROJECTIONS. C.K. Kellogg, M.T. Taylor* and J. Inglefield. Dept. of Psychology, Univ. of Rochester, Rochester, NY 14627.

Environmental stressors markedly influence function of the GABA/benzodiazepine (BDZ) receptor complex in the cerebral cortex. While biologic mechanisms mediating this influence are unknown, adrenalectomy abolishes the influence of stressors, implicating a role for corticosterone (CS). Considering that the norepinephrine (NE) projection to the hypothalamus (HYP) modulates the HYP-pituitary-adrenal axis, we examined the impact of this system on stressor-induced changes in GABA/BDZ receptor function. NE terminals in the paraventricular nucleus of the HYP of male Long Evans rats (60 days old) were destroyed using stereotaxic injections of 6-hydroxydopamine (6-OHDA, 9 μ g in 1.5 μ l). Sham-operated rats received saline injections. Stressor-responses were evaluated two weeks post-lesion. Rats were subjected to either 15 min of restraint or 10 min of forced swimming. Basal measures were made on nonstressed animals. Chloride (Cl) facilitation of BDZ binding, an index of responsiveness of the receptor complex, was measured in the cerebral cortex. The loss of NE terminals was estimated by either analysis of NE levels or by immunocytochemistry. Trunk blood was collected for analysis of plasma CS. 6-OHDA treatment induced a 63% decrease in NE levels in the HYP, and this manipulation markedly altered responsiveness of the GABA/BDZ complex in the cerebral cortex. In control rats, Cl facilitated BDZ binding was enhanced by 15 min of restraint, with maximal facilitation increasing from 20% in the basal state to 36%. The EC50 for Cl was decreased by the stressor, from 42 mM to 28 mM. In contrast, there was little stress-related change in Cl facilitated BDZ binding in 6-OHDA-treated animals. Maximal facilitation was 19% and 13% in basal and stressor states, while the EC50 was 27 and 22 mM, respectively. These studies are beginning to define neural interactions essential for integrated responses to stressors. Supported by grant no. DA 07080.

CATECHOLAMINE RECEPTORS: α AND β

35.1

ISOLATION OF NOVEL G-PROTEIN COUPLED RECEPTOR cDNAs FROM LOCUS COERULEUS BY PCR. J.D. Alvaro¹, J.W. Lomasney², R.J. Lefkowitz², E.J. Nestler^{1,3,4}, and R.S. Duman^{1,3}. ¹Laboratory of Molecular Psychiatry, ³Depts. of Psychiatry and ⁴Pharmacology, Yale Univ. School Med., New Haven, CT 06508; ²HHMI, Duke Univ. Med. Ctr., Durham NC 27710.

Previous cloning studies have identified three α_2 -adrenergic receptors (α_2 -c2, -c4, -c10), but it is unclear whether any of these represent pre-junctional subtypes. We are attempting to isolate novel pre-junctional α_2 -adrenergic receptor clones from cDNA derived from noradrenergic cell bodies of bovine locus coeruleus (LC). Oligonucleotide primers corresponding to highly conserved regions within the second and seventh transmembrane domains of the three mentioned receptors were constructed and used as primers to PCR amplify LC cDNA. This approach has led to the amplification of 2 PCR bands which were purified and cloned into pBluescript. Partial sequence data suggest that these clones are novel G-protein coupled receptors, but neither one shares extensive homology with the α_2 -adrenergic receptors. Northern blot analysis reveals that both clones are differentially expressed in both the central nervous system and peripheral tissues and that one of the clones is enriched in the brain. These clones are being used to probe a bovine LC cDNA library to isolate the full-length clones for each PCR product. The full-length cDNA clones will then be sequenced and expressed *in vitro* in order to study their functional properties.

35.3

STABLE EXPRESSION OF HUMAN RECOMBINANT α_2 -ADRENERGIC RECEPTOR SUBTYPES IN A MOUSE MAMMARY TUMOR CELL LINE. A. Marjamäki, S. Ala-Uotila, K. Luomala, M. Jalkanen, S. Leppä* and M. Scheinin. Depts. of Pharmacology and Medical Biochemistry, Univ. of Turku, SF-20520 Turku, Finland.

Cloning of the human genes encoding distinct α_2 -adrenergic receptor subtypes now allows the use of recombinant expression systems to produce receptor material for structural and functional studies as well as for the testing of new, potentially subtype-selective pharmacological agents. We report here the expression of two human α_2 -adrenoceptor subtypes, α_2 -C4 and α_2 -C10, in mouse mammary tumor cells.

The coding sequences from pSP6 α_2 C10NH and pSP6 α_2 C4BH (Kobilka *et al.*, *Science* 238, 650; Regan *et al.*, *PNAS* 85, 6301) were inserted into the G418-selectable expression vector pMAMneo, which contains the MMTV-LTR promoter. The resulting expression constructs were transfected into S115 cells using the Lipofectin[®] reagent kit (Gibco). G418 (750 μ g/ml) resistant clones from both cell populations were selected and examined for their ability to bind the α_2 -adrenergic antagonist radioligand [³H]rauwolscine.

Scatchard analysis of [³H]rauwolscine binding revealed B_{max} values of about 700 and 600 fmol/mg protein and $K_{0.5}$ of 1 and 6 nM for the recombinant C4 and C10 receptors. Competition assays with oxymetazoline and prazosin yielded the expected K_i -ratios, 1.8 for C4 and 0.004 for C10. The K_i of norepinephrine was increased 6- and 4-fold in the presence of 10 μ M GppNHP, suggesting efficient G-protein coupling of both receptor subtypes.

These recombinant cell lines appear suitable for pharmacological experiments and should be useful in the development of new, subtype-selective drug molecules.

35.2

DEVELOPMENT OF FUSION PROTEINS FROM ALPHA-1 ADRENERGIC RECEPTOR SUBTYPES FOR USE IN THE PRODUCTION OF SUBTYPE-SPECIFIC ANTIBODIES. D.C. Perry¹, R.P. Yasuda² and B.B. Wolfe². Depts. Pharmacology, ¹George Washington Medical Center, Washington, D.C. 20037 and ²Georgetown University, Washington, D.C. 20007

Three separate gene products have been demonstrated for α_1 -adrenergic receptors, α_1 -1, α_1 -1, and α_1 -1. We are employing clones of these receptor subtypes (courtesy of Drs. R. Lefkowitz and M. Caron) to produce subtype-specific antibodies. Polymerase chain reaction was used to clone a 432 base-pair segment from the C-terminus of the α_1 -1 receptor and a 359 base pair segment from the C-terminus of the α_1 -1 receptor. The segments were designed to contain BamHI sites on the ends of both segments, permitting subcloning of each segment into the plasmid vector pET-3b immediately downstream from a T7 promoter site. Successful ligation was confirmed by DNA sequencing. The plasmid was transformed into the *E. coli* strain BL21(DE3), which contains the bacteriophage T7 gene under the control of the lacUV5 promoter. Bacteria were grown in the presence of 1 mM IPTG to activate the T7 gene, causing overproduction of the specific fusion proteins. The fusion proteins consist of the first 11 amino acids of the T7 gene 10 attached directly to the protein coded for by the cloned receptor sequences. SDS-PAGE analysis of timed samples confirmed the presence of induced protein bands at 18,000 daltons, agreeing with the predicted molecular weight for the two fusion proteins. The 4 hr induced culture was purified using a Rotofor automated isoelectric focussing apparatus followed by dialysis. Lowry and SDS-PAGE analysis indicated about 85-90% purity for each fusion protein, with a total yield of approximately 10 mg protein/liter culture. We have initiated production of antibodies in rabbits; such antibodies should prove to be valuable tools for analysis of α_1 -receptor subtypes. (Supported by NS 26934)

35.4

RECEPTOR AUTORADIOGRAPHIC ANALYSIS OF p-iodoclonidine BINDING IN DISCRETE BRAIN AREAS IN GENETICALLY OBESE ZUCKER RATS. M. Koulu, U. Pesonen, T. Miettinen, R. Huuopponen* and M. Scheinin. Dept. of Pharmacology, Univ. of Turku, SF-20520 Turku, Finland.

The obese Zucker rat is a genetic model of obesity. Obese (*fa/fa*) animals are hyperphagic and hyperinsulinemic compared to lean (*Fa/?*) control rats. The mechanisms underlying hyperphagia of obese Zucker rats are not yet resolved, but impaired satiety signals may be involved. We have reported previously that the α_2 -adrenoceptor mediated feeding response to clonidine is enhanced in obese rats (*Neuroendocrinology* 52:503-510, 1990). The present study was performed in order to investigate α_2 -receptor binding characteristics in brain areas involved in the control of feeding behavior. Quantitative receptor autoradiographic analysis of [¹²⁵I]-p-iodoclonidine (PIC) binding in obese and lean Zucker rats was performed.

Brain slices were incubated for 60 min in 180 mM Tris-HCl buffer containing 3 nM PIC. Non-specific binding was determined by 10 μ M phentolamine. After washing, the slides were exposed on Fuji XJ film for 72 h together with plastic ¹⁴C-standards. Images were analyzed with a MacIntosh-based image analysis system (Image, Wayne Rasband, NIMH, Bethesda, MD, USA). The brain areas where PIC binding was determined included the hypothalamic paraventricular nucleus (PVN), anterior hypothalamic nucleus, hippocampus, amygdala, and cerebral cortex. There were no differences between the Zucker phenotypes in PIC binding in any brain area examined.

It is concluded that PIC binding in brain is not altered in genetic obesity, suggesting that the enhanced hyperphagic effect of clonidine in obese Zucker rats is not due to increased α_2 -receptor density. Instead, we propose that an imbalance between inhibitory serotonergic and stimulatory α_2 -adrenergic tone in hypothalamic centers regulating food intake may account for the greater sensitivity of obese rats to clonidine.

35.5

THE ALPHA-2D ADRENERGIC RECEPTOR IN THE BOVINE PINEAL AND RAT SUBMAXILLARY GLAND. H.S. Blaxall, N.A. Hagg* and D.B. Bylund, Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198-6260.

Recently we have identified and characterized the alpha-2 adrenergic receptor in bovine pineal glands (Bylund et al., *Adrenoceptors*: 27-36 Birkhauser Verlag, 1991). [³H]Rauwolscine bound in a saturable manner with a K_d of 1.5 nM. Inhibition studies with twelve adrenergic antagonists indicated that the bovine pineal contained a single class of alpha-2 adrenergic receptor binding sites. The correlations between the pK_i values from the bovine pineal with cell lines expressing only one alpha-2 adrenergic subtypes are respectively: HT29 2A 0.80, NG108 2B 0.46 and OK 2C 0.61. These results suggest that the bovine pineal alpha-2 adrenergic receptor may represent a new pharmacological subtype, the alpha-2D. The alpha-2 adrenergic receptor in rat submaxillary gland has been characterized (Michel et al., *Br. J. Pharmacol.* 98:890-897, 1989). The correlation coefficient for the rat submaxillary gland with the pK_i values for the bovine pineal gland is 0.93, suggesting that it may also contain the alpha-2D subtype. To further characterize this subtype, RNA was isolated from bovine pineal and rat submaxillary glands and subjected to RTPCR using oligonucleotide primers developed to transmembrane regions II and VII using the published sequences of the human α_2C and α_2D . This produced single products of approximately 1 kb which hybridized strongly to a 0.3 kb fragment which includes transmembrane regions I to V from HPa2GEN, a plasmid containing the coding sequence for alpha-2 α_2D . These 1 kb products are currently being used to obtain sequence data for the alpha-2D adrenergic receptor. (NIH grant GM40784).

35.7

FUNCTIONAL DISCRIMINATION BETWEEN CENTRAL AND PERIPHERAL ALPHA₂-ADRENOCEPTORS USING THE ADRENERGIC AGONIST ORG 9987. Th. De Boer¹*, G. Maura²*, J.S. De Graaf¹*, G.S.F. Ruigt¹, J.A.D.M. Tonnaer¹ and M. Raiteri². ¹CNS Pharmacology R&D Labs., SDG, Organon Int.B.V., 5340 BH Oss, The Netherlands, and ²Istituto di Farmacologia e Farmacognosia, Univ. of Genova, 16148 Genova, Italy.

Heterogeneity of alpha₂-adrenoceptors has been studied using the unique discriminating property of the alpha₂-adrenoceptor agonist Org 9987. Functional studies included the inhibition of twitches evoked in the rat vas deferens by electrical stimulation and inhibition of ³H-noradrenaline release from rat cortical synaptosomes, whereas displacement of ³H-rauwolscine binding to three cloned human alpha₂-adrenoceptors was studied in CHO-cell membranes. The twitch response of the vas deferens was fully and concentration-dependently inhibited by azepevole (pD₂=6.3; slope=0.61), clonidine (pD₂=8.2) and Org 9987 (pD₂=7.5; slope=1.16). In contrast to clonidine, Org 9987 was unable to inhibit the release of ³H-noradrenaline from rat brain synaptosomes. Org 9987 showed a 10-fold preference (pK_i=7.0) for a subtype of alpha₂-adrenoceptor preferentially expressed in peripheral organs. It is concluded that terminal autoreceptors differ pharmacologically from peripheral presynaptic alpha₂-adrenoceptors which are discriminated by the novel alpha₂-agonist Org 9987.

PHARMACOLOGICAL CHARACTERIZATION OF α -ADRENERGIC RECEPTORS COUPLED TO PHOSPHOLIPASE C IN CULTURED HUMAN RETINAL PIGMENT EPITHELIAL CELLS. S. Moroi and G.J. Jaffe*. Dept. of Ophthalmology, Duke University, Durham, NC 27710.

The retinal pigment epithelium (RPE), a monolayer of neuroectodermal cells between retina and choroid, is vital for retinal function. In RPE culture, α - and β -adrenergic receptors have been identified, but the receptor subtypes have not been characterized pharmacologically.

Third to sixth passage human RPE cells were seeded in 24 well plates at 40,000-60,000 cells/ml and grown to confluency. Cells were labeled with [³H]inositol (3 μ Ci/well) for 24 hr and stimulated for 30 min with varying concentrations of epinephrine in the presence of pargyline (10 μ M). [³H]inositol phosphate products were separated by anion exchange column chromatography. There was a concentration-dependent increase in [³H]inositol phosphate products which was antagonized by prazosin, but not propranolol. Studies are underway to characterize the α -adrenergic receptor subtype in cultured human RPE. This receptor system may have a role in ion transport, proliferation, and rod outer segment renewal.

35.6

INTERACTION BETWEEN ANGIOTENSIN II AND SUB-TYPES OF α_1 -ADRENOCEPTORS. R. TABRIZCHI* and C. R. TRIGGLE. Department of Pharmacology and Therapeutics, Faculty of Medicine, University of Calgary, Calgary, AB, Canada, T2N 4N1.

Activation of different signal transduction processes by agonists suggests that a further sub-classification of membrane receptors may be necessary. Thus the α_1 -adrenoceptors have been sub-classified into α_{1a} and α_{1b} . We have evidence which indicates that the alkylating agent phenoxybenzamine is capable of selectively inactivating the sub-class of vascular smooth muscle, α_{1b} , α_1 -adrenoceptors coupled to the phosphoinositol pathway, whereas the other sub-type, α_{1a} , is sensitive to calcium channel blockade. Receptor mediated events due to the activation of α -adrenoceptors can also be influenced by peptides such as angiotensin II. We have shown that pretreatment of rats with captopril leads to the inhibition, *in vivo*, of pressor responses initiated by the α_1 -adrenoceptor agonists cirazoline and St 587. Furthermore, the previous exposure to phenoxybenzamine leads to an enhanced inhibitory action of captopril. This suggests that phenoxybenzamine and captopril are acting by different mechanisms and that angiotensin II may act to potentiate receptor mediated responses via the influx of calcium. Moreover we have shown that a combination of captopril and nifedipine does not produce an additive inhibition of the pressor responses to α_1 -adrenoceptor agonists. This also supports our hypothesis that angiotensin II may selectively enhance signal transduction which is mediated by the activation of α_{1a} receptors. (Supported by Alberta Heart and Stroke Foundation)

ACTIONS OF A-75200, A COMBINED ALPHA-2 ANTAGONIST/NOREPINEPHRINE UPTAKE INHIBITOR ON NOREPINEPHRINE-CONTAINING CELLS. G.A. Gerhardt, J. Firestone, M. Browning, P. Bickford-Wimer, T. Sebree, M. Pierce, J.F. DeBernardis, and J.F. McKelvy. Depts. of Pharmacology and Psychiatry, Univ. of Colorado Health Sci. Ctr., Denver, CO and Abbott Laboratories, Abbott Park, IL.

A-75200, (\pm)-(R*,3R*)-3-phenyl-1-(1',2',3',4'-tetrahydro-5',6'-methylenedioxy-1-naphthalenyl)methyl-pyrrolidine, methanesulfonate is a racemic mixture which is a potent alpha-2 antagonist, and an inhibitor of the uptake of norepinephrine (NE) into central neurons which has potential as a novel antidepressant agent. The enantiomers of A-75200 have also been synthesized and these compounds exhibit differential potencies for both the uptake and alpha-2 effects. Receptor binding data showed that A-75200 possesses excellent affinity for the alpha-2 receptor with a K_d of 1.2 nanomolar and a good alpha-1/alpha-2 selectivity (~100 fold; ratio K_{1a1}/K_{1a2}). In synaptosomal preparations from rat hippocampus, A-75200 was found to inhibit the uptake of ³H-NE with an IC₅₀ of 870 nanomolar. Preliminary studies conducted using bovine adrenal chromaffin cells showed that A-75200 inhibits the uptake of ³H-NE into these cells with a relative potency that is less than desipramine and nomifensine and with the reuptake inhibition conferred by the SS enantiomer. Interestingly, the SS enantiomer also appears to have effects on the uptake of ³H-NE into bovine adrenal chromaffin cells. We are currently conducting *in vivo* electrochemical measurements in rat cerebellum using Nafion-coated carbon fiber electrodes coupled with pressure ejection of A-75200 and other uptake inhibitors, to explore the effects of this novel compound on the diffusion/clearance of NE in the intact animal.

35.10

P_{2Y}-PURINERGIC AND α_1 -ADRENERGIC ACTIVATION OF ARACHIDONIC ACID RELEASE. B.L. Firestein, D.A. Craig* and P.A. Insel*. Depts. of Pharmacol and Neurosci, UCSD, La Jolla, 92093.

We have used receptor-stimulated release of [³H]-arachidonic acid (AA) from labeled Madin-Darby Canine Kidney cells (MDCK-D₁ line) as a model system to explore the possible interaction of ATP and norepinephrine (NE) co-released from sympathetic neurons. NE (0.1-3 μ M) activates α_{1b} -adrenoceptors and elicits a 5-6 fold maximal stimulation of AA release; ATP (0.1 μ M-3mM) evokes greater (12-15 fold) AA release. Responses to ATP are mimicked by nucleotides with the following relative potencies: ATP = UTP = 2-CH₃S-ATP > ADP = AMP >>> α, β -CH₂-ATP. AMP, adenosine and cAMP (\leq 3mM) were ineffective. The agonist profile suggests action at a P_{2Y} purinergic receptor, but the broadness of the concentration-effect curves for ATP suggests involvement of multiple purinergic receptor subtypes. Both ATP- and NE-stimulated AA release are dependent on extracellular calcium, but are insensitive to 0.5 mM neomycin, an inhibitor of polyphosphoinositide-phospholipase C. Inhibition of ATP- and adrenergic-evoked release of AA by sphingosine (12 μ M) and staurosporine (100 nM) suggests that protein kinase C (PKC) is involved in AA release. These data support the hypothesis that P_{2Y} receptors and α_1 receptors activate multiple phospholipases, including PLA₂. We further hypothesize that PLA₂ and/or PKC may represent sites of interaction between NE and ATP.

35.11

CHARACTERIZATION OF ALPHA-2A AND ALPHA-2B ADRENERGIC RECEPTORS IN HUMAN BRAIN. G.A. Ordway and A.E. Halaris, Depts. Psychiatry and Pharmacology, Case Western Reserve Univ. and MetroHealth Med. Ctr., Cleveland, Ohio 44109.

Subtypes of alpha-2 adrenergic receptors have been pharmacologically identified in human brain. Studies using ^3H -yohimbine demonstrate that oxymetazoline (OXY) has high and low affinity for alpha-2A and alpha-2B receptors, respectively, while prazosin has low and high affinity for alpha-2A and alpha-2B receptors, respectively. We further characterized alpha-2 receptor subtypes in homogenates of human brain. Competition experiments (30 to 35 point) using caudate (n=6) measured inhibition of binding of ^3H -yohimbine by OXY. Competition curves were best fit (LIGAND) by a two-site model ($p < 0.005$) and were unaffected by GTP. Based on these curves, a concentration (CONC_{opt}) of OXY was calculated which would optimally antagonize binding of ^3H -yohimbine to high affinity sites, minimally inhibiting low affinity binding. In the presence of CONC_{opt} of OXY, competition studies of remaining ^3H -yohimbine binding in caudate revealed pharmacology which was characteristic of alpha-2B receptors. Furthermore, ratios of alpha-2A to alpha-2B receptors were estimated in human frontal cortex (5:1), temporal cortex (5:1), caudate (1:1), hippocampus (5:1), amygdala (2:1), cerebellum (6:1) and locus coeruleus (5:1). Supported by MH42859 and NARSAD.

QUANTITATIVE AUTORADIOGRAPHIC (QAR) COMPARISON OF α_2 -ADRENERGIC RECEPTORS IN RAT BRAIN REGIONS USING MULTIPLE COMPETITORS. D.R. Wallace and N.R. Zahniser. Univ. Colorado Hlth. Sci. Ctr., Dept. Pharmacology, Denver, CO 80262.

As a prelude to investigating aging-related changes in α_2 -adrenergic receptor subtypes in rat brain, binding of tritiated-idazoxan (^3H -IDAZ) and rauwolfscine (^3H -RAUW) was examined using QAR. Brain regions investigated were the cortex, hippocampus, anterior thalamic nuclei, caudate/putamen, entorhinal cortex/amygdala, hypothalamus, inferior colliculus, locus coeruleus and nucleus tractus solitarius. Assays were carried out in 25 mM glycylglycine buffer (pH = 7.5) at room temperature. (-)-Norepinephrine (NE; 1 mM) was used to define nonspecific binding. Specific binding constituted 75-80% of total binding for ^3H -IDAZ and 50-60% for ^3H -RAUW. Monophasic saturation curves for ^3H -IDAZ (0.1-15.0 nM) and ^3H -RAUW (0.1-10.0 nM) were obtained in all brain regions. The affinities for both radioligands ranged from 0.4 - 4 nM. The density of binding sites were 2- to 4-fold higher for ^3H -IDAZ compared to ^3H -RAUW. Competition curves were constructed using a concentration range of 10 pM - 1 mM for a nonselective α_2 -adrenergic receptor agonist (NE), an α_{2A} -preferring compound (oxymetazoline), α_{2B} -preferring compounds (ARC-239 & prazosin) and an IDAZ-like α_2 agonist (guanabenz). For most competitors pseudo-Hill slopes were less than unity, and the curves were better fit by a two-site model. The exception was ARC-239 inhibition of ^3H -RAUW; these curves were fit to a one-site model. The higher density of ^3H -IDAZ binding sites suggests that throughout the brain ^3H -IDAZ binds to a larger population of α_2 -adrenergic receptors than does ^3H -RAUW. Based on the competition curve analyses, the ratio of α_{2A} - and α_{2B} -adrenergic receptor subtypes was determined and will be presented for each brain region. Supported by USPHS AG 04418.

IN SITU HYBRIDIZATION STUDY OF ALPHA AND BETA ADRENERGIC RECEPTORS IN THE RAT. A.P. Nicholas¹, V.A. Pieribone, R.P. Elde and T. Hökfelt, Dept. of Histology and Neurobiology, Karolinska Institutet, Stockholm, Sweden, 104 01.

Previous autoradiographic studies have demonstrated the general location of alpha and beta adrenergic receptor binding by "specific" radioactive ligands; however, it is difficult to quantify or determine the pre- or postsynaptic location of these receptors using this technique. In the present study, we have designed specific 48-mer oligoprobes to recently-described sequences of the rat alpha-1B, alpha-2B, beta-1 and beta-2 adrenoceptors for *in situ* hybridization experiments. Complementary DNA probes were made on a DNA synthesizer to the following nucleotide sequences: 1420-1467 rat alpha-1B receptor, 868-915 of rat brain alpha-2B receptor, 1401-1448 of beta-1 receptor and 2999-3046 of beta-2 receptor. All probes then were labeled at the 3'-end using terminal deoxynucleotidyltransferase and [^{35}S] dATP. Fresh rat tissues, including liver, kidney, lung, gut, brain and spinal cord, were rapidly removed, frozen, sectioned on a cryostat (14 μm), air dried and transferred to humidified boxes at 42° C for 18 hrs with 1 X 10⁶ cpm of an end-labeled DNA oligonucleotide probe diluted in a hybridization solution consisting of 0.02% Ficoll, 0.02% polyvinyl pyrrolidone, 1% sarcosyl, 0.2 M sodium phosphate (pH 7), 10% dextran sulfate, 200 mM dithiothreitol and 500 $\mu\text{g/ml}$ heat-denatured salmon sperm DNA. The sections then were washed 4 X 30 min in SSC at 55° C, dehydrated, dipped in Kodak NTB2 photographic emulsion and exposed for 3-6 weeks before development. Specific labeling with all probes was seen in various tissues. For example, beta-2 receptor signal was very high in the hippocampus, while alpha-1B receptor labeling was intense in the thalamus. Using this technique, not only will the specific localizations of the cells which manufacture these receptors be attained, but also various physiological or pharmacological manipulations can be performed in future studies to quantify any possible up or down regulation of these receptors.

35.12

LOCALIZATION OF α_2 -AGONIST BINDING SITES WITH p-[^{125}I] IODOCLONIDINE: COMPARISON WITH p-[^3H] AMINOCLONIDINE. L.L. Longlet, M.E. Alburques, D.B. Bylund*, M.A. Hunt, N. Narang and J.K. Wamsley. Neuropsychiatric Research Institute, 700 First Avenue South, Fargo, ND 58103; *Department of Pharmacology, University of Nebraska Medical Center, 42nd and Dewey Avenue, Omaha, NE 68198.

[^3H] Para-aminoclonidine (p-[^3H] AC) binds with high affinity and selectivity to α_2 -receptors. Previous investigations utilizing this agonist may have overlooked some regions of α_2 binding due to the subtype selectivity of this ligand. In the present study, p-[^{125}I] AC was shown to be more effective at labeling α_{2A} sites than α_{2B}/α_{2C} sites. In contrast, p-[^{125}I] Iodoclonidine (p-[^{125}I] IC) had only 1000 times more affinity for the α_{2A} than the α_{2B}/α_{2C} sites. The distribution of p-[^{125}I] IC binding was two-fold higher than the p-[^3H] AC binding in many brain areas analyzed. The results obtained with the guanine nucleotide, Gpp(NH)p, suggest that both radioligands bind preferentially to the guanine-nucleotide-sensitive sites of α_2 -receptors. These studies indicate that p-[^{125}I] IC is less selective for α_2 -subtypes than p-[^3H] AC and is a more precise indicator of the density and distribution of α_2 -receptors.

35.14

IN SITU HYBRIDIZATION ANALYSIS OF α -1B, α -2C10 AND α -2C4 ADRENERGIC RECEPTOR mRNAs DURING RAT BRAIN DEVELOPMENT. S.K. McCune, M.M. Voigt* and J.M. Hill. Lab. of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Multiple subtypes of alpha adrenergic receptors have been identified and characterized by pharmacologic and/or molecular biologic means. The regional distribution and functional significance of these subtypes have yet to be fully elucidated. Using pools of oligonucleotide probes specific for the α -1B, α -2C10 and α -2C4 subtypes, frozen sections of E14, E16, E19, newborn, P8, P14 and adult brains were examined by *in situ* hybridization. All three receptor subtypes were present in the brain as early as E14 and each had a unique regional and ontogenic expression.

The α -2C4 mRNA was expressed at higher levels throughout development than the other two subtypes. It was primarily localized in the cortex (especially the cingulate cortex in the postnatal rat), hippocampus, caudoputamen, pons, pineal and cerebellum. In general, the expression levels increased in these areas in the postnatal animal and the message was more abundant in fiber tracts in the adult animal. The α -2C10 receptor mRNA was present in cortex (particularly in the pyriform cortex on P14), hippocampus, pons and cerebellum. High levels of the receptor message were also found in the prenatal inferior olive and P14 locus coeruleus. Levels of α -2C10 mRNA were generally higher in the perinatal animal than in the adult. The α -1B receptor message was primarily expressed in the cortex (especially intermediate layers in the adult), thalamus, hippocampus, pineal, dorsal raphe, and cerebellum (particularly the cerebellar peduncles). In most regions, this receptor subtype mRNA was more abundant in the older animal.

These data confirm the previous observations made by Northern blot of the developmental expression of these three alpha adrenergic receptor subtypes. *In situ* hybridization allowed for more precise localization of these receptors during embryonic and postnatal development and may ultimately be used to correlate function with subtype specific expression.

35.16

GENETIC STRUCTURE OF THE β 1-ADRENERGIC RECEPTOR. R.P. Searles¹, V. Nipper^{1*}, and C. A. Machida^{1,2}, ¹Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006 and ²Dept. of Biochemistry and Molecular Biology, Oregon Health Sciences University, Portland, OR 97201.

The β -adrenergic receptors are members of the superfamily of G protein-coupled neurotransmitter receptors and mediate physiological response to the catecholamines epinephrine and norepinephrine. Three major subtypes (β 1- β 3) have been identified on the basis of pharmacology and genetic structure. Our lab previously reported the isolation and characterization of the rat β 1-AR gene. To identify conserved elements within the flanking elements of this gene, the rhesus macaque β 1-AR gene was cloned and sequenced. This gene codes for a 480 amino acid receptor that is 98% homologous to the human β 1-AR and 94% homologous to the rat. Approximately 1.5 kb each of upstream and downstream flanking sequence of the primate gene was compared to corresponding sequences of the rat gene. Among the elements conserved between the two species are two potential polyadenylation sites, a consensus cyclic AMP response element, and a T-cell response element. Conservation of the gene for 1.5 kb downstream is greater than 76%, suggesting important untranslated and untranscribed sequences in this area. Overall conservation of the 5' flank is 72% for the first 1.5 kb, but this similarity is unevenly distributed. 1.25 kb of rat β 1-AR upstream sequence (-1256 to -1 relative to the initiation codon) in a luciferase expression vector expresses highly when transfected into C6 glioma cells. Expression declines by 95% when the rat sequences -1033 to -1 are used to regulate transcription.

35.17

FUNCTIONAL EXPRESSION OF A HUMAN β -2 ADRENERGIC RECEPTOR IN *XENOPUS* MELANOCYTES. M. N. Potenza and M. R. Lerner, Howard Hughes Med. Inst., Depts. of Int. Med., Pharm. & Cell Bio., Yale Univ. School of Med., New Haven, CT. 06510

Pigment translocation in *Xenopus* melanocytes is mediated by intracellular levels of cyclic AMP (cAMP): high levels induce dispersion whereas low levels induce aggregation. In order to investigate the feasibility of using the melanocytes to study G-protein coupled receptors not normally expressed in these cells, the human β -2 adrenergic receptor (β -2 AR) was selected. In its native environment, the β -2 AR, when stimulated, produces an increase in intracellular cAMP levels. Cultured melanocytes transfected with the gene encoding the human β -2 AR obtained the ability to disperse their pigment in response to the β -2 specific agonist metaproterenol with an E.C.₅₀ value of 75 nM. Metaproterenol did not induce significant pigment translocation when applied to untransfected cells or cells transfected with vector alone. Metaproterenol-induced, but not MSH-induced, dispersion in the transfected cells was blocked by the β -adrenergic antagonist propranolol. The demonstration of the functional expression of an introduced G-protein coupled receptor in cultured *Xenopus* melanocytes has implications for their use as a rapid visual means to study G-protein coupled receptors and the ligands with which they interact.

35.19

CHARACTERIZATION OF A SOLUBLE FORM OF THE β 1- AND β 2-ADRENERGIC RECEPTOR EXPRESSED IN BACTERIA. K. P. J. Dobrowsky, W.H.M.L. Luyten and J.E. Leysen. Dept. of Biochemical Pharmacology, Janssen Research Foundation, B2340 Beerse, Belgium.

Functional β 1- and β 2-adrenergic receptors (β -ARs) have been expressed in *Escherichia coli* as LamB or MalE fusion proteins (Marullo et al. Bio/Technology 7:923;1989). Although previous fractionation studies documented β -AR immuno-reactive material in the cytosol, this form did not appear to bind any ligand (Chapot et al. Eur. J. Biochem. 187:137; 1990).

Bacteria were grown as described by Marullo et al., and lysed (in 50 mM TRIS pH 7.6, 250 mM sucrose, 100 mM NaCl, 1.5 mM PMSF, 1 mM DTT, 1mM MgCl₂) by sonication after lysozyme treatment. The lysate was centrifugated for 30 min. at 150,000xg and ligand binding was performed on the supernatant.

Saturable 125I-iodocyanopindolol binding, displaceable by a variety of β -adrenergic agonists and antagonists was seen for the β 2-AR after incubations for 60 min at 37°C, or for 2-16 hours at 4°C and for the β 1-AR after incubation for 16 hours at 4°C. Prolonged incubations at 4°C yielded the maximum number of binding sites, which was still less than 1% of the specific binding to intact cells. Results of 125I-iodocyanopindolol binding to the soluble cytosolic β -AR form were independent of the 3 methods used to separate bound from free radioligand: polyethyleneglycol precipitation, filtration through polyethyleneimine pre-soaked GF-C filters or Sephadex LH-20 columns. Competition binding with 17 β -adrenergic agonists and antagonists (comprising hydrophilic and lipophilic agents) yielded IC₅₀s comparable to those measured on intact cells. On the whole, this strongly suggests that the soluble binding site is a β -AR.

We do not know how this β -AR remains in solution. The fact that this soluble receptor form could be obtained without the addition of lipids or detergents argues against it being solubilised from a membranous environment. In principle, the hydrophilic MalE part could keep the fusion protein in solution, but previous work showed that β -AR fails to bind ligands while fused to MalE.

35.21

ESTRADIOL REGULATES α_{1B} -ADRENERGIC RECEPTORS WHICH POTENTIATE cAMP FORMATION IN THE HYPOTHALAMUS N. Petitti and A.M. Etgen. Depts. of Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461

Estradiol potentiates α_1 receptor augmentation of β receptor-stimulated cAMP accumulation in slices of the preoptic area (POA) and middle hypothalamus (MH) (J. NEUROSCI. 10:2842-2849, 1990). Present studies examined: (1) whether α_{1A} - or α_{1B} -adrenergic receptors mediate the augmentation phenomenon, and (2) if ovarian steroids selectively alter the binding characteristics of either α_1 -receptor subtype. The irreversible α_{1B} receptor blocking agent chlorethylclonidine eliminated phenylephrine (α_1 agonist) augmentation of isoproterenol (β agonist)-stimulated cAMP formation in POA and MH slices, whereas the α_{1A} antagonist 5-methyl urapidil did not. This suggests that the α_{1B} receptor subtype potentiates cAMP formation. POA and MH membranes from estradiol-treated rats, when compared to ovariectomized rats, had modestly (40-50%) but significantly elevated numbers of ³H-prazosin (α_1) binding sites. Studies with chlorethylclonidine indicated that the estrogen-dependent increase in total α_1 binding sites in POA and MH membranes was attributable to a five- to six-fold increase in α_{1B} receptor number. Progesterone had no measurable effects on α_1 receptor binding. Thus the increased α_1 receptor augmentation of cAMP formation seen in estradiol-treated rats is correlated with increased α_{1B} receptor number.

35.18

PURIFICATION AND CHARACTERIZATION OF THE β -ADRENOCEPTOR FROM RAT CEREBRAL CORTEX. S.B. Lee, K.N. Park, J.S. Ahn and K.H. Ko. Department of Pharmacology, College of Pharmacy, Seoul National University, Seoul 151, Korea.

The β -adrenoceptor of rat cerebral cortex was successfully solubilized by sequential treatment with cholate and digitonin. About 50% of the total receptor pool was released by this solubilization procedure. The β -adrenoceptors in the digitonin extract were identified using the β -adrenergic antagonist, (-)-[³H]dihydroalprenolol ([³H]DHA). The solubilized receptor retained all of the essential characteristics of membrane-bound receptor, namely saturability; stereoselectivity; high affinity to β -adrenergic drugs. In order to facilitate effective purification, the affinity chromatography was adopted in this experiment. A β -adrenergic antagonist, (-)-alprenolol, was immobilized to Sepharose CL-4B by using a hydrophilic spacer arm, bisoxirane. The affinity gel was prepared by the method of Caron et al. (1979). Finally, the β -adrenoceptor of rat cerebral cortex was purified by sequential affinity chromatographic steps. Purified receptor preparations bind [³H]DHA with a specific activity of 13.65nmol/mg of protein, representing a 35,000fold purification from cortical membranes with a 3% overall yield. Sodium dodecylsulfate-polyacrylamide gel electrophoresis of purified receptor revealed a major band of protein of 52,000daltons and a minor band of 24,000 daltons. The binding of [³H]DHA to purified receptor preparations displayed affinity, specificity, and stereoselectivity characteristic of solubilized receptor.

35.20

NEURAL REGULATION OF BETA-1 AND BETA-3 ADRENERGIC RECEPTOR mRNA LEVELS IN BROWN FAT. J.G. Granneman and K. N. Lahners. Center for Cell Biology, Sinai Hospital and Clinical and Cellular Neurobiology Program, Wayne State Univ. Sch. of Med., Detroit MI 48235.

Beta-1 and β -3 adrenoceptor mRNAs levels of several tissues were determined simultaneously using a sensitive nuclease protection assay. The β -1 receptor gene was expressed to varying degrees in all tissues examined. By contrast, the β -3 receptor gene was abundantly expressed only in brown and white adipose tissues. Minor expression of the β -3 receptor was also found in the adrenal gland. These data indicate that the β -3 receptor is essentially fat tissue-specific.

Surgical sympathectomy of brown fat increased β -3 receptor mRNA levels by 2.5 times, but did not affect β -1 receptor mRNA levels. Exposing rats to 4°C, which increases sympathetic nerve stimulation of BAT, reduced β -3 receptor mRNA levels in intact tissue by 50% but did not affect the denervation-induced increase in β -3 receptor mRNA. Cold exposure slightly increased beta-1 receptor mRNA levels in both intact and denervated brown fat. These results indicate that β -1 and β -3 receptor mRNAs are differentially regulated and that sympathetic nerve activity reduces β -3 receptor or mRNA levels in brown fat. (Supported by NIH Grant DK37006).

IMMUNOHISTOCHEMICAL STUDIES OF NORADRENERGIC ACTIVATION OF C-FOS IN RAT CENTRAL NERVOUS SYSTEM. G. Bing, Y. Zhang*, D. Filer*, S. M. John* & E.A. Stone. Dept. Psychiatry, NYU Sch. Med., New York, NY 10016.

Previous experiments have shown that stimulation of brain beta adrenoceptors by i.p. yohimbine injection increases the mRNA of c-fos in the rat CNS. The present study examined the distribution of c-fos protein after this treatment. Rats were perfused 2 hr after injection of yohimbine (5 mg/kg) alone or with the beta blocker, propranolol (10 mg/kg). 30 μ sections were stained immunohistochemically for c-fos, GFAP or neurofilament protein. Yohimbine treated rats were found to show marked increases in c-fos-like immunoreactivity in regions known to be either targets of noradrenergic output or noradrenergic neurons themselves. The most heavily stained regions included the neocortex (layers II and III), olfactory tubercle, piriform cortex, entorhinal cortex, paraventricular n. and locus coeruleus. Cotreatment with propranolol reduced c-fos-reactivity in all of the above areas. Double label experiments with GFAP and neurofilament protein indicated that the stained cells were predominantly neuronal. It is concluded that immunohistochemical staining of c-fos protein after yohimbine injection identifies postsynaptic beta adrenergic targets as well as presynaptic neurons of the central noradrenergic system. AFOSR 89-0208, MH45265 and MH08618.

MEASUREMENT OF ENDOGENOUS CENTRAL NORADRENERGIC NEUROTRANSMISSION FROM LEVELS OF cAMP EFFLUX IN VIVO. E.A. Stone and S.M. John*. Dept. Psychiatry, New York Univ. Sch. Med., New York, NY 10016.

We have previously shown that microdialysis can be used to stimulate brain beta adrenoceptors with exogenous catecholamines and to detect the resulting increases in synthesis and outflow of cAMP. This method has enabled us to measure activation of beta receptors in vivo by exogenous catecholamines. The present experiments were undertaken to determine whether this technique can also detect receptor activation by endogenous norepinephrine (NE) release. Rats were implanted with microdialysis probes (3.5 mm) in the medial prefrontal cortex and given 48 hr to recover. The probes were perfused with Ringer's solution at 1 μ l/min. Drugs were dissolved in Ringer's solution and infused via the input line. Portions of the dialysate were analyzed by HPLC for norepinephrine and by RIA for cAMP. It was found that infusion of the indirect sympathomimetic amine, amphetamine, at 10^{-2} M for 10 min elicited significant increases in NE and cAMP outflow. Studies of the effects of norepinephrine depleting agents on these responses will be reported. It is tentatively concluded that the microdialysis technique can detect endogenous noradrenergic neurotransmission at beta adrenoceptors in the cerebral cortex. Supported in part by grants AFOSR 89-0208, MH45265 and MH08618.

CATECHOLAMINE RECEPTORS: DOPAMINE I

36.1

MOLECULAR CLONING AND EXPRESSION OF THE RHESUS MACAQUE D1 DOPAMINE RECEPTOR GENE. C.A. Machida^{1,2}, R.P. Searles¹, L.B. Kozell^{3*}, K.A. Neve^{4*}, J.E. Thornton¹, J.A. Brown^{1*}, and V. Nipper^{1*}. ¹Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006, Depts. of ²Biochemistry and Molecular Biology and ³Pharmacology, Oregon Health Sciences University, Portland, OR 97201, and ⁴Veterans Administration Medical Center, Portland, OR 97201.

The dopamine receptors are members of the superfamily of G protein-coupled neurotransmitter receptors and serve as key biochemical modulators in motor activity, emotion, and cognition. Several subtypes of dopamine receptors (D1-D5) have been identified on the basis of their pharmacological properties, physiological effects, tissue and cell type specificity, and genetic structure. To begin analyzing the distribution and regulation of D1 dopamine receptors in the retina, we cloned and sequenced the rhesus macaque D1 dopamine receptor gene and expressed these receptors by transfection in C6 glial cells. Nucleotide sequence analyses of the coding region of the rhesus macaque D1 dopamine receptor gene show that it encodes a 446 amino acid protein, with several potential sites for N-linked glycosylation (2), and cAMP-dependent protein kinase phosphorylation. The primary amino acid sequence of the rhesus D1 receptor shows an extremely high degree of similarity (99.6%) to the human D1 receptor. Radioligand binding and adenylyl cyclase analyses of the transfectant demonstrate the expression of high-affinity (0.3nM, [³H]SCH 23390), functional (stimulation of adenylyl cyclase by dopamine) rhesus macaque D1 dopamine receptors.

36.3

EXPRESSION OF THE HUMAN D1 DOPAMINE RECEPTOR IN YEAST. N. Din^{1*}, J.G.L. Petersen¹, M.G. Caron³ and P.H. Andersen². Departments of ¹Microbial Genetechnology and ²Molecular Pharmacology, Bioscience, Novo Nordisk A/S, DK-2880 Bagsvaerd, Denmark and ³Department of Cell Biology, Duke University Medical Center, Durham, NC 27710.

We have constructed a series of *S. cerevisiae* expression plasmids containing the human D1 receptor cDNA, using various regulated and constitutive promoters. In some of the constructs, the coding region for N-terminus of the receptor was exchanged with that of the N-terminus of *S. cerevisiae* α -Factor receptor (STE2), which belongs to the same super family of G-protein coupled receptors as the dopamine D1 receptor. Expression levels were measured in a number of host strains, using Northern blot analysis as well as ligand binding to whole cells or purified membrane fractions. Although mRNA levels were high, only low levels of functional receptors could be detected (10-200/cell), indicating that protein translation, stability and/or targeting were limiting factor(s). Analysis of cell extracts for the presence of non-functional receptors using antibodies are in progress. Also in progress are testing of various protease deficient host strains.

36.2

CLONING AND CHARACTERIZATION OF A NOVEL HUMAN D1 DOPAMINE RECEPTOR SUBTYPE AND ITS PSEUDOGENE. K.R. Janvie, C. Silvia, R.T. Freneau Jr., J.A. Gingrich*, M.G. Caron. Dept. Cell Biology, Duke University Medical Center, Durham, NC. 27710.

Degenerate primers corresponding to conserved transmembrane domains of the dopamine D1 receptor were used with the polymerase chain reaction (PCR) to amplify sequences from sheared human genomic DNA. One of these products was homologous to the sequence between the 5th and 6th transmembrane regions of the human D1 receptor. This product was radiolabeled by PCR and used to screen a human genomic library. Two of the clones obtained (hg3-2 and hg4-2) were highly homologous to each other (~95%) and the dopamine D1 receptor (~72%). The apparently intronless coding region of one of these clones (hg4-2) revealed the presence of an in frame stop codon between the 4th and 5th transmembrane regions. This gene codes for a truncated receptor unlikely to be active and as such this sequence is presumably representative of a pseudogene. The open reading frame of the other clone (hg3-2) codes for a putative receptor which exhibits the seven transmembrane spanning helices typical of receptors coupled to guanine nucleotide regulatory proteins. Additionally, conserved amino acid residues associated with catecholamine receptors are conserved within this sequence. Based on the homology of this sequence to that of the D1 receptor, it is presumed that this sequence codes for a D1 receptor subtype. Potential sites of phosphorylation by protein kinases A and C are observed in the putative intracellular loops and may be involved in the regulation of receptor function. In situ hybridization in human brain tissue should allow for the comparison of the distribution of this receptor and its pseudogene, with that of the previously characterized dopamine D1 receptor.

36.4

FUNCTIONAL EXPRESSION AND CHARACTERIZATION OF A NEW D1 RECEPTOR AND ITS PSEUDOGENE. Nika Adham*, Mary Macchi*, Paul Hartig, Theresa Branchek, and Richard Weinshank*. Neurogenetic Corporation, Paramus, N.J. 07652

Recently, an expansion in the number of receptor subtypes for dopamine has been forthcoming from molecular cloning techniques. We report the cloning of a novel intronless gene (GL30) encoding a G protein-coupled receptor of the dopamine D1 receptor family. Expression of this receptor in Cos-7 cells led to the high affinity binding of a number of dopamine D₁ antagonists, with a binding profile similar to that of the previously described dopamine D₁ receptor. In contrast, the agonist binding profile of this new receptor did not exactly match any previously defined dopamine D₁ receptor, and was notable for its unusually high affinity for its natural transmitter, dopamine. This new receptor was found to couple to adenylyl cyclase activity, where addition of dopamine caused a 13-fold increase in activity. Messenger RNA encoding this new receptor appears to be distributed in a number of regions in the human brain, including cortical regions, choroid plexus, hippocampus, and brain stem. A second closely related gene, GL39, was isolated and shown to represent a pseudogene exhibiting 94% nucleotide sequence homology to the GL30 sequence. One of the amino acid substitutions which is found in transmembrane region V of pseudogene GL39 is an amino acid proposed to participate in the binding of catecholamine ligands. This mutation may have led to a loss of function and subsequent conversion of an active dopamine receptor gene to a pseudogene.

36.5

MOLECULAR CLONING OF A NOVEL D₁ DOPAMINE RECEPTOR FROM RAT KIDNEY. E.J. Monsma Jr., Y. Shen, C.R. Gerfen, L.C. Mahan, P.A. Jose, M.M. Mouradian & D.R. Sibley. Experimental Therapeutics Branch, NINDS and Laboratory of Cell Biology, NIMH, NIH, Bethesda, MD 20892.

We have used the rat kidney proximal convoluted tubule (PCT), which contains D₁ dopamine receptor subtypes linked to the activation of adenylyl cyclase as well as phospholipase C, to investigate the molecular biology of peripherally located D₁ receptors. In order to clone these receptor subtypes, the polymerase chain reaction (PCR) method was used to selectively amplify putative D₁ receptor cDNA sequences from rat kidney PCT mRNA. Poly (A)⁺ RNA was used to synthesize cDNA by reverse transcription followed by PCR amplification using sets of highly degenerate primers derived from the transmembrane sequences of previously cloned dopaminergic, adrenergic, and serotonergic receptors. This process resulted in the amplification of a novel cDNA sequence which exhibits considerable homology to dopaminergic and other members of the G protein-coupled receptor family. Within the transmembrane regions, this cDNA is >80% homologous with the previously cloned D₁ receptor suggesting that it belongs to this category of dopamine receptor subtypes. Northern blot analysis reveals a transcript size of ~3.3 kb which is located in kidney tissue as well as various regions in the CNS. Northern blots of different brain tissues reveals a relative abundance of hippocampus>hypothalamus = mesencephalon>olfactory tubercle>olfactory bulb>striatum. Little to no transcript was detected in the cerebral cortex, cerebellum, pituitary or retina. *In situ* hybridization analysis reveals a low abundance of this mRNA in CNS regions which agrees well with the Northern blot results. Full length cDNA and genomic clones have been isolated and are being expressed to establish the specific pharmacology and function of this novel D₁ dopamine receptor.

36.7

A Chimeric D₁/D₂ Dopamine Receptor Mediates A D₁ Response To A D₂ Ligand. D.E. Frail, N.J. Pollock, A.M. Manelli*, M. Steffey*, C.W. Hutchins* and R.G. MacKenzie. Abbott Laboratories, Abbott Park, IL 60064.

Dopamine (DA) stimulates adenylyl cyclase via the D₁ receptor and inhibits cyclase via the D₂ receptor. DA receptors are coupled to G-proteins and model to seven transmembrane regions (TMs). Work on other receptors of the family show that subtype specificity is partly determined by the 6th and 7th TMs whereas the 3rd cytoplasmic loop specifies the transduction pathway. We constructed a chimeric DA receptor cDNA to have D₁ sequence from the 5'-end through to the 5'-end of the 6th TM and to have D₂ sequence for the remainder of the molecule. We predicted that, relative to wild-type (WT) D₁, the chimera would lose affinity for D₁ ligands, gain affinity for D₂ ligands and mediate a D₁ response to D₂ agonists. WT and chimeric cDNAs were transiently expressed in mammalian cells and radioligand binding showed the chimera affinity to be 40-fold lower for the D₁ ligands SCH23390 and SKF38393 and a 100-fold higher for the D₂ agonist LY17155. Also, LY171555 was able to elevate cAMP levels only in cells transfected with chimeric cDNA.

36.9

ISOLATION OF A cDNA CODING FOR THE OK CELL DOPAMINE D₁ RECEPTOR. D.R. Cerutis and D.B. Bylund. Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198-6260.

Previous studies from our laboratory (Murphy and Bylund, *Mol. Pharmacol.* 34:1-7, 1988) have demonstrated the presence of the serotonin 5HT_{1B} receptor in the OK cell line, an established opossum renal proximal tubule epithelial cell line. We have also shown this cell line to contain the α_2 -adrenergic receptor (Bylund and Murphy, *J. Pharmacol. Exp. Ther.* 244:571, 1988) and in addition, it has been shown to express the D₁ receptor (Bates et al., *Neurosci. Abs.* 16:1, 1990). To clone the 5HT_{1B} receptor, an OK cell λ gt11 cDNA library was screened at reduced stringency with the human β_2 -adrenergic receptor and a 4.2 kb clone was isolated. This clone is unreactive with α_2 -adrenergic or 5HT receptor probes, and sequencing the region inclusive of transmembrane regions I - V reveals greater than 95-97% identity at the amino acid level with the human and rat D₁ receptors (Zhou et al., *Nature* 347:76, 1990; Sunahara et al., *Nature* 347:80, 1990; Deary et al., *Nature* 347:72, 1990). (NIH grant MH47354).

36.6

CHARACTERIZATION OF A DOPAMINE D₁ RECEPTOR GENE FROM GOLDFISH. A.M. Manelli* and D.E. Frail. Corporate Molecular Biology, Abbott Laboratories, Abbott Park, IL 60064

We have isolated and characterized a gene from goldfish (*Carassius auratus*) that encodes a dopamine D₁ receptor. A cDNA probe encoding the catecholamine receptor G-36 (FEBS Letters, 262, 8-12, 1990) was obtained by the polymerase chain reaction using degenerate oligonucleotides. This probe was used to screen a goldfish genomic library. One positive clone was plaque purified, mapped, and G-36 hybridizing DNA fragments were subcloned for sequence analysis. A complete open reading frame, apparently without introns, shares common features of G-protein coupled receptors and is 90% identical to the human D₁ receptor in the transmembrane regions. However, the goldfish sequence lacks the final 79 amino acids of the human sequence. The goldfish and the human receptors were transiently expressed in eukaryotic cells and characterized by radioligand binding. The goldfish receptor showed a higher affinity for SCH23390, a classical D₁ antagonist, than the human receptor. This receptor most likely represents the well-studied D₁ receptor present in goldfish retina horizontal cells.

36.8

LIGAND BINDING DOMAINS OF THE HUMAN DOPAMINE D₁ RECEPTOR DETERMINED BY SINGLE SITE MUTATIONS. N.J. Pollock#, A.M. Manelli*#, C.W. Hutchins*#, R.G. MacKenzie# and D.E. Frail# #Corporate Molecular Biology, #Pharmaceutical Products Div Abbott Laboratories, Abbott Park, IL 60064.

The dopamine receptors are a member of the G-protein coupled receptors that share homology in the seven transmembrane spanning regions. We are using site-directed mutagenesis followed by a pharmacological analysis of transiently transfected mammalian cells to determine which amino acids are important for ligand binding. There are three serine residues in helix five of the β -adrenergic receptor (a G-protein receptor) that are important for agonist binding (Strader et al., 1989). Analogous mutations, which changed serines to alanines in positions 198, 199 and 202 of the dopamine D₁ receptor, were constructed. Using the D₁ antagonist SCH 23390, the K_d for mutant Ala202 was equivalent to wildtype D₁ (0.5nM); mutant Ala199 K_d=15.6nM; and mutant Ala198 was the same as mock transfected cells. Competition studies show that mutant Ala202 caused a decrease in affinity for dopamine, but not for SCH 23390. Alternatively, mutant Ala199 caused a decrease in affinity for both agonists and antagonists. Cells transiently transfected with wildtype D₁ DNA or mutated receptor DNA show similar levels of mRNA by Northern analysis. Therefore, the lack of binding in cells containing mutant Ala198 is not due to the lack of available mRNA for translation into protein.

36.10

CHARACTERIZATION OF THE 5' FLANKING REGION OF THE HUMAN D-1 DOPAMINE RECEPTOR GENE. M.T. Minowa*, T. Minowa*, F.J. Monsma, Jr., D.R. Sibley, and M.M. Mouradian, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

The D-1 dopamine receptor plays an integral role in propagating neural information in the basal ganglia and other brain structures. In an attempt to understand the molecular events leading to the transcriptional regulation of the adenylyl cyclase-linked D-1 gene, a human genomic clone carrying the 5' flanking and coding regions of this gene was isolated using rat D-1 dopamine receptor coding sequence as a probe. The nucleotide sequence of this 5' flanking region extending 2.6Kb upstream from the first ATG codon was determined and the transcription start site defined using S1 nuclease mapping. The gene has neither a TATA box nor a CAAT box. It is rich in GC content with several consensus motifs for transcription factors, such as Sp1 and AP2.

Various fragments of the 5' flanking region were subcloned upstream of a CAT reporter gene to examine promoter/enhancer activity. A 1.1kb fragment was found to have relatively high transcriptional activity in NS20Y cells known to express the D-1 receptor but not in other cell lines tested. The human D-1 dopamine receptor gene belongs to the category of tissue-specific genes lacking a TATA box.

36.11

POSTMORTEM STABILITY OF DOPAMINE D₁ RECEPTORS AND D₁ RECEPTOR mRNA. J.H. Gilmore^{1,3}, C.P. Lawler³, A.M. Eaton³, and R.B. Mailman^{1,2,3}. Departments of Psychiatry¹ and Pharmacology², Brain and Development Research Center³, University of North Carolina¹, Chapel Hill, N.C. 27599.

The D₁ dopamine receptor may have an important role in the development of symptoms associated with, and in the treatment of, schizophrenia. The recent cloning of the D₁ receptor has provided a basis for the study of D₁ receptor mRNA in human brain. The study of D₁ mRNA, especially of its cellular localization in the brains of normals and its possible alteration in the brains of people with schizophrenia, is potentially limited by postmortem degradation of the mRNA.

To assess the effect of postmortem interval on D₁ mRNA and on D₁ receptor binding, rats were decapitated, and the heads were allowed to cool in a controlled manner (to 25°C at six hours and to 4°C after 24 hours) to approximate the cooling and refrigeration of human postmortem brain tissue. Cellular localization of D₁ mRNA in the striatum was determined by *in situ* hybridization emulsion autoradiography in slide mounted sections of caudate, using a mixture of two ³⁵S-labeled oligoprobes. D₁ receptor density was determined in adjacent sections with receptor autoradiography using [¹²⁵I]SCH23982. We found a decrease in the overall density of D₁ mRNA after a 24 hour postmortem interval, resulting in a significant decrease (ca. 15%) in the number of labeled neurons (p < 0.05) compared to control rats (postmortem interval of 0 hours). Quantitative autoradiography of D₁ receptors indicated a corresponding decrease (ca. 20%) in receptor binding compared to controls. We conclude that a postmortem interval of 24 hours effects both D₁ mRNA concentrations and D₁ receptor binding. It will be critical to characterize the time course of these decreases to provide a rational basis on which to interpret data from human postmortem brain tissue. Only then will it be possible to delineate the role of D₁ receptors in human diseases such as schizophrenia.

UNCONVENTIONAL SECOND MESSENGER COUPLING FOR D₁ AGONIST EFFECTS IN THE SUBSTANTIA NIGRA PARS RETICULATA (SNpr) L.P. Martin and B.L. Waszczak. Pharmacol. Sect., Northeastern Univ., Boston, MA.

We have shown that iontophoresis of the D₁ agonist SKF 38393 (SKF) markedly increases firing rates of rat SNpr neurons, whereas the D₂ agonist LY 171555 lessens their inhibitory responses to GABA. The excitatory effect of SKF was later shown to require an intact striatonigral pathway. The current studies were undertaken 1) to determine whether the excitatory effect of SKF could be reproduced by another D₁ agonist of a different chemical class, and 2) to examine the intracellular coupling mechanism by which D₁ agonists increase SNpr firing. First, iontophoresis of the D₁ agonist A-68930 (0.01M; 2-10 nA) produced current-related increases in SNpr cell firing similar to those seen with SKF, indicating that the effect is likely receptor-mediated and not a non-specific action of SKF. Second, we attempted to evaluate the role of Gs and cAMP as mediators of the D₁ agonist effect. Accordingly, the Gi/Go protein inactivator pertussis toxin (PT) was injected into the nigra (1 ug/ul 0.9% NaCl) 24 hrs prior to recording, and the effect of SKF (0.01M, 2-10 nA) was re-evaluated. PT completely abolished the rate-increasing effect of SKF, suggesting that nigral D₁ receptors mediating this response may be linked to their effector by a G-protein other than the conventional Gs. Next, we attempted to assess the role of cAMP in mediating the D₁ agonist response by iontophoresing (5-20 nA) the membrane permeable cAMP analogs, dibutyryl-cAMP (db-cAMP), 8-Br-cAMP, and 8-(4-chlorophenylthio)-cAMP (CPT-cAMP), as well as the non-permeable analog, cAMP. While both db-cAMP and 8-Br-cAMP caused current-related increases in firing similar to SKF, CPT-cAMP and cAMP did not change baseline firing rates. Additionally, all four cAMP analogs were able to reduce the potency of applied GABA, an effect like that previously seen for the D₂ agonist. Thus, cAMP analogs do not possess a profile identical to the D₁ agonists. This may suggest either that cAMP does not mediate this response, or that cAMP analogs can exert effects outside the cell to lessen GABA inhibitions of SNpr cell firing. (Support: NS 23541)

D₁ DOPAMINE RECEPTOR-MEDIATED PHOSPHOLIPASE C (PLC) ACTIVITY IN IMMORTALIZED MURINE CORPUS STRIATUM CELLS. M.S. Wainwright, H. Sali*, A. Heller and B.D. Perry, Depts. of Pharmacological and Physiological Sciences and Psychiatry, The University of Chicago, Chicago IL 60637.

The effects of a differentiating agent, n-butyrate (n-but), and a specific D₁ agonist, SKF81297, on D₁ receptor-mediated activation of PLC activity in immortalized corpus striatum (CS) cells were examined. We have demonstrated a 3 fold increase in D₁ binding site density following n-but treatment in these cells (Wainwright, et al. Soc. Neurosci. Abstr. 16:646, 1990). Immortalized CS cells were prepared from embryonic (E18) murine brain using methods described previously (Hammond, et al. Science 234:1237-1240 1986). One of the fusion products was cultured in 1mM n-but with 10uM SKF38393 (a D₁ agonist) for 5 days. Less than 0.1% of the cells survived this treatment and one colony of cells (E1X cells) was retained for further study.

E1X cells were treated for 5 days with either n-but (1mM) or 10uM SKF 81297 (SKF), a stable D₁ agonist. PLC activity was measured in membrane fragments using [³H]PIP₂ as a substrate. In the untreated E1X cells basal PLC activity was 16364 ± 2372 (values expressed as cpm/mg prot ± SEM). In E1X cells treated with n-but or SKF, the basal activity increased to 70891 ± 13254 and 67425 ± 16861 respectively (p < 0.01). D₁ receptor-mediated stimulation of PLC activity in cell membranes was observed using 10uM SKF38393 (control cells 43 %; n-but 35%; SKF 32%; values are % increase from basal). Stimulation was inhibited by 100uM SCH23390. In the untreated parent N187G2 line basal PLC activity was 23831 ± 5097 which was not increased following treatment with n-but (15868 ± 3253). As SKF38393 also stimulates adenylyl cyclase activity in the E1X cells (ibid), these results suggest that in these immature cells, there are D₁ receptors coupled to both second messenger systems. Further studies are required to determine whether these findings reflect expression of multiple D₁ receptor subtypes or multiple G-proteins, or both. REAL-TIME MEASUREMENTS OF HUMAN D₁ AND D₂ RECEPTOR ACTIVITY WITH A SILICON-BASED BIOSENSOR. J.A. Salon, R.A. Johnson*, and O. Civelli. Vollum Institute for Advanced Biomedical Research, Oregon Health Sciences University, 3181 S.W. Sam Jackson Park Road, Portland, OR 97201.

Classically, dopamine receptors have been functionally and pharmacologically classified into two major types, D₁ and D₂ which couple through G_s and G_i mechanisms respectively. It is known however, that the second messenger response depends not only on the specific properties of the receptor molecule itself, but also on the cell type in which it is expressed. It is likely that the cells overall metabolic response will also be different depending on the biochemical pathways involved in effector activity. However no direct measurements of cellular metabolic rates have been made in response to dopamine. It would therefore be of interest to examine the broad metabolic effects of D₁ and D₂ activation.

A silicon-based biosensor (microphysiometer, mfg. MDC Corp., Menlo Park, CA) has previously been described (Science 246, 243 (1989)) which measures the metabolic activity of cells by monitoring their rates of excretion of acidic metabolites. The ability to measure in real-time a broad cellular response to receptor activation provides us with a practical and general method of monitoring functional ligand-receptor interactions.

In the present study we have used the silicon microphysiometer to measure the dopamine responsive metabolic rates of cells transfected with human D₁ and D₂ receptors. The pharmacology of the metabolic responses are in good agreement with the predicted potency of various dopaminergic agonists and antagonists tested. Interestingly, the kinetic profile of the metabolic responses to D₁ and D₂ agonists appears to be different. Differences in the metabolic kinetics of these two classes of G protein-coupled receptors could be explained by the involvement of different effector coupling mechanisms and may provide insight into their relative roles in mediating a final response in the target cells.

D₁ DOPAMINE RECEPTORS DIFFERENTIALLY COUPLED TO PHOSPHOLIPASE C (PLC) AND ADENYLATE CYCLASE (AC) IN CNS. B.D. Perry, M.S. Wainwright, H. Sali*, J.T. Cuenco* and G. Farfel, Departments of Psychiatry and Pediatrics, The University of Chicago, Chicago, IL 60637

Pharmacological and molecular characterization of the multiple dopamine receptor recognition sites (e.g., D_{1a}, D_{1b}, D₂, D₃, D₄, D₅) has preceded characterization of the transmembrane signal transduction mechanisms linked to these receptor subtypes in a given tissue or species. The present studies examined D₁ mediated signal transduction in brain regions from rat and rhesus monkey. **METHODS:** D₁ binding sites density ([¹²⁵I]SCH 23982 saturation studies) and receptor-linked adenylyl cyclase (AC) activity were determined in CNS membranes using standard methods. Receptor linked PLC activity in membranes was determined using a method developed in our lab. [³H]inositol phosphates were determined following incubation of membranes @ 37 C using [³H]PIP₂ as a substrate. **RESULTS:** In monkey hippocampus and rat cortex, containing relatively few D₁ sites (approx. 100 fmol/mg prot), a consistent 50 % increase in basal PLC activity was observed following stimulation with SKF 38393, a selective D₁ agonist, while D₁ stimulated AC was less reliably observed. In rat caudate with a very high density of D₁ sites, weak D₁ stimulation of AC (50-75 % over basal) was observed. In other regions, low levels of D₁ binding site were demonstrated with no reliable stimulation of either PLC or AC (e.g., rat olfact. tuber.) **CONCLUSION:** These studies demonstrate 1) a method for examining receptor linked PLC activity in CNS membranes and 2) heterogeneity of D₁ mediated signal transduction across brain regions within a species, suggesting differential regional distribution of D₁ 'subtypes' or G-proteins or both. Utilization of clonal cell lines containing D₁ receptors linked to both AC and PLC (see Wainwright et al., accompanying abstract) will allow examination of the relationships between receptor-linked signal transduction and the intramembrane stoichiometry of potential isoforms or subtypes of D₁ receptor and various G proteins. (0-D-A 00250/7)

MULTIPLE D₁-LIKE DOPAMINE RECEPTORS NOT LINKED TO ADENYLATE CYCLASE EXHIBIT DIFFERENT AFFINITIES FOR [³H]SCH23390. D.H. Mooney*, J.M. Petitto*, L.L. Cook, D.E. Nichols, and R.B. Mailman. Curriculum in Toxicology, Departments of Psychiatry and Pharmacology, University of North Carolina School of Medicine, Chapel Hill, N.C. 27599, and Department of Medicinal Chemistry, Purdue University, West Lafayette, IN 47907.

Molecular studies in brain have identified at least two D₁-like dopamine receptors ("D₁" and "D₂"). Both appear to be linked to adenylyl cyclase stimulation, yet exhibit different recognition characteristics for some dopamine receptor ligands. Previously, this lab demonstrated that D₁-like receptors in amygdala are not linked to adenylyl cyclase. In the present series of experiments, the recognition characteristics of these novel D₁-like receptors were compared to those of D₁ binding sites in striatum using the prototypical D₁ receptor ligand [³H]SCH23390. In striatum, competition with SCH23390, as well as several phenothiazines (e.g., chlorpromazine), had kinetics which were consistent with interaction of the ligand with a single population of binding sites. Conversely, in the amygdala these same antagonists showed competition kinetics which clearly fit a model with two (or more) recognition sites.

Experiments were conducted to determine if these additional binding sites might be for other related receptor types. It was found that the binding of [³H]SCH23390 to sites in the amygdala was not inhibited by ligands for serotonin (ketanserin and serotonin), opiate (naloxone), NMDA (MK801), or adrenergic (phenolamine and propranolol) receptors at concentrations of 1 μM or lower. This indicates that these multiple [³H]SCH23390 binding sites were probably D₁-like dopamine receptors. Consistent with this, the new high potency, full efficacy D₁ agonist dihydroxidine competed for all of these [³H]SCH23390 binding sites.

Together, these data provide evidence that there are subtypes of D₁-like receptors in the amygdala that can be partially discriminated by available phenyltetrahydrobenzazepine ligands. We have previously shown that [³H]SCH23390 binding sites in the amygdala are not associated with dopamine adenylyl cyclase. Thus, these data suggest additional multiplicity of this class of receptors, and offer the possibility that new drugs selective for D₁-like receptors can be designed. NON-ADENYLATE CYCLASE COUPLED D₁ RECEPTORS IN THE BASOLATERAL AMYGDALOID NUCLEUS ARE COUPLED TO A GUANINE NUCLEOTIDE BINDING PROTEIN

J.E. Lachowicz and C.D. Killis, Departments of Pharmacology and Psychiatry, Duke University Medical Center, Durham, NC 27710

We have previously demonstrated that activation of D₁ dopamine receptors in the amygdaloid complex does not stimulate adenylate cyclase activity as in the caudate nucleus (*Soc. Neurosci. Abstr.*, 15:1321, 1989). The present study was undertaken to determine whether D₁ receptors in the amygdaloid complex are coupled to a guanine nucleotide binding (G-) protein. Receptors which transduce signals via G-proteins exhibit decreased agonist affinity in the presence of GTP due to receptor-G-protein dissociation. This property was investigated for D₁ receptors in the basolateral amygdaloid complex using quantitative autoradiography of selective D₁ antagonist binding.

Dopamine (0-300 μM) displacement of [¹²⁵I]SCH 23982 (0.1 nM) binding in the presence and absence of GppNHP (10 μM), a non-hydrolyzable analogue of GTP, was measured on serial 10 μm thick coronal sections through the amygdaloid complex and caudate nucleus. GppNHP induced a rightward shift in the dopamine displacement curve for both nuclei, indicative of receptor-G-protein coupling. However, the magnitude of the shift is not as great in the basolateral nucleus as in the caudate. In addition, dopamine is more potent at displacing SCH 23982 in the basolateral nucleus than in the caudate nucleus, suggesting that amygdaloid D₁ receptors may be structurally distinct from those in the caudate nucleus. SELECTIVE DOPAMINERGIC MECHANISM OF SKF38393-STIMULATED FORMATION OF INOSITOL PHOSPHATES IN RAT BRAIN SLICES.

A.S. Undie* and E. Friedman. Neurochemistry Division, Medical College of Pennsylvania, 3200 Henry Avenue, Philadelphia, PA 19129.

We have previously reported that dopamine (DA) and some D₁ receptor-effective agonists stimulate the formation of inositol phosphates (IPs) in rat brain slices. Because dopamine may activate α-noradrenergic receptors, and because some benzazepines have actions on serotonergic receptors, the present experiments were conducted to assess the dopaminergic selectivity of the observed stimulation of phosphoinositide hydrolysis. Rat striatal slices incubated with 0.48 μM (6 μCi/ml) [³H]inositol in the presence of 10 mM LiCl were treated with up to 500 μM DA, serotonin (5HT), norepinephrine (NE), and the selective D₁ agonist, SKF38393 (SKF), and accumulated IPs determined after 90 min. All the agonists dose-dependently stimulated the formation of IPs; the greatest effects were obtained with the dopaminergic agents. The action of NE was dose-dependently blocked by prazosin but not by the selective D₁ antagonist, SCH23390, whereas the actions of DA and SKF were dose-dependently blocked by 1 to 100 μM SCH23390. Similarly, the effects of 5HT were blocked by the selective 5HT₂ antagonist, ketanserin, the mixed 5HT₂/5HT_{1c} antagonist, mianserin, and, with much less potency, by the selective 5HT_{1c} antagonist, mesulergine, whereas neither ketanserin nor mianserin blocked the response to SKF. These observations indicate that the actions of DA and SKF in stimulating the formation of IPs is selectively mediated through a D₁-like DA receptor and not through the α₁-noradrenergic or the 5HT₂/5HT_{1c} receptors.

36.18

DARP-STIMULATED DA RELEASE FROM RAT STRIATAL FRAGMENTS IS BLOCKED BY SPECIFIC D-1 BUT NOT BY D-2 RECEPTOR ANTAGONISTS. V. D. Ramirez, Y. Park* and F. Marcus. Department of Physiology and Biophysics, University of Illinois, Urbana, IL 61801 and Chiron Corporation, 4560 Horton Street, Emeryville, CA 94608.

DARP, a potent dopamine (DA) releasing protein was originally isolated from rat adrenal glands (*Brain Research* 463:385, 1988). The main actions of DA are mediated by at least two types of receptors, D-1 and D-2 which belong to the family of receptors acting thru G proteins. Herein, we report that a DARP preparation from the media of rat primary mesencephalic cell cultures releases DA and its action is blocked by SKF 83566, a specific D-1 antagonist. Rat striatal fragments were superfused *in vitro* as reported previously. After a 25-30 min equilibrium phase, DA in perfusates collected at 10 min intervals for an 80-90 min period was measured by HPLC-EC. The DARP or a control media extract was infused during interval 3 and 4. The data (X̄ ± SEs, pg/mg/min of DA release) from each superfusion were expressed as the difference in DA release between the peak response and the lowest basal value. Curiously, an inverted U bell-shape dose-response was observed: CONTROL 200 μg protein = 8.1±4.6 (n=4). DARP: 14.6±6.9 (n=4); 17.7±6.6 (6); 33.5±6.6 (13); 25.3±11 (4) and 12.3±7 (4) for 25, 100, 200, 300 and 400 μg of protein, respectively. A dose of 200 μg of protein was selected to examine the effect of the antagonists. Spiperone dissolved in KRP and infused continuously from the beginning of the superfusion at concentrations ranging between 10⁻¹⁰M to 10⁻⁸M did not block the response to DARP. On the contrary, SKF 83566 blocked the action of DARP in a dose-dependent manner: 10⁻⁸M = 36.6±7.9 (4); 5x10⁻¹⁰M = 19.3±3.4(4); 10⁻⁹M = 6.5±3.4(8) and 10⁻⁶M = 4.5±1.1(4). These results indicate that DARP interacts with D-1-like receptors and thereby controlling the release of DA.

36.20

DOPAMINE (DA) STIMULATES [³H]Pdbu BINDING TO CULTURED STRIATAL CELLS. M.K. McMillian, K.R. Pennypacker, X.P. He*, J.S. Hong. LMNI/ NIEHS/ NIH RTP, NC 27709

The effect of DA on the binding of [³H]phorbol-12,13-dibutyrate ([³H]Pdbu) in cultured rat striatal cells was examined. DA maximally increased specific [³H]Pdbu binding by 70±10%, an increase comparable to that observed with norepinephrine (NE). This finding suggests that DA activates protein kinase C (PKC) in cultured striatal cells, since increases in [³H]Pdbu binding reflect translocation of PKC. Half-maximal stimulation was observed with 10⁻⁶ M DA. The peak response was observed at two to three minutes after addition of 10⁻⁶ M DA, but [³H]Pdbu binding was still increased above basal at 30 minutes. Prazosin (10⁻⁶ M) blocked the response to NE, suggesting mediation by an α₁ adrenergic receptor, but had little effect on the response to DA. Conversely, the D-1 receptor antagonist SCH23390 (10⁻⁶ M) blocked the response to DA but only partially inhibited the response to NE. Morphine (10⁻⁶ M) inhibited the response to DA by 46±14%, but did not significantly affect the response to NE. The DA effect on [³H]Pdbu binding is apparently independent of the increase in cAMP seen on D-1 receptor activation. Forskolin, apomorphine, and the D-1 agonist SKF38393 all increased cAMP in striatal cells, but were less effective than DA in stimulating [³H]Pdbu binding. The D-2 agonist quinpirole was ineffective in stimulating either cAMP or [³H]Pdbu binding.

CATECHOLAMINES: DOPAMINE RELEASE

37.1

SIMULTANEOUS MEASUREMENT OF EXTRACELLULAR DOPAMINE IN THE MEDIAL PREFRONTAL CORTEX AND CAUDATE-PUTAMEN USING FAST-SCAN CYCLIC VOLTAMMETRY. P.A. Garris and R.M. Wightman. Dept. of Chemistry and Curr. in Neurobiology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3290.

The objectives of this study were to (1) establish the detection of extracellular dopamine (DA) in the medial prefrontal cortex (mPFC) using fast-scan cyclic voltammetry (FSCV) and (2) compare the release and reuptake of DA in this tissue with that in the caudate-putamen (CP). Carbon fiber microvoltammetric electrodes, stereotaxically placed in anesthetized rats, were utilized to monitor changes in DA concentration as a result of medial forebrain bundle stimulation. The identification of DA was tentatively determined on the basis of cyclic voltammograms collected in the mPFC, CP and *in vitro*, and electrode placement. Evoked release in both the mPFC and CP was dependent on the frequency and duration of the pulse train. The maximum concentration of DA elicited by 120 pulses was 2- to 3-times higher in the CP (2 μM) than the mPFC (0.8 μM) at 60 Hz but similar at 30 Hz (0.5 μM). The experimental data derived from the CP but not the mPFC were successfully modeled using a Km of 0.14 μM. **Conclusions:** (1) FSCV is a suitable technique for the measurement of extracellular DA in the mPFC and (2) the dynamics of DA release and reuptake differ in the mPFC and CP.

37.2

NEUROCHEMICAL MODELING OF STIMULATED DOPAMINE OVERFLOW DETECTED USING *IN VIVO* VOLTAMMETRY. K.T. Kawagoe*, D.J. Wiedemann and R.M. Wightman. Department of Chemistry, University of North Carolina, Chapel Hill, NC 27599-3290.

Electrically evoked overflow of dopamine in the rat striatum has been measured at low stimulation frequencies (10-20 Hz) in untreated rats and with single stimulation pulses in rats treated with nomifensine (20 mg/kg). These values are compared to overflow at higher frequencies (30-60 Hz) using a model based on a fixed dopamine concentration released per stimulus pulse ([DA]_p) and Michaelis-Menton uptake kinetics (1). The effects of diffusion and finite electrode response time are also considered. Dopamine overflow was measured using carbon-fiber microelectrodes stereotaxically placed in the striatum of anesthetized rats during electrical stimulation of the medial forebrain bundle. The value for [DA]_p observed at low stimulation frequencies is 2-3 times greater than that obtained at high frequencies. Pharmacological evidence suggest this difference is, at least in part, a result of modulation of release by D₂ autoreceptors.

37.3

TEMPORALLY RESOLVED EFFECTS OF PRESYNAPTIC AUTORECEPTORS ON OVERFLOW OF DOPAMINE FROM SLICES OF CAUDATE NUCLEUS S.R. Jones, R.T. Kennedy and R.M. Wightman, Neurobiology Curriculum and Chemistry Department, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27499

Synaptic overflow of dopamine from rat caudate slices is detected using fast scan cyclic voltammetry at carbon fiber microelectrodes. The electrode potential is scanned at 300 V/s and the current resulting from dopamine oxidation is recorded every 100 ms. The current is directly proportional to the dopamine concentration. 5 s, 10 Hz electrical stimulation was used to elicit overflow. The dopamine concentration profile consists of a peak of approximately 1.5 μM within the first second, and then a reduction to a plateau of approximately 0.2 μM for the duration of the stimulation. This unusual profile is due to autoreceptor activation. The D2 receptor antagonist sulpiride increases overflow by about 40% and alters the concentration profile so that the maximum concentration is maintained throughout the stimulation. The D2 agonist quinpirole decreases the peak height of stimulated dopamine overflow by approximately 50% and the concentration remains at a constant low level for the entire stimulation time. The kinetics of autoreceptor activation were deduced by modeling overflow with a kinetic model that takes uptake and different release rates into account. The data indicate that initial activation occurs within 100 milliseconds of stimulus onset. Autoreceptor off-rate kinetics were measured by the overflow response to a single electrical pulse at increasing times after a train of pulses.

ELECTROCHEMICAL EVALUATION OF THE MICROENVIRONMENT SURROUNDING DIALYSIS PROBES *IN VIVO* AND *IN VITRO*. C.D. Blaha, R.K.Y. Lai, and A.G. Phillips, Department of Psychology, University of British Columbia, Vancouver, BC, Canada, V6T 1Z4.

Changes in extracellular dopamine (DA) concentrations were monitored in the striatum of the anesthetized rat using 1 s chronoamperometry (CA) with stearate-modified graphite paste electrodes placed 0-1mm away from a parallel 4 mm dialysis probe. 2 or 24 hrs following implantation of this assembly, dialysis with Ringers (1.3 mM Ca^{+2}) at various flow rates (0.1-5 ul/min) resulted in a rapid and maximal decrease in the DA baseline CA signal. DA in the dialysate decreased over a similar time-course but in contrast achieved steady-state values (10-50 nM) detectable by HPLC-EC. Maximal decreases in the CA signal were obtained at 40, 30, 25, 18 and 6 min using flow rates of 0.1, 0.2, 0.3, 0.5 and 5 ul/min, respectively. Stopping the flow of dialysate resulted in a gradual (30-40 min) recovery of the CA signal to pre-dialysis baseline levels. The zone of the dialysis-induced depletion of extracellular DA extended 1 mm distal to the dialysis probe (10% decrease in CA baseline). A 20 min dialysis pulse of 100 mM K^{+} increased concentrations of DA in the dialysate by ~20 fold (10 nM to 200 nM). An increase in the CA signal above the dialysis-depleted CA baseline coincided with this change and corresponded to a 200-300 nM increase in extracellular DA concentrations. Inclusion of 5 μM DA in the perfusate resulted in a full recovery of the CA baseline signal at electrodes flush to the probe. Electrode calibration *in vitro* in combination with probe recovery values (~10%) indicated that the amount of dialysis-induced depletion of DA corresponded to ~500 nM. These results indicate that microdialysis induces a significant reduction of DA in the extracellular space surrounding the dialysis probe and may account for the discrepancy between estimations of basal DA concentrations using these two *in vivo* techniques.

37.7

IN VIVO STRIATAL DA RELEASE AND METABOLISM IN CHRONIC NEUROLEPTIC-TREATED RATS FOLLOWING ACUTE INJECTION OF QUINPIROLE AND PILOCARPINE. Ronald E. See and Mary Ann Chapman, Dept. of Psychology, Washington State University, Pullman, WA, 99164-4820.

The present study examined the effects of the dopamine D2 receptor agonist, quinpirole, and the muscarinic receptor agonist, pilocarpine, on DA release and metabolism using *in vivo* microdialysis in chronic neuroleptic-treated rats. Female, Sprague-Dawley rats were administered weekly subcutaneous injections of haloperidol (7.0 mg/kg), raclopride (7.0 mg/kg), or distilled water vehicle. After 28 weeks of neuroleptic treatment, rats were anesthetized with Equithesin and bilateral guide cannulae implanted into the striatum (A +0.2, L +3.0, V -5.0). Following one week of recovery, microdialysis probes with 3 mm of dialysis membrane were inserted into the cannulae (unilateral) and perfusion initiated. Samples were collected every 20 min before and after drug injection. Perfusates were directly injected onto an HPLC column and analyzed for DA, DOPAC, and HVA using electrochemical detection. For the first probe insertion, conducted 5 days after the weekly injection of neuroleptic, rats were administered quinpirole (0.03 mg/kg, SC). One week later, rats were reprobated contralateral to the first side and then administered pilocarpine (1.0 mg/kg, IP). Quinpirole produced a significant decrease in DA release and levels of DOPAC and HVA in all 3 groups. However, the duration of decreased DA release was significantly prolonged in the two neuroleptic treated groups as compared to the control group. Injection of pilocarpine had no significant effect on any measure in any of the 3 groups. Prior long term exposure to neuroleptics thus appears to alter autoreceptor feedback to a DA agonist while direct muscarinic receptor stimulation produces no discernible effects on striatal DA release and metabolism.

37.4

DOPAMINE DIFFUSION AND UPTAKE IN SLICES OF RAT NEOSTRIATUM. C. Nicholson & M.E. Rice, Dept. Physiology & Biophysics, New York University Medical Center, New York, NY 10016.

Migration of dopamine (DA) in the extracellular compartment of the striatum is governed by the structural characteristics of the tissue and by a potent uptake system (Wightman et al., *Neuroscience*, 25: 513, 1988). We recently evaluated the diffusion properties of slices of rat striatum (*J. Neurophysiol.*, 65: 264, 1991), for which the tortuosity factor (λ) was 1.54, the extracellular volume fraction (α) was 0.21 and the concentration-dependent uptake term (k') was 0.01 sec^{-1} . Using these data, we have addressed quantitatively the contributions of diffusion and uptake to the clearance of DA from a local site of release. DA and α -naphthalene sulfonate, (ANS⁻, an extracellular marker ion) were pressure ejected into striatum or adjacent cortex. DA was monitored with a carbon fiber microelectrode and high-speed cyclic voltammetry while ANS⁻ was detected with an ion-selective microelectrode. Diffusion distances were 90-150 μm . The resulting ANS⁻ diffusion profile, which was fitted to a solution of the diffusion equation, was used to estimate the volume ejected. In neocortex, DA diffusion was similar to that of ANS⁻, with small ejected volumes (10-100 pL) that gave rise to micromolar DA increases. In striatum, no DA increase was detectable with the same ejected volumes. This avid uptake could be overcome by increasing ejected volume several-fold or by superfusing nomifensine (10-20 μM) or DA (10-100 μM). Under these conditions, k' was 0.1-0.2 sec^{-1} . That the DA curves could be fitted with this simple uptake term demonstrated that we were working in a linear portion of the DA uptake process. These data could be used to estimate *in situ* uptake parameters in an appropriate mathematical model. Supported by USPHS Grants NS-28642 and NS-28480.

37.6

QUANTITATIVE NEUROTRANSMITTER MICRODIALYSIS: EXTRACELLULAR DOPAMINE IN THE STRIATUM, A.D. Smith, R.J. Olson and J.B. Justice, Jr., Department of Chemistry, Emory University, Atlanta, Georgia, 30322.

An *in vivo* microdialysis method was used to estimate the basal extracellular concentration of dopamine (DA) in the anterior striatum of behaving rats. In this method, anesthetized rats (n=5) were implanted with 20 gauge guide cannula in the striatum at coordinates AP +2.5, LR +2.7 from bregma and DV -2.7 from dura. Four millimeter dialysis probes were inserted in the animals 3-4 days after surgery. Animals were perfused overnight with artificial CSF (149 mM NaCl, 2.8 mM KCl, 1.2 mM CaCl_2 , 1.2 mM MgCl_2 , 0.25 mM ascorbic acid and 5.4 mM d-glucose, pH 7.2-7.4) at a flow rate of 0.2 ul/min. Approximately seven hours after probe insertion, perfusate samples were collected at 20 minute intervals and a 0.5 ul aliquot was injected onto a smallbore HPLC system. Samples were analyzed until stable levels of dopamine were obtained (approximately 2-3 hours), at which time the perfusate containing zero DA was switched in a random order for each animal to an artificial CSF containing 0, 2.5, 5, 10 or 20 nM DA. These concentrations were chosen such that the expected value would fall within the range of the perfusate DA concentration so that the point of no net flux could be determined by linear regression. At this point, the dialysate concentration represents the basal extracellular concentration.

Using this method, the basal extracellular concentration of DA in the striatum was estimated to be $11.1 \text{ nM} \pm 1.57$ (Mean \pm S.E.). The *in vivo* recovery obtained from the slope of the linear regression was $70\% \pm 10\%$. The concentration of DA in the striatum is thus about twice that found in the nucleus accumbens (Parsons et al., *Soc. Neuroscience Abs.* 432.22, 1990) where the basal extracellular concentration of DA was found to be 5 nM.

37.8

EFFECTS OF CLOZAPINE ADMINISTRATION ON STRIATAL NEUROTRANSMITTER OVERFLOW IN THE SQUIRREL MONKEY AND RAT MEASURED BY MICRODIALYSIS. L.W. Cooke, L.M. Ball, F.W. Ninteman, T.G. Heffner, M.D. Davis, Department of Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

Clozapine is an antipsychotic agent with improved efficacy and reduced neurological side effects. We have assessed the effects of clozapine on neurotransmitter overflow in rats and non-human primates, using the method of intracerebral microdialysis (ICMD). Guide cannulae were surgically implanted bilaterally in the striatum of Sprague Dawley rats and the putamen of squirrel monkeys (*Saimiri sciureus*) to allow repeated, acute implantation of 4 mm microdialysis probes. Collected dialysates were analysed for neurotransmitter levels using HPLC separation and electrochemical detection. In rats single doses of clozapine (20 mg/kg S.C.) produced increases in dialysate DA levels of $68 \pm 1.5\%$ similar to published reports. Oral administration and i.p. dosing produced smaller changes. Levels of Dopac, HVA, and 5-HIAA in the dialysates appeared unaffected. In squirrel monkeys oral doses of clozapine (30 mg/kg), resulted in an increased DA overflow of $18 \pm 5\%$. Again, metabolites appeared to be unaffected. In conditioned avoidance tests, the ED50 of clozapine was 4.2 mg/kg (p.o.) for squirrel monkey compared to 22 mg/kg for rat. These data demonstrate similarities between monkey and rat neurochemical responses to behaviorally active doses of clozapine, and support the feasibility of conducting ICMD studies in awake squirrel monkeys.

SYSTEMIC AMPHETAMINE INCREASES STRIATAL EXTRACELLULAR DA AND cAMP AS MEASURED VIA MICRODIALYSIS. A.T. Massey, J.S. Randall, and P.K. Randall. College of Pharmacy and Inst. for Neuroscience, Univ. of Texas, Austin TX, 78712.

The stimulant actions of amphetamine are believed to result from release of endogenous dopamine (DA). In this study we utilized *in vivo* microdialysis to examine the relationship between amphetamine-induced increases in extracellular levels of DA and its second messenger, adenosine 3'5' monophosphate (cAMP), following systemic injection.

Microdialysis probes with a 3mm membrane tip were calibrated *in vitro* (DA recovery=20%, cAMP recovery=23%) and stereotactically inserted into the anterior striatum (AP +0.8, L +3.0, DV - 7.0 from Bregma) of chloral hydrate-anesthetized rats. Probes were perfused at 2 μ l/min with artificial cerebrospinal fluid and sample collection began immediately after insertion. Samples were collected at 30 min intervals for 3 hr prior to IP injection of 0, 0.5, 2.0, or 8.0 mg/kg d-amphetamine sulfate in 0.9% saline. Post-injection samples were collected at 15 min intervals for 1 hr and at 30 min intervals thereafter. In each sample, DA levels were assessed via HPLC with electrochemical detection and cAMP by RIA.

Dialysate levels of DA and cAMP were highly elevated immediately following probe insertion and fell rapidly over the pre-injection period to a stable baseline (DA, 0.6 ± 0.09 pg/ μ l; cAMP, 0.19 ± 0.01 fmol/ μ l). As expected, amphetamine produced a pronounced dose-related increase in DA levels which peaked at all doses during the second 15-min post-injection collection period (i.e. 15-30 min following injection). A similar, though less dramatic, dose-related increase was observed in extracellular cAMP levels. The cAMP response consistently lagged behind the DA response by 1 to 2 time-periods (15-30min). Peak levels after the 8.0 mg/kg dose were elevated by approximately 2 fold over baseline values.

These data show that systemic administration of amphetamine produces a significant elevation of striatal extracellular cAMP *in vivo*. This increase is likely to be the result of increased DA release. cAMP, however, rises and disappears from the extracellular fluid at a less rapid rate than does DA itself. This may provide a convenient *in vivo* response for quantitative studies of DA and DA antagonist action at central D-1 receptors.

37.11

KAPPA-OPIOID AGONISTS DEPRESS RAT STRIATAL DOPAMINE OVERFLOW *IN VIVO* AND *IN VITRO*: AN INTRACEREBRAL MICRODIALYSIS AND NIGROSTRIATAL EXPLANT STUDY. M.D. Davis and L.M. Ball. Neurosciences Section, Parke-Davis Research Division, 2800 Plymouth Rd., Ann Arbor, MI 48105.

Opioid modulation of dopamine (DA) neurotransmission is a poorly understood phenomenon. Mu- and delta-opioid agonists facilitate brain DA release while kappa-opioid agonists attenuate release. Here we have focused on the selective kappa-agonists, U-50488H and CI-977, and their interaction with the nigrostriatal DA projection in the rat. In *in vivo* microdialysis studies, both anesthetized and awake male SD rats were acutely implanted with 4mm BAS/CMA probes into the striatum, while core explants of the intact nigrostriatal pathway were obtained for acute *in vitro* experiments. Dialysate and superfusate samples were collected and analyzed for catecholamine content via HPLC-EC. In some explant studies, microelectrode voltammetry was used to measure DA overflow. CI-977 administered 5 mg/kg ip, 0.1 mg/kg im, 10 mg/kg po or μ M infused directly through the probe caused a marked inhibition of spontaneous DA overflow. DOPAC and HVA levels also dropped appreciably, while 5-HIAA levels were not significantly altered. Infusion of the kappa-antagonist, nor-binaltorphimine (μ M), through the probe blocked the effect of CI-977 and, by itself, elevated DA levels above baseline. Electrical stimulation (5Hz) of the medial forebrain bundle evoked a five-fold increase in DA efflux which was almost totally inhibited by μ M bath administration of CI-977 or U-50488H.

37.13

EFFECTS OF MONOAMINE OXIDASE INHIBITION ON THE *IN VIVO* RELEASE AND METABOLISM OF DOPAMINE IN RAT BRAIN: COMPARISON BETWEEN STRIATUM AND SUBSTANTIA NIGRA. Dora Orosz (1) and James P. Bennett, Jr. (1,2,3). Departments of Neurology (1), Behavioral Medicine and Psychiatry (2) and Pharmacology (3). University of Virginia School of Medicine, Charlottesville, VA 22908.

L-Dihydroxyphenylalanine (L-DOPA), the amino acid precursor of dopamine (DA), is used in the treatment of the DA deficiency state in Parkinson's disease (PD). Selective inhibition of the B isoenzyme of monoamine oxidase (MAO-B) by l-deprenyl is used clinically in PD patients receiving L-DOPA.

We have used regional *in vivo* microdialysis in normal rats receiving L-DOPA to define the contributions of the two MAO-isoenzymes on the metabolism of DA in both the cell body and the axon-terminal region of the nigrostriatal system.

Dialysis probes were implanted unilaterally into the striatum and substantia nigra zona compacta of intact rats; both probes were simultaneously perfused in awake, behaving animals. Dialysate DA and metabolites were quantitated by HPLC-EC detection.

Non-selective inhibition of MAO by pargyline (40 mg/kg i.p.) inhibited DOPAC formation and increased basal efflux of DA and 3-methoxytyramine in striatum and nigra. MAO-B selective doses of l-deprenyl had less pronounced effects on basal DA efflux after acute administration, demonstrating a major role for MAO-A in regulating extracellular DA metabolism in the intact rat nigrostriatal system.

Additional experiments of the effects of MAO-inhibitors on L-DOPA-induced DA efflux demonstrate a similar major role of MAO-A in regulating extracellular DA and are examining the role of alternate DA catabolic pathways in the striatum and substantia nigra under conditions of increased DA synthesis and release.

(Supported by NIH-NINDS grants NS00978 and NS26581. L-deprenyl was a kind gift of Prof. J. Knoll, Semmelweis Univ Med Sch, Budapest, Hungary.)

CHARACTERIZATION OF METHAMPHETAMINE-INDUCED DOPAMINE RELEASE IN MOUSE NOSTRIATUM AS MEASURED BY *IN VIVO* MICRODIALYSIS. G. DeGeorge, A. Giovanni and P.K. Sonsalla. Department of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

The administration of methamphetamine (METH) causes damage to nigrostriatal dopamine (DA) neurons. Although the mechanism by which METH produces neurotoxicity is unknown, there is a role for dopamine itself in mediating this toxicity. It has been shown *in vitro* in several preparations and *in vivo* in the rat by microdialysis that METH causes the release of DA. We have been studying mechanisms of METH-induced neurotoxicity in the mouse. In order to understand these mechanisms better, we have adapted the *in vivo* microdialysis technique to measure levels of monoamines in the extracellular compartment of the mouse striatum. A single i.p. injection of METH (5 mg/kg), produced a 400-500% increase in the amount of DA recovered through the probe, whereas levels of DOPAC fell to approximately 50% of basal values. The peak levels of DA release occurred approximately 60 min after METH treatment whereas DOPAC dropped to its lowest level within 90-120 min. Return to basal levels of DA was not complete at 5 hrs, nor did DOPAC levels fully recover during this time. This effect of METH on DA release *in vivo* in the mouse is similar to that which is seen in the rat. Thus the technique of *in vivo* microdialysis can be done in the mouse and will be useful for studying the many facets of neurotransmitter release in this species.

37.12

EVIDENCE FOR IMPULSE FLOW-DEPENDENT AND -INDEPENDENT RELEASE OF DOPAMINE IN THE RAT PREFRONTAL CORTEX AND STRIATUM. S.J. Chrapusta*, F. Karoum, M.F. Egan* and R.J. Wyatt. Neuropsychiatry Branch, NIMH, Neuroscience Center at St. Elizabeths Hospital, Washington, D.C. 20032.

Dopamine (DA) release from DA cell bodies is impulse flow-independent (IFI); some data suggest a similar mechanism may also exist in the terminals. We examined the effects of gammabutyrolactone (GBL) on DA content and release using accumulation of 3-methoxytyramine (3-MT acc.), 10 min after pargyline (75 mg/kg, i.p.), as an index of DA release. Thirty min after GBL (750 mg/kg, i.p.), DA content in the striatum (ST) and prefrontal cortex (PFC) was maximally increased, and 3-MT acc. was maximally decreased, suggesting maximal impulse flow blockade. GBL produced approximately 90% drop in the striatal 3-MT acc., while in the PFC only approx. 50% reduction was achieved. Changes in 3-MT acc., 30 and 90 min after GBL, suggested faster recovery of DA release in the PFC than in the ST. Our data indicate that most DA release in the ST is impulse flow-dependent, while in the PFC approximately 50% of DA is released via an IFI mechanism that may play an important role during chronic neuroleptic treatment.

37.14

(-) DEPRENYL ALTERS GUINEA PIG STRIATAL DOPAMINE (DA) METABOLISM BUT DOES NOT ALTER EXTRACELLULAR DA LEVELS. I.A. Paterson, A.V. Juorio and M.Y. Zhu*. Neuropsychiatric Research Unit, University of Saskatchewan, Saskatoon, SK, Canada.

It has been shown that acute administration of (-) deprenyl, a specific monoamine oxidase (MAO) B inhibitor, does not alter rat striatal dopamine (DA) metabolism. The guinea pig striatum may be a better model of human DA metabolism since the ratio of MAO-B:MAO-A is higher. Studies were performed on English short-hair guinea pigs to determine the effects of acute administration of (-) deprenyl on striatal dopamine. Striatal MAO activities were determined by radioenzymatic assay. (-) Deprenyl (0.5-4 mg/kg, i.p., 2h) inhibited MAO-B to 29-8% of control without inhibiting MAO-A activity. Striatal levels of DA and the metabolites, DOPAC and HVA, were determined by HPLC-EC. Deprenyl (2-4 mg/kg, i.p., 2h) decreased DOPAC levels to 70% of control but did not alter HVA levels. The 4 mg/kg dose increased DA levels to 123% of control. Intracerebral microdialysis was performed in striata of anaesthetized guinea pigs and dialysates were assayed by HPLC-EC. Deprenyl (2-4 mg/kg, i.p.) did not alter levels of DA in the dialysate for up to 4 h where as pargyline, an inhibitor of both MAO-A and MAO-B, (75 mg/kg, i.p.) produced an increase in DA levels in the dialysate to 256-304% of baseline. It is concluded that in the guinea pig striatum, specific inhibition of MAO-B by (-) deprenyl significantly reduces the deamination of DA to DOPAC but does not result in a change in extracellular DA concentrations.

DEPRENYL (SELEGILINE) AFFECTS DOPAMINERGIC NEUROTRANSMISSION IN RAT VIA METABOLITES. H. Nissbrandt, T. Elebring* and G. Engberg*. Department of Pharmacology, University of Göteborg, P.O. Box 33031, S-400 33 Göteborg, Sweden.

Utilizing behavioral, biochemical, and electrophysiological methods, central effects of the MAO-B inhibitor deprenyl (selegiline) were analyzed. Administration of deprenyl (3 - 30 mg/kg, i.p.) caused a dose-dependent increase in the spontaneous locomotor activity. In the striatum deprenyl (10 and 30 mg/kg) changed the DOPA accumulation following NSD 1015 in a biphasic manner. Deprenyl slightly decreased the firing rate of DA containing neurons in substantia nigra, zona compacta. However, the increases in locomotor activity and DOPA accumulation induced by deprenyl were almost totally prevented by pretreatment with the microsomal liver enzyme inhibitor SKF 525 A (50 mg/kg, i.p., 30 min), indicating that metabolites of the drug are of pharmacological significance for its central actions. Furthermore, administration of l-methamphetamine, a major metabolite of deprenyl, affected spontaneous locomotor activity, striatal DOPA formation and the firing rate of dopamine (DA) containing neurons in the substantia nigra within the same magnitude as deprenyl itself when given in doses relevant to the formation of l-methamphetamine from deprenyl. However, unlike the effect of deprenyl, the l-methamphetamine-induced increase in locomotor activity and striatal DOPA formation was not antagonized by pretreatment with SKF 525 A. The data suggest that the stimulatory effect of deprenyl on locomotor activity and DA synthesis is not related to a MAO-B blocking action of the drug or to a putative effect on DA re-uptake, but rather to effects of metabolites of the drug, e.g. l-methamphetamine. It is proposed that metabolites of deprenyl should not be disregarded to account for the clinical benefits of the drug.

ENDOGENOUS PHENYLETHYLAMINE & PHENYLACETIC ACID AS INDICATORS OF THE SPECIFICITY OF INHIBITION OF MAO IN THE RAT STRIATUM. L. E. Dyck and A. A. Boulton. Neuropsychiatric Research Unit, Dept. of Psychiatry, Univ. of Saskatchewan, Saskatoon, Canada S7N 0W0

Endogenous phenylethylamine (PE) in the rat striatum seems to be a substrate specifically for type B MAO, while tryptamine (TRA), m- and p-tyramine (mTA and pTA) appear to be substrates for both A and B MAO. In the following study, brofaromine (BFO), a reversible type A MAOI, and clorgyline (CLOR), an irreversible A inhibitor, were injected s.c. and i.p. acutely and chronically (7 days) into male Wistar rats and the levels of PE, mTA, pTA, TRA, phenylacetic, m- & p-hydroxyphenylacetic acids and DOPAC in the striatum quantified. While mTA, pTA and TRA levels were increased by BFO administration, PE levels were unaffected. The effects of acute BFO on the levels of these amines did not differ from those of chronic treatment. Similar results were observed with CLOR, but in this case, the effects of chronic CLOR on amine levels were greater than those of acute CLOR. Striatal levels of DOPAC, m- & p-hydroxyphenylacetic were decreased dose - dependently by acute BFO. By contrast, phenylacetic acid levels were not reduced even by 100 mg/kg BFO. It appears, therefore, that striatal PE and phenylacetic acid levels can be employed as endogenous indicators of the specificity of inhibition of MAO, striatal PE levels being increased and phenylacetic acid decreased only by type B and not by type A MAO inhibitors. Supported by Saskatchewan Health and Ciba-Geigy Canada Ltd.

CATECHOLAMINES: GENERAL

38.1

NEUROMELANIN ACCUMULATION WITH AGE IN THE MACACA FASCICULARIS BRAIN-STEM. M.T. Herrero^{1,2}, E.C. Hirsch¹, A. Kastner^{1*}, M.R. Luquin², F. Javoy-Agid¹, J.O. Obeso² and Y. Agid¹. (1) INSERM U289, Hôp. Salpêtrière, 75013 Paris, France and (2) Neurologia Experimental, Univ. Navarra, 31080 Pamplona, Espana.

Neuromelanin (NM) an auto-oxidation by-product of catecholamine synthesis accumulates with age in the locus coeruleus and the substantia nigra in primate and dogs. The present experiments were undertaken in order to examine the time-course dependency of NM accumulation in the mesencephalon of Macaca fascicularis.

The intraneuronal presence of NM was analyzed in the mesencephalon of 5 monkeys (age: 7 days, 1.4, 3.5, 8 and 13 years). The brain-stem was fixed, frozen and cut in 40 μ m serial sections covering the whole span of the mesencephalon from the subthalamic nucleus to the locus coeruleus. Regularly spaced (640 μ m) sets of sections were stained by Fontana method in order to detect NM, by tyrosine hydroxylase immunocytochemistry to visualize catecholaminergic neurons or by thionin for cytoarchitectonic study. "Visible NM" was analyzed on an additional set of sections which were not stained. Each neuron was plotted and total number of neurons were counted using image analysis.

In the youngest monkey (7 days old) catecholaminergic neurons were not melanized. In the 1.4 years old monkey, 30% of the catecholaminergic neurons contained NM visible in Fontana stained sections but not detectable in unstained sections. In the older monkeys, NM-containing neurons represented 60% of the catecholaminergic neurons, without further modification of this proportion with age. Our results suggest that NM content increases with age in the neurons of the mesencephalon and that NM first appears as uncolored NM, the exact nature of which remain to be determined.

38.3

NORADRENALINE RELEASE FROM RAT FRONTAL CORTEX AND HIPPOCAMPUS AFTER ELECTROCONVULSIVE SHOCK (ECS). D.N. Thomas*, D.J. Nutt* and R.B. Holman. Reckitt and Colman Psychopharmacology Unit, The Medical School, Bristol, BS8 1TD, UK.

The extracellular concentration of NA in frontal cortex (FC) is regulated primarily by presynaptic α_2 autoreceptors, while in hippocampus (HI) transmitter uptake is predominant (Thomas et al., 1990 J.Neurochem. 56). Chronic ECS is an effective treatment for depression. Biochemical and behavioural evidence indicate that α_2 -adrenoreceptors are downregulated with chronic treatment. The present study uses *in vivo* microdialysis to assess the effects of acute and chronic ECS on endogenous NA release and on α_2 -adrenoreceptor sensitivity. Concentric dialysis probes were implanted into either the HI or FC of chloral hydrate anaesthetised rats. Basal NA concentrations in the HI and FC were 4.5 ± 0.3 (mean \pm SEM, n=5) and 4.1 ± 0.3 pg/sample (n=4) respectively. Acute ECS significantly and immediately increased NA release in both regions [HI 21.4 ± 1.2 (n=5); FC 11.6 ± 1.2 (n=4) pg/sample] as compared with controls (ear clip). In the HI chronic ECS (100mA; 1sec x 7 days) did not change either basal NA release or the increase in release following an additional ECS on day 8. In contrast, in FC chronic ECS significantly elevated basal release (6.9 ± 1.0 pg/sample, n=4) without affecting the ECS-stimulated NA release on day 8 as compared with the controls. In subsequent experiments, chronic ECS treated rats were challenged with the α_2 antagonist idazoxan (IDX). In the HI, IDX elicited significant increases in NA release in both the chronic ECS and control groups. However, in FC after chronic ECS the response to IDX was abolished as compared with the control. These data show that chronic, but not acute ECS causes a regionally (FC not HI) specific increase in basal NA release. Further, the lack of response to IDX in the FC after chronic ECS is consistent with a downregulation of presynaptic α_2 -adrenoreceptors.

POSTMORTEM STABILITY OF MONOAMINES IN RAT BRAIN REGIONS P.J. Kontur, R.B. Innis, R.H. Roth. Depts. Pharmacology and Psychiatry, Yale U. Sch. Med. New Haven, CT 06510.

Two experimental paradigms that reflect handling of postmortem human brain tissue prior to neurochemical analysis were studied in postmortem rat brain tissue. Time and temperature dependent changes were analyzed by incubating rat brain tissue *in situ* for 0, 1, 3, 6, 9, 12 or 15 hours before it was dissected and stored. The incubation conditions mimicked the typical decrease in temperature of human brain left *in situ* for similar time periods. The effects of time of storage were analyzed by dissecting and storing rat brain tissue at -70°C for 0, 0.5, 1, 6 or 8 months. The levels of monoamines and metabolites in the striatum, cingulate and occipital cortex of these brains were measured using alumina extraction and HPLC methods. The gradual decrease in temperature over 15 hours resulted in 1) decreased levels of striatal DA and DOPAC and increased levels of HVA, 2) decreased levels of cingulate cortex NE and 5HT and increased levels of DA, DOPAC, HVA and HIAA, and 3) decreased occipital cortex NE levels, both increased and decreased 5HT levels and increased HIAA levels. Long term storage resulted in 1) decreased striatal DA levels and an uneven pattern of increase in DOPAC levels, 2) decreased cingulate NE levels and increased DA and DOPAC levels, and 3) decreased occipital cortex NE levels. These results demonstrate that there are time, temperature and storage dependent regional differences in the stability of monoamines and metabolites. The analysis of monoamines and metabolites levels in post-mortem human brain tissue should account for time, temperature and storage parameters in order to accurately interpret the effects of neurological disorders on neurotransmitter dynamics. [³H]-TOMOXETINE: A HIGHLY SELECTIVE, ENANTIOMERICALLY PURE RADIOLIGAND FOR NOREPINEPHRINE UPTAKE SITES IN BRAIN. D. T. Wong, D. W. Robertson, S. L. Gackenheim, L. Reid, D. A. Schober, D. C. Thompson and D. R. Gehlert. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Studies of the presynaptic norepinephrine (NE) uptake carrier have been seriously hampered by the lack of radioligands which bind with high affinity and specificity for this site. Radiolabeled antidepressants, including [³H]-desipramine and [³H]-mazindol, have been used to label the NE uptake carrier, but these agents are fraught with high levels of nonspecific binding and also bind to multiple uptake and receptor sites within the CNS. Racemic [³H]-nisoxetine was recently reported to be a specific radioligand for the NE uptake carrier. A related molecule, tomozetidine, is currently in widespread clinical trials as an antidepressant, and we now report that [³H]-tomoxetine is a potent, highly specific, enantiomerically pure radioligand for the NE uptake carrier. Binding of [³H]-tomoxetine was saturable and it labeled a homogeneous population of sites in synaptosomal membranes of rat cerebral cortex ($K_d = 0.30 \pm 0.01$ nM, $B_{max} = 47.1 \pm 0.6$ fmol/mg protein). Specific binding of [³H]-tomoxetine was sodium dependent, and approximately 70% of total binding was specific at the K_d concentration. Binding was displaced by other compounds which inhibit the NE uptake carrier, including nisoxetine, tomozetidine, desipramine, and nortriptyline, but binding was not displaced by specific inhibitors of the 5HT uptake carrier, including sertraline and fluoxetine. Displacement of [³H]-tomoxetine binding was stereospecific; for example, the (+) enantiomer of nisoxetine was considerably more potent than the (-) enantiomer (IC_{50} values were 1.4 and 26.9 nM, respectively). Autoradiographic studies indicated that [³H]-tomoxetine bound to rat brain regions containing a high density of NE containing fibers and cell bodies, including the locus coeruleus, anterior dorsal thalamus, and the nucleus of the solitarius tract. These data suggest that [³H]-tomoxetine is a useful radioligand for exploration of the physiology and pharmacology mediated via NE uptake carriers.

SYNTHESIS AND ADRENERGIC ACTIVITY OF A SEMI-RIGID ANALOG OF 6-FLUORONOREPINEPHRINE (6-FNE). S. N. Calderon¹, E. Gusovsky, H. M. Garraffo, J. W. Daly, J-Y. Nie, D. C. Furlano, A. H. Newman, K. L. Kirk. Lab. of Bioorganic Chemistry, NIDDK, NIH, Bethesda, MD 20902. ¹NIDA Addiction Research Center, Baltimore, MD 21224.

We reported previously that 2-fluoronorepinephrine (2-FNE) is a selective β -adrenergic agonist while 6-FNE is a selective α -adrenergic agonist. Similar adrenergic selectivities are present in fluorinated epinephrines, phenylephrines and isoproterenols. These observations have led to the development of new pharmacological and potential medicinal agents. The mechanism of fluorine-induced adrenergic selectivities, although studied extensively, is still unknown. We now report further experimental evidence pertinent to this question. The use of semi-rigid analogs has proven to be an effective strategy to investigate the participation of conformational isomerism in drug activity. We have synthesized the semi-rigid analog of norepinephrine and 6-FNE, *trans*-2-amino-5,6-dihydroxy-1,2,3,4-tetrahydro-naphthalenol and *trans*-2-amino-5,6-dihydroxy-8-fluoro-1,2,3,4-tetrahydro-naphthalenol, respectively, by cyclization of the precursor arylbutanoic acids, followed by elaboration of the aminoalcohol functionality and deprotection of the catechol group. The α - and β -adrenergic activities of these analogs were evaluated through inhibition of binding of appropriate ligands for these receptors and through stimulation of cyclic AMP accumulation in C6 glioma cells. While the non-fluorinated analog had selective β_2 -adrenergic activity the fluorinated analog had poor β -adrenergic activity.

THIOPHOSPHORYLATION OF CHROMAFFIN VESICLE MATRIX PROTEINS IN CULTURED BOVINE CHROMAFFIN CELLS. J.C. Brooks and M.H. Brooks. Marquette Univ. Sch. of Dent., Milwaukee, WI 53233.

Cultured bovine chromaffin cells were incubated with medium in which inorganic phosphate was replaced with inorganic [³⁵S]-thiophosphate. Within 5 min., label was found in a broad 97-121 kDa band on SDS-PAGE, with increasing incorporation over a 40 min period. Subcellular fractions were prepared from these cells and cells exposed for 3 days to inorganic thiophosphate. The 97-121 kDa radiolabeled proteins were present in isolated chromaffin vesicles and were released to the medium upon osmotic lysis of the vesicles. Vesicle membrane proteins were not thiophosphorylated.

Vesicles prepared from cells or adrenal medulla in isosmotic media were energized by ATP but not by the corresponding thiophosphorylated analog, adenosine-5'-0-(3-thiotriphosphate) (ATPYS). Neither ATPYS nor TP_i was incorporated into the 97-121 kDa proteins of isolated intact or disrupted chromaffin vesicles although there was incorporation into a 47 kDa protein.

We hypothesize that TP_i is rapidly taken up by chromaffin cells, synthesized into ATPYS and used for thiophosphorylation reactions. The physiological significance of the rapid and intense thiophosphorylation of vesicle matrix proteins is not yet evident. Supported by NIH Grant 1 A15 NS23101-01A2.

PRESENCE OF CATECHOLAMINE TRANSPORT IN RAT BRAIN CELL NUCLEI. Nguyen T. Buu. IRCM, Department of Medicine, Université de Montréal, Montréal, Québec, Canada H2W 1R7

There is increasing evidence that catecholamines (CA) are involved in gene expression and growth although the exact mechanism of their regulation remains unclear. Growth regulation and gene expression occur in the cell nucleus and translocation of several peptides and hormones involved in gene regulation has been demonstrated in the nuclei of different cell lines. However, the translocation of CA into the cell nucleus is not known and is the aim of this study.

Uptake was studied using radiolabeled dopamine (DA) and norepinephrine (NE) in cell nuclei isolated from whole rat brain and verified for purity by electron microscopy. Cell nuclei were also incubated with L-DOPA and CA were measured by HPLC.

The results showed that cell nuclei from rat brain can uptake both DA and NE. This uptake is saturable and can be inhibited by N-ethylmaleimide (10 μ M) but is not affected by reserpine. Incubation of cell nuclei with L-DOPA (1mM) generates DA and this production can be abolished by NSD-1015, suggesting the presence of dopa decarboxylase.

Thus cell nuclei from rat brain uptake CA and generate DA from exogenous L-DOPA. The meaning of the CA system in the cell nucleus remains to be investigated. Supported by the Canadian Heart and Stroke Foundation (Quebec) and le Fonds interne de la Faculté de Médecine, Université de Montréal.

SEROTONIN RECEPTORS: 5HT_{1A} I

39.1

IN VIVO MICRODIALYSIS EVIDENCE FOR CENTRAL 5-HT₁ RECEPTOR BLOCKING PROPERTIES OF THE β -ADRENERGIC ANTAGONIST (-)PENBUTOLOL. S. Hjorth, T. Sharp & D.G. Grahame-Smith. Dept. of Pharmacol., Univ. of Göteborg, Box 33 031, S-400 33 Göteborg, SWEDEN, and MRC Unit of Clin. Pharmacol., Oxford, U.K.

Selected β -adrenoceptor antagonists (e.g. pindolol, alprenolol, propranolol) are currently used as probes for 5-HT₁ receptors in various experimental paradigms. Recently, we found that (-)penbutolol (PB), another β_1/β_2 -adrenoceptor blocking agent, prevents behavioural and biochemical actions of the specific 5-HT_{1A} agonist 8-OH-DPAT (Hjorth et al., in prep.). The putative 5-HT_{1(A)} receptor antagonist profile of PB was further explored, using *in vivo* microdialysis to assess its effects on central 5-HT release. (-)Pindolol was included for comparison. Chloral hydrate-anesthetized male S-D rats (250-350 g) were stereotaxically implanted with *in vivo* brain microdialysis probes into the ventral hippocampus. The probes were perfused with artificial CSF containing the 5-HT reuptake blocker citalopram (1 μ M), and dialysates collected every 20 min for analysis of 5-HT using HPLC-EC. Drugs were initiated after a control period (2-3h), to establish stable baseline 5-HT output. In contrast to (-)pindolol (8.0 mg/kg SC), PB (2.0 or 8.0 mg/kg SC) treatment increased the hippocampal 5-HT output (max. =175-200% of control, $t = +60'$). The PB-induced response was dose-dependent, stereoselective and Ca²⁺-sensitive, and was abolished by omitting citalopram from the perfusion medium; (-), but not (+), penbutolol pretreatment also prevented the 8-OH-DPAT-induced decrease of 5-HT release. The data indicate that (-)penbutolol possesses 5-HT_{1A} and/or 5-HT_{1B} receptor antagonist properties, and may be a useful tool in studies of central 5-HT₁ receptor-mediated function.

39.2

NEUROPHYSIOLOGICAL STUDIES OF WAY-100,135: A NOVEL AND HIGHLY SELECTIVE 5-HT_{1A} RECEPTOR ANTAGONIST. D. E. Jones and J.T. Haskins. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543-8000.

WAY-100,135 (WAY), binds with high affinity and selectivity to the central 5-HT_{1A} site and displays antagonist activity in functional models (Fletcher *et al.*, this meeting). WAY and several other putative 5-HT_{1A} antagonists were examined for effects on central 5-HT neuronal activity utilizing standard neurophysiological techniques in chloral hydrate-anesthetized rats. Among the compounds studied were the full agonist 8-OH-DPAT (DPAT), the partial agonists gepirone (GEP) and buspirone (BUS) and the putative antagonists BMY-7378 (BMY), NAN-190 (NAN), and MDL-73005 (MDL). Following *i.v.* administration, all compounds except WAY, markedly reduced the firing rate of 5-HT neurons recorded in the dorsal raphe nucleus. The rank order of potency (and ID₅₀ μ g/kg *i.v.*) for these effects was DPAT (2.05) > BMY (11.9) > NAN (16.0) > GEP (26.4) > BUS (30.0) > MDL (81.5) >>> WAY (>2500). To follow up these observations we examined the effects of pretreatment (500 μ g/kg *i.v.*) with WAY on DPAT-induced inhibition of 5-HT neuronal activity. In these experiments, DPAT alone inhibited 5-HT neuronal activity with an ID₅₀ of 2.6 \pm 0.2 μ g/kg *i.v.* Following pretreatment with WAY, however, DPAT at doses up to 4.0 μ g/kg *i.v.* reduced baseline activity by only 30%. Clearly, of the compounds examined here, WAY has a profile consistent with that of an antagonist at 5-HT_{1A} receptor sites.

39.3

WAY100135: A NOVEL AND HIGHLY SELECTIVE 5-HT_{1A} RECEPTOR ANTAGONIST. A. Fletcher*, D.J. Bill*, S.J. Bill*, N.T. Brammer*, J.A. Cliffe*, E.A. Forster*, Y. Bejilly* and G.K. Lloyd. Wyeth Research (U.K.) Ltd., Taplow, Maidenhead, Berkshire SL6 0PH, U.K.

We present initial *in vitro* and *in vivo* data on WAY100135, a novel phenylpiperazine derivative [N-tert-butyl 3- 4-(2-methoxyphenyl) piperazin-1-yl-2-phenylpropanamide dihydrochloride] which binds with high affinity and selectivity to the central 5-HT_{1A} site, and which displays only 5-HT_{1A} antagonist activity in functional models.

The IC₅₀ value of WAY100135 (displacement of rat hippocampal ³H-8-OH-DPAT binding) was 25 nM. IC₅₀ values (μM) of WAY100135 at other sites were:- 5-HT_{1B} >10; 5-HT_{1C} >10; 5-HT₂ 6; alpha-1 adrenoceptor 1.8; alpha-2 >10; dopamine D₂ 9. The pA₂ value of WAY100135 for antagonism of 5-carboxamidotryptamine in the transmurally-stimulated guinea-pig ileum was 7.2. The lowest effective dose of WAY100135 to antagonise 8-OH-DPAT-induced syndrome in the rat was 3mg/kg sc. WAY100135 did not display any agonist activity in these models. WAY100135 had no significant effect on raphe 5-HT neuronal firing in the anaesthetised rat, but blocked the inhibitory action of 8-OH-DPAT (Haskins et al., this meeting). Similarly, WAY100135 (up to 10mg/kg sc) had no effect on rat central 5-HT turnover (measured by cortical 5-HTP accumulation following decarboxylase inhibition) but antagonised the decreased turnover induced by 8-OH-DPAT (0.05mg/kg sc) at doses of 1-10 mg/kg sc. In an animal model of anxiety, the mouse two-compartment light:dark box, WAY100135 mimicked the activity profile of benzodiazepine positive controls by selectively increasing exploratory behaviour in the light compartment at doses of 3-10mg/kg sc.

Unlike previous 5-HT_{1A} antagonists (eg: BMY7378, NAN-190), which display agonist activity at raphe autoreceptors, WAY100135 appears to be the first selective and anxiolytic 5-HT_{1A} ligand to act as an antagonist in both presynaptic and postsynaptic receptor models.

39.5

SEROTONIN TYPE 1A AND SEROTONIN TYPE 2 RECEPTORS MEDIATE DISTINCT BEHAVIORAL RESPONSES IN THE MONGOLIAN GERBIL. Robert N. Wright* and Arlene S. Eison. CNS Special Proj. Bristol-Myers Squibb Company, Wallingford, CT 06492.

Although the ability of serotonin (5-HT) receptor subtype activation to induce distinct behaviors has been well documented for the rat, it has thus far been largely unreported for the Mongolian gerbil. We have found that a 5-HT_{1A}/5-HT₂ agonist 5-Methoxy-N,N-dimethyltryptamine, the specific 5-HT_{1A} agonist 8-hydroxy-(di-n-propylamino) tetralin (8-OH-DPAT) and the 5-HT precursor, L-5-hydroxytryptophan all elicit a 5-HT syndrome in the gerbil consisting of: reciprocal forepaw treading (RFT), hindleg abduction (HA), body tremors and Straub tail. The putative 5-HT_{1A} antagonist NAN-190 blocked both RFT and HA in a dose-dependent manner suggesting that these behaviors are mediated via 5-HT_{1A} receptor activation.

We have also identified a unique, dose-responsive behavior in the gerbil induced exclusively by 5-HT₂ agonists such as (+)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) and quipazine. This reciprocal hindleg body scratch (RHBS) is dose-dependently inhibited by pre-treatment with the selective 5-HT₂ antagonist ritanserin.

Similar to that observed in the rat, we have shown interactions between 5-HT_{1A} and 5-HT₂ receptor subtypes. DOI-induced RHBS behavior is potently inhibited by pre-treatment with 8-OH-DPAT. Conversely, simultaneous administration of DOI with 8-OH-DPAT potentiated the 5-HT syndrome.

39.7

BENZODIOXEPERAZINE DERIVATIVES AS NOVEL 5-HT_{1A} ANTAGONISTS: A PHARMACOLOGICAL CHARACTERIZATION M.J. Millan, J.M. Rivet*, H. Canton, F. Lejeune*, M. Brocco*, K. Bervoets* and J.L. Peglion*. FONDAX, Groupe de Recherches Servier, 7 rue Ampère, 92800 Puteaux, Paris, France.

Currently, no selective, pure antagonists at 5-HT_{1A} receptors are known. Proposed antagonists have several problems; e.g., (-)-alprenolol is equipotent at 5-HT_{1B} sites, BMY 7378 and MDL 73005EF are partial agonists and NAN 190 is a potent α₁ antagonist; both BMY 7378 and NAN 190 are D₂ antagonists. In an attempt to improve upon these drugs, we synthesized a series of (benzocycloalkanyl)alkyl derivatives (in the N₁ position) of 4-(1,4-benzodioxan-5-yl) piperazine. These possessed extremely high affinity for 5-HT_{1A} receptors (pK_is of 8.8-9.4). Their affinity for other 5-HT sites (1B/1C/2/3) was several hundred fold lower. *In vivo*, four tests of (post-synaptic) 5-HT_{1A} activity in rats were used; induction of corticosterone secretion, hypothermia, spontaneous tail-flicks and flat-body posture. In these tests, the 5-HT_{1A} ligand, 8-OH-DPAT, was a potent agonist: the benzodioxepiperazine derivatives blocked its action over a dose range of 0.1-2.5 mg/kg, s.c. in the absence of partial agonist effects. *In vivo*, their actions at α₁, α₂, D₁ and D₂ receptors were manifest only at significantly (≥10 fold) higher doses. With respect to their, 1) potency, 2) selectivity over other 5-HT receptor types as well as α₁, α₂, D₁ and D₂ receptors and, 3) purity of antagonism at post-synaptic 5-HT_{1A} sites, the benzodioxepiperazine derivatives offer advantages over other proposed 5-HT_{1A} antagonists such as (-)-alprenolol, BMY 7378, NAN 190 and MDL 73005EF. The activity of these benzodioxepiperazine derivatives at pre-synaptic 5-HT_{1A} receptors remains to be explored. These drugs should prove highly useful in exploring structure-activity relationships at 5-HT_{1A} receptors as well as in determining their functional significance.

39.4

PATCH CLAMP ANALYSIS OF SEROTONIN RESPONSES IN SUBSTANTIA GELATINOSA NEURONS OF THE RAT SPINAL CORD SLICE. M. Yoshimura and S. Nishi. Dept. Physiol., Kurume Univ. Sch. of Med., Kurume, 830 Japan.

The effect of serotonin (5-HT) on substantia gelatinosa (SG) neurons in tissue slices of the adult rat spinal cord was studied with a patch clamp recording technique. Bath application of 5-HT (0.1-40 μM) produced an outward current in 30 % of SG neurons, an inward current in 10 %, a biphasic response consisting of an outward current and an inward current in 30 %, and no responses in 30 %. The 5-HT induced outward current was associated with an increase in membrane conductance and reversed in polarity at membrane potential near the potassium equilibrium potential, suggesting that the outward current was due to activation of a membrane potassium conductance. The outward current was unaffected by tetrodotoxin (0.5 μM) and was reduced but not abolished by Co⁺⁺ (2 mM). Application of 8-OH-dipropylaminotetralin (8-OH-DPAT), a 5-HT_{1A} agonist, produced an outward current which was quite similar, if not identical, to the 5-HT induced outward current. The inward current caused by 5-HT was antagonized by the 5-HT₂ receptor antagonist ketanserin.

These observations suggest that SG neurons are endowed with 5-HT_{1A} and/or 5-HT₂ receptors and that the two receptor subtypes may be involved in modulation of nociceptive transmission in the dorsal horn of the spinal cord.

39.6

FLESINOXAN, NAN-190 AND MOTION SICKNESS IN THE CAT. J.B. Lucot. Dept. Pharmacol., Wright State Univ., Dayton, OH 45435.

This study extends previous work on the ability of 5-HT_{1A} agonists to inhibit motion sickness by evaluating the effects of a new agonist, flesinoxan, and a putative antagonist, NAN-190. Ten susceptible subjects were tested biweekly in a motion device modelled after a Ferris wheel. Tests lasted 30 min followed by 1 min of observation at rest. As expected, flesinoxan suppressed motion sickness. However, unlike 8-OH-DPAT, this effect was not blocked by (-)propranolol. The dose of 3 mg/kg on NAN-190 weakly suppressed motion sickness and produced a strong nictitating membrane response, while lower doses had no effect on motion sickness. Doses of NAN-190 up to 1 mg/kg vs 8-OH-DPAT and up to 0.3 mg/kg vs flesinoxan did not antagonize the agonists. Higher doses are being tested. The mechanism by which flesinoxan suppresses motion sickness is not yet clear. NAN-190 acted as a weak agonist when given alone but moderate doses did not reverse the effects of 8-OH-DPAT.

39.8

S 14671: A NOVEL NAPHTHYLPYPERAZINE 5-HT_{1A} AGONIST OF EXCEPTIONAL POTENCY POSSESSING 5-HT_{1C2} ANTAGONIST ACTIVITY H. Canton, J.M. Rivet*, F. Lejeune*, M. Laubie*, M. Brocco*, K. Bervoets*, G. Lavielle* and M. J. Millan. Fondax, Groupe de Recherches Servier, 7 rue Ampère, 92800 Puteaux, France.

Serotonin (5-HT) is implicated in the control of mood and both 5-HT_{1A} agonists and 5-HT_{1C2} antagonists may possess anxiolytic properties. In an attempt to combine these properties, the naphthylpiperazine, S 14671 (4-[(1-phenyl-2-aminoethyl)-1-(7-methoxynaphthyl) piperazine monohydrate] was synthesized. Its profile was compared with the 5-HT_{1A} agonists, 8-OH-DPAT, (+)-flesinoxan and buspirone and the 5-HT_{1C2} antagonist, ritanserin.

pK _i :	5-HT _{1A}	5-HT _{1B}	5-HT _{1C}	5-HT ₂	5-HT ₃
S 14671	9.3	6.3	7.8	7.8	<6.0
8-OH-DPAT	9.2	5.2	5.0	5.0	<6.0
(+)-flesinoxan	8.7	5.1	5.0	<5.0	<6.0
buspirone	7.9	4.4	5.7	5.8	<6.0
ritanserin	6.0	5.4	8.6	8.6	<6.0

S 14671 had very high affinity for 5-HT_{1A} sites and its 5-HT_{1C2} affinity was only 30-fold less. *In vitro* models of phosphoinositide turnover (rat choroid plexus, 5-HT_{1C} and rat cortex, 5-HT₂), S 14671 was a pure antagonist. *In vivo* 5-HT_{1C2} actions are under evaluation. *In vivo* 5-HT_{1A} models in male rats (induction of corticosterone secretion, hypotension, hypothermia and spontaneous tail-flicks and inhibition of dorsal raphe firing) their relative potencies were S 14671 (= 1) > 8-OH-DPAT (7) > buspirone (200) > (+)-flesinoxan (280). S 14671 was active at doses as low as 5 μg/kg, s.c. 8-OH-DPAT and S 14671 were full agonists and (+)-flesinoxan and buspirone were partial agonists. Thus, S 14671 is a potent 5-HT_{1A} agonist of high efficacy with 5-HT_{1C2} antagonist properties. The evaluation of its potential anxiolytic and other therapeutic properties will be of interest.

39.9

PHARMACOLOGICAL EVIDENCE FOR A MIXED AGONISTIC/ANTAGONISTIC PROFILE OF THE PUTATIVE 5-HT_{1A} RECEPTOR ANTAGONISTS BMY 7378 AND NAN-190. J.M. Geuel, T. Glaser and J. De Vry. Institute for Neurobiology, Troponwerke, Berliner Straße 156, 5000 Köln 80, FRG

The present study characterized the putative 5-HT_{1A} receptor antagonists BMY 7378 (8-[2-[4-(2-methoxyphenyl)-1-piperazinyl]ethyl]-8-azaspiro[4.5]-decane-7,9 dione dihydrochloride) and NAN-190 (1-(2-methoxyphenyl) 4-[4-(2-phthalimido)butyl]piperazine) in a number of test paradigms reflecting activation of pre- and/or postsynaptic 5-HT_{1A} receptors. Both compounds bound with high affinity to 5-HT_{1A} sites in hippocampal membranes. In the hippocampus, the forskolin-stimulated adenylate cyclase assay revealed that both drugs were partial agonists. Increasing concentrations (10⁻¹⁰-10⁻⁶ M) of NAN-190 or BMY 7378 partly reduced the adenylate cyclase activity and partly antagonized the effects of the 5-HT_{1A} agonist 8-OH-DPAT (1 μM). Electrophysiological characterization at presynaptic sites in dorsal raphe neurons in rat brain slices showed that low concentrations (10 nM) antagonized and higher concentrations (> 30 nM) mimicked the effects of 8-OH-DPAT. Based on these results the intrinsic activities of both compounds were estimated to be in the range of 0.1 to 0.3. The suppression of neuronal firing by NAN-190 and BMY 7378 could be completely antagonized with propranolol, indicating that the inhibitory actions of both drugs were not primarily due to α₂-adrenoceptor antagonism. A mixed agonistic-antagonistic profile of BMY 7378 and NAN-190 was also obtained in a 8-OH-DPAT vs saline drug discrimination procedure. It is concluded that both BMY 7378 and NAN-190 are mixed agonists/antagonists at pre- and postsynaptic 5-HT_{1A} receptors. The apparent "full agonism" at presynaptic sites probably reflects the existence of a receptor reserve in the dorsal raphe nucleus.

39.11

TANDOSPİRONE STIMULATES PROLACTIN RELEASE VIA SEROTONIN-1A (5-HT_{1A}) RECEPTORS IN RATS. S.E. Mulrony*, C.M. Skudlarek*, L.A. Pabreza*, A. Shemer* and K.J. Kellar. Georgetown University Medical Center, Washington D.C. and *Pfizer Inc., New York, N.Y.

Tandospirone (Tan), an azapirone drug with antidepressant activity, has high affinity for 5-HT_{1A} receptors. These receptors are involved in mediating the effects of 5-HT agonists on prolactin release in the rat (Hulihan-Giblin et al., Soc. Neurosci. Abst. 15:723, 1989). We have examined the effects of Tan on prolactin release in awake, freely moving rats in which an in-dwelling jugular vein cannula allowed multiple sampling of blood after injections of drugs. Following a single injection of Tan, plasma prolactin levels rose rapidly, peaked within 10 min at 4-6 times preinjection values and returned to baseline within 30 min. The ED₅₀ for this effect of TAN was ~ 0.3 mg/kg i.v. The Tan metabolite 1-PP did not release prolactin. Prolactin release by TAN was blocked in a dose related manner by pretreatment (90 min before Tan) with the 5-HT antagonist metergoline (ID₅₀ = 1 mg/kg). Pretreatment with 8-OHDPAT (0.2 mg/kg) released prolactin and diminished the response to Tan administered 60 min later. Similarly, pretreatment with Tan (1 mg/kg) decreased the subsequent prolactin response to 8-OHDPAT. These diminished responses appear to represent cross-desensitization and are thus further evidence that Tan releases prolactin via 5-HT_{1A} receptors. Repeated administration of Tan (10 mg/kg, i.p.) twice-daily for two weeks did not significantly alter the prolactin response to either Tan or 8-OHDPAT, indicating that receptor sensitivity was not altered by this chronic exposure. These results indicate that the prolactin response to Tan may provide a sensitive *in vivo* measurement of 5-HT_{1A} receptor function and that this function is probably preserved during chronic administration of 5-HT_{1A} agonists.

39.13

AGONISTIC PROPERTIES OF YOHIMBINE AND ITS STEREOISOMERS FOR 5-HYDROXYTRYPTAMINE_{1A} RECEPTOR. N. Kawai*, T. Yamamoto*, A. Baba*, T. Moroji* and Y. Hayashi. Dept. of Psychopharmacology and Molecular Biology, Psychiatric Research Institute of Tokyo, Tokyo 156, JAPAN.

Yohimbine is well-known as a selective α₂-adrenoceptor antagonist. Recently it was reported that rauwolfscine, one of stereoisomers of yohimbine, binds to 5-Hydroxytryptamine_{1A} (5-HT_{1A}) receptors with high affinity (Convents et al., Eur. J. Pharmacol. 1986). In this study, the effects of yohimbine and a series of its stereoisomers on the binding of [³H]8-OH-DPAT, a selective 5-HT_{1A} agonist, to rat hippocampal membranes were examined. In addition, we examined their effects on the forskolin-stimulated adenylate cyclase (A-C) activity. All of them inhibited the binding of [³H]8-OH-DPAT to hippocampal membrane preparations as well as that of [³H]lidazoxan, a selective α₂-adrenoceptor antagonist, to membrane preparations of cortices. 5-HT and 8-OH-DPAT reduced the forskolin-stimulated A-C activity. Yohimbine and its stereoisomers reduced it to approximately the same extent as those for 5-HT and 8-OH-DPAT. This effect was inhibited by spiperone. They did not affect the inhibitory effect of 5-HT on the forskolin-stimulated A-C activity. The present findings suggest that yohimbine and its stereoisomers are not only α₂-adrenoceptor antagonists but also 5HT_{1A} receptor agonists.

39.10

INHIBITION OF SEROTONERGIC DORSAL RAPHE NEURONS BY THE 5-HT_{1A} LIGAND RK-153. Cam P. VanderMaelen and John P. Braselton. Bristol-Myers Squibb Co., CNS Neuropharmacology, 5 Research Parkway, Wallingford, CT. 06492.

Some 5-HT_{1A} antagonist compounds are effective, but are not selective (e.g. spiperone). Other compounds, such as BMY 7378 (Yocca et al., EJP, 1987, 137, 293-294) are more selective, but exhibit both agonist and antagonist actions. In general, compounds which are weak partial agonists exhibit antagonist activities in "postsynaptic" models of 5-HT_{1A} action (e.g. adenylate cyclase; forepaw treading), but exhibit agonist-like actions at 5-HT_{1A} autoreceptors on serotonergic dorsal raphe (DR) neurons. RK-153 (kindly provided by R. Glennon) is a possible "pure" antagonist highly selective for 5-HT_{1A} sites (Raghupathi et al., Soc. Neurosci. Abst., 1990, 16, 1036). We administered this compound *in vivo* to chloral hydrate anesthetized male rats, and measured its effects on the spontaneous discharge of serotonergic DR neurons, using standard extracellular single unit recording techniques. RK-153 potentially inhibited the firing of these neurons (ED₅₀ = 14.5 μg/kg). These results are similar to previous results with 5-HT_{1A} partial agonists like buspirone, and in combination with other data suggest that RK-153 is a partial agonist at 5-HT_{1A} receptors. Additional studies would help confirm that these electrophysiological effects are direct and 5-HT_{1A}-receptor mediated.

39.12

5-HT_{1A} RECEPTOR ANTAGONISTS DO NOT BLOCK THE HYPOTHERMIA CAUSED BY INCREASED PARTIAL PRESSURES OF OXYGEN. L. Fenton, G. Beck, S. Djali and M.B. Robinson. Children's Seashore House; Depts. Ped. and Pharm., U. of PA; Phila., PA 19104.

Rats exposed to oxygen at high pressure (OHP) develop hypothermia, bradycardia and several of the behaviors seen in the serotonin (5-HT) syndrome: head weaving, resting tremor and straub tail. These responses cannot be attributed to high pressure. The purpose of these studies was to investigate the possibility that the hypothermia is related to increased serotonin turnover. 5-Hydroxyindole acetic acid (HIAA) and other neurotransmitters were measured by HPLC in discrete brain regions. HIAA levels were increased (> 50%, p < 0.05) in the parietal-occipital cortex and striatum of rats exposed for 2.5 hours to 4 ATA O₂. Tryptophan, 5-HT, other biogenic amines, and their metabolites did not change. Pre-treatment with the 5-HT_{1A} receptor antagonists pindolol (0.1-10 mg/kg) and NAN-190 (10 mg/kg) did not block hypothermia induced by OHP at doses that block hypothermia induced by 8-OH-DPAT and 5-hydroxytryptophan (5-HTP, 50 mg/kg). Previous studies have demonstrated that the Fawn Hooded (FH) rat is less responsive to hypothermia induced by 8-OH-DPAT. (Pharm. Bio. & Beh., 22:489, 1985) The FH rat did not become hypothermic during OHP. Hypothermia induced by OHP was not blocked by spiperone (3 mg/kg) and methysergide (50 mg/kg) and was additive to the hypothermia induced by 5-HTP. These data suggest that OHP induced hypothermia is not due to excess activation of 5-HT_{1A} receptors, and that the FH rat may have defects in thermoregulation that are independent of the 5-HT_{1A} receptor.

39.14

EVIDENCE FOR A LARGE RECEPTOR RESERVE FOR INHIBITION OF DORSAL RAPHE (DR) CELL FIRING BY 5-HT_{1A} AGONISTS. B.L. Waszczak¹, R.F. Cox¹ and E. Meller². Pharmacol. Sect., Northeastern Univ., Boston, MA¹ and Dept. Psychiat., NYU Med. Ctr., New York, NY².

Previous studies (Meller et al., Mol. Pharmacol. 37: 231, 1990) have shown that DR cells exhibit a large receptor reserve for the inhibition of serotonin (5-HT) synthesis by full 5-HT_{1A} agonists such as 8-OH-DPAT, whereas no reserve exists for the "partial" agonists ipsapirone (IPS) and BMY 7378 (BMY). Using identical methods for receptor inactivation, we carried out parallel single unit recording studies to determine if the above drugs exhibit similar relative efficacies and receptor reserves for inhibiting DR cell firing. *In vivo* dose-response curves (drc's) were constructed in untreated control rats, or in rats which received an injection of the receptor inactivator N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ; 6 mg/kg, s.c.) 24 hrs before recording. All three drugs fully inhibited DR cell firing in control rats (ED₅₀s: 1.5 μg/kg, 8-OH-DPAT; 30.0 μg/kg, IPS; 17.5 μg/kg, BMY). However, unlike effects on 5-HT synthesis, EEDQ treatments caused no depression of the maximal inhibitory response for any of the agonists, although all drc's were shifted rightward (ED₅₀s: 10.1 μg/kg, 6.7-fold shift, 8-OH-DPAT; 139.9 μg/kg, 4.7-fold shift, IPS; 53.8 μg/kg, 3.1-fold shift, BMY). Since the degree of shift in the drc's after EEDQ is an indirect index of agonist efficacies, we conclude that the order of agonist efficacies is similar for both inhibition of 5-HT synthesis and DR cell firing (i.e. 8-OH-DPAT > IPS > BMY). However, a large receptor reserve exists for all three drugs in inhibiting DR cell firing. This suggests that the autoreceptor pools regulating synthesis and firing are either not identical or they have different receptor-effector coupling characteristics (i.e. unique G-protein transducers, effectors, and/or stoichiometries).

39.15

EFFECT OF TANDOSPIRONE (SM 3997) ON THE PRODUCTION OF GROWTH FACTORS FROM PRIMARY CULTURES OF ASTROGLIAL CELLS DERIVED FROM DIFFERENT BRAIN REGIONS. C. Rogers, A. Shemer, E.C. Azmitia and P.M. Whitaker-Azmitia. Dept. of Psychiatry, SUNY at Stony Brook, and Pfizer Incorporated, New York, New York. Our laboratory has previously shown that the 5-HT_{1A} receptor active drug, 8-OH-DPAT, released a growth factor from astroglial cells which stimulated neurite outgrowth from serotonergic neurons in primary cultures. The current study uses a more selective 5-HT_{1A} drug which has clinical potential - SM 3997 or tandospirone. Primary cultures of astroglial cells were grown from cortex, hippocampus, and brainstem regions from 4 day old rat pups. When the cells reached confluence they were incubated for 24 hours with 50, 100 or 500 nM tandospirone. The conditioned media was added to the culture media of the neurons, and growth assessed after three days. Tandospirone released a growth factor, most likely the protein S-100, most potently from brainstem and to a lesser extent from hippocampus and cortex. The lowest concentration of the drug (50 nM) was the most effective.

39.17

EFFECTS OF ADRENALECTOMY AND CORTICOSTERONE ON 5-HT_{1A} AND 5-HT_{1B} RECEPTORS IN THE DORSAL HIPPOCAMPUS AND CORTEX OF THE RAT.

S.D. Mendelson and B.S. McEwen Lab. of Neuroendocrinology The Rockefeller Univ. New York City, NY 10021

Quantitative autoradiography was used to evaluate the effects of adrenalectomy (ADX) and corticosterone (CORT) on binding at 5-HT_{1A} and 5-HT_{1B} receptors in the dorsal hippocampus and cortex of male rats. ADX increased binding of [³H]8-OH DPAT at 5-HT_{1A} receptors in the oriens and lacunosum moleculare layers of CA2 and CA3, in the lacunosum moleculare layer of CA4 region, and in the dentate. In restraint-stressed ADX rats, binding was decreased only in CA2. Restoration of baseline levels of CORT reversed the effects of ADX on 5-HT_{1A} receptors in the hippocampus, while chronic high levels of CORT decreased binding at 5-HT_{1A} receptors in the dentate. No treatment affected 5-HT_{1A} receptors in the CA1 region of the hippocampus or in the cortex. ADX increased binding of [¹²⁵I]iodocyanopindolol at 5-HT_{1B} receptors in the infrapyramidal dentate, but this effect was not observed in ADX rats that were restrained. In ADX and intact rats that received CORT, binding at 5-HT_{1B} receptors was lower than that in both control and ADX rats in the infrapyramidal dentate, and lower than that in ADX rats in the suprapyramidal dentate and CA4. In ADX and intact animals, CORT reduced binding at 5-HT_{1B} receptors in Area 2 of the cortex. Decreases in binding at 5-HT_{1A} and 5-HT_{1B} receptors after chronic exposure to high CORT may mimic changes in binding in animals that fail to adapt to severe stress, with an ensuing vulnerability to depression.

39.16

5-HT_{1A} but not 5-HT_{1D} Agonists Increase Hippocampal Acetylcholine (ACh) Efflux in Conscious Guinea Pig. Wilkinson, L.O., Hutson, P.H., and Middlemiss, D.N. Merck, Sharp and Dohme NRC, Terlings Park, Eastwick Rd, Harlow, Essex CM20 2QR. U.K.

Serotonergic regulation of hippocampal acetylcholine (ACh) release was investigated using *in vivo* dialysis. An increase in ACh efflux was observed following administration of the 5-HT_{1A} agonists 8-OH-DPAT (1 mg/kg, 137%: 10 mg/kg, 324%), buspirone (10 mg/kg, 249%), or NAN-190 (10 mg/kg, 79%) (maximal increase). Following pretreatment with NAN-190 (3 mg/kg), the effects of 8-OH-DPAT (1 mg/kg) were attenuated by 46%. Since NAN-190 is an ineffective antagonist at the 5-HT_{1A} somatodendritic autoreceptor, it is unlikely that a 5-HT_{1A} receptor mediated decrease in 5-HT release is responsible for the observed increase in ACh. In support of this hypothesis, the 5-HT_{1D} agonist sumatriptan administered through the dialysis probe did not alter basal ACh efflux at concentrations which are reported to decrease 5-HT release (1 μM; 115% of control). Administration of 8-OH-DPAT through the dialysis probe (10 μM) did not increase ACh efflux (77% of control), thus 5-HT_{1A} receptors in the hippocampus are not responsible for the effects of systemic 8-OH-DPAT. 5-HT_{1A} agonists may increase ACh efflux through receptors on ACh cell bodies in the septal area.

39.18

EFFECTS OF CHRONIC TREATMENT WITH 8-OH-DPAT (DPAT) AND GEPHRONE (GEP) ON THE SENSITIVITY OF SOMATODENDRITIC 5-HT_{1A} AUTORECEPTORS (5-HT_{1A}-AR). K. Bohmaker, A. Eison, F. Yocca and E. Meller. Dept. of Psychiatry, NYU Medical Center, New York, NY 10016 and ¹CNS Neuropharmacology, Bristol-Myers Squibb Co., Wallingford, CT 06492.

The clinical anxiolytic response to the 5-HT_{1A} partial agonist buspirone requires several weeks of treatment, suggesting that receptor adaptation may be involved. Electrophysiological and autoradiographic binding studies indicate a selective desensitization and downregulation of 5-HT_{1A}-AR after treatment with the partial agonists GEP and ipsapirone. We previously showed that 5-HT_{1A}-AR display a large receptor reserve (RR) for agonist-mediated inhibition of 5-HT synthesis (5-HTP levels after NSD-1015) in terminal areas (cortex (CTX) and hippocampus (HIPPP); Meller et al., Mol. Pharmacol. 37:231, 1990). In the present study the ability of chronic treatment with DPAT and GEP to modify the sensitivity of synthesis-inhibiting 5-HT_{1A}-AR was investigated as a function of agonist efficacy (full or partial), dose and route of administration.

Chronic treatment with the full agonist DPAT (2 weeks, 0.2 or 2.0 mg/kg/day, b.i.d., s.c.) did not alter the dose-response curve (DRC) to DPAT challenge (2 day washout) in CTX or HIPPP. DPAT administration via ALZET minipumps (2 weeks, 0.4 or 4 mg/kg/day) also did not alter 5-HT_{1A}-AR sensitivity to the weak partial agonist BMY-7378. In contrast, GEP administration by minipump (2 weeks, 20 mg/kg/day) resulted in a small but significant rightward shift (2.4-fold) in the DRC to DPAT challenge (2 days after washout) in the CTX, and a slightly smaller shift (1.8-fold) in the HIPPP. Furchgott analysis indicated a reduction in the extent of RR after chronic GEP treatment. These studies suggest that agonist efficacy may be an important factor in vulnerability to desensitization. Additional studies will be reported. Supported by NS 23618.

N-3 FATTY ACIDS MODULATE ARACHIDONIC ACID METABOLISM IN A PRIMARY CULTURE OF ASTROGLIAL CELLS

A. Petroni, M. Blasevich, F. Visioli, M. Salami, and C. Galli Institute of Pharmacological Sciences, University of Milan, 20133 Milan, Italy

The calcium-ionophore A23187 and platelet activating factor (PAF) activate arachidonic acid (AA) metabolism in a primary culture of astroglial cells, by generating cyclo (CO) and lipoxygenase (LO) products. These agents activate also, primarily, phospholipase A₂ and phospholipase C, respectively, as judged on the type of products generated by [³H] AA labeled cells, after stimulation. CO metabolites were generated by cells stimulated with both agonists, but production of Leukotriene C₄ was triggered only by A23187. 12- and 15-hydroxy-eicosa-tetraenoic acids (HETEs) were formed after A23187 stimulation, but these products were detected only when [³H] AA-labelled cells were used, after PAF stimulation. The PAF-induced formation of CO products, but not that induced by A23187, was blocked by PAF antagonists, which, however, did not affect the formation of HETEs from PAF-stimulated AA-labeled cells. Since the astroglial cell cultures, in our conditions, appeared to be depleted of the long chain n-3 fatty acids, especially of 22:6 (DHA) which is the major long chain polyunsaturated fatty acid in brain, we have added to the growth medium different μM concentrations of albumin-bound DHA for different time periods. We have then studied the incorporation of this fatty acid in cell lipids and the subsequent effects on the stimulated AA metabolism. After supplementation with DHA 5 μM for 48 hours, reduction of prostaglandin production was observed, and this was associated with a modified balance between 12- and 15-LO metabolites. Thus the eicosanoid system, which is activated in glial cells by endogenous products such as PAF, is modulated by the relative proportions of AA and DHA in cell phospholipids.

40.2

PLATELET-ACTIVATING FACTOR (PAF) RECEPTOR-MEDIATED SIGNAL TRANSDUCTION IN NEUROHYBRID NCB-20 CELLS. T.-L. Yue, J.M. Stadel, H.M. Sarau, E. Friedman, J.-L. Gu, H.Y. Wang, L.C. Shi, D.A. Powers, and G. Feuerstein. Dept. of Pharmacology, SmithKline Beecham, King of Prussia, PA 19406 and [#]Dept. of Psychiatry and Pharmacology, Med. Coll. of Pa., Phila., PA 19129.

In a previous study we reported that PAF induced a significant increase in intracellular free Ca⁺⁺ [(Ca⁺⁺)_i] in NCB-20 cells (Neurosci. 41:177, 1991). The present study was undertaken to further elucidate the mechanism involved in the regulation of PAF receptor-mediated signal transduction in NCB-20 cells. PI turnover was studied in NCB-20 cells pretreated with myo-[³H]inositol and [³H]inositol phosphates were separated by anion exchange resin column, and confirmed by HPLC. PKC activity was assessed by phosphorylation of histone III-S with [³²P]ATP. ADP-ribosylation of membrane proteins was studied as reported previously (Proc. Natl. Acad. Sci. USA 83:7320, 1986). PAF stimulated PI metabolism with an EC₅₀ of 1.96 nM and inhibited by PAF antagonist BN50739. PKC translocation was induced concentration-dependently by 0.001-10 nM PAF and also inhibited by BN50739. The PKC activator PDBu inhibited PAF-induced IP₃ formation and (Ca⁺⁺)_i elevation which was partially reversed by PKC inhibitor H7. Pretreatment with pertussis toxin (PTX) inhibited PAF-induced IP₃ production and elevation of (Ca⁺⁺)_i with a maximal reduction of 67% and 63%, respectively, at 300 ng/ml of PTX. Pretreatment with PTX inhibited subsequent ³²P labelling of the toxin substrate (a 38-kDa protein) in the membranes and correlated with the uncoupling of the PAF-induced IP₃ formation. However, PAF-stimulated PI turnover was not completely blocked and Ca⁺⁺ influx was only moderately inhibited by PTX. Our results reveal that neuronal cells possess PAFR linked to phospholipase C (PLC) and Ca⁺⁺ channels which are regulated by PKC, and distinct G proteins may couple the PAF receptor to activation of PLC and the increase in (Ca⁺⁺)_i.

AUTORADIOGRAPHIC AND BIOCHEMICAL STUDIES OF PLATELET-ACTIVATING FACTOR IN RAT AND FROG RETINA. J. Cluzel,^{1,2} M. Doly,² D. Torbati, and N.G. Bazan¹. ¹LSU Eye Center and Neuroscience Center, New Orleans, LA 70112 and ²Laboratoire de Biophysique, Faculté de Pharmacie, Clermont-Ferrand, France.

Platelet-activating factor (PAF) exerts effects on the b-wave of the electroretinogram (ERG) obtained from the isolated rat retina. Furthermore, we recently reported the presence of a high-affinity retinal PAF-binding site ($K_d = 2.9 \pm 0.4$ nM and $B_{max} = 0.85 \pm 0.61$ pmol/mg retinal protein). In this study, autoradiography was performed on the sites of PAF binding in the retina. Preliminary experiments showed that the exposure to fixing and dehydrating agents resulted in inactivation of the binding site. Slide-mounted tissue sections from frozen frog or rat eyes were incubated with ³H-PAF at 25°C in a buffer of 10 mM Tris, 2 mM EGTA, 10 mM MgCl₂ and 0.25% BSA. To prevent the loss of the radioactive material, we used double-step fixation with vapors of formaldehyde and osmium tetroxide. The autoradiogram was generated over a period of 2-3 weeks. Using low ³H-PAF concentration (10 nM), specific binding was localized in the inner and outer nuclear layer of the retina. BN 52021, a PAF receptor antagonist, displaced more than 75% of the total binding. Taken together, the *in vitro* binding and autoradiography provide support for the existence of PAF binding in the synaptic region. In addition to its role as an inflammatory mediator in the retina, PAF may also be a functional mediator, acting on synaptic networks of the retina. Supported by EY05121.

SUPPRESSION OF VOLTAGE-DEPENDENT CALCIUM CURRENTS IN HIPPOCAMPAL NEURONS BY SODIUM NITROPRUSSIDE. C.U. Eccles and B.E. Alger. Dept. Pharmacol. & Tox., Sch. of Pharm., and Dept. Physiol., Sch. of Med., Univ. of Md., Balt., MD 21201.

A calcium (Ca)-calmodulin-dependent pathway for the enzymatic formation of the radical nitric oxide (NO) from L-arginine has been identified in neuronal tissue. NO activates guanylate cyclase and generates cGMP. Recent findings that cGMP can regulate ion channels, including Ca channels (Doerner and Alger, Neuron 1:693-699, 1988), suggest a role for this pathway in neurons. We now report that drugs, such as sodium nitroprusside (NaNP), that spontaneously generate NO depress voltage-activated Ca current in hippocampal neurons.

Ca currents were recorded under whole-cell voltage clamp using Ba²⁺ as the charge carrier in acutely dissociated guinea pig hippocampal neurons and in primary cultures of fetal rat hippocampus. Bath- or locally applied NaNP (100-500 μM) produced a 40-90% depression of voltage-activated I_{Ca} in responding neurons. Although onset of the effect occurred within 1-2 minutes, depression of I_{Ca} was long lasting and not always reversible. Furthermore, hippocampal cells were not uniformly responsive to NaNP. Neurons isolated from area CA1, for example, rarely responded, while NaNP had effect in a majority of those from CA3. An NO-stimulated suppression of voltage-activated Ca current could act as a regulatory mechanism that decreases Ca influx from extracellular space after a Ca-triggered event has occurred.

40.7

LOCALIZATION OF ARGININOSUCCINATE SYNTHETASE IN THE BRAIN: RELATIONSHIP WITH NITRIC OXIDE SYNTHASE. S.R. Vincent, L.R.G. Arnt*, and W.E. O'Brien*. Div. of Neurol. Sciences, Dept. of Psychiat., The Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1Z3, and The Howard Hughes Medical Institute and Inst. for Molec. Genetics, Baylor College of Medicine, Houston, TX 77030

Argininosuccinate synthetase (ASS) is a key enzyme in the urea cycle where it catalyzes the conversion of citrulline and aspartate to argininosuccinate which can be cleaved to yield fumarate and arginine. High levels of ASS are found in brain, however its role in the absence of the urea cycle enzymes responsible for citrulline synthesis has been puzzling. Recent studies have indicated that some neurons possess the capacity to synthesize citrulline from arginine directly via the enzyme nitric oxide synthase, which can be localized using NADPH-diaphorase histochemistry. We have used antibodies to localize ASS in the brain and determined its relationship with neurons containing nitric oxide synthase. ASS immunoreactivity was found in distinct populations of neurons in various brain regions, glial cells were not stained. Some ASS-positive neurons, i.e. those in the laterodorsal tegmental nucleus, corresponded to nitric oxide synthase-containing neurons identified histochemically. However, many ASS-positive neurons, including those in layer VI of the cortex, the endopiriform nucleus, and the thalamus did not contain NADPH-diaphorase. In addition, some diaphorase-positive cell groups were not ASS-immunoreactive. Thus in some cell groups ASS may be involved in recycling citrulline formed intracellularly via nitric oxide synthase, while in other neurons it may produce argininosuccinate from extracellular sources of citrulline.

40.4

CELLULAR ELECTROPHYSIOLOGICAL ACTIONS OF NANOMOLAR CONCENTRATIONS OF HEPOXILIN ISOMERS ON HIPPOCAMPAL NEURONS OF THE RAT.

N. Gurevich, P. H. Wu, C. R. Pace-Asciak, E. J. Corey, W. G. Su, & P. L. Carlen. Playfair Neuroscience Unit, Toronto Western Hospital; Dept. of Pharmacology, University of Toronto; Research Institute, Hospital for Sick Children, Toronto, Canada, and Dept. of Chemistry, Harvard University, Cambridge, MA, USA.

In previous studies we have shown that hepoxilin A₃ (HxA₃) caused neuronal membrane hyperpolarization, enhanced afterhyperpolarizations (AHPs), increased inhibitory postsynaptic potentials (IPSPs) and decreased spike threshold (Carlen et al., Brain Res., 497, 171, 1989). HxA₃ can be biotransformed into the glutathione adduct, HxA₃-C (Pace-Asciak et al., PNAS, 87, 3037, 1990). Both the 8R and 8S isomers of HxA₃ and HxA₃-C are found in the CNS. HxA₃ is more active than HxA₃-C in mobilizing intracellular free calcium in human neutrophils (Dho et al., Biochem.J., 266, 63, 1990 and Pace-Asciak, unpublished). The 8R and 8S isomers of HxA₃ and HxA₃-C were tested on hippocampal CA1 neurons *in vitro*. Intracellular recordings were performed using the current clamp mode.

All Hx compounds were effective in causing a membrane hyperpolarization, enhancement of the AHPs and IPSPs and decrease of spike threshold in nanomolar concentrations as low as 5 nM. The compounds caused long-lasting effects and did not exhibit a concentration-response relationship. Due to the high variability of the responses obtained, it was difficult to conclude definitely that 8S isomers were more effective than 8R in influencing the hippocampal neuronal activity in the rat. A synthetic analogue of HxA₃-C in which the glutathionyl residue is located at the 9-carbon position instead of the 11-carbon position as in hepoxilin HxA₃-C was inactive in these neurons. These findings suggest that products in the hepoxilin pathway may function as neuromodulators. (Supported by the MRC, OMH and NIH).

FORMATION OF NITRIC OXIDE FROM L-ARGININE IN ISOLATED BRAIN MICROVESSELS P. Homayoun. Dept. of Mol. Biol., The Cleveland Clinic Foundation, 9500 Euclid Ave, Cleveland, Ohio 44106.

Nitric oxide (NO), the major source of endothelium derived relaxing factor, mediates the effect of vasoactive substances on the blood vessels. NO activates guanylate cyclase in endothelial and/or the neighboring cells. We have previously shown the activation of guanylate cyclase by a number of vasoactive agents in isolated rat cerebral microvessels (Homayoun et al., 1989). This report shows that NO can be synthesized in brain microvessels from L-arginine.

Microvessels were prepared by bulk isolation from rat cerebra and cerebella. [³H]citrulline formation from [³H]arginine was assayed in the 20000g supernatant of microvascular homogenates according to the method described by Bredt and Snyder (1989).

[³H]citrulline formation showed 2.2- and 3.3-fold increase over basal in cerebral and cerebellar microvessels respectively. The enzyme catalyzing this process is NADPH- and Ca⁺⁺-dependent.

[³H]arginine transformation was completely blocked in the presence of N^G-monomethyl L-arginine at the concentration of 200 μM.

These data suggest that hormonal stimulation of guanylate cyclase might be mediated through NO production in brain microvessels.

40.8

A NOVEL METHOD FOR MEASURING PURIFIED NITRIC OXIDE (NO)-SYNTHASE ACTIVITY IN RAT BRAIN: KINETIC CORRELATION OF NADP AND CITRULLINE FORMATION FROM L-ARGININE C.H. Kano, M. Nakane, H.H.H.W. Schmidt, J.F. Kerwin Jr., U. Forstermann, M. Williams and S.P. Amenic. Neuroscience, Pharmaceutical Discovery Division, ABBOTT Laboratories, Abbott Park, IL 60064-3500.

To establish the correlation between the formation of citrulline (CIT) and NADP from L-arginine and NADPH, steady state kinetics were measured under identical assay conditions using purified rat brain NO synthase (Proc. Natl. Acad. Sci. 88: 365, 1990). [³H]-CIT was separated from excess L-arginine on carboxymethyl-cellulose columns. NADP was measured using an enzymatic amplification procedure (alcohol dehydrogenase and diaphorase coupled with a redox dye, lodonitrotetrazolium, INT).

We found that during the 5 min. initial reaction, 8.2 picomoles of CIT and 42.2 picomoles of NADP were produced from the 50 μL assay mixture consisting of 3 nM enzyme, 8 μM arginine, 0.1 mM NADPH as well as Ca²⁺ and calmodulin. The ratio of NADP to CIT remained approximately 5 throughout the reaction. Biosynthesis of CIT from L-arginine by the rat brain enzyme shows a dependence on NADPH as reducing cofactor in the absence of exogenously added tetrahydrobiopterin.

The activity of the rat brain enzyme, as measured by the formation of NADP, was inhibited by the presence of the selective NO synthase inhibitors N^G-nitro-arginine and N^G-methyl-arginine.

CONCLUSION: Detailed kinetic analysis of this novel spectrophotometric assay validates the use of this rapid, sensitive and reliable method to measure the activity of purified NO synthase.

40.9

INHIBITION OF NITRIC OXIDE SYNTHESIS REDUCES THE HYPERTHERMIA INDUCED BY PROSTAGLANDIN INJECTION INTO THE PREOPTIC AREA IN RATS. S. Amir, E. De Blasio* and A. M. English*. Dept. of Psychology and Dept. of Chemistry and Biochemistry, Concordia Univ., Montreal, Quebec H3G 1M8, Canada.

Nitric oxide (NO) is a potent smooth muscle relaxing factor produced from L-arginine by the vascular endothelium. It is also synthesized in brain and has been implicated in neuronal signalling, and specifically in mediation of excitatory amino acid action on cyclic GMP production. We studied the involvement of NO in the thermogenic and hyperthermic actions of E₂ prostaglandin (PGE₂), a potent vasodilator and pyrogen involved in the brain fever mechanisms. PGE₂ (25 ng, 250 nl) was microinjected stereotaxically into the preoptic area of the anterior hypothalamus (POAH) of urethane-anaesthetized rats. The injection stimulated heat production in brown adipose tissue (BAT) and increased interscapular BAT (IBAT) and core temperatures by 2.26±0.07 and 1.22±0.05 °C, respectively (n=30). These thermogenic and hyperthermic effects were significantly attenuated by co-injection of N^G-monomethyl-L-arginine (NMMA, 25 µg), a competitive inhibitor of NO production from L-arginine (IBAT: 1.33±0.08; Core: 0.57±0.04 °C, n=22). Inclusion of L-arginine (50µg), though not D-arginine (50 µg) reversed the inhibitory effect of NMMA (25 µg) on intra-POAH PGE₂-induced increases in IBAT and core temperatures. Intra-POAH injection of NMMA (25µg) or L-arginine (50 µg) alone had no effect on IBAT and core temperatures. The results suggest that the effect on thermogenesis and body temperature induced by PGE₂ injection into the POAH is modulated by a local L-arginine-dependent and NMMA-sensitive NO-generating system.

40.11

IMMEDIATE EARLY GENE EXPRESSION IN ACRYLAMIDE NEUROTOXICITY. S. Kittur¹, H. Endo¹, G.A. Higgins¹, M. Sabri², P. Spencer², J.M. Stephens³, P.H. Pekala³. ¹Mol. Neurobiol., NIA/NIH, Baltimore, MD, 21224. ²Oregon Health Science Univ., Portland, OR 97201; ³Dept. of Biochem., East Carolina Univ., Greenville, NC 27858.

Acrylamide has been shown to be a potent neurotoxin. However, the molecular mechanism by which acrylamide produces pathological changes in the CNS is unknown. Northern blot analysis was used to investigate the expression of mRNA coding for *c-fos* and *c-jun* in brain tissue from acrylamide-treated rats. Male Sprague-Dawley rats (10-12 weeks) were injected with 100mg/kg acrylamide dissolved in normal saline or with saline control for the study of acute acrylamide treatment. Chronic acrylamide treatment and dosage effects were studied on induction of *c-fos* and *c-jun* mRNA. There was a significant increase in the expression of *c-jun* mRNA and *c-fos* mRNA in brain tissue from acute acrylamide-treated rats as compared to control tissue. *c-jun* mRNA was increased in chronic acrylamide-treated rats, but no significant effects were observed on *c-fos* levels. These results indicate that acrylamide may act through immediate early genes in the central nervous system.

40.13

PURIFICATION AND MOLECULAR CLONING OF GUANYLYL CYCLASE-ACTIVATING FACTOR SYNTHASE. M. Nakane, H. H. W. Schmidt* and F. Murad*. Abbott Laboratories, Abbott Park, IL 60064 and Northwestern University Medical School, Chicago, IL 60611.

The soluble form of guanylyl cyclase-activating factor (GAF) synthase from rat brain was purified to homogeneity by 2',5'-ADP-Sepharose and Superose 6 gel-permeation chromatography. SDS-polyacrylamide gel electrophoresis revealed a single protein band with a molecular mass of about 155kDa. The purified GAF synthase was N-terminally blocked. We digested the purified protein by endoproteinase Lys-C, separated the peptides by HPLC, and obtained the amino acid sequences of several peptides. We also produced rabbit polyclonal antisera against GAF synthase from rat brain.

Complementary DNA clones corresponding to GAF synthase have been isolated from rat brain λgt 11 library by screening with the polyclonal antisera against GAF synthase. Blot hybridization of total poly(A)⁺RNA from rat brain detected mRNA of about 8.5 kilobases. The partial amino acid sequences of GAF synthase showed a homology with some NADPH-dependent enzymes, indicating that GAF synthase may utilize a similar electron transfer mechanism from NADPH as these enzymes.

40.10

MODULATION OF ENDOGENOUS ADP-RIBOSYLATION IN BRAIN. M. B. Williams, X. Li and R. S. Jope. Dept. of Psychiatry, Univ. of Alabama, Birmingham, AL 35294.

Post-translational modifications of proteins can regulate their function. One modification consists of attachment of an ADP-ribose donated by NAD, a process which appears to be limited to relatively few proteins. Many studies of this process have utilized exogenous toxins, e.g., pertussis toxin and cholera toxin, to induce ADP-ribosylation of G-proteins. Endogenous mono-ADP-ribosyltransferases are present in some cells, and may be important in modulating G-proteins and other proteins.

Endogenous ADP-ribosylation was studied in homogenates from rat brain regions by measuring the incorporation of label from [³²P]NAD into proteins. Sodium nitroprusside, which spontaneously produces nitric oxide, enhanced the ADP-ribosylation of 47 kD and 39 kD proteins and diminished the ADP-ribosylation of a 49kD protein in the cerebral cortex, hippocampus, striatum, thalamus and cerebellum. In the neonatal cerebral cortex, ADP-ribosylation of an additional 110kD protein was also enhanced by sodium nitroprusside. The effect of sodium nitroprusside was dependent on concentration and time. Each protein demonstrated differential sensitivities to sodium nitroprusside and the rate of ADP-ribosylation was different for each protein. Cyclic GMP did not mimic the effects of sodium nitroprusside. From these and previously published results it is suggested that nitric oxide generated from sodium nitroprusside or endogenous sources may have modulatory effects through regulation of the endogenous ADP-ribosylation of proteins.

40.12

THE ROLE OF CYTOSOLIC FREE CALCIUM IN THE REGULATION OF PYRUVATE DEHYDROGENASE. H.-M. Huang, L. Toral-Barza*, K.-F. R. Sheu*, G.E. Gibson. Burke Med. Res. Inst. Cornell Univ. Med. Coll. White Plain, NY 10605

The pyruvate dehydrogenase complex (PDHC), a key mitochondrial enzyme, is regulated by phosphorylation (i.e. the PDHC activation state, PDHC_A). Studies in peripheral tissues have shown that the PDHC_A is mediated primarily by extramitochondrial calcium. In brain, calcium has been implicated in physiological and pathological processes. Both altered calcium and PDHC_A have been implicated in ischemic cell damage. To examine the relation between the PDHC_A and cytosolic free calcium ([Ca²⁺]_i), they were assessed in isolated nerve terminals under conditions that alter [Ca²⁺]_i, including treatment with KCN, a model for studying ischemia-related changes. In the presence of external calcium, K⁺ depolarization increased [Ca²⁺]_i and activated PDHC from 49.2% to 59.6% (p<0.05). Elevation of [Ca²⁺]_i is required for activation of PDHC by K⁺, since omission of external calcium blocked activation and the elevation of [Ca²⁺]_i. However, an increase of [Ca²⁺]_i is not necessarily correlated to the PDHC_A, since the calcium ionophore A23187 alone increased [Ca²⁺]_i but did not change PDHC_A. K⁺ and A23187 elevated [Ca²⁺]_i more than K⁺ alone, but did not further increase PDHC_A. Although KCN further increased the K⁺-stimulated elevation of [Ca²⁺]_i, it did not exaggerate the change in PDHC_A. Thus, activation of PDHC requires both external calcium and K⁺.

NMDA INDUCTION OF C-FOS IN DENTATE GYRUS NEURONS IS INHIBITED BY THE PHOSPHOLIPASE A₂ INHIBITOR MEPACRINE. L.S. LERA & J.O. MCNAMARA. DUKE AND VA MED CTR, DURHAM, NC

Stimulation of N-methyl-D-aspartate (NMDA) receptors on dentate gyrus neurons causes an increase of intracellular calcium and expression of the immediate early gene (IEG) *c-fos*. The increase in *c-fos* is dependent on the rise in intracellular calcium but the calcium-dependent pathways involved in the induction of *c-fos* have not been defined. NMDA evokes a calcium dependent release of arachidonic acid from CNS neurons via phospholipase A₂ activation (Dumuis et al., Nature 347: 182-184, 1990; Sanfeliu et al., Brain Res. 526: 241-248, 1990). We therefore tested whether phospholipase A₂ is involved in NMDA induced increases in *c-fos*. Dentate gyrus neurons derived from 4 day old rats were maintained *in vitro* for 7-10 days. *c-fos* mRNA expression was measured by *in situ* hybridization using ³²P-dATP incorporated into a 50 base pair oligonucleotide complementary to the coding region of rat *c-fos* (Curran, T., et al., Oncogene 2: 74-87, 1987). Intracellular calcium in individual neurons was measured using the calcium sensitive dye Fura-2.

NMDA (50µM) produced a striking increase in intracellular calcium (75nM to 300nM) in dentate neurons. NMDA also caused a 10-15 fold increase in *c-fos* mRNA levels in individual neurons in a calcium dependent manner. The phospholipase A₂ inhibitor mepacrine (50µM) blocked NMDA induced increases in *c-fos* mRNA (12.8 ± 0.6 silver grains/cell vs. 1.9 ± 0.3 silver grains/cell) but had no effect on NMDA mediated calcium influx. Our results suggest that activating phospholipase A₂ is an absolute requirement for NMDA receptor mediated induction of *c-fos*. The absence of a mepacrine effect on calcium influx indicates that mepacrine did not inhibit NMDA receptor activation. Studies are in progress to further define the sequence of intracellular events coupling NMDA receptor activation to the induction of IEGs.

40.15

MOLECULAR SPECIES ANALYSIS OF PHOSPHATIDYLETHANOL (PE) FORMED IN PHORBOL ESTER-TREATED PC12 CELLS SUGGESTS A PHOSPHATIDYLCHOLINE (PC) PRECURSOR. P.G. Holbrook, L.K. Pannell* and J.W. Daly Laboratory of Bioorganic Chemistry; Bldg. 8, Rm 1A-15; NIH; Bethesda MD 20892

Phospholipase D-catalyzed hydrolysis of a phospholipid produces phosphatidic acid (PA) and in the presence of ethanol, phosphatidylethanol (PEt). Activation of this enzyme is believed to underlie enhanced PC-turnover elicited by the tumor-promoting phorbol ester, 12-O-tetradecanoyl-13-acetate (TPA). PC12 cells were incubated for 5 or 30 minutes with ethanol (1%) in the presence or absence of TPA (80 nM). Phospholipids were extracted and separated by silica-gel thin layer chromatography. Molecular species analysis of phospholipids was performed by fast atom bombardment mass spectrometry (FAB) using a JEOL JMS-SX102 Mass Spectrometer. Fatty acid composition and head group structure were confirmed by link-scan of individual molecular ions. Material which represented 1% of the total lipid phosphorous and comigrated with PA had molecular ions corresponding in mass to phosphatidylglycerol and was shown to be its structural isomer, lysobisphosphatidic acid. The molecular species of PEt formed in TPA-treated cells were similar to those of PC isolated from untreated cells. These studies support the notion that PC is the precursor of PEt formed in TPA-treated cells.

BEHAVIORAL PHARMACOLOGY I

41.1

EFFECTS OF KAPPA OPIOID AGONISTS ON DOPAMINE RECEPTOR-MEDIATED BEHAVIORS. C. Marin, T.M. Engber, P. Chaudhuri*, A. Peppe* and T.N. Chase. ETB, NINDS, NIH, Bethesda, MD 20892.

Current evidence suggests that striatal D-1 dopamine receptors reside largely on neurons which project to the substantia nigra pars reticulata and entopeduncular nucleus (internal segment of globus pallidus in primates). In contrast, striatal D-2 receptors occur primarily on neurons which project to the external segment of globus pallidus (external segment in primates). The opioid peptide dynorphin, an endogenous agonist of kappa opioid receptors, is expressed in D-1 receptor-containing striatonigral cells. To evaluate the contribution of dynorphin-containing projections to motor function, we studied the acute effects of the kappa opioid agonists, spiradoline (U62066E; 0.5, 1 and 5 mg/kg, sc) and U50,488 (1, 10 and 25 mg/kg, sc) on D-1 and D-2 receptor-mediated behavior in rats. SCH 23390-induced catalepsy (0.5 mg/kg, sc) was significantly increased by spiradoline and U50,488 but raclopride-induced catalepsy (2.5 mg/kg, ip) was not affected. SKF 38393-induced grooming (10 mg/kg, ip) was attenuated by both kappa agonists in a dose-dependent manner. Quinpirole-induced stereotypies (1 mg/kg, sc) were also decreased by both drugs, but jerking was observed in these animals. Jerking was blocked by the selective D-1 agonist SKF 38393 (10 mg/kg, ip) and re-established with SCH 23390 (5 mg/kg, sc) pretreatment. These results suggest that kappa opioid receptor stimulation has functional effects on certain striatally mediated motor functions resembling those of D-1 receptor blockade.

41.3

THE KAPPA OPIOID AGONIST PD117302 FACILITATES BEHAVIORAL RECOVERY FOLLOWING FOUR-VESSEL CEREBRAL ISCHEMIA IN RATS. R.F. Genovese, X-C.M. Lu, J.E. Moreton, K. Miller* and F.C. Tortella, Dept. of Med. Neurosci., Walter Reed Army Inst. of Res., Washington, DC 20307 and Univ. of Maryland, Sch. of Pharmacy, Baltimore, MD 21201.

Rats trained to lever press under a multiple schedule of food reinforcement (FR20, FI2') were prepared with bilateral vertebral artery occlusion and common carotid artery (CCA) snares. PD117302 (1.0 mg/kg, IP) (n=4) or saline (n=4) was administered after 15-min CCA occlusion (at reperfusion, and 2, 4, and 6 h post-occlusion). Sham occluded rats also received PD117302 (n=3) or saline (n=3). Although variability between subjects was observed, responding tended to return sooner in rats treated with PD117302 post-occlusion, as compared to rats treated with saline. Some behavioral disruption was also observed in sham occluded rats, however, substantial differences between PD117302 and saline treatments were not evident. These results suggest that PD117302 confers "behavioral protection" against global forebrain ischemia, and are consistent with previous studies demonstrating neuroprotective properties of PD117302 and other kappa opioid compounds.

41.2

EVIDENCE FOR TOLERANCE TO STIMULUS EFFECTS OF MORPHINE IN PIGEONS. S.A. Vanecek and A.M. Young. Department of Psychology, Wayne State University, Detroit, MI 48202.

Pigeons (N=8) were trained to discriminate among i.m. injections of saline, 1.8 mg/kg morphine (MS), and 10 mg/kg MS under FR 30 schedules of food reinforcement. MS (0.1-32 mg/kg) evoked dose-dependent substitution with both training doses during single trial test sessions. Similar results were obtained in tests of cumulative doses, with 0.18 mg/kg MS evoking only saline-appropriate responding, 1.8 mg/kg substituting for the low training dose, higher doses (5.6-32 mg/kg) substituting for the high training dose, and 32 or 56 mg/kg MS markedly suppressing rates. To assess development of tolerance, training was discontinued in four subjects, and 10 mg/kg MS, b.i.d., was administered for 14 days. After this treatment, the dose to suppress rates increased 3- to 5-fold, whereas the doses required to evoke substitution with either training dose did not change. Following an additional week of treatment with 56 mg/kg, b.i.d., the dose required to suppress rates showed no further tolerance, but the dose required to substitute for the low training dose increased by at least 3-fold in all subjects. The dose required to substitute for the high training dose increased 10-fold in one subject, but could not be determined in the remaining three due to severe rate suppression. Acute pretreatment with 56 mg/kg MS 24 h prior to a test did not change the doses required for stimulus or rate-altering effects. These results suggest that repeated MS treatment induces tolerance to discriminative stimulus effects of both low and high training doses of MS and to rate-altering effects of MS. (Supported by DA03796 and K02 DA00132)

41.4

BUPRENORPHINE DRUG DISCRIMINATION IN OPIATE-NAIVE ANIMALS: CROSS GENERALIZATION WITH MORPHINE. S. Pourmaghash and A.L. Riley. The American University, Washington, D.C. 20016

The mixed opioid agonist/antagonist buprenorphine generalizes to morphine in animals trained to discriminate morphine from its vehicle in a drug discrimination procedure (see Shannon et al., *J. Pharmacol. Exp. Ther.*, 229: 768-774, 1984), an effect likely due to the fact that these compounds both act as mu receptor agonists. Because buprenorphine also has kappa antagonist properties, it is possible that this antagonist activity at the kappa receptor could influence the basis of its discriminative control and, thereby, affect the generalization of mu agonists such as morphine. In a test of this, animals were trained to discriminate buprenorphine from its vehicle and then were injected with various doses of morphine (0.56, 1, 1.8, 3.2, 5.6, 10 and 18 mg/kg). For all subjects, morphine dose-dependently generalized to buprenorphine. These effects are consistent with the previously-reported generalization of the two compounds and the position noted by Negus et al. (*Psychopharmacology* 98:141-143, 1989) that in opiate-naive animals buprenorphine's agonist properties overshadow its antagonist properties (which are evident only in opiate-dependent animals).

41.5

ANALYSIS OF THE DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE: INTERACTIONS WITH OPIATES. J. Broadbent and S.I. Dworkin, Department of Physiology and Pharmacology, Wake Forest University, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1083.

While evidence now suggests that inhibition of dopamine (DA) uptake plays an important role in the discriminative stimulus properties of cocaine, DA is also known to interact with many other neurotransmitters, including opiates. Indeed, relatively recent data from both neurochemical and behavioral studies have highlighted this interaction; specific σ agonists increase DA release while the mixed μ agonist/antagonist buprenorphine inhibits cocaine self-administration. The present study therefore assessed potential interactions between opiate receptor systems and the stimulus properties of cocaine in rats trained to discriminate cocaine (10 mg/kg) from saline. Naltrindole, a purportedly selective σ antagonist, did not antagonize the cocaine cue even when tested at high doses (3-30 mg/kg, s.c.). Further, naltrindole did not significantly affect rates of responding. These preliminary data, suggest that blockade of σ opiate receptors does not influence the discriminative stimulus properties of cocaine.

41.7

THE STIMULUS PROPERTIES OF MU AGONISTS BUT NOT A KAPPA AGONIST SUBSTITUTES FOR THOSE OF DOPAMINE D2 AND DOPAMINE D1 AGONISTS IN A DRUG DISCRIMINATION PARADIGM. S.C. Johnson, G.M. Samoriski and D.A. Cory-Slechta, Environ. Health Sci. Center and Program in Neuroscience, School of Med. and Dent., Univ. of Rochester, Rochester, N.Y. 14642.

Neurotransmitter systems in the CNS are thought to interact with one another in a number of ways, both postsynaptically and presynaptically. In vivo and synaptosomal studies have shown that mu opioid agonists enhance dopamine (DA) release, while kappa opioid agonists decrease it. If such interactions have functional or behavioral properties, then mu agonists, but not kappa agonists would be expected to substitute for D2 postsynaptic receptor agonists or for D1 postsynaptic receptor agonists in a drug discrimination (DD) procedure. This hypothesis was tested in rats trained to discriminate an i.p. injection of 0.050 mg/kg of the DA D2 agonist quinpirole HCl from saline or an I.P. injection of 6.0 mg/kg of the DA D1 agonist SKF-38393 from saline in a standard two lever DD. Following acquisition of the discrimination, various doses of the mu agonists morphine, and fentanyl, or the kappa agonist U50,488 were substituted for the training drugs during generalization tests with drugs and doses tested in a random sequence. Morphine, in a dose range of 0.3 to 10.0 mg/kg, engendered SKF-38393 responding in a dose-dependent manner, with levels of generalization reaching > 90% for some individual animals at the highest dose. The mu agonist fentanyl, in a dose range of 0.025 to 0.3 mg/kg, substituted for both quinpirole and SKF-38393, reaching levels of drug lever responding of up to 80% in some rats. In contrast, the kappa agonist U-50,488 did not engender either quinpirole or SKF-38393 responding at any of the doses tested (2 and 4 mg/kg). These results support a role for mu agonists in modulating the behavioral functions of dopaminergic systems, including both D1 and D2 receptor function, and suggest that drug discrimination is a useful method for evaluating the functional properties of interactions between neurotransmitter systems. This work was supported by NIH grant R01 ES05017.

41.9

DOPAMINE AUTORECEPTOR AGONISTS DECREASE LOCOMOTOR ACTIVITY OF 21-DAY- BUT NOT 10-DAY-OLD RATS. M.-Y. Lin* and D.E. Walters, Div. of Pharmacology, Dept. of Pharmacol Sciences, Auburn Univ., Auburn, AL 36849-5503.

In a previous study the DA autoreceptor agonist (-)-3-PPP decreased locomotor activity of 28-day-old rats. In the present study, we examined the effects of (-)-3-PPP and the putative DA autoreceptor agonists apomorphine (APO), B-HT 920, PD 128483 and SND 919 on locomotor activity in developing rats. 10- and 21-day-old rats were injected i.p. with normal saline or an agonist and placed in a 20 x 20 x 30 cm Plexiglass cage set inside a photocell activity monitor containing 8 infrared photocells in each horizontal direction. Their activity was monitored for a period of 15 minutes. All experiments were conducted in a quiet, dimly lit room. Each of the DA agonists produced a dose-related decrease in locomotor activity of 21-day-old rats. At higher doses, APO and B-HT 920 increased locomotor activity whereas (-)-3-PPP, PD 128483 and SND 919 showed no evidence of postsynaptic agonist activity at any of the doses used. In contrast, at 10 days of age, there were no notable changes in locomotor activity in either direction following injection of each agonist at these doses. The results suggest that brain DA autoreceptors are functional behaviorally by 21 days of age and that the ability to exert control over locomotor activity develops between 10 and 21 days of age. Research supported by Auburn Univ. Research Grant-in-Aid.

41.6

DIFFERENT INVOLVEMENT OF D1 AND D2 RECEPTOR SUBTYPES IN DIFFERENT BEHAVIORAL RESPONSES TO DOPAMINE AGONISTS. S. Cabib, S. Puglisi-Allegra Istituto di Psicobiologia e Psicofarmacologia (CNR), via Reno 1, I-00198 Roma, Italy

High doses of the classic Dopamine (DA) agonist apomorphine induce in the mouse a typical stereotyped pattern of cage climbing behavior widely used as test for DA active substances. Neither the D2 nor the D1 selective agonists LY171555 and SKF38393 are able to induce this response. However, coadministration of the two selective agonists produce the same effect as apomorphine. 24 hrs after an intrastriatal injection of the irreversible antagonist EEDQ, apomorphine-induced climbing was totally suppressed, while no change in this response was detectable in mice that received EEDQ injection in the nucleus accumbens septi. A 70% reduction of climbing was also observed in mice protected with $\alpha 1$, $\alpha 2$, 5HT2 antagonists and (-)-sulpiride (D2 antagonist) or SCH 23390 (D1 antagonist) before intrastriatal injection of EEDQ. These results indicate that apomorphine-induced stereotyped climbing in the mouse is dependent on a positive interaction between D1 and D2 DA receptor subtypes at striatal level.

Cocaine, amphetamine, apomorphine at high doses as well as coadministration of high doses of selective D1 and D2 agonists, all induce increased horizontal locomotion in C57BL/6 mice; while selective agonists at D1 or D2 receptors are unable to produce this same response. However, although the selective D1 antagonist SCH 23390, at *per se* ineffective doses, is able to prevent both cocaine- and amphetamine- induced hyperlocomotion, the selective D2 antagonist (-)-sulpiride has no effect on this response even at hypokinetic doses. Taken together, these results support the view that different interactions between D1 and D2 DA receptor subtypes may be involved in the different behavioral effects of DA active substances

41.8

EFFECTS OF CHRONIC SCH 23390 OR ACUTE EEDQ ON THE DISCRIMINATIVE STIMULUS EFFECTS OF SKF 38393

Cao Gui-Hua*, Bruce D. Perry, William L. Woolverton, Drug Abuse Research Center, Pritzker School of Medicine, University of Chicago, Chicago, IL 60637

Three groups of rats (N=8/group) were trained in a two-lever, food-reinforced drug discrimination paradigm, to discriminate the D1 agonist SKF 38393 (SKF; 8.0 mg/kg, i.p.) from saline. After acquisition of the discrimination, the dose-response function for SKF (2.0-16 mg/kg, i.p.) was determined using a cumulative dosing procedure. In one group, the SKF dose-response function was redetermined 1 week after a regimen of 0.25 mg/kg SCH 23390 (SCH), i.p., once/day for 10 days, again 1 week after a second regimen of 0.5 mg/kg SCH, i.p., twice/day for 10 days and a third time after a regimen of 1.0 mg/kg SCH, i.p., twice/day for 21 days. SKF dose-response functions were redetermined in control rats after identical regimens of saline. In the third group, SKF dose-response functions were redetermined 24 hours after an injection of EEDQ vehicle; again 24 hours after an injection of 3.0 mg/kg; again 48 hours after 6.0 mg/kg EEDQ; and again 48 hours after 2 consecutive daily injections of 6.0 mg/kg EEDQ (12 mg/kg total). The dose-response function for the percentage of responses that occurred on the SKF lever (%DL) shifted significantly to the left following the second regimen of SCH; there was no further shift after the third regimen. The effects of SKF on response rate were unchanged. Repeated administration of saline did not alter the SKF dose-response function for %DL or response rate. Administration EEDQ vehicle or EEDQ also failed to alter the SKF %DL dose-response functions. However, EEDQ itself decreased response rate and enhanced the effects of SKF. Binding studies conducted 14 days after SCH or 48 hours after EEDQ exposure indicated an significant increase in Bmax for D1 binding sites in the corpus striatum (CS) in SCH-treated rats. Bmax tended to increase in the nucleus accumbens (NA) but did not achieve statistical significance (p=0.057). EEDQ treatment decreased Bmax in CS but had no effect in NA. Kd was unchanged in either region by either treatment. The results demonstrate that repeated administration of the D1 antagonist SCH can sensitize rats to the DS effects of the D1 agonist SKF, perhaps via an up-regulation of D1 receptors in the brain. Further, the results suggest that drug discrimination is a useful *in vivo* bioassay for measuring changes in CNS receptors. (Supported by NIH grant GM-22220).

41.10

EVIDENCE AGAINST DIFFERENT MOTOR BEHAVIOUR ELICITED BY SELECTIVE D-2 AND D-1 RECEPTORS STIMULATION IN MONKEYS

MR Luquin, J. Laguna* and JA Obeso

Department of Neurology, Movement Disorders Unit, Clinica Universitaria, Pamplona SPAIN

We have studied the motor responses elicited by independent administration of a D-2 agonist

(+)-PHNO and of a D-1 agonist (CY 208 243) to 5 parkinsonian monkeys. +-PHNO (0.04, 0.12, 0.3, 0.4 μ g/kg) and CY 208 243 (0.1, 0.2, 0.4, 0.8 mg/kg) induced a similar relief of parkinsonism with regard to reduction in the disability score (p>0.05). Intensity and type of dyskinesias elicited by either drug were also similar for the whole range of doses (p>0.05).

Reserpine pretreatment (1.5 mg/kg) gave rise to a significant reduction in the duration of motor benefit induced by (+) PHNO (p<0.0001) and CY 208 243 (p<0.05) and increased the latency to the maximal effect (p<0.001). The magnitude of the motor response to each drug and the dyskinetic score did not change (p>0.05). These results indicate that selective D-1 or D-2 stimulation induces similar motor response in parkinsonian monkeys which seems to be independent of endogenous dopamine.

41.11

CAN SPONTANEOUS EYE BLINK RATE ASSESS CENTRAL DOPAMINE FUNCTION? *M.S. Lawrence**, J.R. Taylor, J.D. Elsworth, R.H. Roth, J.R. Sladek, Jr. & T.J. Collier, and D.E. Redmond, Jr. Dept. of Psychiat. & Pharm., Yale Univ. Sch. of Med., New Haven, CT 06510, §Dept. of Neurobiol. & Anat., Univ. Rochester Sch. of Med. & Dent., Rochester, N.Y. 14642.

Previous studies have suggested a dopaminergic regulation of spontaneous eye blink rate in human and non-human primates. MPTP-treatment induces decreases in eye blink rates (Lawrence & Redmond, 1991). Dihydroxidine, a full D1 agonist, produced a rapid and dose-dependent (up to 1 mg/kg i.m.) increase in blink rate in 5 normal *Cercopithecus aethiops sabaeus* (St. Kitts green monkeys). The elevation in blink rate elicited by 0.3 mg/kg dihydroxidine was completely reversed by prior administration of a specific D1 antagonist, SCH 23390 (0.01 mg/kg i.m.), but was unaffected by prior administration of a specific D2 antagonist, remoxipride (1 mg/kg i.m.) The specific D2 agonist, (+)-4-propyl-9-hydroxy-naphoxazine (PHNO) (up to 0.01 mg/kg i.m.) also increased blink rate, reversed by pretreatment with D2 antagonists (Lawrence & Redmond, 1991; Elsworth, et al, unpublished). Since these data indicate that spontaneous blink rate is independently regulated by both D1 and D2 dopamine receptors, blink rate was measured from videotapes of 4 monkeys after possible reinnervation of the caudate nucleus by viable dopamine-containing grafts of fetal substantia nigra tissue, compared with 3 monkeys that received control grafts. A trend toward increases in blink rate was seen in the SN-caudate grafted monkeys, but not in the control subjects. However, spontaneous improvement in blink rates in mildly symptomatic monkeys has also been observed after MPTP-treatment alone, raising the question as to whether blink rates correlate with direct brain biochemical measures of dopamine function.

41.13

COMPARISON OF THE EFFECT ON LATENT INHIBITION OF DOPAMINE AGONISTS AND ATYPICAL ANTIPSYCHOTICS IN RATS. L.A. Dunn, R.J. Scibilia*, J.A. Franks*, C.D. Kilts. Dept. of Psychiatry, Duke Univ. Med. Ctr. Durham, NC 27710.

Latent inhibition (LI) of a conditioned response is a behavioral index of the stimulus filtering aspect of selective attention which is commonly observed to be defective in schizophrenia. LI is enhanced by typical antipsychotic drugs and is attenuated by amphetamine treatment in rats. Atypical antipsychotic drugs do not increase serum prolactin levels and have low or no liability for extrapyramidal side effects, neuroleptic malignant syndrome or tardive dyskinesia. We have reported previously that one atypical antipsychotic, clozapine, causes an amphetamine-like attenuation of LI (Dunn et al., Soc. Neurosci. Abstr., 16,2:1053, 1990). We have now evaluated the effects of the D₁ agonist SKF 38393, the D₂ agonist quinpirole and the atypical antipsychotics fluperlapine and amperozide on LI of the formation of a CER following 0 or 20 stimulus preexposures. A 2 x 3 ANOVA showed dose related attenuation of LI (p<0.05) by both the acute administration of SKF 38393 (0, 3 and 10 mg/kg sc.) and quinpirole (0, 0.1, 0.3 and 0.56 mg/kg). The atypical antipsychotics amperozide (1 mg/kg, i.p., 7 days) and fluperlapine (10 mg/kg, i.p., 7 days) also significantly decreased LI (p<0.05). The fact that the atypical antipsychotic drugs clozapine, fluperlapine and amperozide mimic the effects of D₁, D₂ and indirect dopamine agonists suggests that the therapeutic effects of these drugs are mediated by unique actions relative to typical antipsychotic drugs. (Supported by the Scottish Rite Foundation).

41.15

EFFECTS OF CHRONIC HALOPERIDOL AND CLOZAPINE ADMINISTRATION IN RATS WITH LESIONS OF THE FRONTAL CORTEX. G. Hussain*, G.E. Jaskiw, H.Y. Meltzer. Psychobiology Dept., Case Western Reserve University and Veterans Administration Medical Center, VAMC Cleveland, OH 44106.

Chronic administration of typical but not of atypical antipsychotic drugs (AAPDs), upregulates both mesolimbic and striatal dopamine (DA) type II (D₂) receptors, and augments higher order stereotypic responses to apomorphine (APO). Such indices of DA transmission can also be modulated by the frontal cortex (FCx). The present study assessed effects of chronic AAPD treatment in rats with FCx lesions. Male Zivic-Miller rats (220-250 gr) had trepaninations (SHAM) or knife cuts made across the frontal cortex (FCx) (AP ± 3.7, ML ± 4.0, VD ± 4.0). After 28d recovery, rats received a 21d treatment with haloperidol (HAL) 2 mg/kg/d, clozapine (CLZ) 20 mg/kg/d or vehicle in drinking water. Stereotypy after APO 0.75 mg/kg SC and catalepsy after HAL 1.0 mg/kg IP were assessed 3d and 7d after the last day of chronic treatment respectively. Overall, biting stereotypies were enhanced both by the FCx lesion and by HAL treatment but not by CLZ treatment. Furthermore, biting behaviors were not increased in the CLZ/FCx group. Overall the FCx lesion as well as HAL treatment reduced the intensity of HAL-induced catalepsy. The effects of CLZ on catalepsy were subtle and complex. Our data indicate that the differential effects of CLZ on stereotypy are not significantly altered by the type of FCx lesion induced here.

41.12

EFFECT OF D1 AND D2 ANTAGONISTS ON COCAINE-INDUCED TASTE AVERSIONS. C.M. Ferrari and A.L. Riley. The American University, Washington, D.C. 20016.

Recently, subcutaneous (SC) cocaine has been shown to produce robust conditioned taste aversions (CTA), with subjects decreasing saccharin consumption by 95% by the fourth saccharin-cocaine (32 mg/kg) pairing (Ferrari, O'Connor & Riley, *Pharmacol. Biochem. & Behav.*, 38: 267-271, 1991). To address the role of dopamine in this aversion, the present study compared the effects of SCH-23390, a D₁ antagonist, and haloperidol, a D₂ antagonist, on its acquisition. Water-deprived rats were given 20-min access to saccharin followed by an injection of SCH-23390 (0, 0.056, 0.10, 0.18, 0.32 or 0.56 mg/kg) or haloperidol (0, 0.42, 0.75, 1.3 or 2.4 mg/kg) followed 30 min later by a SC injection of 32 mg/kg cocaine. This procedure was repeated every fourth day for a minimum of five conditioning trials. On intervening days, subjects were given 20-min access to water. SCH-23390 antagonized the cocaine aversion at all doses except the lowest (0.056 mg/kg) for at least one trial. Haloperidol antagonized the cocaine aversion at all doses for at least seven trials. Although these data suggest that activation of either the D₁ or D₂ receptor is sufficient to induce the aversion (based on the antagonism with either SCH-23390 or haloperidol), some interaction between the subtypes in mediating the aversion to cocaine remains a possibility (see Wanibuchi & Usada, *Psychopharmacology*, 102: 339-342, 1990).

(+)-3-PPP FAILS TO ANTAGONIZE AN APOMORPHINE-INDUCED MODEL OF PSYCHOSIS IN A PRIMATE SOCIAL COLONY. D.J. McGinness Grimes^{1,2}, R.F. Schlemmer^{1,2}, N.L. Katz¹, D.P. Taylor³ & J.M. Davis^{1,2}. ¹U. of Ill. at Chgo., ²Ill. St. Psych. Inst., Chicago IL 60612 & ³Bristol-Myers Squibb, Wallingford, CT 06492

The role of CNS sigma (σ) binding sites in the mediation of behavior has not been elucidated. Since many antipsychotic (AP) agents bind to σ sites as well as dopamine (DA) receptors, there is considerable interest in the potential role of σ ligands as AP. One model for screening compounds for potential AP activity is DA agonist-induced behavioral changes in nonhuman primate social colonies. In a stable adult stump-tail macaque (*Macaca arctoides*) social colony, the DA agonist apomorphine (APO) induces behavioral changes that model human stimulant-induced psychosis. Known AP reverse the core behavioral changes in this model. The σ ligand BMY14802, an AP candidate, produces a dose-dependent antagonism of core behavioral changes induced by APO administration to members of a social colony. The purpose of this study was to examine the behavioral profile of another σ ligand with a low affinity for D₂ sites, +(3-(3-hydroxyphenyl)-N-(1-propyl)-piperidine, (3-PPP) in the APO model. After determination of baseline behavior, 4 doses of 3-PPP (0.1-3.0 mg/kg) were administered i.m. to 4 monkeys in a crossover design for 2 days/dose. 3-PPP was given 1.0 hr prior to the start of the first 60 min observation session on both days. APO (1.0 mg/kg, i.m.) was administered 15 mins after the first observation session and 15 min later a second observation session was conducted. Each session employed a "blind" observer who recorded > 40 behaviors. 3-PPP alone induced only minor changes (increased self-grooming) and did not induce movement abnormalities or sedation. APO increased the distance between monkeys in the cage, checking (visual scanning), submissive gestures and induced stereotypy. Unlike BMY14802, 3-PPP did not block the behavioral changes induced by APO administration. These results do not predict that 3-PPP has AP activity but they do not clarify the role of σ ligands as AP.

41.16

HALOPERIDOL SLOWS LOCOMOTION AND INDUCES WITHIN-SESSION DECREMENTS IN EACH COMPONENT OF A RUN-CLIMB-RUN BEHAVIORAL CHAIN. S.C. Fowler and L. Senyuz*. Depts. of Psychol. and Pharm., Univ. of Miss., University, MS 38677

To determine if haloperidol differentially affects locomotor responses with different topographies, 10 hungry rats were successfully trained to traverse a 1.35-m-long rubber mat, climb a .59-m vertical rope, and cross a .8-m mat to reach and lick sweetened milk for 5 s. As recorded by video tape, absolute speed of locomotion was greatest in the first segment and least in the rope-climb link of the behavioral chain. Haloperidol (0.04 - 0.32 mg/kg, ip, 45 min) decreased locomotion speed and produced within-session decrements (across the 10 trials given per day) in all 3 components of the behavioral chain. Drug-induced failures to complete a trial increased as a joint function of dose and trial number. The drug did not attenuate normal increases in speed between trial 1 and trail 2. Taken together the results are more consistent with pseudoParkinsonism than with incentive/motivational deficits induced by haloperidol. Supported by MH43429.

DESENSITIZATION & CROSS-DESENSITIZATION TO THE BLADDER IRRITANT EFFECTS OF CAPSAICIN AND RESINIFERATOXIN IN RATS: BLOCKADE BY RUTHENIUM RED. V.J. Carlisi, A. Mattia and F. Porreca. Dept. of Pharmacology, Univ. of Arizona HSC, Tucson, AZ 85724

Capsaicin (CAP) and resiniferatoxin (RTX) may act at the same primary afferents to alter the micturition reflex. This study characterized the acute excitatory properties, development of desensitization and possible cross-desensitization of CAP and RTX after intravesical (*i.ves.*) administration to previously catheterized (4 d earlier) female, Sprague-Dawley rats. Additionally, the sensitivity of these effects to ruthenium red (RR) was studied. Lick/bite behaviors were scored during a 15 min observation period after *i.ves.* vehicle (VEH), CAP, or RTX. The incidence of lick/bite after CAP (1 μ mol) was (41.2 \pm 5.4%), a value significantly higher than that with VEH (15.3 \pm 1.5%). Lower (0.1 μ mol) and higher (3 μ mol) doses of CAP were ineffective and behaviorally toxic, respectively. Following CAP (1 μ mol), a second exposure to CAP (1 μ mol) decreased the response to the control level (18.6 \pm 1.4%), indicating desensitization. The irritant effects of RTX were also dose-related, with a lick/bite score of 34.6 \pm 2.5, 67.0 \pm 5.6 and 88.0 \pm 2.4%, after 0.1, 1 and 3 nmol of *i.ves.* RTX, respectively; desensitization was produced by successive RTX (1 nmol) application. After *i.ves.* CAP (1 μ mol) or RTX (1 nmol), the opposite treatment (RTX or CAP, respectively) after 30 min, failed to elicit a response differing from VEH, indicating cross-desensitization. Further, the desensitizing effect of CAP (1 μ mol) was overcome by RTX (10 nmol). The acute irritant and desensitization responses for CAP and RTX were decreased by pretreatment with RR (1.5 mg/kg, *s.c.*, -15 min), a treatment which did not itself produce effects. Thus, CAP and RTX appear to act on the same nerves in the bladder, via a RR-dependent mechanism.

41.19

A DEMONSTRATION OF THE GRADED NATURE OF THE GENERALIZATION FUNCTION OF DRUG DISCRIMINATION LEARNING WITHIN THE CONDITIONED TASTE AVERSION PROCEDURE. A.L. Riley, M.A. Kautz, B. Geter, S.T. Smurthwaite, S. Pournaghash, P.M. Melton & C.M. Ferrari. The American University, Washington, D.C. 20016.

Prior work has suggested that generalization within drug discrimination learning is primarily quantal in nature with animals displaying either vehicle-appropriate or drug-appropriate responding, depending upon their detection of the drug stimulus. It has been questioned whether this reflects a characteristic response to drug stimuli or whether such responding is a function of the specific training and testing procedures used to establish and measure drug discrimination learning. The present experiment evaluated this issue by analyzing the generalization functions of individual subjects trained and tested within the conditioned taste aversion design under three different conditions. Specifically, animals were trained and tested with the same drug, trained with distilled water and tested with a drug or trained and tested with different drugs. The generalization functions under all three conditions were generally graded. Quantal responding, thus, is not a necessary outcome of drug generalization assessments. The nature of generalization in drug discrimination learning appears to be a function of the specific procedure utilized in training and testing the discrimination.

SUBSTITUTION OF ELECTRICAL STIMULATION OF THE MEDIAL HYPOTHALAMUS FOR PENTYLENETETRAZOLE IN A TWO-CHOICE DISCRIMINATION TASK. R. Depoortere* and M. W. Emmett-Oglesby. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107-2690.

The pentylenetetrazole (PTZ) discrimination paradigm, in which an animal (rat) is trained to press a lever in the presence of PTZ and an alternate lever in the presence of saline, has been proposed as an animal model of anxiety. The present study was aimed at assessing if the cue induced by electrical stimulation of the medial hypothalamus (MH), a brain structure whose electrical stimulation is known to induce aversive effects, would substitute for the discriminative cue induced by PTZ. Ten rats were trained to discriminate between PTZ (20 mg/kg *i.p.*) and saline, using a FR10, food reinforced choice-task. After acquisition of the discrimination task, these rats were unilaterally implanted with a pair of stimulating electrodes in the medial hypothalamus (4.5 mm AP, 0.3 mm ML, 9.5 mm DV with respect to lambda). After a further period of PTZ/saline discrimination training to habituate the rats to the electrical brain stimulation procedure, these rats were tested for stimulus substitution. During substitution sessions, rats were stimulated in the MH (monophasic cathodal pulses of 0.1 ms duration, frequency of 50 Hz, intensities varying from 10 to 80 μ A), following a saline *i.p.* injection. Substitution of the cue induced by MH electrical stimulation was observed in 7 of 10 rats, at an average intensity of 50 μ A (std 11 μ A). This set of data further supports the hypothesis that the anxiogenic/aversive nature of PTZ is a major component of its discriminative properties. This study was supported by grants DA 03521 and AA 06890.

THE STRIATO-PALLIDAL-TEGMENTAL PATHWAY AND ORO-FACIAL DYSKINESIA: A BEHAVIOURAL AND ANTEROGRADE TRACING STUDY IN CATS. W. Spooen, J. Veening, B. Ellenbroek and A. Cools. Dept. Pharmacology, Univ. of Nijmegen, P.O. Box 9101, Nijmegen, The Netherlands.

Oro-facial dyskinesia (OFD), i.e. abnormal movements of the ear, eyelid and cheek in combination with tongue protrusions, can be elicited from the dorsolateral (r-CRM) but not the medial part (CRM) of the feline caudate nucleus. These effects are known to be funneled via the sub-commissural part of the globus pallidus (scGP), i.e. a first order output station of the r-CRM but not the CRM. OFD can also be elicited from the scGP by inhibition of GABA and stimulation of acetylcholine and dopamine D1 receptors. In order to find the destination of the r-CRM/scGP elicited OFD the efferent connections of the feline substantia innominata, which encompasses the scGP, were investigated using Phaseolus Vulgaris L-agglutinin (PHA-L). It has been found that the scGP projects, among other sites, to the peri-peduncular area (PPA). In contrast to the effects elicited from the scGP only tongue protrusions could be elicited from the PPA. Furthermore, OFD elicited from the scGP could, except for tongue protrusions, not be attenuated at the PPA suggesting that only tongue dyskinesias are funneled via the PPA but not ear, eyelid and cheek dyskinesias. These data suggest that at least tongue dyskinesias are funneled via the striato-pallidal-tegmental pathway.

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: GLUCOCORTICOID RECEPTORS

42.1

Early Experience Alters Glucocorticoid Receptor Concentrations in the Hippocampus. L.A. Wilson, S.G. Warren, D.L. Amerski, L. Nadel, and G. Henk. Dept. of Psychology, Univ of Arizona, Tucson, AZ 85721.

Some events early in life alter long-term structural and functional changes in the nervous system. Handling of infant rat pups increased body and brain size, reduced emotionality and enhanced learning. Handling also increases glucocorticoid receptor (GR) number in the hippocampus, which has the net effect of providing a more rapid return to baseline corticosterone (CORT) levels following the termination of stress (Meaney, et al., Science, 1988). Isolation of young rat pups from their mother also interferes with the normal development of the hippocampus. Although the first 3 weeks of life are normally marked by a reduced tendency of animals to respond to stressful events with elevation of glucocorticoid hormones, pups do exhibit a stress response following a period of maternal isolation (Stanton, et al., Dev Psychobiol, 1987). The presence of CORT during the developmental phase may interfere with cell production, particularly postnatal development in the hippocampus. We hypothesize that handling and isolating rat pups would alter behavior that depends on the hippocampus and CORT levels and glucocorticoid receptor concentrations. As previously reported (Wilson & Nadel, Neurosci Abst, 1990) handling and isolating animals impaired acquisition of a spatial task at 60 days of age, and handling and isolating combined enhanced performance. We now report that CORT levels differ between these groups, and that the behavioral changes are accompanied by alterations in the concentrations of GR in the hippocampus.

42.2

KAINIC ACID-INDUCED DECREASE IN HIPPOCAMPAL CORTICOSTEROID RECEPTORS. M.T. Lowy. Dept. of Psychiatry, Case Western Reserve University, Cleveland, OH 44106

The potential role of excitatory amino acids in the regulation of hippocampal glucocorticoid receptors (GR) and mineralocorticoid receptors (MR) was examined using systemic administration of kainic acid (KA). KA (5,10,15 mg/kg) administered to 24 hr adrenalectomized (ADX) rats which were sacrificed 3 hr later produced large dose-related decreases in hippocampal GR (23-63%) and MR (50-71%). Significant decreases in hippocampal GR (26%) and MR (23%) could be detected as early as 1 hr after administration of KA (10 mg/kg). When ADX rats were sacrificed 24 hr after KA (10 mg/kg), large decreases in hippocampal GR (38%) and MR (47%) were still present. To assess the effects of KA under more physiological conditions, KA (10 mg/kg) was administered to adrenal-intact rats which were ADX 24 hr later and then sacrificed following an additional 24 hr. Under these conditions KA produced a 35% decrease in both hippocampal GR and MR. The KA-induced decrease in receptor binding was due to a decrease in the number of binding sites with no change in the dissociation constants. KA added *in vitro* failed to displace the radioligands from the GR and MR. These results indicate that excitatory amino acids play a prominent role in hippocampal GR and MR regulation. Supported by MH44699.

42.3

INCREASED LEVELS OF GLUCOCORTICOID RECEPTOR mRNA, GLUCOCORTICOID BINDING AND SENSITIVITY TO GLUCOCORTICOID IN CELL CULTURES AND IN MOUSE BRAIN FOLLOWING ANTIDEPRESSANT TREATMENT

Marie-Claude Pepin and Nicholas Barden Molecular Psychogenetics, CHUL Research Centre and Laval University, Ste-Foy, Québec, Canada G1V 4G2
Increased cortisol secretion caused by hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis and non-suppression of cortisol secretion following dexamethasone administration often characterize depression. A decreased number of glucocorticoid receptors (GR) in brain areas could explain this lack of feedback regulation seen in non-suppressors. Since non-suppressive responses of serum cortisol to dexamethasone revert to normal during successful antidepressant (AD) therapy, drug-induced modification of GR content and restoration of glucocorticoid sensitivity is possible. To test this hypothesis, we have investigated the effect of ADs on GR mRNA and glucocorticoid binding in both cell cultures (Ltk⁻ and neuroblastoma) and in desipramine-treated (20mg/kgBW for 12 days) mouse brain. GR mRNA, isolated from cells or tissues fragments, was subjected to Northern blot analysis using a 1.8kb fragment of the GR cDNA as probe. In desipramine-treated cells we observed a two fold increase in GR mRNA compared to untreated cells and up to a seven fold increase in [³H]-dexamethasone binding activity. Sensitivity to glucocorticoids was measured in cells stably transfected with a reporter plasmid carrying the chloramphenicol acetyl transferase (CAT) gene under MMTV-LTR (a glucocorticoid inducible promoter) control. When these cells were incubated in the presence of desipramine, a 2 to 3 fold increase in CAT activity was observed. *In vivo*, treatment of mice with desipramine increased the glucocorticoid binding in brain by 40%. These results suggest a mechanism whereby antidepressants could restore the sensitivity of cells to glucocorticoids and thus re-instate the normal feedback inhibition of glucocorticoids on the HPA axis.

42.5

ADRENAL STEROID RECEPTOR ACTIVATION IN BRAIN AND PITUITARY BY DEXAMETHASONE AND CORTICOSTERONE. A.H.Miller, R.L.Spencer, M.Pulera*, S.Kang*, B.S.McEwen and M. Stein. Mt. Sinai Sch. of Med., NY, NY 10029.

The 1 mg dexamethasone suppression test (DST) has been used extensively to evaluate feedback inhibition of the HPA axis by adrenal steroids (AS). Nevertheless, it remains unclear at what level of the HPA axis and through which AS receptor subtype dexamethasone (DEX) exerts its inhibitory effect. Type I and II AS receptor activation in the pituitary (PIT), hypothalamus (HYP) and hippocampus (HC) was assessed in rats after exposure to three separate doses of DEX. The low and medium doses were designed to reproduce DEX blood concentrations consistent with those found in humans following 1 mg of DEX. Receptor activation after steroid administration was determined by comparing AS receptor binding in the various treatment groups. Since AS receptors occupied and activated *in vivo* do not rebinding radiolabeled steroid *in vitro*, a decrease in AS receptor binding as measured by an *in vitro* exchange assay reflects receptor occupation/activation by steroid *in vivo*. Results with DEX were compared to similar studies using corticosterone (CORT). All doses of DEX were associated with significant activation of type II receptors in the PIT, while only the high dose of DEX activated type II receptors in the HYP and HC. DEX did not significantly activate type I receptors in any tissue at any dose. In contrast, CORT significantly activated type I receptors in all tissues at all doses, while activating type II receptors primarily in the brain (especially HC) and not the PIT. These results suggest that the DST in humans may be primarily a test of PIT function, whereas CORT at low doses may provide an assessment of AS feedback inhibition at or above the level of the HYP. (Supported by MH00680)

42.7

CRF-INDUCED DOWN REGULATION OF GLUCOCORTICOID RECEPTOR(GR) EXPRESSION IN AIT20 CELLS IS NOT POTENTIATED BY THE PROTEIN KINASE C ACTIVATOR PMA. K.E. Sheppard and D.J. Autelitano Baker Medical Research Institute, Melbourne, AUSTRALIA
In the rat pituitary corticotroph, AVP and phorbol esters potentiate CRF-induced secretion of POMC-derived peptides but not POMC gene expression. The major inhibitor of both POMC gene expression and peptide secretion are glucocorticoids. Studies on the regulation of corticotroph POMC suggest there is interplay between CRF and glucocorticoids, such that they influence the responsiveness of the corticotroph to each other. Recently we have demonstrated that CRF down-regulates GR mRNA levels and GR binding in a mouse corticotroph tumor cell line (AIT20). In the present study we have used AIT20 cells to determine the effects of PMA alone and the possible PMA potentiation of the CRF-induced decrease in GR expression. In addition, the effect of PMA and CRF on Bendorphin(βEP) secretion was measured. PMA (100nM) treatment for 1-24h did not alter levels of GR binding in AIT20 cells. To examine the possible synergism of CRF and PMA, cells were preincubated with CRF (100nM) for 23h. Following incubation, media were removed and fresh media added containing either CRF or CRF plus PMA(100nM); cells were then incubated for a further 1h. In these cultures, GR binding was significantly reduced to a similar extent by either CRF or CRF plus PMA. In contrast to GR binding, PMA significantly potentiated β-EP release from CRF pretreated cultures. These data confirm previous reports of synergism between CRF and PMA on POMC-derived peptide release, and in addition demonstrate that PMA does not potentiate the CRF-induced repression of GR expression.

42.4

Heterologous down-regulation of Type II adrenal steroid receptors by corticosterone-Type I receptor complexes in mouse brain. W.G. Luttig, M.E. Rupp* and M.M. Davda*. Dept. of Neuroscience, Univ. of Florida, Gainesville, FL 32610.

In previous work (*Endocrinology* 125: 817-824, 1989), we found that adrenalectomy-induced increases in Type I adrenocorticosteroid receptor binding capacity in mouse hippocampus (HPC), cerebral cortex (CX), hypothalamus (HTH), brain stem (BS) and cerebellum (CB) could be inhibited by a subcutaneous injection of aldosterone (ALDO) given 24 h prior to tissue removal. The increases in Type II receptor binding capacity in HPC and CX, but not those in HTH, BS and CB, were also inhibited by ALDO. Since co-administration with a 50-fold excess of the Type I receptor antagonist, RU 26752, blocked ALDO-induced down-regulation of Type I and Type II receptors, we hypothesized that the Type II receptor down-regulation was mediated by ALDO-Type I receptor complexes. In the present study we extend this proposed mechanism, by examining the receptor-specificity properties of corticosterone (CORT)-induced Type I and Type II receptor down-regulation in female mice adrenalectomized for three days.

In our first experiment we used the same dose of CORT as in our earlier work with ALDO (0.5 µg/g) and, as expected, the magnitude of Type I and Type II receptor down-regulation was similar to that seen with ALDO. However, in contrast to our findings with ALDO, a 50-fold excess of RU 26752 was unable to block CORT-induced down-regulation of Type II receptors and it was only marginally effective against CORT actions on Type I receptors. In our second experiment we established the minimally-effective dose of CORT (0.1 µg/g) for Type I and Type II receptor down-regulation in hippocampus. In the third experiment we used this dose of CORT ± a 250-fold excess of RU 26752 to show that the Type I receptor antagonist could now not only block CORT-induced down-regulation of Type I receptors in HPC, CX, HTH, BS and CB, it also reduced the down-regulation of Type II receptors in HPC, but not in other brain regions. We interpret these findings as supporting a heterologous (*i.e.*, CORT-Type I receptor-mediated) mechanism for CORT-induced down-regulation of Type II receptors. The reduced efficacy of RU 26752 suggests that a homologous (*i.e.*, CORT-Type II receptor-mediated) mechanism is also operable. Follow-up studies examining Type I and Type II mRNA content are in progress. Supported by NS 24404.

42.6

GLUCOCORTICOID SUPPLEMENTATION, HYPOTHALAMIC-PITUITARY ADRENAL (HPA) AXIS REGULATION AND GLUCOCORTICOID RECEPTORS. E.A. Young, Mental Health Research Institute, University of Michigan, Ann Arbor MI, 48109

The HPA axis is under the negative feedback control of glucocorticoids, which are secreted in a circadian manner with a peak at lights-off and the nadir at lights-on. To determine the effects of raising the nadir level of corticosterone on circadian HPA function and glucocorticoid receptors, normal rats were implanted with subcutaneous pellets of corticosterone and cholesterol which serve as a slow release form of corticosterone supplementation. Two different concentrations of corticosterone pellets were explored: 25% and 50%. Baseline hormones and receptors were examined in the a.m. and p.m. at two time points, days 3 and 6. The rats with low dose (25%) pellets demonstrated a circadian rhythm of corticosterone with increased corticosterone levels on day 3. By day 6 the levels of corticosterone were increased in the a.m. only. The adrenal weight and thymus weights were decreased, but not significantly. There were no changes in hippocampal Type II glucocorticoid receptors by receptor binding. Type I receptors were too low to detect reliably in these intact rats.

The 50% pellets rats demonstrated an increase in a.m. corticosterone levels to ~5 µg/dl. This increase was enough to block the circadian p.m. rise in corticosterone, resulting in a flat corticosterone rhythm. This dose also resulted in a significant decrease in adrenal weight and thymus weight. Despite increased mean corticosterone levels resulting in decrease in thymus weight, an effect that is mediated via Type II receptors in thymus, there was no evidence of decreases in Type II glucocorticoid binding in hippocampus, hypothalamus or cortex. These data suggest that increased levels of corticosterone do not lead to changes in glucocorticoid receptor number in brain areas associated with negative feedback.

42.8

SECOND MESSENGER REGULATION OF GLUCOCORTICOID (GC) RECEPTOR BINDING IN CULTURED BOVINE ADRENAL MEDULLARY CELLS. K. Betito, J. Diorio*, M.J. Meaney, & P. Boksa. McGill University, Depts. of Pharmacology & Psychiatry, Douglas Hospital Research Center, Montreal, Quebec H4H 1R3, Canada.

The sensitivity of target tissues to circulating GCs depends, to a large extent, on the concentration of GC receptors. Modulation of GC receptor number in response to cyclic nucleotides has been found in rat hippocampal, human skin fibroblast, murine lymphoma, and AIT20 cells in culture. In all but the AIT20 cell line, cAMP increases GC receptor binding and/or mRNA. Cyclic GMP either has no effect or slightly decreases GC receptor binding. In this study, we have investigated the regulation of GC receptor binding in bovine adrenal medullary cells in culture in response to cAMP and cGMP. GC receptors are present in adrenal medullary cells in culture and are involved in the regulation of catecholamine synthesis. Four day treatment of cells with 8 bromo cAMP (1 mM) or forskolin (10µM), decreases GC receptor binding by 60% and 54%, respectively. Preliminary results suggest that 1 mM 8 bromo cAMP requires as little as 1 day to reduce GC receptor binding. Four day 8 bromo cAMP (10 µM) treatment reduces GC receptor binding by 36%, and this effect is reversed by the cyclic nucleotide dependent protein kinase inhibitor H-8 (10 µM). The effects of both cAMP and cGMP on GC receptor binding are concentration dependent. Preliminary results suggest that 8 bromo cAMP can reduce GC receptor binding in highly purified chromaffin cell preparations, suggesting that 8 bromo cAMP acts directly on the chromaffin cells to modulate the GC receptor. These results demonstrate that GC receptor levels in adrenal medullary cells in culture can be regulated by the cyclic nucleotide second messengers cAMP and cGMP. Supported by FRSQ and MRC of Canada.

ESTROGEN (E) EFFECTS GLUCOCORTICOID RECEPTOR (GR) MEDIATED NEGATIVE FEEDBACK AND GR mRNA LEVELS IN THE RAT. L.H. Burgess and R.J. Handa. Dept. of Cell Bio., Neurobio., and Anat., Loyola Univ., Stritch Sch. of Med., Maywood, IL 60153.

We have previously shown that ACTH and CORT secretion following stress are elevated and prolonged in E treated ovariectomized (OVX) rats. This suggested an impairment of negative feedback by corticosterone (CORT). In these studies, we explored this possibility by examining feedback suppression by dexamethasone (DEX 100ug) or the synthetic GR agonist RU 28362 (100ug) in rats given E or sham treated for 17 days. Rats received daily sc injections of RU 28362, DEX, or oil for 4 days. One day later, the rats were subjected to a 1 min. ether stress. Plasma CORT levels at 0 min. and 20 min. post-stress showed an injection by E treatment interaction ($p < 0.0001$). At both time points CORT levels were decreased ($p < 0.01$ vs. oil controls) by DEX in both OVX and OVX + E rats, while RU 28362 decreased ($p < 0.01$) CORT levels only in OVX rats. This demonstrates that E interferes specifically with GR mediated negative feedback. We have also previously shown that MR mRNA levels (3.6 fmoles/mg RNA) in the 21 day OVX rat hippocampus (HIPPO) were decreased ($p < 0.01$) by 1 day or 21 days of E treatment to 2.47 and 2.37 fmoles/mg RNA respectively. We have now examined GR mRNA levels, using an RNase protection assay, and found an increase ($p < 0.03$) in 21 day OVX rat HIPPO GR mRNA from 2.78 to 3.22 fmoles/mg RNA following 1 day of E treatment. In the anterior pituitary gland of OVX rats, 21 days of E treatment resulted in a decrease ($p < 0.0005$) in GR mRNA from 1.86 to 0.79 fmoles/mg RNA. These data demonstrate a tissue specific effect of E on GR mRNA which may underlie the impairment of GR mediated negative feedback seen in the presence of E.

RESPIRATORY REGULATION I

HYPOXIA DECREASES INTRACELLULAR CALCIUM IN RAT CAROTID BODY GLOMUS CELLS. D. Kholwadwala and D.F. Donnelly. Dept. Ped., Section of Respiratory Medicine, Yale Univ. School of Medicine, New Haven, CT 06510

Most theories of carotid body (CB) transduction postulate that hypoxia enhances secretion of neurotransmitters by raising intracellular calcium (Ca_i). We tested this hypothesis by examining changes in Ca_i of acutely isolated, adult rat glomus cells using fluo3 and confocal microscopy.

Glomus cells were isolated by repeated trituration after trypsin/collagenase digestion and plated on glass cover slips. Acute exposure to hypoxia (30-60s, $PO_2=0$ at nadir) caused a rapid and significant reduction in Ca_i ($\Delta F/F = 0.32 \pm 0.03$, mean \pm SEM, $n=43$) which returned during reoxygenation. Acidity (pH 6.9, 5min) also caused a significant reduction in Ca_i ($-.06 \pm .02$, $n=12$). Superfusion in Ca-free solution (+1mM EGTA) caused a reduction in Ca_i , but hypoxia continued to cause a reversible reduction in Ca_i from -0.33 ± 0.06 to -0.64 ± 0.04 ($n=16$). These results show that: 1) hypoxia causes a reversible reduction in Ca_i in rat glomus cells, 2) this reduction is likely due to sequestration to an intracellular site. Thus, it is unlikely that transmitter secretion from glomus cells is triggered by increases in Ca_i ; rather, hypoxia may increase the binding of calcium to an intracellular regulatory site.

43.3

NOREPINEPHRINE INDUCED BLOOD OXYGEN DESATURATION. D.G. Bernard, L.M. Sexcius, R.M. Millis, C.O. Trouth, and D.H. Wood. Dept. of Physiol. & Biophysics, & Neurol., Coll. of Med., Howard Univ., Washington, D.C. 20059.

To determine the relationship between arterial oxygen desaturation and increased plasma norepinephrine (NE) levels during sleep apnea, we administered NE (3mg/Kg) to ten dogs anesthetized with Nembutal. Arterial blood pressure and ventilation were monitored continuously. Arterial blood and expiratory gas tensions were measured by spectrometry. Following a 30-minute control period, half of the animals ($n=5$) were given NE while breathing spontaneously and the remainder ($n=5$) were given NE during volume-controlled, positive-pressure mechanical ventilation at hypocapnic levels. Results showed that in the spontaneously breathing animals, intravenous NE produced an acute systemic vasopressor response with transient apnea, arterial oxygen desaturation, and hypercapnia. In the mechanically ventilated animals, arterial oxygen desaturation and hypercapnia were associated with a systemic vasopressor response and a decrease in the expiratory tidal volume. In sleep apnea endogenous NE may produce arterial oxygen desaturation. **SUPPORT: MBRS 806 GM 08016.**

43.2

REGULATION OF INTRACELLULAR pH IN RAT GLOMUS CELLS.

T.R. Cummins and D.F. Donnelly. Sect. Resp. Med., Dept. Pediatrics, Yale Univ. Sch. of Med., New Haven, CT 06510

Carotid body chemoreceptors transduce blood acidity and hypoxia into increased neural activity on the sinus nerve. It has been proposed that these stimuli may converge at the level of glomus cell intracellular pH (pH_i). The purpose of this study was to examine the mechanism(s) of pH_i regulation and examine how pH_i changes during chemostimulation. Glomus cells were acutely isolated from adult rat carotid bodies and plated onto glass cover slips. Cells were loaded with a pH sensitive dye, SNARF-1, and observed with a laser confocal microscope using single excitation/dual emission ratio technique. In HEPES saline, control pH_i was 7.21 ± 0.04 (mean \pm SEM, $n=40$), and cells recovered from an acid load. pH_i recovery was not blocked by amiloride (1 mM) or by Na⁺ free solution, suggesting that these cells have a proton pump similar to renal tubule cells. Perfusion with Ringer's saline (HCO_3^- base) caused pH_i to acidify by 0.34 ± 0.08 pH units ($n=5$). Removal of Cl^- in the presence of HCO_3^- caused pH_i to shift alkaline by 0.32 ± 0.06 pH units ($n=5$).

Anoxia (5 min, $PO_2=0$) caused an acidification (-0.35 ± 0.1 pH units, $n=12$) which recovered following reoxygenation. Extracellular acidity (pH 6.9) did not significantly effect pH_i . These results show that: 1) adult rat glomus cells may regulate pH_i by at least three mechanisms: a Na⁺/H⁺ exchanger, a H⁺ pump and a HCO_3^-/Cl^- dependent mechanism. 2) Hypoxia causes an intracellular acidification.

43.4

ETHMOIDAL STIMULATION INHIBITS RESPIRATION RELATED NEURONES IN THE NUCLEUS TRACTUS SOLITARIUS (NTS) OF THE CAT. F.M. Boissonade and G.E. Lucier. Dept. of Medical Physiology, University of Calgary, Calgary, AB. T2N 4N1. CANADA.

Stimulation of the nasal mucosa initiates a number of respiratory protective reflexes, i.e. sneezing, coughing and apnea. Previous anatomical and electrophysiological studies have shown that afferents from the laryngeal mucosa of the cat, which are capable of initiating similar reflexes, project via the superior laryngeal nerve (SLN) directly to respiratory neurones in the NTS. The afferent fibres supplying the nasal mucosa travel to the brainstem within the ethmoidal nerve, a branch of the trigeminal nerve whose only direct projection is to the trigeminal nucleus. The purpose of the present series of experiments was to determine whether the activity of respiratory related neurones within the NTS could be inhibited by stimulation of the ethmoidal nerve. Extra-cellular recordings have been made from 133 respiration related neurones within the NTS of chloralose-anaesthetised cats and the effects of stimulation of the SLN and the ethmoidal nerve studied. Results demonstrate that the rhythmic firing of respiratory related neurones within the NTS can be inhibited by stimulation of the ethmoidal nerve. Previous reports that these neurones can be inhibited by SLN stimulation have been confirmed. The proportions of respiration related neurones within NTS inhibited by ethmoidal and SLN stimulation are similar (23% and 26% respectively). These results indicate that the NTS is a possible relay site for respiratory reflexes initiated by stimulation of the nasal mucosa, even though ethmoidal afferents do not project directly to this nucleus. (Supported by Canadian MRC.)

C-FIBER EVOKED RAPID SHALLOW BREATHING: EFFECTS ON MEDULLARY INSPIRATORY AND EXPIRATORY NEURONS. A.C. Bonham and J.P. Joad. Division of Cardiovascular Medicine and Department of Pediatrics, University of CA, Davis, Davis, CA 95616.

Phenyldiguanide (PDG) injected in the right atrium of spontaneously-breathing rats elicits the classic C-fiber response: rapid shallow breathing, bradycardia, and hypotension. The purpose of these studies was to extend previous work to determine the central neural mechanisms underlying PDG-evoked rapid shallow breathing. Studies were performed in urethane-anesthetized rats, in which phrenic nerve activity, arterial pressure, heart rate, and arterial blood gases were monitored. Action potentials were recorded extracellularly from neurons in the region of the ventral respiratory group (VRG) which discharged with inspiratory periodicity, expiratory periodicity, or phase-spanning activity. Neuronal discharge patterns were studied during the period of rapid shallow breathing evoked by right atrial injection of PDG (5 µg/kg). Neurons which discharged with inspiratory periodicity (n = 30) were inhibited; those with expiratory periodicity (n = 12) were excited and discharged throughout inspiration during the period of rapid shallow breathing. Neurons with respiratory phase spanning activity were first inhibited then excited (n = 3). These preliminary data suggest that PDG-evoked rapid shallow breathing is associated with complex inhibitory and excitatory effects on neurons with respiratory-related periodicities. Future studies will attempt to determine the projection and function of these neurons. (Supported by ALA RG007 and Tobacco-Rel. Dis. Res. Prog RT-411.)

DIFFERENTIAL EFFECTS OF VAGAL AFFERENT INPUTS ON VENTRAL AND DORSAL MEDULLARY INSPIRATORY-RELATED NEURONS. M.I. Cohen, W.-X. Huang*, R. Barnhardt* and W.R. See. Dept. of Physiol., Albert Einstein Col. Med., Bronx NY.

In decerebrate paralyzed cats, we observed the responses of inspiratory-related (I or IE) neurons to vagal (V) afferent inputs (lung inflation and/or electrical stimulation at 100 Hz). Stimulus trains started 100 ms after I onset and ended at I offset, with the stimulus current set to shorten I without net facilitation of phrenic discharge. 39/72 ventral respiratory group (VRG) neurons were excited, and 27 were inhibited by either type of V input; 10/17 dorsal respiratory group (DRG) neurons were excited and 4 were inhibited. Of those neurons excited by V electrical stimulation, stimulus-unit locking (indicated by significant coherence between stimulus and unit pulses) was shown by 6/7 DRG neurons but by only 4/38 VRG neurons. Further, excitation latencies < 20 msec were shown by 5/7 DRG neurons, but by only 3/38 VRG neurons. This difference indicates that the VRG neurons are more distant synaptically from the afferent inputs. Of the 39 VRG neurons that were excited by V inputs, 10 late-I neurons had patterns suggestive of an I off-switch function: a) V input produced earlier onset of firing as well as shortening of the I phase; b) the timing of discharge in relation to the end of I was very similar between control and stimulation phases. These neurons may play a role in I termination. (Supported by N.I.H. Grant HL-27300.)

CONCURRENT EFFECTS OF CAROTID CHEMORECEPTOR STIMULATION ON DISTRIBUTED BRAIN STEM RESPIRATORY NEURAL NETWORKS. K. F. Morris, A. Arata, R. Shannon and B. G. Lindsey. Dept. Physiol. & Biophysics, Univ. South Florida Med. Ctr., Tampa, FL 33612.

We studied the responses of brain stem respiratory related neurons to carotid chemoreceptor (CCR) stimulation in anesthetized, vagotomized, artificially ventilated cats. CCRs were stimulated by injection of 200 µl of CO₂ saturated saline solution via the external carotid artery. Carotid sinus pressure was monitored and manipulated to control for baroreceptor effects. As many as five independently controlled arrays of electrodes (n=34) were used to monitor simultaneously single neuron spike trains in the ipsilateral n. tractus solitarius, rostral (region of retrofacial n.) and caudal ventral respiratory group (VRG), the contralateral VRG, and medullary raphe n. Spike train data files were analyzed with respiratory cycle-triggered and peristimulus-time histograms and correlational methods. Of 135 neurons, 69 increased and 23 decreased activity with CCR stimulation. Cells in all sampled domains responded to chemoreceptor stimulation; 34 of 38 pairs of neurons with short-time scale correlations included at least one responsive cell. The results include evidence for: (a) inhibitory connections from neurons excited by chemoreceptors to neurons that responded with decreased activity; (b) chemoreceptor mediated inhibition of rostral VRG inspiratory (I) - driver neurons and concurrent excitation of their caudal I neuron targets. The analysis of "many-neuron" recordings will be useful in elucidating the distributed actions of peripheral chemoreceptors on respiratory networks. Supported by NS19814 & BRSG S07 RR05749.

MORPHOLOGY OF SLOWLY ADAPTING PULMONARY STRETCH RECEPTOR (SAR) AFFERENTS IN THE NUCLEUS TRACTUS SOLITARIUS OF THE RAT. S.K. Coles, F. Hayashi*, R. Behnia*, and D.R. McCrimmon. Depts. Physiology & Anesthesia, Northwestern University Medical School, Chicago, IL 60611

Activation of SAR afferent fibers gives rise to the Breuer-Hering reflex (*i.e.*, shortening of inspiration and lengthening of expiration). To identify potential central pathways responsible for the Breuer-Hering reflex, experiments were designed to study the axonal arborization patterns of SAR primary afferents and the distribution of synaptic boutons in the rat.

Glass pipettes (R = 20-30 MΩ) suitable for intracellular recording and dye injection were inserted into, or immediately medial to, the tractus solitarius at a level between 0.4 and 0.7 mm rostral to calamus scriptorius. Impaled axons were identified as SAR primary afferents if they discharged in phase with lung inflation and exhibited sustained firing of action potentials during maintained lung inflation. Neurobiotin (Vector Labs, 4% in 1.0 M KCl) was injected intra-axonally using depolarizing current pulses (1-2 Hz, 0.4 s) for 5-10 min. Tissue was sectioned (100 µm coronal) on a cryostat, processed using a conventional immunoperoxidase procedure and reacted with diaminobenzidine tetrahydrochloride.

SAR afferents arborized over about a 1 mm rostrocaudal extent at the level of the area postrema. Extensive axonal arborizations were observed with *en passant* and terminal varicosities appearing immediately medial, ventral and lateral to the tractus solitarius. Labelled primary afferent fibers could also be followed to their exit from the medulla in the vagus nerve several hundred microns rostral to the area postrema.

Supported by NIH grants HL 40336 and NS 17489 and NRSA HL 08298.

PROPERTIES AND EFFERENT PROJECTIONS OF SECOND ORDER NEURONS ACTIVATED BY RAPIDLY ADAPTING LUNG RECEPTORS (RARs). I. Lipski, K. Ezure, K. Otake and R. B. Wong She. Dept. of Physiology, Univ. of Auckland, New Zealand and Dept. of Neurobiology, Tokyo Metropolitan Inst. for Neurosciences, Japan.

RARs are responsible for a number of reflexes which affect respiration. Although the central terminations of afferents from these receptors have been traced to the caudal subdivisions of the nucleus tractus solitarius (NTS; Davies and Kubin, 1986, J.Physiol. 373: 63), the properties of the second order neurons are unknown. In Nembutal-anesthetized cats, extracellular and intracellular recordings were made in the caudal NTS. RAR-activated cells (RAR-cells) were identified by: (a) electrical stimulation of vagal nerve afferents; (b) deflation and hyperinflation of the lungs; and (c) inhalation of ammonia vapour. The majority of the RAR-cells (85/100) were located in the commissural subnucleus of the NTS. Intracellular recordings of synaptic responses evoked by electrical stimulation of myelinated vagal afferents suggested monosynaptic EPSPs. Bilateral lesions of the commissural subnucleus abolished the reflex responses induced by ammonia inhalation or hyperinflations of the lungs, but not the Hering-Breuer reflex. A strong projection of the RAR-cells to the dorso-lateral pons was revealed by antidromic stimulation. This was confirmed in 3 cats by extracellular biocytin injection in the commissural subnucleus. Anterogradely labeled terminals were also found in respiration-related areas of the medulla oblongata. These findings suggest that at least some commissural NTS projections to the rostral pons are involved in the reflex pathways from RARs. (Supported by the AMRF and the Wellcome Trust, U.K.)

EXCITATORY AMINO ACID RECEPTORS IN THE COMMISSURAL NUCLEUS TRACTUS SOLITARIUS (SoIC) MEDIATE CAROTID-BODY (CB) CHEMORECEPTOR REFLEX RESPONSES (CBCR) IN THE RAT. A. Vardhan, A. Kachroo, J. Murugaian & H.N. Sapru, Section of Neurosurgery & Pharmacology, UMDNJ-New Jersey Medical School, Newark, NJ 07103.

In spontaneously breathing, urethane-anesthetized rats, unilateral stimulation of CB chemoreceptors by saline saturated with 100% CO₂ produced an increase in minute ventilation (64%) and a decrease (17%) in mean arterial pressure (MAP). L-glutamate (GL; 0.88 nmole (nm)/site) was injected (20 nl) into the following areas of the SoIC: (1) mid-line at the calamus scriptorius (CS) & 0.3 mm deep from the dorsal surface & (2) midline, 0.3 mm deep & 0.5 mm caudal to the CS). GL increased minute ventilation (28.75%) and MAP (23%). Injections of carbachol (Carb; 50 pmole (pm)/site) in these areas produced similar respiratory and cardiovascular effects. GL and Carb did not elicit these responses from adjacent areas. Inhibition of areas (1) and (2) by injections of muscimol (1-2.5 nm/site; used as a tool to depress neurons) abolished the CBCR. Injections of kynurenic acid (Kyn; 500 pm; a non-selective excitatory amino acid receptor antagonist) into the areas (1) and (2) blocked the CBCR. The specificity of Kyn was indicated by its lack of action against the excitatory actions of Carb. These results indicate: (a) CB chemoreceptor afferents project to areas (1) & (2) in SoIC and (b) excitatory amino acid receptors located in these areas mediate CBCR. Support: NIH (HL 24347) and AHA (NJ).

DIFFERENTIAL CHEMOSENSITIVITY TO CO₂ AND H⁺ WITHIN THE IN VITRO PERFUSED ADULT BRAINSTEM PREPARATION. M.P. Morin-Surun, E. Boudinot and M. Denavit-Sauble, Laboratoire de Physiologie Nerveuse, CNRS, 91198 Gif sur Yvette, France.

The brainstem contains chemosensitive elements which induce respiratory responses to changes in CO₂ and H⁺ concentration. However, the question of the location of these central respiratory chemoreceptors is not solved: are they situated at the ventral surface or deeper into the brainstem? Recently we have developed an adult brainstem preparation perfused through the basilar artery. This preparation presents two advantages allowing this issue to be addressed. 1- The functional respiratory network is preserved (Morin-Surun et al, Soc. Neurosc. Abstr., p.226, 1989). 2- It is possible to control independently the extracellular fluid (ECF) by the perfusion through the basilar artery and the cerebrospinal fluid (CSF) by the bath perfusion. Under control conditions, the brainstem was perfused by a Krebs's solution saturated with 95% O₂ and 5% CO₂ (pH 7.4). The pH of the different solutions tested was adjusted to desired level (pH 7.0 and 7.8) by modifying the HCO₃ concentration without changing CO₂ content. Change in CO₂ concentration with constant pH was performed by modifying the HCO₃ concentration and the percent of CO₂ (HCO₃ 60 mM, CO₂ 9%, pH 7.4). Respiratory output was recorded from the hypoglossal roots. Changes of the hypoglossal integrated inspiratory activity were analysed. With different routes of application, the extracellular fluid or the cerebrospinal fluid, changes of the pH produced similar respiratory effects whereas changes of CO₂ induced different modifications. These results suggest different targets for CO₂ and H⁺ respiratory chemosensitivity. Supported by the Fondation pour la Recherche Medicale.

ENERGY SUPPLY OF THE RESPIRATORY NETWORK IN THE ISOLATED BRAINSTEM OF NEONATAL RATS

K. Ballanyi*, J. Brockhaus*, J.C. Smith* and D.W. Richter
Physiol. Inst., Univ. Göttingen, 3400 Göttingen, F.R.G.

*Dept. Kinesiol., UCLA, Los Angeles, CA 90024-1568, USA
We have measured tissue profiles of oxygen-pressure (pO₂), pH (pH_e) and K⁺ activity (aK_e) to determine the microenvironment of respiratory neurons in the *in vitro* respiratory network of 1 to 4 day old rats. In the respiratory pool, ventrolateral to the N. ambiguus, rhythmic increases of aK_e (50-300 μM) and concomitant decreases of pO₂ (0.1-0.5 mmHg) occurred synchronously with the respiratory activity recorded from phrenic rootlets. Tetanic spinal cord stimulation elicited aK_e increases by up to 4 mM and decreases of pO₂ by up to 50 mmHg. These responses were reduced by 75% after blockage of synaptic transmission by 5 mM Mn²⁺. In the presence of 5-50 μM ouabain, there was a reversible increase of aK_e by 0.3-1 mM and a concomitant delay in the post-tetanic aK_e recovery.

The sensitivity of the respiratory neurons to hypoxia was tested by superfusion with a N₂-gassed solution. An initial increase in respiratory frequency was followed by a secondary slowing and, after about 10 min, by complete loss of activity. This disturbance of respiratory rhythm was accompanied by a fall in pO₂ to nominally 0 mmHg, a transient increase of aK_e by up to 1.8 mM and a decrease of pH_e by up to 0.3 units. These effects were reversible if hypoxia was shorter than 20 min.

It is concluded that the energy supply of the respiratory network is sufficient to maintain synaptic connectivity and Na⁺/K⁺-pump activity.

VAGALLY MEDIATED, HEXAMETHONIUM-INSENSITIVE RELAXATIONS OF GUINEA PIG TRACHEALIS. B.J. Canning* A.C. Myers, B.J. Undem*, Johns Hopkins Univ., Baltimore, MD 21224.

The guinea pig trachea with its extrinsic innervation intact was isolated and placed dorsal side down in a water-jacketed dissecting dish overfilled at a rate of 20 ml/min with warmed (37°C), oxygenated Krebs solution containing 3 μM indomethacin, 1 μM atropine, 1 μM propranolol and 1 μM prazosin. The sixth and seventh tracheal rings caudal to the larynx were cut open opposite the trachealis and prepared for isometric tension measurements. The rings were contracted by adding 1 μM PGF_{2α} to the buffer. Relaxations in response to nerve stimulation were measured and expressed as % reversal of this contraction. The nerves were stimulated with 10 sec trains of square pulses (1 msec, 150V) via suction electrodes at frequencies ranging from 1-32 Hz. Stimulation of the vagus nerves caudal to the nodose ganglia caused relaxations that were maximal at 32 Hz (55±17%) and abolished by hexamethonium (0.1 mM). Stimulating the vagi rostral to the nodose ganglia in preparations where the vagi were cut below the nodose also caused relaxations (26±5% at 24 Hz, n=8). These relaxations were, however, insensitive to 1 mM hexamethonium. By comparison, stimulating the rostral end of the cut cervical sympathetic trunks evoked relaxations (82±6% at 24 Hz, n=16) that were abolished by propranolol or hexamethonium. We conclude that the rostral trachealis of the guinea-pig receives two distinct types of nonadrenergic relaxant innervation from the vagi: 1) a hexamethonium-sensitive parasympathetic relaxant innervation, with preganglionic fibers carried by the recurrent laryngeal nerves, and 2) a hexamethonium-insensitive relaxant pathway projecting to the rostral trachealis from the vagus nerves via the superior laryngeal nerves. (Supported by NIH, HL 38095).

VENTROLATERAL MEDULLA (VLM) CARBONIC ANHYDRASE (CA) INHIBITION: CHANGES IN PHRENIC NERVE ACTIVITY (PNA) AND LOCALIZATION OF CENTRAL CHEMORECEPTION SITES.

E.L. Coates, A. Li, and E.E. Nattie, Dartmouth Medical School, Department of Physiology, Hanover, NH 03756

The purpose of this experiment was: 1) to determine the effect of VLM CA inhibition on baseline PNA, medullary tissue pH, and the response of PNA to transient and steady state increases in end-tidal CO₂, and 2) to localize sites of central chemoreception with acetazolamide (AZ) microinjections. AZ (10⁻⁴M) pledgets applied to the surface of the VLM or AZ microinjected (1 nl, 10⁻⁴M) beneath the medullary surface in chloralose-urethane-anaesthetized, vagotomized, carotid denervated, paralysed, servo-ventilated cats produced long-lasting increases in PNA. VLM AZ application by pledgets produced a long lasting decrease in extracellular pH but this was not a good predictor, in each individual animal, of changes in PNA. VLM AZ also reduced the slope and the half-time of the phrenic response to rapid step CO₂ increases but did not effect the phrenic response to steady state CO₂ increases. Localized induction of medullary tissue acidosis with AZ microinjections in the rostral, intermediate, and caudal chemosensitive areas of the VLM stimulated PNA. We conclude that localized inhibition of VLM CA causes a centrally mediated increase in ventilation attributable to medullary tissue acidosis, that medullary CA may play a role in central CO₂ chemotransduction, and that central chemoreceptors may be distributed throughout the VLM. (Supported by HL 28066 and HL 07449).

EFFECTS OF HYPOXIA ON POSTSYNAPTIC POTENTIALS IN MEDULLARY RESPIRATORY NEURONS OF THE CAT. M.C. Bellingham, C. Schmidt*, U. Windhorst* and D.W. Richter. Physiol.Inst., Univ. Göttingen, 3400 Göttingen, F.R.G.

To investigate the reduction and eventual loss of rhythmic inhibitory inputs seen in cat medullary respiratory neurons *in vivo* during hypoxia, intracellular recordings were made from 16 expiratory neurons of the caudal ventral respiratory group, in 7 anesthetized, paralysed and artificially ventilated cats, which were vagotomized and glomectomized. Hypoxia was induced by ventilation with 5 or 10% O₂ in N₂, and continued until neuronal apnea occurred. IPSPs and EPSPs, evoked by ipsi- or contralateral superior laryngeal nerve stimulation (0.1 ms, 0.5-4 V, 2-3 Hz), were averaged (10-150 responses in the different phases of the respiratory cycle); their amplitude and neuron input resistance (R_n) were measured.

After 0.5-2 minutes of hypoxia and before the loss of rhythmic activity, IPSPs were decreased (mean change, -25%), EPSPs were decreased or increased (+12%), and R_n rose (+35%). During apnea (2-6 min. hypoxia), IPSPs were greatly reduced or abolished (-72%), EPSPs were reduced but not abolished (-18%), and R_n was increased (+60%).

These results indicate that decreased inhibition plays a significant role in the disruption of respiratory rhythm during hypoxia. The increases in R_n compared to reductions in PSP amplitude suggest that presynaptic factors, rather than postsynaptic properties, are involved in this decrease. Supported by SFB 330/B 10

MECHANOSENSITIVITY OF REGENERATING SPROUTS OF GROUP I AND II MUSCLE AFFERENTS IN CATS. J.B. Munson and R.D. Johnson. Dept. of Neuroscience, College of Medicine and Dept. of Physiological Sciences, College of Veterinary Medicine, University of Florida, Gainesville, FL 32610.

We recently demonstrated that Group I and II muscle afferent fibers in cats were able to regenerate into the hairy skin and function as sensitive mechanoreceptors (Nishimura et al., Soc. Neurosci. Abst. 16:561, 1990). Almost all (98%) of the cross-innervated muscle afferents exhibited slowly adapting properties typical of Group I and II afferents in muscle but atypical of hairy skin afferents. This suggested that the slowly adapting pattern might be an inherent property of the muscle afferent axon terminal. We tested this hypothesis by axotomizing the nerves to the triceps surae muscles in cats and inserting the proximal cut end of each nerve into a Matrigel-filled Gore-Tex cuff. Six days later the properties of mechanosensitive nerve sprouts were studied by mechanically stimulating the cuff and recording from single afferents in L7-S1 dorsal root filaments. Of the 44 units that had developed mechanosensitivity, almost all exhibited a slowly adapting and regular discharge pattern to cuff stretch. Compared to Group I afferents, Group II afferents exhibited significantly lower stretch thresholds and were more likely to have a resting discharge. We conclude that the physiological signature of large diameter muscle afferents, namely a slowly adapting response to mechanical stretch, is an inherent property of the axon itself independent of its usual muscle spindle or musculotendinous target. After six days of regeneration, the axonal sprouts of Group II muscle afferents seem better able to transduce mechanical stretch stimuli. Supported by NS15913.

ROLE OF MECHANICS IN CUTANEOUS MECHANORECEPTOR RESPONSE. M. A. Srinivasan and K. Dandekar, Research Lab. of Electronics and Dept. of Mechanical Engineering, MIT, Cambridge, MA 02139.

The relationship between the mechanical stimuli imposed on the skin and the resulting stresses and strains at the mechanoreceptor locations plays a fundamental role in the neural coding of tactile information. Although empirical determination of the stress or strain state of a mechanoreceptor is not possible at present, mechanistic models of the skin and subcutaneous tissues enable prediction and verification of the mechanisms of transduction. By using analytical models with simplifying assumptions for mathematical tractability, Phillips and Johnson (J. Neurophys. 46(6), 1981) demonstrated the power of mechanistic analysis in predicting peripheral neural response. In order to eliminate many of the limiting assumptions of these models, we employed numerical techniques of computational mechanics.

Finite element analysis was performed on a series of mechanistic models of the fingerpad under a variety of mechanical stimuli. The models ranged from a semi-infinite medium to cylindrical distal phalanx, composed of either a homogeneous elastic material or a thick elastic shell containing a fluid. Simulations of the mechanistic aspects of neurophysiological experiments involving mapping of receptive fields with single point loads, determination of spatial resolution of two-point stimuli, and indentations by single bars as well as periodic and aperiodic gratings were carried out. The results show, for example, significant differences in the loading imposed by a grating indented into the plane surface of a semi-infinite medium as compared to indenting a cylindrical finger. Also, the strain energy density at the receptor site emerges as a leading contender for the relevant stimulus that causes the responses recorded from slowly adapting afferent fibers. More generally, we demonstrate the power of computational mechanics in investigating the relationship between tactile stimuli imposed on the skin and the resulting peripheral neural response. IMMUNOCYTOCHEMICAL STUDIES ON THE PACINIAN CORPUSCLE. J. E. Landcastle*, J. E. Savage*, N. B. Slepceky* and S. J. Bolanowski, Institute for Sensory Research, Syracuse University, Syracuse, NY 13244.

Using a variety of antibodies to cytoskeletal proteins (e.g., tubulin, filamin, glial fibrillary acidic protein (GFAP), tau, neurofilament 200, microtubule associated protein-2 (MAP-2), actin, S-100, and collagen) we performed immunocytochemistry on Pacinian corpuscles (PCs) obtained from cat mesentery. The purpose was to define and locate cell type specific proteins present in the different regions of this mechanoreceptor. Upon their removal, PCs were appropriately fixed (e.g., 2% paraformaldehyde, acetone, 95% ethanol, or Bouin's fix) and embedded in araldite. One-micron sections were cut, placed on gelatin coated slides and prepared for immunocytochemistry using commercially available primary antibodies and secondary antibodies coupled to FITC. The results showed: a) anti-S-100 protein specifically labeled the inner core of the PC but not the outer core or the neurite; b) anti-neurofilament 200 produced specific staining within the neurite, but no label was found in the inner or outer cores; c) anti-GFAP was found only surrounding the neurite; d) anti-tubulin was localized within the neurite. The results show that glial specific structural and calcium-binding proteins are found in the inner and outer cores surrounding the terminal neurite, and confirm the presence of cytoskeletal proteins within the neurite. Supported by NS 23933 and DC 00098.

44.2

IMMUNOCYTOCHEMICAL PROPERTIES OF RAT DORSAL ROOT GANGLION (DRG) NEURONES INNERVATING MUSCLE, SKIN OR VISCERA. (SPON: J.Wood) M.J. Perry*, S.N. Lawson* and J.Wood. Dept. of Physiology, The Medical School, University of Bristol, Bristol, UK.

This study set out to correlate the peripheral innervation of DRG neurones with their immunocytochemical properties. The study extends the findings of previous workers and examines markers to carbohydrate (cbh) groups for the first time.

Female 10-12 week rats were anaesthetized with pentobarbitone (45mg/kg) and the gastrocnemius, saphenous or greater splanchnic nerve was exposed. The nerve was cut and placed in a tube containing 1µl 3% fast blue solution. After 2-3 days, the rats were re-anaesthetized and perfused with Zamboni's fixative. Appropriate DRGs were removed, frozen serial sections cut and immunocytochemistry performed. A computer system was used to count cells and record their labelling.

An interesting pattern was found with markers to cbh groups. The antibody 2C5 recognises a lactoseries cbh group and most labelling was found in skin afferents with less muscle and few visceral afferents labelled. Many of all three types of afferents showed binding for the lectins peanut agglutinin and soybean agglutinin but the highest percentages were for skin afferents and the lowest for muscle afferents. The antibodies against globoseries cbh groups, SSEA-3 and SSEA-4, were found to label a few muscle and skin afferents but no visceral afferents.

Over 80% of splanchnic visceral afferents were found to be neurofilament poor and were thus small dark (SD) cells whereas muscle afferents contained the greatest proportion of light (L) cells. A third of muscle afferents contained carbonic anhydrase which was present in very few skin and visceral afferents.

The results with all the markers examined in this study thus indicate that the chemical phenotype of DRG neurones is related to their peripheral innervation.

Supported by the Wellcome trust. The SSEA-3 and -4 antibodies were gifts from P. Goodfellow and the anti-carbonic anhydrase antiserum a gift from W. Cammer.

FREQUENCY-RESPONSE FUNCTIONS IN THE PACINIAN CHANNEL USING THE PROPERTY OF TEMPORAL SUMMATION. C.M. Checkosky and S.J. Bolanowski, Institute for Sensory Research, Syracuse University, Syracuse, NY 13244

A model establishing a psychophysical-physiological link in the vibrotactile P channel (Bolanowski, et al, J. Acoust. Soc. Am.: 1988) was based on correlations among the psychophysical frequency response obtained on human glabrous skin and physiological functions measured on two Pacinian-corpusele (PC) preparations: PC fibers innervating human glabrous skin (Johansson, et al, Brain Res.: 1982) and PCs isolated from cat mesentery. Although the three frequency responses were qualitatively similar, the low-frequency slope for the PC fibers differed from the other two functions by being 3 dB/octave less steep. The difference can be explained theoretically by differences in methodology and the property of temporal summation known to exist in the P channel (i.e., a 3 dB increase in sensitivity per doubling of stimulus duration). To test this, psychophysical experiments and physiological measurements on PCs isolated from cat mesentery were performed using two stimulus paradigms: a) constant stimulus duration and b) constant number of stimulus cycles (5) as used by Johansson, et al. When the stimulus duration was held constant at different test frequencies, the low-frequency (40-100 Hz) slopes of both the psychophysical and physiological curves were -12 dB/octave. However, when the stimulus duration was varied across frequency by holding the number of stimulus cycles constant, the low-frequency slopes were -9 dB/octave. The resulting low-frequency slopes agree with the theoretical expectations, the differences explained by methodology and the property of temporal summation. Supported by NS23933 and DC00380.

44.6

VELOCITY DEPENDENT RESPONSES OF PRIMARY AFFERENT MECHANORECEPTORS TO BRUSHING OF FELINE HAIRY SKIN. J.D. Greenspan and S.L.B. McGillis*, Depts. of Neurosurgery and Physiology, SUNY Health Science Center, Syracuse, NY 13210

All types of cutaneous mechanoreceptors respond to a surface-parallel movement across the skin ("brushing"). The brushing velocity influences the neuron's mean firing rate in a systematic manner: a faster velocity produces a greater response up to at least 50cm/s (except for the C-mechanoreceptor).

The relationship between stimulus velocity and response rate is well fit by a power function. The exponent for the power function varies across mechanoreceptor type, but is always less than 1.0. An analysis of 48 mechanoreceptors in the cat's distal hindlimb produced the following mean power function exponents: Field 1=0.72, Guard 1=0.54, SA1=0.46, Guard 2/Int.=0.43, Field 2/Int.=0.39, D-hair=0.26, PC=0.17.

A larger exponent can indicate a better ability to encode stimulus velocity information. However, consideration of the exponent alone does not take response variability into account. A discriminability estimate (d') was calculated for each mechanoreceptor's response to 5.0 vs. 10.0 cm/s stimuli. Only the Field 1 (mean d' =4.3) and the Guard 1 (mean d' =5.6) had values consistent with human perceptual d' on hairy skin (4.3-5.1; Essick et al., 1988). All other afferent types showed d' values below 3.5. Thus, the various classes of hairy skin mechanoreceptors have different capacities for encoding stimulus velocity information.

AN UNBIASED METHOD RELATING CELL DIAMETER OR CROSS-SECTIONAL AREA TO CELL NUMBERS. C.M. Pover and R.E. Coggeshall. The Marine Biomedical Institute, Department of Anatomy and Neurosciences and Department of Physiology & Biophysics., The University of Texas Medical Branch, Galveston, TX. 77550

Studies using histograms to relate cell numbers to cell size will only be accurate if the cell profiles measured are representative of the population. Unfortunately, the assumption that measurements of profiles present in a random histologic section, the "classical" method, truly represent cell sizes is incorrect. This is because a large cell is more likely to be sectioned than a small one.

Using the "disector" method, we have obtained a random sample of rat dorsal root ganglion cells, which have been used to estimate total cell numbers and also to produce area and diameter histograms. If it is accepted that the disector identifies cells in an unbiased way, then comparisons show that the classical histograms over-represent large diameter cells. Supported by NIH grants NS10161 and NS11255.

SENSORY ENDINGS IN THE INNER CONICAL BODY OF THE RAT MYSTACIAL VIBRISSA

T.M. MOSCONI¹, F.L. RICE², AND M.J. SONG³

¹Department of Anatomy and Cell Biology, UCLA, Los Angeles, CA, ²Department of Anatomy, Cell Biology, and Neurobiology, Albany Medical College, Albany, NY, ³Wadsworth Center for Laboratories and Research, Albany, NY

Previously we reported the existence of two types of sensory endings in the rat inner conical body (ICB), a superficial site of innervation in the mystacial vibrissa (Mosconi *et al.*, Proc. XII Int. Cong. Electron Microscopy, (1990):410-411). Lanceolate endings are supplied by myelinated axons, and blebbed endings are supplied by unmyelinated axon bundles. Both sets of endings are embedded in parallel sheaves of collagen, arrayed circumferentially within the ICB around the hair shaft. The two ending types are densely and reciprocally distributed with the lanceolate endings more prevalent in dorsal and ventral quadrants, and the blebbed endings more prevalent in rostral and caudal quadrants. Within the unmyelinated set of endings there are subsets identified immunohistochemically with antibodies to CGRP, galanin and substance P, as well as with the lectin GSA-IB₄. Taken together, these results support a wider role for thin caliber afferents in the ICB than simply nociception, possibly including low or high threshold mechanoreception and/or an efferent role in maintenance of the collagen and vascular matrix.

LOSS OF KNEE JOINT INNERVATION WITH AGING IN THE MOUSE. P.T. Salo and W.G. Tatton. Centre for Research in Neurodegenerative Diseases and Department of Physiology, University of Toronto, Toronto, Ontario M5S 1A8 CANADA

Loss of joint afferents with aging may result in degeneration of articular cartilage due to the failure of reflexes necessary to protect articular surfaces from abnormal loads. Some populations of murine neurons die progressively with age (Tatton *et al.*, 1991). C57 mice develop knee osteoarthritis (OA) with age. Hence we sought to determine if knee joint afferents (KJ-DRGNs) die over the lifespan of C57 mice. Retrograde axonal tracing with Fluoro-Gold (FG, Fluorochrome, Inc.) was used to identify DRG neurons innervating the knee joint in young adult (3 months, n=6), middle aged (8 months, n=5) and aged (16 to 18 months, n=5) C57 isogenic mice (mean lifespan: about 24 months). Mice were injected with 2% FG (0.8 µL) into one or both knees. After 5-7 days DRGs from T13 to L6 were harvested. Serial sections were counterstained with toluidine blue and examined alternately under bright field and UV illumination with appropriate filters (Leitz Filter Block A). FG-labelled somata innervating the mouse knee were distributed over 3 to 5 dorsal root ganglia in a quasi-normal distribution that was centered either at L3 or L4. We found that there are 158.2 ± 6.3 (mean ± S.E.) KJ-DRGNs per knee in 3-4 month old mice declining to 135.2 ± 10.7 at 8 months and 98.8 ± 10.7 by 16 to 18 months, representing a 37% loss over 15 months. Measurement of the KJ-DRGN somal diameters at the youngest and oldest ages indicated that all sizes are lost at similar rates.

Progressive loss of joint afferent innervation occurs in aging C57 mice which may contribute to the development of osteoarthritis in this species. Supported by MRC Grant #MA5218 and The Arthritis Society (Canada)

RESPONSES OF TRIGEMINAL GANGLION CELLS PROJECTING THROUGH DEEP OR SUPERFICIAL VIBRISAL NERVES. P.M.E. Waite & M.F. Jacquin. Anat., Univ. New South Wales, Sydney, Australia; Anat. & Neurobiology, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

The rat vibrissal follicle-sinus complex is innervated by a deep vibrissal nerve (DVN) and several smaller fascicles traveling in the dermis (conus or superficial vibrissal nerves, SVNs). The function of the SVNs is unknown, although it has been suggested (Rice *et al.*, *JCN* 252:154, '86) that they form part of a diffuse, multivibrissal system. Anatomical and electrophysiological methods were used to test this hypothesis. No ganglion cells were double-labeled after HRP and DY injections in the DVN and SVNs of single follicles. In 15 rats, recordings were made from 58 ganglion cells with A-row receptive fields before and after cutting the DVN and/or SVNs to the responsive vibrissa. 83% of this sample projected through a DVN, 17% via a SVN. 15 other SVN cells were assessed after severing all A-row DVNs. No SVN or DVN cells were spontaneously active. All cells responded to single vibrissae; none were responsive to intervibrissal hairs. Latencies to electrical stimulation were similar for DVN (0.94 ± 0.25 ms) and SVN (1.0 ± 0.18) cells. In the DVN group, 40% were rapidly adapting and 60% were slowly adapting (SA); for SVNs, respective values were 20% and 80%. Directional sensitivity was not seen in any rapidly adapting cell, but it was found in all DVN and SVN SA cells. DVN SA cells had no group directional preference; SVN cells were more commonly responsive to caudal deflection. SVN SA cells had higher mechanical thresholds than DVN SA cells. No injury discharges occurred after cutting SVNs, but were present in 44% of DVN cells. Thus, DVN and SVNs differ in some response properties, although SVNs do not provide multivibrissal inputs. NIH DE07734, DE07662.

INNERVATION OF NONMYSTACIAL VIBRISSAE IN THE RAT. B.T. Fundin* and F.L. Rice. Anatomy dept., Albany Medical College, Albany, NY 12208.

Vibrissal follicle-sinus complexes (F-SCs) in the mystacial pad of mammals are heavily innervated by different types of sensory nerve endings (Rice *et al.*, *JCN* 252:154). One site - inner conical body (ICB) - in mystacial F-SCs was uniquely well innervated only in species such as the rat that rhythmically whisk their mystacial vibrissae. In this study we examined the innervation of F-SCs of rat vibrissae that are not whisked and are in other locations on the body. The Winkelmann silver technique was used on 100µm thick frozen sections of F-SCs from: supraorbital (SO), temporal (T), lateral submental (LSM), antero-medial submental (aMSM), postero-medial submental (pMSM), median cervical (MC) and carpal forelimb (CF). Much of the innervation of the nonmystacial F-SCs was similar to that of mystacial F-SCs. All are innervated by a large deep vibrissal nerve (DVN) and several small superficial vibrissal nerves (SVNs). In all F-SCs, SVNs provide qualitatively similar distributions of Merkel endings to the rete ridge and circumferentially oriented endings to the ICB. DVNs provide Merkel and lanceolate endings at the level of the ring sinus and reticular endings at the level of the cavernous sinus. However, in comparison to others, F-SCs from SO,T,LSM,MC and pMSM have few lanceolates, aMSM have diffusely distributed Merkel endings, and CF have few Merkel endings that are diffusely distributed and limited to the superficial portion of the ring sinus. CF F-SCs also have a unique substantial contribution of DVN afferents to the ICB and numerous presumptive corpuscular endings in the cavernous sinus that are rarely seen in other F-SCs. These results failed to find variations in ICB innervation related to whisking but do suggest that some physiological differences should exist among vibrissae from different locations.

TRIGEMINAL SENSORY AXONS PROVIDE PEPTIDERGIC INNERVATION TO GLOMERULI OF THE OLFACTORY BULB. T.E. Finger and B. Böttger. Rocky Mountain Taste & Smell Center, Univ. Colorado Med. Sch., Denver, CO 80262.

Nerve fibers containing both substance P and CGRP occur in the olfactory nerves and glomeruli of the olfactory bulb. Although many investigators presumed that these were olfactory axons, speculation has arisen recently that these peptidergic fibers are derived from trigeminal sensory axons. In order to test this hypothesis, electrolytic stereotaxic lesions of the ophthalmic division of the trigeminal nerve and ganglion were produced in adult Sprague-Dawley rats. Success of the lesion was assessed by testing for abolition of a vigorous blink reflex. After survival periods ranging from 3 to 21 days, the animals were prepared for immunocytochemistry. In control animals and in animals which retained the blink reflex, numerous substance P-immunoreactive and CGRP-immunoreactive varicose fibers were present in the olfactory nerve and in glomeruli of the olfactory bulb. Trans epithelial peptidergic axons, those that reach near the surface of the epithelium, also were present in the mucosa of the dorsal, caudal nasal cavity. In animals lacking the blink reflex, both CGRP- and substance P-immunoreactive fibers were absent from the olfactory nerve and glomeruli. Similarly, trans epithelial peptidergic axons were sparse or absent in the nasal mucosa although subepithelial peptidergic fibers remained. The abolition of peptidergic fibers by trigeminal lesion indicates that these fibers originate from the trigeminal, not the olfactory system. Trigeminal peptidergic fibers also traverse the nasal epithelium and probably serve as the substrate for the sense of irritation produced by strong "odorants". If the peptidergic bulbar fibers are collaterals of those innervating the mucosa, these fibers would provide the basis for an axon reflex whereby irritating "odorants" might cause modulation of bulbar processing of subsequent pure olfactory stimuli.

SENSITIVITY TO SMALL MAGNETIC VARIATIONS IN THE TRIGEMINAL SYSTEM OF THE BOBOLINK. R.C. Beason and P. Semm*. Biology Dept., State Univ. of New York, Geneseo, NY 14454

Electrophysiological recordings from the ophthalmic nerve and the trigeminal ganglion of the bobolink (*Dolichonyx oryzivorus*) indicate the presence of units that are sensitive to small or large changes in the magnetic field. The most sensitive units responded to changes of 200 nT (<0.5% of the earth's total field), but other units responded only to large changes of 30,000 nT or more. Most responses were to rectangular pulses of the magnetic field but other stimuli that units responded to included a 0.5 Hz sinusoidal variation of the magnetic field and a hand-held bar magnet. Fast adapting units responded to the rectangular stimulus with a burst of spikes that was logarithmically correlated with the total change in magnetic intensity. These sensitivities can be best accounted for by a magnetite-based receptor. Financial support was provided by NIH (1R15 NS2601601) to R.C.B. and the Deutsche Forschungsgemeinschaft (Heisenberg Program) to P.S.

PAIN MODULATION: BEHAVIOR

45.1

BEHAVIORAL AND PARAMETRIC ANALYSES OF THE TAIL-FLICK: FURTHER EVIDENCE THAT ALL FLICKS ARE NOT ALIKE. E.A. Bolan*, V.N. Iannone*, J.G. O'Neill*, and J.T. Cannon. Dept. of Psychology & Neuroscience Program, University of Scranton, Scranton, PA 18510-4596.

Several lines of evidence suggest that variations in the intensity of the heat stimulus can alter some neural substrates of the tail-flick and/or its sensitivity to antinociceptive mechanisms (e.g., Cannon et al., 1990; Jensen & Yaksh, 1986; Ness & Gebhart, 1986). The consequences of varying the inter-flick interval (IFI) for testing the tail-flick are less clear.

This study examined tail-flick latencies during 90 min sessions as they were elicited by one of the 9 permutations of 3 heat settings (generating latencies of approximately 2.5, 3.5, and 8.0 sec) and 3 IFIs (1, 5, and 10 min). Several topographical characteristics of the tail-flicks were also recorded.

Ten male albino rats (Holtzman) were individually housed and tested during the dark phase of a 12/12 hr light/dark cycle. On separate days, at about the midpoint of the testing sequence, 24 hr water and saccharin (3mM) intakes were measured. We previously found that the latter covaries with morphine analgesia and an opioid form of stress-induced hypalgesia.

Factor analysis across the 3 heat levels revealed 2 factors: mean latencies elicited by the lowest and highest settings loaded on factor 1 (.74 and .94, respectively), and those elicited by the middle setting loaded on 2 (.96). When saccharin and water intake were added, 3 factors emerged: 1—water (.95) and middle stimulus flicks (.94); 2—saccharin (.98) and low stimulus flicks (.81); and 3—high stimulus flicks (.99). A 3(heat) x 3(IFI) x 10(flicks) obtained at 10 min intervals ANOVA and subsequent analyses revealed that IFI significantly affected latencies at only the lowest heat setting at which 1 min IFIs produced a greater warmup effect with shorter tail-flick latencies occurring after 20 min. The speed of tail movement and most topographical measures varied significantly across heat levels, but not IFIs. At higher heat settings, the behavioral data suggest that animals continue to react to the test stimuli after tail withdrawal. Although the tail-flick occurs at a consistent tissue temperature regardless of the rate of heating (e.g., Ness & Gebhart, 1986), our observations suggest that with higher intensity test stimuli, residual heat in the skin can continue to stimulate nociceptors post-flick. Such suprathreshold stimulation could interact with nociceptors and antinociceptive mechanisms and thereby contribute to some conflicting observations across laboratories.

45.3

EFFECTS OF PREPARATORY SURGERY ON THE THRESHOLD OF THE JAW OPENING REFLEX TO TOOTH PULP STIMULATION IN CONSCIOUS CATS. D. Banks*, M. Kuriakose* and B. Matthews. (SPON: Brain Research Association). Dept. Physiology, University of Bristol, BS8 1TD, England.

Previous experiments in this laboratory have shown that the threshold of the jaw opening reflex (JOR) to toothpulp stimulation is increased following noxious stimulation, including surgery, to other regions of the body in anaesthetized cats. In the present experiments we have investigated changes in this threshold during recovery from surgery. Three male cats were initially prepared under general anaesthesia (alphaxalone/ alphadolone, 18mg/kg I.M. and 5-8mg/kg/h I.V.). An occipital craniotomy was made and covered with a headpiece. A connector block was fixed to the skull over the frontal sinus. An indwelling cannula was inserted into an external jugular vein. Six stainless steel wires were passed subcutaneously from the connector block to the right anterior digastric muscle for recording EMG and Ag/AgCl fillings in the upper and lower right canine teeth for electrical stimulation. The JOR threshold was monitored every 2-10 hours for 7 days.

At the point of recovery from anaesthesia (usually 1-3 hours post operation) the JOR threshold to stimulating either the upper or lower canine tooth was >1000µA/1.0ms. In the following 2 hours both thresholds fell to 800-900µA/0.1ms and continued to decrease for 2.5 to 6 days, finally reaching a value of 17-34µA/0.1ms. The latter values are similar to those obtained in lightly anaesthetized animals without surgery. The threshold changes were similar for both teeth in each animal. In one animal requiring additional maxillary surgery several months after the first operation, there were similar changes in the JOR threshold but they were restricted to the upper canine tooth. In conclusion we suggest that the sustained nociceptor afferent barrage which follows preparation surgery leads to long lasting changes in the threshold of the jaw opening reflex.

POWER SPECTRUM (PS) ANALYSIS OF ELECTROSTATIC WIRE DETECTOR DETECTS POST-SURGICAL MOVEMENT DEFICIT IN THE RAT. Vahn A. Lewis, Univ. of Texas, Dental Branch, Houston, Tx. 77030.

P.D. Wall proposed that following injury, animals experience a behavioral depression that is evident at 24 hours following surgery and may last for several days. J. Olds employed a simple wire movement detector which records movement induced electrostatic potentials. Here scoring of such signals by calculating the PS of the signal is reported. Resultant data can be used to assess movement and movement contamination of coincident EEG signals. 11 Sprague-Dawley rats were anesthetized with pentobarbital for surgery and implanted with recording pedestals for the purpose of recording EEG activity. The "wire" detector was fashioned from 34 cm. of Beldon 8430, audio-connecting cable circling the EEG recording cables. The movement signal was amplified, digitized and PS determined. Recordings were at 4, 8 and 27 hours post surgery, yoked control were made seven days later.

In controls, movement PS progressively increased following anesthesia, $P < 0.001$. Post surgical rats had decreased movement at 27 hours ($P < 0.001$, control=34X surgery). There was no correlation between movement PS and EEG PS.

45.4

PHENTOLAMINE SYMPATHETIC BLOCKS MISLEAD DIAGNOSIS.

R. Verdugo*, S. Rosenblum*, J. Ochoa. Depts. of Neurology and Neurosurgery, Good Samaritan Hosp. and Oregon Health Sci. Univ., Portland, OR 97210.

Phentolamine sympathetic block (PSB) is reputed as pivotal in differential diagnosis of causalgiform neuropathic syndromes and in identifying "sympathetically maintained pain" (Anesthesiology 1989, 71:A732). Prevailing opinions on the matter recommend a "10-15 minute" observation period for placebo response (Arch Neurol 1987, 44:555). We evaluated both effectiveness of PSB and time course of placebo response (a: saline, b: propranolol) in a population of 46 patients, by extending the placebo phase to 30 minutes. Magnitude of spontaneous pain, mechanical hyperalgesia, cold hyperalgesia, and Tinel sign were tested every 5 minutes. Diminution of pain by 50% was considered significant response. Development of nasal congestion, red eyes and thermographic changes documented occurrence of sympathetic block.

Twenty seven of 46 patients did not respond to placebo or PSB; 13 responded significantly to placebo, and 6 to PSB but apparently not to placebo. In 12 of the 13 placebo responders, the effect was not saturated by 15 minutes; four of these would have been considered PSB responders if such short placebo phase had been used. In the 6 who appeared to respond to PSB, progressive pain relief was already witnessed during placebo phase, but by 30 minutes relief had not quite reached 50%. Phentolamine sustained, but did not change, the rate of placebo-induced relief, implying slow cooperative placebo response rather than specific effect of PSB on pain. There was no correlation between thermographic change and response to placebo or PSB.

Conclusions: 1) Placebo accounts for a high percentage of PSBs traditionally considered positive. 2) Placebo incidence in this population is greater than the assumed, 3) PSB is not a viable means for classifying causalgiform syndromes, 4) Proper evaluation of placebo effect demands at least a 30 minute observation period; placebo response develops slowly over time.

45.5

THE ROLE OF NORADRENERGIC NEURONS IN MEDIATING THE ANTINOCICEPTION INDUCED BY LOCUS COERULEUS STIMULATION IN TWO DIFFERENT SUBSTRAINS OF SPRAGUE-DAWLEY RATS. W.L. West*, D.C. Yeomans and H.K. Proudfit. Department of Pharmacology, University of Illinois at Chicago, Chicago, IL 60680.

There is evidence that electrical stimulation of noradrenergic neurons in the rat locus coeruleus (LC) produces antinociception (Jones and Gebhart, 1986a) that is mediated by the inhibition of nociceptive neurons in the spinal cord dorsal horn (Jones and Gebhart, 1986b). However, we have recently demonstrated that noradrenergic LC neurons innervate the ventral horn in one substrain of Sprague-Dawley rats (Sasco, Inc.) and the dorsal horn in another Sprague-Dawley substrain (Harlan, Inc.).

Behavioral experiments were performed in lightly anesthetized rats to define the functional significance of these anatomical differences. Electrical stimulation of the LC produced antinociception in both Harlan and Sasco rats, but only the antinociception in Harlan rats could be reversed by intrathecal injection of yohimbine, an alpha-2 adrenergic antagonist. In addition, the antinociception induced by LC stimulation in Sasco rats could not be reversed by either methysergide or naloxone. These results indicate that stimulation of the LC in Harlan Sprague-Dawley rats produces antinociception that is mediated by noradrenergic neurons. In contrast, the antinociception produced by LC stimulation in Sasco rats is not mediated by noradrenergic neurons. These results suggest that noradrenergic LC neurons are involved in modulating nociception in one rat substrain, but not in the other. ELECTRICAL STIMULATION IN THE MIDBRAIN: EFFECTS ON PSEUDOAFFECTIVE RESPONSES TO COLORECTAL DISTENSION. A. Burnett and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242.

Colorectal distension (CRD) is a characterized noxious visceral stimulus which results in pseudoaffective cardiovascular (CV) and visceromotor (VMR) responses (Brain Res. 450:153-169, 1988). While activation of descending inhibitory systems on cutaneous nociception have been extensively investigated, the effects of these systems on visceral nociception has not been systematically examined.

Present experiments examined descending modulation of visceral nociception from the midbrain periaqueductal gray (PAG). Experiments were conducted in male Sprague-Dawley rats anesthetized with halothane (0.5 - 0.9%). The pseudoaffective responses to CRD (80 mmHg, 20s) were a pressor response, tachycardia and a vigorous VMR (measured from the integrated EMG of the abdominal musculature). Electrical stimulation in the PAG (100 Hz, 100 μ s pulses) inhibited the VMR in an intensity-dependent manner (10 - 100 μ A), while the pressor response to CRD was unaffected at any intensity tested.

These data suggest that the VMR and CV response to CRD are perhaps mediated via different mechanisms, and/or are not modulated by the same centrifugal systems.

45.9

EVIDENCE THAT THE INHIBITORY EFFECTS OF ROSTRAL HYPOTHALAMIC STIMULATION ON NOCICEPTIVE REFLEXES INVOLVE A RELAY IN THE PERIAQUEDUCTAL GREY IN THE RAT. B.M. Lumb* & F.M. Semenenko*. (SPON: Brain Research Association). Department of Physiology, Medical School, Bristol, BS8 1TD, U.K.

Activation of neurones in the anterior hypothalamus/preoptic area (AH/POA) reduces nociceptive responses in the spinal dorsal horn (Lumb, B.M. *J. Physiol.*, 424, 427-444, 1990). Since there are no known direct projections from AH/POA to the spinal cord, these effects must be mediated via a supraspinal relay. One possibility is the periaqueductal grey (PAG).

We have demonstrated in a retrograde tracing study, using fluorescent latex microspheres, that individual neurones in AH/POA project to either the dorsal or the ventral aspect of the PAG and that very few neurones project to both. We have also tested, in six chloralose-anesthetised rats, whether AH/POA stimulation that inhibits spinal reflexes also evokes activity in the PAG. Neurones in the AH/POA were activated by microinjection of the excitatory amino acid DL-homocysteic acid (DLH; 50nl, 0.5M). Descending influences on spinal nociceptive reflexes were assessed by monitoring changes in reflex activity recorded from a lumbar spinal nerve in response to stimulation of visceral afferent fibres in the splanchnic nerve (SPLN).

At 18 of 25 sites tested in AH/POA, microinjection of DLH led to a marked reduction in reflex activity which in all but 5 cases was accompanied by an increase in multi-unit activity in the dorsal and/or ventral PAG. Increases in PAG activity had a similar timecourse to the depression of viscerosomatic reflexes. Interestingly, any SPLN-evoked responses recorded at the same sites in the PAG were depressed over the same timecourse. These data indicate that descending inhibition evoked from the AH/POA involves an excitatory relay in the midbrain PAG. [Supported by the MRC, U.K.]

45.6

THE DEVELOPMENT OF STIMULATION PRODUCED ANALGESIA (SPA) FROM THE PERIAQUEDUCTAL GRAY (PAG) IN NEWBORN RATS. H. van Praag* and H. Frenk. Dept. of Psychology, Tel-Aviv Univ., Ramat-Aviv 69978, Israel.

In adult animals, electrical stimulation of the PAG produces inhibition of nociceptive spinal reflexes, such as the tail-flick (TF). The present study investigated at which age SPA can be first evoked from the PAG in rats. In addition, naltrexone reversibility of SPA was tested. Pups aged 7, 14 or 21 days, and adult rats were anesthetized with Equithesin (3 ml/kg). A monopolar stimulating electrode was lowered into the dorsal or ventral PAG. After assessment of baseline TF latencies, constant current cathodal pulses (100 Hz, 100 μ sec) were delivered, starting 10 sec before and continuing throughout each TF trial until a response occurred, or until cut-off (7 sec). Current intensity (3 to 200 μ A) was increased stepwise for each 2 subsequent TF trials, which were separated by 1 min intervals. It was found that SPA can be elicited starting at 21 days, but not earlier. Effective current intensities were higher in 21-day-old animals (75-100 μ A) than in adults (10-30 μ A). Naltrexone inhibited SPA from the ventral PAG in 21-day-olds but not in adults. These findings indicate that supraspinal modulation of nociception develops only 3 weeks after birth and that the contribution of endogenous opioids to SPA does not remain constant throughout the ontogeny of rats.

45.8

EFFECTS OF LIDOCAINE INJECTION INTO THALAMIC NUCLEI IN THE FORMALIN TEST.

J.E. McKenna and R. Melzack*. Dept. of Psychology, McGill University, 1205 Dr. Penfield Ave., Montreal, Quebec, Canada H3A 1B1.

Pain behavior expressed in the late, tonic phase of the formalin test is not solely dependent upon peripheral input, but may also rely to a large extent on changes within the CNS induced by nociceptor-generated activity which occurred during the earlier phase. Since various thalamic nuclei have been proposed as mediators of separate aspects of the pain experience, this experiment was undertaken to determine if pain behaviors change within the formalin test after the temporary deactivation of ventrobasal, anterior, intralaminar or posterior nuclei of the thalamus. Long-Evans rats received 1.0 μ l intracranial infusions of 2% lidocaine or saline, either before or after a 60 μ l subcutaneous injection of 2.5% formalin acetate in the plantar surface of one hindpaw. The behavioral consequences of lidocaine infusion differed according to the site of delivery and time of administration relative to the formalin injection. Implications of these results are discussed. Supported by NSERC grant A7896.

BILATERAL LESIONS OF THE CENTRAL NUCLEUS OF THE AMYGDALA ATTENUATE ANALGESIA INDUCED BY ENVIRONMENTAL CHALLENGES. R.J. Fox* and C.A. Sorenson. Neuroscience Program, Amherst College, Amherst, MA 01002.

Studies involving shock controllability, exposure to natural predators, and classical conditioning indicate that higher brain regions are likely to be involved in stress induced analgesia. These environmental challenges also induce fear-related behavioral and physiological responses. Since the central nucleus of the amygdala (CNA) has been observed to be a very important brain region for fear-related responses (Davis et al. *Psych. of Learning and Motiv.* 21:263, 1987), it also may be an essential component of the neural circuitry supporting analgesia induced by some environmental challenges. This study tested this hypothesis by examining the effects of radiofrequency lesions of the CNA on analgesia induced by three different forms of environmental challenge: exposure to a cat, acute footshock (1.6 mA, 1 min), and classical conditioning to an environment previously associated with footshock. CNA lesions significantly attenuated analgesia induced by all three forms of environmental challenge, indicating that this nucleus may be critically involved in analgesia induced by environmental challenge as well as fear responses produced by these challenges.

45.11

THE EFFECTS OF DECORTICATION OR HEMISPHERECTOMY ON AUTOTOMY (AT) BEHAVIOUR IN RATS. N.E. Saadé, S.F. Atweh and S.J. Jabbur. Faculty of Medicine, American University of Beirut, Beirut, Lebanon.

Although lesions of the somatosensory cortex in rats have been reported to produce no effect on AT of the denervated contralateral hindleg (Wall, P.D. et al., Pain 35:327, 1988), various types of decortication have been reported to decrease pain in humans and experimental animals (Rampin, O. et al., Somatosensory Res. 4:237, 1987). In this study, two groups of rats (n=5 for each) were subjected under deep anesthesia, to either a massive decortication (group A) or to a massive hemispherectomy (group B) on one side and, after a recovery period (10-15 d), to denervation of the contralateral hindleg by sectioning and ligating the sciatic and saphenous nerves.

In group A, all rats exhibited a delay in onset of AT (27.4±0.87 days, control 12.7±4.14 days). In group B, rats did not show any signs of AT during 7 weeks of observation but a second denervation of the ipsilateral hindleg elicited an accelerated AT, starting simultaneously in both hindlegs (7.8±1.96 days). We conclude: (1) Hemispherectomy (including basal ganglia) abolished while decortication delayed AT. (2) The presence or absence of AT is not related only to neglect or awareness of an insensate appendage, because it was elicited in both hindlegs following an ipsilateral denervation. (Supported by grants from LNRC and DTSabbagh Fund).

PAIN MODULATION: OPIOIDS I

46.1

THE EFFECT OF NOCICEPTIVE FOOTSHOCK AND MORPHINE ON GLUCOSE UTILIZATION IN THE RAT. B. Gescuk*, S. Lang*, D. Huston-Lyons and C. Kornetsky. Boston University School of Medicine, Boston, MA 02118.

The present experiment determined the effects of morphine sulfate (MS) on local cerebral metabolic rates for glucose (LCMR_{glu}) in male F-344 rats required to turn a wheel manipulandum in order to escape from footshock. Four groups of animals were studied: control-saline, control-MS, footshock-saline, and footshock-MS. The two footshock groups were exposed to a maximum of 11 days of half hour sessions of footshock. All animals were administered MS (4mg/kg sc) or saline 7 days, 3 days, and 10 min prior to the start of the LCMR_{glu} experiment. Footshock caused an increase in the medial prefrontal cortex (PFC) and the anterior pretectal area. This effect in the PFC appeared to be reversed by MS, suggesting an inhibition of cortical processing of pain. However, in other sites, MS in the presence of footshock caused an increase in metabolism when compared to footshock or MS alone. These areas were the subthalamus, mammillary bodies, red nucleus and several thalamic regions: VL/VPL, gelatinosus, and parafascicular nuclei. Results suggest that MS in the presence of pain increases metabolic activity in those regions associated with descending inhibitory pain pathways. (Supported in part by NIDA grant DA02326 and Research Scientist Award DA00099 to CK).

46.3

"NON-OPIATE" ANALGESIA IS REALLY OPIATE: APPARENT PARALLEL ACTIVATION OF MULTIPLE SPINAL OPIATE SYSTEMS. L.R. Watkins, E.P. Wiertelak, L.H. Silbert* & S.F. Maier, Dept. of Psych., Univ. of Colorado, Boulder, CO 80309.

Repeated tailshocks (5 s, 1mA, 1 min ITI) elicit 3 sequential analgesias, as defined by s.c. naltrexone (tail flick test): an early opiate after 2 shocks, non-opiate after 10-40 shocks, & a late opiate after 80-100 shocks. The present study identified critical spinal & supraspinal opiate receptors using intracerebroventricular (ICV) & intrathecal (IT) injection of specific opiate antagonists (CTOP, naltrindole, binaltorphimine).

ICV (3rd ventricle injection; 4th ventricle occlusion) studies show that: (1) only the late opiate analgesia is blocked by 7 µg ICV naltrexone; (2) the late opiate analgesia involves supraspinal delta opiate receptors; & (3) neither the early opiate nor the "non-opiate" analgesia is mediated by supraspinal opiates.

IT (lumbar sacral) studies show that: (1) 7 µg naltrexone "non-specifically" attenuates all 3 analgesias; (2) spinal kappa opiate receptors mediate both early & late opiate analgesias; & (3) none of the specific antagonists, when injected singly (equimolar to 7 µg naltrexone), affects "non-opiate" analgesia. (4) However, when a combined injection of mu, delta & kappa antagonists is made (combined dose equimolar to 7 µg naltrexone), "non-opiate" analgesia is abolished. (5) Mu-delta & mu-kappa antagonist pairs also abolish "non-opiate" analgesia; the delta-kappa pair had no effect.

Thus multiple opiate systems are activated during tail shock. The early opiate analgesia involves only spinal kappa receptors. The late opiate analgesia involves both spinal kappa & supraspinal delta receptors. "Non-opiate" analgesia is in fact opiate. Here, parallel spinal processes seem to be involved since analgesia is only blocked by combined mu-delta or mu-kappa receptor blockade. Other putative non-opiate analgesias are now being studied. To date, the data indicate that "non-opiate" analgesias are really opiate. NSF grant BNS 88-09527.

46.2

BEHAVIORAL EVIDENCE FOR THE EXISTENCE OF "ANTI-ANALGESIA" SYSTEMS: CONDITIONED REVERSAL OF OPIOID ANALGESIA. E.P. Wiertelak, L. Subel*, S.F. Maier & L.R. Watkins. Dept. Psych., Univ. CO, Boulder, CO 80309.

The existence of opiate analgesia systems has long been recognized. In recent years, it has been proposed that endogenous "anti-opiate" systems exist as well, serving to antagonize opiate analgesia. The existence of both opiate and anti-opiate systems raises the question of their relative physiological roles in the normal, intact organism. It has been previously hypothesized that endogenous analgesia systems serve to suppress pain in response to danger signals, to aid the animal in escaping life-threatening situations. We propose that the endogenous anti-analgesia systems serve to return the organism to basal pain sensitivity in response to safety signals, so that recuperative behaviors can ensue.

This idea suggests that analgesia elicited by learned danger signals should be reversible by learned safety signals. Therefore, we developed a paradigm to test this notion. Analgesia to learned danger signals was produced by repeatedly pairing contextual cues (general cues provided by the experimental room) with tailshock (see Subel et al., companion abstract). This paradigm rapidly elicits a powerful opioid conditioned analgesia, which is reversible by intrathecal naltrexone (1 µg), intracerebroventricular naltrexone (10 µg) & naltrexone delivered over the frontal cortex (1 µg). The safety signal was provided by a light which was illuminated at shock termination. The animals rapidly learned this safety signal as well, as evidenced by the ability of the light cue to induce the immediate & complete reversal of conditioned analgesia. Summation and retardation-of-acquisition tests established that the light cue served as a conditioned inhibitor of analgesia.

These data provide the first empirical behavioral evidence for the existence of endogenous anti-analgesia mechanisms. NSF grant BNS 88-09527.

ENDOGENOUS OPIOID MEDIATION OF ANALGESIA CONDITIONED TO CONTEXTUAL VS. DISCRETE CUES. L. Subel*, E.P. Wiertelak, S.F. Maier, & L.R. Watkins. Department of Psychology, University of Colorado, Boulder, CO 80309.

Previous work has shown that animals can learn to activate endogenous analgesia systems in response to danger signals. This has been called *conditioned analgesia* (CA). While CA has been observed in response to both discrete (e.g. light cues) & contextual (e.g. room cues) signals, no clear comparison has been made of the two. The purpose of the present study was to: (1) develop paradigms in rats for eliciting CA (tail flick test) to discrete cues (discrete CA) & to contextual cues (contextual CA); & (2) begin defining whether contextual & discrete CAs are mediated by the same systems, by testing each for antagonism by subcutaneous (s.c.) naltrexone, intrathecal (IT) naltrexone, and IT specific opiate receptor subtype antagonists (CTOP, Naltrindole, Binaltorphimine).

In the 1st series of studies, contextual CA was acquired in response to room cues (conditioned stimulus; CS) paired with tailshock (unconditioned stimulus; UCS). Contextual CA was powerfully produced within 3 training sessions. Both s.c. (7, 1, & 0.1 mg/kg) & IT (1 µg) naltrexone completely reversed CA, compared to controls, strongly suggesting opioid mediation of this analgesia, with specific involvement of a critical opioid synapse at the level of the spinal cord. Further IT studies using specific opiate receptor-subtype antagonists showed that µ was primarily, δ was partially, and κ was not observably involved in contextual CA.

In the 2nd series of studies, discrete CA was acquired in response to a light cue (CS) paired with tailshock (UCS). Again, this association was powerfully and rapidly learned. Both s.c. (1 mg/kg) & IT (1 µg) naltrexone abolished discrete CA. IT studies with specific opiate antagonists are in progress. To date, the data indicate that the two analgesias are mediated by common systems. NSF grant BNS 88-09527.

46.5

WHETHER CONDITIONED ANALGESIA IS OPIOID MEDIATED DEPENDS ON SHOCK INTENSITY BUT NOT STIMULUS DURATION.

A.R. Allen*, P.A. Illich, M.W. Meagher, & J.W. Grau. Dept. of Psychology, Texas A&M Univ., College Station, TX 77843.

Pairing a neutral stimulus (the CS) with an aversive event (the US) can endow the CS with the capacity to elicit a decrease in pain reactivity. Although it is commonly held that this conditioned analgesia is opioid mediated, it is clear that a CS can sometimes elicit an analgesia which is not affected by opioid antagonists, suggesting that nonopioid systems can also be engaged. Here we test whether US intensity or CS duration determines the form of the conditioned response (CR). A differential conditioning paradigm was employed in which one auditory stimulus (the CS+) was paired with shock while another (the CS-) was presented alone. Subjects received 6 CS+ and CS- trials spaced across two training sessions. Tail-flick latencies were then assessed during the CS+ and CS- over 2 days. Prior to testing, subjects received saline or naltrexone. Experiment 1 revealed that a 60 s CS elicits a nonopioid CR when paired with an intense (1.0 mA, 0.5 s) tailshock, but an opioid CR when it is paired with a weak tailshock (0.3 mA, 0.5 s). Experiment 2 showed that a 1.0 mA (0.5 s) US elicits a nonopioid CR irrespective of the CS duration (60 versus 300 s). Interestingly, naltrexone enhanced the nonopioid mediated CR in both experiments. The results suggest that US severity, and not CS duration, determine the form of the CR. DISSOCIATION OF ANTINOCICEPTIVE AND MOTOR EFFECTS PRODUCED BY INTRATHECAL ADMINISTRATION OF A SELECTIVE μ -OPIOID AGONIST L.Franck*, C.Miaskowski, K. Sutters*, J. Putris* and J.D. Levine*. University of California San Francisco, San Francisco, CA 94143

The purpose of this study was to determine whether the DAMGO-induced decrease in motor coordination (MC) was correlated with increases in nociceptive thresholds (NT); whether the decrements in MC were also opioid receptor mediated; and whether the time course of recovery of MC and NT differed. The Randall-Selitto paw-withdrawal (PW) test was used to measure mechanical NT. MC was tested using a Ugo Basile accelerating Rotarod treadmill. IT administration of DAMGO produced significant, dose-dependent increases in mechanical NT that correlated with decreases in MC ($R = -0.66$, $p < 0.001$). IT naloxone (5 μ g) reversed the decreases in MC produced by 5 μ g of DAMGO by 90.73%. After administration of the highest dose (5 μ g) of DAMGO, PW and MC testing were continued at 45 min intervals for 225 mins. Statistical analysis demonstrated that MC recovered significantly sooner than nociception. These data confirm spinally mediated motor as well as antinociceptive effects of DAMGO and suggest that both these effects are mediated through an action at an opioid receptor. However, effects may be mediated at different populations of opioid receptors.

46.9

INTRATHECAL MORPHINE AND WITHDRAWAL RESPONSES TO A WIDE RANGE OF STIMULUS INTENSITIES IN THE RAT. M. Strimbu*, F. Guirmand*, J.C. Willer* and D. Le Bars*. INSERM U161, 75014 Paris; Dep. Anesthesiologie, Hôp. Ambroise Paré, 92100 Boulogne-Billancourt; Lab. Neurophysiologie, Hôp. Pitié-Salpêtrière, 75013 Paris.

Most data related to pain and analgesia deal with threshold measurements or studies of responses to a single suprathreshold stimulus. We aimed to determine the effects of various doses of intrathecal morphine on responses to a wide range of stimulus.

Electromyographic (EMG) activities were recorded from the biceps femoris muscle in halothane (0.8%) anesthetized rats. C-fiber evoked reflex responses were elicited by percutaneous electrical stimulation of the sural nerve receptive field applied every 6s in increasing intensities. EMG responses were digitized, full-wave rectified and integrated. Recruitment curves were built by plotting the integrated areas versus the current intensities in the 0-5 times the C-fiber threshold range before and following drug injections.

Below 0.04 μ g, morphine did not modify the recruitment curves; in the 0.04-0.4 μ g range, it produced both an increase in the threshold and a decrease in the slope of the recruitment curves in a dose-related and naloxone-reversible fashion; above 0.4 μ g it completely erased the curves. Interestingly, systemic naloxone (0.4mg/Kg,i.v.) not only reversed these effects, but also facilitated the stimulus-response curves for the higher stimulus intensities, i.e. in the 3-5 times the C-fiber threshold range.

In conclusion, intrathecal morphine not only produces a shift of the encoding functions of the spinal cord but also reduces the gain of these functions, in a narrow range of doses.

46.6

A PERIOD OF RESTRAINT IS NECESSARY TO OBSERVE A STRONG OPIOID ANALGESIA AFTER MILD SHOCK OR A LOW-DOSE OF MORPHINE IN RATS. M.K. Biles & J.W. Grau.

Dept. of Psychology, Texas A&M Univ., College Station, TX 77843.

We have previously shown that exposure to mild shock (3, 0.75-s, 1.0 mA tail-shocks) can elicit both a transient nonopioid and a long-lasting opioid analgesia on the tail-flick test. Unlike the analgesia observed after other "brief shock" paradigms, the analgesia observed in our paradigm appears to be hormonally mediated since it is attenuated by adrenalectomy and dexamethasone (Biles et al., *Neurosci. Abs.*, 16, 99, 1990). We hypothesized that the pituitary-adrenal axis may play a role in our paradigm because subjects are restrained for 20 min before they receive mild shock. The present experiments test this hypothesis. Experiment 1 showed that removing this 20 min period of restraint attenuated the opioid analgesia normally observed 6-10 min after mild shock. Experiment 2 demonstrated that this period of restraint has relatively little impact on the naltrexone-insensitive, nonopioid, analgesia observed 2 min after shock. The last experiment showed that the 20 min of restraint also potentiates the analgesia observed after a low dose (1 mg/kg) of morphine. The results suggest that a period of restraint acts to potentiate opioid mediated analgesic effects. Supported by a Tex. Adv. Res. Proj. (010366-097) to J.W.G.

MICROINJECTION OF MU, BUT NOT DELTA, OPIOID RECEPTOR AGONISTS INTO THE MEDULLARY DORSAL HORN (MDH) PRODUCES NALOXONE-REVERSIBLE FACIAL SCRATCHING IN THE MONKEY. D.A. Thomas, G.M. Williams, K. Iwata, R. Dubner, and D.R. Kenshalo, Jr. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Epidural opioid administration to humans can produce facial itch that is naloxone-reversible. We investigated the effects of selective mu and delta receptor agonists microinjected unilaterally into the MDH on facial scratching in cynomolgus monkeys (microinjection method: Oliveras, et al., *J. Neurosci.* 6:3086, 1986; volume = 0.4 μ l). Scratching was scored for 1-2 hrs following microinjection, and the number of scratches in each of the trigeminal nerve divisions (mandibular, maxillary, and ophthalmic) was counted. The selective mu-receptor agonist, DAMGO (0.0031, 0.0125, 0.0250 μ g), produced a dose-dependent increase in scratching with 0.0250 μ g yielding 106 ± 11 scratches/5 min (saline = 3 ± 1 scratches/5 min) ipsilateral to the injection. Naloxone (0.5 mg/kg; IM) administered 10 min after DAMGO (0.0250 μ g) reversed its effect. In contrast to the effect of DAMGO, the selective delta agonist, DPDPE (1.0, 2.5, 5.0 μ g), produced little or no scratching. Additionally, the delta selective antagonist, naltrindole (1 mg/kg; IM), was ineffective in reversing morphine (5.0 μ g) induced scratching. These data suggest that the activation of mu, but not delta, receptors within the MDH produces facial itch.

46.10

SPINAL ANALGESIA IN FROGS: STUDIES WITH HIGHLY-SELECTIVE OPIOID AGENTS. C. W. Stevens, Oklahoma State University, College of Osteopathic Medicine, Tulsa, OK 74107.

Intraspinal (i.s.) administration of morphine in the amphibian, *Rana pipiens*, has been previously shown to produce a dose-dependent, naloxone-sensitive increase in the nociceptive threshold (NT). The present studies were conducted to examine the specific opioid receptor(s) mediating spinal analgesia. Male and female frogs (25-35 g) were obtained from commercial suppliers and maintained in individual plastic cages. NT was determined by the acetic acid test which consists of log-spaced concentrations of dilute acid applied dropwise onto the frog thigh until a wiping response is elicited. NT was determined 60 min before (baseline) and 60, 120, 180, and 240 min after the i.s. administration of morphine (0.3-10 nmol), the mu opioid, DAMGO (0.03-1 nmol), the delta opioid, DPDPE (1-10 nmol) or the kappa opioid, Dyn A₁₋₉ (10 and 30 nmol). Maximum percent effect was calculated and dose-response curves constructed. ED₅₀'s ($\pm 95\%$ C.I., in nmol/frog) were 2.3 (1.7-3.0), 0.1 (0.08-0.2), and 3.3 (2.3-4.7) for morphine, DAMGO, and DPDPE, resp. I.s. Dyn A₁₋₉ (30 nmol) produced motor dysfunction of the hindlimbs which subsided after 60 min and mild analgesia at a lower dose (10 nmol). Naloxone (10 nmol/g) administered s.c. 1 h before maximal doses of i.s. morphine, DAMGO, and DPDPE, significantly blocked the rise in NT.

These results suggest that specific mu and delta opioid receptors mediate the suppression of chemogenic pain in the amphibian spinal cord. Additionally, Dyn A₁₋₉ appears to produce motor dysfunction in amphibians much like that previously reported for rats.

MORPHINE MODULATION OF STATIC VERSUS DYNAMIC RESPONSES OF COLD-RECEPTIVE NEURONS IN THE MEDULLARY DORSAL HORN. S.S. Mokha, Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

It has previously been reported that highly selective agonists at mu, delta (Mokha, S.S., *J. Physiol.*, 394:152p, 87; Mokha, S.S., *J. Physiol.*, 398:85p, 87) and kappa (Soc. Neurosci. Abs., 16:409p) opioid receptors modulate the static responses of cold-receptive neurons. The present study investigated in detail the effects of morphine on the static versus the dynamic responses of these neurons. Extracellular single unit recordings were made in the superficial dorsal horn of the trigeminal nucleus caudalis in rats anesthetized with halothane. The effects of morphine (1-2 mg/kg, i.v.) were tested on the static and dynamic responses of cold-receptive neurons. Static responses were reduced in a majority of neurons (75%), however, responses of 25% of neurons were enhanced (25%). Effects of morphine, excitatory or inhibitory, were similar on the dynamic and static responses of neurons if the static firing frequency was low. However, morphine had little effect on the dynamic responses of neurons that had a high static firing frequency irrespective of the effects of morphine, excitatory or inhibitory, on the static responses. These latter results are consistent with the evidence obtained in behavioral studies showing little effect of morphine on the mean detection latency to cooling stimuli in the monkey (Oliveras et al., 1986). MORPHINE ENHANCES THE ACTIVITY OF THERMORECEPTIVE-SPECIFIC LAMINA I SPINOTHALAMIC NEURONS IN THE CAT. A.D. Craig and S.J. Hunsley*, Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

The actions of morphine on lamina I spinothalamic (STT) cells have not been determined, although these form half of the STT. The goal of the present work is to test the hypothesis that morphine has differential effects on nociceptive and thermoreceptive STT and "non-STT" lamina I cells. Units recorded with tungsten microelectrodes in L7 in barbiturate-anesthetized cats were characterized with natural stimulation and with antidromic activation from the thalamic sites previously identified anatomically as lamina I STT targets. Stimulus-response functions were measured with a computerized sequence applied with a Peltier thermode. The effects of increasing doses of systemic morphine (0.125-2.0 mg/kg iv) were examined on 9 thermoreceptive-specific (cold sensitive) lamina I STT cells, as well as on other nociceptive-specific and multicreceptive STT and non-STT cells. Morphine significantly enhanced a portion or all of the response functions of 7 of 9 "cold" cells at nearly all doses. Mean overall increases to 105-163% of control across the temperature range of 6-34°C were observed. This result contrasts strongly with the predominant inhibition of nociceptive lamina I cells by morphine. It is consistent with reports that morphine does not affect thermoreception, that morphine in low doses induces choice of a warmer environment (and hyperthermia), and that morphine analgesia is greatly potentiated in a cold environment. These observations support the concept of selective opiateergic modulation of the integration of thermoreceptive and nociceptive activity in the lamina I STT projection system. SUBCORTICAL VISUAL PATHWAYS: MIDBRAIN

47.1

ORGANIZATION OF RETINOTECTAL FIBERS IN THE OPTIC CHIASM OF *Rana pipiens*. R. Waldeck, J. Tsai* and E. Gruberg. Biology Dept., Temple University, Philadelphia, PA 19122

In earlier work we found that after hemisection of the optic chiasm, frogs can accurately respond to visually presented prey throughout the visual field. The retinorecipient optic tectum mediates visually guided prey catching. We therefore investigated the distribution of retinotectal fibers in the optic chiasm of normal animals using horseradish peroxidase (HRP) histochemistry. In each animal we applied HRP to a circumscribed region of the dorsal tectum. After 6-17 days survival parasagittal sections were cut in a cryotome. In the sagittal plane the optic chiasm has roughly the shape of an obtuse triangle with a narrow ventral base and an obtuse angle between the base and caudal boundary. After medial injections labeled fibers are found in ventral areas of the chiasm distributed in a wide rostrocaudal band. After lateral injections labeled fibers are located in the narrower dorsal part of the chiasm. The fibers extend over a large rostrocaudal extent. In each case labeled tissue occupies a much greater proportion of the area of the chiasm section than of the retina. Larger tectal injections result in more than one band of labeled fibers in the chiasm. The bands are separated by unlabeled bands even though there is continuous labeling of retinal tissue within a circumscribed zone. Retinotectal fibers projecting to circumscribed locations in the tectum have a rostrocaudal spread in the chiasm thus accounting for the sparing of prey catching after chiasm hemisection. Supported by NIH Grant EY04366.

EXTRAGENICULATE RETINAL PROJECTIONS IN THE FERRET STUDIED WITH WGA-HRP. S.K. Itaya, E.H. Polley, and T.J. Drolsum*. Dept. of Biomedical Sciences, Univ. of South Alabama, Mobile, AL 36688, and Dept. of Anatomy and Cell Biology, Univ. of Illinois at Chicago, Chicago, IL 60612.

The ferret visual system is a model which has been used in many anatomical and physiological studies, most of which have focused on retinogeniculate and geniculostriate pathways. We have examined the ferret retinal pathways in order to map extrageniculate projections and targets. Following intravitreal injection of WGA-HRP, brain sections were processed for TMB histochemistry. Three cases have been studied to date, with results showing retinal pathways in compliance with the general mammalian model, and several "nonvisual" retinorecipient areas. Extrageniculate retinal axons project to the suprachiasmatic nuclei, the pretectal area, the tectum, and the accessory optic system. All areas receive bilateral input, except the dorsal terminal nucleus.

There were six "nonvisual" retinal pathways, four rostral to the pretectum, and two caudal to the superior colliculus. Three groups of retinal axons continue rostrally from the brachium of the superior colliculus and form focal terminal areas. These axons project to: 1) an area between the dorsomedial and lateral dorsal nuclei, near the surface of the thalamus; 2) a caudal level of the dorsomedial nucleus adjacent to the lateral habenular nucleus; and 3) the parafascicular nucleus. A fourth group of axons continues from the lateral geniculate nucleus, along the stria terminalis; most of these fibers appear to terminate in the bed nucleus of the stria terminalis.

Labeled fibers also project from the caudal border of the superior colliculus into the inferior colliculus, where they appear to terminate in a scattered manner around the periphery. In addition, a sparse projection extends further caudally, to the parabrachial nucleus in the upper pons.

47.2

ABSENCE OF A RAPIDLY-CONDUCTING COMPONENT FROM THE IPSILATERAL RETINOFUGAL PATHWAY OF FERRETS. G.E. Baker* & M.P. Stryker. Dept. of Physiology and Neuroscience Graduate Program, University of California, San Francisco, California 94143-0444, U.S.A.

Anatomical evidence indicates that the ipsilaterally-projecting population of retinal ganglion cells in the ferret lacks alpha cells or large diameter axons (Vitek et al., 1985, *J. Comp. Neurol.* 241 1-11; Reese & Baker, 1990, *Eur. J. Neurosci* 2 34-49). The present study sought physiological confirmation of these findings.

Electrodes placed in the optic chiasm and both optic tracts of adult sable ferrets were used for stimulation and recording. Antidromic responses to stimulation of these sites were recorded from the region of the optic disk. As previously reported (Baker & Stryker, 1990, *Nature* 344 342-5), stimulation of either the optic tract contralateral to the recording electrode or the optic chiasm resulted in optic disk potentials displaying two early peaks, a short latency (t_1) mode and a longer latency (t_2) mode, along with (at higher intensities of stimulation), much later peaks of much smaller amplitude. In contrast, responses evoked by stimulation of the optic tract ipsilateral to the recording electrode showed only one peak, with a latency comparable to that of the t_2 mode in the crossed projection. Similar observations were made when stimulating from the retina and recording orthodromic responses in both optic tracts: the uncrossed pathway lacked the short latency peak which was observable in the response of the crossed pathway.

The t_1 and t_2 conduction velocity peaks are believed to reflect respectively the responses of the Y and X retinal ganglion cell populations. We conclude therefore that the uncrossed projection of the ferret's retinofugal pathway lacks a significant Y cell component.

47.4

ULTRASTRUCTURAL ANALYSIS OF RETINAL, CORTICAL AND PARABIGEMINAL TERMINALS WITHIN THE SUPERFICIAL GRAY OF THE PRIMATE SUPERIOR COLLICULUS. S. Feig*, D.P. Van Lieshout* and J.K. Harting. Department of Anatomy, University of Wisconsin-Madison, Madison, WI 53706

We have used electron microscopic anterograde autoradiography to analyze the synaptic relationships of retinal, cortical and parabigeminal axon terminals within the superficial gray (SGS) of the Galago superior colliculus.

Following an injection of an equal mixture of 3H-proline and 3H-leucine into one eye, labeled retinal terminals within the SGS contain round vesicles, pale mitochondria, exhibit asymmetrical synapses and contact dendrites, some of which contain vesicles. Based upon terminal diameter and morphology, two populations of ipsilateral and contralateral retinal terminals are apparent.

Injections of tritiated amino acids into area 17 result in the labeling of terminals in the SGS which contain round vesicles, dark mitochondria, make asymmetrical contacts and terminate upon conventional spines (most frequently), dendrites and (occasionally) vesicle filled profiles. There appear to be two populations of cortical terminals. This distinction is based upon differences in size (small vs. large) and vesicle distribution (densely packed vs. dispersed).

Following injections of amino acids into the parabigeminal nucleus, labeled terminals within the SGS contain round vesicles and make asymmetrical contacts; such contacts are less pronounced than those associated with retinal and cortical terminals. Parabigeminal terminals contact spines, vesicle filled profiles and dendrites. The latter are more frequently contacted by parabigeminal terminals than by retinal or cortical terminals.

47.5

LAMINAR DISTRIBUTION AND ORIGINS OF THE CATECHOLAMINERGIC INNERVATION OF THE OPTIC TECTUM IN THE PIGEON (*Columba livia*). H.R. Rodman and H.J. Karten. U.C. San Diego Department of Neurosciences, La Jolla, CA 92093.

Combined immunohistochemical and retrograde tracing methods were used to characterize the catecholaminergic (CA) innervation of the pigeon optic tectum (TeO), the major target of retinal projections in birds. Antibodies against tyrosine hydroxylase (TH) revealed that CA innervation is most dense in the superficial, retinorecipient layers of the dorsal TeO, where three bands are evident: 1) a band in layer 4 of Cajal; 2) a dense band of tortuous fibers with prominent varicosities in upper layer 5; and 3) a band of predominantly horizontal and oblique fibers in layer 7. Ventrally, the pattern of staining in the superficial layers becomes fainter and more uniform and a dense plexus of thick varicose fibers becomes evident in layers 10-11. Dense terminal-like labelling was also evident adjacent to the tectal ventricle (layer 15). Unilateral injections of fluorescent latex microspheres or cholera toxin into the TeO in combination with TH immunohistochemistry revealed double-labelled cells bilaterally in the locus coeruleus (LoC), the nucleus subcoeruleus, and in a zone immediately medial to and extending around the nucleus pretectalis. This pretectal CA group has not been previously described in birds and appears to have no mammalian equivalent. Intraperitoneal injections of the noradrenergic neurotoxin DSP-4 produced a moderate depletion of TH staining in all layers of the TeO at survival times of 2-3 mos. and no effect at shorter survival times, in contrast to the total depletion seen in mammalian superior colliculus after DSP-4 treatment (Fritschy & Grzanna, 1989). Thus, the CA innervation of the avian TeO appears to involve noradrenergic modulation of incoming visual information in the superficial layers by the LoC, as in mammals, but derives from other sources as well.

GABAA SUBUNIT RECEPTOR DISTRIBUTION IN THE CAT SUPERIOR COLLICULUS USING ANTIBODY IMMUNOCYTOCHEMISTRY. Ranney Mize and Grace Butler, Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, TN 38163.

GABA neurons are found throughout the cat superior colliculus (SC). They are distributed densely within the zonal (ZL) and superficial gray layers (SGL) and more sparsely within the deep layers. We have used the antibody mAb 62-3G1 directed against the β subunit of the GABAA receptor/benzodiazepine receptor/Cl⁻ channel complex to compare the distribution of this receptor subunit with that of GABA neurons. The antibody was localized using light and electron microscope immunocytochemistry. Particulate reaction product was found densely distributed through the ZL and SGL of SC and more lightly within the deeper layers. Within the ZL and SGL, there were few somata labeled by the antibody, although some cells contained a halo of reaction product on their outer membrane surfaces. Within the optic and deeper layers, numerous cells contained internalized cytoplasmic label as well as a dense rim of reaction product around the edge of the cell. At the ultrastructural level, label was found along the membrane surfaces of many cell bodies and dendrites. Often this label filled the synaptic cleft and coated the membranes at synaptic sites between axon terminals and dendrites. However, membrane associated label was also found at non-synaptic sites and sometimes coated much of the outer membrane surface of a cell. Often, but not invariably, the synaptic vesicles which were presynaptic to labeled membranes were flat-tened or pleomorphic in shape. Rarely, membrane associated label was found coating a presynaptic vesicle-containing profile. These results suggest that the GABAA receptor β subunit is often postsynaptic in location and associated with flattened vesicle synapses, many of which are known to be GABAergic. However, it is also found at non-synaptic membrane sites and occasionally on presynaptic profiles. Supported by NIH EY-02973. Antibody kindly supplied by Dr. A.L. de Blas.

47.9

SOMATOSTATIN LOCALIZATION WITHIN THE PRETECTAL COMPLEX AND ADJACENT MIDBRAIN STRUCTURES: AN *IN SITU* HYBRIDIZATION STUDY. I.T. Weber, I.-L. Chen*, H. Shay*, and D.L. Hurley. Neuroscience Training Program and Department of Anatomy, Tulane University School of Medicine, New Orleans, LA 70112.

We previously used immunocytochemical (ICC) methods to demonstrate the locations of somatostatin (SOM) positive neurons within the pretectal complex of the cat. ICC revealed SOM-positive neurons within the oculomotor complex and the interstitial nucleus of Cajal which had not been previously reported. The present study employed *in situ* hybridization to detect preproSOM (ppSOM) mRNA in the regions of the midbrain. An ³⁵S-labelled antisense RNA probe was transcribed from a cDNA obtained from Dr. Richard Goodman (New England Med. Ctr.), and hybridized to tissue sections according to standard procedures. Specific ppSOM hybridization signals were noted in several regions, confirming ICC results. Within the pretectal complex, ppSOM mRNA containing neurons were located within the nucleus of optic tract, the pretectal olivary nucleus and the posterior pretectal nucleus. Neurons containing ppSOM mRNA were also found within the red nucleus, Edinger-Westphal nucleus, nucleus of Darkschewitsch, nucleus of the posterior commissure, superior colliculus, periaqueductal gray, and the interpeduncular nucleus. Neurons containing ppSOM mRNA were also located with the oculomotor nucleus and the interstitial nucleus of Cajal. These data furnish additional evidence that SOM mRNA and peptide is expressed within these important midbrain visual structures. Supported by PHS grant EY03731 (JTW).

THE SYNAPTIC ORGANIZATION OF THE RAT PRETECTO-COLLICULAR SYSTEM. AN ULTRASTRUCTURAL DEMONSTRATION OF GABAERGIC AND NONGABAERGIC PROJECTION NEURONS. J.J.L. VAN DER WANT*, J.J. NUNES CARDOZO* and C. VAN DER TOGT*. (SPON: EUROPEAN NEUROSCIENCE ASSOCIATION). Dept. of Morphology, The Netherlands Ophthalmic Res. Inst., P.O. Box 12141, 1100AC Amsterdam, The Netherlands.

Neurons in the pretectal Nucleus of the Optic Tract (NOT) have been investigated with retrograde WGA-HRP tracing from the Superior Colliculus (SC) and postembedding with an antiserum against GABA. The specific objective of this study was to identify and characterize the projection neurons that form part of the GABAergic circuitry interconnecting two primary visual, subcortical centers, that are involved in eye movement regulation.

Small iontophoretic injections of WGA-HRP were placed at different depths in the SC. Retrogradely labeled cell bodies were visualized with DAB and preembedding gold substituted silver peroxidase treatment. Identified neurons in the contralateral NOT are large to medium sized, show deeply indented nuclei, electron lucent cytoplasm with dark mitochondria, extensive Golgi apparatus and stacks of endoplasmic reticulum. GABA reactivity was observed in a substantial number of labeled cell bodies and dendrites in areas that contain also non GABAergic retrogradely labeled neurons. The pretecto-collicular neurons are partly surrounded by glial processes, but are also in receipt of axon terminals (F) that are nonGABAergic, in this respect they differ from the pretecto-olivary neurons that show limited glial coating and receive, apart from F terminals, also retinal (R) terminals and terminals of dendritic origin (P) on the soma. The dendrites of identified neurons are contacted by R, F and P terminals. The GABAergic projection is in agreement with light microscopic observations in the cat and supports the idea that GABAergic circuits might play an important role in the inhibitory control in subcortical visual centers related to eye movements.

47.8

LOCALIZATION OF THE m1 MUSCARINIC ACETYLCHOLINE RECEPTOR IN THE CAT SUPERIOR COLLICULUS. Chang-Jin Jeon¹, B. Ranney Mize¹, Gary R. Luthin,² and Chia-Sheng Lin², ¹Dept. of Anatomy and Neurobiology, Coll. of Medicine, Univ. of Tennessee, Memphis, TN, and ²Dept. of Physiology and Biophysics, Hahnemann Univ. Philadelphia, PA.

The m1 muscarinic acetylcholine receptor (mAChR) has been localized in the cat superior colliculus (SC) with antibody immunocytochemistry. Two patterns of labeling were found. Within the superficial SC, the receptor antibody formed a dense band of reaction product within the zonal (ZL) and upper superficial gray layers (USGL). The reaction product was evenly distributed through the neuropil and sometimes coated membrane surfaces of neurons. Within the deeper layers (DL), the antibody was internalized within the cytoplasm of cell bodies and proximal dendrites, where it formed a dense particulate reaction product. In some cases, the antibody also appeared to coat the outer membrane surfaces of these cell bodies. To better characterize these cells, we plotted their laminar position and measured their size. Only a few labeled neurons were found within the ZL and USGL. By contrast, the optic and DL contained numerous labeled cells with the densest distribution within the intermediate gray layer (IGL). Anti-m1 mAChR labeled neurons were medium to large size (range 9.3-80.8 μ m) including some very large "predorsal bundle" cells in the DL. Adjacent sections labeled by antibodies to choline acetyltransferase (ChAT) showed no obvious correlation between the distribution of ACh fibers, which form distinctive patches in the IGL, and the m1 receptor labeled cell bodies. However, the dense band of m1 immunoreactivity in the ZL and SGL did partially overlap the band of ChAT fibers in that region of SC. This band may contain primarily presynaptic receptors given that very few cells in this region internalize the receptor. By contrast, the internalization in the DL suggests the cells may be ACh fiber recipient neurons. Supported by NEI EY-02973 (R.R.M.) NIH NS-23006 & Scottish Rite Foundation (G.R.L.)

CALBINDIN-D_{28K} AND PARVALBUMIN LOCALIZATION IN THE PRETECTAL COMPLEX AND ADJACENT VISUAL STRUCTURES OF THE SQUIRREL MONKEY. J. Scriptor, L. Harrison, C.G. Cusick, and J.T. Weber. Neurosciences Training Program and Department of Anatomy, Tulane Medical School, New Orleans, LA 70112.

Standard immunocytochemical methods were used to localize calbindin-D_{28k} (CB) and parvalbumin (PB) within the pretectum complex and adjacent visual structures in the squirrel monkey. Within the pretectum, CB-positive neurons are located predominantly in the pretectal olivary nucleus and to a lesser extent in the nucleus of the optic tract and the posterior pretectal nucleus. PB-positive cell bodies are numerous within all pretectal nuclei except the pretectal olivary nucleus where only a few scattered PB-positive cell bodies are seen. The complementary nature of these two calcium binding proteins is also seen within other visual structures. Thus, in the dorsal lateral geniculate nucleus, CB-positive neurons are found primarily in the S-layers and the interlaminar layers: PB-positive cell bodies occupy the entire magno and the parvocellular layers. Within the parabigeminal nucleus, PB-positive neurons are abundant, and CB-positive neurons are absent. CB neurons within the superior colliculus are located in the superficial, optic and upper intermediate layers, while PB neurons were most numerous within the intermediate layers. These data suggest that PB and CB are concentrated within different functional pathways in the primate visual system. Supported by NIH grant EY03731.

DISTRIBUTION OF CALCIUM BINDING PROTEINS IN THE CAT PRETECTAL COMPLEX. H. Shay, C.G. Cusick, F.R. Domer and J.T. Weber. Neuroscience Training Program and Department of Anatomy, Tulane Medical School, New Orleans, LA. 70112

Standard immunocytochemical methods were used to localize calbindin-D_{28k} (CB) and parvalbumin (PB) within the pretecal complex of the cat. The most significant finding is the presence of several dense plexuses or patches of immunoreactivity (IR). These patches of IR, in both the CB and PB tissue, 1) contain labeled axon terminals and cell bodies; 2) appear to overlap with retinal input; and 3) precisely overlap each other. The IR appears as continuous columns, rostrally within the pretecal olivary nucleus (ON) and nucleus of the optic tract (NTO) and caudally within the posterior pretecal nucleus and NTO. Within the patches, CB-labeled neurons are more numerous than PB-labeled neurons. IR in nonpatch pretecal regions includes scattered labeled CB neurons in the NTO and PB-labeled neurons in the NTO, ON, and anterior pretecal nucleus (APN). The most obvious difference in the CB and PB material is the abundance of PB terminals and PB-positive neurons in the APN, whereas this nucleus is almost devoid of CB staining. These data are in contrast to the locations of calcium binding proteins in the primate pretecal (see Scriptor et al., *Neurosci. Abstr.*, 1991); and underscore the non-complementary nature of CB and PB in some cat nuclei. While CB and PB can delineate certain nuclei in the cat, they do not discriminate different functional pretecal subsystems. Supported by grant EY03731.

NEURONAL AND SYNAPTIC ORGANIZATION OF THE OLIVARY PRETECTAL NUCLEUS IN THE RHESUS MONKEY INVESTIGATED BY THE IMMUNOHISTOCHEMICAL LOCALIZATION OF CALCIUM BINDING PROTEINS AND GABA. Robert F. Spencer and R. Ranney Mize. Dept. Anat., Med. Coll. of Virginia, Richmond, VA, 23298, and Dept. Anat. & Neurobiol., Univ. Tenn. Coll. Med., Memphis, TN 38163.

The olivary pretecal nucleus (OPN) is a retinorecipient area in the rostral dorsal midbrain as demonstrated by intraocular injections of WGA-HRP. Monoclonal antibodies to the calcium binding proteins calbindin D-28k (Calb) and parvalbumin (PA) reveal a distinct organization of neurons within the OPN. Calb-immunoreactive (IR) neurons are arranged as clusters and comprise the majority of neurons in the OPN. Fewer neurons are PA-IR, and, although also clustered, these are located predominantly along the medial border of the nucleus. GABA-IR neurons comprise only a small minority of the neurons in the OPN. By electron microscopy, the clustering arrangement of Calb-IR and PA-IR neurons is attributable largely to compartments of neuropil comprised of the dendrites of these neurons and synaptic endings, many of which are of retinal origin and establish axodendritic synaptic connections with both Calb-IR and PA-IR neurons. Most Calb-IR dendrites are conventional, whereas many PA-IR dendrites contain synaptic vesicles and establish dendro-dendritic synaptic contacts. The density of synaptic endings that contain pleiomorphic synaptic vesicles, many of which are GABA-IR, appears to exceed what might be expected from the few GABA-IR neurons within the nucleus, suggesting the existence of a significant extrinsic inhibitory input to the OPN in the monkey.

Supported by USPHS Research Grants EY02191 and EY02973.

DESCENDING PATHWAYS FROM THE NUCLEUS OF THE OPTIC TRACT IN THE FUSCATA MONKEY. S. Watanabe*, I. Kato, S. Sato*, T. Okada*, and M. Norita. Dept. Otolaryngol., St. Marianna Univ. Sch. Med., Kawasaki 213, and Dept. Anat. Niigata Univ. Sch. Med., Niigata 951, Japan.

The nucleus of the optic tract (NOT) is the visuo-motor relay between the retina and preculomotor structures in the pathway mediating optokinetic nystagmus (OKN). In the present study, how OKN signals are transmitted from the NOT was investigated using biocytin as an anterograde tracer. After identifying the position of the NOT electrophysiologically, biocytin (Sigma, 5% in 0.05 M Tris-HCl buffer at pH 7.6, total 0.3-0.7 µl) was injected mechanically through a micropipette into this nucleus. Descending fibers from the NOT consisted of the following three major pathways: 1) the NOT-contralateral NOT fibers which traversed in the posterior commissure into the contralateral NOT, the superior colliculus, and the dorsal terminal nucleus; 2) the NOT-dorsolateral pontine nucleus (DL) fibers which descended along the lateral border in the ventral part of the lateral terminal nucleus, the parabrachial nucleus, mesencephalic reticular formation and terminated in the DL; and 3) the NOT-NRTP-PH and IO fibers which descended into the frontal tegmental field ventromedially and reached the medial lemniscus. At the level of the nucleus reticularis tegmenti pontis (NRTP), fibers terminated partly in the rostrocaudal 2/3 of the nucleus and passed through it, forming two separate fiber bundles at the level of 7th nucleus and terminated in the rostral part of the prepositus hypoglossi (PH) and the dorsal cap of the inferior olive (IO), respectively. In conjunction with the physiological data, OKN tract from the NOT may terminate directly in the prepositus, sending bifurcating their axons to the pontine nuclei.

CALBINDIN LABELED NEURONS RECEIVE SIGNIFICANT SYNAPTIC INPUT FROM RETINAL TERMINALS WITHIN THE CALBINDIN CELL CLUSTERS OF THE CAT PRETECTUM. S. Emami*, G.D. Butler*, B. Nabors, Q. Luo, R.F. Spencer, and R.R. Mize. Dept. of Anat. Neurobiol., Univ. of Tennessee, Memphis, TN 38163.

We have previously shown (Nabors and Mize, *J. Neurosci.*, 1991) that the cat pretecal contains four clusters of neurons that are labeled by the calcium binding protein calbindin (CaBP). These clusters form four continuous zones that cross nuclear boundaries but perfectly overlap the retinal terminal zones found in the pretecal of cat. The CaBP neurons are medium to large in size and many project to the lateral geniculate nucleus (LGN). They are not labeled by GABA antibodies and GABA cells are almost always smaller. In this study, we have determined whether CaBP cluster neurons actually receive synaptic contacts from retinal terminals and whether they are the only neurons which receive these contacts. We examined thin sections treated with a CaBP antibody. At the electron microscope level, we found numerous somata, dendrites, and myelinated axons labeled by CaBP within the pretecal cell clusters. The somata were mostly medium to large neurons with plentiful cytoplasm. Many of the dendrites were quite thick with parallel arrays of labeled microtubules. Many of the axons were large and heavily myelinated. Retinal terminals were frequently found in contact with thick and thin labeled dendrites, some of which were found within retinal glomeruli. However, we did not find examples of CaBP labeled F2 presynaptic dendrites, which are thought to be GABAergic. F2 presynaptic dendrites frequently receive input from retinal terminals in both the pretecal and dLGN. We therefore conclude that CaBP labeled neurons are not the only cells within the pretecal clusters which receive retinal innervation, and retinal input must not be the sole determinant of whether a pretecal cluster cell will or will not contain calbindin. Supported by USPHS grants NIH EY-02973, NIH DK-07405, and the Howard Hughes Medical Institute.

AFFERENT AND EFFERENT PATHWAYS OF THE TURTLE BASAL OPTIC NUCLEUS IDENTIFIED USING FLUORESCENT TRACERS. A. E. Hurrianko and M. Ariel. Dept. of Behavioral Neuroscience, University of Pittsburgh, Pgh., PA 15260.

The connectivity of the basal optic nucleus (BON) of the turtle accessory optic system was investigated using fluorescent tracers. Solutions of tetramethylrhodamine dextran (n=16) or 1,1'-dioctadecyl-3,3,3',3'-tetramethylindocarbocyanine perchlorate (di I, n=9) were injected with a micropipette into the BON or habenula of *Pseudeis scripta elegans* using an *in vitro* preparation of the turtle brain with eyes attached (Rosenberg & Ariel 1988). Tissues were maintained for 12-24 hrs. in oxygenated Ringers (dextran) or 1-3 mos. in 4% paraformaldehyde (di I) before cutting 60 µm transverse sections.

BON injections retrogradely labeled many ipsilateral neurons in the oculomotor nuclei, pretecal nuclei, ventral tegmentum, ventral habenular nucleus and the dorsal and ventral nuclei of the posterior commissure (the latter receive input from the striatum). Fibers were seen which project to the contralateral BON via two paths: across the posterior commissure and through the tegmental decussation. Longitudinal fibers ran along the ventralmost aspect of the brain, some of which appeared to terminate in tiny puncta located in the Purkinje cell layer of the cerebellar cortex. In addition, a sub-population of ganglion cells were labeled in the retina.

The habenular injections labeled the small, round cells of the ventral nucleus, as well as fibers coursing in bundles toward the interpeduncular nucleus or BON, showing the anterograde aspect of the latter connection.

The pathways revealed by these experiments indicate the important role that the BON plays in relaying retinal information into the brainstem. The BON signals may be influenced by cortical projections, as well as relayed to the cerebellum for interaction with motor systems (Supported by EY05978).

ELECTRON MICROSCOPIC EVIDENCE OF CAPSAICIN-INDUCED DEGENERATION IN RAT BRAIN AND RETINA. T.T. Dinh and S. Ritter. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Using various silver stains, we have demonstrated capsaicin-induced argyrophilia in specific sites throughout the rat central nervous system. The purpose of this experiment was to confirm the presence of capsaicin-induced degeneration in several of these sites with electron microscopy. To date, we have examined two capsaicin-sensitive sites, the nucleus of the solitary tract (NTS) and retina. Twenty-day-old rat pups were anesthetized, treated with 90% dihydrocapsaicin (Sigma, 75 mg/kg, s.c.) or the alcohol/Tween 80 vehicle solution, and killed 6 hrs later by anesthetic overdose. In the NTS, degenerating terminals appeared as highly condensed, electron dense aggregations of disorganized intracellular organelles, devoid of cytoplasm and frequently surrounded by or in close proximity to microglial processes. In the retina, degenerating bipolar and ganglion cell soma were recognizable by their highly condensed cytoplasm, nuclei and organelles. Degenerating soma appeared to be shrunken away from adjacent normal cells. Results further demonstrate the neurotoxicity of capsaicin for specific neuronal populations in the central nervous system. Supported in part by PHS #RO1 DK40498.

48.1

Physiology and morphology of identified projection neurons in rat visual cortex studied *in vitro*

Ekkehard Kasper*, Alan U. Larkman*, Colin Blakemore and Stuart Judge.
University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, U.K.

We have investigated the correlation between the electrophysiology and the morphology of identified projection neurons in an *in vitro* slice preparation of adult rat visual cortex. Cells were prelabelled via stereotaxic injections of rhodamine conjugated latex microspheres into either the ipsilateral superior colliculus or the primary visual cortex of the contralateral cortical hemisphere two days prior to the date of slice preparation. Prelabelled pyramidal neurons were visualized in the slice by fluorescence microscopy and injected carboxyfluorescein during the recording procedure to obtain intracellular staining for subsequent morphological classification.

Cells projecting to the superior colliculus fired action potentials in bursts in response to depolarizing suprathreshold current pulses and all had an apical dendrite arborizing in layer I. Callosal projecting cells had an apical dendrite that did not arborize in layer one and these cells did not fire action potentials in bursts but had a regular spiking pattern. The two populations differed significantly in some other features of their electrophysiology, e.g. cells projecting to the superior colliculus had shorter membrane time constants and lower input resistances compared to cells projecting to the contralateral hemisphere.

48.3

TRANSMISSION OF NEURAL EXCITATION IN RAT VISUAL CORTICAL SLICES VISUALIZED BY OPTICAL RECORDING.
M. Tanifuji, A. Yamanaka*, and K. Toyama.

Natl. Inst. Physiol. Sci., Okazaki, 444, JAPAN
Transmission of neural excitation in rat visual cortical (VC) slices stained with a voltage sensitive dye (RH482) was visualized using a cooled CCD video camera as time-lapse images taken by strobe illumination at different time-lags after white matter (WM) stimulation. A sequence of events were found: 1) impulses propagating from WM to the cortical surface, 2) monosynaptic excitation produced in layers IV and V-VI, 3) polysynaptic excitation in layer II-III transferred from layer IV, 4) higher order polysynaptic excitation transmitted back to layers V and VI. The main component of excitation propagation was restricted to a vertical stripe probably corresponding to columnar structure with some lateral spread in layers II-III and V-VI. The lateral spread was abolished by blockade of synaptic transmission with DNQX and APV, but the columnar component remained unaffected, indicating that the latter component represents impulse propagation. The spread of excitation was greatly affected by pharmacological modification of cortical inhibition by GABA antagonists and agonists.

SYNAPTIC PROPERTIES OF NEURONS IN TURTLE VISUAL CORTEX IN AN APPARENT MOTION PARADIGM STUDIED *IN VITRO*.
P. S. Ulinski, L. J. Larson-Prior and N.T. Slater. Dept. Organismal Biology and Anatomy, Univ. Chicago, Chicago, IL 60637, and Dept. Physiology, Northwestern University, Chicago, IL 60611.

Apparent motion properties of neurons in visual cortex of turtles (*Pseudemys scripta*) were studied in an *in vitro* preparation of isolated cortex by sequential, electrical stimulation of geniculocortical fibers carrying information from two different regions of visual space. Postsynaptic potentials elicited by stimuli applied to two bundles of geniculocortical fibers in sequence were recorded intracellularly from cortical neurons. The ratio (P) of the second PSP to its control value was plotted as a function of interstimulus interval (t) between 25 and 1,000 msec. These P(t) curves show a fast facilitatory peak, an intermediate inhibitory peak and a slow facilitatory peak. P(t) curves could be modeled as a function of the form:

$$P(t) = 1 + N_1 t \exp(-a_1 t) + N_2 t \exp(-a_2 t) + N_3 t \exp(-a_3 t).$$

The times to peak (1/a_i) for the three components were 25-50, 75-100 and 200-500 msec. Bath application of the NMDA receptor antagonist AP-5 (100 μM) significantly reduced the amplitude of the late component. These experiments indicate that circuitry within the cortex generates a complex form of synaptic interaction that likely plays an important role in the temporal integration involved in visual motion analysis. Supported by grants EY68352 (PSU) and NS17489 and NS25682 (NTS).

48.2

SPATIAL INPUT SPECIFICITY OF SYNAPTIC POTENTIATION AND DEPRESSION IN THE VISUAL CORTEX.
J.P. Burke*, Y. Fregnaç and M.J. Friedlander. Neurobiology Research Center and Department of Physiology and Biophysics, University of Alabama at Birmingham, Birmingham, Alabama, 35294.

We previously reported (*Soc. Neurosci. Abstr.*, 16:798, 1990) that temporal conjunctions of pre- and postsynaptic activity in the visual cortex can change synaptic efficacy. To determine the degree to which these effects are confined to the active synapses, we tested individual cortical neurons' responses to activation of different synaptic inputs, including those that were or were not paired with current injection into the postsynaptic cell. Conventional slices (500 μm thick) of visual cortex were obtained from anesthetized guinea-pigs and kittens. Intracellular recordings were made in bicuculline-free ACSF from neurons in layer 3/4 of cortical area 17. Compound post-synaptic potentials (PSPs) were evoked by microstimulation at two spatially separate sites. Separability of synaptic inputs from the two stimulation sites was evaluated by testing for occlusion. Postsynaptic membrane potential was altered by intracellular current injection through the recording micropipette. Protocols included temporal pairings of 80 ms membrane depolarization (S⁻) or hyperpolarization (S⁺) with activation of one synaptic pathway at 0.2 Hz for 30-80 trials, while the other synaptic pathway was inactive. To date, 23 experimental pairing protocols with dual electrode stimulation have been characterized for 11 cells. In 3 of 14 cases, the synaptic pathway that was paired with membrane depolarization was significantly potentiated (K-S test, p < 0.05) while the unpaired pathway was not. In 1 of 9 cases, the synaptic pathway that was paired with membrane hyperpolarization was significantly depressed while the unpaired pathway was not. The average peak amplitude change of the PSP for the significant cases was +41% during S⁻ pairing and -33% during S⁺ pairing. Thus, temporal conjunctions of pre- and postsynaptic activity in visual cortex seem to be specific for the active synapse. Supported by NIH EY05116 and HFSP.

OPTICAL RECORDINGS OF EVOKED ACTIVITY IN GUINEA PIG NEOCORTICAL SLICES.
B. Albowitz* and U. Kuhnt. Dept. of Neurobiology, Max-Planck-Institute for biophys. Chemistry, 3400 Göttingen, FRG.

The distribution and flow of activity in neocortical slices was studied by use of voltage sensitive dyes. Coronal slices were prepared from guinea pig visual cortex and stained with the fluorescence dyes RH 414 or RH 795. Voltage dependent light intensity changes following electrical stimulation of the white matter (WM) or layer I (LI) were monitored from a 10x10 photodiode matrix. The system provided a spatial resolution of 60 μm or 94 μm and a temporal resolution of 0.2ms or 0.4ms.

Following stimulation of WM, peaks of activity were reached in layers V and III. Activity in layer III appeared only with higher stimulation intensities in an almost all-or-none mode, indicating a predominantly polysynaptic pathway. Potentials in layer III were of shorter duration than those in lower layers and were occasionally followed by hyperpolarizations. Following stimulation of LI, peaks of activity were also found in layers III and V, but activity in layer V was very low. Potentials in layer III increased gradually with stimulation intensity and were never followed by hyperpolarizations. Thus, although stimulation of LI and WM both activate predominantly neurons in layer III, different synaptic pathways and/or neuronal populations seem to be involved. This is also reflected in the horizontal distribution of activity, which was wider for potentials elicited by stimulation of LI than for those elicited by stimulation of WM, even though presynaptic signals were more restricted following stimulation of LI. Also, potentials elicited by stimulation of WM frequently had an asymmetric horizontal amplitude distribution. Conduction velocities for potentials elicited by stimulation of LI were slower than for potentials elicited by stimulation of WM, measuring both post- and presynaptic activity. The latter shows that stimulation of LI activates slower conducting fibers.

48.6

MEDIAL AND LATERAL DIFFERENCES IN POPULATIONS OF GABAergic NEURONS IN LAYER 3 OF TURTLE VISUAL CORTEX.
J.M. Nicolaus and P. S. Ulinski. Dept. Org. Biol. and Anat., U. Chicago, Chicago, IL 60637.

Distinct medial-lateral differences exist in the organization of turtle visual cortex (e.g. Ulinski, 1990, *Soc. Neurosci. Abstr.*). It is known that GABA-positive neurons are found in layers 1 and 3 of this cortex, but previous studies (Blanton, et. al., 1987, *JCN*, 259:277-297) have focused on the medial portion of cortex. We used a flattened, *whole-mounted* cortex to analyze distributions and morphologies of neurons showing GABA-like immunoreactivity in the medial and lateral parts of cortex. Cortices were incubated with anti-GABA antibody (Sigma) and visualized with an avidin-biotin-HRP protocol. Most GABA-positive cells in medial and lateral caudal cortex fell along two morphological continua of fusiform cells with spine-free, varicose or beaded dendrites showing limited branching. One continuum consisted of cells having an asymmetrically oriented dendritic field, with an extensive dendrite of large diameter at one pole and two smaller dendrites extending from the opposite pole. The somata and dendrites were compressed in the horizontal plane, so these cells were termed "horizontal cells." The second continuum consisted of "multipolar cells" whose 3-5 dendrites extended both horizontally and vertically from the somata. At least twice as many GABA-positive cells are present medially as laterally. The size spectra of somata in medial and lateral populations are the same; therefore the two continua of horizontal and multipolar cells are present in both parts of cortex in about the same proportions but with a different density distribution.

Supported by PHS grant EY 68352 and by an NSF graduate fellowship.

MOVING VISUAL STIMULI INDUCE cFOS EXPRESSION IN THE VISUAL CORTICES OF THE RAT. S.L. Craner, J.S. Lund, G.E. Hoffman, and R.D. Lund. University of Pittsburgh School of Medicine, Pittsburgh PA 15261.

Previous work has shown that stationary flash stimulation of the rat eye induces cFos expression in the superior colliculus (SC) and pretectal region (PT) but not in the dorsal lateral geniculate nucleus (dLGN) or the visual cortices (VC). Here we examine cFos activation patterns in rat brain in response to motion stimuli. Anesthetized rats were subjected to either a moving grating or a moving random pattern (14.3°/sec) for one hour. The animals were euthanized after a further 30 mins and the brain processed for immunohistochemical labeling of the cFos protein. Appropriate control groups (bilaterally enucleated and nonstimulated animals) were also processed.

Similar to animals stimulated with a stationary flash, animals subjected to a motion stimulus exhibited stimulus-specific cFos expression in both the SC and PT but not in the dLGN. We postulate that the lack of label in the dLGN may be due to the strong postexcitatory inhibition normally experienced by its cells. Unlike animals stimulated with a stationary flash, motion-stimulated animals did express cFos in the VC. With monocular stimulation, labeled cells in the contralateral area 17 were found predominantly in layers II, IV, and VI, with fewer cells in layer V. Labeled cells were also present in area 18 and 18a. Nonstimulated animals and animals stimulated with light flash exhibited labeling only in deep layer VI of visual cortex. These data suggest that 1) motion, but not flash, is effective for evoking cFos expression in the VC, 2) cortical cFos expression may be stimulus specific and 3) dLGN neurons, though activated, may not readily express cFos. Supported by NIH grants EYO6194 (SC), EYO5282 (JL), NIH-284-77 (GH), and EYO5283 (RL).

DISTRIBUTION OF GLUTAMATE NEURONS AND TERMINALS IN STRIATE CORTEX OF NORMAL AND MONOCULARLY DEPRIVED MONKEYS. R.K. Carder, E.G. Jones and S.H.C. Hendry. Dept. of Anatomy and Neurobiology, Univ. of California, Sch. of Med., Irvine, CA 92717

The morphology and distribution of glutamate immunoreactive neurons and terminals was examined with reference to the well defined laminar and columnar subdivisions of monkey striate cortex (area 17). Observations were made in normal adult monkeys and in adults deprived of input from one retina by intravitreal injection of tetrodotoxin (TTX) to determine whether select populations of cortical glutaminergic neurons are regulated by changes in visual input.

A large proportion of the glutamate immunoreactive neurons display morphological features characteristic of pyramidal neurons while other small, round glutamate positive neurons are presumably spiny stellate neurons. In normal monkeys glutamate immunostaining is dense in layers II-IVA, IVC and VI, and light in layers I, IVB and V. Staining of tangential sections through layers II-III reveal no preferential distribution within or surrounding the cytochrome oxidase patches. Staining in layer IVC of normal monkeys is also homogenous. However, following TTX injections, glutamate immunoreactive somata and puncta are greatly reduced in layers IVA and IVC of deprived eye columns. These data indicate that relative levels of glutamate immunostaining in monkey visual cortex vary across layers and are acutely sensitive to changes in afferent input. Supported by NIH grants EY 06344, EY 06432, and EY 07193.

48.11

DISTRIBUTION OF IMMUNOCYTOCHEMICALLY LOCALIZED GABA_A RECEPTOR SUBUNITS IN MONKEY AND HUMAN VISUAL CORTEX. M.M. Huntsman, E.G. Jones, H. Möhler and S.H.C. Hendry. Dept. Anatomy & Neurobiol., Univ. Calif., Irvine, CA, USA 92717 and Institute of Pharmacol., Univ. Zurich, Switzerland

The GABA_A receptor is a complex molecule that is composed of several subunits and that contains binding sites for GABA, benzodiazepines and barbiturates. We have found that three of these subunits, localized by immunocytochemistry, are unevenly distributed in the visual cortex (area 17) of monkeys and humans. The greatest density of $\beta 2/\beta 3$ subunits in monkey area 17 is in the zones containing the densest geniculocortical terminations and GABA terminations (layer IVC, the honeycomb of layer IVA and the cytochrome oxidase patches of layers II-III; Hendry et al., 1990; J. Neurosci. 10: 2438). Most of the $\beta 2/\beta 3$ staining is punctate and present in the neuropil. Immunostaining for $\alpha 1$ and $\gamma 2$ subunits produces a similar laminar pattern and a similar punctate distribution. In addition, the $\gamma 2$ subunit is localized very densely to the cell bodies and proximal processes of a small population of neurons. Within area 17 of humans the immunostaining for all three subunits is densest in layer IVC, where they form strips of intense immunoreactivity, separate by narrow regions of light immunoreactivity. For none of the three is there any evidence of intense staining in layer IVA. As in the monkey, the $\gamma 2$ subunit in human area 17 has a distinct pericellular localization along a small population of neurons. These data demonstrate that three subunits of the GABA_A receptor have a similar laminar distribution in monkey area 17 and an identical distribution in human area 17. However, the subcellular localization of the three subunits differs, which may give rise to variations in the pharmacological properties of GABA receptors in the primate visual cortex. Supported by USPHS Grants EY 06432 and EY 07193

DISTRIBUTION OF EXCITATORY AMINO ACID BINDING SITES IN ADULT FERRET VISUAL CORTEX. A.L. Smith* and I.D. Thompson* (SPON: Brain Research Association). University Laboratory of Physiology, Oxford University, Parks Road, Oxford OX1 3PT, U.K.

We have used radioligand binding techniques to characterize the distribution of glutamate receptor subtypes in adult ferret visual cortex. Incubation of tissue homogenates prepared from posterior neocortex with the appropriate tritiated ligands revealed four of the five putative receptors for excitatory amino acids. Saturation analyses were performed by centrifugation binding assay with [³H]-kainate, [³H]-AMPA, [³H]-CGP39653 and [³H]-L-glutamate. These demonstrated the presence of kainate (high and low affinity), quisqualate-ionotropic (AMPA), N-methyl-D-aspartate (NMDA) and chloride-sensitive glutamate binding sites. In this preparation no quisqualate-metabotropic receptor could be detected.

The binding of these radioligands to cryostat sections of adult ferret brain was then investigated by quantitative *in vitro* autoradiography. Visual cortex was found to express all five known excitatory amino acid receptor subtypes. The distribution of these binding sites is not uniform, with the different subtypes exhibiting markedly different patterns of lamination. These differences may be indicative of the different roles fulfilled by the receptors.

This work was supported by a grant from the Wellcome Trust.

48.10

DIFFERENTIAL INTRANEURONAL REGULATION OF GAD AND β -PREPROTACHYKININ mRNAs IN MONKEY VISUAL CORTEX FOLLOWING MONOCULAR DEPRIVATION. D.L. Benson and E.G. Jones. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717

Neural activity can profoundly affect detectable levels of certain neurotransmitters, neuropeptides, receptors and protein kinases in the primary visual cortex of adult monkeys (Benson et al. J. Neurosci., 11:31, 1991). Following monocular deprivation by tetrodotoxin injection, *in situ* hybridization revealed that β -preprotachykinin (β -PPT) mRNA decreased in ocular dominance columns corresponding to the deprived eye. This change in β -PPT mRNA expression or stability was most apparent in the middle layers of cortex and parallels deprivation decreases in tachykinin and GABA immunoreactivity (Hendry et al. J. Neurosci., 8:1225, 1988). Tachykinin immunoreactive neurons in these layers are also immunoreactive for GABA. However, unlike β -PPT mRNA, GAD mRNA levels do not change in response to monocular deprivation. To determine whether β -PPT mRNA levels were decreasing in the same cells demonstrating an apparent maintenance of GAD mRNA levels following monocular deprivation, we conducted double labeling *in situ* hybridization studies using radioactive β -PPT and nonradioactive GAD antisense RNA probes. We found that neurons in layer IVC colocalized both mRNAs, indicating that GAD and β -PPT mRNAs are differentially regulated by activity in the same neuron. This suggests that although the immunodetectable products of these neurons are coincidentally decreasing, the mechanism dictating this change is targeting different levels of gene expression. Supported by USPHS grant EY 07193.

48.12

NEUROTRANSMITTER PLASTICITY IN ADULT MONKEY VISUAL CORTEX: THE ROLE OF INTEROCULAR INTERACTIONS. S.H.C. Hendry and K.K. Welty. Dept. of Anat. & Neurobiol., Univ. of California, Irvine, CA 92717

Elimination of input from one retina in an adult monkey reduces the immunoreactivity for GABA and its synthesizing enzyme, GAD, in neurons of the visual cortex (area 17; Hendry and Jones, 1986; Nature 320: 750). The most robust changes are seen in the major geniculo-recipient layer, IVC, of the deprived-eye columns. These and other neurochemical changes in cortical neurons deprived of normal visual input are interpreted as activity-dependent events. To determine whether activity changes alone or interactions between inputs from the two eyes produces the changes in GABA and GAD immunoreactivity, two sets of experiments were performed: 1) area 17 in the two hemispheres of adult monkeys were compared following complete lesions of the dorsal lateral geniculate nucleus (LGN) on one side; 2) the monocular segments in area 17 contralateral to an eye injected with tetrodotoxin (TTX) were compared with injected-eye and normal-eye columns of the same hemisphere. With both kinds of experiments the GABA and GAD immunostaining in regions without competing inputs were found to be qualitatively and quantitatively normal. Thus, in area 17 denervated of LGN inputs for 5 or 7 days and in the monocular segments dominated by the TTX-injected eyes (retinal activity blocked for 5-20 days) the immunostaining is identical to that in the normally innervated or active area 17. Stereological analyses demonstrate that in layer IVC of the denervated area 17 and of the deprived monocular segment, GABA-immunoreactive cells make up the same proportion of neurons as in the normally innervated and active hemispheres and columns. These data indicate that interactions between inputs from the two eyes play an important role in the neurotransmitter plasticity of the adult monkey visual cortex. LATERAL INHIBITION BETWEEN BASKET CELLS IN THE VISUAL CORTEX OF CAT (AREA 18) Z.F. Kisvárdy¹, C. Beaulieu² and U.T. Eysel¹
¹Dept. Neurophysiol, Ruhr - Univ. Bochum, P.O. Box 102148, D - 4630 Bochum, FRG
²Dept. Pathol, Univ. Montreal, Montreal, Quebec, Canada H3C 3J7

Somata of GABAergic large basket cells receive dense synaptic input from GABAergic terminals, suggesting that they are strongly inhibited by other basket cells. We tested this hypothesis using extracellular ionophoretic injections of biocytin in combination with immunostaining for parvalbumin (PV) in the same material.

The injected tracer labelled many large basket cells around the injection sites in their entire morphology while PV labelled somata of a subpopulation of GABAergic cells, including cells with large soma size characteristic of large basket cells. The axonal fields of two biocytin-labelled large basket cells, BC₁ and BC₂, were reconstructed in 3-dimensions from horizontal sections in layers III and V, respectively. They contacted 58 and 33 PV+ somata distributed at about 100 µm intervals up to 1.6 mm from the somata of the parent basket cells. The synaptic contacts to 5-5 PV+ somata provided by BC₁ and BC₂, respectively, were additionally verified by electron microscopy. Quantitative soma size distribution showed that the PV+ cells targeted by BC₁ and BC₂ comprise the largest cells of the total population of PV+ cells and they do not differ significantly from that of identified large basket cells, including BC₁ and BC₂.

The results show that large basket cells in addition to their well-known pyramidal cell targets mutually inhibit each other. This indicates that along their oriented long axons they result in a cascade of disinhibition of certain pyramidal cells and direct inhibition of other pyramidal cells. Z.F.K. is supported by the A. von Humboldt Foundation.

TRANSNEURONAL TRANSPORT OF TETANUS TOXIN C-FRAGMENT REVEALS SECOND-ORDER LOCAL CIRCUITS IN CAT VISUAL CORTEX.

J.A. Matsubara^{1,2}, J. Zhang^{2*} and J.D. Boyd². Depts of ¹Anatomy and ²Ophthalmology, Univ of British Columbia, Vancouver, BC, Canada, V5Z 3N9.

Locally projecting neurons in area 18 of the cat are organized into discrete groups, or patches, which exhibit an interpatch spacing of about 1 mm. Previous studies from our lab showed that the intrinsic patches of neurons interconnected sites of different preferred orientation. We further studied the local connectivity amongst these patches by utilizing the retrograde transneuronal tracer, C-fragment of tetanus toxin (TTC). Solutions containing a mixture of 1% TTC and 0.5% WGA-HRP were injected into area 18. Following a 1-4 day survival, the animal was euthanized and perfused with standard fixatives. Blocks of tissue were cut in the horizontal plane, tangential to the cortical surface. Every other section was reacted for HRP (1st order neurons), while the alternate sections were first incubated in a solution of 3% H₂O₂ and 10% methanol to deactivate peroxidase activity, and then placed into a primary antibody solution against TTC. Subsequent incubations in avidin biotin solutions allowed us to immunohistochemically identify TTC labeled (2nd order) neurons.

Our study revealed two types of labeling derived from the transport of TTC: dark spots of heavily labeled neuropil and clusters of labeled cell bodies. The dark spots aligned with the WGA-HRP patches and probably represent 1st order labeling. TTC cell bodies were found both within and outside of the dark spots. Cells falling inside the dark spots may represent unlysed 1st order cells, or more interestingly, 2nd order neurons contacting 1) cells in the same column or 2) cells in the other WGA-HRP patches of a reciprocally connected network. TTC cells located outside the dark spots either formed their own separate clusters at the outskirts of, thus extending, the WGA-HRP pattern or they formed clusters which adjoined the WGA-HRP patches. The significance of these disynaptic circuits to visual processing of receptive field properties will be discussed. This work was funded by MRC 5-99150 (Canada).

MORPHOLOGY OF AREA 18 NEURONS OF CAT VISUAL CORTEX STUDIED BY CONFOCAL MICROSCOPY OF LUCIFER YELLOW FILLED NEURONS IN PRELABELLED, FIXED BRAIN SLICES. D.M. Theijmaven¹ and J.A. Matsubara^{1,2}. Depts of ¹Anatomy and ²Ophthalmology, University of British Columbia, Vancouver, British Columbia, Canada, V5Z 3N9.

Cells projecting from one cortical area to another cortical area and to given sites within an individual cortical area are distributed in a number of discrete clusters or patches, as shown by horseradish peroxidase (HRP) tracing experiments. We used intracellular dye injections in lightly fixed cortical slices to examine the morphology of layer II/III neurons of these patchy, columnar systems. Neurons of area 18 that project to area 17 and the ones which participate in local connections within area 18 were retrogradely labeled with fluorescent latex microspheres. 300 µm thick vibratome sections of the perfusion fixed brains were transferred to a epifluorescence microscope equipped with long working distance objectives. Under visual guidance prelabelled layer II/III neurons were selectively impaled and intracellularly injected with lucifer yellow (LY) until all dendrites appeared brightly fluorescent.

We used a confocal laser scanning microscope (Biorad MRC 600) to collect serial optical sections and to perform three-dimensional reconstructions and rotations of LY filled neurons in wholemount preparations. This technique provided us an efficient alternative to tedious camera lucida reconstructions as well as a means to study the spatial arrangement of the dendrites in three dimensions. When layer II/III neurons of area 18 were examined, we saw that the dendritic trees of many cells, which appear symmetric in the coronal plane, were in fact, quite asymmetric with processes extending further antero-posteriorly. Other neurons in our preliminary sample exhibited a 'slab-like' or planar arrangement of dendrites. These differences in the spatial arrangement of the dendritic arborizations will be related to the corticocortical and intracortical patches. This work was funded by MRC 5-99150 (Canada).

SPECIFICITY OF LATERAL INHIBITORY CONNECTIONS IN CAT VISUAL CORTEX U.T. Eysel and Z.F. Kisvárdy. Department of Neurophysiology, Ruhr - University Bochum, P.O. Box 102148, D - 4630 Bochum 1, FRG.

Small microiontophoretical injections of the neuronal tracer biocytin into areas 17 or 18 of the cat were made to visualize a detailed pattern of excitatory and inhibitory connections. The tracer was delivered in a small volume occupying about one orientation column only (100 µm). Orientation and direction selectivity within a cortical region containing the injection site were recorded in detail at 50-200 µm steps. Somata, dendritic trees and axonal arborizations of cells connected with the injection site are filled by the tracer. Labelling and recording sites were analyzed in horizontal sections of the supragranular layers. In addition to pyramidal and spiny stellate cells a number of large basket cells with characteristic smooth dendrites and perisomatic axons were connected with the injection sites. The somata of the inhibitory (large basket) cells were distributed predominantly within 1 mm from the recording site in area 17 and 18 and the majority was situated in the range between 200 to 500 µm. Most of the basket cells and their dendrites fell outside the regions occupied by the excitatory network formed by pyramidal cells and their axons. Some basket cells, however, were sharing the territory with the patchy excitatory network.

The map of orientation selectivities superimposed to the anatomical reconstruction of the irregular mosaic of basket cells indicated that the basket cells connected with the injection sites originated from regions comprising the whole range of orientation selectivities, including iso- as well as cross-orientation with respect to their target regions. This suggests that basket cells can be involved in neuronal computations contributing to directionality as well as orientation selectivity in visual cortex. 48.16

THE CALLOSAL PATHWAY IN CAT VISUAL CORTEX IS PATCHY AND ORIENTATION SPECIFIC. J.D. Boyd¹ and J.A. Matsubara^{1,2}. Depts of

¹Ophthalmology and ²Anatomy, University of British Columbia, Vancouver, British Columbia, Canada, V5Z 3N9.

Although the patchy nature of local connections is well known, the spatial organization of most callosal connections is not. We examined callosal connections between the area 17/18 border regions, representing the vertical meridian.

1% wheat germ agglutinin conjugated horseradish peroxidase (HRP) and/or 1% cholera toxin subunit B (CTB) was injected through micropipettes into the lateral gyrus, in most cases after making an electrophysiological map. The cortex was flattened, sectioned tangentially and the tracers visualized with tetramethylbenzidine histochemistry (HRP) and/or diaminobenzidine immunohistochemistry (CTB).

Large injections (10-12 µl at 18 sites) of HRP gave retrograde callosal labeling which, while uniform on a large scale, contained fine scale fluctuations in labeling at 200-250 µm intervals. Focal injections (0.02 µl) resulted in patches of callosal labeling with an interpatch distance of about 1 mm. The patches often aligned parallel to the mediolateral axis. When injections of different tracers were made into areas of similar preferred orientation, the labeled patches from the two tracers overlapped with an abundance of double labeled cells. After injections into areas of orthogonal orientation, the two sets of labeled patches mostly interdigitated and fewer retrogradely labeled cells contained both tracers.

Orientation bands near the 17-18 border tend to run perpendicular to the border, and have a periodicity of about 1 mm. Thus, the orientation selectivity of callosal connections in this region could account, in part, for the patchy distribution described above. The making of patchy connections by zones of all orientation preferences would interdigitate to such an extent as to explain the large scale uniformity when large injections were made. The explanation of the 200-250 µm density fluctuations is less clear. This work was funded by MRC(Canada).

EXTRACELLULAR BIOCYTIN STAINING OF CELLS IN THE VISUAL CORTEX SLICE PREPARATION. G. Kenan and H. Katz*, Center for Neurosciences, The Weizmann Institute of Science, Rehovot 76100, Israel.

Using the cortical slice preparation, Biocytin (2.5%) was applied at different layers of rat visual cortex by diffusion from a broken micropipette inserted into the slice (10-30 µm tip diameter) for 1-5 min, or by drop application (5-10 µl). After 20 min-3 hrs incubation, the slices were fixed over night (4% paraformaldehyde) and processed for HRP staining.

Biocytin was taken by cells at the area of injection and revealed the detailed morphology of dendritic trees of pyramidal and none pyramidal cells. The quality of neuronal staining, i.e. spine density and fine dendritic branches was comparable to intra-cellular injections of Biocytin. In some cases parts of the axonal arbor could be traced. Stained cells were not limited to the area of injection e.g. injection in layer I revealed pyramidal cells in layer V. Injection sites varied in size from few cells to several hundred µm. When Biocytin was introduced by drop application, Golgi-like staining of cells could be observed throughout the cortical layers.

RELATIONSHIP OF BIOCYTIN LABELED NEURONAL PROCESSES TO THE CYTOCHROME OXIDASE (CO) RICH BLOBS IN MONKEY STRIATE CORTEX. R. Malach Weizmann Inst. Rehovot, Israel 76 100.

How segregated are the CO blobs from the surrounding interblob tissue? To address this question, the tracer biocytin was injected at numerous sites in macaque monkey striate cortex resulting in Golgi-like staining of neuronal processes. These were related, in tangential sections, to the pattern of CO blobs. As was found previously in Golgi material of squirrel and marmoset monkeys, (Malach 1990, Soc. Neurosci. Abst. 130.2) dendritic arbors of upper layer neurons appeared to cross freely through blob boundaries. The axons of these neurons, studded with boutons, ramified extensively for about 100 μ m around the injection sites. Further away, and up to a distance of 1-1.2mm, axons tended to form clusters 150-200 μ m wide. The same axon could often be traced to more than one cluster.

In agreement with previous reports (Livingstone and Hubel 1984, J. Neurosci. 4:2830) axons from centers of blobs and interblobs tended to arborize in similar tissue compartments. Individual axons, labeled by border injections, crossed freely through blob boundaries and ramified in both blob and interblob territories. These results suggest that processes of upper layer neurons are organized in periodic, blob-related but smoothly shifting patterns. (BSF 88-275)

PATCHY INTRINSIC CONNECTIONS IN MACAQUE AREA V4.

J.B. Levitt, T. Yoshida, and J.S. Lund. Center for Neuroscience, University of Pittsburgh, Pittsburgh, Pa. 15261.

We have examined the pattern of intrinsic connectivity of area V4 in the macaque monkey by making focal (200-500 μ m) iontophoretic injections of the neuronal tracer biocytin into the dorsal portion of V4. We noted prominent, focused interlaminar projections at each injection site. In addition, we found laterally-spreading fibers to be restricted to two bands, one in lower layer 3 and one in layer 5. These laterally-spreading fibers were conspicuously absent from layer 4, even in cases where the injection zone included layer 4. Neuronal processes could be found over 3 mm from an injection site, though the majority of fibers spread within 2 mm of an injection. Long-distance connections travelled in the layer 3 band; lateral connections in layer 5 seemed more restricted in extent. The spread of label around injections seemed preferentially elongated in the mediolateral direction.

These lateral connections were not uniformly distributed across V4, but often clustered into discrete patches of terminal label. These patches were between 250-500 μ m in diameter, and the spacing between the patches varied from 0.5 to 1.5 mm. Patches of label were generally found from 0.3 to 2 mm from an injection site, though we occasionally observed patches over 3 mm away. These injections also retrogradely labelled clusters of cells in V4. These cells were predominantly located in layer 3, and were pyramidal in morphology. The clusters of labelled cells often, but not always, coincided with the patches of terminal labelling.

These results indicate that area V4 contains focused columnar projections, as well as more widespread and divergent lateral projections, a pattern of intrinsic connectivity previously observed in other visual areas.

CELL MORPHOLOGY AND BLOB PATTERN IN MONKEY STRIATE CORTEX. M. Hübener and J. Bolz. Friedrich-Miescher-Labor der Max-Planck-Gesellschaft, Spemannstr. 37-39, 7400 Tübingen, Germany.

Cytochrome oxidase staining reveals a regular pattern in primate striate cortex, the blobs. Neurons within the blobs often have unoriented, color selective receptive fields, whereas cells in the interblob region usually have oriented receptive fields and respond to all wavelengths. In addition, cells in the blob and interblob compartment receive different input and project to different sites. We studied the relationship between the blob pattern and the morphology of single cells in the striate cortex of macaque monkeys. Lucifer yellow was injected into individual cells in lightly fixed tangential sections from area 17. Adjacent sections were stained for cytochrome oxidase, radially running blood vessels were used as landmarks to determine the position of each stained cell with respect to the blob pattern. We confined our study to the analysis of pyramidal cells in layer 2/3. A comparison of the morphology of blob and interblob cells showed that there are no differences between the two groups with respect to soma size, spine density, and dendritic field structure. The dendritic field elongation of blob and interblob cells, determined by a quantitative statistical analysis, was found to be similar, indicating that cortical orientation selectivity is not generated through dendritic field elongation. We found many cells with dendrites freely crossing the borders between blob and interblob regions. However, a number of cells had a tendency to stay within one compartment. A quantitative analysis revealed that on average cells in the vicinity of the borders tend to avoid crossing a border. Thus there is a weak bias for the basal dendritic fields of layer 2/3 pyramidal cells to be segregated into blob and interblob compartments. Our observation that many cells send dendrites into a blob as well as into the interblob region demonstrates that a structural basis for crosstalk between the different channels exists already at an early stage of cortical processing.

CHEMICAL SENSES: PERIPHERAL MECHANISMS I

49.1

NEUROCHEMICAL ORGANIZATION OF CAROTID BODY (CB) AFFERENT NEURONS. J.C.W. Finley¹, J. Polak² and D.M. Katz^{1,2}, Depts. Medicine¹ and Neuroscience², CWRU Sch. of Med., Cleveland, OH 44106.

A large subset of CB afferents in the rat petrosal ganglion (PG) express tyrosine hydroxylase (TH) and catecholamine fluorescence; these cells do not express dopamine beta hydroxylase and therefore appear to be dopaminergic (Katz, et al., 1983; Katz & Black, 1985). To further characterize transmitter properties of these cells we examined expression of dopa decarboxylase (DDC), the dopamine synthesizing enzyme. The majority of TH+ CB afferents in the distal PG specifically co-localized DDC, consistent with a dopaminergic phenotype. Ultrastructural studies demonstrated that TH+ afferents synapse directly with CB glomus cells, supporting a role for these fibers in chemoreception. Parallel studies on the expression of peptidergic properties in CB afferents examined the localization of Substance P (SP) neurons retrogradely labeled by microinjection of Fluorogold into the vascularily isolated CB. In contrast to TH+/DDC+ cells, SP+ CB afferents were localized primarily to the proximal PG and jugular ganglion (JG) of the glossopharyngeal nerve. SP+ afferents were also larger than most TH+/DDC+ cells. The CB is therefore innervated by at least two neurochemically and morphologically distinct populations of afferents that are also topographically segregated within the glossopharyngeal sensory ganglia. Parker B. Francis Foundation Pulmonary Fellowship (JCWF) and HL-39921 (DMK).

49.2

MECHANISM OF ACTION OF ATRIAL NATRIURETIC PEPTIDE (ANP) IN RABBIT CAROTID BODY. L. He*, J. Chen, B. Dinger and S. Fidone. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108.

Our previous studies have shown that ANP is stored in type I (glomus) cells in the carotid body and that submicromolar concentrations of the synthetic ANP fragment, atriopeptin III (APIII), inhibit carotid sinus nerve (CSN) activity evoked by hypoxia. Furthermore, APIII elevates the content of cyclic GMP (cGMP) in the tissue in a dose-related manner. In the present study we have: 1), evaluated CSN inhibition and cGMP production in the presence of the biologically inactive ring-deleted analog of ANP, C-ANP; 2), examined the effects of APIII on nerve discharge produced by direct depolarization of CSN endings; and 3), examined whether met-enkephalin (ME), an agent known to be inhibitory in the carotid body, may be involved in the mediation of the ANP-produced inhibition of CSN activity.

cGMP levels were increased 20-fold in carotid bodies incubated *in vitro* for 10 min in the presence of 100nM ANP. C-ANP (100nM), however, failed to alter cGMP levels in the tissue. Similarly, C-ANP (100nM or 1000nM) also failed to inhibit CSN activity evoked by hypoxia *in vitro*, while in the same preparations APIII (100nM) reduced the integrated nerve discharge by 44.1% \pm 4.6%. APIII did not alter CSN activity evoked by 20mM K⁺, either in the presence or absence of Ca²⁺. Finally, APIII inhibition of CSN activity was blocked by a concentration of naloxone (10⁻⁸M) sufficient to occupy delta opiate receptors in other peripheral and central nervous tissues. Our data are consistent with the hypothesis that APIII inhibition in the carotid body is mediated by preneuronal type I cells via specific ANP receptors coupled to guanylate cyclase. Furthermore, the ability of naloxone to antagonize APIII inhibition suggests the involvement of endogenous ME. Supported by USPHS grants NS12636 and NS07938.

49.3

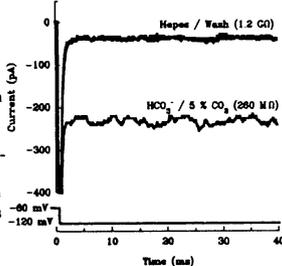

LOCALIZATION OF ATRIAL NATRIURETIC PEPTIDE RECEPTORS IN THE CAROTID BODY. Z.-Z. Wang, S. Hirose*, B. Dinger, S. Fidone and L.J. Stensaas. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108, and Dept. of Biol. Sci., Tokyo Inst. of Technology, Tokyo, Japan.

Previous studies in our laboratory have shown that atrial natriuretic peptide (ANP) is stored in preneuronal type I cells of the carotid body and that the synthetic ANP analog, atriopeptin III (APIII), applied *in vitro* inhibits chemoreceptor activity evoked by hypoxia. Our recent RIA and immunocytochemical experiments also showed that APIII significantly increased the level of cyclic GMP in type I cells. Although the mechanisms of ANP-mediated inhibition of carotid sinus nerve discharge and the accompanying activation of guanylate cyclase observed in our experiments remains unclear, the striking correspondence between the effective dose-range for ANP actions in the carotid body and its effects in other tissues known to contain ANP receptors (Rugg *et al.* BBRC 162: 1339, 1989) strongly implicates the involvement of specific ANP receptors in our experiments. In the present immunocytochemical study, receptors for ANP were localized to type I cells of the pig carotid body using a specific polyclonal antibody combined with the avidin-biotin-peroxidase method. Staining was absent in the type II cells and nerve fibers in the tissue. Using a double labeling post-embedding immunocytochemical technique, we further demonstrated that the cGMP produced in response to APIII stimulation is colocalized with ANP in type I cells. These data are consistent with the notion that endogenous ANP released by type I cells modulates chemoreceptor function by acting at specific autoreceptors coupled to guanylate cyclase. Supported by USPHS grants NS12636 and NS07938.

49.5

DO CHLORIDE CHANNELS MEDIATE BOTH CO₂-CHEMOSENSITIVE AND OSMOSENSITIVE FUNCTIONS IN ARTERIAL CHEMORECEPTORS? C.A. Nurse and A. Stea. Dept. of Biology, McMaster University, Hamilton, Ontario, L8S 4K1.

Elevated arterial CO₂ is thought to excite carotid body chemoreceptors via intracellular acidification of (receptor) glomus cells, which contain the enzyme carbonic anhydrase (Nurse, Cell Tiss. Res. 261:65). Using the perforated patch technique we recently showed (submitted) that an acidic pH_i depressed voltage-activated currents in cultured rat glomus cells, at constant pH_o maintained by HEPES-buffered media (HBM). To compare the effects of CO₂ stimuli we have shifted to bicarbonate-buffered media (BBM). Unexpectedly, we found that in 10 of 13 cells tested, simply switching the perfusate from HBM to 5% CO₂/BBM resulted in a substantial (up to 5-fold) decrease in input resistance and the appearance of large conductance single channel events superimposed on whole cell leakage currents (see figure). We are testing the hypothesis that cell volume changes or osmotic stress in CO₂/BBM activated these channels and that they correspond to the HCO₃⁻-permeable Cl⁻ channels (≈ 296 pS) we characterized in inside-out patches (Stea and Nurse, AJP 257:C174). This hypothesis incidentally provides an explanation for osmoinsensitivity in glomus cells. These preliminary findings raise further questions about the physiological interpretation of recordings based solely on the use of HBM.

49.7

ELECTRIC PROPERTIES AND CHEMICAL REACTIVITY OF NODOSE GANGLION NEURONS IMPLANTED ONTO CHICK EMBRYO CHORIOALLANTOIS. J. Eugenin and C. Eyzaguirre. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108, U.S.A.

Electric properties and responses to chemical stimuli of adult rat nodose neurons grafted for 4-10 days onto the chorioallantoic membrane of chick embryos were compared with those from normal neurons.

Normal and implanted ganglia were placed *in vitro* under flowing saline equilibrated with 100% O₂. Only neurons showing resting potentials (E_m) larger than -40 mV and action potentials (APs) with overshoot followed by hyperpolarizing afterpotentials (AHPs) were included in this analysis. Comparisons were made with the Mann-Whitney (U-test) using a significance level, p < 0.01.

Implanted nodose cells (n=18) had a mean E_m of -57.7 mV ± 2.5 (SE), input resistance of 72.7 MΩ ± 10.9, input capacitance of 67.1 pF ± 15.2 and membrane time constant of 3.5 ms ± 0.5. These parameters were similar to those from control nodose neurons (n=20). Neither control nor implanted neurons showed spontaneous APs. However, both groups showed time-dependent rectification to inward current and responded with single or multiple APs to depolarizing pulses. The APs of grafted nodose cells were smaller, with lower overshoot, and longer than those of control neurons. The AHPs were of a lower amplitude in implanted nodose cells.

Implanted and normal neurons responded to chemical stimuli. Switching to saline equilibrated with 100% N₂ and applications of 5-10 μl of lactic acid (6.8 to 13.4 μg/μl) depolarized the neurons by 5 to 20 mV. NaCN (10-50 μg), on the other hand, induced a transient dose-dependent hyperpolarization (5 to 30 mV).

Results show that implanted nodose neurons retain their passive electric properties and respond to chemical stimuli. The increase in AP duration and decrease in the amplitude of AHPs may be an effect secondary to chronic axotomy. Supported by grants NS05666 and NS07938. J.E. is a Fogarty International Fellow.

49.4

ALTERATION OF ATRIAL NATRIURETIC PEPTIDE (ANP) IMMUNOSTAINING IN THE RAT CAROTID BODY EVOKED BY HYPOXIA. L.J. Stensaas, Z.-Z. Wang, B. Dinger and S. Fidone. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108

Our previous immunocytochemical and electrophysiological studies demonstrated that type I cells in the carotid body contain ANP, and that submicromolar concentrations of the synthetic ANP analog, atriopeptin III (APIII), inhibit carotid sinus nerve discharge evoked by hypoxia. These findings suggest that endogenous ANP may modulate chemoreceptor activity during physiological conditions that promote ANP release from type I cells. However, the ability of the carotid body to synthesize and release ANP has never been demonstrated. In the present investigation we have utilized immunocytochemical techniques to monitor the relative content of ANP in rat carotid body type I cells exposed to prolonged periods of hypoxia. Following 3 hr of breathing 10% O₂ (balance N₂), ANP immunostaining was significantly reduced in type I cells; ANP staining intensity recovered in rats which subsequently breathed room air for 2 hr. Parallel experiments were performed *in vitro* to eliminate possible interference due to uptake of circulating ANP. Carotid bodies incubated for 3 hrs with superfusates equilibrated with 10% O₂ likewise demonstrated marked depletion of ANP immunoreactivity, whereas ANP levels appeared normal in similarly treated tissue samples which were allowed to recover for 2 additional hrs in superfusates equilibrated with 100% O₂. The observed reductions in ANP immunoreactivity are consistent with the hypothesis that hypoxia evokes the release of ANP from type I cells. Furthermore, the recovery of immunostaining *in vitro* (and *in vivo*) suggests that carotid body type I cells synthesize ANP *de novo* following depletion of the peptide. Supported by USPHS grants NS12636 and NS07938.

CO₂ STIMULANTS DIFFERENT CLASSES OF LINGUAL TRIGEMINAL NEURONS. B.P. Bryant¹, M. Komal^{1,2*} and M. Wachowiak¹, ¹Monell Chemical Senses Center, Philadelphia, 19104 and ²Tohoku University, Sendai, Japan.

CO₂ is a potent trigeminal stimulant. When applied orally at a high enough concentration, it produces a tingling or slight burning sensation. As a first approach to understanding the neural basis of oral CO₂ sensation, we examined single unit responses in the lingual nerve of the rat to a panel of stimuli: 8°, 24° and 53°C H₂O, solutions of CO₂ (5-6,000 ppm = 114-136 mM) at 8°, 24° and 28°C, 0.5 M HCl, 2.5 M NH₄Cl and tactile stimulation. In agreement with previous findings (Kawamura, 1967), some units that were sensitive to CO₂ were also sensitive to cold stimuli. However, in the present study, not all cold units were sensitive to CO₂. The pattern of chemical sensitivity was not identical across all units tested; responsiveness to CO₂ was not a good predictor of responsiveness to HCl and/or NH₄Cl. Several units responded solely to both hot and CO₂ stimuli. In spontaneously active cold units, CO₂ caused suppression followed by an excitatory response. In most CO₂ sensitive neurons, the excitatory response to CO₂ was delayed 4-9 sec relative to stimulus onset and thermal responses. This complex response suggests, among other possibilities, a temperature-dependent diffusion delay. Acetazolamide (15 mg/kg b.w.) was used to demonstrate the possible role of carbonic anhydrase (CA) and intracellular acidification in trigeminal sensitivity to CO₂. Responses to CO₂ were specifically inhibited whereas responses to thermal and other chemical stimuli were unaffected.

ELECTROPHYSIOLOGICAL PROPERTIES OF LIGHT AND DARK CELLS ISOLATED FROM MUDPUPPY TASTE BUDS. M. McPheeters, A.J. Barber, J.C. Kinnamon and S.C. Kinnamon. Dept. of Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523 and Dept. of Molecular, Cellular and Developmental Biology, Univ. of Colorado, Boulder, CO 80309.

Cells within taste buds have been characterized as light cells or dark cells based on their appearance in the electron microscope. The physiological significance of these cell types, however, remains unclear. Light cells constitute a minority of taste cells, and previous recordings have been almost exclusively from dark cells. We now report recordings from both light and dark cells, using quinacrine staining to select light cells prior to giga-seal whole cell recording (Delay *et al.* Soc. Neurosci. Abstr. 16:878, 1991). Depolarizing voltage steps and pharmacological agents were used to examine the current profiles of different cells. After recording, cells were fixed and prepared for electron microscopy. Dark cells were distinguished by dense granules in the supranuclear and apical regions. Mitochondria and microtubules were plentiful in these cells. Light cells were identified by abundant stacks of smooth endoplasmic reticulum found throughout the cell and the lack of apical granules. Light cells often had empty-appearing cytoplasmic inclusions which may reflect metabolic instability during isolation and/or recording. Results show that both light and dark cells contain voltage-sensitive Na⁺ and K⁺ currents. To date, Ca²⁺ currents have been observed only in dark cells. Thus, both light and dark cells have the capacity to generate action potentials in response to taste stimuli.

49.9

CALCIUM-RELATED CONDUCTANCES IN FROG OLFACTORY RECEPTOR NEURONS. S.J. Kleene¹, R.Y.K. Pun, & R.C. Gesteland. Anatomy & Cell Biology, Univ. of Cincinnati Medical Center, Cincinnati, OH 45267-0521.

An influx of Ca^{2+} may play a role in odorant transduction in some olfactory receptor neurons. We have measured the effects of cytoplasmic Ca^{2+} on the conductance of single cilia excised from frog olfactory neurons. When free cytoplasmic Ca^{2+} is buffered at or below $0.1 \mu M$, ciliary conductance is low. As Ca^{2+} is increased, ciliary conductance increases. Maximal conductance averages 7-fold higher than that measured in the absence of Ca^{2+} . We estimate that the $K_{1/2}$ for Ca^{2+} is about $5 \mu M$. Activation by Ca^{2+} is rapid and fully reversible. The maximal Ca^{2+} -activated conductance averages 3.6 ± 0.2 nS ($n=55$, range 1.3 to 7.9 nS). The reversal potential of the Ca^{2+} -activated current shifts 57 mV for each tenfold change in cytoplasmic Cl^- concentration, suggesting that Cl^- is the principal current carrier. Replacement of Na^+ and K^+ by choline⁺ has no detectable effect on the Ca^{2+} -activated conductance. Analogues of the Cl^- -channel inhibitor diphenylamine 2-carboxylate reduce the Ca^{2+} current by as much as 90%. We cannot yet define the role of the Ca^{2+} -activated ciliary Cl^- conductance, since the intracellular concentrations of Ca^{2+} and Cl^- are unknown.

To look for Ca^{2+} currents in the intact neuron, we apply 25 mM tetraethylammonium⁺ externally. This depolarizes the membrane and prolongs the duration of the action potential several-fold. Under voltage-clamp with K^+ and Na^+ currents blocked, a sustained inward current is recorded in the presence of 5 mM extracellular Ca^{2+} . This current activates near -20 mV and peaks between +5 and +20 mV. The sustained current shows little inactivation even with 500-msec pulses, but shows marked rundown, disappearing within 10 min after the onset of whole-cell recording. Rundown of the fast inward current is not seen. External application of $50 \mu M$ Cd^{2+} reversibly blocks most of the sustained inward current, indicating that it is Ca^{2+} -dependent.

BIOCHEMICAL CHARACTERIZATION OF A NOVEL INOSITOL-1,4,5-TRIS-PHOSPHATE (IP₃) RECEPTOR PROTEIN IN OLFACTORY CILIA. D.L. Kalinoski¹, A.G. Boyle², J.F. Marecek², G.D. Prestwich² and D. Restrepo¹. ¹Monell Chemical Senses Center, Phila, PA and ²SUNY, Stony Brook, NY.

Certain olfactory stimuli elicit increases in IP₃ in olfactory cilia of catfish (Huque & Bruch, *BBCR* 137:36, 1986) and rat (Breer & Boekhoff, *Chem. Sens.* 16:19, 1991). In catfish IP₃ is believed to cause opening of an IP₃-gated channel located in the ciliary membrane (Restrepo et al. *Science* 249:1166, 1990). Opening this channel presumably causes membrane depolarization leading to generation of action potentials. To determine the biochemical properties of this channel we characterized the binding of [³H]-IP₃ to olfactory cilia from the catfish. We find a single saturable binding site for 1,4,5-IP₃ with a K_d of $1.1 \pm 0.31 \mu M$ and B_{max} of 17.6 ± 5.8 pmol/mg. The rank order for potency of inhibition of [³H]-IP₃ binding is 1,4-IP₂ < 1,3,4-IP₂ < 1,3,4,5-IP₂ = 1,4,5-IP₂ < 2,4,5-IP₂. IP₃ binding increases slightly when free [Ca^{2+}] is increased from < 10 nM to 1 mM. These characteristics are different from those of an IP₃ receptor characterized in cerebellum and other peripheral tissues (Guillemette et al. *PNAS* 84:8195, 1987; Spat et al. *Nature* 319:514, 1986; Worley et al. *JBC* 262:12132, 1987). In addition, we have used a photoactivatable analogue of IP₃ (¹²⁵I-ASA-IP₃) to identify the olfactory IP₃ receptor protein. Catfish and rat cilia were exposed to short-wavelength UV light in the presence of ¹²⁵I-ASA-IP₃ plus or minus excess 1,4,5-IP₃ or analogues. After SDS-PAGE separation of the membrane proteins autoradiograms detected several labeled bands. ¹²⁵I labeling was specifically displaced from a band of 100 kDa by addition of $50 \mu M$ 1,4,5-IP₃ or 1,3,4,5-IP₂ or of 100 $\mu g/ml$ heparin. Labeling could not be displaced by 1,4-IP₂ or 1,3,4-IP₂. In control experiments we show that ¹²⁵I-ASA-IP₃ specifically labels the IP₃ receptor protein in rat brain (200 kDa). These results indicate that olfactory cilia possess a novel IP₃ receptor protein which is presumably the IP₃-gated calcium channel recently identified by us in catfish olfactory cilia.

THE ROLE OF ADENOSINE IN STIMULUS-EVOKED CYCLIC AMP PRODUCTION IN THE RABBIT CAROTID BODY. J. Chen, B. Dinger and S. Fidone. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108

Previous studies have shown that adenosine and its related agonists increase respiratory minute volume and excite carotid body chemoreceptors (McQueen and Ribeiro, *Br. J. Pharmacol.* 88: 615, 1986; Monteiro and Ribeiro, *N.S. Arch. Pharmacol.* 340: 230, 1989). Furthermore, adenosine antagonists inhibit the excitatory effects of adenosine and reduce the sensitivity of carotid chemoreceptors to hypoxia. Pharmacological studies have indicated that adenosine actions in the carotid body are mediated by the A-2 subtype of adenosine receptor, which in other tissues is positively coupled to adenylate cyclase. Because our recent studies have shown that hypoxia elevates cyclic AMP (cAMP) in the carotid body, we have investigated the possible role of adenosine in this hypoxia-mediated response.

cAMP levels in carotid bodies superfused *in vitro* for 10 min were increased in a dose-related manner in the presence of adenosine (10 μM , 100 μM and 1000 μM adenosine; maximum increase = 127%, $p < 0.01$). Basal cAMP levels were also increased 46% ($p < 0.01$) by the adenosine uptake blocker dipyrindamole (100nM), and this drug potentiated the hypoxia-induced increase in cAMP by 65% ($p < 0.01$; 10 min incubation in solution equilibrated with 10% O₂). Finally, the adenosine receptor antagonist 1,3-dipropyl-8(p-sulphophenyl)xanthine (DPSPX, 1 μM) blocked the effect of hypoxia in increasing cAMP in the carotid body. Our data suggest that the carotid body contains specific adenosine receptors positively coupled to adenylate cyclase. Furthermore, the data are consistent with the notion that increases in cAMP associated with hypoxia may be mediated in part by the release of endogenous adenosine. AMILORIDE MODULATION OF MEMBRANE ELECTRICAL PROPERTIES OF RAT FUNGIFORM TASTE CELLS. M.S. Herness. Lab. of Neurobiology & Behavior, Rockefeller University, New York, NY 10021.

The salt taste quality is hypothesized to utilize amiloride-sensitive (AS) sodium channels as a transductive utensil. The effect of amiloride (10^{-4} M) was tested on dissociated rat fungiform taste cells using the patch clamp technique in the whole cell configuration. The most common response was a decrease in a stationary-inward current when an amiloride-ECF solution was applied to the bath. This is likely to be an amiloride block of a depolarizing sodium leak from the extracellular fluid (containing 126 mM NaCl) occurring via the AS sodium channel. This response was often accompanied by diminished voltage-sensitive outward currents. At least part of this diminished current appears to be carried by outward sodium currents occurring above E_{Na} . Another possibility may be a previously unnoticed influence of apical AS sodium channels on basolateral g_K . In other cells amiloride increased a stationary inward current and augmented outward currents supporting the notion of receptor cell heterogeneity. Both depolarizations and hyperpolarizations of the resting potentials (measured by the zero current) were observed.

REDUCTION OF OLFACTORY NEURON ADENYLATE CYCLASE ACTIVITY BY AMITRIPTYLINE IN VITRO
B.L. Mania-Farnell, R.C. Bruch, A.I. Farbman
Dept. of Neurobiology and Physiology,
Northwestern Univ., Evanston, IL 60208

Adenylate cyclase (AC) plays an important role in olfactory transduction. Because the tricyclic antidepressant, amitriptyline (AMI), inhibits AC activity in embryonic chick neurons (Wong et al., *J. Neurochem.* In Press), we measured the effect of AMI on forskolin-stimulated AC activity in olfactory membrane preparations from normal and unilaterally bulbectomized (OB-X) adult rats. On unoperated animals AMI (0.5 μM -8.0 μM) inhibited forskolin-stimulated AC activity in the presence of Gpp(NH)p. To determine whether this effect was specific for neurons in olfactory epithelium we made membrane preparations from OB-X animals 4 days after surgery. In these preparations we saw significantly ($p < .005$) lower AC levels and no significant AMI effect, in comparison to unoperated animals. Our data support the hypothesis that AMI lowers AC activity via a GTP-mediated mechanism and also indicate that in olfactory tissue this decrease is specific for olfactory neurons.

CYTOCHEMICAL LOCALIZATION OF ECTO-ATPASE/PHOSPHATASE ACTIVITY IN OLFACTORY SENSILLA OF THE SPINY LOBSTER.
R.A. Gleason,* L.M. McDowell,* H.G. Trapido-Rosenthal, H.C. Aldrich* and W.E.S. Carr.* Whitney Laboratory, University of Florida, St. Augustine, Florida 32086.

Electrophysiological studies have shown that the olfactory organ (antennule) of the spiny lobster, *Panulirus argus*, has chemoreceptors which are selectively stimulated by adenine nucleotides in seawater. Biochemical studies have revealed that these same nucleotides can be rapidly dephosphorylated by ectoenzymes associated with the olfactory sensilla (aesthetascs). In this study the distribution of ecto-ATPase/phosphatase activity within aesthetascs was examined by monitoring the deposition of cerium phosphate. The distribution of ATP-dephosphorylating activity was similar to that shown previously for AMP and β -glycerol phosphate (Gleason et al. *Cell and Tissue Res.* In press); i.e., cerium phosphate reaction product was specifically localized to the transitional zone where the sensory dendrites develop cilia and branch to form the outer dendritic segments. Reaction product was found within extracellular spaces adjoining both dendrites and auxiliary cells in this region. Unlike the dephosphorylation of AMP and β -glycerol phosphate, Mg^{++} or Ca^{++} was required in the incubation medium for ecto-ATPase/phosphatase activity. Degradative ectoenzymes in the transitional zone may be of importance in clearing exogenous chemical stimuli from this region. Supported by NSF Grant BNS 8908340 and Univ. of Fla Interdisciplinary Center for Biotech. Research.

INDIRECT EVIDENCE FOR A CALMODULIN REGULATED CALCIUM PUMP IN PARAMECIUM CHEMOSENSORY TRANSDUCTION. J. L. Van Houten, N. Elwess, M. V. Wright, C. Lamoureux, M. Frantz. Univ. of Vermont, Dept. Zoology, Burlington, VT 05405, USA.

There appear to be two chemosensory transduction pathways in *Paramecium*. One involves the possible coupling of receptors to a Ca-ATPase pump that generates a hyperpolarizing current. Hyperpolarization, in turn, changes ciliary beat, behavior of the cells, and accumulation in attractant stimuli. Our evidence for the involvement of this pump in chemosensory transduction is indirect and includes: the correlated effects of lithium on both chemoresponse and calcium efflux from whole cells (both are inhibited) and the failure of a calcium homeostasis mutant (courtesy of T. Evans and D. Nelson) to show normal chemoresponse. We have been able only indirectly to demonstrate calmodulin regulation of the putative Ca-ATPase pump activity through calmodulin inhibitors and calmodulin overlays of blots. Therefore, in order to study the role of the calcium pump further and to gather more indirect evidence for the regulation of the Ca-pump by calmodulin, we turned to mutants that harbor alterations in the gene for calmodulin and consequently have different conductances affected by their altered calmodulin molecules (Kink et al., Cell 62: 165-174, 1990). These mutants present an unusual opportunity to study a variety of changes in calmodulin, some of which may affect the activity of the plasma membrane Ca-ATPase. Two mutants show abnormal efflux of ^{45}Ca from preloaded cells and altered Ca-ATPase activities, consistent with the interpretation that their calmodulins regulate the Ca-pump abnormally. Additionally, these mutants have abnormal responses to chemical stimuli, reinforcing the notion that the calmodulin-regulated pump plays a role in chemosensory transduction. (NSF, NIH, VRCC)

CHARACTERIZATION AND DETERGENT-SOLUBILIZATION OF THE PUTATIVE HYDRA GLUTATHIONE CHEMORECEPTOR. S.L. Bellis, G. Kass-Simon and D.E. Rhoads. Univ. of R.I., Kingston, RI 02881.

Feeding behavior in the coelenterate, Hydra, is initiated by the association of glutathione (GSH) with an external chemoreceptor. In the present study, the binding of ^{35}S -GSH to Hydra membranes has been characterized. Seventy-one percent of the specific binding was eliminated by treating membranes with inhibitors of the GSH-metabolizing enzyme, γ -glutamyl transpeptidase. The remaining 29% of the specific binding demonstrated all of the characteristics expected of a ligand-receptor interaction. The binding was rapid, reversible and saturable. A Scatchard analysis of saturation isotherms indicated a dissociation constant (K_D) of 3.0 μM , a value which is in good agreement with concentrations of glutathione which are known to induce feeding behavior. The detergent, CHAPS, was used to solubilize the membrane preparation, resulting in release into the soluble fraction of 45% of membrane proteins and 40% of the saturable, reversible GSH binding activity. The K_D for GSH binding to the solubilized preparation was estimated as 2.7 μM , a value which is not appreciably different from the K_D for GSH-binding to intact membranes. The fidelity of GSH-binding in the solubilized preparation suggests that this preparation will be useful in further characterization of the receptor.

CIRCUITRY AND PATTERN GENERATION I

PROPERTIES OF PROPRIOSPINAL NEURONS INVOLVED IN THE RHYTHMIC EXCITATION OF MOTOR POOLS IN THE ISOLATED EMBRYONIC CHICK SPINAL CORD. Stephen Ho and Michael O'Donovan. Laboratory of Neural Control, NIH, Bethesda, MD 20892.

Previous studies of rhythmic motor activity in the isolated lumbo-sacral cord of the chick embryo have shown that motoneurons in different segments discharge synchronously at the onset of each cycle. The aim of this study was to identify the mechanisms that coordinate motoneurons during rhythmic activity.

After cutting the ventrolateral white matter (LW) tracts, the discharge of motoneurons caudal to the lesion was delayed when compared to the contralateral control. Caudal motoneurons were no longer active when a Co^{++} gel was applied over the lesion site to block synaptic transmission in the remaining grey matter. The Co^{++} gel alone did not affect the timing of rostral and caudal motor activity if the LW tracts between them were left intact. A brief burst of discharge at the onset of each cycle and rhythmic electrotonic potentials in synchrony with motoneuron depolarization could also be recorded from the LW axons across a Co^{++} gel. These findings suggest that the tight coupling between rostral and caudal motoneurons is mediated by the LW axons.

Retrograde labelling at LS5 was used to locate the cell bodies of the axons traveling in the LW tracts and revealed a column of cells located dorsomedial to the motor column extending from the injection site to LS1. Electrical stimulation of the LW axons produced a powerful synchronized discharge in motoneurons, especially in the extensors. Whole cell voltage clamp recordings in motoneurons and other spinal neurons showed that the synaptic currents arising from LW tract stimulation were facilitated during episodes of motor activity. This suggests the last order interneurons responsible for the LW tract evoked synaptic currents are also driven by the central pattern generator, or alternatively, the synaptic efficacy of these propriospinal neurons is modulated during rhythmic activity.

50.3

PHYSIOLOGICAL AND PHARMACOLOGICAL CHARACTERIZATION OF RHYTHMIC EXCITATORY AND INHIBITORY INPUTS ONTO MOTONEURONS IN THE CHICK EMBRYO SPINAL CORD. Evelyn Sernagor and Michael J. O'Donovan. Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Whole-cell patch clamp recordings from identified motoneurons (MN's) in the isolated chick embryo spinal cord (E7-E12) have revealed rhythmic synaptic currents during motor activity. From E10 both sartorius (flexor) and femorotibialis (extensor) MN's express a common sustained excitatory drive and firing in sartorius MN's is modulated by a more transient inhibitory input. At E7-E8 the predominant current expressed in sartorius MN's is inhibitory. The pharmacological nature of these inhibitory and excitatory currents has been investigated either with pressure ejections of antagonists on the ventral surface of the spinal cord (1 or 10 mM) or with injections of these drugs in different segments of the cord, in the vicinity of the lateral motor column (100 μM , 1 or 10 mM) while recording from the muscle nerves. This experimental approach allowed us to study the effects of the drugs without blocking the motor rhythm. The sartorius inhibition was completely blocked by the GABA_A antagonists bicuculline and picrotoxin and also by curare, a cholinergic nicotinic blocker. The inhibition was blocked to a lesser extent by strychnine, a glycinergic antagonist, by atropine, a cholinergic muscarinic blocker and also by the NMDA antagonists AP5, 7Clkynurenic acid and kynurenate, but not by pancuronium bromide, a specific nicotinic antagonist. On some occasions kynurenate also reduced the sartorius excitation. However, it was possible to reduce the sartorius excitation significantly with 2,4DHPAA, a specific glutamate antagonist. The duration of activity in femorotibialis MN's was significantly reduced by AP5 and the activity was almost abolished by kynurenate. These results suggest that (1) the inhibition expressed in sartorius MN's during motor activity is mediated by the effect of GABA on GABA_A receptors. The effects of curare, atropine and strychnine may result from a non-specific blockade of these receptors, while the action of AP5, kynurenate and 7Clkyn suggest that these drugs block the excitation of the GABAergic interneurons; (2) the excitatory inputs onto femorotibialis and sartorius MN's during motor activity is mediated by the release of glutamate.

50.2

REAL-TIME IMAGING OF IDENTIFIED PROPRIOSPINAL NEURON ACTIVITY FOLLOWING BATH APPLICATION OF FURA-2AM AND MICROINJECTION OF FURA2-DEXTRAN INTO FIBER TRACTS. Michael O'Donovan, Stephen Ho, Wayne Yee & Miklos Antal. Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Real-time Fura-2 imaging during motor activity in the isolated chick spinal cord has revealed a high proportion of rhythmically active cells in and around the lateral motor column (LMC). The goal of the present experiments was to identify these cells and to characterize their behavior in more detail. Retrograde labelling was used to show that many of these cells are propriospinal neurons that project their axons in the ventro-lateral white matter (LW) over several segments. Propriospinal neurons could be imaged in Fura-2AM loaded spinal cords by high frequency stimulation of LW in the presence of excitatory amino acid antagonists, and were found dorsal to the LMC. Neurons in this region can receive a powerful synaptic excitation from the LW and exhibit synchronized fluorescence oscillations during rhythmic motor activity. These optical findings were corroborated by imaging the activity of propriospinal neurons that had been selectively loaded with Fura2-Dextran by microinjection into LW at LS4-LS5. This procedure results in an optically active population of labelled neurons in a rostrocaudal column similar in distribution to that found with retrograde labelling techniques. Whole cell patch recording from ventrolateral interneurons located outside the LMC revealed their depolarizing synaptic drive was in phase with that of motoneurons, confirming the optical findings.

Our findings support the hypothesis that propriospinal neurons may play an important role in the origin or coordination of motoneuron activity in the developing spinal cord.

50.4

THE DEVELOPMENT AND VISUALIZATION OF MOTOR ACTIVITY IN THE ISOLATED BRAINSTEM/SPINAL CORD PREPARATION OF THE CHICK EMBRYO. G.N. Sholomenko and M.J. O'Donovan. Laboratory of Neural Control, NINDS, NIH, Bethesda, MD.

The isolated brainstem/spinal cord preparation (iBST/SC) was used to study the development of descending pathways involved in the regulation of motor activity in the chick embryo. The cooled embryo (E5-E14) was removed either from the egg or from the dish in which a shell-less embryo (*ex-ovo*) was incubated. The embryo was decerebrated and placed in a dissecting dish containing recirculating oxygenated Tyrode's solution. The brainstem/spinal cord was removed from the surrounding tissue and fore- and hindlimb muscle nerves or ventral roots were dissected for recording motor activity. The iBST/SC was then placed in a double partition bath which allowed isolation of the brainstem, cervical and lumbosacral cord into independently perfused chambers. In some experiments, the fluorescent tracer dextran tetramethylrhodamine (RH) was injected into the cervical (iBST/SC) or lumbosacral (*ex ovo*) spinal cord to retrogradely label cells of origin of supraspinal pathways. In preliminary studies, the calcium indicator Fura-2AM (Fura) was bath applied to examine the activity of cells on the cut face of the brainstem. Our results indicate that: 1) in E6-14 embryos, the iBST/SC produced spontaneous bouts of alternating activity in flexor and extensor muscle nerves indistinguishable from that seen in the isolated spinal cord preparation. 2) electrical stimulation of relatively discrete regions of the brainstem in E6-14 embryos consistently evoked episodes of rhythmic neural activity closely resembling spontaneous activity, but no activity could be elicited in the E5 preparation. 3) the addition of a 0 calcium/high magnesium solution to the middle bath (cervical cord) did not abolish brainstem stimulation-evoked rhythmic activity recorded from hindlimb muscle nerves. 4) the cell bodies, axons and dendrites of neurons retrogradely labelled with RH injected into the cervical and lumbosacral spinal cord could be visualized *in vitro* on the cut face of the brainstem. 5) Fura-labelled neurons on the cut brainstem face oscillated synchronously with the lumbosacral motor activity.

These results suggest that in the chick embryo, supraspinal pathways make functional connections with the lumbosacral spinal cord as early as E6. Further, by combining retrograde tracing and optical methods, the means now appear available to examine the relationship of individual brainstem neurons to the central pattern generator for locomotion present in the spinal cord.

50.5

FICTIVE SPINAL MOTOR OUTPUT ELICITED BY STIMULATION OF THE MIDBRAIN OF GOLDFISH. J.R. Feicho. Dept. Neurobiology and Behavior. SUNY at Stony Brook, NY 11794.

Kashin et al., (1974) stimulated the midbrain tegmentum in teleost fish and produced rhythmic axial EMGs and tail movements. I have confirmed their observations in goldfish and extended their techniques to produce fictive motor output. Rhythmic alternating movements of the tail, similar to swimming, were elicited in nine decerebrate goldfish by mid-brain stimulation (50-100Hz square pulses, 0.2 msec duration, 50-100 μ A) at sites along the midline just rostral to the cerebellum and about 2 mm deep. After locating optimal sites for producing these movements, I paralyzed the fish and recorded extracellularly from ventral roots or branches of roots from the trunk and tail. During midbrain stimulation, motor axons in the nerves were active in repetitive bursts. The frequency of bursts varied with stimulus strength and among fish, ranging from 1.5 to 12.5 Hz. The duration of bursts was correlated with cycle time, with longer bursts associated with longer cycles. The bursts occupied a mean of 0.45 of the cycle times (n = 24; s.d. = 0.086). Bursts from nerves on opposite sides of the same segment alternated, with one side active when the other was silent. Thus, as in other vertebrates, the CNS in teleosts can produce rhythmic motor output in this case with some similarities to swimming in the absence of movement. This fictive preparation will allow intracellular studies of the circuitry for comparison with the spinal networks for other motor behaviors such as escape. Supported by NIH NS26539.

INTEGRATIVE PATTERNS OF DORSAL NECK AND HINDLIMB MUSCLE ACTIVITIES DURING THE SCRATCH CYCLE. P. Carlson Kuhta and J.L. Smith. Neuromotor Control Lab., Dept. Kinesiology, UCLA, Los Angeles, CA 90024-1568.

The normal cat scratch response consists of cyclic hindlimb motions at an average frequency of 5-7 cycles/s, with each cycle containing a contact phase that occupies about 50% of the cycle period. The paw accurately contacts the stimulated area of the head suggesting a coordination between the hindlimb and neck muscles to correctly position the paw and head. To gain insight into this coordination, we implanted wire electrodes in four dorsal neck muscles, bilaterally (i, ipsilateral; c, contralateral): biventer cervicis (BC), splenius (SP), complexus (CM), and obliquus capitis caudalis (OC). In addition three hindlimb muscles, medial gastrocnemius (MG), soleus (SOL), and tibialis anterior (TA) were implanted, and ankle extensor, tendon-forces were measured with a buckle force transducer. Scratches were elicited by ear stimulation and EMG & force measurements were synchronized with 100 fr/s ciné film; for further methods see Carlson Kuhta and Smith (*J. Neurophysiol.*, 64:1653-1667, 1990).

Of the neck muscles, the iSP, iBC, and cOC were phasically active most often during the cyclic period of scratching, while the other neck muscles usually had tonic low-level activities. The iSP was active during the contact phase with onset occurring after the onset of paw contact and iSP offset occurring at or just after peak tendon-force. Also, bursting in iSP appeared to occur only after a threshold tendon-force level (~7N) was reached. The iBC was also coactive paw contact but onset during the precontact phase and offset near peak tendon-force. The cOC bursts were brief and occurred during the postcontact phase.

Our preliminary results suggest that several neck muscles help coordinate head movement with the paw. The iBC appears to anticipate paw contact, while the iSP appears to compensate for paw contact, possibly via proprioceptive or cutaneous feedback. Activity in both iBC and iSP would tend to reduce head motion evoked by paw contact and hindlimb extension. The cOC, a neck rotator, would tend to move the pinna away from the paw and may thus help terminate the contact phase. Funded by NIH NS19864.

50.9

ORGANIZATION OF THE PRE-ECYDYSIS MOTOR PATTERN IN *MANDUCA SEXTA*. A. Novicki and J.C. Weeks. Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

Pre-ecdysis behavior serves to loosen the old cuticle before it is shed at ecdysis. The larval pre-ecdysis motor pattern includes rhythmic bursts in two motor neurons, MN-2 and MN-3, which are synchronous in all abdominal ganglia and on the left and right body sides. The organization of the motor pattern in the isolated abdominal nerve cord was investigated by cutting the connectives or by using low calcium saline to block synaptic transmission in single ganglia. The working hypothesis resulting from these experiments is that the pre-ecdysis motor pattern is coordinated and maintained along the nerve cord by a bilateral ascending projection from the terminal ganglion. This projection appears to ascend the nerve cord without interposed chemical relays, and may synapse directly on MN-2 and MN-3, as well as acting through premotor interneurons. Previous work [*J. Comp. Physiol.* (1991) 168:179] has shown that the larval pre-ecdysis motor pattern is severely attenuated at larval-pupal pre-ecdysis, and this model of the organization of the pre-ecdysis motor pattern will be useful for investigating the sites of developmental plasticity of this behavior.

Multiple electrode recordings along the isolated lamprey spinal cord during fictive swimming reveal strong coupling among segmental oscillators. N.M. Mellen¹*, T. Kiemel²*, and A.H. Cohen³. ³Department of Zoology, University of Maryland, College Park, MD. 20742, ¹Department of Psychology, Cornell University, Ithaca, NY 14853, ²Mathematical Research Branch, NIDDK, NIH, Bethesda, MD. 20892.

A method of positioning 16 electrodes ca. 5mm apart along the isolated spinal cord of the lamprey has been developed. This technique allows for the investigation of temporal regulation of drug-induced (D-glutamate) fictive swimming at a higher spatial and temporal resolution than previously possible. Through the use of these methods we observed that during stable fictive swimming, the correlations between phase delays measured one or more cycles apart are small, suggesting that the coordinating system is sufficiently strong to damp out intrinsic perturbations within one cycle of activity. In addition, data obtained with the new method reveals that stable phase delays can also be preserved in the absence of stable periodicity even between segments separated by some distance. Taken together, these data suggest that both long and short coordinating neurons provide strong coupling among the spinal segments.

DISCHARGE DYNAMICS OF RED NUCLEUS NEURONS IN RESPONSE TO SPINAL CORD STIMULATION IN THE *IN VITRO* TURTLE BRAIN. R.R. Carter, J.B. Andersen*, S. Hansen*, and J.C. Houk. Department of Physiology, Northwestern University School of Medicine, Chicago, IL 60611.

In several species, red nucleus neurons have demonstrated action potential discharge patterns which are linked temporally with several parameters of limb movements. These discharge patterns are postulated to be the result of reverberating activity within a positive feedback loop formed by the red nucleus, cerebellar nuclei, and other brainstem nuclei. Loop activity is thought to be sculpted into motor programs by the inhibitory action of Purkinje cells located in the cerebellar cortex. We have employed an *in vitro* preparation from the turtle (Keifer and Houk, *Neurosci. Lett.*, 97: 123-128, 1989) in which the cerebellum, brainstem and spinal cord are maintained intact to study the dynamic characteristics of these loop generated motor commands. Electrical stimulation of the spinal cord by single pulses or brief trains was used to simulate a sensory input to the cerebellorubrospinal loop and the evoked discharge pattern of single red nucleus units was recorded extracellularly. Our results show that the discharge patterns were repeatable given identical stimuli. This suggests that the response does not depend appreciably on initial loop conditions which could be a function of highly variable spontaneous Purkinje cell activity. The magnitude of the discharge (average firing rate over the 1 s period following the stimulus) was graded at low levels of stimulus amplitude and saturated for higher levels of stimulus amplitude. The stimulus typically drove a unit to a higher firing rate from which it began to decline immediately to its resting rate in a manner well described by a two-exponential model. We propose a two-neuron reciprocal neural network model of the cerebellorubral circuit based on these results.

50.10

Chaos in the Lobster Stomatogastric Network
Norman Herterich and AI Selverston, UCSD

The pyloric system normally produces simple "1:1" rhythms; i.e., each neuron produces one burst of activity for each pacemaker burst, and successive bursts in each cell are similar. Under various experimental paradigms, dynamic complexity is observed as a consequence of network interactions. Increasing the strength of LP's synapse onto the PDs slightly induces 2:2 rhythms (i.e. successive bursts differ, but a repeating cycle consisting of 2 PD and 2 LP bursts is observed); 1:2, 1:3, and 2:3 rhythms are frequently observed at greater strengths. Plots of pacemaker burst period versus synaptic strength reveal bifurcations similar to those seen in transitions to chaos. For the greatest synaptic strengths, the period return diagram, though complex, exhibits structure which may be indicative of chaotic dynamics. Additionally, 2:1 oscillations are often observed in the IC neuron when VD is killed, due to sequential phasic inhibition from the pacemakers and the PY neurons.

JAW MOVEMENTS AND MUSCLE (EMG) ACTIVITY DURING DRINKING IN THE PIGEON. R. Bermejo, M. Remy and H. P. Zeigler. Biopsychology Program, Hunter College (CUNY), New York, NY 10021

In birds, variations in gape during ingestive behavior are produced by the coordinated movements of the two beaks and the jaw muscles are innervated by both the trigeminal and the facial cranial nerves. To relate these movements to neuromotor mechanisms, the displacement of each beak was monitored during drinking, while recording electromyographic activity in representative jaw and tongue muscles.

Individual drinking cycles begin with a rapid closing movement of the lower beak, followed, first, by elevation of the upper beak and then by depression (opening) of the lower beak. Beak movements during drinking are correlated with nearly synchronous activity in the protractor (opener) of the upper jaw and several jaw closer muscles as well as with alternating activity in tongue protractor and retractor muscles, suggesting that opening movements of the lower beak are passively produced and related to concurrent tongue movements. The results represent a first step in relating the generation of cyclic drinking movements to activity in specific motoneuronal pools.

Effects of serotonin on NMDA, kainate, and sensory induced locomotor activity in the lamprey. J. L. Schotland, T. Matsushima, and S. Grillner, Nobel Institute for Neurophysiology, Karolinska Institute, Stockholm, Sweden.

The isolated lamprey spinal cord can generate a pattern of neural activity that closely resembles swimming, consisting of reciprocally organized bursts of activity with a rostro-caudal intersegmental phase lag. By changing the excitability of the locomotor circuitry, a physiological frequency range may be covered (0.2-10 Hz). Low frequencies may be elicited by applying NMDA to the bath whereas higher frequencies are induced by kainate. The overall activity is determined by the segment with the highest frequency and the phase lag by the frequency differences between this segment and other segmental oscillators (Matsushima and Grillner 1990). 5-HT has pronounced effects on the locomotor network. While a great deal is known about the morphology, ultrastructure, and cellular mechanisms of action of the 5-HT system, little is known of the physiological significance of this ubiquitous transmitter. Previous studies of 5-HT locomotor effects have been performed on locomotor activity elicited by bath application of excitatory amino acids. It was therefore important to test the effects during a physiological activation of the network by using sensory stimuli (Brodin and Grillner 1985). 5-HT could elicit the same type of effects under these conditions. In a spinal split bath preparation, 5-HT (0.1-1 μ M) or the 5-HT reuptake blocker, citalopram (10 μ M) applied to the rostral half of the cord reversed the intersegmental phase lag in NMDA-mediated locomotor activity. This action is not mediated by altering intersegmental synaptic strength, since EPSP amplitudes were unchanged following 5-HT. The 5-HT induced reduction in the after hyperpolarization may account for these effects. The relative contribution of 5-HT effects on synaptic versus plateau potentials was evaluated by applying 5-HT (2-5 μ M) to kainate-induced (10-25 μ M) fictive swim in which NMDA receptor mediated effects were blocked (50 μ M APV). In contrast to 5-HT effects when NMDA receptors were not blocked, the pattern of swimming could be severely disrupted. Often two frequencies of activity were present; burst frequency could increase on one side (e.g. 5 Hz) without contralateral burst activity, while a slow alternation (e.g. 0.01 Hz) was induced between the two sides.

ARTIFICIALLY COUPLED STOMATO-GASTRIC NEURONS IN PRIMARY CELL CULTURE. Andrew A. Sharp* and Eve Marder. Biology Department, Brandeis University, Waltham MA 02254.

Our goal is to determine how the connections among cells influence the functioning of individual neurons and the networks that they comprise. In ganglia, the complexity of the interconnections makes it difficult to determine what effect any of the connections has on the network. We have devised techniques which allow us to artificially couple physically isolated neurons which may be located next to each other in the same dish or in separate chambers. To mimic electrical coupling, the potential from two cells is compared and equal and opposite currents are injected into the cells based on the magnitude of the intercellular potential difference. To mimic chemical synapses, iontophoretic application of transmitter is controlled by the membrane potential of the presynaptic neuron.

One of our interests is how electrical coupling affects the frequency and waveform of coupled oscillators. Computer modeling has indicated that when an oscillatory cell is electrically coupled to a more hyperpolarized cell it slows down if the oscillation is dominated by the inward current phase and speeds up if dominated by the outward current phase (Kepler et al., 1990, Science, 248:83). When neurons from the stomatogastric ganglion of the crab Cancer borealis are dissociated and placed into primary cell culture, many behave as conditional oscillators. We are now studying artificially coupled pairs of neurons to determine how oscillators with various intrinsic properties and waveforms are modulated by oscillatory or non-oscillatory neurons. 50.12

MOTOR NEURON FEEDBACK TO THE VENTILATORY CENTRAL PATTERN GENERATOR IN THE CRAB. R. A. DiCaprio. Dept. of Zoological & Biomedical Sciences, Ohio University, Athens, OH 45701.

Previous studies have demonstrated that motor neurons as well as interneurons are involved in the generation of the ventilatory motor pattern in Crustacea. This conclusion is based on the observation that perturbation of the membrane potential of individual motor neurons with intracellular current injection can start, stop and reset the ventilatory motor output and also modulate the frequency of the ventilatory rhythm (Simmers & Bush, J. Comp. Physiol., 150:1-21, 1983; DiCaprio & Fournier, J. Comp. Physiol., 155:397-405, 1984).

To further define the role of motor neuron feedback in the organization of this system, single motor neurons were injected with the fluorescent dye Lucifer Yellow and then killed by photoinactivation (Miller & Selverston, Science, 206:702-704, 1979). Analysis of the motor pattern before and after photoinactivation indicates that the basic structure of the ventilatory motor pattern is unaltered, but that some parameters of the motor pattern such as burst duration, burst phase and intraburst frequency are altered. These results support the conclusion that a functional role of motor neuron feedback is to fine-tune the temporal pattern of the ventilatory rhythm. MECHANISMS UNDERLYING RHYTHM INITIATION AND GENERATION BY NEUROMODULATORS OF THE GASTRIC MILL NETWORK IN LOBSTERS. R.C. Elson* and A.I. Selverston. Department of Biology, UCSD, La Jolla, CA 92093-0322.

Central generation of gastric mill motor rhythms by the lobster stomatogastric ganglion (STG) depends on modulatory inputs from higher centers. When isolated from these inputs the gastric central pattern generator becomes non-rhythmic. We studied mechanisms by which specific modulators (proctolin, muscarinic agonist) initiate gastric rhythms from the quiescent network in the isolated STG. Rhythm initiation is correlated with induction of bursting pacemaker potential properties in particular neurons. Induction of such non-linear membrane properties enables individual cells to burst endogenously and specific subcircuits of neurons to generate patterned rhythmic activity. Gastric rhythmicity may arise from several loci within the network. Burst oscillations are coordinated by graded synaptic transmission and slow or biphasic postsynaptic potentials. Supported by NIH grants 09322 and P01NS25916.

EFFECTS OF LOCAL OSCILLATOR FREQUENCY ON INTERSEGMENTAL COORDINATION IN THE LAMPREY LOCOMOTORY CPG: THEORY AND EXPERIMENT. K.A. Sigvardt, N. Kopell*, G.B. Ermentrout* and M.P. Reimer. Neurology, University of California-Davis, VAMC, Martinez CA 94553; Mathematics, Boston University, Boston MA 02215; Mathematics, University of Pittsburgh, Pittsburgh PA 15260.

The mathematical analysis of chains of coupled oscillators developed by Kopell and Ermentrout (SIAM J. Appl. Math. 50:1014, 1990) makes predictions about the effects upon intersegmental phase lags of varying the intrinsic frequency of the oscillators within the chain. In a series of experiments on intersegmental coordination in the in vitro lamprey spinal cord, intersegmental phase lags were examined following changes in the intrinsic frequency of the local segmental oscillators by changing the concentration of excitatory amino acid bathing the rostral half of the spinal cord relative to the concentration bathing the caudal half. In experiments where the concentration of D-glutamate was higher in the caudal compartment than in the rostral compartment, the intersegmental phase lags in the caudal half of the spinal cord remained the same as controls whereas the phase lags in the rostral half of the cord decreased. Within the context of coupled oscillator theory, this result indicates that in the lamprey spinal cord ascending intersegmental coupling is dominant over descending coupling and determines the intersegmental phase lags.

A NEUROPEPTIDE EXERTS ITS EFFECTS ON THE LOBSTER CARDIAC SAC MOTOR PATTERN AT MULTIPLE SITES. P. S. Dickinson and J. Helling*, Dept. of Biology, Bowdoin College, Brunswick, ME 04011

The foregut of decapod crustaceans is controlled by four semi-discrete motor networks, each of which generates characteristic patterns of rhythmic activity. We have previously shown that the neuropeptide Red Pigment Concentrating Hormone (RPCH) activates one of these networks, the cardiac sac network, in the spiny lobster, *Panulirus interruptus* (Dickinson and Marder, J. Neurophysiol. 61: 833-844, 1989). We now show that RPCH exerts its effects directly on one element of the cardiac sac motor pattern generator, the inferior ventricular nerve (*ivn*) fibers. The *ivn* fibers pass through two ganglia, the oesophageal ganglion and the stomatogastric ganglion. When synapses in either ganglion are blocked and RPCH is applied to that ganglion, rhythmic activity in the *ivn* fibers is induced, even though neither ganglion contains the *ivn* cell bodies. In addition to inducing rhythmic activity in the *ivn* fibers and thus in the cardiac sac network, RPCH causes the post-synaptic potentials from the *ivn* fibers to increase significantly in amplitude. This increase is mediated partly through facilitation and partly through a direct effect of RPCH on the terminals of the *ivn* fibers in both the oesophageal and the stomatogastric ganglia. BILATERAL ACTIVATION OF INTERNEURONS DURING FICTIVE SCRATCHING IN SPINAL TURTLES. A. Berkowitz and P.S.G. Stein, Dept. of Biology, Washington University, St. Louis, MO 63130.

The turtle spinal cord contains sufficient neural circuitry to generate an appropriate scratch reflex in response to cutaneous stimulation (Ann. NY Acad. Sci. 563:1, 1989). In a low-spinal, immobilized turtle, many spinal interneurons with axons descending in the hindlimb enlargement are activated during all fictive scratching evoked by ipsilateral stimulation (Abstr. Soc. Neurosci. 16:1091, 1990). We extended investigation of such neurons, using ipsilateral or contralateral stimulation and bilateral motor nerve recording.

Units were recorded with a micro suction electrode from descending axons in the white matter in the caudal face of a multisegmental spinal cord preparation (ibid.). Many interneurons were activated during either ipsilateral or contralateral stimulation. Others were activated by stimulation of one side only; of these, some were inhibited by stimulation of the opposite side. Some units were tonically activated during all fictive scratching. Many others displayed rhythmically modulated firing in phase with motor output. The strength of modulation varied, with the activity of some units restricted to bursts during a particular phase of fictive scratching. For many units, when ipsilateral stimulation evoked unit activity in phase with a particular ipsilateral motor pool, contralateral stimulation evoked activity out of phase with the homologous contralateral motor pool.

This work suggests that a large percentage of cutaneous-activated spinal interneurons with a descending axon in the hindlimb enlargement either participate in scratch motor pattern generation or receive feedback from scratch pattern generators during stimulation of either side. POCKET SCRATCH, CAUDAL SCRATCH AND FLEXION REFLEX MOTOR PATTERNS PRODUCED BY THE *IN VITRO* TURTLE SPINAL CORD. Scott N. Currie and Paul S.G. Stein, Department of Biology, Washington University, St. Louis, MO 63130.

The turtle spinal cord responds to tactile stimulation within specific areas on the body surface by generating either a flexion reflex or one of three forms of the scratch reflex in hindlimb motor neurons (Stein, Ann. NY Acad. Sci. 563:1, '89). The turtle CNS is ideally suited for *in vitro* studies because it is extremely resistant to anoxia (Chan and Nicholson, J. Physiol. 371:89, '86); previous work demonstrated that an *in vitro* turtle spinal cord can generate the rostral form of the scratch reflex (Keifer and Stein, Brain Res. 266:148, '83). We have extended this work by developing an *in vitro* spinal cord-peripheral nerve preparation that expresses pocket scratch, caudal scratch and flexion reflex motor patterns. The spinal cord hindlimb enlargement and several adjacent spinal segments are exposed by dorsal laminectomy, removed along with associated peripheral nerves, and placed in flowing, oxygenated turtle saline. We record motor output from selected hindlimb muscle nerves and electrically stimulate specific nerves containing cutaneous afferents to elicit the pocket or caudal scratch. Stimulation of specific dorsal roots evokes the flexion reflex. Preparations continue to express robust motor responses for up to several days *in vitro*. These motor patterns display a prolonged excitation after brief sensory input similar to that previously demonstrated *in vivo* (Currie and Stein, J. Neurophysiol. 60:2122, '88 and 64:1134, '90). The technical advantages provided by the *in vitro* preparation will assist future studies aimed at revealing the cellular mechanisms responsible for the selection and generation of these motor patterns. Supported by NSF Grant BNS-8908144 to PSGS.

DEVELOPMENT OF MOTOR PATTERNS IN NEUROLOGICAL MUTANT MICE. V.J. Bolivar*, E.M. Coscia*, W. Danilchuk*, J.C. Fentress, and K. Manley*, Department of Psychology, Dalhousie University, Halifax, N.S., Canada, B3H 4J1.

Neurological mutant mice have been employed with success in a number of cellular and circuit level analyses. However, few systematic behavioral studies of these animals exist. We examined the ontogeny of natural movement sequences of swimming and grooming in four strains of neurological mutant mice: jimpy (*jp*), reeler (*rl*), staggerer (*sg*), and weaver (*wv*). Double recessive and littermate controls were video-taped at 2 day intervals from the 3rd to the 21st postnatal day. Primary tests included both supported and free swimming in 38±2 C water for 10-30 s. and subsequent self-grooming in a heated chamber. We report data that have been examined quantitatively with a video/computer-based motion analysis system (*Peak*), capable of generating stick figures, from which limb trajectories, accelerations, velocities and angles of movement were calculated. Myelin (*jp*), cortical laminar (*rl*), cerebellar (*sg*), and striatal (*wv*) disorders in these mice are differentially expressed in movement.

CIRCUITRY AND PATTERN GENERATION: MODELS

51.1

MODEL OF LOBSTER GASTRIC MILL CPG CONSTRUCTED FROM RELAXATION OSCILLATORS. P.F. Rowat and A.I. Selverston Biology 0322, U.C. San Diego, La Jolla, CA 92093-0322.

We use a one-compartment cell model with one fast current, one slow current, and two parameters. One parameter controls whether the fast current has a region of negative resistance, while the other sets the amplitude and gain of the slow current. By appropriately setting the parameters, the model cell may exhibit plateau potentials, post-inhibitory rebound (PIR), or endogenous oscillations. Synapses were modeled by a post-synaptic current calculated as the product of a post-synaptic conductance varying with the presynaptic potential, and a driving potential given as the difference between the post-synaptic potential and the synaptic reversal potential. A network with all known gastric connections was constructed. Very wide ranges of parameter values are sufficient for the model to produce approximately correct patterns (ACP). The model is deterministic but exhibits bounded chaos similar to the biological variability. When parameters that control the network oscillation frequency were adjusted, so that network frequency varied by an order of magnitude, ACP was still obtained. When parameters were set so that each cell, if isolated, had a frequency randomly assigned in a broad band ($T \pm 10\%$), and the network connections then re-introduced, the cells quickly entrained to a common frequency with ACP. It is not necessary for any individual cell to be an oscillator. Provided each isolated cell has PIR, the fully connected network oscillates with ACP. The cell model is a latent, generalized, relaxation oscillator. The effect of connections is to convert cells that are quiescent in isolation into an ensemble of relaxation oscillators, with chaotic variability. It is proposed that the pattern generating properties of the gastric mill should be understood in terms of the entrainment and phase-locking properties of networks of relaxation oscillators. Supported by ONR N00014-88-K-0328.

THE LAMPREY LOCOMOTOR CPG AS A CHAIN OF COUPLED OSCILLATORS: ANALYSIS OF NETWORK SIMULATIONS. Thelma L. Williams, Dept. of Physiology, St. George's HMS, London, SW17 0RE, U.K.

Experiments on the lamprey spinal cord, interpreted in light of the behaviour of coupled nonlinear oscillators, have revealed properties of intersegmental coupling (Williams et al, 1990: J. Neurophysiol. 64, 862; Kopell & Ermentrout, 1988: Math. Biosci. 90, 87). In such analysis, coupling is mediated by "H-functions", which describe the effects of neighbouring oscillators upon each other. This approach will be illustrated by experiments on simulated chains of coupled oscillators. The unit oscillators have the structure proposed by Buchanan & Grillner (1987: Science 236, 312), and the intersegmental connections are between cells in neighbouring oscillators (Buchanan, 1990: Eur. J. Neurosci. Supp. 3, 184). The H-functions for various coupling combinations have been determined, and the resulting behaviour of the oscillator chain has been shown to obey the predictions of the mathematical theory. In particular, uniform phase lags can be produced by any of a number of coupling mechanisms, without the need of extra excitation at the rostral end of the spinal cord.

51.3

NEURAL NETWORK SIMULATIONS OF FICTIVE LOCOMOTION. J.T. Davis and L.E. Moore, Department of Physiology & Biophysics, University of Texas Medical Branch, Galveston, Texas 77550.

Fictive locomotion is defined as the response pattern of spinal cord neurons that occurs during the application of exogenous excitatory amino acids. This pattern consists of alternating individual activities of neurons on either side of the cord leading to oscillatory outputs of action potential bursts in the ventral roots supplying the musculature, similar to that of normal swimming in the intact animal.

Neural network simulations of a single spinal cord segment were made for specific conditions of fictive locomotion, namely, those induced by different concentrations of excitatory amino acid agonists and antagonists. The specific measures of the network consist of records of (1) intracellular potentials of the neurons involved in the pattern generation and (2) the bursting discharge of motoneurons. Under these conditions both the frequency and waveforms of the intracellular potentials are dependent on the relative activation of different amino acid receptors. Especially noteworthy are the relative effects of NMDA and non-NMDA receptor activation and the ensuing fictive locomotion.

Single cell voltage clamp and constant current experimental data were used to constrain the parameters used in neural network simulations of fictive locomotion. Specific cable models of neuronal units with voltage dependent membrane properties were constructed to reflect anatomical and physiological behavior. The network simulations for three classes of models are compared with the fictive locomotion data using a limited number of free parameters. The three classes of models are:

- 1) Passive, simple summation units with sigmoidal activation functions,
- 2) Hodgkin-Huxley models with passive integrating dendrites,
- 3) Non-linear units based on experimental data from spinal cord neurons.

OFF-LINE SORTING OF SPIKES USING AN ARTIFICIAL NEURAL NETWORK. I. Espinosa E. and J. Quiza T.*, Cybernetics Lab., Physics Dept., Faculty of Sciences, UNAM, México, DF 04510

We are developing a computer environment for transforming and analyzing multi-recording spike trains (SPT). The SPT can come from multi-recording experiments with multiple microelectrodes as well as from neural network simulations. This facility will be used for functional connectivity analysis in neural assemblies recorded simultaneously in the brain of the rat.

We have produced software (ENTRENADOR) that classifies noisy action potentials by means of a 3-layer neural network using the back-propagation learning algorithm (Espinosa and Quiza, Soc. Neurosci. Abstr., Vol. 16, Part 2, p.1092, 1990). Now we have improved the network's architecture and added off-line classification of action potentials embedded in a SPT. The digitized version of the SPT is fed to the program (CLASIFICADOR) that detects spikes using the Haar transform and then classifies them with the trained neural network. The program delivers a list containing the class and points of occurrence of the spikes and also produces a separate list for each class of spikes as well as special format files for cross-correlation and gravitational analyses (Lindsey et al., Brain Research 483: 373-378, 1989). The system works reasonably fast and with a low error percentage. However, it has problems with overlapping spikes. We expect to improve this and add on-line analysis and sorting of SPT. METHOD FOR INCORPORATING DISCONTINUOUS ELEMENTS IN CONTINUOUS-TIME NEURONAL NETWORK MODELS. C.D. Myre and D.J. Woodward, Dept. of Cell Biology and Neuroscience, UT Southwestern, Dallas, Texas 75235.

A strategy has been devised for computational simulation of both continuous- and discrete-time neuronal network models. Discrete-time simulations are suitable for networks with large numbers of elements, but suffer from limited accuracy, whereas continuous-time simulations require excessive time to determine values for more than a few elements. Our approach in modeling is to replace some components (especially the "stiff", or slow-computing components) within a complex network model with discontinuous elements, so that continuous components run with stepsizes relatively independent of the stepsizes of the discontinuous components. This allows hybrid networks to be assembled using combinations of neuronal definitions. The strategy allows efficient computation of temporal properties of channel conductances, electrotonic properties of dendrites, or critical time-dependent interactions. The influence of such physiological properties can be examined within large neuronal ensembles which include many elements which are more appropriately computed at large, discrete time steps. We are employing this approach to characterize influences of detailed physiological mechanisms on memory phenomena in models inspired by neostriatum, which include interactions between mutually-inhibitory medium spiny neurons. In our model, the basal ganglia are observed to operate as a system for asynchronous accumulation of information from cortical signals, with storage and output of sets of analog values employed in motor programs.

51.4

PHASE RESETTING AND FIXED-DELAY STIMULATION OF A SIMPLE MODEL OF NEURAL RHYTHMOGENESIS: IMPLICATIONS FOR RESPIRATORY RHYTHM GENERATION. J.E. Lewis, L. Glass, M. Bachoo and C. Polosa, Dept. of Physiol., McGill Univ., Montréal, Québec, Canada, H3G 1Y6.

The aim of this study was to investigate the response of a simple three-phase neural network model to perturbation, in the context of previous experimental studies on the effects of superior laryngeal nerve (SLN) stimulation on the respiratory rhythm in cats. SLN stimuli produced a phase-dependent shortening or prolongation of the respiratory cycle. These effects were illustrated in the form of phase resetting curves (PRCs). Fixed-delay stimulation, which entails delivering stimuli at a constant delay after the onset of a cycle, was also used. Certain combinations of delay, stimulus intensity, and number of cycles between stimuli, resulted in (1) a variable, rather than consistent, response, and (2) a transient increase in cycle duration during and after stimulation. PRCs of the model were similar to those obtained experimentally. The results of fixed-delay stimulation in the model were comparable to the experiments in that variable combinations of shortened and prolonged cycles were observed. However, the increases in cycle duration during and after stimulation were not evident in the model. Thus, in the model, stimulus dependent properties with a longer time course are needed to account for the transient increases in unstimulated cycle duration observed experimentally. These comparisons show that several properties of oscillators in addition to phase resetting must be considered in the evaluation of theoretical models of rhythmogenesis. (This work was supported by M.R.C. and N.S.E.R.C. of Canada, and F.C.A.R. du Québec.)

51.6

BISTABLE NEURONS AND MEMORY PATTERNS IN THE INHIBITORY FEEDBACK MODEL INSPIRED BY NEOSTRIATUM. A.B. Kirillov, C.D. Myre and D.J. Woodward, Dept. of Cell Biology and Neuroscience, UT Southwestern, Dallas, Texas, 75235.

We have reported previously that a three dimensional array of mutually inhibitory model neurons (inspired by the extensive inhibitory feedback network of the medium spiny neurons in the neostriatum) is capable of maintaining patterns of activity and exhibits bistable neuronal firing. The neurons either fire repeatedly (the "on" state), or do not fire at all (the "off" state). Global noise can induce spontaneous switching between states: some "on" neurons switch "off" and some "off" neurons switch "on". Further analysis of this model revealed the following features. 1) Spontaneous switches of neuron states can occur in a wide range of model parameters. In a typical switch, only two mutually inhibitory neurons interact and "swap" their states. 2) If inhibition is extended only to nearest neighbors, an artificial checkerboard pattern of "on" and "off" neurons appears. Often two alternative checkerboard patterns arise in different regions with most switching found at the border in space between these patterns. 3) When the domain of local inhibition for each neuron is increased, which makes the model more realistic, a great variety of stable patterns of "on" and "off" neurons is possible. A specific local pattern may then be set by stimulatory inputs with weighted projections, and the network can maintain the pattern over several seconds (functioning as a short-term memory register). 4) The local connection strengths can be adjusted so that the network has several patterns as "preferred" long term memory states. When a part of such a pattern is set "on" by stimulation, the network can recall the rest of the pattern if the global noise is powerful enough to allow spontaneous switches. Our hypothesis is that such an array may operate as a form of local temporary memory in a motor control system. Support from the Texas Adv. Res. Prog., Biol. Humanics Found., MH44337, DA02338 and AFOSR 90-146.

51.8

SYNAPTIC INTERACTIONS AMONG PATTERN GENERATING NEURONS IN BUCCAL GANGLIA OF APLYSIA. D.A. Baxter and J.H. Byrne, Department of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225.

Several neurons have been identified that are believed to be members of a central pattern generator (CPG) in the buccal ganglia. Susswein & Byrne (1988) identified cells B31/32 and B35 on the caudal surface of the buccal ganglia, and Plummer & Kirk (1990) identified cells B51 and B52 on the rostral surface. To further examine how these neurons might function as a CPG, we have characterized the synaptic interactions among B31/32, B35, B51 and B52.

Simultaneous intracellular recordings were made from either B31/32 or B35 on the caudal surface of the left buccal ganglion and from B51 and/or B52 on the rostral surface of the right buccal ganglion. Stimulation of B51 produced an IPSP in B31/32 and B35. In contrast, stimulation of B52 had no effect on the membrane potential of either B31/32 or B35. Stimulation of B31/32 produced IPSPs in B51 and a mixture of IPSPs and EPSPs in B52. Stimulation of B35 produced EPSPs in B51 and IPSPs in B52. As previously reported, we observed that B51 and B52 reciprocally inhibited each other and that B35 excited B31/32. In addition, we recorded from these neurons during patterned activity. Activity in B52 coincided with activity in B31/32, whereas activity in B51 occurred while B31/32 and B52 were inhibited.

This pattern of connectivity is only one of the factors determining how this neural circuit may function as a CPG. Additional factors, such as the intrinsic properties of the neurons, also must be considered. We are using the simulation program SNNAP (Ziv et al., this volume) to construct a model representing the properties and interconnections of these identified neurons, and to examine how this neural circuit may function as a CPG. The simulations indicate that elements of this neural circuit can produce patterned activity, but that additional elements are probably necessary to account fully for the CPG.

51.9

SIMULATOR FOR NEURAL NETWORKS AND ACTION POTENTIALS (SNNAP): APPLICATION TO A CENTRAL PATTERN GENERATOR. J. Ziv, D.A. Baxter and J.H. Byrne. Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

An understanding of the causal role that individual neurons play in complex behaviors can be facilitated by computer simulations of the neural circuit that includes descriptions of both the detailed properties of each neuron and the pattern of synaptic connectivity. SNNAP was developed to achieve this goal.

The program is capable of simulating a network of up to 20 fully connected neurons. Intrinsic voltage-dependent membrane currents are described by a H-H type membrane model that may include up to 20 different ionic conductances which can be individually specified for each cell. Each conductance is described by a first order ordinary differential equation (ODE) for activation and inactivation with voltage-dependent steady-state values and time constants. Connections to other cells can be made by either electrical or chemical synapses. Chemically mediated postsynaptic conductances are simulated by the numerical solution of a second order ODE driven by a pulse equal to the duration of the presynaptic spike. Using this solution, the postsynaptic cell can respond to a change in the duration of a presynaptic spike. Moreover, PSP's from successive presynaptic spikes summate in real time. Operational features of SNNAP include callable files for each cell which include its unique membrane properties and parameters, and files of cell connectivity matrices.

We are using SNNAP to simulate a central pattern generator (CPG) in the buccal ganglia of *Aplysia* in order to understand the mechanisms that produce and modify the pattern. As a first step we simulated the intrinsic properties of cells B51 and B52 (Plummer & Kirk, 1990) including the postinhibitory rebound in B52 and regenerative activity of B51. Depolarizing both cells leads to simulated cyclic activity, but the activity is different from that of the CPG. Currently, we are incorporating additional elements, such as B31/32 (Susswein & Byrne, 1988; Baxter & Byrne, this volume) into the network, to simulate the CPG and evaluate the contribution that each element of the network makes to the pattern.

51.11

ANALYTICALLY DERIVED FUNCTIONAL CONNECTIVITY USING NEURAL NETWORKS S. Shah*, W.E. Faller and M.W. Luttgies. Departments of Electrical and Aerospace Engineering Sciences, University of Colorado, Boulder, Colorado 80309-0429.

Can the analysis of "simple units" in a trained artificial neural network reveal the "functional connectivity" of a biological neural network? The analysis of an artificial neural network capable of reproducing the spike train activity of many individual neurons suggests it is possible. Spike histories of over 50 cells in the dragonfly mesothoracic ganglion were simultaneously recorded and decomposed into individual spike trains. These raw spike train data were transformed to a stochastic spike train representation and used in training a standard backpropagation artificial neural network. Training yielded a mean sum squared error for the network that indicated successful network learning. The trained network contained the information required to predict neurobiological spiking activity. The artificial network model accurately reproduced the relative timings of spike events among cells as well as the intrinsic complex temporal patterns of individual spike train histories. To evaluate the functional connectivity developed between trained units a lesioning technique was used to remove individual cells from the artificial network. By lesioning an input unit and measuring the change in each of the output units we were able to compute the "functional influence" of each unit on the stochastic behavior of the network. Different units clearly made different overall contributions to network performance. Units may have both positive and negative (facilitatory and inhibitory) influences within the network. And, individual units can apparently have both global and specific influences on network performance. Since such information is difficult to obtain directly from analyses of the neurobiological data the neural network lesioning technique may provide important information about the function of biological nervous systems.

REPETITIVE DISCHARGE IN A COMMAND NEURON. J.L. Johnson. USD School of Medicine. Dept. of Physiol. & Pharmacol., Vermillion, SD 57069

A simple model was constructed for initiation of repetitive discharge in the earthworm medial giant fiber (MGF). The MGF receives two types of synaptic inputs: a long duration synaptic depolarization (SL) which is larger in amplitude than a heterogeneous group of brief synaptic depolarizations (SB). Alone, SL can initiate one MGF action potential (AP) but can initiate repetitive discharge with great difficulty. SB pulses are always subthreshold unless they summate with another depolarization. The function of SL, besides directly initiating only one AP, is to enhance the probability that SB pulses will initiate discharge. The initiation of repetitive discharge is primarily dependent upon the occurrence of SB pulses during the time of SL. The equation for the enhancement of responsiveness to SB pulses under these conditions is

$$\ln(\text{SB}) = 0.078 - 0.597 (\text{SL}),$$

($r = 0.992$) where the stimulation strength of SL is given in relative terms, with values being 1.0 for AP initiation. Values calculated for SB will initiate an AP. The discharge rate initiated in the MGF is dependent upon the rate of delivery of SB pulses during SL PLUS the inherent ability of the MGF to also excite itself once activated. ISLANDS IN THE MIND: Dynamic Subdivisions in "Association" Cortex as a Darwin Machine that Augments Intelligence.

WILLIAM H. CALVIN. University of Washington NJ-15, Seattle WA 98195 USA

The population-shaping known from darwinism provides a conceptual model (a "Darwin Machine") for the second-to-second activities of multifunctional cerebral cortex. The temporary cortical "map" might resemble a patchwork quilt, decision-making involving competition between islands of differing patterns against a background sea of inhibition. An island's spatiotemporal pattern of neural activity might successfully resonate with a schema's long-term memory (widespread spatial-only patterns, similar to a bar code on a grocery package representing apples or oranges; movement schema patterns might be more like the roll for a player piano). Because adjacent islands could merge, with takeover by one pattern, the number of schemata held simultaneously in this cache memory would depend on regulating inhibition. Creating sequences of schemata such as unique sentences, while approachable as a travelling salesman problem, is best done with a specialized sequencing area, such as the one at the core of language cortex. In analogy to eukaryotes, each island in the sequencer archipelago would contain a potpourri of patterns drawn from a few islands in the cache; each island chimera would reproduce depending on its near-neighborhood with episodic memories and grammar rules, the population evolving for generations until one multipattern took over (the sentence "understood," the movement plan "good enough" to initiate). Island biogeography shows that small-island species evolve more quickly than those on large ones when climate or sea level fluctuates; attention shifts and EEG rhythms might similarly speed word or face recognition.

Many intelligence tests stress recognition speed; individuals who are fast also tend to be among those who can readily maintain many items "in mind" simultaneously. This fast-and-many correlation (part of intelligence's general factor g) could be aided by a learned or innate ability to subdivide a workspace into many small islands.

USING NEURAL NETWORKS TO GENERALIZE A NEURAL CODE W.E. Faller, S. Shah and M.W. Luttgies. Aerospace Engineering Sciences, University of Colorado, Boulder, Colorado 80309-0429.

Neural network simulations of experimental neural data have been implemented and tested in our laboratory. The developed networks retained the experimentally resolved spatial distribution of cells, the physiologic operating range and stochastic firing history of each neuron. In the present work the firing histories from 55 simultaneously recorded cells in the dragonfly mesothoracic ganglion were used to determine if such a network, following training, could generalize the cell spiking histories for time periods not used in training. A 20 second record of the firing histories from these cells was separated into 10 consecutive records (1-10) of 2 seconds each. The network was then trained using a gradient spike train representation to predict the cell firing histories at time ($t+5$ msec) given the cellular firing patterns at time (t) for 5 alternating (1,3,5,7,9) records in this 10 record set. Following 1000 cycles of training the network was "asked" to predict the firing patterns of the 55 cells in all of the 10 records. The results indicated that the network accurately predicted the future cell firing patterns based on past firing history information for all 10 data sets. Although slightly worse performance was evident for previously "unseen" data sets, in all cases the mean sum squared error was less than 0.03 and the majority of spike train temporal histories were accurately reproduced. Despite this it seems highly unlikely that the solution of the network is a direct reproduction of the biological synaptic connectivity patterns between cells within the ganglion. However, it is asserted that the weight matrices of the network must contain a generalized statistical representation of the neural coding "rules" through which these neural cells interact with each other within this biological assembly. This assertion is strongly supported by the ability of the network to generalize solutions of cell firing patterns for "unknown" data sets. Detailed analyses of the weight matrices in turn should permit this neural code to be defined.

A NOVEL VECTORIAL MEASURE FOR DETECTING TEMPORALLY CORRELATED FIRING PATTERNS IN MULTIPLE SPIKE TRAINS. D.C. Tam and G.T. Kenyon. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

A novel vectorial measure, the "cross-interval vector", is developed to detect temporally correlated firing patterns in multiple spike trains recorded simultaneously. The scalar quantity of this cross-interval vector is similar to the analogous first-order "conditional cross-interval" measure introduced by Tam *et al* (*J. Neurosci. Methods* 23:23-33, 1988). The x- and y-components of this vector are given by the reciprocal of the cross-intervals between the neighboring spikes in another train and the reference spike. The direction of this vector is given by the arctangent of the ratio of the preceding cross-interval and the succeeding cross-interval. For n spike trains, there are a total of n such vectors for any pair of neurons. The resultant vectorial sum of the n vectors provides a quantitative measure of a specific firing pattern in these n neurons based on any reference spike in any train. The time evolution of these resultant vectors describes quantitatively the changes in firing patterns in these n neurons. Clusters of the resultant vectors delineate the sets of repeated firing patterns. The Euclidean distance between consecutive resultant vectors can be used to quantify the repeated firing patterns in the set of neurons. This method captures not only a scalar measure for determining any repeated firing patterns, but also a vectorial measure for determining the specific neurons contributing to the repeated patterns. Furthermore, this vectorial measure encapsulates the correlated patterns among all n neurons, not just the pair-wise correlations between any two neurons. (Supported by ONR N00014-90-J-1353 and NIH NS07182-10).

AN OBJECT-ORIENTED PARADIGM FOR SIMULATING INTERCONNECTED NEURAL SYSTEMS. D. G. Boney, L. J. Feinswog, R. K. Hutson, G. T. Kenyon and D. C. Tam. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The dynamics of realistic neuronal networks are implemented in two simulators using an object-oriented programming paradigm. The first simulator (MacNeuron) employs a detailed reconstruction of physiological nerve cells and is appropriate for the investigation of underlying physiological properties. The second simulator (MacNerveNet) describes the dynamics of simplified interconnected neurons and is optimized for studying the collective computational properties of large neuronal systems. The former simulator implements a conventional compartmental model, incorporating known biophysical and biochemical properties. The membrane "patches" and ionic mediums are decomposed into an arbitrary number of "compartments" forming the basic computational elements. The latter simulator implements a generalized integrate-and-fire neuron model, such that the idealized neuron itself forms the basic computational element; summing synaptic potentials with different time constants in different "compartments" to generate a spike when a threshold level is reached. Common to both simulators is the incorporation of hierarchical structures using an object-oriented paradigm. This greatly reduces the complexity of the model and allows easy incorporation of additional capabilities into the simulation. For instance, different ionic channels (i.e., Na⁺, K⁺, Ca⁺⁺) and (voltage/ligand-gated) conductances are implemented as subclasses of a generic conductance. Both simulators employ customized numerical algorithms designed to enhance computational efficiency. (Supported by ONR N00014-90-J-1353 and NIH NS07182-10).

STATISTICAL COMPARISON OF COMPLEX WAVE FORMS. J. A. Schetz, R. M. Friedman and C. M. Leonard. Department of Neuroscience and The Whitney Laboratory, University of Florida, Gainesville, Florida 32610

Simple wave form functions can be adequately compared by a combination of Fourier transformation and correlation techniques. Since correlation methods either rely upon a normal distribution or a linear assumption, they are not applicable to comparison of complex wave form functions whose differences are non-parametrically distributed. The transformation step for a complex wave form can become problematic if a mathematical expression for a given complex wave form is not known or obvious. For these reasons I have developed a simple and rapid method for comparison of complex wave forms that does not depend upon transformations or correlations.

A novel computer-aided method for statistically comparing complex wave forms (Statistical Wave Form Comparator version 1.54 S copyright (C) J. Schetz 1991) will be presented. This method employs a two-step algorithm that first finds the region(s) of best fit for two complex wave forms slid past one another, and then calculates a non-parametric matched pair signed-rank statistic for the differences over this entire region of mutual overlap. Comparison values are reported as an overall confidence interval for regions of best fit. Additional comparison information is displayed graphically and as bins of positive and negative point distributions.

Example wave forms include: (1) hydrophobicity plots of peptide neurotoxins that act on the voltage-dependent sodium channel, (2) voltage clamp records from single cells, (3) somatosensory evoked potentials prior to and following lesion, (4) and anatomical patterns of normal versus pathological brain gyri.

DO HIPPOCAMPAL CA3 PYRAMIDAL CELLS PROJECT INTO THE DENTATE HILUS? J. Pokorný* and P.A. Schwartzkroin. Dept. of Neurological Surgery, Univ. of Washington, Seattle, WA 98195.

Although there has been much recent interest in the role of the dentate gyrus, and particularly of dentate hilar neurons, we still know relatively little about the connectivity of the hilus with other parts of hippocampus. Morphological studies suggest a strong interaction between some hilar neurons - the mossy cells - and the granule cells; physiological data have shown a potent excitatory projection from granule cells onto these mossy cells. There are, in addition, some tantalizing indications that CA3 pyramidal cells send axon collaterals into the hilus. Physiological data suggest a potent CA3-to-hilar connection, but morphological studies have failed to support such a pathway.

In the present study, we have combined intracellular injections of CA3 pyramidal cells (with neurobiotin and lucifer yellow) and hilar stimulation to explore the connectivity between the hilus and CA3 regions. In rat hippocampal slices, most CA3 pyramidal neurons tested for antidromic activation from the hilus showed no spike invasion, even with relatively strong stimulation. However, when cells were depolarized, stimulation at localized hilar sites sometimes evoked antidromic action potential invasion. We hypothesize that antidromic invasion normally does not occur because of the fine caliber of the hilar-projecting axonal branch. When antidromically-activated cells were dye-injected, segments of fine axon collaterals were found projecting toward the hilar region. The extent of their projection, and their postsynaptic targets have still to be determined.

52.2

INTRASEPTAL CONNECTIONS REDEFINED: LACK OF A LATERAL SEPTUM TO MEDIAL SEPTUM PATH. T. Deller,^{1*} C. Leranthe,¹ and G. Buzsáki.² ¹Section of Neuroanatomy, Department of Obstetrics and Gynecology, Yale University, New Haven, CT 06510 and ²Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102

The integrity of the septohippocampal system is essential for memory formation and spatial behavior as well as for the electrical stability of the hippocampus. For many years it has been presumed or explicitly stated that the reciprocal septohippocampal loop is closed by a massive lateral septum-medial septum path. In the present study we reexamined the intraseptal connectivity in the rat using phaseolus vulgaris leucoagglutinin tracing combined with choline acetyltransferase and immunohistochemistry at both the light and electronmicroscopic levels. We found that the previously hypothesized lateral septum to medial septum projection is extremely sparse or non-existent and that the major medial septum to lateral septum path is GABAergic. The main targets of the lateral septal area is the lateral preoptic area, lateral hypothalamus, and amygdala. The redefined circuitry has important implications for the understanding of the septal regulation of hippocampal electrical activity and the operations of the septo-hippocampal system.

52.3

PRESENCE OF SOMATOSTATIN OR NEUROTENSIN IN LATERAL SEPTAL AREA (LSA) DOPAMINERGIC AXON TERMINALS OF KNOWN ORIGINS. R.L. Jakab¹ and C. Leranthe². Dept. of Obstetrics and Gynecology¹ and Section of Neurobiology², Yale University, School of Medicine, New Haven, CT. 06510

A new approach is proposed to demonstrate the coexistence of dopamine (DA) and neuropeptides in axon terminals, using targeted injection of 6-hydroxydopamine (6-OHDA) to DA cell groups and immunocytochemistry. We have studied the possible presence of somatostatin (SOM) and neurotensin (NT) in dopaminergic boutons of the rat LSA, because of the earlier reports that some periventricular hypothalamic DA neurons contain SOM (Sakanaka et al. 90), while a population of ventral tegmental area (VTA) DA neurons contain NT (Hökfelt et al. 84), and both DA systems project to the LSA (Lindvall and Stenevi 78). We focused our study on the afferents of the LSA somatospiny neurons which are surrounded by both DA- and SOM-containing pericellular baskets (Jakab and Leranthe 90, 91). The animals were treated with 25 mg/kg desmethylimipramine ip. to protect the noradrenergic fibers, and 45 min later 6-OHDA (1µg in saline-L-ascorbic acid) was unilaterally injected into the periventricular hypothalamus (group 1) or the VTA (group 2). After 48 hours the rats were sacrificed, and the septal area of group 1 was immunostained for SOM, while that of group 2 was immunostained for NT. Electron microscopy revealed numerous axon terminals on the treated side of the LSA which were immunopositive for SOM (group 1) or NT (group 2), and contained autophagous cytolysosomes. These organelles represent characteristic signs of catecholamine fiber degeneration which can be induced by 6-OHDA (Orteniente et al. 87) or catecholamine pathway transection (Leranthe et al. 88). Between these axon terminals and somatospiny neurons synaptic contacts were detected. In conclusion, LSA neurons receive double innervation from a "somatostatinergic" DA system of the hypothalamus and a "neurotensinergic" DA system of the midbrain. (Supported by NIH grants NS 26068 and HD 23830, C.L.).

52.4

SEIZURE-SENSITIVE SUBSTANCE P (SP) NEURONS IN THE HIPPOCAMPAL FORMATION OF THE NON-HUMAN PRIMATE AND HUMAN. C. Leranthe¹ and N. de Lanerolle². Dept. of Obst. & Gyn.¹ and Sects. of Neurobiol.^{1,2} and Neurosurg.² Yale Univ. New Haven, CT 06510.

We examined the distribution and synaptology of SP cells and axons in the vervet monkey (*Cercopithecus aethiops*). The majority of these cells are concentrated in the dentate hilar area while others were found in all layers of the ammon's horn. SP boutons in the dentate gyrus formed exclusively asymmetric synaptic contacts with granule cell dendrites in the external molecular layer, as well as with parvalbumin (PA)-immunoreactive neurons. In the ammon's horn, where the CA2 subfield was the most heavily innervated, the majority of the contacts were asymmetric; however, symmetric synapses could also be observed.

In order to determine the physiological significance of this rich hippocampal SP innervation, we examined the distribution of SP in human hippocampal seizure foci obtained from patients with intractable temporal lobe epilepsy (TLE). In the dentate hilar area of cryptogenic epileptic patients a loss of SP-immunoreactive neurons was observed. Although there was a major loss in CA1 pyramidal neurons, SP interneurons of this area were unaffected. In comparison, the hippocampi of TLE patients with extrahippocampal temporal lobe lesions, were essentially similar to those of normal human and primate hippocampi.

SP is a well known excitatory transmitter. In addition to innervating the excitatory granule cells, SP boutons terminate on PA-containing (presumably GABAergic) cells. Therefore, one can speculate that their loss affects the initiation of GABAergic inhibitory mechanisms. (Supported by NS-26068, C.L. and NS-27081, N. de L.)

52.5

LIGHT AND ELECTRON MICROSCOPY OF PARVALBUMIN-IMMUNOSTAINED NEURONS AND AXON TERMINALS IN THE AMMON'S HORN AND DENTATE GYRUS OF THE PRIMATE HIPPOCAMPUS. C. E. Ribak, L. Seress* and C. Leranth. Dept. of Anatomy and Neurobiol., Univ. of Calif., Irvine, CA 92717 and Sect. Neurobiol. & Ob/Gyn, Yale Univ. Sch. Med., New Haven, CT 06510.

Previous studies have described the localization of parvalbumin-immunoreactive (PARV-ir) neurons in the rodent hippocampus but similar descriptions of PARV-ir neurons in monkeys have not appeared. The present study examined light and electron microscopic preparations obtained from PARV-ir sections of hippocampus from six green monkeys. Light microscopy showed PARV-ir neurons and axon terminals in all layers of the dentate gyrus and Ammon's horn with some regional differences in the latter site. For example, the stratum moleculare in only CA2 showed many PARV-ir terminals but no PARV-ir cells were ever found in this layer in this region or in any of the other subfields of Ammon's horn. Most of the PARV-ir cells were located in or adjacent to the principal cell layers and had features that were described previously for PARV-ir cells in the rat. Except for CA2, the hippocampus displayed the most PARV-ir axon terminals among the somata of the principal cells both in the dentate gyrus and Ammon's horn. Electron microscopy showed that the PARV-ir axon terminals formed symmetric synapses with somata, dendrites and axon initial segments of principal and PARV-ir cells. Of the cells in the principal cell layers, pyramidal cells in CA2 showed the greatest number of axosomatic synapses formed by PARV-ir axon terminals whereas granule cells displayed the least. These results indicate areal differences in the GABAergic inhibitory innervation of hippocampal neurons. (Supported by NIH grants NS-15669, NS26068 and MH 44866)

52.7

EVIDENCE FOR A PRESYNAPTIC CO-LOCALIZATION OF KAINIC ACID RECEPTORS AND ACETYLCHOLINESTERASE IN THE DENTATE GYRUS OF THE RHESUS MONKEY. K. J. Rhodes, D. L. Rosene and M. B. Moss. Dept. of Anat. and Neurobiology, Boston Univ. Sch. of Med., Boston, MA 02118.

The aim of this study was to determine the cellular localization of kainic acid (KA) receptors and acetylcholinesterase (AChE) and that occupy the inner third of the molecular layer (ML) of the dentate gyrus (DG). To accomplish this, we examined the distribution of AChE and KA receptors in nine rhesus monkeys that received unilateral experimental lesions (14-21 day survivals) designed to destroy specific afferent axons or cell populations while sparing afferent fibers. Brains were fresh-frozen, cut into 15µm sections, and processed histochemically for AChE and by *in vitro* [³H]KA binding and autoradiography for KA receptors. Quantitative analysis of the histochemically stained sections and autoradiograms revealed the following: 1) fornix transections (n=2) reduced the density of AChE in the inner third of the ML by 15-20% but had no effect on the density of KA receptors, suggesting that only a small proportion of this AChE is associated with septohippocampal afferents; 2) ibotenic acid lesions (n=3) that destroyed dentate granule cells and polymorph cells but spared afferent fibers reduced the density of KA receptors in the inner third by 35%, but had no effect on the density of AChE, suggesting that some KA receptors are located postsynaptically on DG neurons; and 3) hippocampal transections that destroyed axons of the intrinsic, caudally directed dentate gyrus association (DGA) pathway reduced the density of AChE and KA receptors in the inner third at levels caudal to the lesion, suggesting that the two markers are co-localized presynaptically on axons of the DGA pathway. Interestingly, the density of both AChE and KA receptors is increased in the DG of Alzheimer's brains and following long-term entorhinal lesions. The results of the present study suggest that sprouting of intrinsic DGA fibers rather than septohippocampal afferents may account for this "plasticity". (Supported by NIH 16841, and 04321)

52.9

TERMINAL ORGANIZATION OF PROJECTIONS FROM PRESUBICULUM AND PARASUBICULUM IN RELATION TO IDENTIFIED ENTORHINAL-HIPPOCAMPAL PROJECTION NEURONS. M.P. Witter and M. Caballero Bleda*, Dept. Anatomy, Vrije Universiteit, Amsterdam, The Netherlands.

Cells in layers II and III of the entorhinal cortex give rise to projections to the hippocampus and distribute their fibers to dentate gyrus/CA3 and CA1/subiculum, respectively. Since layer II receives fibers from the parasubiculum (PaS) and layer III from the presubiculum (PrS; Kohler, '85), it is conceivable that layers II and III convey different types of information to the different subdivisions of the hippocampus. As a first attempt to elucidate this presumed specificity in the relation between the terminal distribution of inputs from the PrS and PaS and the origin of the two components of the entorhinal-hippocampal projection, we used a combination of anterograde and retrograde tracing and subsequent intracellular filling of retrogradely identified projection neurons in lightly fixed slices of the entorhinal cortex. Subsequently, the cell type, its position in the cell layer, its relation to the anterogradely labeled afferents from PrS/PaS, and the number of presumed synaptic contacts between the afferents and the projection neurons was assessed.

Our results show that the dendrites of neurons that are located close to the border between layers II and III cross this border into the adjacent, non-parent cell layer. Since also the terminal plexuses from PrS and PaS are not confined to the cell layer of preference, such "borderline" neurons appear to be innervated by both the inputs from PrS and PaS. We noted that projection neurons, classified as "horizontal" cells, are also located in the most superficial part of layer IV. Their dendrites are innervated at regular intervals by fibers from the PrS that course through layers VI-IV to the superficial layers of the entorhinal cortex. Whether these cells receive similarly organized input from PaS is subject of further study.

52.6

POSTSYNAPTIC TARGETS OF TIMM-LABELED MOSSY FIBERS IN RAT AND MONKEY HIPPOCAMPUS: A LIGHT AND ELECTRON MICROSCOPIC STUDY. L. Seress*, R.A.E. Bakay and C. E. Ribak. Dept. of Anatomy and Neurobiol., Univ. of Calif., Irvine, CA 92717 and Div. Neurosurgery, Emory Clinic, Atlanta, GA 30322

A comprehensive study of Timm-labeled terminals and their postsynaptic targets has not been described in electron microscopic preparations of the rat and monkey hippocampus. The present analysis used a modified Timm method that employed unossicated tissue and postembedding histochemistry. In the electron microscopic preparations, axon terminals of granule cells including the large mossy fibers were selectively labeled with numerous silver grains. The distribution of these terminals in thin sections was identical to that found in light microscopic preparations using the routine Timm method. The hilar neurons displayed two different distributions of mossy fibers; some displayed numerous terminals on their cell body and dendrites whereas others were much less frequently contacted by these terminals. Within the granule cell layer, smooth dendrites and somata of basket cells as well as unidentified spines were targets of Timm-labeled axon terminals, but not granule cell bodies. In the CA3 region, mossy fibers in stratum lucidum were labeled and they formed synapses with the typical thorny excrescences of the apical dendrites of rat pyramidal cells whereas both apical and basal dendrites were contacted by these terminals in monkeys. Also, Timm-labeled terminals formed synapses with dendrites and spines of unknown origin in the stratum oriens of the CA3 in rats. In conclusion, the main targets of the granule cells for both normal rats and monkeys are the pyramidal cells of CA3, the inhibitory neurons of the dentate gyrus and other hilar neurons. (Supported by NIH grant NS 15669)

52.8

ORGANIZATION OF EFFERENT PROJECTIONS FROM THE ENTORHINAL CORTEX TO THE POSTERIOR PARAHIPPOCAMPAL GYRUS IN THE RHESUS MONKEY. D. L. Rosene, G. J. Blatt, K. J. Rhodes and D. N. Pandya, Dept. of Anatomy and Neurobiology, Boston Univ. School of Medicine, Boston, MA 02118.

The entorhinal cortex (EC, area 28) is widely recognized as the major link by which input from cortical association areas reaches the hippocampal formation (HF). The posterior parahippocampal gyrus (PPHG) provides the major source of this cortical association input. Recent data from this and other labs demonstrates that the EC receives direct projections from the HF, amygdala and presubiculum and in turn sends projections back to the association cortices. To investigate the organization of EC projections to the PPHG (areas TH, TL, and TF), complementary retrograde and anterograde tracers were used. To localize the cells of origin in the EC, injections of fast blue and diamidino yellow were made into subdivisions of the PPHG. To determine the laminar and areal pattern of EC termination in the PPHG, injections of ³H-amino acids were made into the EC. A large anterograde tracer injection into the EC labeled layers I and II in all three PPHG subfields, but in TL and TF there was additional label in layers V and VI. An injection centered in area 28L labeled layers I and II in TH and layers II and superficial III and V and VI in TL and TF. An injection centered in area 28I labeled primarily layer II in all three PPHG subfields and layer V and VI in rostral TL and TF. Retrograde tracer injections into isocortical area TF or proisocortical area TLc labeled cells in layer V in the caudal two-thirds of areas 28L and 28I, and throughout area 28S. In contrast, retrograde tracer injections into proisocortical area TH labeled cells in layers III and V throughout the entire extent of the EC. Since hippocampal efferents terminate heavily in layer V while layer III receives major input from the amygdaloid and the presubiculum, the information flow to the different subdivisions of the PPHG may be quite different. Thus the EC should be viewed as an important *bidirectional* link between the hippocampal formation and the PPHG as well as a *relay* for the amygdala and presubiculum to both the hippocampus and PPHG. (Supported by NIH grants NS16841 and AG04321.)

52.10

CORTICAL AFFERENTS TO THE RAT ENTORHINAL CORTEX STUDIED WITH AXONAL TRACERS. R. Insausti. Dept. of Anatomy, University of Navarra, Apdo. 273, 31080 Pamplona, Spain.

The rat entorhinal cortex is the main source of afferents to the hippocampus. The exact origin of the information to the entorhinal cortex is relevant to understand the hippocampal mnemonic function. Cortical afferents to rat entorhinal cortex has been studied by both pressure and iontophoretic injection of WGA-HRP after direct surgical exposure of its surface. Series of 50 µm sections were obtained through the brain and reacted according to Mesulam's protocol. Caudally placed injections resulted in retrogradely labeled cells in temporal and temporo-occipital cortices, but in little labeling in perirhinal cortex. In contrast, injections of rostral entorhinal cortex gave heavy labeling in perirhinal cortex, as well as in medial frontal (infralimbic) and orbital cortices, but not in temporal cortex. Our study shows that the cortical afferents to the entorhinal cortex are less numerous than subcortical afferents, and that they are arranged in a differential rostrocaudal topographic fashion (supported by a grant from the Government of Navarra, Spain).

52.11

SPATIOTEMPORAL ORGANIZATION OF THE ENTORHINAL (E) INPUT TO THE HIPPOCAMPUS: MULTIPLE ELECTRODE RECORDING FROM THE ADULT GUINEA PIG BRAIN MAINTAINED *IN VITRO*. D. Paré and R.R. Llinas, Dpt. Physiol. and Biophys., New York Univ.

In order to test the lamellar hypothesis, field potential responses to E stimulation (STM) were recorded with multiple electrodes from the CA1 pyramidal layer of the arterially perfused adult guinea pig isolated brain maintained *in vitro*. Only tri-synaptic population spikes (PSs) were evoked by low-intensity E STM. However, they were widely distributed along the septotemporal (ST) and transverse (T) axes. Irrespective of the E region stimulated, the latency of CA1 responses gradually increased from the CA3/CA1 border toward the subiculum. In the ST axis, the E projection was organized topographically, each ST segment of the CA1 region responding at a shorter latency to a particular rostrocaudal level of the E cortex. This early response then propagated further septally and temporally with a conduction velocity roughly proportional to the stimulation intensity (0.5-2 m/sec). Transections interrupting the connections between the various E STM sites did not prevent the propagation of the response. Moreover, direct stimulation of the dentate gyrus (DG) at different ST levels gave rise to a similar pattern of activity in the CA1 region. These results suggest that each region of the E cortex projects preferentially at a particular ST level of the DG and that the associative pathways linking CA3-CA1 regions in the ST and T axes are powerful enough to transmit DG influences to the whole hippocampal formation. These results call for a revision of the lamellar hypothesis. Supported by NIH grant NS-13742 and MRC of Canada.

THE DOPAMINERGIC INNERVATION OF MONKEY ENTORHINAL CORTEX. M. Akil and D.A. Lewis. Depts. of Psychiatry and Behav. Neurosci., Univ. of Pittsburgh, PA 15213

The dopaminergic (DA) system and the entorhinal cortex (ERC) have both been implicated in the pathophysiology of schizophrenia. Little is known, however, about the DA innervation of primate ERC. In this study we used immunohistochemical methods to characterize the distribution of tyrosine hydroxylase (TH)-containing axons in monkey (*M. fascicularis*, *M. mulatta*) ERC. The relative density and laminar distribution of TH-immunoreactive (IR) axons differed among cytoarchitectonic regions of ERC. In general, fiber density decreased following a rostral-caudal gradient; some changes in density were stepwise whereas others were gradual. In most regions of ERC, TH-IR axons were present in greatest density in layers deep I and VI. In contrast, in the densely innervated olfactory ERC, TH-IR axons were more evenly distributed across all cortical layers although the highest density was in layer I. Dense TH-immunoreactivity was also noted in temporal regions rostral to ERC where vertical columns of TH-IR fibers were seen. Dual-label experiments with TH and dopamine- β -hydroxylase antibodies, as well as preliminary studies with DA antisera confirmed that the majority of TH-IR axons described in this study are DA. These data suggest a lamina- and region-specific role of the DA system in the function of monkey ERC.

52.15

THE CORTICOTHALAMIC PROJECTIONS OF THE ANTERIOR CINGULATE AND PRECENTRAL AGRANULAR CORTICES IN THE RAT. G.D. Fisk, T. van Groen and J.M. Wyss. Dept. of Cell Biology, The University of Alabama, Birmingham, Alabama 35294.

The present study characterizes the corticothalamic projections of anterior cingulate (area infraradiata; anterior, IR α ; posterior, IR β) and precentral agranular cortices using the anterograde tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L). In agreement with previous findings, the present data demonstrate that IR α , IR β and precentral agranular cortices project to anteromedial, mediadorsal, laterodorsal, lateroposterior, ventromedial, centrolateral, paraventricular and reuniens thalamic nuclei. In addition to these similarities, each cortical area has distinct projections. IR α , but not IR β , has a dense projection to the parataenial nucleus, while IR β , but not IR α , projects to anterodorsal and anteroventral nuclei. Further, while both IR α and IR β project most densely to anteromedial, ventromedial and mediadorsal nuclei, precentral agranular cortex has denser projections to ventrolateral, laterodorsal and lateroposterior nuclei. Within IR α and IR β , dorsal and ventral regions have different projection patterns. Compared to ventral IR α , dorsal IR α has denser projections to parataenial and anteromedial nuclei, but a less dense projection to the paraventricular nucleus. In IR β , dorsal (compared to ventral) IR β projects more densely to mediadorsal and ventromedial nuclei. Together, these data demonstrate that while the subregions of the anterior midline cortex project to many common thalamic targets, each cortical subregion has a distinct pattern of termination.

COMPARISON OF THE INTRINSIC ORGANIZATION OF MONKEY AND HUMAN ENTORHINAL CORTEX. M.J. Beall and D. A. Lewis. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15213.

Inferences about the connectivity of human entorhinal cortex (ERC) arise mainly from tracing studies conducted in monkey. The accuracy of such inferences may depend upon the degree to which monkey and human ERC have a similar intrinsic organization. Left ERC was obtained at autopsy from 6 humans (ages 32-63) with no known neuropsychiatric disorders and both ERCs were obtained from 5 perfused adult monkeys (*M. fascicularis*). Comparisons of cytoarchitectonic features were made between monkey and human using Nissl stained sections and the criteria of Amaral et al. (JCN 264: 326, 1987) for ERC subdivisions in the monkey. In general, the cytoarchitecture of ERC was similar in both species although specific laminar differences were observed. As a result, modifications of the monkey criteria were necessary for the identification of human ERC subdivisions. Immunohistochemical markers were also used to compare the distribution of distinct subpopulations of neurons across species. Antibodies labeling neurofilament proteins (NF) and two calcium binding proteins, calbindin and parvalbumin, revealed both similarities and differences in the distribution of immunoreactive neurons in the two species. For example, the gradient in NF immunoreactivity in layer II neurons was comparable in both species, however the two species had dissimilar patterns of labeling in the deeper layers that paralleled species differences in cytoarchitecture. Although many similarities were present in the organization of human and monkey ERC, significant differences were also evident and should be considered when using monkey ERC as a model for the human.

CONVERGENCE OF PROJECTIONS FROM THE RAT HIPPOCAMPAL FORMATION, THALAMUS, AND BASAL FOREBRAIN ONTO NEURONS OF THE ANTERIOR CINGULATE CORTEX: AN *IN VIVO* PHYSIOLOGICAL STUDY. D.M. Finch and A.M. Tan*. Department of Neurology and Brain Research Institute, University of California, Los Angeles, CA 90024.

A number of anatomical and physiological studies have shown projections from the hippocampal formation, from the medial dorsal nucleus of the thalamus, and from the cholinergic basal forebrain to the anterior cingulate cortex. We examined the possibility of synaptic convergence from these inputs onto single cingulate neurons. Sprague-Dawley albino rats were anesthetized with chloral hydrate (400 mg/kg, i.p.), and stimulating and recording electrodes were placed stereotaxically. Extra- and intracellular responses from anterior cingulate neurons were recorded *in vivo* after electrical stimulation of the hippocampal formation (dentate gyrus, hippocampal fields CA3 and CA1, subicular complex, and entorhinal cortex); thalamus (medial dorsal nucleus and vicinity); and basal forebrain (diagonal band, ventral pallidum, septum). The predominant response to stimulation of each of these regions was inhibition, though short latency excitatory responses were also seen in some cells. Individual cingulate neurons could show responses to two, or all three, of the stimulation sites. This indicated that synaptic influences from these areas converges onto single cingulate neurons, and provides a basis for synaptic integration. Supported by NIH Grants NS 23074 and NS 16721.

AGE RELATED BREAKDOWN OF DENDRITIC BUNDLES IN THE RETROSPLLENAL CORTEX OF THE RAT. J.M. Wyss and T. van Groen. Department of Cell Biology, University of Alabama at Birmingham, Birmingham, AL 35294.

In retrosplenial granular cortex (Rg), the apical dendrites of layer II pyramidal neurons bundle together tightly in layer Ic and Ib and spread out in layer Ia, where they appear to receive the projection from the anteroventral thalamic nucleus. In the present study, we tested the hypothesis that these dendritic bundles become disorganized in aging rats. At 3, 6 and 14 months of age, male Sprague Dawley rats received a large, unilateral injection of the retrograde tracer, Fluorogold, in Rg. In the 3 month old rats, nearly all densely labeled, layer II neurons in Rg contralateral to the injection have apical dendrites that are confined to the layer I dendritic bundles. This pattern is relatively undisturbed in the 6 month old rat. In contrast, in 14 month old rats, the dendritic bundles are somewhat disorganized. In these rats (compared to the younger rats), a similar number of layer II neurons are labeled, but fewer of them have dendrites in the bundles. In some locations, the apical dendrites do not collateralize in layer Ia, while in other locations an apical dendrites appear to be broken off in layer Ic, and short collaterals arise from the remaining shaft. These characteristics are not observed in younger rats. In the 14 month old rats, labeled apical dendrites arising from layer II-VI of Rg display no obvious signs of age-related changes. Preliminary data suggest that this disorganization progressively worsens in rats that are older than 14 months. These data suggest that compared to other neurons, the layer II neurons in Rg are more vulnerable to the deleterious effects of aging, an effect that could impair learning in aging individuals.

IMMATURE-LOOKING DENDRITES IN MATURE HIPPOCAMPAL CA1. I. Esch, * M. S. Heydenreich, * W. B. Levy and N. L. Desmond. Dept. Neurosurgery, Univ. Virginia Hlth. Sci. Ctr., Charlottesville, VA 22908.

Using rapid Golgi-impregnated material from a developmental series of rat hippocampi, we find that some pyramidal cell dendrites in adult CA1 s. moleculare (s. mol.) have morphological characteristics similar to immature dendrites. At 7 dpn, s. mol. dendrites consist of asymmetric varicose segments interconnected by filiform segments. Thin, zigzagging processes longer than dendritic spines at this age, and sometimes possessing small varicosities, may extend from these dendrites. Few dendritic spines are seen at 7 dpn. With maturation, the varicose segments become smaller and more symmetric, and the intervaricose, filiform segments become shorter and less frequent. Dendritic spines increase in number. In adult (45-60 dpn) CA1 s. mol., dendrites have a fairly uniform diameter. Dendritic varicosities do exist, but their appearance is suggestive of sessile dendritic spines extending from the parent dendrite. Overall, dendritic spines are more numerous and more uniformly dispersed across the dendritic length in the adult. 'Immature'-looking dendrites sometimes appear in the mature CA1 s. mol., generally in the most distal s. mol. Like the dendrites from immature animals, the 'immature' adult dendrites have both asymmetric varicose segments and filiform segments. An 'immature' adult dendrite can either be a terminal branch or can bifurcate into 2 additional 'immature' terminal branches. The young appearance of these adult CA1 s. mol. dendrites suggests on-going dendritic growth and synaptogenesis in the adult hippocampus.

CHARACTERIZATION OF "DARK" CELLS INDUCED BY NORADRENERGIC DEPLETION IN THE RAT HIPPOCAMPUS. Y.-P. Lee and H.-M. Hwang. Dept. Anatomy, Chang Gung Medical College, Taoyuan, Taiwan, R.O.C. Noradrenergic depletion, caused by neonatal administration of 6-hydroxydopamine (6-OHDA), 10 mg/kg dissolved in 0.9% saline containing 0.04% L-ascorbic acid for 4 days, was found to produce an increase of beta-adrenergic receptor activity in the hippocampus and an occurrence of "dark" cells in the dentate gyrus and CA4 area. In order to examine the ultrastructure of "dark" cells and to search possible correlation to the increase of beta-adrenergic receptors, electron microscopy was performed on hippocampi treated by 6-OHDA or DSP-4. The "darkness" appeared to be due to fine and fuzzy particles distributed over the whole neuron, including nucleus, somata, axon, and dendrite. They revealed the features as neurons in an active metabolism. In comparison with usual neurons with "light" appearance, their soma seemed to contain more mitochondria, rough endoplasmic reticulum, and ribosomes. Their nuclei appeared to be vesicular with invagination. Study on possible correlation of "dark" cells with receptor activity is in progress. (supported by NSC80-0412-B182-28)

AN ANATOMICAL MARKER FOR ENDOGENOUS LTP IN THE DENTATE GYRUS EXTENDS TO HIPPOCAMPAL CA1. N. L. Desmond. Dept. of Neurosurgery, Univ. of Virginia Hlth Sci Ctr, Charlottesville, VA 22908.

Previously¹ we hypothesized that concave spine synapses, with their set of defining features, were a structural marker for endogenous LTP in the hippocampal dentate gyrus (DG). Here the ultrastructural features of concave and nonconcave spine synapses in normal, adult rat CA1 s. radiatum (s. rad.) and s. moleculare (s. mol.) were compared with existing DG data to assess whether the hypothesized marker extends beyond the dentate gyrus. Concave spine synapses, on average, differ from nonconcave spine synapses in both CA1 s. rad. and s. mol. in the same manner as they do in the DG. Concave spine synapses have larger spine heads (0.199 μm^2 ; 0.273 μm^2 area) than do nonconcave spine synapses (0.097 μm^2 ; 0.172 μm^2) in CA1 s. rad. and CA1 s. mol., respectively. Concave spine synapses have larger PSDs than do nonconcave spine synapses in both CA1 s. rad. and CA1 s. mol. As in the DG, the probability of a polyribosome associated with a dendritic spine is less for a concave spine synapse (0.034; 0.086) than for a nonconcave spine synapse (0.055; 0.146) in both s. rad. and s. mol., respectively. In all three regions, the same relative characterization exists for concave and nonconcave spine synapses. Thus, by virtue of the structural similarity with synapses of the DG, it is conceivable that these structural distinctions in the two CA1 regions reflect the existence of a normal, ongoing DG-like LTP there.

DEGENERATION OF THE HIPPOCAMPAL PYRAMIDAL NEURONS IN THE SOCIALLY STRESSED TREE SHREW. H. Uno, G. Flüge, C. Thieme*, O. Jöhren*, and E. Fuchs. Wisconsin Regional Primate Research Ctr., Madison, WI 53715, and German Primate Center, Göttingen, Germany.

The tree shrew (*Tupaia belangeri*) has provided a useful model for studying the consequences of psycho-social stress. Male cagemates often behave in a hostile, territorial-defending manner and develop a dominant/subordinate relationship. The subordinate animal, harassed and attacked by the dominant, loses body weight and catecholamine and glucocorticoid urinary levels increase. The behavior and physiological parameters in nine pairs of male tree shrews were studied. After the establishment of hierarchical order all the animals were euthanized at 1, 2, and 4-week periods. The hippocampuses cut from perfusion-fixed brains were studied in both light and electron microscopy. Degeneration of the pyramidal neurons in CA3 and CA1 regions was observed in 6 subordinates kept under the stress conditions for 2 to 4 weeks. Ultrastructurally, the degenerated neurons showed highly condensed axoplasmic organelle and nuclear chromatin, and vacuolization and shrinkage of perikarya, nucleus, and dendritic branches. This model provides a study of the correlation between the degree of stress and brain damage. (Supported by NIH Grant RR00167.)

LEARNING AND MEMORY—ANATOMY I

53.1

DISSOCIABLE ROLES OF HIPPOCAMPUS AND ORBITOFONTAL CORTEX IN AN ODOR-GUIDED DELAYED NON-MATCH TO SAMPLE TASK. T. Otto & H. Eichenbaum. Dept. of Psychology, University of North Carolina, Chapel Hill, NC 27514.

Converging evidence indicates that rats' excellent abilities for odor-guided learning can be exploited for the development of rodent models of primate memory capacities. The present study focused on development of an odor-guided analog of the visually-guided delayed non-match to sample (DNM) task commonly used in studies of the neural substrates of memory formation in humans and monkeys.

Successful performance in our continuous DNM task (cDNM) requires the rat to remember the odor presented on the immediately preceding trial, and to respond for water reinforcement only if the odor presented on the current trial is a *non-match*. In normal rats performance in this task is sensitive to increased delay or interference.

The acquisition of cDNM and subsequent performance across increasing delay and levels of interference in separate groups of rats with lesions of the fornix (FX, n=6), of the orbitofrontal cortex (OFX, n=4), or of the entorhinal cortex (ECX, n=7) was compared to that of controls. FX rats performed as well as normal rats on all aspects of cDNM. In contrast, OFX rats were severely impaired in cDNM acquisition, but subsequent performance across even long delays or increased interference was unaffected. Conversely, ECX rats acquired cDNM normally, but their memory decay was abnormally rapid and sensitive to interference. Thus it appears that, like primates, rats with FX lesions are unimpaired on cDNM. Moreover, the frontal and temporal cortical targets of olfactory projections play critical and complementary roles in cDNM. The orbitofrontal cortex is required for odor discrimination or acquisition of the cDNM rule, while entorhinal projections to the hippocampus are critical to maintaining a memory representation across a delay.

53.2

TRANSVERSE, BUT NOT LONGITUDINAL HIPPOCAMPAL CONNECTIONS ARE NECESSARY FOR SPATIAL LEARNING. E. I. Moser*, M. B. Moser* & P. Andersen. Institute of Neurophysiology, Univ. of Oslo, Box 1104 Blindern, 0317 OSLO 3, Norway.

We investigated whether spatial learning in the rat requires integration of impulses from different septo-temporal levels of the dorsal hippocampus. Longitudinal connections were severed by exposing the dorsal hippocampus and placing transverse cuts through the dorsal hippocampus at 1 or 3 septo-temporal levels. The knife penetrated either the CA3 or the CA1 and the underlying dentate gyrus. In a separate group of rats, longitudinal lesions were made by aspiration of a 5mm long, 1 mm wide strip within the CA1 and the dentate gyrus of the dorsal hippocampus. Following the lesions, place learning was tested in a Morris water-maze.

Longitudinally oriented CA1 lesions gave the expected increase in escape latency and abolished spatially biased swimming. Rats with one, or three separate, transverse sections of the CA3 or the CA1/dentate gyrus all had escape latencies similar to the neocortical control rats. However, on removal of the platform, rats with transverse cuts spent somewhat less time in the central one-third of the target quadrant, suggesting less precise spatial navigation.

In conclusion, spatial learning seems to depend primarily on transmission of impulses in the lamellar direction. Longitudinal integration of impulses may improve the precision of spatial performance.

53.3

A TEST BATTERY FOR ASSESSING NONSPATIAL MEMORY IN BRAIN-DAMAGED RATS. D.G. Mumby, J.P.J. Pinel, & D.S. Anzarut*, Dept. of Psychology, University of British Columbia, Vancouver, B.C., Canada V6T 1Y7.

Studies of brain-damage-produced amnesia in monkeys often employ a battery of nonspatial memory tasks to assess the mnemonic abilities of individual subjects. We tested normal rats on a battery of tasks that were designed to mimic some of those used with monkeys: (1) Object discrimination and reversal, (2) concurrent object discriminations, (3) delayed nonmatching-to-sample with various retention delays (4, 15, 60, & 120 s) and list lengths (1, 3, 5, & 7 items), and (4) temporal-order recognition. Each task made use of the same apparatus and, like the monkey versions of these tasks, each one used similar test stimuli (objects). The rats acquired each of these tasks and their performance on each paralleled that of monkeys (e.g., scores on delayed nonmatching-to-sample decreased as either the delay or list length increased). In previous experiments, rats with brain lesions similar to those that cause anterograde amnesia in monkeys (e.g., mediodorsal thalamus, hippocampus plus rhinal cortex) were impaired on concurrent object discriminations and delayed nonmatching-to-sample. The resemblance that these tasks bear to those used in studies of brain-damage-produced amnesia in monkeys suggests that this test battery might be useful in similar models of amnesia in rats.

53.5

CONTEXTUAL RETRIEVAL OF ASSOCIATIVE INFORMATION IS IMPAIRED IN RATS WITH IBOTENIC ACID LESIONS OF THE HIPPOCAMPUS. M.A. Good and R.C. Honey. (SPON: Brain Research Association) Dept. Pharmacology, University of Edinburgh, Scotland, EH8 9JZ, and Dept. Psychology, University of York, England, YO1 5DD.

Using a Pavlovian contextual switching paradigm, Good and Honey (*Behav. Neurosci.*, in press) recently showed that rats with electrolytic lesions of the hippocampus (HPC) are impaired in the use of contextual cues to retrieve associative information (see Hirsh, 1974, *Behav. Biol.*, 12, 421-444). The aim of the present study was to determine whether rats with ibotenic acid lesions of the HPC are impaired in contextual retrieval using the same switching procedure. In this task subjects receive reinforced presentations of stimulus X (train of clicks) in context A and of stimulus Y (offset of a light) in context B and nonreinforced presentations of both X in context B and Y in context A. The contexts (Skinner boxes) were discriminated by odour and visual cues. Initial results indicate that ibotenic lesioned animals are impaired in the acquisition of contextual switching ($F=10.29$, df 1/14, $p<0.01$), but showed no impairment in the acquisition of a Pavlovian contextual discrimination in which food is delivered in context A but not in context B. These findings imply that damage to hippocampal cell fields are responsible for the impairment in contextual retrieval, but it is not yet possible to determine whether the magnitude of the deficit following ibotenic acid lesions is comparable to that observed following electrolytic lesions of the HPC.

53.7

THE ROLE OF THE HIPPOCAMPUS IN OLFACTORY DISCRIMINATION LEARNING IN RATS. I.C. Reid, D.M. Bannerman and R.G.M. Morris. SPON: B.R.A. Dept. of Pharmacology, 1 George Square, University of Edinburgh EH8 9JZ, Scotland.

We have previously reported that although olfactory discrimination learning in rats is both very rapid and shows progressive improvement across serial novel problems, these characteristics of olfactory learning do not, as has been claimed, represent true 'learning set' acquisition (Reid and Morris, 1989, *Soc. Neurosci. Abstr.* 15). Rodent olfactory discrimination learning may, nevertheless, be a useful 'model system' for investigating specific issues in the neurobiology of learning and memory. As studies of the effects of indirect interference to the hippocampal formation (e.g. fornix, entorhinal and lateral olfactory tract lesions) have produced conflicting results, we examined the effects of selective hippocampal lesions.

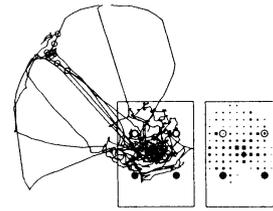

Rats ($n=20$) were trained on a simultaneous 2-odour discrimination problem and, after matching for initial discrimination score, half the subjects were given bilateral ibotenate hippocampal lesions (Jarrard, 1989, *J. Neurosci. Meth.*). They and sham lesioned rats were then trained on a further 5 different 2-odour problems, followed by a reversal of the final problem. In conflict with findings using fornix lesions (Eichenbaum et al, 1988, *Behav. Neurosci.*), no significant impairment was found on any of the 5 postoperative problems ($F<1$). The reversal training revealed no evidence of forgetting over 24 hours, nor any enhancement in reversal learning. The same hippocampal lesioned rats were, however, impaired in acquisition of a watermaze spatial reference memory task and in searching the correct quadrant during a transfer test after training ($F=5.4$, df 2/36, $p<0.005$).

These findings call into question the notion that the integrity of the hippocampus is required for simple olfactory discrimination learning.

53.4

THE MANHATTAN MAZE: A NEW TECHNIQUE FOR ANALYSING SPATIAL LEARNING. R.G.M. Morris, R. Biegler and R. Spooner. SPON: B.R.A. Dept. of Pharmacology, Univ. of Edinburgh, Edinburgh, EH8 9JZ, Scotland.

Research on the neurobiology of spatial learning and memory would benefit from better understanding of the strictly psychological processes involved, notably, by analogy with studies of associative conditioning, of the content and conditions of learning. Following the work of Collett et al (*J. Comp. Physiol.*, 1986), we have

developed a technique in which rats are trained to find food reward within a large arena (3.6 m diameter) containing wood-shavings (4 cm depth). Landmarks ('skyscrapers') are placed within the arena at various predefined positions which move between trials, with the rewards hidden in the shavings at specific locations near the landmarks. The environment is directionally polarised. The animals' searching movements are tracked automatically using an image-analyser, and a computer is used to plot time spent near the landmarks (Fig left: paths of 7 rats from periphery to vicinity of landmarks; right: cumulative pixel time plot). The results show that rats concentrate their search in specific locations relative to the landmarks, perhaps by computing vectors specifying distance and direction, and we are now investigating whether 'classical' phenomena such as discrimination, overshadowing and blocking occur within the spatial domain. For the latter, rats are trained to find food whose location is defined by two cues, two further cues are then added, and a final test trial is used to examine control of behaviour by the added cues.

53.6

CONCURRENT SPATIAL AND NONSPATIAL DISCRIMINATION LEARNING: DISRUPTION OF LEARNING BY INTERFERENCE AND HIPPOCAMPAL LESIONS. C.A. Stewart, M.A. Good and R.G.M. Morris. (SPON: B.R.A.) Dept. Pharmacology, Univ. Edinburgh, Edinburgh EH8 9JZ, Scotland.

Concurrent discrimination tasks have proved a puzzling part of test batteries for examining the contributions of the medial temporal lobe to memory in primates (Malamut et al, 1984, *Behav. Brain Res.*; Zola-Morgan and Squire, 1985, *Behav. Neurosci.*). The usual procedure involves simultaneous training on a number of problems of the same class (eg discrimination learning) with each problem having distinct stimulus items. However, the concurrent learning of different types of task has rarely been studied in either primates or rats.

Rats were trained in a watermaze on both a 2-platform spatial task and a similar 2-platform visual discrimination. Each task employed a rigid platform providing escape from the water and a floating platform which did not. These platforms were identical in appearance for the former task or visually distinct for the latter. Both tasks could be learned by normal rats ($N=8$) to a criterion of 90% correct when training was conducted on each task alone (10 trials/day). However, when training on the two tasks was combined on the same day (10+10 trials/day), normal rats learned the spatial task but failed to learn the visual discrimination. One possible explanation could be interference with visual learning by spatial information. As rats with aspiration hippocampal (HPC) lesions are impaired in learning this spatial task (Morris et al., 1986, *Q.J.E.P.*), we investigated whether rats with ibotenate HPC lesions ($N=4$) would, when trained concurrently, learn the visual task because they would fail the spatial version. However, the results showed that control rats ($N=4$) again learned the spatial but not the visual task, while HPC-lesioned rats failed to learn either task. These findings imply that either HPC-lesioned rats process spatial information (even though they fail to learn the spatial task), or that other aspects of the training procedure are responsible for the interference between tasks.

53.8

7-CHLOROKYNURENIC ACID, AN NMDA RECEPTOR ASSOCIATED GLYCINE SITE ANTAGONIST, IMPAIRS PLACE NAVIGATION PERFORMANCE. D.M. Bannerman, S.P. Butcher and R.G.M. Morris. (SPON: B.R.A.) Dept. of Pharmacology, Univ. of Edinburgh, Edinburgh, EH8 9JZ, Scotland.

Blockade of NMDA receptors by the competitive antagonist D-AP5 impairs spatial learning across a comparable dose range to inhibition of hippocampal LTP *in vivo* suggesting that LTP-like events in hippocampus may be part of the neural mechanisms of spatial learning (Davis et al, 1991, *submitted*). Antagonism of the NMDA-associated glycine receptors provides a different method of investigating this issue. 7-Chlorokynurenate (7CK), which limits the induction of hippocampal LTP *in vitro* (Bashir, Tam and Collingridge, 1990 *Neurosci. Letts* 108, 261-266), was chronically infused via osmotic minipumps into the right lateral ventricle. Performance of drug treated animals in a transfer test after spatial reference memory training in a watermaze was impaired relative to CSF infused and unoperated controls ($F=11.63$, $p<0.005$). However, when LTP was subsequently examined *in vivo* under urethane anaesthesia (1.5 giv/kg) in the left hippocampus, a proportion of drug treated animals showing behavioural deficits failed to exhibit any blockade of LTP. Tissue levels of 7CK from various brain regions were assayed using a novel analytical technique involving reverse phase HPLC followed by fluorescence detection enhanced by post-column application of zinc acetate. Preliminary measurements indicate that 7CK levels were substantially lower in the left hippocampus (28.9 pmoles/mg wet weight) than in the right hippocampus (50.1) and lower still in other brain regions (mean for visual cortex, frontal cortex and anterior striatum = 3.9), suggesting that 7CK may be rapidly removed from the brain and only found in high concentrations adjacent to the infusion cannula. The uneven cerebral distribution of 7CK may explain our failure to block LTP in the left hippocampus in animals which, nevertheless, show a behavioural deficit. Further investigations are underway.

53.9

EFFECTS OF ENTORHINAL LESIONS ON TESTS OF SPATIAL AND NONSPATIAL MEMORY IN THE RAT. L.A. Rothblat, A.M. Brown*, T.C. Gleason*, A.D. Davis*, N. Vnek*, and L.F. Kroner, Dept. of Psychology, The George Washington University, Washington, D.C., 20052 and Dept. of Anatomy and Cell Biology, Georgetown University School of Medicine, Washington, D.C., 20007.

Entorhinal cortex is a key relay station between the neocortex and the hippocampus, and as such is thought to play a critical role in mnemonic functions. To further explore the role of the entorhinal region, we tested rats with aspiration or excitotoxic (NMDA) lesions on tests of spatial (discrete trial rewarded alternation) and nonspatial (concurrent object discrimination) memory. The concurrent task has previously been used to assess mnemonic disturbances in monkeys with hippocampal system damage and amnesic patients, including those with Alzheimer's Disease.

Both entorhinal groups were impaired on the concurrent task. Rats with aspiration lesions were also impaired on the spatial task, whereas rats with NMDA lesions did not differ from controls.

The results indicate that concurrent object discrimination may be a particularly sensitive assay of entorhinal/hippocampal dysfunction, and that these circuits in the rat may serve mnemonic functions which are qualitatively similar to those of human and nonhuman primates. Supported by ONR N00014-88-K-0227.

53.11

CONTINUOUS RECOGNITION OF 3-DIMENSIONAL OBJECTS IN RATS WITH HIPPOCAMPAL AND MEDIAL PREFRONTAL CORTEX LESIONS. P. Jackson-Smith, R.P. Kesner, and A.A. Chiba, Dept. of Psychology, Univ. of Utah, Salt Lake City, UT 84112.

The purpose of the present experiment was to compare performance on a spatial continuous recognition task (Jackson-Smith & Kesner, 1990) with performance on an analogous nonspatial task with the same processing demands, in hippocampal and medial prefrontal cortex lesioned rats. Each session involved sequential presentation of eight new objects, and four repeated objects (chosen from the eight). The objects consisted of 3-dimensional 'toys' in various shapes, sizes, textures and brightnesses. Repeated objects had lags ranging from 0 to 4 (from 0 to 4 different object presentations between the first and the repeated presentation). An object was presented on one side of a long table divided in half by an opaque Plexiglas guillotine door, and latency to move the object upon opening the door was measured. The first presentation of the object resulted in food reinforcement; however, no food was available upon the second presentation of the same object. For each block of 15 sessions the objects were randomly presented, and 8 new objects were chosen for each session without repetition (120 distinct objects). Rats were assigned to groups and received surgery upon completion of 3 blocks of 15 sessions. The latencies at each lag prior to surgery were shorter for object continuous recognition as compared to the analogous spatial task, however, all of the rats showed a decreasing function with long latencies for the shorter lags and decreasing latencies with increasing lag. There were no deficits following sham lesions, and, in contrast to the spatial continuous recognition task, there were mild deficits following lesions to the hippocampus and no deficits following lesions to the medial prefrontal cortex. In conclusion, hippocampus has a disproportionately greater involvement in recognition of spatial locations versus recognition of 3-dimensional objects.

53.13

HIPPOCAMPAL LESIONS DO NOT DISRUPT ACQUISITION OF LEARNING IN AN OCCASION SETTING PARADIGM. D.M. Skinner, G.M. Martin*, C. Harley, B. Kolbt, A. Pridgar*, A. Bechara and D. van der Kooy, Dept. of Anatomy, University of Toronto, Toronto, M5S 1A8, †Dept. of Psychology, Memorial University, St. John's, A1B 3X9, ‡Dept. of Psychology, University of Lethbridge, Lethbridge, T1K 3M4.

Hippocampal lesions do not disrupt simple Pavlovian conditioning, but performance on more complex conditional and configural tasks is impaired. We examined whether removal of the hippocampus would impair performance on a discrimination learning task that employed conditioned taste aversions. On some days rats were injected s.c. with a drug (either 15 mg/kg sodium pentobarbital or 5 mg/kg morphine sulfate) 15 min prior to 15 min access to a flavored solution. Removal of the solution was followed by an i.p. injection of LiCl. On alternate days injections of physiological saline preceded and followed access to the same flavored solution. Animals rapidly acquire the discrimination, consuming significantly more of the flavored solution after saline injections than after drug injections. Animals with aspiration or ibotenic acid lesions of the adult hippocampus or neonatal aspiration lesions of the cortex (a major source of afferents to the hippocampus) learned the task as well as controls. However, these lesions did disrupt spatial learning in the Morris water maze in the same animals. Animals with hippocampal lesions also learned, as well as controls, a discrimination task in which visual and textual cues, rather than drug states, predicted whether access to a flavored solution would be followed by an injection of LiCl or saline. We have shown previously that animals do not learn the discrimination tasks on the basis of simple Pavlovian associations (*J. Exp. Psych.- Anim. Beh. Proc.* 16: 56-68, 1990), suggesting that these may be configural tasks. The present data clearly demonstrate that the hippocampus is not necessary for the acquisition of such discrimination learning. The hippocampus may mediate only a subset of learning classed as configural. The robust (and non-cortically mediated) nature of taste-sickness associations may permit configural learning involving these associations that is independent of the hippocampus.

53.10

DIFFERENTIAL EFFECTS OF ENTORHINAL CORTEX AND HIPPOCAMPAL LESIONS ON PERFORMANCE OF A SPATIAL LOCATION RECOGNITION TASK. D.L. Johnson and R.P. Kesner, Dept. of Psychology, Univ. of Utah, Salt Lake City, Utah 84112.

Rats were trained on an 8-arm radial maze on a spatial location recognition task. In this task, on each trial animals were allowed to visit 5 arms in a sequence predetermined by the experimenter. This was followed by a test phase in which the animals were required to choose between an arm visited and an unvisited arm. Tests were balanced across all 5 serial positions. A win-stay rule was required to receive additional reinforcement.

After the animals displayed better than chance performance for all serial positions, they received electrolytic lesions of either the entorhinal cortex (ENTO) or the hippocampal formation (HIPPO).

Following small (medial and lateral) ENTO lesions, performance for all serial positions except the first was at chance levels. Conversely, the small HIPPO lesions resulted in chance performance at all serial positions except the last. These results imply that the ENTO mediates the primacy component of the serial position curve, whereas the HIPPO mediates the recency component. Large lesions of the ENTO and the HIPPO resulted in chance performance at all serial positions. Based on the small lesion data, there appears to be a clear dissociation between the entorhinal cortex and the hippocampus, suggesting that even though the two structures are closely interrelated, each may play a unique role in a spatial location recognition task.

53.12

A DOUBLE DISSOCIATION BETWEEN IMPLICIT AND EXPLICIT SPATIAL MEMORY FOLLOWING HIPPOCAMPAL AND PARIETAL CORTEX LESIONS. A.A. Chiba, P. Jackson-Smith and R.P. Kesner, Department of Psychology, University of Utah, Salt Lake City, UT 84112.

Rats were trained on a 12-arm radial maze using a continuous recognition procedure. Animals were allowed to visit a sequence of 12 arms per day in an order predetermined for that trial. Of the 12 arms visited, either 3 or 4 of the arms were repeated within the running sequence. The arms selected for repetition varied according to lag (0-6), or the number of arms which occurred between the first visit to an arm and its repetition. In order to gain access to each arm, the animal was required to orient to a cue on the Plexiglas door at the entrance of the arm. Once the animal oriented to the cue, the door was lowered and the latency for the animal to reach the end of the arm was measured. Two groups of animals were trained, one on an implicit training procedure and one on an explicit training procedure. The implicit group received reinforcement at the end of each arm regardless of whether the arm was a novel arm or a repeated arm. This group showed decreased latencies when visiting repeated arms. The explicit group received reinforcement only when visiting an arm for the first time in a given sequence. This group showed increased latencies for repeated arms. Following total hippocampal ablation, the performance of the animals in the implicit condition did not differ significantly from preoperative performance, whereas animals in the explicit condition showed a deficit i.e., a significant decrease in latency to return to an arm. Following parietal lesions, animals in the implicit condition showed a deficit i.e., an increase in latency to return to an arm, whereas the performance of animals in the explicit condition did not differ significantly from preoperative performance. Sham operated control animals and cortical control animals did not differ significantly from preoperative performance in either reinforcement condition. Thus, a double dissociation appears to exist between parietal cortex and hippocampus for implicit versus explicit memory for spatial location.

HIPPOCAMPAL LESIONS IMPAIR ACQUISITION OF THE TRANSVERSE PATTERNING PROBLEM BUT NOT OF SIMPLE DISCRIMINATIONS. M.C. Alvarado and J.W. Rudy, Psych. Dept., University of Colorado, Boulder, CO 80309

Sutherland and Rudy (*Psychobio.*, 17, 1989) have proposed that the hippocampal formation (HF) contributes to learning and memory by providing the neural basis for the acquisition of configural associations. Such associations are necessary when the conditional relations among groups of stimuli are more predictive of reward than the individual elements. To test this theory, we have developed a task that demands a configural solution and have tested the effects of HF lesions on performance of that task. We have reported that animals with lesions of the HF are impaired on retention of the Transverse Patterning (TP) problem (Alvarado & Rudy, *Soc. Neurosci. Abst.*, 1989). Briefly, this problem requires animals to solve three simultaneous visual discriminations as follows: A+ vs B-; B+ vs C-; C+ vs A-. Animals trained to solve this problem were impaired on reacquisition when subjected to post-training lesions of the HF. The present study examined the effects of HF lesions on acquisition of the TP problem and of three simultaneous non-configural discriminations (A+ vs B-; C+ vs D-; E+ vs F-). Twenty male Long-Evans rats received combined colchicine/kainic acid lesions of the HF or sham-lesions. After recovery, animals were trained to solve either the (TP) problem or three simultaneous simple discriminations. HF lesioned animals were unable to solve the TP problem, although they could learn any two of the TP discriminations concurrently. HF lesions did not affect learning of simple discriminations. These results are consistent with the hypothesis that the HF is necessary for acquisition of configural but not simple discriminations. HIPPOCAMPAL LESIONS DO NOT IMPAIR INSTRUMENTAL CONDITIONING WITH DELAYED REINFORCEMENT. R.L. Port, K.S. Curtis*, C. Inoue*, J. Briggs* and K.S. Seybold. Departments of Psychology, Slippery Rock University, Slippery Rock, PA 16057 and Grove City College, Grove City, PA 16127

Damage to the hippocampus has been reported to abolish or marginally affect classical trace conditioning. Recent data suggests that the level of impairment may be related to the difficulty inherent to the specific task. Hippocampectomized animals show no impairment in instrumental conditioning when reinforced immediately after the response is given. The present experiment evaluated the ability of lesioned animals to associate a response with reinforcement given after a 5 sec delay.

Adult male rats were randomly assigned to nonoperated control, cortical or hippocampal lesioned groups. Aspiration lesions were accomplished while the animals were anesthetized. After a two week recovery period, animals underwent daily 20 min sessions of instrumental bar press conditioning using a 5 sec delay procedure. Results showed that all groups acquired the response at equivalent rates.

53.17

QUINOLINIC ACID LESIONS OF THE DORSAL HIPPOCAMPUS IMPAIR ACQUISITION, BUT NOT WORKING MEMORY IN RATS. G.R. Dawson*, P. Bayley*, A.C. Foster & S.D. Iversen. Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow. UK. CM20 2QR.

Lesions of cholinergic innervation to the hippocampus by neurotoxin- infusion into the medial septal area or by transections of the fimbria-fornix, induce working memory deficits in rats. We trained rats on a partially-reinforced-discrete-trial Fixed Interval 30s (prd FI30s) schedule prior to bilateral infusions of quinolinic acid into the dorsal hippocampus to destroy intrinsic neurons. Successful performance on the prd FI schedule requires intact reference memory and working memory. Post-lesion and pre-lesion performance on the prd FI 30s was comparable indicating that reference and working memory were intact and functioning normally. However, when the animals were transferred to a prd FI 8s schedule sham lesioned rats readily transferred to the new schedule requirements while lesioned rats transferred only after extensive training. It appears that a dorsal hippocampal lesion with quinolinic acid impairs the transfer of information to reference memory which is necessary for learning, but is without effect on working memory or retrieval from reference memory.

EFFECTS OF UNILATERAL ENTORHINAL CORTEX LESION AND GM1 GANGLIOSIDE TREATMENT ON WATER MAZE PERFORMANCE. M. Glasier*, X. Chen*, R. Sutton and D. Stein. Brain Research Laboratory, I.A.B., Rutgers University, Newark, NJ 07102.

Adult male rats with sham (S) or electrolytic lesion (L) of the left entorhinal cortex received GM1 (30 mg/kg, i.p.) or saline (SAL) injections for 14 days after surgery. From day 7 to 16 rats were given 2 daily trials (T), spaced 1 hr apart, in a water maze task where the escape platform position changed daily (clockwise rotation over 4 quadrants). Daily starting positions remained constant with respect to platform, with T2 beginning on the pool side opposite T1. S+GM1 and S+SAL groups did not differ on any of the dependent measures (swim distance on T2, perseverations, T1 - T2 latency). ANOVAs revealed that L+SAL rats were significantly ($p < .05$) impaired (vs shams) on all measures whereas L+GM1 animals did not differ significantly from shams or L+SAL. However, L+GM1 were better than L+SAL rats in all measures on 9 of 10 test days ($p < .01$; binomial and chi-square analyses). Location and size of L did not differ between groups.

MK-801 FAILS TO ALTER INSTRUMENTAL CONDITIONING IN RATS. K.S. Seybold, R.D. Miller* and R.L. Port. Departments of Psychology, Grove City College, Grove City, PA 16127 and Slippery Rock University, Slippery Rock, PA 16057.

Long-term potentiation is a form of synaptic plasticity that appears to be mediated by NMDA-receptors and is a primary candidate for a neurobiological mechanism underlying associative learning. MK-801, a potent and selective non-competitive NMDA receptor antagonist, has been shown to impair various forms of associative learning (classical conditioning, spatial cognition and passive avoidance). The present experiment evaluated the effects of MK-801 on instrumental conditioning of adult, male hooded rats. Animals were given daily, i.p. injections of either isotonic saline (CONT), .025 mg/kg MK-801 (LOW DOSAGE) or .05 mg/kg MK-801 (HIGH DOSAGE). Training consisted of daily 30 min sessions in which a bar-press response was autoshaped. Animals were trained to criteria and subsequently placed on extinction training. Results showed that MK-801 had no effect on acquisition or extinction rates. Consequently, this form of learning does not appear to be dependent on NMDA receptors.

53.18

LATENT LEARNING AFTER RETROHIPPOCAMPAL CORTEX LESIONS IN RATS. H. Sundberg* and A. Bøkenes*. Inst. of Biological and Medical Psychology, University of Bergen, NORWAY. (SPON: European Brain and Behavior Society)

O'Keefe and Nadel (1978)¹ suggest that hippocampus might function as a neural substrate for a tolmalian cognitive map. Thus, destruction of the hippocampal area would abolish the latent learning effect in a maze.

By large lesions in the retrohippocampal area hippocampus was deprived of its main cortical input in 2 groups of rats. After operation one (N=8) explored a Lashley III maze for 10 min during 4 days, while the other (N=7) explored an open field. Two non-lesioned control rats were treated identically. Immediately after the last pre-exposure the rats were water deprived. After 24 hours of deprivation the rats were tested on 4 consecutive sessions with 5 reinforced trials in the maze. Numbers of errors were scored.

The opportunity to explore the maze significantly reduced the number of errors during training in both the lesioned and non-lesioned rats as compared to their non-exposed controls.

We therefore conclude that rats with hippocampus deprived by its main cortical input can establish 'maps' of its environment.

RETROGRADE AMNESIA OF LONG-TERM FEAR MEMORY FOLLOWING HIPPOCAMPAL LESIONS IN THE RAT. J.J. Kim and M.S. Fanselow.

Department of Psychology, UCLA, Los Angeles, CA 90024-1563.

The hippocampus seems to serve a temporary memory storage function because when damaged, recent but not remote memories are selectively impaired. This retrograde amnesia has been demonstrated in monkeys in a positively reinforced two-choice object discrimination task (Zola-Morgan & Squire, 1990). In the present study, we examined whether retrograde amnesia can be demonstrated in rats by using fear conditioning as assessed by the freezing response. Animals were placed in a novel context where they received 15 tone-footshock pairings (tone: 2000 Hz, 90 dB, 30-s; footshock: 1 mA, 2-s). A 3-min fixed ITI was used to ensure reliable conditioning to both tone and context. After training, electrolytic lesions were made in the hippocampus either 1, 7, 14 or 28 days after training. Contextual fear was completely abolished in the rats which received lesions 1 day after training. However, significant contextual fear was shown when lesions were made 7 days after training. The fear response to the tone was not affected by the lesions at any time. Thus, retrograde amnesia, selective to contextual fear, can be demonstrated in hippocampal lesioned rats.

54.1

THE RESPECTIVE ROLES OF THE HIPPOCAMPUS, AMYGDALA AND CAUDATE NUCLEUS IN LEARNING AND MEMORY: A TRIPLE DISSOCIATION. R.J. McDonald and N.M. White, Department of Psychology, McGill University, 1205 Dr. Penfield Ave, Montreal, Quebec, Canada H3A 1B1.

A standard set of experimental conditions for studying the roles of the hippocampal formation, the amygdala and the caudate nucleus in learning and memory was used employing the 8-arm radial maze: (1) a win-shift version that is sensitive to damage to the hippocampal system (Olton, Walker & Gage, 1977). (2) a win-stay version that is sensitive to damage to the cortico-striatal system (Packard, Hirsh & White, 1989). (3) a conditioned cue preference (CCP) version that is sensitive to damage to the amygdalo-ventral striatal system (Hiroi, McDonald & White, 1990). The three tasks used visual cues to guide behaviour and food as the reinforcer. Electrolytic lesions of the fimbria impaired performance on the win-shift task but not the win-stay or CCP tasks. Neurotoxic (NMDA) lesions of the hippocampal formation also impaired performance on the win-shift task. Electrolytic lesions of the lateral amygdala impaired performance on the CCP task but not the win-shift or win-stay tasks. Neurotoxic lesions that included the lateral amygdala also impaired performance on the CCP task. Electrolytic lesions of the caudate nucleus impaired performance on the win-stay task but not the win-shift or CCP tasks. The results support the notion that learning and memory in the mammalian nervous system is mediated by anatomically distinct structures that may acquire different kinds of information in parallel about the organism's internal and external environment.

54.3

ACQUISITION OF SPATIALLY CUED LEARNING BEHAVIORS FOLLOWING HIPPOCAMPAL LESIONS IN NEWBORN RATS. K. L. Altemus and C. R. Almlie. Devel. Neuropsychobiol. Lab., Washington University, St. Louis, MO 63110.

Neuropsychological evidence obtained from amnesic patients and behavioral data from studies on hippocampally lesioned adult rodents and primates suggest that the hippocampus mediates some types of learning and memory, including object localization in space.

This spatial learning ability develops as early as postnatal day 18 in rats, and the early emergence of this ability is influenced by previous experience on the task.

The present research evaluated the effects of electrolytic hippocampal lesions sustained on postnatal day 1 on the development of spatial learning abilities of albino rats in the Morris water maze. As suggested by previous reports of neurochemical lesions, the present results indicate that spatial learning abilities are disrupted (delayed or abolished) by neonatal hippocampal damage. (Conducted under NIH Guide for Care and Use of Laboratory Animals)

54.5

DEFICIT IN RESPONSE SUPPRESSION IN THE JUVENILE RAT AFTER NEONATAL HIPPOCAMPAL X-IRRADIATION. J. L. Diaz-Granados, P. L. Greene, N. J. Lobaugh & A. Amsel. Department of Psychology and Institute for Neuroscience, University of Texas, Austin, Texas, 78712

Response suppression (inhibition) has been related to mature and intact hippocampal function (Altman, Brunner, Bayer, 1973; Douglas, 1972). One way to test for response suppression is to use discontinuously negatively correlated reinforcement (DNC), differential reinforcement of slow responding. In our case, the rat is reinforced for traversing a straight runway, but only if it takes 4 s or longer. Weanling-age rats, with still developing hippocampi, do not suppress responding on a DNC schedule as adult rats do (Chen, Gross, Stanton, & Amsel, 1980). Adult rats, treated with a glutaminergic antagonist (into hippocampus), are deficient in response suppression on a DNC task, an operant analog of DNC (Tonkiss, Morris, and Rawlins, 1988). We examined the effects on DNC in juvenile rats of x-irradiation-induced hippocampal insult. Neonatal rats were x-irradiated from postnatal day (P) 2 to P15, resulting in severe agenesis in postnatally arising granule cells of the hippocampal dentate gyrus. Controls were sham-irradiated. Rats were tested at P35-39. X-irradiated subjects received a significantly lower percentage of reward throughout training than the controls. Running speeds were also significantly higher in the x-irradiated animals. This finding suggests that hippocampal damage in infancy, which reduces the capacity to inhibit or suppress behavior may be related to hyperactivity. Supported by NSF grant BNS-8609877 and NIAAA grant AA07052.

54.2

RADIAL-ARM MAZE RESPONSE STRATEGIES IN JUVENILE AND ADULT RATS. J.L. Hall & R.F. Berman. Department of Psychology, Wayne State University, Detroit, MI 48201.

Previous research demonstrates that juvenile rats solve the radial arm maze by selecting adjacent arms, while adult rats use a less restrictive response strategy. The present experiment replicates and extends these findings to include a third group of rats tested both as juveniles and as adults, and compares these response patterns in two strains of rats.

Radial 8-arm maze performance was assessed daily for 10 days in juvenile and adult Long Evans and Sprague-Dawley rats. In both strains of rats, juveniles made significantly more adjacent arm entries than did adults. Additionally, both strains of rats when re-tested as adults, continued to use the adjacent arm entry strategy established during juvenile training, rather than adopting the maze-naive adult strategy.

Together, these results support previous findings demonstrating that juvenile rats use an adjacent arm entry strategy to solve the radial 8-arm maze, while adult rats do not. Additionally, these findings suggest that juvenile maze experience produces a long lasting change in the response patterns used by rats in the radial 8-arm maze. THE EFFECTS OF NEONATAL LIMBIC LESIONS ON LONG-TERM RECOGNITION MEMORY IN THE ADULT Rhesus MONKEY. R.C. Saunders, R.S. Richards*, and J. Bachevalier, Clinical Brain Disorders Branch, NIMH, Washington, D.C., 20032 and Lab. of Neuropsychology, NIMH, Bethesda, MD 20892.

When tested on a paired comparison recognition memory task, normal adult monkeys perform at a high level of proficiency even at delays of several weeks (>80%), whereas monkeys with amygdalo-hippocampal removals remain at chance with delays of only a few min. Equally impaired on the task are infant monkeys with the same limbic lesions. Here, we re-evaluated the performance of adult monkeys with neonatal removals of the amygdala (A), hippocampus (H), or both (AH) in a paired comparison task. Preference for novelty was assessed for delays of 10s, 5-10 min, 24-48 hrs, and 1-2 wks. Although neonatally operated monkeys in all 3 groups performed at chance when they were 1 month old, they all showed substantially better performance on this task when they were retested as adults (6-7 years). Indeed, the animals in Groups A and H performed nearly as well as normal controls at all delays, whereas our preliminary data indicate that those with the combined AH removal, though improved, never reached the level of proficiency of controls, even at the short delays. These data indicate that there exist some level of recovery of visual recognition memory in adult monkeys with neonatal limbic lesions.

54.6

GRANULE CELL LOSS FOLLOWING ADRENALECTOMY HAS NO EFFECT ON THE ACQUISITION, RETENTION AND REVERSAL OF PLACE LEARNING IN THE MORRIS WATER MAZE. J. N. Armstrong, D. C. McIntyre, S. Neubert and R. S. Sloviter. Department of Psychology, Carleton University, Ottawa, Ontario, K1S 5B6; Neurology Research Center, Helen Hayes Hospital, West Haverstraw, New York 10993.

Adrenalectomy of adult male rats results in substantial granule cell loss in the dentate gyrus 3 to 4 months after surgery. We report here that 4 months after surgery, 45 adrenalectomized (ADX) rats, with weight gain 50-200 grams below controls, displayed behaviour in the Morris water maze which was similar to 16 sham-operated control rats and 16 ADX rats maintained on corticosterone throughout the study. The loss of granule cells in the ADX rats varied from minimal to extensive, with the latter characterizing those with lowest weight gain. In spite of extensive granule cell loss, these ADX animals performed similar to controls in acquisition and retention of place learning. They also quickly learned a new location (reversal), resisted manipulation of a subset of extramaze cues and maze rotation (intramaze cues), but like controls, performed poorly when the hidden platform was randomly varied. Thus, under these conditions, a normal compliment of granule cells is not necessary for spatial learning or retention.

54.7

PATTERNS OF NATURAL SPATIAL BEHAVIOR PREDICT HIPPOCAMPAL SIZE IN KANGAROO RATS. L.F. Jacobs and W. Spencer*. Department of Psychology, University of Utah, Salt Lake City, UT 84112.

The size of the hippocampus, a forebrain structure in birds and mammals that mediates spatial learning, correlates with foraging demands on spatial memory in passerine birds and with sex-specific patterns of space use in microtine rodents (Jacobs et al. 1990. *PNAS*, 87, 6349-6352). Here we report that natural space-use patterns predict hippocampal size within and between two species of kangaroo rats (*Dipodomys*). Differences in foraging behavior suggest that Merriam's kangaroo rat (*D. merriami*) experiences greater selective pressure on spatial abilities than bannertail kangaroo rats (*D. spectabilis*); sex-specific differences in mating strategy suggest that males of both species experience greater selection pressure on spatial cognition than females. As predicted, hippocampal size (relative to brain size) is larger in Merriam's than in bannertail kangaroo rats (19%); allometric arguments suggest the difference is closer to 31%. Also as predicted, males have larger hippocampi than females (12% in *D. merriami*, 16% in *D. spectabilis*). This suggests that two types of selection pressures, natural selection for foraging efficiency and sexual selection for the efficient location of mates, operate on hippocampal size. These results also suggest that sex differences in hippocampal size may be the dominant mammalian pattern. Supported by NSF Environmental Sciences Postdoctoral Fellowship BSR-880271 to L.F.J.

54.9

ULTRASTRUCTURAL LOCALIZATION OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVITY IN THE RAT HIPPOCAMPAL FORMATION. T.A. Milner and E. Veznedaroglu. Dept. of Neurology and Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021

The immunocytochemical localization of neuropeptide Y (NPY) was studied quantitatively in each lamina of CA1 & CA3 of the hippocampus and the dentate gyrus of adult rats. Intraperikaryal localization of NPY-like immunoreactivity (NPY-LI) was seen in Golgi complexes & rough endoplasmic reticulum. Neurons with NPY-LI often lacked astrocytic appositions and were contacted mostly on the shafts of large and small dendrites by unlabeled terminals forming asymmetric synapses. The types of associations and distribution of NPY-labeled terminals on targets were similar in each lamina. NPY-labeled terminals were associated (1) with one unlabeled perikaryon or dendrite; (2) with two unlabeled perikarya or dendrites simultaneously; or (3) with one NPY-containing perikaryon or dendrite. Most terminals with NPY-LI formed symmetric synapses or appositions without any glial intervention with small dendritic shafts. The remaining NPY-labeled terminals were closely apposed to unlabeled & NPY-labeled terminals or had no neuronal associations. These results provide cellular substrates for the inhibition (symmetric synapses) and modulation through presynaptic interactions of hippocampal neurons by NPY terminals. Moreover, they support the concept that hippocampal NPY neurons may be vulnerable to damage due to the presence of numerous presynaptic terminals which form excitatory (asymmetric) synapses and the sparsity of astrocytic invagination. Supported by MH42834 & HL18974.

THE ENTORHINAL CORTEX IN HUMANS: A CYTOARCHITECTONIC AND COMPARATIVE STUDY WITH NON-HUMAN PRIMATES. T.M. Hyde and R.C. Saunders. Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032.

The entorhinal cortex has long been considered a relay for cortical sensory information into and out of the hippocampal formation. There is renewed interest in the entorhinal region because recent experimental work with monkeys has demonstrated extensive subcortical projections and the ability of these connections to support some level of cognitive memory function. In addition, recent clinico-neuropathological reports have found neurodegenerative changes in the entorhinal cortex related to Alzheimer's disease and developmental abnormalities associated with schizophrenia. As part of our ongoing work studying the entorhinal cortical region in primates we have examined 7 normal human brains. Nissl, AChE and fiber staining methods were used to identify morphologically the architectonic regions of area 28. For comparison we have emphasized the cytoarchitectonic features previously described in the Rhesus monkey. Like the monkey the different regions of entorhinal cortex are distinguished largely by the appearance of layer II and the lamina dissecans, and can be divided into five main regions. Differences between the monkey and human entorhinal region are addressed.

54.8

ANATOMICAL CONNECTIONS AND ELECTROPHYSIOLOGICAL INTERACTIONS BETWEEN PREFRONTAL AND PARAHIPPOCAMPAL CORTICES IN RABBIT. D.G. Harden*, N.E. Coniglio*, T.W. Berger*, and D.J. Weisz*. Departments of Behavioral Neuroscience* and Neurological Surgery*, University of Pittsburgh, Pittsburgh, PA 15260.

We have begun to investigate the anatomical connections and electrophysiological interactions between the prefrontal cortex and parahippocampal regions. Anatomical studies were conducted using intracranial injection of WGA-HRP, with subsequent reaction of tissue sections using tetramethylbenzidine. In the first experiment, we injected tracer into the mediodorsal nucleus of the thalamus, to establish the boundaries of the prefrontal cortex in rabbit. Both retrograde and anterograde label were present in the prelimbic area, the medial and lateral precentral area, and the anterior cingulate cortex. In the second experiment, we investigated the connectivity between prefrontal cortex and parahippocampal regions by injection into the prefrontal cortex. Retrogradely labeled cells were observed in the CA1 pyramidal layer, the subiculum, and the entorhinal cortex. Terminal fields were observed in the entorhinal cortex.

In electrophysiological experiments, the effects of prefrontal stimulation on dentate granule cell field potentials elicited by perforant path stimulation were examined. The dentate population spike could be facilitated by prior stimulation of the prefrontal cortex. Results of these studies indicate that reciprocal connections exist between prefrontal and parahippocampal cortices in rabbit and that these connections can alter the excitatory influence of entorhinal afferents on intrinsic hippocampal neurons. (Supported by MH45156 and MH00343)

54.10

MORPHOLOGY OF NEURONS IN THE ENTORHINAL CORTEX THAT PROJECT TO NEOCORTEX IN THE RAT AND MONKEY P.E. Good¹, P.R. Hof^{1,2} and J.H. Morrison^{1,2} ¹Fishberg Res. Ctr. for Neurobiology, and ²Dept of Geriatrics, Mt Sinai Med. Ctr. N.Y., N.Y., 10029

The entorhinal cortex (ERC) is the cortical link between neocortical and parahippocampal cortices and the hippocampal formation. Transport studies have demonstrated that polymodal and limbic areas such as the superior temporal gyrus, cingulate and insular cortices project to the ERC. However, few data are available concerning the reciprocating projections in particular, as well as the general organization of the ERC efferents to the neocortex. We have injected the retrograde tracer fast blue (FB) into premotor cortex of the rat and the dorsal bank of the superior temporal sulcus (STS) in the cynomolgus monkey. FB containing neurons within the ERC were subsequently filled with the fluorescent dye lucifer yellow and neuronal morphology analysed by confocal microscopy. The projection from ERC to STS arises from layer V of the caudal-lateral region of the ERC; fields Ei, Elc, and Ec of Amaral et al. (*J. Comp. Neurol.* 1987), along with a few neurons in the medial region. In the monkey, these neurons can be grouped into three morphological types: 1) pyramidal, some with apical dendrites reaching layer I; 2) multipolar with dendrites confined to layer V, and 3) vertical fusiform with a long basal dendrite reaching the white matter. ERC neurons projecting to premotor cortex in the rat displayed a similar pattern of laminar distribution and morphologies with many neurons having their dendrites in a strict laminar confinement and extending 1000-2000 microns in the horizontal axis. Thus, some of these neurons may sample only a restricted set of afferents, likely to be hippocampal in origin while other neurons are in a position to receive afferents synapsing in all lamina of the entorhinal cortex and may monitor either hippocampal and/or neocortical input. Supported by NIH grants AG05138 and AG06647.

54.12

PROJECTION OF THE ENTORHINAL LAYER II NEURONS AS REVEALED BY INTRACELLULAR PRESSURE-INJECTION OF NEUROBIOTIN

N. Tamamaki and Y. Nojyo* Dept. of Anatomy, Fukui Medical School, Matsuoka, Fukui 910-11 Japan

The hippocampus plays a key role in short term memory formation and its information processing is initiated by input conveyed through the perforant path. In this study, the major part of the perforant path, projection of the entorhinal layer II neurons was investigated by neurobiotin pressure intracellular-injection in anesthetized rats. Thus far, three spinous neurons were well labeled including their axonal arbors in the hippocampus. Some collaterals originating from the axon project also to the subiculum. An axon of the single spinous neuron covers the hippocampus more than 2 mm in septo-temporal direction, and the infrapyramidal blade, the suprapyramidal blade, the str. moleculare of field CA3 and CA2 at the same time by making a sheet-like form. The sheet of axon branches was thin in the suprapyramidal blade, the str. moleculare of field CA2 and CA3. However the sheet became not clear in the crest and in the infrapyramidal blade. This study shows that the entorhino-hippocampal circuit is not a simple circle but more complex than ever thought.

THREE DIMENSIONAL MAPPING OF BRAIN LESIONS IN THE PRIMATE BRAIN. H. Damasio, R. Frank*. Dept. of Neurology (Div. of Behavioral Neurology and Cognitive Neuroscience) and the Image Analysis Facility, The University of Iowa, Iowa City, IA 52242.

We have developed a technique for 3-dimensional reconstruction and analysis of brain lesions *in vivo*, based on the manipulation of high resolution magnetic resonance raw data obtained with a particular protocol. The technique permits the direct visual identification of neuroanatomical landmarks such as sulci and gyri in each individual brain specimen and eliminates the need to rely on averaged templates of standard brain sections, the use of which is a source of inevitable lesion localization error. The technique allows for the bi-directional cross reference between marked data points in the 2-dimensional sections and in the volume reconstructions, and for the projection of marked subcortical structures onto the 3-D cortical surface. The technique also allows for volume or surface measurements of individual brain structures or lesions. We will present examples of the application of this technique which include, among others: (1) research with the lesion method in both human and nonhuman primates; (2) planning of neurosurgical approach to abnormal tissue to be excised in humans; (3) anatomical analysis of P.E.T. data; (4) the teaching of neuroanatomy.

54.15

METABOLIC ACTIVATION OF DORSOLATERAL PREFRONTAL AND INFERIOR PARIETAL CORTEX BY COGNITIVE PROCESSING: A 2-DG STUDY IN RHESUS MONKEYS PERFORMING MNEMONIC TASKS.

H.R. Friedman, S. Bhalla and P.S. Goldman-Rakic. Sect. of Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

The dorsolateral prefrontal cortex (PFC) and the inferior parietal lobe (IPL) of the rhesus monkey are related both anatomically and functionally. In the course of our 2-DG studies of the pattern of metabolic activation underlying working memory processing in the rhesus monkey, we examined these cortical regions to elucidate their contribution to cognitive performance in the monkey. For the present analysis, we also examined activity in the lateral posterior (LP)-pulvinar complex of the thalamus-components of which are known to be reciprocally connected with both IPL and, to a lesser extent, with dorsolateral PFC. In these 2-DG experiments, monkeys were trained to perform on either 1 of 3 working memory tasks (Work group) or on 1 of 2 control tasks that do not engage working memory (Cont group). ^{14}C -2DG (100 $\mu\text{Ci}/\text{kg}$) was administered before the final 45 min test session. Local cerebral glucose utilization (LCGU) rates were determined for specific brain regions using a computerized image analysis system and were compared across groups using the analysis of covariance.

The results of this analysis showed that LCGU in the Principal Sulcus region of the dorsolateral PFC and in several regions of IPL (7a,b, 7ip, 7m) was significantly enhanced in the Work group relative to the Cont group. However, LCGU in the LP-pulvinar complex was not enhanced. These findings for the LP-pulvinar complex contrast with our previous report that LCGU in the mediodorsal thalamus (MD) is significantly enhanced in monkeys performing working memory tasks (Friedman et al., *J. Cog. Neurosci.*, 2, 18-31, 1990). As MD is the principal thalamic connection of the dorsolateral PFC and, the dorsolateral PFC and IPL are reciprocally interconnected, the present data, taken together with our previous findings, suggest that working memory processing in the monkey activates a selective complement of brain regions which can be characterized by their association with the prefrontal cortex. ALTERED SERIAL POSITION LEARNING AFTER HUMAN FRONTAL LOBE LESIONS. L.M. Grattan & P.J. Eslinger. Depts. of Neurology, Univ. of Maryland, Baltimore, MD. 21201 & Penn State Univ., Hershey, PA 17033.

The serial position function refers to the more rapid learning of the early (primary effect) and late (recency effect) items of a list relative to middle items. Human and experimental animal studies have demonstrated impaired primacy but not recency following hippocampal lesion and in most amnesias. However, serial position effects after frontal lobe lesion are less well known. Such data may provide insight into the learning difficulties of frontal lesion patients. Furthermore, several processes associated with the frontal lobe, such as learning in the presence of interference and temporal ordering, may be important contributors to normal serial position effects. To test this hypothesis, we studied 40 patients with CT/MR verified frontal and non-frontal lesions with a standardized measure of word list learning. Findings indicated that despite a similar number of free recall responses, the groups differed in serial order effects. A prominent, significant serial position curve was found in the non-frontal lesion group. In contrast, the frontal lesion group demonstrated no significant differences among primacy, middle and recency items. This change in the serial position function suggests that altered learning processes are evident after frontal lobe damage.

HUMAN-LIKE SHORT-TERM MEMORY FOR TEMPORAL ORDER IN NON-HUMAN PRIMATES. E.C. Gower. Boston VAMC and Boston University School of Medicine, Boston, MA 02130.

A normal adult cynomolgus monkey tested in a manually operated testing apparatus (WGTA) mastered an order discrimination problem of the following type: if the presentation of object A is followed by object B, choose A when the two objects are presented simultaneously. The performance rule is isomorphic with the formulation "choose the first object in the list". An expanded version of the two-object problem was then used to evaluate memory for temporal order. The paradigm was modeled on a two-alternative, forced-choice judgment of recency (JOR) protocol used to study serial order memory in human subjects. The discriminanda were familiar objects randomly drawn from a pool of 200. On any trial, 5 objects were presented successively at 10 s intervals followed by a single test probe. The probe was a pair of objects representing one of all possible pair-wise comparisons of the order of objects in a series of 5, and the subject signaled 'which came first' by making a choice of the least recent of the two. A single object from each list position was also tested against a foil. A foil was an object that did not appear in the list, and therefore was always the least recent object when it appeared in the test probe. Eighty trials were accumulated in each of the 15 possible probe combinations.

The accuracy of order discriminations depended on the lag of both objects in the probe. Probe lag is the serial distance of an object in the presentation list from its appearance at test: the last object in the list has a lag of 1, and the penultimate object a lag of 2, etc. For any lag of the most recent object in the probe, accuracy increased directly with increasing lag of the distant object in the probe (the one that was chosen); and for any lag of the distant object, accuracy increased directly with decreasing lag of the most recent object. This dual dependence on probe lag is characteristic of human JOR. The monkey, like human subjects in a comparable design, also treated the foils as if they were objects with a lag greater than the longest lag of any object in the list. These findings suggest that both monkeys and humans rely upon similar cognitive processes in recalling the order of random events.

TASK SPECIFIC MODULATION OF CEREBRAL BLOOD FLOW WITHIN THE HUMAN FRONTAL CORTEX. M. Petrides, B. Alivisatos*, A.C. Evans* and E. Meyer*. Montreal Neurological Institute, McGill Univ., Montreal, Quebec, CANADA H3A 2B4.

Patients with frontal cortical excisions are impaired on tasks in which they must monitor self-ordered responses and on tasks in which the responses are conditional upon the stimulus presented. Regional cerebral blood flow (rCBF) was measured by means of positron emission tomography in nine normal male volunteers in a) a control condition involving pointing to an abstract design, b) a self-ordered task in which the subjects had to monitor their pointing responses to abstract designs, and c) a conditional task requiring pointing to designs in response to differently colored stimuli. The normalized CBF in the control condition was subtracted from that in the two experimental conditions. Within the frontal cortex, there was, in the self-ordered task, a focal increase in rCBF in the right mid-dorsolateral frontal region and an increase extending over a slightly larger area within the left dorsolateral frontal cortex. By contrast, in the conditional task there were focal decreases in rCBF within the right lateral frontal cortex.

RELATIONSHIP BETWEEN CT MEASURES OF REGIONAL BRAIN ATROPHY AND PET MEASURES OF REGIONAL GLUCOSE UTILIZATION IN ALCOHOLIC KORSAKOFF'S SYNDROME. E.M. Joyce*, D.E. Rio*, M.J. Eckardt. Lab. of Clin. Studies, NIAAA, DICBR, Bethesda MD 20892.

In a previous report, patients with alcoholic Korsakoff's syndrome were shown to have relatively reduced rates of 18FDG uptake in cingulate, precuneate and right sensorimotor cortex and right thalamus, as well as increased uptake in cerebellum (Soc. Neurosci. Abstr. 16:571, 1990). To assess whether this might be due to reduced neuronal mass rather than reduced neuronal function, regional brain atrophy was estimated on the CT scans of the same subjects (9 Korsakoff, 10 normals) by measuring sulcal and ventricular CSF content. Korsakoff patients had increased ($p < 0.01$) CSF in third and lateral ventricles, Sylvian fissures, and sulci of sensorimotor cortex, and had a trend ($0.01 < p \leq 0.05$) towards increased CSF over frontal cortex and cerebellar vermis. When group differences in relative rates of regional glucose utilization were re-analysed using appropriate regional estimates of tissue atrophy as covariates, the differences in right thalamus, sensorimotor cortex and cerebellum disappeared whereas those for cingulate and precuneate cortex remained significant. The data suggest that the structural lesions in this disorder give rise to dysfunction in a neural circuit which includes cingulate cortex and which is thought to mediate arousal and memory.

54.19

THE ROLE OF THE FRONTAL LOBES IN FREE RECALL: INTERFERENCE, ORGANIZATION, AND SERIAL POSITION EFFECTS. F.B. Gershberg and A.P. Shimamura. Department of Psychology, University of California, Berkeley, CA 94720.

Free recall ability was tested in patients with unilateral damage in dorsolateral prefrontal cortex. Patients and control subjects learned two lists of 15 unrelated items, with five study-test trials for each list and a break between lists. Frontal patients recalled fewer items overall but showed learning across trials. To assess interference effects, performance on the first trial of each list was analyzed, revealing a significant Group (patients vs. controls) X List (first list vs. second list) interaction. Specifically, the recall deficit shown by the frontal patients was greater for the second list than for the first list. The pattern of results suggests that the interaction was due to both the control subjects' "learning to learn" and the frontal patients' increased susceptibility to interference. A measure of subjective organization (the extent to which the same items are reported together across trials, corrected for level of recall) was used as an indicator of organizational strategies. Frontal patients were found to use less subjective organization, which may reflect a general deficit in the development and use of strategies. Serial position effects were also examined. Frontal patients showed a significant recency effect, but their recall of recency items was significantly lower than control subjects' recall of those items, indicating that short-term memory might be disrupted. These results suggest that dorsolateral prefrontal cortex normally plays a role in short-term (working) memory, developing and using learning strategies, and reducing the effects of interference. DATA-BASED AND KNOWLEDGE-BASED MEMORY FOR TEMPORAL DISTANCES IN HYPOXIC BRAIN INJURED SUBJECTS. R.O. Hopkins and R.P. Kesner. Dept. of Psych., University of Utah, Salt Lake City, Ut 84112.

Subjects who have experienced a hypoxic episode and normal age matched control subjects were tested for temporal distance in both data-based and knowledge-based memory. Temporal distance is determined by the number of items that occur between the two test items. Temporal distances for words and spatial locations for new data-based memory were assessed. Subjects were shown a series of 8 words or 8 spatial locations. The items are shown one a time and then in the test phase subjects are shown 2 words or 2 X's each of which occurred in the study phase. Subjects are asked to choose the item that occurred earlier in the sequence. Choices occur across temporal distances of 0 to 6, with eight observations for each distance. Assessment of memory for temporal distances in the knowledge-based system is carried out using scripts and map tasks. Scripts are overlearned standardized episodes which occur both for linguistic and spatial information. Subjects are asked to remember 4 structured scripts (e.g. restaurant) and familiar routes (Salt Lake City) and 4 unstructured scripts (e.g. parade) and unfamiliar routes (Santiago). Data are collected for temporal distances of 0, 2, 4, and 6 with 4 observations for each distance.

Results show that hypoxic subjects are impaired across all distances for words and spatial locations. On the structured scripts and maps tasks hypoxic subjects are similar to control subjects across all distances. On the unstructured scripts task hypoxic subjects are impaired relative to control subjects for distances of 0 and 2, and then are the same as control subjects for distances of 4 and 6. On the unstructured maps task hypoxic subjects perform poorly relative to controls for all temporal distances. Subjects with hypoxic brain injury are impaired for new data-based temporal distance information but show no impairments for knowledge-based temporal distance information.

LEARNING AND MEMORY--PHARMACOLOGY: ACETYLCHOLINE I

55.1

SCOPOLAMINE DISRUPTS MAZE RETENTION IN TURTLES. C. A. Ritter* and A. S. Powers. St. John's University, Jamaica, NY 11439.

Recent studies from our laboratory have shown that lesions of the basal forebrain in turtles produce deficits in learning and memory. The basal forebrain of turtles contains cholinergic cells. The present study was conducted to determine whether scopolamine, a muscarinic receptor blocker, would disrupt maze retention in turtles.

Turtles (n=25) were trained in an X-maze for water reward. After reaching criterion, they were given five days rest and then retested on the maze to be certain their performance was at criterion. On the day following the second achievement of criterion, they were injected 30 min before running with either saline, scopolamine (1.6, 3.2, or 6.4 mg/kg IP), or methylscopolamine (6.8 mg/kg) (n=5 in each group). They were run on the maze under the drug condition on that day and then, without injection, until they again achieved criterion.

The results showed a dose-dependent disruption of maze retention by scopolamine. Methylscopolamine had no effect on performance. A supplementary study showed that the highest dose of scopolamine had no effect on three measures of unlearned behavior. The results suggest that acetylcholine plays an important role in associative functions in turtles.

55.3

THE EFFECTS OF SCOPOLAMINE, MECAMYLAMINE, AND QUINPIROLE ON RADIAL-ARM MAZE PERFORMANCE OF RATS WITH FORNIX TRANSECTIONS. B. Osborne, R. Liddell* and J. Feeley*. Department of Psychology, Middlebury College, Middlebury, VT 05753-6145.

Both cholinergic manipulation and hippocampal damage disrupt memory function as measured by deficits in radial-arm maze performance. In the present experiment, rats with fornix transections and sham control rats were trained to asymptote on the radial arm maze and then tested following injections of the muscarinic blocker scopolamine (0.04 mg/kg; Sigma) the nicotinic blocker mecamylamine (2.5 mg/kg; Merck) and the D₂ agonist quinpirole (0.01 mg/kg; Lilly), both alone and in combination. All rats received all treatments separated by recovery days. Cholinergic blockers given singly or in combination reduced accuracy as measured by trials to repeat and increased run time; quinpirole had no effect alone. Quinpirole, however, reversed the effects of mecamylamine and scopolamine and mecamylamine in combination. The response to the drugs for the fornix transected rats differed significantly from those of controls but were fundamentally similar. The results suggest major differences between the hippocampal and cholinergic syndromes.

BEHAVIORAL CONSEQUENCES OF THE DIFFERENTIAL EFFECTS OF EXCITOTOXIC LESIONS IN THE NUCLEUS BASALIS MAGNOCELLULARIS. Cheryl A. Harrington and Gary L. Wenk. Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Loss of cholinergic (CH) neurons in the nucleus basalis magnocellularis (NBM) is seen in Alzheimer's Disease (AD) and may underlie the associated memory impairment. Animal models of AD use excitotoxins to produce NBM lesions that mimic this CH cell loss. Ibotenic (IBO) and quisqualic (QUIS) acids produce a differential loss of NBM CH cells. We attempted to manipulate the differential vulnerability of CH NBM cells to IBO and QUIS by co-injection of selected ions (e.g. Zn & Mg), anti-oxidants (e.g. cystine & glutathione), receptor antagonists (e.g. CNQX) and neuromodulators (e.g. muscimol). The consequences of these injections on spatial memory was determined using a continuous non-match-to-sample task in a T-Maze. Performance was correlated to the loss of CH and non-CH neurochemical markers in the NBM, amygdala, and neocortex. The pattern of results suggests that non-CH NBM cells may play a role in learning and memory. Supported by the National Science Foundation (BNS 89-14941).

MUSCARINIC ACTIVATION OF THE MEDIAL SEPTAL AREA: IMPROVEMENTS IN WORKING MEMORY AND MODULATION OF HIPPOCAMPAL PHYSIOLOGY IN AGED RATS. B. Givens, A.L. Markowska and D.S. Olton. Department of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

Cholinergic dysfunction in the septohippocampal system may underlie age-related mnemonic impairments in aged rats. This study investigates whether activation of the septo-hippocampal pathway by infusion of the muscarinic agonist oxotremorine (OXO) into the medial septal area (MSA) can improve working memory (WM) and modulate hippocampal physiology in male Fisher rats (24 mo old). Intraseptal OXO (0.1, 0.5, 2, 5 & 10 µg) produced a dose-dependent increase in choice accuracy in a spatial alternation task. The lowest effective dose, 0.5 µg OXO, did not improve WM performance when infused into the lateral ventricles. Intraseptal OXO increased 3 measures of the population response (EPSP) of the dentate gyrus to perforant path stimulation: the initial slope, the amplitude and the area. The values returned to baseline levels by 90 min after infusion. The hippocampal theta rhythm was shifted to a lower frequency following intraseptal OXO infusions. These data suggest that (1) changes in hippocampal physiology may underlie changes in WM, and (2) the cholinergic input to the MSA may be a useful target for drugs designed to improve WM in aging.

55.5

OPIOID SYSTEM IN THE MEDIAL SEPTAL AREA: THE EFFECT OF MICROINFUSION OF BETA-ENDORPHIN ON SPATIAL WORKING MEMORY IN RATS. B.Q.Wan, B.Givens and D.Olton. Dept. of Psychology, The Johns Hopkins University, Baltimore, MD. 21218.

Systemic and central administrations of opioid antagonists facilitate, whereas opioid agonists impair, memory in a variety of tasks. The present study investigated the role of the opioid system in the medial septal area (MSA) on spatial working memory (SWM). SWM was evaluated in a T-maze continuous alternation task. Each session had 20 trials with a 20-sec intertrial interval. Hippocampal θ rhythm (θ) was recorded while rats performed the task. β -endorphin (β -END, 50, 250, and 500 ng) was infused into the MSA immediately prior to behavioral testing. Muscimol (20 ng), a GABAergic agonist, was infused for a comparison. Both β -END (500) and muscimol (20) suppressed the power of θ . However, muscimol (20) greatly impaired choice accuracy, whereas β -END (250, 500) only slightly reduced choice accuracy. The behavioral impairment following intraseptal muscimol indicates a role of the MSA in SWM. The difference in magnitude of behavioral impairment produced by muscimol and β -END suggests a differential role of opioid and GABAergic systems in the MSA on SWM.

ACETYL-L-CARNITINE: CHRONIC DIETARY TREATMENT IMPROVES SPATIAL MEMORY IN AGING RATS. A. Caprioli and D. S. Olton. Dept. of Psychology., The Johns Hopkins Univ., Baltimore, MD 21218.

Acetyl-L-carnitine (ALCAR) may be capable of reducing age-related memory impairments. The present experiment examined the effect of chronic ALCAR treatment on spatial memory in Fisher-344 rats. Each rat, 18 months old, was trained in a place discrimination in a water maze. Performance in this task was used to assign each rat to one of two groups, good performance or poor performance, based on their latency to reach the platform. Half of the rats in each group received 100 mg/kg/day of ALCAR for the next 4 months; the other half received water. At 22 months of age, during the first two sessions of retention, the ALCAR treated rats performed better than the control rats. The effect of ALCAR was more evident in the poor performance group than in the good performance group. Acquisition of a new spatial discrimination was tested two weeks later in a new environment. Neither control nor ALCAR rats improved their performance in the new environment, but ALCAR rats performed better than controls. These data indicate that ALCAR can improve spatial memory; the magnitude of the improvement is more pronounced in poor performance rats than in good performance rats. Supported by Sigma Tau, Institute for Research on Senescence. Italy.

55.9

ATTENTION AND THE NUCLEUS BASALIS MAGNOCELLULARIS. K. Pang, D.S. Olton and H. Egeth. Dept. of Psychology, Johns Hopkins University, Baltimore, MD 21218.

The nucleus basalis magnocellularis (NBM) may have an important role in attention. The present experiment assessed the role of the NBM in attention as measured in a two-choice reaction time task. The task had two stimuli (light and tone), each of which had a specific response (left or right) rewarded. On each trial, a single stimulus was presented. The rat responded by releasing a lever. Attention to each stimulus was manipulated by varying the probability of stimulus occurrence (20%, 50% or 80%). The stimulus probability remained constant for a block of 7 sessions (1 session/day). Muscimol (MUS, 1 and 15 ng), a GABA agonist, was infused into the NBM prior to two sessions within each block of seven sessions, with two or more days between infusions. These infusions increased reaction time to both stimuli. The slowing due to MUS was inversely related to the probability of the stimulus: greatest with 20% stimulus, moderate with 50% stimulus and smallest with 80% stimulus. This same pattern occurred for both light and tone stimuli, suggesting that the observed impairment was not due to a sensory deficit. MUS decreased the number of correct responses for 20% stimuli, but not for 50% and 80% stimuli. The greater impairment observed for unexpected stimuli than for expected stimuli suggests that the NBM is involved in shifting of attention or the ability to divide attention.

55.6

BLOCKADE OF MUSCARINIC RECEPTORS IN MEDIAL SEPTAL AREA OR NUCLEUS BASALIS MAGNOCELLULARIS IMPAIRS SPATIAL MEMORY. A.L. Markowska, A. Caprioli*, K. Pang, and D.S. Olton. Department of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

Intraseptal administration of scopolamine, a muscarinic antagonist, impairs working memory. The present experiment reports the results of intraseptal infusion of scopolamine on another type of memory, reference memory, and in another cholinergic area, the nucleus basalis magnocellularis (NBM). Fisher-344 rats were tested in a spatial discrimination task in the water maze. Saline (SAL), scopolamine 30 μ g (SCOP-30), or 60 μ g (SCOP-60), was infused into the medial septal area (MSA) before each training session. SCOP-30 and SCOP-60 decreased the rate of acquisition and impaired asymptotic performance. The magnitude of these decreases was dose-dependent. All rats were then trained to criterion performance without infusions. Subsequently, retention was tested after infusions into the MSA or NBM. Both MSA and NBM infusions of SCOP-60 and SCOP-30 produced a dose-dependent impairment in performance. These results suggest, that the memory deficits produced by scopolamine are due to impairment of retrieval, and that both cholinergic systems, MSA and NBM, contribute to processing of spatial information.

55.8

INTRASEPTAL INFUSION ALTERS ACETYLCHOLINE RELEASE IN THE HIPPOCAMPUS OF THE RAT. L.K. Gorman, K. Pang, B. Givens, C. Kwon, & D.S. Olton. Neuromnemonics Laboratory., Psychology Dept. The Johns Hopkins Univ., Baltimore, MD 21218.

To study the kinetics of acetylcholine release in the hippocampus, cholinergic and GABAergic drugs were infused directly into the medial septal area (MSA). ACH release in the hippocampus and overlying cortex was assayed using *in vivo* microdialysis and HPLC with electrochemical detection. Rats were anesthetized with a gas mixture containing 2% ethrane. A 3 mm microdialysis probe containing a Ringers solution and 100 μ M neostigmine bromide was perfused for 30 min prior to drug infusion and for 1 hr after the start of the drug infusion. Dialysate samples were collected over 5 min intervals. Drugs were infused into the MSA at a rate of 0.1 μ l/min for 5 min. The anatomical placement of the microdialysis probe and drug infusion cannula was verified. Muscimol, 30 μ g, a gabaergic agonist, increased ACH release between 15-20 minutes after the infusion. Carbachol, 2 μ g, a muscarinic agonist increased ACH release 10 min. after the infusion. In both cases, ACH returned to baseline. Oxotremorine, 5 μ g, a muscarinic agonist, steadily decreased ACH release which started at the onset of the drug infusion and continuing through the entire session. These results demonstrate that cholinergic and GABAergic systems in the MSA alter ACH release in the hippocampus.

55.10

BEHAVIORALLY INDUCED CHOLINERGIC ACTIVITY:ROLE OF ASSOCIATIVE AND NONASSOCIATIVE PROCESSES. S.Golski, L.K.Gorman, D.S.Olton. Department of Psychology, The Johns Hopkins University, Baltimore, MD, 21218.

The role of the basal forebrain cholinergic system in different kinds of memory was assessed. Changes in [3]hemicholinium-3 (HC3) binding were measured in four conditions which differed in their mnemonic requirements. In two conditions, rats learned a discrimination on a radial arm maze. The spatial working memory group (SWM) used space as a discriminative stimulus. The cued reference memory group (CRM) used a single cue as the discriminative stimulus, irrespective of space. In two other conditions, no discrimination was required. The Forced choice group (FORC) was variably reinforced for visiting the single arm to which the gate was raised. No contingencies existed between space, cue, and food. The Cage (CAGE) group had no experience with the maze. The SWM group had more cholinergic activity than the CRM group, suggesting that the type of discrimination influenced cholinergic function. The FORC group had more cholinergic activity than the CAGE group, suggesting that maze experience also influenced cholinergic function. Mean HC3 binding (and SEM) for dorsal hippocampus (HD) and ventral hippocampus (HV) immediately following the last trial was:

	CAGE	FORC	SWM	CRM
HD	10.7(1.5)	16.2(1.3)	13.3(1.7)	10.4(.8)
HV	12.9(1.2)	18.1(1.6)	18.0(2.0)	14.3(1.6)

The results suggest that cholinergic activity is influenced by associative and nonassociative processes and that the hippocampus may process spatial information even when such information is noncontingent with reward.

55.11

MEDIAL SEPTAL AREA AND HIPPOCAMPAL SYNAPTIC PLASTICITY: EFFECTS OF OXOTREMORINE IN AGED RATS. A. Balogh, K. Pang and D.S. Olton. Depts. of Psychology and Biomedical Engineering, The Johns Hopkins University, Baltimore, MD 21218.

Impaired memory in aged rats may be due to changes in synaptic plasticity in the hippocampus. Interventions that ameliorate age-related mnemonic impairments, including microinfusion of the cholinergic agonist oxotremorine (OXO) into the medial septal area (MSA), may do so by affecting hippocampal plasticity. The present study examines long-term potentiation in aged rats following infusion of OXO into the MSA. Fisher 344 rats, 25 months old, were implanted with cannulae dorsal to MSA, recording electrodes in the hilar region of the dentate gyrus and stimulating electrodes in the perforant path (PP). High frequency stimulation of PP was preceded by one of the following treatments: no infusion (CON-HFS), saline infusion (SAL-HFS), or OXO (2ug) infusion (OXO-HFS). Each rat received each of the treatments. Percentage increase in EPSP slope following OXO-HFS treatment was greater than that for either CON-HFS or SAL-HFS, suggesting increased hippocampal plasticity following intraseptal microinfusion of OXO. This increase may contribute to the mnemonic improvements seen in aged rats after MSA infusions of OXO.

55.13

DA-ACH INTERACTIONS IN THE HIPPOCAMPUS AND MEMORY IN THE RAT. G.N.O. Brito and L.S.O. Brito*. Setor de Neurociências, UFF, Brasil.

We showed that intrahippocampal injections of the muscarinic antagonist scopolamine (SCO) impair the performance of rats on a working-memory task (WM -- T-maze alternation), whereas injections of the D2 antagonist sulpiride (SUL) do not. We additionally demonstrated that intrahippocampal injections of either SCO or SUL have no effects on performance of a reference-memory task (RM -- visual discrimination) in the same maze. We now report data on the effects of bilateral 1ul intrahippocampal injections of scopolamine (7.5 ug), SCH-23390 (a D1 blocker -- 1.5 ug) or a combination of the same doses of scopolamine and SCH-23390, on performance of the same T-maze tasks. We found that injections of SCH-23390 had no effect on performance of either task. Importantly, combined injections interfered with performance of the WM task as much as SCO and the two drugs interacted to lower performance of the RM task to chance. We conclude that the hippocampal ACH system is critically involved with WM mechanisms and interacts with the hippocampal DA system in the mediation of RM processes.

SEPTAL GABA-ERGIC INTERNEURONS AND THE TRANS-SYNAPTIC CONTROL OF BASAL ACTIVITY AND MEMORY TEST-INDUCED ACTIVATION OF SEPTO-HIPPOCAMPAL CHOLINERGIC NEURONS IN MICE. J.P. DURKIN and J. KOENIG. Laboratoire de Neurosciences Cognitives et Comportementales, URA CNRS n°339, and Lab. Neurobiol. Cellulaire, Universités de Bordeaux*1 et 2, 33405 Talence Cédex, France.

A neurochemical study of the trans-synaptic interaction established between septal GABA-ergic interneurons and the cholinergic septo-hippocampal neurons was conducted using mice. The effects of acute *in vivo* injections of either muscimol (20-500 ng/0.2 µl), bicuculline (100 ng-1 µg/0.2 µl) or saline vehicle (0.2 µl) into the medial septum on septo-hippocampal cholinergic activity was evaluated using measures of hippocampal high affinity choline uptake 30 min post-injection in two main groups of mice. The first (quiet control) remained in their home cages during the post-injection period whereas the second (active) were submitted, 10 min following injection to a 20 min period of spatial working memory testing. Both muscimol and bicuculline produced significant (25-35%) inhibition of hippocampal cholinergic activity in quiet conditions (basal) as compared to intact or saline-injected mice. In the active groups whereas memory testing induced significant cholinergic activation (+15-20%) in intact and saline injected mice at 30-sec post-test no such activation was observed in either muscimol or bicuculline-injected mice at any dose. The role of septal GABA-ergic mechanisms in the trans-synaptic control of septo-hippocampal cholinergic activity is discussed with respect to the concept that this neuronal interaction contributes to the modulation of working memory performance. (Supported by CNRS, URA 339)

55.12

GALANIN-INDUCED AMNESIA: EFFECTS OF DOSE AND TIME OF ADMINISTRATION. D.H. Malin, S.J. Radulescu*, B.J. Novy*, J.R. Lake, R.E. Plotner*, A. Lett-Brown*, P.J. Schaefer*, M.K. Crothers*, B. May* and L.D. Osgood*. University of Houston-Clear Lake, Houston, TX 77058.

Galanin (GAL) negatively modulates cholinergic transmission in the septohippocampal pathway. Previously, 8 µg GAL i.c.v. prior to a single rewarded acquisition trial prevented subsequent retention. The present study determined the dose-relatedness of this impairment, and whether a similar impairment would result from injecting GAL before the retention trial. Apparatus and procedure for one-trial discriminative reward learning are described in Malin et al. *Neurobiol. Aging* 12:181,1991. Each rat's retention scores are its decrease in errors and increase in speed from the single training trial to the retention trial 24 hrs. later. Groups of 9 rats were injected i.c.v. with either 0, 0.5, 2, or 8 µg GAL in saline 20 mins. prior to the training trial. Retention was impaired in a non-monotonically dose-related manner.

(M ± SEM)	0	0.5	2	8
Error Decrease	10.8 ± 4.0	0.4 ± 1.7	3.6 ± 1.2	-1.0 ± 1.0
Speed Increase	4.3 ± 1.4	1.7 ± 1.3	3.3 ± 0.9	0.1 ± 0.8

In a second experiment, 8 µg GAL (n=9) or saline alone (n=9) was injected i.c.v. 20 mins. prior to retention trial. Both groups showed high and not significantly different retention, suggesting that GAL impairs memory formation rather than retrieval or performance.

55.14

PHYSOSTIGMINE FAILS TO ATTENUATE SPATIAL WORKING AND REFERENCE MEMORY DEFICITS IN THE MORRIS WATER MAZE IN RATS WITH MEDIAL SEPTAL LESIONS. C.P.J. Dokla and J. J. Boitano*. Depts. of Psychology, ¹Saint Anselm College, Manchester, NH 03102 and ²Fairfield Univ., Fairfield, CT 06430.

F-344 rats sustained electrolytic lesions (1.0 mA/10 s) of the medial septal nucleus (MS) at two sites or sham-operations (SHAM). Reference memory testing in the Morris water maze was conducted for 12 consecutive days using a single, fixed escape platform location. One group of MS rats received physostigmine (PHYSO; 0.06 mg/kg, ip) 15 min prior to daily two-trial tests, whereas MS-control and SHAM groups received distilled water (vehicle) only. MS groups were highly deficient on acquisition of the task, particularly during days 7-12 of testing. PHYSO did not improve performance and probe-trial behavior was normal for all groups. Spatial working memory was assessed using a procedure similar to the one described by Wesierska et al (*Behav. Neurosci.*, 104: 74, 1990). Escape platform location was changed daily and a single training trial (60 s limit) was followed 5 min later by two successive retention trials. Four-day blocks of testing followed by 3-day washout periods were used to evaluate 5 doses of PHYSO (0.015, 0.03, 0.06, 0.12, 0.24 mg/kg). Retention measures were highly impaired in the MS groups, and PHYSO, at all doses, did not improve performance.

AMPA-INDUCED CHOLINERGIC LESIONS OF THE VERTICAL LIMB OF THE DIAGONAL BAND (VDB) IMPAIR PERFORMANCE OF A CONDITIONAL VISUAL DISCRIMINATION (CVD) TASK. H.L. West, T.W. Robbins, and B.J. Everitt. Dept. of Expt. Psych., Univ. of Cambridge, Downing Street, Cambridge CB2 3EB, UK.

Rats were trained on a CVD task in which they were required to discriminate two temporal frequencies (0.83 and 5 Hz) of flashing lights matched for flux. Training continued until a stable baseline of at least three consecutive sessions averaging over 75% correct responding was attained. Subjects were then exposed to modified versions of the CVD task in which either the duration of the stimulus (ST-DUR) was gradually decreased or the delay between stimulus presentation and opportunity to respond (DEL) was gradually increased within a session in order to titrate the minimum ST-DUR and maximum DEL at which the subjects could successfully perform the task. Animals achieved a baseline success rate of 77.7%, minimum ST-DUR of 1.2 seconds, and maximum DEL of 8.4 seconds on average before surgery. Rats then received bilateral injections of either buffer or the cholinergic neurotoxin AMPA (0.015 mM, 0.5 µl/site) in the VDB (AP+0.2 from bregma, ML±0.6, DV-6.8 mm from dura), an intervention that has been demonstrated in experimentally lesioned animals to produce an average reduction in ChAT activity of 60% on average in cingulate cortex but only 24% in hippocampus. After a 14-day recovery period, rats were retrained to criterion and again challenged with the ST-DUR and DEL titration tests. VDB lesioned animals took significantly longer to reacquire the CVD to a 75% correct criterion than the sham controls but performed as well as controls on both the ST-DUR and DEL challenges. These results suggest that the disruption in use of decision rules produced by AMPA-induced cingulate cholinergic depletion evidently does not result from long-lasting deficits in attentional or working memory function.

BEHAVIORAL EFFECTS OF CHOLINERGIC HYPOFUNCTION IN RHESUS MONKEYS: VISUAL VS SPATIAL DISCRIMINATION. E. Grauer and Y. Kapon*. Dept of Pharmacology, IIBR, Ness-Ziona, Israel.

Rhesus monkeys were tested in a system that allows testing of monkeys in their home cage, while in the presence of other caged monkeys. An array of 12 press keys is used to present either a visual (V) or a spatial (S) discrimination task. All trials are initiated by the monkey. In the V procedure, key lights signal the "correct" keys. In the S procedure, some unsignalled keys are randomly designated as "correct" keys. In both tests only one press per key is required and it is secondarily reinforced by a brief blink of the lights above the reinforcement levers. Initial responses on "incorrect" keys are indicative of "reference memory" errors (RME) and repeated presses are indicative of "working memory" errors (WME). Scopolamine, a cholinergic antagonist, differentially affected these two tests. While no cognitive decrements were detected in the V task, the S task was susceptible to scopolamine. A specific increase in WME with no changes in RME was seen following administration of 1µg/kg of scopolamine. The data demonstrate the cholinergic involvement in the working memory process, with specific reference to spatial requirements.

STRIA TERMINALIS LESIONS ATTENUATE MEMORY ENHANCEMENT INDUCED BY POST-TRAINING INTRACAUDATE INJECTION OF OXOTREMORINE. J. L. McCaugh, M. G. Packard*, J. B. Introini-Collison. Center for the Neurobiology of Learning and Memory and Dept. of Psychobiology, University of California, Irvine, CA 92717.

Lesions of the stria terminalis (ST), a major afferent-efferent pathway of the amygdala, attenuate the memory enhancing effect of peripheral post-training injection of the cholinergic agonist oxotremorine (OXO) [Introini-Collison et al., 1989]. One possible explanation of these findings is that the amygdala modulates the memory improvement produced by OXO via ST innervation of some other cholinergic brain system. The caudate nucleus receives amygdala input via the ST. Further, several previous studies have shown that post-training manipulation of cholinergic function in the caudate nucleus affects memory. The present study examined the hypothesis that amygdala output is necessary for the memory improvement produced by post-training intracaudate injection of OXO.

Groups of rats with either sham operations or bilateral lesions of the ST were trained on a one-trial inhibitory avoidance task and received a unilateral post-training intracaudate injection of either vehicle or OXO (0.3 µg/0.5 µl) into a region of the caudate nucleus innervated by the ST. Intracaudate injection of OXO improved memory in sham-operated rats. Although ST lesions did not affect retention in rats that received intracaudate injection of vehicle, the memory improvement produced by post-training intracaudate injection of OXO was blocked by ST lesions. The findings show that amygdala output via the ST is a cofactor required for memory enhancement by intracaudate injection of a cholinergic agonist, and suggest that the role of the amygdala in memory may involve modulation of memory processes during the post-training period in brain loci receiving amygdala efferents.

POST-TRAINING ADMINISTRATION OF CHOLINERGIC M2 RECEPTOR ANTAGONIST AFDX 384 MODULATES MEMORY PERFORMANCE ON WIN-STAY AND WIN-SHIFT TASKS. A. Wilson*, N.M. White, & R. Quirion. Department of Psychology and Douglas Hospital Research Centre, McGill University, 1205 Dr. Penfield Avenue, Montreal, Quebec, Canada H3A 1B1.

Previous evidence indicates that post-training injections of a cholinergic M2 receptor antagonist, AFDX 116, enhances retention and acquisition on two tasks: One sensitive to lesions of the caudate nucleus (win-stay); the other sensitive to lesions of the hippocampal system (win-shift). The extent to which a similar but more selective M2 receptor antagonist, AFDX 384, modulates performance on these tasks was examined. In the win-stay task rats were given one trial per day and injected with AFDX 384 (0.50 mg/kg) and d-amphetamine (3.0 mg/kg) following trial seven. Rats in these groups required significantly more trials to reach criterion than saline treated controls. While alternative interpretations of the results are possible the results suggest that these doses of these drugs may have impaired acquisition of this task. In the win-shift task post-training administration of a low dose of AFDX 384 (0.25 mg/kg) enhanced retention while a higher dose (1.0 mg/kg) had no effect. These findings support the view that presynaptic mechanisms which increase cholinergic activity can modulate performance on memory tasks associated with hippocampal and/or caudate function.

CALCIUM-BINDING PROTEINS IN ORGANOTYPIC SLICE CULTURES OF A LEARNING-RELEVANT FOREBRAIN AREA IN CHICKS. K. Braun¹, A. Malouf², C. Robins², P. Schwartzkroin², H. Scheich¹. ¹Inst. Zool., Techn. Univ. Darmstadt, Schnittspahnstr. 3, 6100 Darmstadt, FRG; ²Dept. Neurosurg., Univ. of Washington, Seattle, WA 98195, USA

Parvalbumin (PV), calbindin-D28K (CaBP) and calretinin (CaR) characterize distinct neuron populations forming an intrinsic network in the medial neostriatum/hyperstriatum (MNH), an area which undergoes dramatic synaptic plasticity during auditory filial imprinting. Using these proteins as neuronal markers, we are now investigating critical parameters underlying these changes in cultures of MNH taken from newly hatched chicks. Many PV- and CaBP-immunoreactive (IR) neurons, and numerous PV-, CaBP- and CaR-IR puncta on dendrites and somata of immunostained neurons indicate the presence of a similar intrinsic neuronal network in culture and in vivo. However EM-analysis reveals numerous synapses with some unusual ultrastructural features. In vitro, dendritic spines contain reduced amounts of Ca-binding proteins. Given the activity-regulated expression of either Ca-binding protein, these differences may reflect different activity levels within in vitro networks.

TIME COURSE OF CHANGES IN NERVE GROWTH FACTOR IMMUNOREACTIVITY (NGFi) IN THE DENTATE GYRUS FOLLOWING ENTORHINAL CORTEX LESION. J.M. Conner, B. Fass-Holmes and S. Varon. Department of Biology, 0601, UCSD, La Jolla, CA 92093

Removal of the entorhinal input to the hippocampal formation provokes a sprouting response by many adjacent afferent systems. The molecular cues regulating this response are unknown at present, although a possible role by trophic factors has been suggested (Crutcher and Collins, 1986). The cholinergic basal forebrain neurons, which have a well documented sprouting response following entorhinal cortex lesion (ECL), presumably rely upon NGF for their trophic support. Using affinity purified antibodies to NGF, we have previously shown that NGFi is exclusively localized within cholinergic neurons of the basal forebrain and in the hilus of the dentate gyrus (DG) (Conner, et al. 1990). To determine whether NGF plays a role in lesion-induced cholinergic sprouting, we examined changes in NGFi in the DG of adult female rats at 3, 8, 16 and 30 days following unilateral ECL. At 3 days post-lesion (PL3), prior to any reported sprouting, a band of NGFi appeared in the denervated zone of the ipsilateral DG. At PL8, a time at which cholinergic axons have begun sprouting, NGFi was most intense. At PL16 and PL30 NGFi within the denervated zone began to diminish but still remained more intense than in the corresponding region contralateral to the lesion. The pattern of NGFi was discretely localized within the denervated zone but could not be seen in association with cell bodies or fibers. NGFi most likely was not attributable to lesion-induced shrinkage since the time course of NGFi intensification does not parallel the time course for tissue shrinkage. Our findings demonstrate that ECL is associated with an increase in NGFi within the denervated zone of the DG and suggest that NGF may play a trophic/tropic role in regulating lesion-induced cholinergic sprouting. CONTINUED EXPRESSION OF POLYSIALYLATED ('EMBRYONIC') N-CAM IN CENTRAL STRUCTURES CAPABLE OF STRUCTURAL PLASTICITY IN ADULTHOOD. D.A. Poulain¹, D.T. Theodosis¹, L. Bonfanti¹ and G. Rougon². Lab. de Neuroendocrinologie Morphofonctionnelle, Univ. Bordeaux II, F33076 Bordeaux, France.

The neural cell adhesion molecule, N-CAM, changes at the cell surface during development, from an isoform highly enriched in polysialic acid (PSA), to 'adult' isoforms containing much less PSA; the type and content of N-CAM thus varies as a function of tissue source and age. The timing of the conversion has suggested that N-CAM and especially its PSA may serve as overall regulators of contact-dependent cell-cell interactions during development. The use of a monoclonal antibody that specifically recognises PSA-N-CAM, with immunocytochemical and immunocytochemical procedures at the light and electron microscopic levels, revealed that neurons and astrocytes in discrete areas of the rat CNS continue to show high PSA-N-CAM immunoreactivity in adulthood. One of the most striking is the hypothalamo-neurohypophysial system, which undergoes important, reversible neuronal-glia and synaptic changes in response to physiological stimuli, such as lactation. PSA-N-CAM immunoreactivity was also present in other areas, including the arcuate nucleus of the hypothalamus and the dorsal horn of the spinal cord, known to undergo physiological- or lesion-induced plasticity, respectively. Our observations thus support the hypothesis that the continued expression of PSA-N-CAM in certain areas of the adult CNS enables them to undergo morphological plasticity in adulthood.

DIFFERENTIAL mRNA DISTRIBUTION IN CHICK BRAIN OF TWO PROTEIN KINASE C (PKC) SUBSTRATES, F1/GAP-43 AND MARCKS. P.J. Meberg¹, B.J. McCabe², G. Horn², J.P. Rosenfeld¹ and A. Routtenberg¹. 1. Northwestern Univ., Evanston, IL 60208. 2. Univ. of Cambridge, Cambridge, U.K.

Using *in situ* hybridization the most striking difference in F1/GAP-43 expression was the low level of hybridization in the paleostriatal complex in comparison to robust hybridization in the hyperstriatal complex, the neostriatum and a ventromedial telencephalic region. The hyperstriatal complex includes the intermediate and medial part of the hyperstriatum ventrale (IMHV). Hybridization was weak in the ectostriatum. Hybridization was strong in the tectum, the hippocampus and the mitral cell layer of the olfactory bulb, and moderate in cerebellar granule cells—similar to that seen in the rat (Meberg and Routtenberg, 1991, *Neuroscience*, in press).

The pattern of MARCKS mRNA expression differed from F1/GAP-43. MARCKS hybridization was apparent in the Wulst, IMHV and neostriatum, with medial structures more strongly labelled than lateral ones. Hybridization was weaker in the paleostriatal complex. Hybridization was also apparent in the tectum and over cerebellar granule cells. It was surprisingly strong over cells immediately adjacent to the ependyma of the lateral ventricles.

These data, together with recent evidence which indicates increased PKC substrate phosphorylation with imprinting (B. J. McCabe et al., this meeting), provide a basis for studying transcriptional regulation of such substrates in chick learning. (Supported by NIMH 25283 and AFOSR 90-0240)

SELECTIVE REDUCTION OF B-50/GAP43 PHOSPHORYLATION IN HIPPOCAMPUS OF RATS TREATED WITH METHYLAZOXYMETHANOL AT GESTATIONAL DAY 19 Di Luca M., Cimino M., De Graan P.N.E., Gispen W.H. and Cattabani E. Inst. of Pharmacol. Sci. Univ. of Milano 20133 Milano, Italy, and Rudolf Magnus Inst., Inst. Mol. Biol. Univ. of Utrecht 3584 CH Utrecht, NL.

The prenatal treatment at different gestational days with a potent alkylating agent (Methylazoxymethanol acetate, MAM) produces hypoplasia of specific brain areas associated with different patterns of cognitive impairments. We have previously demonstrated that the administration of MAM to pregnant rats at gestational day 15 (GD 15) produces a dose-dependent reduction in cerebral cortex and hippocampus in the offspring. GD 19 corresponds to the active mitotic phase of granule cells of hippocampus whereas the formation of cortical interneurons is completed. The treatment with MAM at GD 19 produces little morphological changes in brain; however, these animals show specific behavioural abnormalities. We have, therefore, studied in brain areas of GD 15 and GD 19 treated animals, the *in vitro* phosphorylation of B-50/GAP43. In membrane preparations of GD 15 MAM-treated rats B-50/GAP43 phosphorylation is reduced of 42±5% if compared to control levels both in cortex and in hippocampus (1); in GD 19 treated rats the 32P incorporation into B-50/GAP43 is reduced of 44±3% in the hippocampus whereas no modifications are observed in the cortex of these animals. *In situ* hybridization studies, performed utilizing an oligonucleotide probe designed on amino acid sequence 8-21 of B-50, revealed no statistically significant differences in B-50 expression in GD 15 and GD19 MAM-treated animals with respect to controls. These data indicate that the phosphorylation of B-50/GAP43 is correlated with different patterns of cerebral damage induced by MAM administration at different gestational days and therefore these animals are an interesting model to study the involvement of the protein in synaptic plasticity, since these animals show selective changes in LTP (2).

MEMORY ALTERS PROTEIN KINASE C SUBSTRATE (MARCKS) PHOSPHORYLATION. B.J. McCabe¹, F.-S. Sheu², G. Horn¹ and A. Routtenberg². 1. Dept. Zoology, Cambridge Univ., CB3 3EJ (UK). 2. Northwestern Univ., Evanston, IL 60208.

Phosphorylation of acidic proteins F1/GAP-43 and MARCKS are involved in synaptic plasticity, including rat hippocampal long-term potentiation (*J. Neurosci.* 9:381). We have enquired whether a measure of learning is related to F1/GAP-43 and MARCKS phosphorylation in the left IMHV, a forebrain region crucial for imprinting in the domestic chick. Imprinting entails the learning of an object's characteristics.

Chicks were exposed to an imprinting (training) stimulus and then given a preference test by exposure to the training stimulus and a novel object; the preference score (proportion of approach activity during the test directed towards the training stimulus) is a measure of learning. Control chicks were dark-reared. Left IMHV samples were incubated with [³²P]ATP and subjected to 2-dimensional gel electrophoresis. Phosphorylation of a heat-stable, 67 kDa protein kinase C substrate, having two acidic components with pIs of -5.0 and -4.0, and provisionally identified as MARCKS protein, was measured. Also measured were F1/GAP-43 (50 kDa) as well as a 48 kDa and a 52 kDa phosphoprotein. Of these phosphoproteins, only the phosphorylation of the less acidic component of MARCKS with pI -5.0 was significantly greater in trained than dark-reared chicks ($t=4.10$, 22 d.f., $p<0.001$), and was significantly correlated with preference score in trained chicks ($r=0.62$, 10 d.f., $p<0.05$). The partial correlation between preference score and phosphorylation, holding constant the effect of training approach, was significant ($r=0.75$, 9 d.f., $p<0.01$). Phosphorylation of this acidic component (pI-5.0) of MARCKS was therefore specifically related to an index of learning. Phosphorylation of the more acidic component (pI-4.0) of MARCKS was not significantly affected by training and was not significantly correlated with preference score, even after correcting for the effect of training approach. The left IMHV probably functions as a long-term store (*Exp. Brain Res.* 48:22). Hence the learning-related increase in phosphorylation of MARCKS (pI-5.0 component) may be implicated in mechanisms of recognition memory. (Supported by NIMH 25283 and AFOSR 90-0240).

INTRACELLULAR LOCALIZATION OF PKC SUBSPECIES IN HIPPOCAMPUS AND ITS INVOLVEMENT IN LTP. N. Saito, A. Kose*, T. Tsujino*, S. Tominaga, and C. Tanaka Dept. of Pharmacology, Kobe University School of Medicine, Kobe 650, Japan.

Protein kinase C (PKC) is a key enzyme for various transmembrane signalling systems and also known to be associated with long term potentiation (LTP) in the hippocampus. Recent molecular cloning revealed that PKC is a large family consisting of more than eight subspecies, but the physiological difference between the function of each subspecies is not identified. We demonstrate here the intracellular localization of each PKC subspecies of PKC in the hippocampus to elucidate the PKC subspecies which is involved in LTP. *In situ* hybridization demonstrated that considerable amount of mRNAs for α -, β II-, γ -PKC and ϵ -PKC were present in the hippocampus. The precise localization in the synapse of the PKC subspecies was studied in rat and monkey hippocampus by immunocytochemical technique. In rat, γ -PKC was seen in the dendritic spine as well as peripheral dendrites, while β II-PKC was present only in the peripheral dendrites but not in the dendritic spine. Both γ - and β II-PKC was found in the axon but neither was seen in the presynaptic terminals. Contrary, in monkey hippocampus, γ -PKC was present in the presynaptic terminals and in the dendritic spines. These findings suggests that in rat, both β II- and γ -PKC may be involved in LTP postsynaptically and γ -PKC but not β II-PKC may act within dendritic spine.

EXPRESSION OF HUMAN TYROSINE HYDROXYLASE AND UNREGULATED SIGNAL TRANSDUCTION ENZYMES IN NEURONS IN THE MAMMALIAN BRAIN, FROM HSV-1 VECTORS. M.J. During, A.I. Geller, A.Y. Deutch, R.L. Neve, K.L. O'Malley. Sect. Neurosurg., Yale U. Sch. Med., New Haven, CT 06510; Div. of Cell Growth and Regulation, Dana Farber Can. Inst., Boston, MA 02115; Dept. Psychiatry, Yale U. Sch. Med.; Dept. Psychobiol., U. Cal., Irvine, CA 92717; Dept. Neurobiol., Wash. U. Sch. of Med., St. Louis, MO 63110.

We have recently developed Herpes Simplex Virus (HSV-1) vectors that can stably express a gene in cultured neurons, and *in vivo*, following stereotaxic injection into the adult rat brain. A HSV-1 vector that stably expresses human tyrosine hydroxylase (pHSVth) in cultured striatal cells directs regulated release of L-dopa and dopamine from these cells. Direct, intrastriatal injection of pHSVth, and the subsequent expression of TH in striatal neurons and glia surrounding the injection site, is a promising approach to Parkinson's Disease (PD). The efficacy of intrastriatal injection of pHSVth on behavioral and biochemical recovery in the 6-hydroxydopamine rodent model of PD is being investigated.

Additional groups of unlesioned rats received intranigral stereotaxic injection with HSV-1 vectors expressing the catalytic domains of either protein kinase C or adenylate cyclase; these unregulated enzymes stably activate a particular signal transduction pathway. Both vectors increase long term basal and/or stimulated neurotransmitter release (e.g. dopamine, glutamate) from neurons *in vitro*; a similar effect *in vivo* may be realized, perhaps causing asymmetric rat rotation. These studies, currently in progress, represent a first step towards using genetic intervention techniques to clarify the mechanisms by which specific signal transduction pathways might modify behavior.

HIPPOCAMPAL SYMPATHETIC INGROWTH ALTERS CARBACHOL STIMULATED INOSITOL PHOSPHOLIPID HYDROLYSIS.

L.E. Harrell, V. Ayyagari, D.S. Parsons*, A. Peagler* and D. Connors
Dept. Neurology, University of Alabama, Birmingham, AL 35294.

Following cholinergic denervation of the hippocampus, via medial septal (MS) lesions, peripheral sympathetic fibers, originating from the superior cervical ganglia, grow into the hippocampus. To assess the functional significance of hippocampal sympathetic ingrowth (HSI), hydrolysis of inositol phospholipids (InsP) was examined. In control, MS lesions plus sham ganglionectomy (HSI group) and MS lesions plus ganglionectomy groups, three to four months after lesioning. Both NE and carbachol were found to produce a dose-dependent increase in the hydrolysis of InsP in hippocampal slices from all groups. However, the presence of HSI was found to significantly elevate the hydrolysis of InsP when stimulated by carbachol but not NE. In further studies, the time course of this effect was found to parallel the ingrowth of HSI, so that by 4 weeks after lesioning, carbachol stimulated InsP hydrolysis was equivalent between controls and animals with HSI but greater than that found in MS ganglionectomized animals ($p < .05$). This effect was blocked by atropine suggesting mediation through muscarinic cholinergic receptors. The results of these studies suggest that HSI is accompanied by functional metabolic alterations within the hippocampus.

INDUCTION OF THE IMMEDIATE EARLY GENE ZIF-268 IN THE CORTEX AND HIPPOCAMPAL FORMATION OF WEANLING RATS AFTER BRIEF EXPOSURE TO ENVIRONMENTAL COMPLEXITY. G.S. Withers, C.S. Wallace, I.J. Weiler and W.T. Greenough, Neurosci. Prog., Depts. of Psych. and Cell & Struct. Biol., Beckman Inst., Univ. of Illinois, Urbana, 61801.

Modifications in neuronal structure have been reported following various learning experiences. Differential housing, in which littermate rats are assigned to either a complex environment (EC) or an individual cage (IC), has been valuable in exploring structural plasticity related to long term information storage. We have detected significant increases in cortical thickness and dendritic length in occipital cortex of EC animals after only 4 days in EC (Kilman et al., 1988). This suggests that neurons undergo very rapid structural remodeling after behaviorally relevant experience. However, many questions remain about the mechanisms by which interaction with the environment might rapidly activate the coordinated gene expression required for dendritic growth. Transcription factors (proteins which bind to specific DNA sequences and regulate the transcription of other mRNA species) seem well suited to this process. A family of genes encoding transcription factors known as immediate early genes (IEG) has been described. One of these, ZIF-268 (known also as Egr-1, NGFI-A, Krox 24) has been correlated with NMDA receptor activation during the induction of LTP using electrical stimulation (Cole et al., 1989; Wisden et al., 1990). To investigate the sensitivity of an IEG to more natural stimulation, we used *in situ* hybridization to measure ZIF-268 mRNA levels after brief exposure to environmental complexity.

Preliminary results indicate that after 4 days exposure to EC/IC, expression of ZIF-268 is detectably elevated in the EC occipital cortex and hippocampal formation. This is one of the first demonstrations that behaviorally relevant experience can induce a transcription factor. Work is ongoing to further examine the regional activation of ZIF-268. Supported by ONR and NIMH 35321

FOS-LIKE IMMUNOREACTIVITY IN DEVELOPING RAT HIPPOCAMPUS, CEREBRAL CORTEX, AND CEREBELLUM. W.T. Greenough and A.A. Alcantara, Depts. of Psych. and Cell & Struct. Biol., Beckman Institute, Univ. of Illinois, Urbana-Champaign, IL 61801.

Cellular immediate-early gene (iEG) influences in the nervous system have been described extensively (Greenberg et al., J. Biol. Chem., 260:14101, 1985; Curran and Morgan, BioEssays, 7:255, 1987). The nuclear phosphoprotein product (Fos) of the IEG, *c-fos* binds as a heterodimer with the product of *c-jun* to specific DNA regulatory sequences, thereby modulating transcription of target genes. *c-fos* expression in the adult is induced by a variety of external stimuli. Fos and Fos-related antigens (FRAs) expression was examined in this study in intact developing animals ages P5-P10, a time when the brain is naturally undergoing many plastic changes. 10µm alternate cryosections were immunolabelled with either Alu antiserum which appears specific to Fos or with M5 antiserum which recognizes Fos as well as several FRAs such as Fra-1, Fra-2, and FosB (Cohen et al., Genes & Develop., 3:173, 1989). In general immunolabelling was either cytoplasmic or nuclear and showed region and cell-specificity. Labelling changed across ontogenetic development. Fos-like immunoreactivity detected with the Alu antiserum was developmentally regulated in the cerebellum, whereas immunoreactivity detected with the M5 antiserum was expressed in hippocampus, cerebral cortex and cerebellum. M5 labelling in hippocampal pyramidal cell nuclei was intense at P5 and became virtually absent by P10. Cerebral cortex pyramidal cells showed exclusive cytoplasmic M5 labelling whereas, layer VI cells displayed nuclear labelling. Immunoreactivity was very intense at P5 and reduced or absent by P10. Cerebellar Purkinje cells showed nuclear M5 and Alu immunoreactivity at P5. Labelling of these cells became increasingly cytoplasmic. Purkinje cell dendrites became intensely labelled by P7 and was greatly reduced or absent by P10. Supported by MH-40631, MH-35321, and MH-18882.

INDUCTION OF IMMEDIATE EARLY RESPONSE GENES IN SOMATOSENSORY CORTEX AFTER TACTILE STIMULATION. K.J. Mack and P.A. Mack*, Waisman Center On

Mental Retardation, University of Wisconsin, Madison, WI 53705

Immediate early response genes (IEGs) have been shown to be inducible in subcortical regions of the CNS after a variety of stimuli. In this study it was demonstrated that brief tactile stimulation can induce IEGs (*c-fos*, NGFI-A, and NGFI-B) in somatosensory cortex.

Adult male rats were lightly anesthetized with urethane. Tactile stimuli was delivered by an artist's paint brush gently stroking an animals whiskers on one side of its face intermittently over a fifteen minute period. Two hours later, the animals were sacrificed and tissue sections were prepared for immunohistochemical analysis. Cortex contralateral to the stimulation was compared with ipsilateral cortex using antibodies raised against the IEG products of NGFI-A, NGFI-B, and *c-fos*. The different transcription factors showed slightly different patterns of induction to the tactile stimulus. Cell counts indicated that the increase in the number of positively staining cells was approximately half of that observed after a metrazole-induced seizure. In contrast to seizure stimulation, the induction of immunohistochemical staining after tactile stimulation was most prominent in layer 4 with all antibodies under study.

These data demonstrate that physiologic stimulation can induce IEGs in cortical cells, and that multiple IEGs react differentially to a stimulus.

This research was supported by a grant from the PMA.

FOS IS EXPRESSED IN THE RAT DURING A FORELIMB REACHING TASK. A.A. Alcantara, N.D. Saks, and W.T. Greenough, Depts. of Psych., and Cell & Struct. Biol., Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

Most studies showing expression of the immediate-early gene, *c-fos* and its phosphoprotein product, Fos in the adult nervous system have shown its induction in response to invasive stimuli such as direct electrical stimulation. The purpose of this study was to examine whether Fos expression could be behaviorally induced. Animals were trained in a forelimb reaching task to reach for small pellets of food. (Peterson, Comp. Psychol. Monogr., 9:1, 1934; Whishaw et al., Brain, 109:805, 1986). Fos expression was detected by an immunoperoxidase procedure using the Alu antiserum. Animals that reached as few as 30 reaches on training day 1 revealed intense Fos immunoreactivity in cortico-fugal fibers within the corpus striatum. These fibers include sensorimotor cortex projections which govern forelimb movement. It is probable that Fos expression of glial cells may be contributing to this labelling since Fos positive glial cells have previously been identified in white matter tracts. In cerebellar lobules, particularly the paramedian lobule (PML), an area specifically involved in forelimb movement, Fos was detected in nuclei of Purkinje cells and inhibitory interneurons. Animals which reached on 3 consecutive days, showed an absence of labelling which resembled naive, nonreaching animals. This suggests that Fos expression in these regions may be involved in the earlier but not later stages of acquisition of the task. Parietal cortex, which receives forelimb cortex input, and other association cortices showed Fos expression. Cortical labelling was most pronounced in cell nuclei of layer II/III cells, which are involved in cortico-cortico input. This would further suggest an associational learning component of the pattern of Fos expression during the forelimb reaching task.

SPATIALLY DISTRIBUTED INCREASES IN C-FOS mRNA IN ODOR-ACTIVATED REGIONS OF THE MAIN OLFACTORY BULB. K.M. Guthrie, A.J. Anderson, M. Leon and C.M. Gall, Depts. of Anatomy & Neurobiology and of Psychobiology, Univ. of Calif., Irvine, CA 92717

Odor responsive regions of the main olfactory bulb can be revealed with ¹⁴C 2-deoxyglucose (2-DG) autoradiography. This mapping technique is limited in some aspects, particularly in its lack of cellular resolution. The expression of the immediate early gene (IEG) *c-fos*, which encodes a transcription regulatory protein, has been shown to respond to neural activation in a number of different neuronal systems. We report here the mapping of odor responsive regions of the rat olfactory bulb using cellular localization of mRNA for *c-fos*. Young rats (PN20-22) were injected with ¹⁴C-2-DG (20 µCi/100g, s.c.) and exposed to either air, peppermint odor or isoamyl acetate odor (1:10 dilution in air; flow rate = 2L/min) for 30 min. Animals were then decapitated and the brains dissected out and frozen in methylbutane (-50°C). Alternate sections were processed for 2-DG autoradiography and *in situ* hybridization with *c-fos* 35S-cRNA. Periglomerular, tufted and granule cells were labeled with *c-fos* riboprobe. In air-exposed animals, low levels of hybridization were seen throughout the glomerular layer (GL), while in odor-exposed animals, dense cell labeling occurred in discrete regions of the GL. Analysis of adjacent sections indicated that these glomerular areas corresponded to regions of high 2-DG uptake. Differential cRNA hybridization also occurred in the granule cell layer of odor-exposed animals, with those areas underlying the activated glomeruli exhibiting the heaviest cell labeling. These data demonstrate that odor stimulation activates *c-fos* expression in cells of the olfactory bulb, and that this technique is a more sensitive and precise means of identifying odor-responsive regions of the olfactory bulb than 2-DG autoradiography.

ODOR-STIMULATED INCREASES IN C-JUN mRNA IN THE RAT MAIN OLFACTORY BULB. A.J. Anderson, K.M. Guthrie, M. Leon and C.M. Gall. Depts. of Anatomy & Neurobiology and of Psychobiology, Univ. of Calif., Irvine, CA 92717

The protein products of the immediate early genes (IEGs) *c-fos* and *c-jun* combine to form a transcriptional regulatory factor. We have shown previously that areas of increased *c-fos* mRNA expression in the olfactory bulb correspond to areas of odor activation revealed by ¹⁴C 2-deoxyglucose (2-DG) autoradiography. We report here the mapping of odor responsive regions of the rat olfactory bulb using cellular localization of mRNA for *c-jun*. Young rats (PN20-22) were injected with ¹⁴C 2-DG (20μCi/100g) and exposed to either air, peppermint, or isoamyl acetate odor (1:10 dilution in air) at a flow rate of 2L/min for 30 minutes. Animals were sacrificed and their brains frozen in methylbutane (-50°C). Alternate cryostat sections were cut and processed for 2-DG autoradiography and *in situ* hybridization with ³⁵S-cRNA probes for *c-fos* and *c-jun*. Periglomerular, tufted, and granule cells labeled with *c-jun* cRNA; unlike *c-fos* cRNA, *c-jun* cRNA also labeled mitral cells. Odor-stimulated animals exhibited increased levels of *c-jun* expression in the glomerular, mitral, and granule cell layers compared to air controls. Examination of adjacent sections revealed that areas of increased cell labeling with *c-jun* cRNA in the glomerular layer corresponded to regions of elevated *c-fos* mRNA expression. Areas of elevated *c-jun* expression in the mitral cell layer were broader than those labeled with *c-jun* cRNA in the glomerular layer, or *c-fos* cRNA in the glomerular and granule cell layers. Mitral cells are responsive to odor-stimulation, however, changes in the mitral cell layer have not been observed using 2-DG autoradiography. These data demonstrate the differential expression of IEGs by olfactory bulb cell populations, and suggest that these genes may be co-activated by odor-stimulation in some neurons. Moreover, the induction of *c-jun* but not *c-fos* mRNA in mitral cells suggests the odor-activation of transcription factors with different regulatory specificities. GENE REPRESSION IN THE AVIAN SONG CONTROL SYSTEM. J.M. George and D.F. Clayton. Lab of Animal Behavior, The Rockefeller University, NY, NY 10021, & Dept. of Cell & Structural Biology, University of Illinois, Urbana, IL 61801

We have identified several mRNAs which are generally enriched in the forebrain but specifically repressed in parts of the song control circuit of canaries and zebra finches. These RNAs were identified using a combination of differential cDNA cloning and *in situ* hybridization. One of these, HAT-3, predicts a novel protein with unusual structural properties. Decreased gene expression in the song circuit was first observed in birds when song is stable and behavioral plasticity is low. Thus we hypothesize that regulation of plasticity in the song system may be achieved through repression and activation of specific genes such as HAT-3. To test this, we are measuring the expression of these genes in the song control centers of young zebra finches during the critical period for song development, and in adult canaries at different points in the seasonal cycle of song learning and production.

INGESTIVE BEHAVIOR: MONOAMINES

INHIBITION OF FEEDING BY THE NON-SPECIFIC 5-HT AGONISTS, 5-HTP AND FLUOXETINE. M.A. Prendergast*, K. Skaar*, S.E. Hendricks, D.P. Yells*, and D.F. Fitzpatrick*, Dept. of Psychology, Univ. of Neb. at Omaha, and Dept. of Psychiatry, Univ. of Neb. Med. Ctr., Omaha, NE 68182.

We assessed the effects of 5-HT agonism on sucrose consumption in food-deprived and free-feeding rats. In Experiment 1, food-deprived, but not free-feeding, rats receiving 2 mg/kg i.p. injections of the 5-HT precursor, 5-HTP, showed reduced consumption of a 10% sucrose solution. Both food-deprived and free-feeding rats receiving 20 mg/kg i.p. injections of 5-HTP showed reduced consumption of the sucrose solution. In Experiment 2, free-feeding rats receiving 10 mg/kg i.p. injections of fluoxetine showed reduced consumption of a 10% sucrose solution. These results support the conclusion that at low doses, 5-HT agonists inhibit feeding motivated by metabolic need and that higher doses inhibit feeding motivated by both metabolic need and palatability. The methodology described in Experiment 1 will be employed to assess the effect of Fluoxetine on both food-deprived and free-feeding rats and the results will be presented.

57.3

AGONISTS AT 5-HT_{1B} AND 5-HT_{1C} RECEPTORS SUPPRESS EATING WITHOUT ADVANCING THE BEHAVIOURAL SATIETY SEQUENCE. L.M. Dixon, A.M.J. Montgomery¹ and P.J. Fletcher. Clarke Inst. Psychiatry, Toronto, Ontario M5T 1R8, Canada and ¹City London Poly., London E1 7NT, England.

As rats feed to satiety they exhibit a characteristic sequence of behavioural changes. The cessation of feeding is followed by activity and grooming which, in turn, give way to resting. Enhancing satiety by prefeeding advances the behavioural satiety sequence (BSS): feeding ends earlier and resting starts sooner. Activation of 5-HT_{1B} receptors (using RU 24969), 5-HT_{1B/1C} receptors (using TFMPP) or 5-HT_{1C} receptors (using DOI) have each been shown previously to suppress food intake. The present study sought to examine the effects of these manipulations on feeding and the BSS. Drug effects were assessed in non-deprived rats during 1h meals of palatable wet mash. Throughout the meals each rat was observed every 15s and its behaviour scored into one of four mutually exclusive categories (eating, active, grooming and resting). Both RU 24969 and TFMPP (0,0.23,0.7 and 2.1 mg/kg; IP) dose dependently suppressed intake, eating time and eating rate. Activity was enhanced and resting suppressed, with the effects of RU 24969 being more pronounced. DOI enhanced activity and almost totally suppressed resting even at sub-anorectic doses (0.33 and 1 mg/kg; IP). Eating time was not altered because animals showed low levels of feeding throughout the 1h test. At an anorectic dose (3 mg/kg) DOI reduced feeding by decreasing eating rate. In summary although all three drugs suppressed eating RU 24969 and DOI disrupted the BSS while TFMPP left the sequencing of behaviours intact without advancing the termination of eating or the start of resting. The data show that none of these drugs suppress intake by enhancing satiety, but illustrate that activation of different 5-HT receptor sub-types induces different behavioural profiles.

57.2

EFFECTS OF THE 5-HT_{1B/1C} AGONISTS TFMPP AND RU 24969 ON FOOD INTAKE FOLLOWING PERIPHERAL OR MEDIAL HYPOTHALAMIC INJECTION. P.J. Fletcher, Z.H. Ming, M.H. Zack and D.V. Coscina. Clarke Institute of Psychiatry, Toronto, Ontario M5T 1R8, Canada.

It is well established that manipulations of 5-HT alter feeding behaviour. For example, indirect 5-HT agonists such as fenfluramine and fluoxetine reduce food intake. Previous studies have indicated that activation of 5-HT_{1C} and/or 5-HT_{1B} receptors are important for mediating these effects and that the medial hypothalamus, particularly the paraventricular nucleus (PVN) may be an important site of action in the brain. Experiments were conducted to test these hypotheses by examining the effects of activating 5-HT_{1B/1C} receptors (using TFMPP) or 5-HT_{1B} receptors (using RU 24969) on feeding in rats following peripheral or intra-hypothalamic injection. For intra-hypothalamic injections rats were equipped with chronic, indwelling, stainless steel guide cannulae aimed at the PVN. When injected peripherally RU 24969 and TFMPP (0.3-5 mg/kg, IP) dose dependently reduced feeding stimulated by three separate stimuli: (1) infusion of 25 nmol noradrenaline (NA) into the medial hypothalamus, (2) a palatable wet mash diet or (3) 20 hr of food deprivation. However, following microinjection into the medial hypothalamus neither drug (12.5-50 nmol in 0.4μl) altered food intake. In contrast both 5-HT and fluoxetine infused into the medial hypothalamus induced a mild attenuation of the feeding response to NA. The results indicate that while activation of 5-HT_{1B/1C} receptors following peripheral drug injection leads to marked reductions in food intake, the site of action of this effect is not the medial hypothalamus. However, it is possible that activation of multiple hypothalamic 5-HT receptor sub-types as occurs with 5-HT, and presumably fluoxetine, may suppress food intake.

57.4

EFFECT OF AN ANORECTIC AGENT - DEXFENFLURAMINE (DF) - ON NEUROPEPTIDE Y (NPY) RELEASE IN THE PARAVENTRICULAR NUCLEUS (PVN) OF FOOD-DEPRIVED RATS. M.G. Dube, C. Phelps, S.P. Kalra and P.S. Kalra, Dept. of Obstet. and Gynecol., Univ. of Fla. Gainesville, FL 32610, ¹Dept. Anat., Univ. So. Fla., Tampa, FL 33612

Our studies indicate that NPY release in the PVN may be a physiological signal for initiation of feeding in the rat. This is based on the demonstrations that (a) central administration of NPY evokes robust feeding; (b) NPY levels and release in the PVN are significantly increased after 3 days of food deprivation and return to control levels after refeeding, and (c) NPY levels rise and fall in association with food availability in rats on a scheduled feeding regimen. Since DF is an anorectic agent, we tested the hypothesis that DF's effect may be due to changes in NPY release in the PVN.

In a preliminary experiment, adult male rats were food-deprived for 24 h and then injected with either DF (10 mg/kg, IP, n=8) or saline, IP (n=8). After 30 min rats were allowed access to preweighed rat chow for 1 h. While control rats ate 6.15 ± 0.7 g, the DF-treated rats failed to eat. To test DF's effect on NPY release, rats were implanted with push-pull cannula aimed at the PVN. Following 3-5 days of recovery, they were food-deprived for 3 days, then injected with either DF or saline and perfused with aCSF. Samples, collected at 10 min intervals, were lyophilized and NPY measured by RIA. NPY levels in samples collected from DF and controls fluctuated considerably (range 2.0 - 218.3 pg/10 min). The mean rate of NPY efflux in the PVN 30-90 min after injection was 42.7 ± 9.7 pg/10 min in the DF group and 31.7 ± 12.7 pg/10 min in control rats. Thus, despite suppression of food intake by DF there was no significant change in NPY output in the PVN suggesting that inhibition of NPY release in the PVN may not be necessary for the anorectic effect of DF. It is likely that DF may act within the PVN or at other sites in the brain to inhibit the action of NPY at target sites in the PVN (Supported by NIH DK 37273).

57.5

THE ANORECTIC ACTION OF PERIPHERAL SEROTONIN (5-HT) IS NOT ATTENUATED FOLLOWING BLOCKADE OF ENDOGENOUS CCK-A RECEPTORS WITH DEVAZEPIDE IN RATS. K. Eberle-Wang and K.J. Simansky, Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

There is evidence that 5-HT-ergic antagonists can reverse anorexia following systemic cholecystokinin (CCK-8) (Stallone et al., 1989). Conversely, Cooper et al. (1989) demonstrated that the selective CCK-A receptor antagonist, devazepide (DVZ), reversed anorexia produced by fenfluramine. We examined the effect of devazepide pretreatment on anorexia produced by peripheral administration of serotonin as well as CCK-8 in rats given a 30-min test meal of sweetened mash following 3h of food deprivation. 5-HT (4.0 and 10.0 $\mu\text{mol/kg}$) or CCK-8 (4.0 nmol/kg) was administered (i.p.) 6 min prior to mash presentation and 24 min following pretreatment with either DVZ (.75 $\mu\text{mol/kg}$, i.p.) or its vehicle (0.1% DMSO in 0.5% carboxymethylcellulose). In these experiments DVZ did not alter anorexia produced by either 4.0 or 10.0 $\mu\text{mol/kg}$ 5-HT. However, under the identical testing conditions, DVZ reversed CCK-induced anorexia [$n=7-8$; $\text{veh/veh}=7.8\pm 0.6$; $\text{dvz/veh}=8.3\pm 0.8$; $\text{veh/cck}=3.5\pm 1.0$; $\text{dvz/cck}=7.3\pm 0.8$ g/30-min]. Subcutaneous injection of the same dose of DVZ also failed to alter the anorectic response to peripherally-administered 5-HT (4.0 $\mu\text{mol/kg}$, i.p.) [$n=8-9$; $\text{veh/veh}=10.6\pm 0.8$; $\text{dvz/veh}=8.9\pm 1.4$; $\text{veh/5-HT}=4.5\pm 1.0$; $\text{dvz/5-HT}=5.4\pm 1.0$ g/30-min]. Therefore, a dose of DVZ which completely blocked CCK-8-induced anorexia did not alter 5-HT-induced reductions in food intake under these testing conditions. These results suggest that peripherally-administered 5-HT produces anorexia in rats independently of CCK-A receptor stimulation. Supported by MH41987 to KJS.

D-FENFLURAMINE: EFFECTS ON MICROSTRUCTURE OF LICKING FOR WATER AND SUCROSE. D.A. Morris* and S.J. Cooper, Lab. of Psychopharmacology, University of Birmingham, B15 2TT.

We investigated the effects of d-fenfluramine (F) (0.3-3.0 mg/kg; i.p.), on i) characteristics of licking responses ii) microstructure of licking iii) temporal patterns of drinking in two groups of rats. Group I was adapted to water deprivation and trained to consume water, while Group II was not deprived but was trained to consume a palatable 3% sucrose solution. (F) at 1.8 and 3.0 mg/kg, significantly reduced sucrose and water consumption during a 20 min. test period ($P<0.01$; $N=10$). The groups showed no sign of impaired oral motor function except for a significant reduction in lick rate for Group I at 3.0 mg/kg, but these animals also displayed flattened body posture. Microstructural analysis showed that (F) reduced the mean duration of bursts of licking for water at 3.0 mg/kg ($P<0.05$; $N=10$), and sucrose at 1.8 mg/kg ($p<0.05$; $N=10$) and 3.0 mg/kg ($P<0.01$; $N=10$). The temporal distribution of drinking was different for the two groups. Group I showed a high initial level of drinking followed within 7.5 min. by clear signs of satiation; little drinking occurred after 10 mins. Group II consumed sucrose throughout the test period without signs of satiation. In both groups, after 3.0 mg/kg, drinking occurred more intermittently. Thus, (F) reduced water and sucrose intake by altering drinking patterns, and not by any general motor impairment. (This research is supported by a grant from IRIS).

CIRCADIAN EFFECTS OF D-AMPHETAMINE ON THE MEAL PATTERNS OF RATS R. Bauman and R. Pastel. Dept. of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307.

The meal patterns of non-deprived rats were used to evaluate the effects of d-amphetamine (AMP) on food intake. A 12 hour light/dark cycle was maintained in each rat's cage and at any time a rat could eat by pressing a lever once for each 45mg food pellet. A meal was defined as a bout of eating that was not interrupted by a pause longer than 10 mins. At first, either saline or a (0.5, 1.0, or 2.0 mg/Kg) dose of AMP was delivered intraperitoneally within the 30 minutes that preceded light offset; subsequently, the same doses were delivered before light onset.

During the dark, AMP caused a dose-dependent reduction of meal size and duration, but increased meal frequency. Similar, but non-significant effects were evident during the light. Despite an increase in meal frequency, AMP selectively reduced intake during the dark. Similar doses of DOI, a serotonergic agonist, also reduce meal size and duration during the dark, but only AMP induces a compensatory increase in meal frequency.

57.6

FEEDING SPECIFICITY OF 8-OH-DPAT. D.V. Coscina, J. Jarry*, and P.J. Fletcher. Section of Biopsychology, Clarke Institute of Psychiatry, and Department of Psychology, University of Toronto.

8-hydroxy-2-(di-n-propylamino)tetrain(8-OH-DPAT) is a serotonin_{1A} agonist known to increase solid as well as powdered food intake in satiated rats but does not enhance intake of sucrose or glucose solutions and can increase gnawing of wooden blocks. Therefore, some question exists surrounding its feeding specificity. This study investigated the ability of 8-OH-DPAT to elicit feeding in rats allowed to run in wheels as an alternative to eating. If this drug truly produces feeding specific effects, we expected the amount of food consumed to be the same in rats offered this choice compared to other rats wherein eating was the only option. Subjects were 24 adult male Sprague-Dawley rats adapted to living in running wheels with separate side cages equipped with food cups containing powdered lab chow. On different days, each animal received one of four doses of 8-OH-DPAT (0, 60, 120 and 240 $\mu\text{g/kg}$ s.c.) in saline 30 min prior to a 1 hr test. Half of the animals were allowed to both eat and run during these tests while the other half were confined to their side cages so that only eating was possible. One-way analyses of variance showed no reliable dose-dependent feeding in either test condition nor dose-dependent running in the choice group, due to high levels of baseline behaviours. However, when data across drug trials were averaged and compared to the saline condition, paired *t*-tests showed that rats only allowed to eat consumed more food after 8-OH-DPAT. Although paired *t*-test of running between saline and mean drug conditions revealed no reliable activity effects, rats offered the choice of eating and running did not overeat in response to the drug. These results suggest that when another source of motivated behaviour is made available to rats, 8-OH-DPAT does not reliably enhance intake. Such findings continue to question the specificity of feeding produced by this agent.

57.8

A COMPARISON OF THE ANORECTIC EFFECTS AND RECEPTOR SPECIFICITY OF MK212 OR QUIPAZINE IN PREVIOUSLY FOOD-DEPRIVED RATS S. M. Snyder, F. R. Davis*, L. L. Van Dyke*, R. A. Smith*, L. R. Reid*, and D. T. Wong. Toxicology Research Laboratories, Lilly Research Laboratories, A Division of Eli Lilly and Company, Greenfield, IN 46140.

The arylpiperazine class of serotonin (5-hydroxytryptamine, 5-HT) agonists is known to suppress food consumption in rats. In the present study, food-deprived male Sprague-Dawley rats were treated with 0.3-10 mg/kg of either MK212 or quipazine. A dose-related suppression of food intake was observed in both groups at 1 and 3 hours after food access. The anorectic effect of MK212 or quipazine at 5-10 mg/kg was reversed by pretreatment with 0.1-5 mg/kg i.p. of metergoline (a nonselective antagonist of 5-HT₁ and 5-HT₂ receptors) and partially reversed by pretreatment with 1-5 mg/kg i.p. of 1-naphthyl-piperazine (an antagonist of 5-HT_{1a,b,c} and 5-HT₂ receptors), or 3-10 mg/kg i.p. of mianserin, (an antagonist of 5-HT_{1c} and 5-HT₂ receptors). The anorexia was not reversed by 0.01-0.3 mg/kg i.p. of spiperone (a 5-HT_{1a} and 5-HT₂ antagonist). The anorectic effect of quipazine, but not MK212, was partially reversed by 1-10 mg/kg i.p. of ketanserin or 1-5 mg/kg s.c. of ritanserin (antagonists of 5-HT₂ receptors). The present findings suggest that the 5-HT₁ receptor is involved in mediating the anorectic effect of MK212, while the 5-HT₁ and 5-HT₂ receptors are involved in mediating this effect of quipazine.

57.10

EFFECTS ON FEEDING OF THE ALPHA1-ADRENOCEPTOR AGONIST CIRAZOLINE IN RATS. P.J. Wellman and B.T. Davies*. Dept. of Psychology, Texas A&M University, College Station, TX 77843-4235.

Activation of alpha₁-adrenoceptors within the hypothalamic paraventricular nucleus (PVN) in rats results in the suppression of feeding. Injections into the PVN of the alpha₁-adrenoceptor agonist phenylpropranolamine suppress feeding whereas antagonism of alpha₁-adrenoceptors within the PVN prevents the feeding suppressive action of systemically administered phenylpropranolamine (*Pharmacol. Biochem. Behav.*, 1991, 38: 905-908). In this study, we extended these experiments to assess the effects on feeding of intra-PVN and systemic administration of cirazoline (RAZ), a potent alpha₁-adrenoceptor agonist. Rats underwent stereotaxic placement of unilateral guide shafts aimed at the PVN and after recovery were shown to reliably eat (> 3.0 grams) following 25 nMol norepinephrine administered into the PVN. Feeding trials were 30 min in duration and were conducted in the late afternoon in non-food deprived rats. In Phase 1, the rats were treated with either 0.0, 0.05, 0.1, 0.2 or 0.4 mg/kg RAZ (IP) 15 min prior to each feeding trial. In Phase 2, intra-PVN injections of either 0, 3, 6, 12 or 24 nMol RAZ were given 6 min prior to each feeding test. Systemic injections of RAZ significantly suppressed feeding ($\text{ED}_{50} = 0.05 \text{ mg/kg}$) as did intra-PVN administration of RAZ ($\text{ED}_{50} = 23.4 \text{ nMol}$). Systemic RAZ administration suppressed consumption of water but to a lesser degree than the effect of systemic RAZ on food intake ($\text{ED}_{50} = 0.22 \text{ mg/kg}$). Intra-PVN administration of RAZ did not reduce water intake. These results support the hypothesis that alpha₁-adrenoceptors within the PVN act specifically to suppress food intake.

57.11

INTRACEREBROVENTRICULAR INJECTIONS OF α_2 -NORADRENERGIC AGONISTS INCREASE CALORIC INTAKE IN GENETICALLY OBESE (*ob/ob*) MICE. P. J. Currie and L. M. Wilson. Dept. of Psychology, University of Manitoba, Winnipeg, MB, CANADA R3T 2N2.

Hypothalamic paraventricular injections of norepinephrine [NE] and clonidine [CLON], the α_2 agonist, elicit feeding, particularly of carbohydrate, in the satiated rat. In the genetically obese (*ob/ob*) mouse, which exhibits hyperphagia and increased hypothalamic NE, we have previously shown that peripheral injection of CLON produces a biphasic effect on caloric intake (in 6-h meal-feeding *ob/ob* mice). The stimulatory effect of CLON (at doses of 25-50 μ g), associated with a preferential increase in carbohydrate ingestion, was blocked by α_2 receptor antagonism. The present studies examined the impact of ICV CLON and NE on feeding in obese and lean mice maintained under free-feeding conditions. Following adaptation to carbohydrate, fat, and protein diets, pre-satiated obese ($n=8$) and lean ($n=8$) mice were injected with CLON [10-20 nmol ICV] or sterile physiological saline, in counterbalanced order, approximately 1 h (16h00) before dark onset, in a 12 h L-D cycled colony room. (Fresh diets were given 1 h before testing to ensure maximal satiation). Macronutrient intakes were assessed at 1 h and 2 h postinjection. Similar tests were conducted with 1-norepinephrine-d-bitartrate [40-80 nmol ICV]. Drug effects were also examined in mice maintained on standard rodent chow diet. CLON and NE increased feeding of chow as well as macronutrient (caloric) intake in both *ob/ob* and lean mice, although carbohydrate intake was particularly affected in obese mice. This resulted in a substantial increase in the proportion of carbohydrate ingested, relative to total caloric intake, an effect that was less pronounced in lean mice, suggesting enhanced pharmacological sensitivity in the *ob/ob*. PARAVENTRICULAR HYPOTHALAMIC CLONIDINE INCREASES RATHER THAN DECREASES SUSCEPTIBILITY TO ACTIVITY-BASED ANOREXIA IN THE RAT. I.S. Bieg, S.N. Downing, and P.F. Aravich. Dept. of Anat. & Neurobiol., Eastern Virginia Medical School, Norfolk, VA 23501, and Veteran Affairs Medical Center, Hampton, VA 23667.

It has been proposed that anorexia nervosa is related to a reduction in the activity of the paraventricular hypothalamic (PVN) noradrenergic-feeding system. The purpose of this investigation was to determine if chronic administration of the alpha-2 adrenergic agonist, clonidine (CLON), into the PVN reduces susceptibility to activity-based anorexia (ABA) in the rat. Male Sprague-Dawley rats were stereotaxically implanted with a PVN cannula attached to an osmotic minipump. Exp 1 used seven groups of adolescent (192 g) rats chronically infused with either 0, .75, 3, 6, 12, or 48 nM CLON/hr. Following recovery from surgery all animals were exposed to ABA (1.5 hrs/day access to food; 22.5 hrs/day access to running wheels without food). It was found that CLON increased susceptibility (number of days to 25% weight loss) to ABA with the highest dose animals taking the least amount of time to reach the weight-loss criterion. There was also a dose-related suppression of food intake. No differences in activity levels were found. Exp 2 was similar to the first, except adult (292 g) rats were infused with three drug doses (0, 6, or 48 nM CLON/hour). No differences were found in the amount of food consumed or the amount of activity. However, both CLON-treated groups took less time to reach the weight loss criterion than the saline treated group. These data indicate that CLON infused chronically into the PVN does not produce hyperphagia and that, under these conditions, it exacerbates rather than attenuates susceptibility to ABA. AN ANORECTIC ACTION OF 2-METHYLSEROTONIN (2-Me-5-HT) WITHOUT APPARENT BEHAVIORAL TOXICITY. K. J. Simansky, F. C. Sisk* and J. Jakubow*, Dept. Pharmacology, Med. Coll. Pennsylvania, Philadelphia, PA 19129.

The serotonin (5-HT) analog, 2-Me-5-HT, is the prototypical agonist at 5-HT₂ receptors. 5-HT₂ antagonists are antiemetic agents. This study compared the actions of 2-Me-5-HT, given i.p., on feeding with its ability to act as an unconditional stimulus in a taste aversion paradigm (CTA). In a 30-min test using milk after overnight food deprivation, 2-Me-5-HT (.33-40 μ mol/kg) produced anorexia with 20 and 40 μ mol/kg reducing intakes by 38% and 59%. In a separate study using time-sampling analysis, 20 μ mol/kg 2-Me-5-HT decreased milk intake by 27% (16.8 \pm 1.6 ml vs. 23.1 \pm 1.8 ml for controls, $p < .05$). 2-Me-5-HT reduced feeding frequency, shortened meal length and increased resting without altering nonfeeding activity or the normal periprandial sequence of behavior. This dose of 2-Me-5-HT was not an aversive stimulus in a two-bottle CTA although 20 μ mol/kg of 5-HT (but not 10 μ mol/kg) does produce a taste aversion. Neither the 5-HT₂ antagonist, methysergide (METHY) nor the 5-HT₃ antagonist, ICS 205-930 antagonized anorexia after 2-Me-5-HT in the milk test. METHY did prevent the anorectic effect of the ID₅₀ dose of alpha-Me-5-HT, a 5-HT₂ agonist. 2-Me-5-HT also decreased 30-min intakes of mash after deprivation (16.5 \pm 1.6 g vs. 32.8 \pm 1.4 g, con, $p < .01$) and METHY and ICS (20 μ mol/kg) failed to reverse the anorexia. It appears that 2-Me-5-HT can inhibit feeding without producing behavioral toxicity. A receptor not of the serotonin-1, 2, 3 or 4 subclasses seems to mediate this action. Grant MH41987 to K.J.S.

AUTORADIOGRAPHIC ANALYSIS OF ALPHA2-NORADRENERGIC RECEPTORS IN HYPOTHALAMIC NUCLEI: RELATION TO LIGHT/DARK CYCLE AND NUTRITIONAL STATE OF ANIMALS. G.B. Kovachich¹, M. Jhanwar-Unival², S.F. Lejbowitz² VA. Med. Ctr.¹, Philadelphia PA, Dept. of Psychiatry, Univ. Pa.¹, Philadelphia PA and The Rockefeller Univ.², New York NY.

Alpha2-noradrenergic receptors in the paraventricular nucleus (PVN) of rats are believed to be involved in the control of feeding behavior, particularly at the onset of the dark cycle. Binding procedures with [3H]p-aminoclonidine have shown that the density of alpha2-adrenoceptors in the PVN increases at dark onset and declines after food deprivation (FD). The present study used quantitative autoradiography to examine further the alpha2-adrenoceptor density in the PVN and other hypothalamic areas under similar conditions.

Male Sprague-Dawley rats, maintained on 12 hr light/dark cycle, were sacrificed at light and dark onset of period and after 48 hrs FD. Binding was done using alpha2-adrenoceptor antagonist [3H]idazoxan (3nM), with non-specific binding determined in the presence of phentolamine. The results show: a) at the dark onset, relative to light onset, there occurs an increase in alpha2-adrenoceptors in the magnocellular PVN (PVNm; $p < 0.05$) and a trend towards an increase in the parvocellular PVN (PVNp; $p < 0.09$); b) a decline in alpha2-adrenoceptors in both the PVNm and PVNp after FD, as compared to satiated condition; c) opposite changes in alpha2-adrenoceptor density in the median eminence (ME), namely an increase at the light onset and after FD. The findings confirm, through autoradiographic measurements, that PVN as well as ME alpha2-adrenoceptors shift in relation to the diurnal cycle and nutritional state.

STIMULATORY EFFECTS OF THE ALPHA-2-ADRENOCEPTOR ANTAGONIST IDAZOXAN ON FOOD AND WATER INTAKE IN RATS H. C. Jackson* and I. J. Griffin*. (SPON: Brain Research Association). Reckitt & Colman Psychopharmacology Unit, School of Medical Sciences, University of Bristol, Bristol, BS8 1TD, England.

Idazoxan is an alpha-2-adrenoceptor antagonist which binds with high affinity at non-adrenoceptor idazoxan binding sites (NAIBS). These sites are localised in the hypothalamus and area postrema (Hudson et al. *Br. J. Pharmacol.* 102:4P, 1991) and may play a role in the control of appetite. Hence we have compared the effects of idazoxan on food and water intake with those of its 2-ethoxy and 2-methoxy analogues RX811059 and RX821002, which act more selectively at alpha-2-adrenoceptors, having only minimal affinity at NAIBS (Mallard et al. *Br. J. Pharmacol.* 102:221P, 1991), and with those of the peripherally-acting alpha-2-antagonist L-659,066 (Clineschmidt et al. *J. Pharmacol. Exp. Ther.* 245:32, 1988).

Experiments were performed during the light phase on singly-housed male Wistar rats (250-350g) with free access to powdered diet and water at all times. Feeding jars and water bottles were weighed at the time of drug administration (i.p.) and after 1, 2 and 4 hours to enable calculation of mean group cumulative intakes g/kg rat weight \pm s.e. mean ($n=6$).

Idazoxan (1, 3, 10 mg/kg) significantly increased both food (over five-fold) and water (two-fold) intake in the first 1-2 hours after injection. RX811059 (0.3, 1, 3 mg/kg), RX821002 (0.3, 1, 3 mg/kg), and L-659,066 (1, 3, 10 mg/kg) had no effect on feeding during the 4 hour test but the highest doses of each antagonist significantly increased drinking (over two-fold) in the first 1-2 hours following drug administration. These results suggest that the effects of idazoxan on water intake may be mediated by blockade of peripherally-situated alpha-2-adrenoceptors whereas its effects on feeding may be related to its high affinity at NAIBS.

THE STRYCHNINE-INSENSITIVE GLYCINE RECEPTOR ANTAGONIST 7-CHLOROKYNUINIC ACID INDUCES FEEDING IN SATIATED RATS. T.L. Sorrels and E. Bostock. Department of Psychology, Queens College-CUNY, Flushing, NY 11367.

We tested whether the strychnine-insensitive glycine receptor antagonist, 7-chlorokynurinic acid (7-CK), induced feeding, stereotypies, and locomotor deficits following icv administration. Using a within subjects design, six rats were administered vehicle (v), 10, 20, or 30 μ g of 7-CK icv 1/wk for 4 weeks in a random order. Immediately following the injections food intake was measured for 2 30 min intervals, and the presence of stereotypies and locomotor deficits was rated 1/min for 60 min. 7-CK induced a significant dose-dependent increase of food intake. The mean intake for the v, 10, 20, and 30 μ g groups was .34, 1.5, 1.9, and 3.6 g respectively. The mean latency for the onset of this effect was 4.1 min in the 30 μ g group. There was also a dose-dependent increase in locomotor deficits. No stereotypies were observed. A second group of rats received icv v, .015, .15, 1.5, or 3.0 μ M D-serine (D-s), a strychnine-insensitive glycine receptor agonist, 2 min prior to icv injection of 20 μ g 7-CK, and food intake was measured for 60 min. D-s produced a significant dose-dependent reduction of 7-CK induced intake, such that the 3 μ M D-s/20 μ g 7-CK group did not significantly differ from the v/v group. These findings suggest a role of the strychnine-insensitive glycine receptor, either via modulation of the NMDA receptor or otherwise, in the regulation of food intake.

57.17

CYCLIC AMP REDUCTION IN THE PREPYRIFORM CORTEX AFTER AN AMINO ACID IMBALANCED DIET. D.W. Gietzen, S.M. Wimberg* and O.R. Rogers. Depts. VM:Physio. Sci., Med: Psychiatry and Food Intake Lab., Univ. Calif. Davis, Davis, CA 95616.

The anorectic responses to imbalanced amino acid diets (IMB) have been associated with an increase in norepinephrine (NE) activity and protein synthetic processes in the prepyriform cortex (PPC), an area essential for the initial feeding responses of rats to IMB. Clonidine, an α_2 autoreceptor agonist increased intake of IMB, suggesting that NE acts at the α_2 receptor in the feeding responses to IMB. Because clonidine can inhibit the production of cyclic AMP (cAMP) via the α_2 receptor and cAMP has been linked to protein synthesis, we measured cAMP concentrations in the PPC of rats fed either threonine IMB or a basal control diet (BAS). After prefeeding BAS for 10 days, rats were given IMB or BAS for 2 hours at dark onset. They were rapidly decapitated, the brains frozen in liquid N_2 , and stored at $-80^\circ C$. The PPC and the anterior cingulate cortex (AC), which does not show the changes in NE after ingesting IMB, were dissected, sonicated in ETOH/HCl, centrifuged and the supernatant evaporated under N_2 . The pellet was assayed for the concentration of cAMP using a kit (Amersham). To control for any generalized changes in cAMP, the data for the PPC were compared to those for the AC. In animals fed IMB, the cAMP in PPC = 0.84 ± 0.12 (mean \pm SE, pmol/mg wet tissue wt) AC = 2.22 ± 0.16 ; for the BAS group PPC = 1.2 ± 0.22 , AC = 1.82 ± 0.31 ; $p < 0.05$ due to differences between tissue values in IMB. This decrease in cAMP in the PPC after eating IMB suggests a link between the NE system and protein synthesis in the PPC upon ingestion of imbalanced amino acid diets. Supported by USDA: CRCR-1-2418 and NIH: BRS-RR05457.

STRESS, HORMONES AND THE AUTONOMIC NERVOUS SYSTEM

THREE SESSIONS OF TAILSHOCK PRODUCE AN INCREASE IN THE PLASMA CHOLESTEROL LEVELS OF RATS MAINTAINED ON A LOW-FAT DIET. Francis X. Brennan, Jr., R. F. Soames Job*¹, Linda R. Watkins and Steven E. Maier. Psychology Department, University of Colorado, Boulder, CO. 80309, ¹Psychology Department, University of Sydney, Sydney, Australia.

Increases in plasma cholesterol have been demonstrated to be a risk factor for the development of atherosclerosis, the most common form of Coronary Heart Disease (CHD). Animal subjects exposed to stress typically show elevated levels of cholesterol in plasma, relative to nonstressed controls. These studies, however, generally utilized relatively long stress procedures, and also used animals maintained on a high-cholesterol diet. As a first step towards analyzing the mechanisms responsible for stress produced increases in cholesterol, we sought to determine whether a brief stress paradigm might produce reliable increases in plasma cholesterol in animals maintained on standard lab chow.

Our experimental animals were male Sprague-Dawley rats, approximately 90 days old at the beginning of the stress procedure. Subjects had free access to standard lab chow and water, with food being removed from all animals four hours prior to all blood samples in order to minimize acute feeding-induced variations in cholesterol levels. A stress session consisted of 100 1.6 mA 5 sec tail shocks, presented on the average of one shock per minute. Stressed animals were given one stress session a day for three consecutive days. Blood samples were taken 2 hrs after the end of each shock session. Results indicated that stressed animals had significantly higher plasma cholesterol levels than did nonstressed controls after the third stress session.

These results differ from prior reports in the literature in both the length of the effective stress procedure, and the lack of a high cholesterol diet. We believe that this paradigm will allow us to begin to efficiently investigate the neural and hormonal mechanisms responsible for the cholesterol increases observed in our stressed subjects. Preliminary research suggests that the endogenous opioid peptides, for example, may be involved in mediating stress-induced hypercholesterolemia. Supported by NSF BNS 88-09527.

STRESSFUL INTERVIEW INCREASES PLASMA LEVELS OF THYROID STIMULATING HORMONE (TSH) AND GROWTH HORMONE (GH) IN HUMANS. E.H. Mougey, M.A. Oleshansky and J.L. Meyerhoff. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

As part of a continuing effort to study neuroendocrine responses to psychological stress in humans, we examined plasma TSH and GH responses in normal male military volunteers (N=16) undergoing a 30-minute job-related structured interview. The soldiers gave written informed consent prior to appearing before a panel of senior non-commissioned officers to compete for the honor of "Soldier of the Month". This type of interview has been shown to elicit marked plasma ACTH and cortisol increases in these subjects as previously reported [Psychosomatic Medicine, 50, 295-303 (1988)]. Blood samples were taken at three time points prior to entering the room, twice while participating in the interview and two times after leaving the room. Samples were drawn from an indwelling catheter into EDTA tubes and the plasmas were stored frozen until assayed. IRMA kits (Nichols Institute) were used to determine TSH and GH in unextracted plasmas. ACTH (INCSTAR Corp.) and cortisol were determined by radioimmunoassay in extracted plasmas.

ACTH and cortisol showed significant increases as a result of the interview, replicating our previous report. Mean plasma TSH levels increased 13% during the interview and returned to baseline levels immediately afterward. Mean plasma GH levels were slightly elevated at the end of the interview and continued to increase to four times baseline levels immediately afterward.

STRESS DEPRESSES [^{125}I]MELATONIN BINDING IN RAT SUPRACHIASMATIC NUCLEI. C.Tenn* and L.P. Niles. Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

The effect of swim-stress, which increases circulating melatonin, was examined on high-affinity binding of [^{125}I]melatonin ([^{125}I]MEL) in rat suprachiasmatic nuclei (SCN). Twenty min after a 10-min swim at $20 \pm 2^\circ C$, stressed animals and controls were rapidly decapitated and trunk blood and brains collected. Serum melatonin levels were significantly higher in stressed animals than in controls ($p < .001$). Saturation binding was measured in washed hypothalamic sections (20 μ m) in which binding is predominantly confined to the SCN. There were no differences in binding affinity between the two groups (control $K_d = 52 \pm 2$ pM; stress $K_d = 47 \pm 3$ pM), but the density of receptor sites in the stress group was significantly lower (control $B_{max} = 6.4 \pm 0.3$ fmol/mg protein; stress $B_{max} = 3.3 \pm 0.2$ fmol/mg protein; $p < .001$, $n=4$).

These findings indicate that an acute stress-induced increase in circulating melatonin causes rapid down-regulation of SCN receptors for melatonin. Supported by NSERC Canada.

58.4

EFFECT OF STRESS ON CHOLECYSTOKININ (CCK) RECEPTOR LEVELS IN THE RAT BRAIN. K.D. Richardson Morton, L.D. Van de Kar*, J.B. Ackman and N.J. MacLusky. Div. of Reproductive Sci., Univ. of Toronto, ONT M5G 1L7, and *Dept. of Pharmacology, Loyola Univ. Med. Ctr, Maywood, IL 60153.

Adrenalectomy (ADX) increases CCK immunoreactivity in corticotrophin-releasing factor (CRF) neurons of the paraventricular (PVN) nucleus (Mezey et al PNAS 83:3510, 1986) suggesting that, in addition to its role in the control of appetite, CCK may also be involved in neuroendocrine responses to stress. In female rats, CCK receptor levels are down-regulated by estrogen (Morton et al., *Neurosci. Abstr* 451.3, 1990; Akesson et al. *Neuroendo* 45:257, 1987). We tested the hypothesis that steroids involved in stress responses might also modulate CCK receptor levels in the brain. Male rats were either ADX, sham-ADX, or ADX and treated with dexamethasone (DEX, 200 μ g/kg/day, s.c., for 3 d). Animals were killed on day 3 and their brains immediately frozen. CCK receptors in brain sections (10 μ m) were labelled by incubation with 0.1 nM [^{125}I]CCK-8 (1h, r.t.) in 50 mM Tris-MgCl₂ buffer (pH 7.7) containing 0.2% bovine serum albumin, 1mM dithiothreitol, and 0.2% bacitracin, then exposed against Hyperfilm (Amersham) for 2 weeks. Film densities were assessed using computerized densitometry in the following brain regions: cingulate cortex, hippocampus, ventromedial nucleus and PVN. No differences were observed in CCK binding between ADX and sham-ADX rats, for any brain region. However, in the ADX DEX-treated group, CCK binding was slightly but significantly lower than in controls. Addition of DEX ($10^{-6}M$) to brain sections *in vitro* had no effect on CCK binding. To study the effects of increased endogenous glucocorticoid levels, male rats were stressed by immobilization for 20 min. on 5 consecutive days and sacrificed immediately following the last immobilization. Control animals were handled identically, but did not undergo the stress procedure. The stressed rats had significantly increased corticosterone levels and gained less weight than controls. However, no significant differences were observed in CCK receptor levels between control and stressed rats, in any brain region. These data suggest that high doses of DEX may have a slight inhibitory effect on CCK binding in the brain; but that neither physiological levels of adrenal steroids nor 5-day immobilization stress have a significant impact on brain CCK receptor levels (Supported by MRC Canada).

BASAL SYMPATHOADRENAL FUNCTION IN POST-TRAUMATIC STRESS DISORDER. M. M. Murburg, M. E. McFall*, E. Petric* and R. C. Veith*, Seattle VAMC, University of Washington, Seattle WA 98108

Previous findings of elevated resting blood pressure (BP) and heart rate (HR) in patients with Post-traumatic Stress Disorder (PTSD) suggest that basal sympathetic nervous system (SNS) activity may be increased in this disorder. We have measured Epinephrine (EPI) and Norepinephrine (NE) in arterialized venous plasma (Study #1) and assessed plasma norepinephrine kinetics in arterialized plasma using a radioisotope dilution technique (Study #2) in order to investigate basal SNS function in patients with PTSD compared with asymptomatic normal controls. In the first study, eleven Viet Nam combat veterans (mean age=40.3 years) with PTSD were compared with eleven asymptomatic normal controls (mean age=40.2 years). PTSD patients did not exhibit statistically significant differences from controls in HR (62±7 vs 62±1 beats per minute), systolic (124±11 vs 120±7 mm hg) or diastolic BP (79±8 vs 76±7 mm hg) or in resting plasma levels of NE (237±52 vs 232±70 pg/ml) or EPI (67±33 vs 81±36 pg/ml). In the second study, six Viet Nam combat veterans with PTSD diagnosed by the SCID (mean age=40) and five asymptomatic normal controls (mean age=37) have been compared to date. Neither the rate of appearance of NE into plasma (0.211±0.033 vs 0.351±0.109 µg/min/m²), nor the rate of clearance of NE from plasma (1.259±0.128 vs 1.363±0.207 L/min/m²) differed significantly between the PTSD patients and the control subjects. The results of these two studies do not lend support to the hypothesis that SNS activity is tonically increased in patients with PTSD.

NEUROCHEMICAL RESPONSES TO ADRENALECTOMY. K. Kolasa and R. S. Jope. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

The hippocampus appears to be one of the principal targets of glucocorticoids in the brain. Removal of circulating glucocorticoids by adrenalectomy of adult male rats results in degeneration of granule cells in the dentate gyrus (Sloviter et al., Science 243:535, 1989). Therefore, we examined behavioral and neurochemical responses to adrenalectomy in rats.

Adrenalectomy caused a slight deficit in the acquisition of a conditioned avoidance response measured after 4 weeks. Choline acetyltransferase activity, a marker of cholinergic cells, was not different from controls 7 or 28 days after adrenalectomy. Therefore, the learning impairment did not appear to be due to a cholinergic lesion.

Phosphoinositide hydrolysis is an important second messenger-generating system which can modulate calcium concentrations and protein kinase C activity. Several types of brain lesions have been reported to result in enhanced receptor-activated phosphoinositide hydrolysis. Adrenalectomy caused increased stimulation of phosphoinositide hydrolysis induced by norepinephrine or by excitatory amino acid agonists when measured 4 weeks after adrenalectomy in hippocampal slices, but did not alter the response to carbachol and had only slight effects in cortical slices.

These results show that adrenalectomy alters the modulation of phosphoinositide metabolism in rat hippocampus.

58.9

SUBCHRONIC CORTICOSTERONE TREATMENT LEADS TO MINOR LEARNING IMPAIRMENT IN THE RADIAL ARM MAZE IN YOUNG RATS. A. Levy and S. Dachir*. Pharmacology Dept., Israel Inst. Biological Research, Ness Ziona, 70450, ISRAEL.

High levels of corticosterone are associated with stress, and may lead to hippocampal damage and memory impairments. Corticosterone slow release pellets, implanted subcutaneously into four months old Fischer rats (200 mg released over 3 weeks), resulted in elevated corticosterone plasma levels, comparable to those found in rats under stress. Radial arm maze training which followed this treatment revealed significant difference between corticosterone and placebo treated groups only in one of the monitored parameters (first error entry, n=12 in each group, p<0.05 by ANOVA). Only minor morphological changes were found in the hippocampal area under histological observations. Longer period of treatment might be needed to substantiate a more robust cognitive impairment.

58.6

SWIM STRESS INDUCED ALTERATIONS IN REGIONAL 2-DEOXYGLUCOSE (2-DG) UPTAKE AND C-FOS PROTEIN INDUCTION: DIFFERENTIAL MODIFICATION BY IMIPRAMINE. G.E. Duncan, K.B. Johnson, W.E. Stumpf, and G.R. Breesse Brain and Development Research Center, School of Medicine, University of North Carolina, Chapel Hill, NC 27599

The effects of imipramine were assessed on regional brain 2-DG uptake and c-fos like immunoreactivity in rats that were processed in the forced swim test. Swim stress induced a marked increase in 2-DG uptake in a specific region of the lateral septal nucleus (LSN). In rats given IMP, the stress-induced activation of the LSN was almost completely abolished. Swim stress induced c-fos in a select region of the LSN that corresponded in part to the region that displayed increased 2-DG uptake. However, IMP treatment did not antagonize the induction of fos in the LSN. Swim stress also induced fos protein in the parvocellular paraventricular nucleus (PVN) and IMP antagonized this response. Swim stress had no apparent effect on 2-DG uptake in the PVN. The results show that IMP antagonizes swim stress induced activation in select brain regions and that 2-DG uptake and c-fos induction provide distinct and complementary information. Supported by MH 39144 and MH-33127.

STRESS-INDUCED CHANGES IN DAILY ACTIVITY IN THE RAT ARE MODULATED BY DIFFERENT FACTORS THAN ARE STRESS-INDUCED ESCAPE LEARNING DEFICITS. W.W. Woodmansee, L.H. Silbert*, & S.F. Maier. Dept. of Psychology, Univ. of Colorado Boulder, CO 80309

Exposure to stressful stimuli produces a variety of behavioral alterations in the rat. The escape learning deficit that follows exposure to some stressors is one of the best studied. Escape learning deficits in tasks such as shuttlebox escape occur following inescapable shocks (IS), but not following equal amounts of escapable shock (ES). This behavioral change persists for 48-72 hours after IS, can be blocked by administration of opiate antagonists before IS, and can be produced by antagonists such as FG-7142.

More recently, we have found a stress-induced behavioral change that follows a more prolonged time course. Daily running wheel activity (RWA) was depressed for 14-42 days following exposure to IS. Experiments were undertaken to determine whether factors known to be important in the development of the short-term behavioral changes following IS would also be important in the production of the long term effect of IS on daily RWA. We assessed the impact of three factors on daily RWA: escapability of the stressor, reversal with naltrexone pretreatment, and induction with FG-7142. The results indicated that daily RWA is not sensitive to escapability of the stressor. IS and ES produced the same degree of depression of daily RWA. Naltrexone (10 mg/kg) given 20 min prior to IS did not prevent the stress-induced reduction in daily RWA. Additionally, rats given the anti-genetic β -carboline, FG-7142 (10 mg/kg), did not differ from controls. FG-7142 did not mimic IS in its ability to reduce daily RWA. These results suggest that the prolonged reduction in daily activity following IS is a fundamentally different phenomenon than many of the behavioral consequences of IS that are of shorter duration. Supported by NSF Grant BNS 88-09527.

CHRONIC STRESS: EFFECTS OF STRESS CONTROLLABILITY. G.J. Kant, R.A. Bauman, S.M. Anderson and E.H. Mougey. Dept. Medical Neurosciences, Walter Reed Army Institute of Research, Washington DC 20307-5100.

Our laboratory has been characterizing the physiological and behavioral effects of chronic stress utilizing a rodent paradigm in which rats are maintained 24hr/day in operant cages and required to avoid/escape signalled intermittent footshock. We have shown that rats exposed to this stressor have elevated levels of plasma corticosterone, decreased leverpressing for food pellets and disturbed circadian temperature rhythms. However, after several days, food intake, corticosterone levels and temperature rhythms gradually return toward control levels. In the present study, a yoked stressed group, which was given no control over shock delivery, was added to the paradigm. Each yoked rat was paired to a controlling stressed rat and the controlling rat could avoid/escape for both rats by pulling a chain. After 3 days of stress, yoked animals were found to have higher levels of plasma corticosterone than the paired controlling rats, greater disruptions of temperature rhythms and more marked decreases in leverpressing for food.

58.11

ANIMAL MODELS FOR POST-TRAUMATIC STRESS DISORDER. B.I. Diamond, M.B. Hamner, T.L. Chalker, and R.L. Borison. Medical College of Georgia, Augusta, GA 30912

It has been hypothesized that exposure to inescapable stress resulting in learned helplessness (LH) may provide an animal model for post-traumatic stress disorder (PTSD). Changes in noradrenergic function may occur in both LH and PTSD. Male Sprague Dawley rats (160g) underwent either acute stress (SA) or 6 days of either chronic variable (CVS) or chronic homogeneous stress (HMS). They were then challenged with either yohimbine (YB) (7.5mg/kg, i.p.) or clonidine (CL) (0.1mg/kg, i.p.) to stimulate or inhibit norepinephrine release. The effect of these drugs on immobility during a 5 min. swim test was quantified. In all groups CL antagonized the effects of stress (SA $1.2 \pm .2$ (mean \pm SD); CVS 1.0 ± 1.4 ; HMS 3.1 ± 1.1 ; $p < .05$). There were no differences between the types of stress on immobilization. Moreover, SA produced the same effects as did chronic. The differential effects of YB ($4.25 \pm .84$) and CL ($1.18 \pm .25$) were most noticeable in the the SA group, indicating that SA may be a better model for PTSD than chronic stress.

58.13

BEHAVIOR AND PHYSIOLOGY OF SOCIALLY STRESSED RATS: ANTI- AND PRO- STRESS EFFECTS OF ANXIOLYTICS. W. Tomatzky and K.A. Miczek. Dept. of Psychology, Tufts University, Medford, MA 02155

In an intense social confrontation an intruder rat is briefly forced to the limits of its physiological and behavioral capacities. The function of these acute reactions is to cope with the high demand of this significant situation. However, potentially detrimental long-term consequences of such stressful confrontations persist. In an attempt to delineate the magnitude and temporal sequence of social stress responses, we implanted adult male Long Evans rats with senders. The transmitted heart-rate (HR) and temperature (T_c) data were monitored via telemetry (Mini-Mitter, Dataquest III) and evaluated together with the recorded data on behavior and ultrasounds. Repeated daily defeats on 5 consecutive days changes circadian rhythmicity (cosinor analysis) of HR and T_c . The amplitude of these rhythms remains decreased for 10 days after the last contact with the resident rat, indicating the longlasting and severe impact of the challenge on physiological regulation. In order to investigate the potential anti-stress effects of anxiolytic drugs, we pretreated intruder rats with diazepam (1 - 10 mg/kg, IP), gepirone (0.3 - 6.0 mg/kg, IP), and clonidine (0.01 - 0.1 mg/kg, IP). In contrast to the sedative effects on locomotor activity, none of the compounds affected the prominent defensive postures and acts of the experimental rat in reaction to intense threats of the resident rat. The large elevations of T_c and HR during the threat period are dose-dependently decreased by clonidine. The hyperthermia is attenuated at the higher gepirone and diazepam doses. Diazepam as well as gepirone do not effectively decrease the HR response. Ultrasonic vocalizations (20-30 kHz range) emitted at high rate are not decreased by clonidine nor diazepam. At 3.0 and 6.0 mg/kg these vocalizations are almost abolished by gepirone.

Physiological and behavioral stress markers are alleviated differentially by the compounds. However, the prevention to cope within a relevant behavioral context by a compromising dose may by itself induce an increased stress response.

THE EFFECTS OF MUSIC TEMPO VERSUS MUSICAL STYLES UPON MUSCLE TENSION REDUCTION. D. F. Harris, and S. R. Harris. Harris and Associates, 715 W. Sherman, Harrison, AR 72601

The primary purpose of this study was to discover if there was a difference in relaxation states while listening to fast versus slow music and secondarily, if there was a difference between rock music versus classical music. Eight subjects listened to either fast classical, fast rock, slow classical, or slow rock conditions. An Autogenic 1100 feedback myograph was used to measure muscle tension across the frontalis muscle. Relaxation was inferred by lowered muscle tension levels after a five minute session. Significance was found at the $p < .01$ level concerning musical tempo but not style. Further statistical analysis indicated a slow tempo would significantly ($p < .01$) decreased muscle tension. These results could indicate a specific tempo or rhythm may synchronize with a biological homeostatic rhythm.

58.12

GASTRIC EROSION FORMATION INDUCED BY LESIONS OF THE SUBSTANTIA NIGRA OR VENTRAL TEGMENTAL AREA. C.V. Grijalva, B. Roland, G. Burcham*, K. Branch*, T.M. Nguyen*. Dept. of Psychology, UCLA, Los Angeles, CA 90024.

Lateral hypothalamic (LH) lesions produce a host of behavioral and autonomic symptoms including anorexia, sensorimotor deficits, and glandular gastric erosions. Many of these symptoms have been attributed to disruption of dopamine systems originating in the pars compacta, substantia nigra (SN) or ventral tegmental area (VTA). The present study examined the possibility that direct damage to the SN or VTA induces gastric erosions. Groups of rats were food deprived (18 h), anesthetized, and then given control operations (N=9) or electrolytic lesions of the SN (N=7) or VTA (N=11). Animals were sacrificed 24 h postoperatively. Only Group SN display significantly more gastric erosions than controls ($p < .05$). A second experiment demonstrated that the formation of erosions induced by SN lesions could be blocked by atropine methyl nitrate. The results suggest that the nigral striatal system may be involved in parasymphatically mediated gastrointestinal function. (Supported by UCLA Univ. Research Grant PZ-06)

58.14

SELECTIVE BREEDING OF RATS FOR SUSCEPTIBILITY TO THE EFFECTS OF UNCONTROLLABLE SHOCK: ELECTROPHYSIOLOGICAL AND BEHAVIORAL EFFECTS. P.A. Scott, C.A. Lorenz, E.F. Hargrove, and J.M. Weiss. Dept. of Psychiatry, Duke University Medical Center, Durham, NC 27710

One effect of exposure to uncontrollable electric shock in rats is to decrease motor activity as measured in a swim test; however, not all animals within a given population show this effect. We have previously reported the results of three generations of selective breeding of Sprague Dawley rats to be either susceptible or resistant to this effect of uncontrollable shock (Scott, Cierpial, & Weiss, *Soc. Neurosci. Abstr.*, 15, Part 1, p.801, 1989). In the current (5th) generation, heritability remains a significant factor; rats bred for susceptibility (SUS) continue to show significantly lower levels of activity in the swim test after stress while rats bred for resistance (RES) show no such decrease in activity.

Decreased swim activity is correlated with increased levels of spontaneous and evoked activity of locus coeruleus (LC) neurons (Simson & Weiss, *Neuropsychopharmacology*, 1, 287-295, 1988). When electrophysiological recordings of single unit activity were made, LC neurons of SUS rats showed significantly higher levels of both spontaneous and evoked activity following stress compared to nonstressed SUS rats, while LC neurons of RES rats did not show significant increases in either spontaneous or evoked activity compared to nonstressed RES rats. Interestingly, the evoked activity of nonstressed RES rats was significantly higher than the evoked activity of nonstressed SUS rats.

SUS and RES rats were tested for differences on a number of behavioral measures known to be affected by shock exposure, including 24 hr homecage activity and food and water intake. Differences in these measures did not match the differences seen in the swim test. For example, male SUS rats displayed significantly depressed homecage activity (during dark period) for 3 days after stress, while male RES rats showed depressed activity for a full two weeks after stress.

59.1

EFFECTS OF THE 5-HT_{1A} AGONIST GEPİRONE DEPEND UPON PRE-TREATMENT TIME. J.B. Richards, D.C. Jolly, K.E. Sabol, L.S. Seiden. University of Chicago, Dept. of Pharm./Phys. Sci., Chicago, Ill 60637

The differential reinforcement of low rate 72-s (DRL 72-s) schedule reinforces only those responses which occur > 72-s since the last response. In rats trained to bar press for water, the contingency of reinforcement enforced by the DRL 72-s schedule generates a pattern of responding which is very sensitive to drug effects. This pattern of responding is reflected in the distribution of interresponse times (IRTs) which has a peak (modal point) near the 72-s criterion for reinforcement. The effects of drugs on the IRT distribution can be quantitatively characterized by measuring the temporal location of the peak and the area under the curve formed by the IRT distribution. Antidepressant drugs cause the temporal location of the peak to shift toward longer IRT durations without decreasing the area under the curve.

Previously, we reported that in rats trained on the DRL 72-s schedule (1hr sessions) the 5-HT_{1A} agonist gepirone causes dispersion of the IRT distribution as indicated by a decrease in the area under the curve. Here we report that this effect is dependent upon pre-treatment time. When given with a pre-treatment time of 0 min, gepirone (2.5, 5.0, 10.0 mg/kg) disperses the IRT distribution toward random, decreasing the area under the curve. In contrast, gepirone (2.5, 5.0, 10.0 mg/kg) given with a pre-treatment time of 1 hr does not decrease the area under the curve and shifts the peak location to the right. This latter effect is consistent with the effects seen with antidepressant compounds.

Dispersion of the IRTs associated with gepirone (0 min) could be mediated by decreased 5-HT release produced by stimulation of 5-HT_{1A} autoreceptors. (Supported by: MH-11191; RSA-10562 L. Seiden)

ESTROUS CYCLE MODULATION OF THE HYPERPHAGIA INDUCED BY THE 5-HT_{1A} AGONIST, 8-OH-DPAT. S. Salamanca*, M. Pastuszkka-Caldarola* and L. Uphouse. Department of Biology, Texas Woman's University, Denton, Texas, 76204.

Treatment with the 5-HT_{1A} agonist, 8-OH-DPAT, produces several behavioral syndromes characteristic of increased serotonergic activity; other behaviors appear paradoxical. Since 5-HT inhibits eating behavior, the unexpected hyperphagia elicited by 8-OH-DPAT has been attributed to the presence of 5-HT_{1A} autoreceptors on raphe neurons. This is of particular interest since 8-OH-DPAT's ability to decrease firing of raphe neurons is attenuated by estradiol treatment. Thus, variations in raphe autoreceptor activity could contribute to known estrous cycle variations in eating behavior. 8-OH-DPAT (0.1-1.0 mg/kg, s.c.) -induced hyperphagia was examined in male rats and in female rats on the days of diestrous 2, proestrus and estrus. Hyperphagia was most evident in males and in diestrous females and least evident in proestrous and estrous females. Studies of 8-OH-DPAT-induced hypothermia (thought to result from an action at postsynaptic sites) demonstrated a significant sex difference, but changes during the estrous cycle were small. Thus, the present findings suggest that the somal/dendritic 5-HT autoreceptor may be functionally modulated during the estrous cycle.

8-OH-DPAT DISRUPTS PREPULSE INHIBITION OF ACOUSTIC STARTLE IN WISTAR RATS. R.E. Kucharik*, J.A. Moyer and K.L. Marquis. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

Prepulse inhibition (PPI) is a measure of sensorimotor gating that may be elicited in humans as well as in animals. In rats, previous studies have described the ability of dopaminergic agonists and glutamatergic antagonists to disrupt PPI. In addition, these animal studies have shown that GABA antagonists and cholinergic agonists also disrupt the PPI response. The role of serotonin (5-HT), however, has not been examined in depth. In the current study, the selective 5-HT_{1A} agonist 8-OH-DPAT (0.1-3.0 mg/kg sc) was given to male Wistar rats (Charles River) 30 minutes prior to being placed in a San Diego Instruments startle apparatus. Startle responses to a 114 dB acoustic stimulus (PULSE) were collected (digitized over 100 ms) during trials with and without a 71 dB stimulus (PREPULSE/PULSE occurring 100 ms prior to PULSE) against a 65 dB background. Trials consisting of no stimulus and prepulse alone were also given. Data collected on PREPULSE/PULSE trials were expressed as a percent of PULSE alone. Vehicle-treated rats had a startle response on PREPULSE/PULSE trials which was 50-60% of that occurring in PULSE alone trials. 8-OH-DPAT, at 0.3 and 1.0 mg/kg, disrupted PPI in a manner similar to that observed in rats treated with apomorphine (0.3-3.0 mg/kg sc). Likewise, PPI was disrupted in rats treated with BMY-7378 (1.0 and 3.0 mg/kg sc), a weak 5-HT_{1A} partial agonist. Haloperidol (1.0 mg/kg sc) blocked the disruption of PPI induced by apomorphine (0.6 mg/kg sc), but not that induced by 8-OH-DPAT (0.3 mg/kg sc). BMY-7378 (0.3 mg/kg sc), at a dose which did not affect PPI per se, was also unable to block a 8-OH-DPAT-induced disruption of PPI. In contrast, WAY-100135, a novel 5-HT_{1A} antagonist (see J.T. Haskins *et al.*, and P. Mitchell *et al.*, this meeting), given at 10.0 mg/kg sc, attenuated 8-OH-DPAT-induced PPI disruption. Thus, these data support a potential role for the 5-HT_{1A} receptor in this sensorimotor gating phenomenon. Moreover, as PPI is disrupted in schizophrenic patients, it is possible that serotonergic systems may contribute to these PPI deficits.

DEPLETION OF BRAIN SEROTONIN WITH 5,7-DIHYDROXYTRYPTAMINE IS ASSOCIATED WITH A PERSISTENT BEHAVIORAL DEFICIT IN RATS PERFORMING ON THE DIFFERENTIAL REINFORCEMENT OF LOW RATE-72 SECOND OPERANT SCHEDULE OF WATER REINFORCEMENT. D. C. Jolly, J. B. Richards, and L. S. Seiden, Dept. of Pharmacol. and Physiol., University of Chicago, Chicago, Illinois. 60637.

The Differential Reinforcement of Low Rate-72 second (DRL-72s) operant schedule of water reinforcement is a behavioral screening procedure for antidepressant drugs. The purpose of this experiment was to assess the involvement of the brain serotonergic system in the performance of DRL-72s behavior. Trained rats were given bilateral, intracerebroventricular (icv) infusions of 200 µg of 5,7-dihydroxytryptamine (5,7-DHT). A control group received icv infusions of vehicle. After the rats recovered from surgery, DRL-72s performance was continually assessed for a total of 17 weeks. At 15 weeks post-lesion, a 5-hydroxytryptophan (5-HTP) dose-effect determination was made. Throughout the experiment, under drug free baseline conditions, the 5,7-DHT rats made more responses and obtained fewer reinforcers than they did in pre-lesion baseline sessions. The behavioral deficit in the 5,7-DHT treated rats was, apparently, secondary to a derangement of the temporal distribution of operant responding. In the sham operated control rats, the DRL-72s baseline response and reinforcement rates remained unchanged, and the temporal distribution of responding was unaltered. Administration of 5-HTP to the 5,7-DHT treated rats was associated with a partial amelioration of the behavioral deficit. The neurochemical assay results indicated specific, extensive depletion of serotonin (5-HT) in the 5,7-DHT treated rats, in all brain regions examined. These results suggest that a certain level of 5-HT system activity is necessary for normal response timing in the performance of DRL-72s behavior.

EFFECTS OF ISOLATION REARING ON INDICES OF 5-HYDROXYTRYPTAMINE FUNCTION IN RAT HIPPOCAMPUS. L.S. Wilkinson*, F.S. Hall, T. Humby* and T.W. Robbins. SPON: Brain Research Association. Experimental Psychology, University of Cambridge, Cambridge CB2 3EB, U.K.

Isolation rearing has been shown to precipitate a variety of behavioural changes in the rat, including increased reactivity to novelty, deficits in rule learning, hyperphagia and enhanced responding in reward-related situations. Most work on the neurochemical changes underlying the "isolation syndrome" has centred on dopamine. The present study examined the effects of isolation rearing on indices of 5-hydroxytryptamine (5HT) function in hippocampus. In the first experiment male weanlings (21 days postnatal) were divided into isolates and social controls. After 90 days the animals were killed and tissue levels of indoleamines in hippocampus determined. 5HIAA/5HT ratios were significantly lower in isolates than in controls. In the second experiment weanlings were isolated as above, anaesthetised with halothane and hippocampal extracellular 5HT monitored using *in-vivo* microdialysis. Potassium-evoked release of 5HT (intraprobe, 100mM, 20 min.) was significantly reduced in the isolated group. These data are consistent with there being a reduction in the releasable pool of 5HT in the hippocampus of isolates.

FACILITATED ACQUISITION OF A CONDITIONAL VISUAL DISCRIMINATION. FOLLOWING 5,7-DIHYDROXYTRYPTAMINE-INDUCED LESIONS OF FOREBRAIN SEROTONINERGIC PROJECTIONS IN RATS. B. Ward, *1 B.J. Everitt, † T.W. Robbins, 2 L.S. Wilkinson, 2. (Spon: Brain Research Assn). ¹Dept Anatomy, ²Dept Experimental Psychology, University of Cambridge, Cambridge CB2 3DY, England.

The role of forebrain serotonin (5-HT) in cognition is unclear, although previous studies suggested that depleting 5-HT centrally may facilitate learning. In these experiments, the effects were investigated of forebrain 5-HT depletion on the acquisition of a conditional visual discrimination, which is known to depend on frontal cortical mechanisms. Lesions were made by infusing a selective 5-HT neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT), into the lateral ventricles (icv) of adult male Lister hooded rats that were pre-treated with desipramine and nomifensine to protect noradrenergic and dopaminergic neurons, respectively, from damage. Infusion icv of 5,7-DHT resulted in 90% reductions in forebrain 5-HT, but minimal effects on noradrenaline and dopamine concentrations. The results showed that animals with 5-HT depletions acquired the task markedly and significantly faster than sham-operated controls, both in terms of errors and sessions to criterion. This was true at all criteria of acquisition up to the most stringent of 85% correct responses. Performance on-the-baseline showed that rats with lesions were significantly worse when a delay was introduced between stimulus presentation and the opportunity to respond, but significantly better at short inter-stimulus intervals. Rats with lesions were also slower in extinction of the task. The results will be discussed in the context of functions of 5-HT in learning, memory and attention.

59.7

5-HT_{1A} AGONISTS, 8-OH-DPAT AND IPSAPIRONE, LOWER THE EJACULATORY THRESHOLD OF RHESUS MONKEYS. S.M. Pomerantz, Dept. of Physiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

Although numerous studies in rats have demonstrated an influence of serotonin on male copulation, no studies have yet to demonstrate whether such a relationship exists in primate species. The present study evaluated two 5-HT_{1A} agonists, 8-OH-DPAT (DPAT) and ipsapirone (IPSAP), on male copulatory behavior of rhesus monkeys.

DPAT (1-200 µg/kg, N=9). Compared to vehicle-based performance, administration of 5 or 10 µg/kg DPAT lowered the ejaculatory threshold of the monkeys as evidenced by a shortening of the ejaculation latency (time from initiation of copulation to ejaculation) and a reduction in intromission frequency (number of intromissive copulatory mounts prior to ejaculation). At higher doses (>50 µg/kg), DPAT had an inhibitory effect on sexual behavior, with a number of males failing to mount the female and an increase in intromission latency (time from the start of the test to first intromission) being observed.

IPSAP (50-800 µg/kg, N=7). At all doses being tested, administration of IPSAP resulted in a shortening of ejaculation latency. Intromission frequency was reduced following either 200 or 400 µg/kg IPSAP. No adverse effects of IPSAP on copulation were observed, even at the highest dose being administered.

The lower ejaculatory threshold of the monkeys following 5-HT_{1A} agonist administration is presumably due to presynaptic/autoreceptor agonist activity of these compounds, whereas the broader dose-response effect with IPSAP compared to DPAT may be related to differences in postsynaptic activity (partial versus full agonist) of these compounds.

EFFECTS OF SEROTONIN TYPE 3 (5-HT₃) RECEPTOR ANTAGONISTS AND OPIATES ON REPRODUCTIVE BEHAVIOR IN MALE AND FEMALE RATS. S.A. TANCO, N.V. WATSON, AND B.B. GORZALKA, Dept. of Psychology, University of British Columbia, Vancouver, B.C. V6T 1Y7

Serotonergic effects on reproductive behavior vary as a function of sex and subtype of receptor involved (Gorzalka et al. *Ann N.Y. Acad. Sci.* 600:435-446, 1990). The influence of 5-HT₃ activity on reproductive behavior is unknown; however, 5-HT₃ antagonists are known to antagonize morphine-induced place-preference conditioning (Carboni et al. *Eur J Pharmacol*, 151:159-160, 1988) and morphine-induced stimulation of dopamine release in the nucleus accumbens (Carboni et al. *Eur J Pharmacol*, 164:515-519, 1989). Opiates inhibit sexual behavior in both males and females. Thus, 5-HT₃ antagonists may attenuate opiate-induced sexual inhibition independent of their potential effect when administered alone. In both male and female rats, low doses of morphine (1.5mg/kg) profoundly inhibited copulatory behavior. In females MDL 72222 alone (0.5-5mg/kg) did not affect lordosis nor did it attenuate morphine-induced sexual inhibition. Similarly, GR38032F (0.8-20mg/kg) alone and in conjunction with morphine did not affect copulatory behavior in males or females. Analogous studies employing ICS 205-930 are currently underway. At present, results obtained with 5-HT₃ antagonists do not support the idea that 5-HT₃ activity is implicated in reproductive behavior.

NON-INVOLVEMENT OF 5-HT₂ RECEPTORS IN DEFENSIVE ANALGESIA IN MICE. R.J. Rodgers, P. Donat¹ and J.K. Shepherd². Dept. of Psychology, University of Leeds, U.K. and ¹Institute of Pharmacology, Czechoslovak Academy of Sciences, Prague.

Recent evidence from our laboratory has delineated a major role for serotonin (5-HT) in the non-opioid analgesic consequences of social defeat in male mice. This form of adaptive pain inhibition is potently and dose-dependently inhibited by 5-HT_{1A} receptor agonists (e.g. 8-OH-DPAT, buspirone, (+) MDL 72832) and by 5-HT₂ receptor antagonists (e.g. ondansetron, ICS205-930, MDL 72222). In the present study, we have assessed the effects of two 5-HT₂ receptor antagonists (ritanserin & ICI 169,369) on basal nociception and defeat analgesia. Although both antagonists were found to have intrinsic analgesic effects at higher doses, neither compound specifically influenced defeat analgesia over the dose ranges tested (0.05-10 mg/kg ritanserin; 0.3-10 mg/kg ICI 169,369). It is concluded that 5-HT₂ receptor populations do not play an important role in this ecologically-relevant component of the defensive repertoire.

EFFECTS OF 5-HT₂ RECEPTOR SELECTIVE DRUGS ON RAT SEXUAL BEHAVIOR. N.V. Watson, S. Tanco and B.B. Gorzalka, Dept. Psychology, Univ. British Columbia, Vancouver, B.C., Canada V6T 1Z4

Serotonin (5-HT) may facilitate or inhibit rat sexual behavior, depending on the subtypes of 5-HT receptors activated (for review: Gorzalka, Mendelson and Watson, *Ann N.Y. Acad. Sci.* 600:435-446, 1990). In contrast to work on the 5-HT₁ and 5-HT₂ receptor subtypes and rat sexual behavior, little is known concerning effects mediated by 5-HT₃ receptors. Among other central effects, activity at these sites has been implicated in social interaction, suggesting a role of 5-HT₃ receptors in the effects of 5-HT on rat sexual behavior.

In male rats, intracerebroventricular administration of the putative 5-HT₃ agonist 1-phenylbiguanide (1-PBG) significantly decreased ejaculation latency at all doses tested (0.4, 2.0, 10.0 and 50.0 µg/rat). However, the putative 5-HT₃ agonist 2-methyl-5-HT was without effect in males (1.5 - 40.5 µg/rat, icv). Neither 1-PBG nor 2-methyl-5-HT altered the sexual behavior of female rats. Furthermore, the 5-HT₃ antagonists GR38032F and BRL 43694 did not affect male rat sexual behavior. Overall, these data suggest that 5-HT₃ receptor activity may have only slight effects on rat sexual behavior. It is possible that these effects are mediated by dopamine, as 1-PBG has been reported to induce carrier-mediated dopamine release.

PYRIDOXINE FACILITATION OF COPULATORY BEHAVIOR: POSSIBLE SEROTONERGIC MEDIATION? B.B. Gorzalka and I.V. Moe^{*}. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C., Canada V6T 1Z4.

Serotonin type 2 (5-HT₂) receptor activity has been reported to have an inhibitory effect on sexual behavior in the male rat (for review see Gorzalka, Mendelson and Watson, *Ann. N.Y. Acad. Sci.*, 600, 435-446, 1990). Recent research has revealed that chronic pyridoxine (vitamin B₆) administration decreases the number of 5-HT₂ receptors in areas such as the cerebral cortex, the hypothalamus, and the brainstem (Dakshinamurti, Sharma and Bonke, *Klin. Wochenschr.*, 68, 142-145, 1990). Therefore, pyridoxine may act to facilitate sexual behavior in the male rat by inhibiting 5-HT₂ receptor activity.

In the present experiment we recorded the sexual activity of male Sprague-Dawley rats during 17 days of chronic pyridoxine or saline administration. Sexually naive males were given 100 mg/kg pyridoxine or saline intraperitoneally. Behavioral testing commenced on day 8 of the chronic injections and continued at 3 day intervals. Pyridoxine significantly reduced ejaculation latencies ($p < .05$) and increased the proportion of animals ejaculating ($p < .05$). All other measures of sexual behavior revealed trends toward a facilitatory effect of pyridoxine. Taken together, these findings confirm our hypothesis that pyridoxine acts to facilitate sexual behavior in the male rat. It should be noted however, that pyridoxine's effect on sexual behavior is not necessarily selective to 5-HT₂ receptor inhibition. For example, pyridoxine has been shown to elevate serotonin and dopamine levels. It remains to be confirmed that 5-HT₂ activity mediates the effects of pyridoxine on sexual behavior.

59.12

BETA-NORADRENERGIC ANTAGONIST IMPAIRS ACQUISITION OF A NOVEL LOCOMOTOR TASK. Christine Heron, Kevin Poth¹, and Paula Bickford-Wimer². Vet. Admin. Med. Ctr. and Dept. of Pharmacology, Univ. Colorado Health Sci. Ctr. Denver, CO 80262.

Several theories of motor learning implicate a role for cerebellar structures as being critical for learning to occur. In addition, noradrenergic innervation of this structure has been shown to be necessary for the acquisition of novel locomotor tasks. Depletion of central stores of NE results in impairment of acquisition in a motor learning task. NE is known to act as a neuromodulator in the cerebellar cortex and it is this modulatory action which may be important for its effects on the rate of learning motor tasks. The action of NE to increase the effect of GABA_A receptor activation is mediated via a β noradrenergic receptor. Thus, it was the purpose of this study to determine if β noradrenergic receptors were important in the acquisition of this task. Fischer 344 rats were trained to run on regularly spaced pegs for a water reward. After a two week delay, animals were then tested for performance on irregularly spaced rods. Prior to daily testing, rats were injected with propranolol (10 mg/kg, ip) or saline. The rats injected with propranolol were significantly impaired with respect to the rate of acquisition of this novel motor task ($p < 0.05$, ANOVA). Thus, these data support the hypothesis that beta noradrenergic receptors are important in motor plasticity. This work was supported by the VA Medical Research Service, USPHS grant AG04418, and the American Federation for Aging Research.

EXCITATION AND INHIBITION OF SYMPATHETIC PREGANGLIONIC NEURONS (SPGNs) BY AMPHETAMINE: POSSIBLE CLUE TO MECHANISMS IN ADDH. D.N. Franz, C. Sangdee* and L.C. Miner*. Pharmacology, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

The mechanism by which amphetamines reduce symptoms of ADDH are poorly understood although they are known to depress locus coeruleus (LC) neurons which may be hyperactive. Recent evidence that clonidine is effective in ADDH suggests that alpha-2 receptors may account for the effects of amphetamines. Both LC neurons and SPGNs are markedly depressed by activation of their alpha-2 receptors which are negatively coupled to adenylate cyclase and are innervated by C1 epinephrine (EPI) neurons. SPGNs are also innervated by descending NE pathways to alpha-1 receptors that are positively coupled to adenylate cyclase.

In the present study, i.v. dextroamphetamine was tested on intrasplinal transmission to SPGNs in spinal cats, activated by cervical spinal stimulation and recorded from preganglionic rami. Small doses (0.25-0.5 mg/kg) doubled or tripled transmission whereas larger doses (1-4 mg/kg) produced progressively smaller and briefer increases. Changes after the 4 mg/kg dose alone were insignificant but, after yohimbine, it increased transmission to 300% for more than 4 hrs. After blocking alpha-1 receptors with chlorpromazine, this dose only depressed transmission by 80%. The larger doses appear to release more EPI or sufficient NE to reach inhibitory alpha-2 receptors to counteract its effects on excitatory alpha-1 receptors. Likewise, amphetamine may inhibit LC neurons by enhancing release of EPI from its terminals or of NE from LC neurons to activate their alpha-2 receptors. Such a mechanism suggests a defect in one of these inhibitory processes in ADDH.

59.15

THE EFFECTS OF NORADRENERGIC NEUROTOXIN, DSP-4, ON HIGH VOLTAGE SPINDLE ACTIVITY DIFFER BETWEEN YOUNG AND AGED RATS. P. Riekkinen Jr., J. Sirviö, R. Lammintausta*, T. Ekonsalo, M. Aaltonen and P.J. Riekkinen. Dept. of Neurology, Univ. of Kuopio, P.O.B. 1627, Kuopio, Finland. Orion Co, Farmos Group, Turku, Finland*

The present study investigated the role of alpha2-adrenoceptors in the regulation of neocortical EEG activity. The EEG effects of D-medetomidine (DMED, an alpha2-agonist; Farmos Group, Finland) were studied in intact and dorsal noradrenergic bundle (DNB)-lesioned rats. Waking-immobility related high voltage spindle (HVS) activity was increased dose-dependently (0.3 < 3.0 µg/kg-30 µg/kg; no HVS at 300 µg/kg) in intact rats. Synchronized slow wave activity was increased dose-dependently by DMED: 0.3 µg/kg had no effect on quantitative EEG (qEEG); 3.0 µg/kg increased waking immobility related theta (4-8 Hz) activity, but had no effect on running-related qEEG values; 30 µg/kg increased delta (1-4 Hz), theta, alpha (8-12 Hz) and beta (12-20 Hz) activity during waking-immobility and increased delta and theta during running; 300 µg/kg produced greatest increase in waking-immobility related qEEG activity. Atipamezole, and alpha2-antagonist (Farmos Group, Finland), dose-dependently reversed DMED induced HVS and slow wave activity. Pinching of the tail blocked slow wave and HVS activity, and produced desynchronized EEG activity in rats injected with DMED at 0.3, 3.0 and 30 µg/kg. Rats treated with DMED at 300 µg/kg showed no change in the qEEG values after tail pinching. In DNB-lesioned rats, DMED produced similar effects on HVSs and slow waves. The present study demonstrates that EEG slow wave activity and HVSs are regulated by alpha2-adrenoceptors located post-synaptically.

NEUROCHEMICAL AND BEHAVIORAL EFFECTS OF DEXMEDETOMIDINE IN NEONATAL RATS. K. Laitinen, E. MacDonald* and L. Tuomisto. Dept Pharmacol and Toxicol, Univ Kuopio, 70211 Kuopio, Finland.

Dexmedetomidine (d-MED), a selective α₂-agonist causes sedation in adult rats. Its effects in neonatal animals, however, are unknown. We have studied behavioral and neurochemical effects of a single injection of d-MED in 7-d-old pups. Animals were injected s.c. at doses 0, 10, 30 and 100 µg/kg. Pups were divided in two groups (kept at 30°C or at 21°C). Oral temperature, righting reflex and behavior were monitored and biogenic amines were determined using HPLC methods.

All doses of d-MED caused hypothermia in pups kept at 21°C but not at 30°C. Instead of sedation, d-MED induced hyperactivity in 7-d-old rats. Hyperactivity, including intense movements of limbs while animals lying on their back and clonic-like convulsions, increased in a dose-dependent manner. The righting reflex in those animals was negative. d-MED increased tissue levels of noradrenaline (NA), serotonin (5-HT) and histamine (HA) and decreased tissue level of MHPG-SO. Neurochemical changes were more significant in animals kept at 21°C suggesting a connection between thermoregulatory impairment and NA, HA and 5-HT metabolism.

NOREPINEPHRINE-INDUCED DEPRESSION OF POPULATION SPIKE: DIRECT MICROAPPLICATION OF LIGAND TO STRATUM PYRAMIDALIS OF THE RAT HIPPOCAMPAL SLICE. D. Dahl, D.J. Hayes, P.J. Watson, E. Rich-Bennett, J. Easley, and C.J. Frederickson. The University of Texas at Dallas, and Microfab Technologies, Inc., Plano, TX.

A novel system (the TISSUE-JET), adapted from the printer ink jet, has been developed for dispensing micro-quantities of water-soluble ligands directly onto brain slices. The TISSUE-JET applies ligands as individual droplets, each 50 µm in diameter, at any rate, to any location on the slice surface. Concurrent electrophysiological recordings provide an index of ligand-induced effects on neuronal activity.

Norepinephrine (NE)-induced potentiation or depression of field excitatory postsynaptic potentials (EPSPs) and population spikes, or unit activity have been reported. These results were obtained from studies in which NE and related ligands were applied by perfusion or iontophoresis. In this work, we report results obtained with TISSUE-JET application of NE on activation of CA1 pyramidal neurons.

In an interface chamber, recordings of CA1 population spikes were taken from a hippocampal slice preparation to orthodromic or antidromic activation of Schaffer collateral afferents. Following a control period, droplets of L-NE (1 mM) were directed toward the pyramidal cell layer, near the location of the recording electrode tip. A dose-dependent, NE-induced reduction in population spike amplitude was obtained. This reduction persisted for up to 10 min. The NE-induced reduction was reversibly blocked by concurrent perfusion of the slice with the α-adrenergic antagonist phentolamine (50 µM). Although the population spike amplitude was reduced with NE application, there was no concurrent reduction in the slope or amplitude of the pyramidal cell layer EPSP.

These results are interpreted as an α-adrenergic-induced reduction of excitability of CA1 pyramidal cells. This is in contrast to perfusion studies, in which the concurrent exposure of the whole slice to NE and phentolamine was associated with an increase in CA1 population spike amplitude. The α-adrenergic agonist clonidine, however, induced a reduction of CA1 population spike amplitude with no change in EPSP.

EFFECT OF LESION SIZE AND REMOTE DAMAGE ON MOTOR RECOVERY AFTER SENSORIMOTOR CORTEX ABLATION. K. Nishino, H. Ooyu, M. Kowada. Dept of Neurosurgery, AKITA University School of Medicine, JAPAN

Norepinephrine (NE) is considered to play a critical role in amphetamine-facilitated beam walking recovery after a sensorimotor cortex ablation (Feeny 1982, Goldstein and Davis, 1988). In order to characterize the phenomenon and try to determine the site at which NE act and facilitate the recovery, a selective alpha-2 adrenergic antagonist, yohimbine (5mg/Kg) was administered after the same and larger lesions. L-DOPS (400mg/Kg, Sumitomo, Pharma. Co Ltd, Japan) and benserazide (1-2 mg/Kg, extracerebral decarboxylase inhibitor), and L-DOPA (30mg/Kg) were also tested in this model. Male Sprague Dawley rats (270-350gm) were subjected to training for beam walking and the subsequent ablation. The agents were administered 24 hours after the injury. And then beam walking was consecutively evaluated using a seven grade scale until the 14th days. All animals were decapitated and the removed brains were photographed for measurement of lesion size. The results showed single dose of yohimbine or L-DOPS facilitated the beam walking recovery as compared to the control injected the vehicle (t-test: yohimbine [N=9] vs control [N=8] at 6 and 24 h; p<0.025, p<0.05, L-DOPS [N=11] vs control [N=9] at 1, 2, 3, 4, 5, 6 d; 0.005 < p < 0.05). Yohimbine, however, was less effective when the cortical lesion surface was larger than approximately 35mm². There were no statistically significant difference in the lesion size between treated and control groups in each experiment. With HPLC measurement, the NE levels did not increase after administration of L-DOPS (400mg/Kg) plus benserazide [N=5] as compared to the control [N=5], while MHPG levels increased in the cerebellum and the hippocampus after the administration [N=10] (t-test; p<0.005, P<0.025, respectively). We conclude that 1) these data are consistent with the hypothesis of NE-facilitated recovery, 2) the cerebral cortex adjacent the lesion and the cerebellum would be relevant to the facilitated recovery, and 3) such agents would predict the functional prognosis at acute stage of brain injury.

POSSIBLE MECHANISMS UNDERLYING ENHANCED NOREPINEPHRINE RELEASE AND SYNTHESIS IN HIPPOCAMPUS OF CHRONICALLY STRESSED RATS. L.K. Nisenbaum and E.D. Abercrombie. Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pgh., PA and Center for Molecular and Behavioral Neuroscience, Rutgers Univ., Newark, NJ.

We have investigated the effect of chronic cold stress on the release and synthesis of norepinephrine (NE) in hippocampus using the technique of microdialysis. Whereas the basal levels of NE release and synthesis are unchanged in chronically stressed rats, exposure to a novel stressor elicits a greater increase in these parameters (Nisenbaum et al., *J. Neurosci.*, in press). To determine whether alterations at the terminal level might be involved in the enhanced noradrenergic response, we infused a ACSF containing 30 mM K⁺ through the dialysis probe. In naive rats, a 20-min exposure to 30 mM K⁺ produced 104% and 63% increases in extracellular NE and DOPAC, respectively. In chronically cold-stressed rats, significantly greater increases in NE (254%) and DOPAC (84%) were observed. Since extracellular DOPAC may provide an *in vivo* measure of NE biosynthesis, these data suggest that alterations at the terminal level are sufficient to maintain enhanced evoked NE release and synthesis in chronically stressed rats. Given that presynaptic alpha-2 receptors modulate both release and synthesis of NE, we examined whether a change in receptor sensitivity might contribute to the chronic stress-induced alterations we have observed. In chronically cold-stressed rats, 0.1 µM clonidine applied through the dialysis probe produced a significantly greater decrease in extracellular NE than in naive controls, suggesting that an increase in the sensitivity of presynaptic alpha-2 receptors had occurred. Thus, while an alteration in alpha-2 receptor sensitivity cannot explain the enhanced evoked noradrenergic response, the observed increase in this variable may allow for a normalization of basal levels of NE release in the chronically stressed rats. (Supported by USPHS grants MH43947 and MH09920.)

STRESS-INDUCED SENSITIZATION OF NOREPINEPHRINE RELEASE IN MEDIAL PREFRONTAL CORTEX. J.M. Finlay and E.D. Abercrombie. Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pgh., PA, and Center for Molecular and Behavioral Neuroscience, Rutgers Univ., Newark, NJ.

Prior exposure to a chronic stressor results in enhanced efflux of hippocampal norepinephrine (NE) in response to a novel stressor (Nisenbaum et al., *J. Neurosci.*, in press). The present experiment assessed whether the enhanced responsiveness of noradrenergic neurons following chronic stress also occurs in the medial prefrontal cortex (mPFC). We examined the effect of prior exposure to chronic cold stress on cortical NE efflux elicited in response to a novel stressor (30 min of tail-pressure), using *in vivo* microdialysis in freely moving rats. Tail-pressure stress elicited a greater increase in NE efflux in the mPFC of rats previously exposed to chronic stress than in naive rats (196% and 150% of baseline, respectively). NE levels remained elevated longer in chronically stressed rats such that, at 30-60 min after cessation of the tail-pressure, NE efflux was 147% of baseline in chronically stressed rats whereas it had returned to basal values in naive controls. The enhanced stress-induced efflux of NE in the mPFC of chronically stressed rats was not attenuated by pretreatment with the anxiolytic benzodiazepine diazepam (2.5 mg/kg, IP); tail-pressure stress increased NE levels to 182% of baseline in chronically stressed rats given an injection of diazepam 1 h prior to presentation of the acute stressor. These data demonstrate that prior exposure to chronic stress results in enhanced release of NE in mPFC in response to a novel stressor. This finding corroborates previous observations regarding the impact of chronic stress on hippocampal NE efflux and suggests that NE projections to forebrain may respond in a homogenous manner to chronic stress. [³H]DIHYDROALPRENOLOL BINDING TO B-ADRENERGIC RECEPTORS IS UNCHANGED IN THE BRAINS OF CHRONICALLY STRESSED RATS. S.M. Anderson, E.H. Mougey and G.J. Kant. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

It has been reported that repeated immobilization stress induces down-regulation of brain B-adrenergic receptors. To evaluate this phenomenon in a model of chronic stress we used a behavioral paradigm in which 300 g male S-D rats, habituated to press a lever to receive food, were trained in an active shock avoidance/escape task. Trials were presented around the clock using a 5 min intertrial interval. Animals housed in identical operant chambers but not exposed to footshock were used as controls. We found no difference in the amount of 0.9 nM [³H]dihydroalprenolol ([³H]DHA) bound to membranes from olfactory bulbs, frontal cortex, motor/somatosensory cortex, caudate/putamen, hippocampus, or hypothalamus between controls and animals stressed for either 4 or 14 days in this "sustained performance" stress paradigm. A small decrease in 0.9 nM [³H]DHA binding was found in the mesolimbic area (olfactory tubercle and nucleus accumbens) in stressed rats in some, but not all, experiments. However, saturation binding data indicate no differences in either the density of B-adrenergic receptors or the affinity of those receptors for [³H]DHA. We suggest that the stress-induced down-regulation of brain B-adrenergic receptors reported previously by other investigators may be due to transient factors and/or experimental specific parameters, but are not related to chronic stress, in general.

60.1

ANXIOLYTIC AND ACTIVATING EFFECTS OF DIAZEPAM IN DS AND DR MICE TESTED ON THE PLUS MAZE. N.D. Courtney, G.E. Jones* and E.J. Gallaher. VA Medical Center and Oregon Health Sciences University, Portland, OR 97201.

Diazepam-sensitive (DS) and -resistant (DR) mice were previously developed using a selective breeding technique, with matings based on the duration of diazepam-induced rotarod impairment. DS mice are about 10-15 fold more sensitive to diazepam when tested on the rotarod. A finding that DS mice are also more sensitive to anxiolytic effects would support the hypothesis that rotarod impairment and anxiolysis have common genetic bases.

In the current study we used the elevated plus maze to monitor the anxiolytic effect of diazepam (DZ) in DS and DR mice. In general mice explore the maze, but tend to avoid the open arms. A count of total entries (TEs) provides a measure of activity, while an increase in open-arm entries (OEs) following treatment with known anxiolytic drugs is interpreted as an anxiolytic effect.

Vehicle-treated DS and DR mice performed similarly, with about 5-8 TEs and 15-20% OEs during a 5-min trial. Following doses of 0.1 to 10 mg/kg DZ, DR mice exhibited a dose-dependent increase in activity, which decreased at higher doses (30-170 mg/kg) due to frank sedation, OEs also increased in a dose-dependent manner in DR mice, from 17% (vehicle) to 70% (30 mg/kg); results with higher doses were unreliable due to sedation. DS mice exhibited no changes in either TEs or OEs, in opposition to the expected result.

Antagonism of the activating and anxiolytic effects was tested in DR mice with the competitive antagonist RO 15-1788. The antagonist had no significant effect on TEs, but produced a dose-dependent decrease in OEs. These results suggest a dissociation of the activating and anxiolytic effects in DR mice.

60.3

TOLERANCE TO THE DISCRIMINATIVE STIMULUS EFFECTS OF MIDAZOLAM (MDZ) IN RATS. C.A. Sannerud & R.R. Griffiths*. Dept. of Psychiatry, Johns Hopkins Univ. Medical School, Baltimore, MD 21205.

The ability of behavioral variables to modify the development of tolerance to the discriminative stimulus (DS) effects of MDZ were evaluated. Rats were trained to discriminate 0.32 mg/kg MDZ s.c. from no-drug in daily experimental sessions consisting of multiple discrete 20 min trials: 15 min time-out (TO), 5 min fixed-ratio 15 schedule of food-delivery. Generalization testing was accomplished by administering progressively increasing doses of MDZ prior to each TO period. During the chronic phases, twice daily injections of 10 mg/kg MDZ or saline were given while discrimination training was either suspended or continued; generalization gradients for MDZ were determined weekly for 4 weeks. Chronic saline given when training was continued or suspended produced slight fluctuations in the MDZ minimal discriminable dose (MDD) (the first dose of MDZ in an individual generalization gradient to produce $\geq 90\%$ drug-lever responding).

Tolerance developed to the DS effects of MDZ when it was given while training was suspended: at week 4 chronic MDZ produced 0.5-2 log-unit increases in the MDD of MDZ. In contrast, continued training during chronic MDZ produced no tolerance to MDZ's DS effects: at week 4 chronic MDZ the MDD of MDZ was not different than pre-chronic and not different than either saline condition. (Supported by NIDA Grant DA 04147).

EFFECTS OF 5-HT_{1A} AGONISTS ON BENZODIAZEPINE WITHDRAWAL IN RATS. A.J. Goudie and M.J. Leathley*. Psychology Dept., Liverpool University, Liverpool, L69 3BX, U.K.

Effects of ipsapirone and gepirone in rats withdrawn from chlordiazepoxide were studied. Subjects were injected for 21 days with saline or CDP. Subsequently, some animals received saline, others received ipsapirone (3, 10 or 30 mg/kg b.i.d.) or gepirone (3, 9 or 27 mg/kg b.i.d.). Withdrawal indices recorded were weight and food intake. Significant withdrawal signs were seen. At 30 mg/kg, but not lower doses, ipsapirone potentiated withdrawal. Gepirone potentiated withdrawal at 9 and 27 but not 3 mg/kg. These effects were not due to drug-induced "malaise", because animals pretreated with saline gained weight on gepirone. The likely cause of the potentiation of withdrawal involves the metabolite 1-PP. Ipsapirone and gepirone did not attenuate withdrawal. Patients withdrawn from benzodiazepines will therefore experience withdrawal if treated with ipsapirone and gepirone. At high doses, withdrawal may be exacerbated. These findings may be related to reports that buspirone-type anxiolytics are poorly tolerated by patients with a history of benzodiazepine treatment.

60.4

ACUTE AND CHRONIC EFFECTS OF DIAZEPAM ON BRAIN NORADRENERGIC NEURONS. R. Shickhattar, S.F. de Boer, R.I. Valentino, and G. Aston-Jones. Div. Behav. Neurobiol., Dept. Mental Health Sciences, Hahnemann Univ., Philadelphia, PA 19102.

Chronic treatment with benzodiazepines (BZ) induces tolerance to most acute behavioral effects, and withdrawal reactions when the drug is abruptly discontinued. Given the possible involvement of the noradrenergic nucleus locus coeruleus (LC) in stress/anxiety processes as well as in addictive behaviours (e.g. opiate tolerance, dependence and withdrawal), we examined the acute and chronic effects of BZ-treatment on the spontaneous and sensory-evoked discharge of LC neurons in anesthetized rats. Acute i.v. injection of diazepam (DZ; 2.5 mg/kg, n=4 rats) decreased LC spontaneous discharge rate by 24% and suppressed responses evoked by subcutaneous electrical stimulation of the rear footpad (FS) by 51%. In 6 rats chronically administered DZ (2.5 mg/kg, b.i.d. for 14 days) LC spontaneous and sensory-evoked discharge rates were decreased 14% and 50%, respectively. Acute i.v. injection of DZ (2.5 mg/kg) in 6 chronically treated rats attenuated (29%) LC spontaneous firing rate but, in contrast to drug-naive rats, had no effect on their FS-evoked responsiveness. Administration of the BZ receptor antagonist, flumazenil (FLU; 10 mg/kg, i.v.), to a vehicle-treated rat had no effect on LC discharge rate or FS responses, but completely reversed the DZ-induced depression of LC spontaneous activity and FS responses of 3 cells in 3 rats. However, in chronically DZ-treated rats, FLU-injection caused a robust increase in the discharge rate in 3 of 7 cells (7 rats). These findings suggest that 1) acute DZ-injection attenuates both the spontaneous and sensory-evoked firing rate of LC neurons in drug-naive rats, 2) chronic DZ treatment results in decreased LC spontaneous and sensory-evoked discharge rates, 3) tolerance may develop with chronic administration to the effects of DZ on LC sensory-evoked discharge characteristics, 4) the flumazenil-induced activation of LC neurons may be indicative of precipitated withdrawal. MODULATION OF AGGRESSIVE BEHAVIOR AND GABA_A-BENZODIAZEPINE RECEPTORS IN MICE SELECTIVELY BRED FOR AGONISTIC BEHAVIOR. E. Weems¹, L.G. Miller², K.E. Hood³ and K.A. Miczek¹. Dept. Psychology¹ and Pharmacology², Tufts University, Medford, MA 02155 and Boston, MA, 02111 and College of Health and Human Development³, Pennsylvania State University, University Park, PA 16802.

The GABA_A-Benzodiazepine receptor complex is important for both inhibition and enhancement of aggressive behavior. Three lines of male ICR mice that had been selectively bred at Penn. State for either low levels of aggressive behavior, or high levels of aggressive behavior, as well as unselected controls were isolated for 21 days. In 5-minute confrontations with group-housed, CFW outbred mice in a novel test cage, low-aggressive mice spent more time walking, rearing and interacting socially than high-aggressive mice. Interestingly, high-aggressive mice treated with chlordiazepoxide (17 and 30 mg/kg) display similar reductions in aggressive behaviors and increased levels of walking, rearing and social behavior as untreated low-aggressive mice. In a separate group of animals, these lines also differ in benzodiazepine binding *in vivo*, as determined by specific uptake of [³H] Ro15-1788 per fmol/g brain tissue, and in GABA_A receptor function as measured by Cl⁻ uptake (nmol/mg protein) in cortical synaptosomes treated with muscimol (1-50 μM) and [³⁶Cl⁻]. The low-aggression line showed increased benzodiazepine binding in cerebral cortex, hypothalamus and hippocampus and increased GABA_A receptor function when compared to the high-aggression line. Thus, enhanced benzodiazepine receptor binding and GABA_A receptor function are related to suppression of aggressive behavior. The similarity between the low-aggressive line and animals treated with benzodiazepines is consistent with this hypothesis. This suggests a direct relationship between GABA_A-benzodiazepine receptor function and inhibition of aggressive behavior.

60.7

SEROTONERGIC MEDIATION OF THE ANXIOLYTIC EFFECTS OF DIAZEPAM WITHDRAWAL. N. Andrews* and S.E. File. Psychopharmacology Research Unit, UMDS Division of Pharmacology, London University, Guy's Hospital, London SE1 9RT, UK.

There is both neurochemical and behavioural evidence for a serotonergic role in the benzodiazepine withdrawal syndrome. We found significant increases in [³H]-5-HT release from hippocampal slices taken from rats 24h after the last of 21 daily injections of diazepam (2 mg/kg i.p.). This increased release was reversed by (±) baclofen (1 mg/kg i.p. 30 minutes before sacrifice), which has been previously found to reverse the increased anxiety detected on diazepam withdrawal (File et al. 1991). Both 5-HT_{1A} and 5-HT₃ receptors are implicated in the serotonergic modulation of this anxiogenic response. Low doses of the 5-HT_{1A} receptor partial agonist buspirone (0.2 mg/kg s.c.) and the 5-HT₃ receptor antagonist, zacopride (0.01 mg/kg i.p.) reversed or significantly reduced the anxiogenic responses detected on withdrawal from diazepam. The 5-HT₃ receptor agonist 1-(3-chlorophenyl)-biguanide (1 & 10 mg/kg i.p.) exacerbated this anxiogenic response. We therefore suggest that during diazepam withdrawal there is increased serotonergic function, at least in some brain areas such as the hippocampus. We suggest that the reversal of the anxiogenic withdrawal response by buspirone is due to an action on 5-HT_{1A} autoreceptors in the dorsal raphe, and that drugs acting at post-synaptic 5-HT₃ receptors can also modulate this anxiogenic response.

EFFECTS OF TRIAZOLAM ON MEMORY CONSOLIDATION IN RATS ON A RADIAL MAZE NON-MATCH-TO-SAMPLE TASK. S.A. McBride, G.R. Sessions, J.J. Pilcher and E.L. Closser-Gomez*. Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

Triazolam, a short-acting benzodiazepine hypnotic, has been associated with memory impairments in humans. A delayed non-match-to-sample radial maze paradigm was used to study the effects of this drug on memory consolidation in rats. Rats were first trained to obtain food rewards from each of eight arms of a radial maze (one trial/day). Working memory errors were scored when the rats re-entered an arm after having obtained the food pellet from that arm during a particular trial. Following training, the rats were tested in a memory consolidation task. After obtaining the fourth of eight available rewards, the animals received drug injections (0, 0.05 or 0.20 mg/kg ip), followed by a 3 hr delay, after which the trial was resumed. Retroactive errors were scored when the rats re-entered an arm from which a reward was obtained prior to the delay. Drug injections did not increase either error score. Triazolam did not impair memory consolidation nor produce residual effects on working memory for a spatial task.

60.6

ANXIOLYTIC EFFECTS OF INTRASEPTAL BENZODIAZEPINES IN THE CONFLICT TEST AND THE ELEVATED-PLUS-MAZE. H. Grishkat. Department of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010.

In the conflict test thirsty rats were permitted to lick water for 2 min and were then trained to suppress licking for 2 min during which a tone was presented, in order to avoid foot-shock. This sequence was repeated for a total session length of 8 min. The number of unpunished and punished licks was recorded. Guide cannulae were implanted unilaterally into the lateral septum. One week after surgery, animals were retested in conflict. Intraseptal administration of chlordiazepoxide (CDP, 60 μg/ul) or midazolam (MDZ, 30 & 60 μg/ul) produced a significant increase in punished licking.

Following conflict testing, the exploratory behavior of these same rats was examined in the elevated-plus-maze after intraseptal administration of MDZ (30 or 60 μg/ul) or vehicle. Rats were placed in the center of the maze facing an enclosed arm. The number of open and enclosed arm entries and the time spent in those arms was recorded during a 5-min test session. Animals given intraseptal MDZ showed a tendency to enter the open arms of the plus maze more frequently and remained in those arms significantly longer than vehicle injected rats.

These findings support the lateral septal area as a site of action of benzodiazepine anxiolytics.

60.8

TOLERANCE/CROSS-TOLERANCE TO THE DISCRIMINATIVE STIMULUS EFFECTS OF CHLORDIAZEPOXIDE AND Ro16-6028. M.E. Bronson, M. Picker and L. Dykstra. The University of North Carolina, Dept. of Psychology, Chapel Hill, NC 27599.

Rats were trained to discriminate 10 mg/kg chlordiazepoxide (CDAP), from saline in a 2 lever drug discrimination procedure. Following training, substitution tests were conducted in which cumulative doses of CDAP and the non-sedative benzodiazepine partial agonist, Ro16-6028, were evaluated. Both CDAP and Ro 16-6028 dose-dependently substituted for the training dose of CDAP. Training was then suspended, and half of the rats were placed on chronic CDAP and the other half received vehicle. During this period, the CDAP dose-effect curve was redetermined once a week. Tolerance to the discriminative stimulus effects of CDAP developed after one month and a final dose of approximately 110 mg/kg/day, as evidenced by the fact that the training dose of CDAP no longer produced drug-appropriate responding. Tolerance also developed to Ro16-6028, as no rat responded on the drug-appropriate lever at doses as high as 56 mg/kg, whereas in the pre-chronic dose-effect curve, 1 mg/kg of Ro16-6028 produced 100% drug-appropriate responding. Ten days after chronic CDAP was discontinued, the dose-effect curve for CDAP was comparable to that obtained in the pre-chronic phase, indicating that the rats were no longer tolerant to CDAP. In contrast to CDAP, the Ro16-6028 dose-effect curve did not return to its pre-chronic position, as no dose produced 100% drug-appropriate responding in all of the rats. In the chronic vehicle group, the dose-effect curves for CDAP and Ro16-6028 were essentially the same before, during and after the chronic regimen. Thus, suspension of training for more than two months does not result in loss of the discriminative stimulus properties of benzodiazepines. Chronic exposure to CDAP, however, does result in tolerance to the discriminative stimulus effects of CDAP with cross-tolerance to the non-sedative benzodiazepine, Ro16-6028. Supported by USPHS grants DA02749 & DA00033 and Biomedical Research Support Grant S07 RR07072, Div. of Research Resources, NIH.

60.10

EFFECTS OF TRIAZOLAM ON SCHEDULE CONTROLLED BEHAVIOR IN A RADIAL MAZE MODEL OF FORAGING. J.J. Pilcher, G.R. Sessions, S.A. McBride and E.L. Closser-Gomez*. Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

Drug-induced performance deficits and disruptions of scheduled-controlled behaviors involving memory were studied in rats injected with the benzodiazepine triazolam. Rats were allowed one hour access to a radial maze where delivery of food was controlled by concurrent fixed interval schedules of reinforcement in each of 8 arms, ranging from 55 to 759 sec. Triazolam (0.025-0.3 mg/kg ip) produced dose-dependent decreases in measures of performance at doses above 0.05 mg/kg, but the overall patterning of responding was altered only at doses which produced severe motor deficits. The proportion of time spent in each arm relative to proportion of rewards obtained (time matching) was relatively unaffected. The response matching also remained relatively unaffected at doses below 0.3 mg/kg. Triazolam produced performance decrements consistent with its hypnotic actions, especially at the highest doses. The relative robustness of the matching functions across doses free of severe motor impairments argues against impairments of memory processes required to perform this task.

60.11

BENZODIAZEPINES MODULATE ULTRASOUNDS IN RESPONSE TO SOCIAL STRESS AND ACOUSTIC STARTLE. J.A. Vivian, William J. Farrell* and K.A. Miczek. Dept. of Psychology, Tufts University, Medford, MA 02155.

The role of benzodiazepine receptors in affective behavior was studied in adult rats that emitted ultrasonic vocalizations. Ultrasounds ("low": 20-30 kHz, and "high": 40-50 kHz) are emitted by rats as part of their submissive responses to an attacking opponent and when exposed to intense sensory stimuli. The effects of full agonists, antagonists and inverse agonists at benzodiazepine receptors were investigated in male Long-Evans rats (*Rattus norvegicus*) exposed to: (1) 9 105 dB and 9 115 dB startle stimuli, or (2) attack and threats by a resident opponent while displaying defensive and submissive responses followed by protection from physical contact with a wire mesh. Diazepam (0.1-6.0 mg/kg IP) dose-dependently decreased the rate of 22 kHz ultrasounds during startle; this rate decreasing effect was reversed with flumazenil (10 mg/kg IP). Conversely, diazepam had no effect on the rate or duration of 22 and 50 kHz vocalizations during the threat of attack. However, flumazenil (3-30 mg/kg IP) increased the rate and duration of 22 kHz vocalizations, and 10 mg/kg flumazenil increased the rate of 50 kHz vocalizations during the threat of attack. There was no effect on startle amplitude or tail flick analgesia with the drugs and doses studied. Because the startle (hindbrain) and tail flick (spinal cord) reflexes were unaffected, a mid- or forebrain site of diazepam action is suggested; this is consistent with neural sites mediating affect and ultrasound production. Furthermore, the differential diazepam effects may result from the eliciting stimulus intensity or behavioral salience.

DRUGS OF ABUSE--COCAINE: BINDING AND NEUROPHYSIOLOGY

61.1

ELECTROPHYSIOLOGICAL AND BEHAVIORAL EFFECTS OF REPEATED COCAINE ADMINISTRATION ON THE MESOACCUMBENS DOPAMINE SYSTEM: FURTHER EVIDENCE FOR ENHANCED D1 DA RECEPTOR TRANSMISSION. D.J. Henry, R.J. Brooderson and F.J. White. Wayne St. Univ. Sch. Med., Dept. Psychiatry, Cellular and Clinical Neurobiology Program, Neuropsychopharmacol. Lab., Lafayette Clinic, Detroit, MI 48207.

Repeated cocaine (COC) administration to rodents increases the locomotor stimulating effect of subsequent COC challenge. Although augmented dopamine (DA) release within the nucleus accumbens (NAc) is clearly involved in this sensitization, we have recently used single-unit electrophysiological recordings to demonstrate that NAc neurons from COC treated rats (2 x 10 mg/kg, i.p., 14 days) exhibit enhanced inhibitory responses to iontophoretic application of DA or the D1 agonist SKF 38393. The present studies extend these findings, demonstrating that this COC treatment regimen results in augmented locomotor responses to COC challenge (10 mg/kg, i.p.) and enhanced grooming responses following SKF 38393 challenge (8.0 mg/kg, s.c.). In addition, NAc neurons from COC treated rats displayed enhanced inhibitory responses to both iontophoretically applied and i.v. COC challenges. Although this COC treatment decreases the inhibitory effects of DA and direct DA agonists on A10 DA neurons (autoreceptor subsensitivity), the inhibitory responses of these neurons to i.v. COC were not significantly different from controls. This may be due to enhanced NAc-A10 feedback inhibition via sensitized NAc D1 responses since a subset of A10 DA neurons from COC-treated rats displayed partial inhibitory responses to i.v. SKF 38393 (max 4 mg/kg dose), an effect not observed in control rats. These studies provide additional support for enhanced NAc D1 receptor transmission following repeated cocaine treatment. (Supported by MH 40832 and DA 04093).

61.3

ELECTROPHYSIOLOGICAL EFFECTS OF COCAINE AND PROCAINE ON NEURONS OF THE CENTRAL NUCLEUS OF THE AMYGDALA. H. Ni, J. Zhang, R.K. Harper and R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

Local administration of cocaine to the central nucleus of the amygdala (ACE) suppresses ACE neuronal discharge in half of recorded cells, and causes 45% of respiratory and 37% of cardiac related cells to change their dependency relationships. These effects may be elicited by local anesthetic properties of cocaine, or may result from cocaine effects on neurotransmitter action.

The effects of procaine were compared to those of cocaine on neuronal spontaneous activity within the ACE in the freely moving cat using extracellular single neuron recording and microinjection techniques. Microinjection of both agents (100µg/0.2µl) into the ACE elicited a potent and reversible inhibition of firing rate with cocaine (16/30, 53%) and procaine (4/9, 44%). Neither agent altered spike waveform duration or amplitude. However, the inhibitory effects of cocaine on ACE neurons were slower in onset and longer in duration than those of procaine. The maximal suppression of discharge from procaine occurred within 3-7 minutes, while the maximal cocaine effect occurred as late as 17 minutes. The duration of procaine induced suppression lasted 16-38 minutes, while that of cocaine was sustained as long as 91 minutes. The data suggest that cocaine exerts effects with substantially different time courses on ACE neurons than procaine.

COCAINE BLOCKS LONG TERM POTENTIATION IN THE CA1 REGION OF THE RAT HIPPOCAMPUS. D. A. Smith, M.D. Browning, and T. V. Dunwiddie. Dept. of Pharmacology, University of Colorado Health Sciences Center and VA Medical Center, Denver, CO 80262.

High frequency (1 sec., 100Hz) stimulation of the Schaffer collateral/commissural pathway in the hippocampal slice produces robust long term potentiation (LTP). 30 µM cocaine, by itself, produced a 0-15% suppression in the amplitude of the population spike, but if present during stimulation totally blocked the LTP measured at 20 min. Two local anesthetics, lidocaine (30µM) and procaine (60µM) also blocked LTP. D-amphetamine sulfate (30-60 µM), a drug that blocks dopamine reuptake, had no effect on LTP when administered under these conditions. In our attempt to explain the mechanism for cocaine's antagonism of LTP, we are currently examining several hypotheses: a) Cocaine selectively blocks the NMDA receptor; b) Cocaine, at the doses tested, is a calmodulin inhibitor; c) Cocaine blocks phosphorylation of synapsin I, a presynaptic protein that may also be involved in LTP (See E.M. Dudek et al., this meeting). We have found that cocaine significantly reduces the ability of the tetanized axons to fire during the full length of the tetanizing stimulation. Use dependent blockade of presynaptic axonal conduction may, therefore, be one reason for the inhibiting effect of cocaine on LTP. However, we also find that cocaine blocks the potentiation of LTP produced by 25mM TEA. This suggests that the suppression of high frequency firing cannot entirely account for cocaine's action on LTP.

61.4

SENSITIZATION OF LOCUS COERULEUS NEURONS FOLLOWING CHRONIC EXPOSURE TO STIMULANTS AND ANTIDEPRESSANTS. G.C. Harris and J.T. Williams. Vollum Institute, Oregon Health Sciences University, Portland OR 97201

These experiments examined the effects of chronic exposure to drugs that block the reuptake of noradrenaline (NA) using intracellular recordings from locus coeruleus (LC) neurons in a slice preparation. Rats were treated with either cocaine (20 mg/kg/i.p./daily), amphetamine (6 mg/kg/i.p./every third day), or desipramine (10 mg/kg/i.p./daily) for a total of 14 days. Following 7 days of abstinence from drug treatments, experiments were performed that evaluated the sensitivity of a NA mediated inhibitory postsynaptic potential (IPSP) to amphetamine and cocaine and the sensitivity of the α_2 autoreceptor to clonidine. Cells recorded in slices taken from animals in all three treatment groups showed a significant ($p < .01$) dose related shift to the left in sensitivity to the effects of cocaine and amphetamine on the NA IPSP and also in response to the hyperpolarizing effects of clonidine as compared to saline injected controls. All drug treatments led to a 10-20% increase in the maximum response to clonidine. These data suggest that exposure to drugs that block the reuptake of NA can lead to significant increases in the sensitivity of NA neurons to the blockade of NA reuptake. Supported by USDHHS DA 04523 and DA 05387.

61.5

EFFECTS OF COCAINE ON FIRING RATES AND OLFACTORY-EVOKED RESPONSES IN NUCLEUS ACCUMBENS AND OLFACTORY TUBERCLE UNITS IN RATS.

Charles H.K. West and Richard P. Michael. Department of Psychiatry, Emory University School of Medicine, and Georgia Mental Health Institute, 1256 Briarcliff Road, Atlanta, GA 30306.

The mesolimbic dopamine terminal regions of the nucleus accumbens (NAC) and olfactory tubercle (OT) have been associated with reward produced by psychostimulant drugs such as amphetamine and cocaine. We have previously reported that amphetamine differentially affects the firing rates of NAC and OT neurons in anesthetized rats. Here we report that cocaine, like amphetamine, decreased the firing rates of NAC units but increased those of OT units. Since many units in these brain regions respond to olfactory stimuli, we also tested if cocaine affects sensory-evoked responses. Single units were recorded in adult male urethane (1.3 g/kg, ip) anesthetized rats (n = 21). Cocaine was administered intravenously in a cumulative dose range of 0.25 to 4.0 mg/kg such that each dose doubled the previous dose. The firing rates of the 12 NAC units recorded to date were significantly ($P < 0.001$) decreased in a dose-related fashion, with the 4.0 mg/kg dose reducing the mean firing rate to 26% of the pre-dose rate. In contrast, the firing rates of OT units (n = 6) were significantly ($P < 0.01$) increased by cocaine. These effects were antagonized by the dopamine antagonist haloperidol (0.5 mg/kg, iv). Firing rates of some additional units in the border between NAC and OT were unaffected by cocaine. The magnitude of the responses evoked by olfactory stimuli was reduced by cocaine in most of the NAC and OT units tested. Differences in the effects of cocaine on NAC and OT neurons may help to separate the roles of these two structures in drug-induced reward. (Supported by the Emory University Research Committee and by the Georgia Department of Human Resources.)

WITHDRAWAL OF CHRONIC COCAINE DECREASES BINDING OF [³H]WIN 35,428 IN THE RAT NUCLEUS ACCUMBENS. N.S. Pilotte, J.W. Boja, L.G. Sharpe, E.P. Kornak, M.J. Kuhar. NIDA, Addiction Research Center, Baltimore, MD 21224.

Cocaine increases the extracellular concentrations of dopamine (DA) by inhibiting DA uptake at transporter sites. Although the binding of the transporter appears normal immediately after repeated administration of cocaine, fewer sites in the nucleus accumbens (Nac) are evident 10 days after withdrawal of cocaine than after withdrawal of its vehicle. To assess the time course of the recovery of the binding of transporter sites in the Nac, we treated male Lewis rats repeatedly with infusions of cocaine (1 mg/kg IV) or 0.15 M NaCl (0.1 ml/kg IV) every 12 min for 2 hr per day for 10 days. The rats were killed within 15 min of the last infusion (Day 0), or 10 or 30 days later. The binding of [³H]WIN 35,428 to the membranes from the striatum and the Nac was assessed in each animal. The [³H]WIN 35,428 binding was significantly reduced in the Nac but not in the striata of rats withdrawn from cocaine. Reductions of 30% were found after both 10 and 30 days of withdrawal when compared to the vehicle controls. Additionally, binding decreased by 40% in both withdrawn groups when compared with cocaine-treated rats killed on Day 0. The reduction of [³H]WIN 35,428 binding during cocaine withdrawal thus appears to be persistent and may be involved in sensitization or other long-lasting effects of cocaine.

COCAINE BINDING SITES IN MOUSE STRIATUM, DOPAMINE AUTORECEPTORS, AND COCAINE-INDUCED LOCOMOTION. M.E.A. Reith and G. Selmecki. Division of Neurochemistry, N.S. Kline Institute, Orangeburg, New York, NY 10962.

A possible regulation of cocaine (COC) binding sites and dopamine (DA) autoreceptors was studied in a COC sensitization model. Male BALB/cBy mice were treated once daily with saline (SAL) or COC (25 mg/kg IP) for 3 days. The locomotor response to COC on day 3 was significantly higher than on day 1 as opposed to the locomotion following SAL. One day after the last session, the striatum was prepared for the measurement of the binding of the COC analog [³H]WIN 35,428 (CFT) under conditions of single-site kinetics. There was no difference between the SAL and COC group in the K_d (12 nM) or B_{max} (5.8 pmol/mg prot.). In a similar experiment, mice that showed sensitization to the locomotor stimulatory effect of COC on day 3, responded on day 4 to a low dose of apomorphine (0.03 mg/kg SC), targeted at DA autoreceptors, with the same reduction in locomotor behavior as mice pretreated for 3 days with SAL, indicating the importance of mechanisms other than regulation of striatal COC binding sites or DA autoreceptors.

Although C57BL/6ByJ mice showed a greater locomotor response to acute COC administration (25 mg/kg IP) than BALB/cByJ mice, the affinity and density of [³H]CFT binding to striatal membranes was the same in the two strains. Differences other than striatal COC binding appear to be involved, with our previous work suggesting a role for brain cocaine disposition. (Supported by NIDA 03025)

EVIDENCE THAT THE HIGH AFFINITY DA REUPTAKE INHIBITOR GBR12909 IS LESS EFFECTIVE AT ENHANCING MESOLIMBIC DOPAMINE FUNCTION THAN COCAINE. B.B. Rothman¹, A. Kim¹, N. Greig², B.R. de Costa³, K.C. Rice³, F.L. Carroll⁴, and A. Per⁵. ¹NIDA Addiction Research Center, Baltimore, MD 21224. ²LN, NIA, Bethesda, MD 20892. ³LMC, NIDDK, Bethesda, MD 20892. ⁴RTI, Research Triangle Park, NC 27709. ⁵BPB, NIMH, Bethesda, MD 20892.

Dopamine (DA) uptake inhibitors appear to stimulate locomotor activity by elevating extracellular levels of mesolimbic DA. In the present study, rats received i.p. injections of behaviorally equipotent doses of cocaine (COC, 20 mg/kg), GBR12909 (GBR, 20 mg/kg), nomifensine (NOM, 5 mg/kg), WIN-065-2 (WIN, 1 mg/kg) or saline (SAL). Locomotor activity and stereotypy were measured for 30 min. The subjects were sacrificed. Brain supernatants were prepared and kept frozen at -70°C. Aliquots of the supernatants were serially diluted, and assayed for inhibition of [³H]DA reuptake by a striatal synaptosomal preparation. The percent inhibition produced by 200 μM of supernatants were 0, 13.5, 37.9, 25.2, 90.3 for SAL, COC, NOM, WIN, and GBR groups. The brain level of GBR was calculated to be about 1 μM. Control studies determined that brain supernatant did not metabolize these agents. In vivo binding assays demonstrated 61.2, 78.1, 58.1 and 100% occupancy of the DA transporter in the COC, NOM, WIN, and GBR groups, respectively. These data support the hypothesis that COC, WIN and NOM enhance mesolimbic DA function at substantially lower occupancy of the DA transporter than does GBR.

SODIUM REGULATION OF [³H]COCAINE BINDING TO THE DOPAMINE TRANSPORTER. A.J. Eshleman, A.T. Eldefrawi, and M.E. Eldefrawi. Dept. Pharmacology and Experimental Therapeutics, Univ. Md., Baltimore, Md. 21201.

The interaction between Na⁺ and buffering ions in regulating cocaine binding to the dopamine transporter in bovine striatum was studied. [³H]Cocaine binding to membranes was measured in several buffers with varying concentrations of Na⁺ but constant osmolarity. Na⁺ decreased significantly the transporter's affinity for [³H]cocaine in either 10 mM Na₂HPO₄ or 20 mM NaHCO₃. Little change was observed in maximal number of binding sites (B_{max}). However, in 50 mM Tris, the B_{max} of [³H]cocaine increased in a dose-dependent manner in presence of NaCl, peaking at 70 mM Na⁺. There was little or no change in the affinity. In absence of Na⁺, [³H]cocaine binding in Tris was extremely suppressed; the addition of Na⁺ increased B_{max} to the levels observed in the other two buffers. These results show that there is an interaction between the Na⁺ and cocaine binding sites and that Na⁺ is inhibitory in the physiologically relevant bicarbonate buffer. It is suggested that Tris may bind to the Na⁺ site and inhibit cocaine binding allosterically. (Supported by NIDA grant #DA036805.)

CHARACTERIZATION AND LOCALIZATION OF ³H-WIN 35,428 BINDING SITES IN RABBIT BRAIN. V. J. Aloyo, A. L. Kirifides, S.E. McMaster, J. Guo and J.A. Harvey. Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

The binding of the potent cocaine analog, WIN 35,428 (WIN) was investigated using adult rabbits. Coronal brain sections incubated with [³H]-WIN in the presence or absence of 30 μM [-]cocaine revealed a high density of specific WIN binding sites in the caudate-putamen. Binding assays were performed using a crude membrane fraction prepared from caudate-putamen at 0°C in 20 mM phosphate buffer, pH 7.4 containing 0.32 M sucrose and [³H]-WIN. Nonspecific binding was defined as the binding remaining in the presence of 1 μM WIN. Scatchard analysis revealed a single binding site with a K_d of 3 nM and a B_{max} of 2.3 pmoles/mg tissue. [-]Cocaine completely displaced bound WIN and Hill plot analysis demonstrated a single site ($n = 0.89$) and an IC_{50} of 44nM. Dopamine also competed with WIN binding at a single site; Hill analysis ($n = 0.92$) and an IC_{50} of 3.3 μM. The presence of a single WIN binding site in rabbit brain, in contrast to other species, will facilitate investigation of the properties of WIN binding. (Supported by NIDA Grant DA04944-04).

COMBINING PCR AMPLIFICATION WITH SUBTRACTION HYBRIDIZATION TO DETECT COCAINE-REGULATED G-PROTEIN COUPLED RECEPTORS IN RAT NUCLEUS ACCUMBENS. J.R. Walker, R.S. Duman, E.J. Nestler, and K.A. Sevarino, Lab. of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

Behavioral, electrophysiological, and neurochemical studies indicate that the nucleus accumbens (NAc) plays a major role in the reinforcing actions of cocaine. To define the biochemical changes that underlie this reinforcement we are developing methods to identify mRNA species regulated in the NAc by chronic cocaine.

We initially used subtraction hybridization (SH) and a lambda-based NAc cDNA library to identify cocaine-regulated mRNAs. We could detect moderately abundant and more common mRNAs, but not rarer species. To overcome this limitation, we optimized electrotransformation of the bacterial strain DH10B and synthesized plasmid-based libraries that were an order of magnitude more complex than in lambda phage (10^7 versus 10^6 per μg cDNA).

A second difficulty encountered in SH is poor selectivity resulting in many false-positive clones. To reduce this problem we utilized degenerate primers in a PCR amplification step to detect G-protein coupled receptor sequences in an SH-enriched cDNA population. Preliminary studies indicate that this approach allows for detection of cocaine-regulated sequences that otherwise would escape PCR amplification if nonsubtracted material were used.

SH and PCR offer novel ways to identify some of the molecular adaptations to cocaine that underlie its addictive actions.

IN VIVO BINDING TO DOPAMINE AND SEROTONIN UPTAKE SITES IN THE MOUSE WITH THE COCAINE ANALOG [^{125}I]-RTI-55; AUTORADIOGRAPHY, REGIONAL DISTRIBUTION, AND PHARMACOLOGY. E.J. Cline, U. Scheffel¹, J.W. Boja, W.M. Mitchell, F.I. Carroll^{2*}, and M.J. Kuhar, Neuroscience Branch, N.I.D.A./A.R.C., Baltimore, MD 21224, ¹Dept. of Radiology, The Johns Hopkins Med. Inst., Baltimore, MD 21205, and ²Research Triangle Inst., Research Triangle Park, NC 27709.

[^{125}I]-RTI-55 is a cocaine analog with high *in vitro* affinity for dopamine transporters and potent behavioral effects. *In vivo* binding studies were carried out to assess the possibility of using radiolabeled RTI-55 for visualizing cocaine binding sites by PET or SPECT. Mice were injected i.v. with 2-4 μCi [^{125}I]-RTI-55 and binding was determined in whole brain autoradiograms and in several dissected brain regions. Autoradiography revealed highest binding in DA rich areas and lesser binding in 5-HT rich areas. Highest regional radioactivity concentrations (%dose/gram) occurred at 1-2 hours. Specific to non-specific (cerebellar) ratios in DA rich areas increased from 0.88 at 15 min to 14.60 at 8 hrs and decreased significantly by 24 hrs. WIN 35,428 and unlabeled RTI-55 produced dose dependent inhibition of [^{125}I]-RTI-55 accumulation in dopamine rich brain areas. Paroxetine and citalopram produced a similar effect in 5-HT rich areas. Results with RTI-55 suggest it will be a useful tool for labelling DA and 5-HT uptake sites *in vivo*.

ANALOGS OF CFT AND CIT FOR IMAGING COCAINE RECEPTORS. J.L. Neumeyer, S.Y. Wang*, R. Zong*, R. Baldwin*, Y. Zea-Ponce*, M. Lanielle, and R. Innis, Research Biochemicals Inc., 1 Strathmore Road, Natick, MA 01760 and Yale University School of Medicine, West Haven, CT 06516.

Our recent finding that the potent cocaine analog, 2 β -carboxymethoxy-3 β -(4-fluorophenyl)-tropane (CFT, also known as WIN 35,428) when tritiated or labeled with $^1\text{CH}_3$ was a superior radioligand probe for cocaine receptors [*Mol. Pharmacol.* 36, 518 (1989)] led to the development of analogs suitable for PET and SPECT imaging. The corresponding 3 β -(4-iodophenyl)tropane analog [*Eur. J. Pharmacol.* 194, 133 (1991)] designated as CIT, the iodo analog of CFT, was found to be the most potent ligand so far prepared for binding to the dopamine transporter and was selected as an *in vivo* labeling ligand. The receptor affinities of CIT, CFT and related iodo-fluoro analogs as well as a series of carbamates related to cocaine were determined from displacement studies using brain tissue homogenates prepared from baboon striatum and ^3H -CFT as the radioligand.

MULTIPLE DOPAMINE TRANSPORTERS: DIFFERENT MOLECULAR WEIGHTS IN RAT STRIATUM AND NUCLEUS ACCUMBENS. R. Lew, R. Vaughan*, R. Simantov and M.J. Kuhar, Neuroscience Branch, National Institute on Drug Abuse/Addiction Research Center, Baltimore, MD 21224.

The molecular weight of the dopamine transporter in rat striatum and nucleus accumbens was examined using the photoaffinity probe [^{125}I]-DEEP and SDS-PAGE electrophoresis. Using molecular weight standards, analysis revealed that the apparent molecular weight of the dopamine transporter in the nucleus accumbens (77 kDa) was significantly higher than that in the striatum (72 kDa; $P < 0.004$, $n = 5$). In some experiments, [^{125}I]-DEEP binding to the dopamine transporter in the nucleus accumbens and striatum was performed in the absence or presence of mazindol, nomifensine, GBR 12909, (-) & (+) cocaine, desipramine and citalopram. The pharmacological binding characteristics of [^{125}I]-DEEP binding in the nucleus accumbens was identical to that in striatum and was consistent for binding to the dopamine transporter. Treatment with neuraminidase (2 U/ml) removed terminal sialic acid residues from [^{125}I]-DEEP labeled transporter from both regions resulting in proteins of similar apparent molecular weights. It appears a major reason for the difference in the apparent molecular weight of the dopamine transporter in these two regions is due to a difference in glycosylation. Additional experiments examining this hypothesis is in process.

61.14

In Vitro Autoradiographic Characterization of 3 β -[4-iodophenyl]-tropane-2 β -carboxylic Acid Methyl Ester ([^{125}I]-RTI-55) Binding to Dopamine and Serotonin Uptake Sites in Rat Brain. W.M. Mitchell, J.W. Boja, E.J. Cline, R. Lew, F.I. Carroll¹, A. Lewin², M.J. Kuhar, NIDA/ARC, Baltimore, MD 21224. ¹Research Triangle Inst., Research Triangle Park, NC 27709.

The cocaine analog ([^{125}I]-RTI-55) binds with high affinity to both dopamine and serotonin uptake sites in rat brain. Brain sections incubated with [^{125}I]-RTI-55 (50pM) alone or together with 10 μM mazindol revealed mazindol displaceable binding in the striatum, nucleus accumbens, olfactory tubercle, ventral tegmental area, and substantia nigra. Citalopram (50 μM) inhibited [^{125}I]-RTI-55 binding in cortex and hindbrain. Competition studies with [^{125}I]-RTI-55 (50pM) and citalopram, (-)cocaine, (+)cocaine, mazindol, GBR 12909, haloperidol, and desipramine in coronal sections through striatum/accumbens resulted in IC₅₀ values corresponding closely with those reported in rat striatal membrane preparations. These findings indicate that the high affinity and specific activity of [^{125}I]-RTI-55 make it an excellent ligand for autoradiographic studies of cocaine binding site.

61.16

A ROTATING DISK ELECTRODE VOLTAMMETRIC INVESTIGATION OF THE INHIBITORY MECHANISM OF COCAINE ON THE DOPAMINE UPTAKE CARRIER *IN VITRO*. J.S. McElvain and J.O. Schenk, Depts. of Biochemistry and Chemistry, Washington State University, Pullman, WA 99164.

A rotating disk electrode (RDE) system was used to study the effects of cocaine on the kinetics of exogenous and endogenous dopamine (DA) uptake into rat striatal homogenates. The homogenates were incubated at 37°C in 500 μL of physiological buffer in the presence or absence of increasing amounts of cocaine (0.5-8 μM). Approximately two minutes after the addition of cocaine, either exogenous (by direct addition) or endogenous (by KCl stimulation) DA was introduced into the incubation medium. The resulting DA uptake signal was monitored by the RDE, and the raw uptake rate data was analyzed graphically using the Eadie-Hofstee linear transformation of the Michaelis-Menten kinetic mechanism to determine the kinetic parameters, V_{max} and K_{m} . Under resting conditions it was found that cocaine inhibits exogenous DA uptake uncompetitively however endogenous DA uptake was inhibited noncompetitively in homogenates depolarized with KCl. Hill plot analyses showed that there was one DA, one sodium, and one chloride binding site on the DA uptake carrier. Isosmotic replacement of sodium in the incubation medium with choline in the presence and absence of cocaine demonstrated that cocaine is noncompetitive with the sodium site on the DA uptake carrier under resting conditions. In contrast, it was shown that cocaine competes directly with the chloride site on the DA uptake carrier under resting conditions when chloride was substituted isosmotically with isethionate.

Supported by the Washington Alcohol and Drug Abuse Program and MH 42759 (JS).

IN VIVO AUTORADIOGRAPHIC DISTRIBUTION OF COCAINE RECOGNITION SITES IN MONKEY BRAIN. M.J. Kaufman, R.D. Spealman and B.K. Madras. Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772-9102.

The cocaine congeners [³H]CFT ([³H]WIN 35,428) and [¹²⁵I]CIT ([¹²⁵I]RTI-55) were used to map cocaine recognition sites in squirrel monkey (*Saimiri sciureus*) brain by *in vivo* autoradiography. Cocaine recognition sites labeled by [³H]CFT were distributed heterogeneously in primate brain. The regions of highest density were the caudate-putamen, nucleus accumbens-olfactory tubercle, substantia nigra-ventral tegmental area and amygdala. Lower densities were found in the subthalamus including the zona incerta and the hypothalamus. This distribution pattern parallels *in vitro* autoradiographic distribution reported previously (Soc. Neurosci. Abstr. 16:746). The distribution of [¹²⁵I]CIT binding *in vivo* was similar to that observed for [³H]CFT. The striatal: cerebellar ratios for both radioligands were at least 3:1. Higher levels of binding were detected with [¹²⁵I]CIT in the thalamus, cortex, and brainstem nuclei. The results suggest that [³H]CFT and [¹²⁵I]CIT label similar though not identical populations of binding sites in squirrel monkey brain, and both can be useful imaging probes for detecting cocaine receptors *in vivo*. Supported by DA06303, DA00499, RR00168 and MH14275.

PRELIMINARY EVIDENCE FOR MULTIPLE [³H]GBR12935 BINDING SITES OR STATES ASSOCIATED WITH THE DOPAMINE TRANSPORTER IN RAT STRIATAL MEMBRANES. H. C. Akune¹, G. C. Char², B. R. de Costa¹, K. C. Rice¹ and R. B. Rothman². ¹LMC, NIDDK, Bethesda, MD 20892; ²NIDA Addiction Research Center, PO BOX 5180, Baltimore, MD 21224

We conducted quantitative binding studies using [³H]GBR12935 and [³H]mazindol to label the dopamine transporter in rat striatal membranes. Binding surface analysis of the interaction of GBR12935, CFT and BTCF with [³H]GBR12935 demonstrated that a two site model fit the data better than a one site model. The Bmax values of the [³H]GBR12935 binding sites were about 3000 (site 1) and 15,000 fmol/mg protein (site 2). The Ki values of mazindol for sites 1 and 2 were about 600 nM and 50 nM. GBR12935 had similar affinity for both sites (Kd about 1 nM). [³H]Mazindol binding surfaces were best described by a one site model: Bmax about 16,000 fmol/mg protein, Kd about 150 nM, Ki of GBR12935 about 1 nM. Given the low affinity of mazindol for site 1, these data support the hypothesis that [³H]mazindol selectively labels site 2. These preliminary findings suggest that single ([³H]mazindol) or multiple ([³H]GBR12935) affinity sites/states of the DA transporter can be resolved depending on which radioligand is used.

61.18

PHARMACOLOGICAL CHARACTERIZATION OF SOLUBILIZED COCAINE RECEPTORS FROM RHESUS STRIATUM. L.M. Gracz and B.K. Madras. Harvard Med. Sch., NERPRC, Southboro, MA 01772.

High- and low- affinity binding components for [³H]cocaine and [³H]CFT (2 β -carbomethoxy-3 β -(4-fluorophenyl)-tropane) have been identified in homogenates of monkey caudate-putamen. The heterogeneity of binding sites in membranes was not due to ligand degradation. Cocaine receptors were solubilized from the caudate-putamen of rhesus monkey with 1% digitonin in Tris-HCl buffer (~60% yield). Binding properties were determined in competition experiments with [³H]CFT. [³H]CFT binding was fully inhibited by cocaine congeners, monoamine uptake inhibitors, and monoamine neurotransmitters with the same order of potency observed in membranes ($r = 0.994$, $p < 0.001$), suggesting that [³H]CFT binding sites are associated with the dopamine transporter. CFT, cocaine, and (-)norcocaine inhibited [³H]CFT binding with shallow competition curves (n_H 0.61-0.89) in both membrane and solubilized material. Monoamine uptake inhibitors structurally unrelated to cocaine (GBR 12909, Lu 19-005, and bupropion) also inhibited [³H]CFT binding but with steeper competition curves (n_H 0.94-1.1). This suggests that these drugs bind differently to the [³H]CFT labeled sites. Thus the nature of [³H]CFT binding heterogeneity can be studied in solubilized preparations. Supported by USPHS grants DA06303, DA00499, RR00168, and MH14275.

DRUGS OF ABUSE--COCAINE: DEVELOPMENT

62.1

PRENATAL COCAINE EXPOSURE EFFECTS THE LOCOMOTOR RESPONSE TO ACUTE AMPHETAMINE ADMINISTRATION IN WEANLING RATS. H. E. Hughes and D. L. Dow-Edwards. Laboratory of Cerebral Metabolism, Department of Pharmacology, SUNY Health Science Center, Brooklyn, N. Y., 11203

Our lab has previously demonstrated that gender differences in the baseline activity of 21-22 day old control rats were absent following prenatal cocaine exposure. The present study investigated the effects of prenatal cocaine exposure on locomotor activity following acute amphetamine injection in weanling rats. Pregnant rats were gastrically intubated with 30 or 60 mg/kg/day cocaine HCl or vehicle during gestational days 8-22. Vehicle-treated rats were pair-fed/watered to rats receiving 60 mg/kg cocaine. A non-treated control group was maintained. At parturition, litters from all four groups were surrogate fostered. At 21-22 days of age, four offspring per litter were sequentially placed in a Digiscan Activity Monitor. Activity counts were collected in one minute intervals over a 15 min. baseline period. Subjects then received either 0.1 or 0.25 mg/kg amphetamine sulfate sc followed by a 95 min. period of activity monitoring. Pending completion of the statistical analysis, preliminary data indicate that weanling rats in the 60 mg/kg group traveled more distance than pair-fed controls in response to amphetamine. In particular, pair-fed males tended to remain at rest throughout the session. Therefore, prenatal cocaine administration appears to enhance the locomotor response to amphetamine in weanling rats. Supported by ADAMHA grant #DA04118.

62.2

PRENATAL COCAINE IN RATS ALTERS IMMUNOCOMPETENCE IN OFFSPRING. G.D. Royall, L. McGurk, R.F. Smith, M. Coss*, P. Naylor* and K. K. Oates. Dept of Psychology, George Mason U. Fairfax, VA 22030, and *Dept of Biochemistry, Geo. Washington U., Washington, D. C. 20037

Since we previously found that prolactin (PRL) levels are reduced in neonatal rats dosed prenatally with cocaine, we dosed rats with 5, 10, 20, or 40 mg/kg/d cocaine from GD7 through GD20, and evaluated components of cellular immune functioning in the offspring at several ages. At P1, high dose offspring had reduced thymus weights but no significant changes in thymosin alpha-1 (TA1). At P21, high dose offspring had substantial thymic hypertrophy, high TA1 levels, and reduced mitogen-induced T cell proliferation. At approximately P95, phagocyte-killing index following *C. albicans* infection was reduced in high dose animals. These data suggest that low PRL levels in neonates experiencing withdrawal after prenatal cocaine may have lasting effects upon a number of components of the immune system.

62.3

SEX DIFFERENCES IN RESPONSIVENESS TO AMPHETAMINE IN ADULT RATS: THE ROLE OF TESTOSTERONE EXPOSURE DURING THE NEONATAL PERIOD FOR SEXUAL DIFFERENTIATION. M.L. Forgie and J. Stewart. Center for Studies in Behavioral Neurobiology, Dept. of Psychology, Concordia University, Montreal, Quebec, Canada, H3G1M8.

Sex differences in both acute responsiveness to amphetamine (AMPH), and sensitization to its behavioral effects following repeated administration, have been reported (e.g., Camp & Robinson, 1988). Females show higher levels of behavioral activation than males. These sex differences have been suggested to be due in part to differences in circulating levels of gonadal hormones in the adult animals (i.e. an "activation effect"). In the present studies, the extent to which adult sex differences in responsiveness to AMPH can be attributed to differential exposure to testosterone (T) during the critical period for sexual differentiation was investigated. In Experiment 1, at birth, male pups were sham-operated or gonadectomized, while female pups were given T or a control injection. At 80-90 days of age all animals were gonadectomized or sham-operated, and were tested in the absence of circulating gonadal hormones. In Experiment 2, the same procedure was followed except that all animals received 5.0 ug estradiol benzoate (s.c.), 30-40 min. prior to each behavioral test. Locomotor activity in response to either 1.5 mg/kg AMPH (i.p.) or the saline vehicle was measured for 2 h. every 3 days, on 5 occasions. On the 6th occasion all animals received 0.75 mg/kg AMPH (i.p.) in a test for sensitization.

The results of the first experiment suggest that neonatal exposure to T suppresses responsiveness to AMPH in adulthood. The results of Experiment 2, were similar, but further suggest that in the presence of circulating estrogen (E), female animals may be more responsive to AMPH regardless of neonatal T exposure. These results suggest that lifetime exposure to E alters responsivity to this hormone in adult animals.

62.5

BRIEF MATERNAL D-AMPHETAMINE EXPOSURE PRODUCES HYPERDOPAMINERGIC BEHAVIORS IN ADULT OFFSPRING. M. Lyon and W.O. McClure. Center for Neuropsychiatry and Schizophrenia Research, Univ. Arkansas for Medical Sciences, Little Rock, AR 72205 and Neurosciences Program, Univ. Southern California, Los Angeles, CA 90089.

This experiment was designed as a rodent model of brief drug abuse during pregnancy, hence treated mothers raised their own young. D-amphetamine was chosen for its abuse potential, anorexic effect, and dopamine stimulation. Procedure: 14 pregnant Sprague-Dawley rats received either saline (N=4), d-amphetamine 2.0 mg/kg (N=5), or 5.0 mg/kg (N=5). Treatment occurred on gestational days 11-14, during early fetal neurotransmitter formation and cell migration. Results: At weaning, there was a dose-related weight reduction in both drug groups compared to the saline control group (Total N=110). The 5.0 mg/kg group weighed less than the 2.0 mg/kg group $P < 0.002$, and the 5.0 mg/kg group remained lighter as adults. As juveniles, drug exposure reduced eating time in both sexes ($P < 0.006$), but not foraging ability in the hole-board. In the 5.0 mg/kg group, hole-board behavior showed decreased rearing at the wall ($P < 0.03$) and less mid-field locomotion ($P < 0.0005$), but in females only. Drug-exposed young adults had strongest conditioned turning preference from the startbox in both sexes ($P < 0.05$). Perseveration in turning occurred in the 5.0 mg/kg group even when food location changed ($P < 0.04$; Chi-square). Turning preferences peaked at 2PM in all groups, paralleling seasonal ultradian rhythms in striatal dopamine receptor-binding (Kafka et al., 1981). Amphetamine challenge (1.0 mg/kg) significantly increased rearing at the wall in females, yet reduced rearing in mid-field for both sexes.

Conclusion: Taken together, these results indicate that hyperdopaminergic behavior results, especially in female young, from even brief maternal abuse.

THE EFFECTS OF GESTATIONAL COCAINE EXPOSURE ON LOCOMOTOR ACTIVITY IN ADULT RATS. L. Rajachandran, C.J. Heyser, and L.P. Spear. Center for Developmental Psychobiology, Dept. of Psychology, SUNY, Binghamton, NY 13902-6000.

In a recent study in our laboratory examining cocaine-induced conditioned place preference, adult offspring exposed gestationally to cocaine were observed to exhibit more crossing between chambers on the test day (Heyser et al., submitted). Although hyperactivity has been observed early in life following gestational cocaine treatment (Hutchings et al., 1989; Spear et al., 1989; Henderson & McMillen, 1990) exposed offspring have been reported to exhibit normal levels of activity as adults (Giordano et al., 1990; Henderson & McMillen, 1990; Sobrian et al., 1990). The present study examined open field activity in adult offspring using a treatment regimen previously observed to produce neurobehavioral alterations in developing as well as adult offspring (e.g., Spear et al., 1989; Scalzo et al., 1990; Heyser et al., 1990). Adult female offspring from Sprague Dawley dams injected s.c. from gestational day 8-20 with 40 mg/kg/3cc cocaine HCl, offspring from two types of nutritional controls, and untreated dams were tested in a 56 x 66 x 45 cm open field for 15 min/day over three consecutive days. No differences among the prenatal treatment groups were observed in open field activity, with all groups showing comparable levels of habituation within each test session. Thus, although adults offspring exposed gestationally to cocaine exhibit apparent increases in motility in certain testing situations (Heyser et al., submitted), these animals do not appear to be hyperactive in the open field.

PRENATAL COCAINE ADMINISTRATION AFFECTS RADIAL-ARM MAZE PERFORMANCE IN YOUNG ADULT RATS. F. J. Seidler and E. D. Levin. Departments of Pharmacology and Psychiatry, Duke University Medical Ctr., Durham, N.C. 27710

In utero cocaine exposure has been shown to cause delays in early behavioral development. However, it is not known if this exposure affects performance on cognitive tests in older animals. The current study examined the effects of prenatal cocaine administration (30 mg/kg, s.c. from gestational day 8 through 20) on 8-arm radial maze performance in young adult rats. Starting approximately day 50, animals were given 18 training sessions; these sessions were grouped into 3 blocks of 6 sessions each for analysis. Three-way ANOVA (factors = treatment x sex, repeated measure = session block) indicated that, while there was no significant main effect of cocaine treatment, there was a significant cocaine x sex x session block interaction in choice accuracy ($p < 0.005$). Further analysis revealed choice accuracy deficits in cocaine-treated females during the third phase of training ($p < 0.005$); in contrast, cocaine-treated males exhibited improved choice accuracy during this phase ($p < 0.05$). Response latency was not significantly affected by cocaine exposure. These results demonstrate that prenatal cocaine exposure can cause long-lasting alterations in cognitive task performance. (Supported by grants from the United Way, Duke University Medical School Research Fund and USPHS DA05031)

62.6

EFFECTS OF PRENATAL COCAINE EXPOSURE ON FETAL RAPHE DEVELOPMENT. E.M. Factor, R.P. Hart and G.M. Jonakait. Dept. Biol. Sciences, Rutgers Univ., 101 Warren St., Newark, NJ 07102.

Disorders among cocaine-exposed infants suggest the medullary raphe nuclei (MRN) as potential targets for cocaine-induced disabilities. Serotonin (5-HT) and substance P (SP) are colocalized in individual neurons of the MRN. Colocalization is an early-appearing and enduring feature of these cells (Ni and Jonakait, Neuroscience 30:257). In order to determine possible neurochemical abnormalities resulting from prenatal cocaine exposure, we measured levels of mRNA coding for the SP prohormone preprotachykinin (PPT), SP peptide levels, and the activity of tryptophan hydroxylase (TPH, the rate-limiting enzyme in 5-HT synthesis) throughout perinatal and early postnatal development.

Pregnant rats at embryonic day 7 (E7) were implanted (s.c.) with Alzet osmotic minipumps dispensing either 10 or 40 mg/kg cocaine HCl dissolved in sterile saline daily for two weeks. Controls received sham surgery, but no pumps. Maternal plasma cocaine concentrations one and two weeks after pump implantation were ≥ 30 ng/ml for the lower dose and ≥ 160 ng/ml for the higher dose. Maternal weight gain, duration of pregnancy and fetal viability were normal at both doses. Levels of PPT mRNA in the MRN, assessed from E17 through postnatal day 14, were found to be normal in pups receiving the lower dose. SP peptide levels in the ventral spinal cords (sites of raphe termini) and TPH activity in the first postnatal week were also unchanged by this dose. These data suggest that exposure throughout gestation to low concentrations of the monoamine uptake inhibitor, cocaine, have negligible consequences for the development of these neurotransmitters.

GESTATIONAL EXPOSURE TO COCAINE DECREASES SENSITIVITY TO THE REWARDING PROPERTIES OF COCAINE IN INFANT RAT PUPS. C.J. Heyser, G.A. Goodwin, C.A. Moody, and L.P. Spear. Center for Developmental Psychobiology, Dept. of Psychology, SUNY, Binghamton, NY 13902-6000.

Previous work from our laboratory has shown that adult offspring exposed gestationally to cocaine did not exhibit a cocaine-induced conditioned place preference (CPP), findings that could reflect either a learning deficit or a decrease in the reinforcing properties of cocaine (Heyser, Miller, Spear, and Spear, submitted). In order to further characterize the effects of gestational exposure on the later reward efficacy of cocaine, offspring derived from Sprague Dawley dams that received daily subcutaneous injections of 40 mg/kg/3cc cocaine hydrochloride (C40) from Gestational Day 8-20, nutritional control dams receiving daily saline injections (NC), and nontreated control dams (LC) were tested for cocaine-induced odor preference early in life. On Postnatal Day 6, each pup received an intraperitoneal injection (i.p.) injection saline and was placed into a chamber scented with 1 cc of orange odor for 30 min. On Postnatal Day 7 (P7), each pup was given an i.p. injection of either 0 (saline), 2.0, 5.0, or 10.0 mg/kg cocaine HCl, and placed into a chamber scented with 1 cc of lemon odor for 30 min. On the third day (P8) a preference test for location was conducted between the two odors (Lemon vs Orange). Both the LC and NC offspring were observed to exhibit a preference for the odor paired with 2.0, 5.0, and 10.0 mg/kg cocaine when compared to saline controls. In contrast, C40 offspring exhibited a preference for the odor only when paired with 5.0 or 10.0 mg/kg cocaine. These results, combined with our previous CPP data in adult animals (Heyser, et al., submitted), provide evidence that prenatal cocaine exposure results in a decrease in the later rewarding properties of cocaine.

62.9

EFFECTS OF NEONATAL COCAINE (COC) EXPOSURE ON SEROTONIN (5HT) RECEPTORS IN RATS. M.A. Kosek, G.A. Ordway and R.M. Kliegman, Depts. of Pediatrics and Psychiatry, Case Western Reserve Univ., Rainbow Babies & Childrens Hosp. and MetroHealth Med. Ctr., Cleveland, Ohio 44106.

Knowledge of the long-term effects of COC on development of the brain is crucial to understanding the outcome of infants born to mothers who abused COC during pregnancy. We have studied the effect of COC on development of the brain monoamine system in a rat model. Previously, we found that exposure of neonatal rats to COC for 15 to 30 days resulted in profound reductions in central beta-1 adrenergic receptors, particularly in the hippocampus, and no changes in D1 or D2 dopamine receptors. Since COC also potently inhibits the neuronal reuptake of 5HT, its presence during development could interfere with maturation of the brain 5HT system. In this study, we measured 5HT-2 receptors in rats treated with saline or COC 15 mg/kg three times daily from birth to 15 days. The binding of 2 nM ³H-ketanserin was quantitated in homogenates of frontal cortex, using 10 uM methysergide to define non-specific binding. There was no difference in the binding of ³H-ketanserin in frontal cortex from saline (103±13 fmol/mg protein) or COC (100±8 fmol/mg protein) exposed rats. Based on these and previous monoamine receptor studies, neonatal COC exposure seems to alter only noradrenergic receptor development.

62.11

PRE- AND PERINATAL EXPOSURE TO COCAINE INCREASES SENSITIVITY OF FEMALES TO LOW DOSE OF APOMORPHINE. J.H. McLean, J.Thomas, B.L.Slifer*, and P.Stevens*. Dept. of Psychology, University of New Orleans, New Orleans, LA 70148.

Preliminary investigations were conducted to determine whether the reported increase in dopamine (DA) metabolic activity in females exposed to cocaine (COC) during early development had behavioral significance. Adult male and female rats that had been exposed to COC (40 mg/kg) or a control treatment during prenatal and early postnatal development were injected with apomorphine (APO; 0, .1, or 1.0 mg/kg) and observed for its effects on rearing and sniffing. The results revealed that the low dose of APO which reportedly stimulates pre-synaptic receptors, had a significantly greater effect on sniffing in females exposed to COC than on sniffing in either females given control treatments or males exposed to COC. The findings suggest 1) that females are more vulnerable to exposure to COC during development; 2) that the enhanced activity of the DA system reported previously may be related to pre-synaptic function; and 3) that among APO modulated behaviors, sniffing is more strongly affected.

62.13

PRENATAL COCAINE EXPOSURE ALTERS AGGRESSIVE BEHAVIOR IN ADULT SPRAGUE-DAWLEY RAT OFFSPRING. J.M. Johns, L.W. Means, E.W. Bass, M.J. Means*, L.I. Zimmerman* and B.A. McMillen, Depts. of Pharmacol. and Psychol., E. Carolina Univ., Greenville, N.C., 27858.

Gravid rats received one of 3 treatments throughout pregnancy: s.c. injections b.i.d. of saline, 15 mg/kg cocaine (Coke I), or cocaine on a 2 day on, 4 day off schedule (Coke II). Saline treated dams were pair fed with Coke I dams. Male pups were cross fostered to surrogate dams within 24 hr of birth. At PND 180, one offspring from each litter was placed in co-habitation with an ovariectomized female for 2 weeks. Frequency, duration and latency of behaviors were recorded during two 15 min sessions for subjects exhibiting any of 13 social/aggressive behaviors while the female was replaced by a smaller male intruder. Subjects received a s.c. saline injection before session I and 2.0 mg/kg of gepirone, a 5HT_{1A} agonist, 30 min prior to session II. Five of 11 Coke I and 0/10 control offspring exhibited all 3 aggressive behaviors of circle threat, aggressive posture and fight attack (p<0.05, Fisher's Exact test). In session II, differences in most aggressive behaviors were no longer significant and aggressive behavior was reduced by gepirone in all groups. Prenatal cocaine treatment resulted in aggressive (or social) behavioral changes in adult rat offspring, but did not alter the behavioral response to a 5HT_{1A} agonist. (Supp. by grant DA 04895)

62.10

IN UTERO METHAMPHETAMINE DIFFERENTIALLY REGULATES ADULT BRAIN MONOAMINE UPTAKE SITES. A.D. WEISSMAN AND S. CALDECOTT-HAZARD. Addiction Research Center, NIDA, Baltimore, MD 21224 and Univ Southern Calif, Los Angeles, CA 90089.

Chronic amphetamine-like drugs exert a profound effect on monoamine systems in the brains of mature animals. These changes appear as deficits in neurochemical function (e.g. neurotransmitter uptake) that probably relate to the neurotoxicity of the compounds. We examined both the behavioral and biochemical consequences of prenatal methamphetamine (MA) exposure where a greater potential effect may occur as compared to adults. Female rats were chronically treated with either 2 or 10 mg/kg MA prior to conception and throughout the pregnancy. Pups were not given any additional drug after birth and were behavioral tested beginning at 30 days of age. Only the litters given 10 mg/kg showed behavioral deficits as compared to control litters (Caldecott-Hazard, *Soc Neurosci Abst*, 16, 586, 1990). A postmortem examination of regional brain serotonin (5HT), dopamine (DA) and norepinephrine (NE) uptake sites showed a paradoxical effect of the two dose regimens. 5HT uptake was reduced in the cortex, striatum and hippocampus for the 2 mg/kg group, but was normal in most areas or increased in the hippocampus and pons of the 10 mg/kg litters. DA uptake was reduced in the striatum after both treatments, but the effect was attenuated in the striatum and also showed an increase in the pons of the 10 mg/kg group. A decrement occurred in NE uptake in the posterior cortex with both doses, but mirrored the effects in the other uptake systems with the greatest decrease at the lowest dose of MA. The novel dose-related changes in the monoamine uptake sites may indicate a regional regenerative process in the brain that is a function of MA exposure *in utero*. Monoamine levels are currently being assessed in the same animals. (Grants NINDS #K07NS00979 and USC FRIG).

COCAINE INJECTED ICV PRODUCES PLACE PREFERENCE CONDITIONING IN THE NEONATAL RAT. S. Wang and G.A. Barr. New York State Psychiatric Institute, 622 W. 168th St., NY, NY 10032 and Dept. Psych., Hunter College, 695 Park Ave. NY, NY 10021

Conditioned place preference (CPP) in adult animals has been used to study the reinforcing properties of cocaine and other drugs. These drugs likely act on the mesolimbic dopamine system, in particular, the ventral tegmental area (VTA) and nucleus accumbens (NAcc), to produce their reinforcing properties. Similar reward mechanisms may be present in infants: rat pups show a CPP when morphine is administered peripherally or to the VTA, and cocaine facilitates intracranial self-stimulation of limbic forebrain sites. In the present experiments, the CPP paradigm was used to investigate whether cocaine would produce a conditioned preference in the neonate, and if so, at which site(s) in the CNS. Three or 4-day old pups were injected with cocaine (i.p.; i.c.v.; or directly to the NAcc or VTA) and then confined to an odor-cued environment for 30 minutes. Four to 5 hours later, they were tested for 4 trials of 2 minutes each with the conditioned odor on one side and unscented wood shavings on the other side. The pups injected peripherally with cocaine (0.0-30.0 mg/kg) showed no preference. The pups administered cocaine i.c.v. (0.0, 3.0, 10.0, 30.0, 100.0 µg) displayed a dose-dependent preference for the side paired with the drug injections, with a significant preference induced by the two highest doses. Results from cocaine microinjected directly into either VTA or NAcc at doses of 0-25.0 µg are still preliminary. These overall results indicate that the reinforcing properties of cocaine are present at early ages in rat and are mediated through CNS. The reasons why systemic administration of cocaine did not produce conditioned odor preference are not known. (Supported in part by DA-06600)

STRIATAL PATCH-MATRIX ORGANIZATION AND COCAINE-MEDIATED C-FOS INDUCTION IN RATS PRENATALLY EXPOSED TO COCAINE. A.M. Snyder-Keller and R.W. Keller, Jr. Wadsworth Ctr., New York State Dept. Health, Albany, NY 12201, and Dept. of Pharmacol. & Toxicol., Albany Medical College, Albany, NY 12208.

Previous studies have described morphological changes in the basal ganglia following chronic cocaine administration, particularly during development. Development of the patch/matrix organization of the striatum was examined in rats prenatally exposed to cocaine (20 mg/kg SC, maternal admin.) daily from gestational day 7-21. Immunocytochemical staining for tyrosine hydroxylase (TH), substance P (SP), enkephalin, and calbindin was used to reveal the patch-matrix organization at different ages. Overlapping patches of TH-immunoreactive terminals and SP-immunoreactive cells were visible during the first week of life. Normal compartmentalization was also revealed at 18 days of age, when neurons of the matrix were immunoreactive for enkephalin and calbindin. A greater density of 5-HT-immunoreactive fibers was apparent relative to controls. Acute cocaine (20 mg/kg, IP) produced widespread fos-immunoreactive neurons in the medial 2/3 of the striatum. Pretreatment with the NMDA antagonist MK-801 (1 mg/kg, IP) blocked cocaine-mediated c-fos induction in this medial region, but resulted in the appearance of dense fos immunoreactivity in the lateral region. These results were similar to those obtained in normal animals, and suggest that the basic organization of striatal neurons, and DA and glutamatergic afferents, is not altered by prenatal cocaine exposure at the dose used. PRENATAL COCAINE INCREASES EXTRACELLULAR DOPAMINE IN DEVELOPING RATS AS MONITORED BY IN VIVO MICRODIALYSIS.R.W. Keller, Jr., I.M. Maisonneuve, D. Nuccio*, J.N. Carlson, S.D. Glick
Dept. of Pharmacol. & Toxicol., Albany Medical Col., Albany, NY 12208

Pregnant rats were given injections of saline (SAL) or cocaine (COC, 10 mg/kg twice daily, SC) between gestational days 7-21. Offspring were examined by microdialysis to study the effects of prenatal COC on the nigrostriatal dopamine (DA) system. Awake rats were examined between postnatal days 12-60. 20-min samples were assayed for DA, DOPAC, and HVA. After 4 baseline samples, the rat was exposed to 20 min of intermittent tail pinch and monitored for 4 samples; an acute injection of COC (20 mg/kg, IP) followed and 6 samples were collected.

Basal extracellular fluid (ECF) levels of all DA markers, estimated from pre-implantation calibration of the probes, were markedly reduced in young rats (12 d) as compared with adult rats (60 d). Basal DA, as well as DOPAC and HVA, were elevated in the prenatal-COC rats examined at the earliest ages. The response to tail pinch was minimal in both groups. In absolute magnitude, the increase in ECF DA induced by acute COC was greater in prenatal-COC rats; however, expressed as percent of baseline the groups did not differ. Furthermore, the increase in ECF DA after acute COC was more prolonged in prenatal-COC rats. As the rats aged, the levels of DA and metabolites in the prenatal-COC rats approached those of the prenatal-SAL controls. By 60 days of age there were no differences in any of the DA parameters. Thus prenatal exposure to COC produces an elevation in ECF DA after birth that gradually returns to normal as the rat ages. [Supported by DA-06199]

DEVELOPMENTAL GENETIC MODELS

FURTHER CHARACTERIZATION OF THE DOPAMINERGIC DENDRITE DEFICIT IN SUBSTANTIA NIGRA PARS RETICULATA OF HETEROZYGOUS AND HOMOZYGOUS WEAVER MUTANT MICE: GOLGI, MAP2 AND SYNAPTIC CONNECTIVITY STUDIES. L.C. Triarhou & B. Ghetti.
Dept. Pathol. (Neuropathol.) & Med. Neurobiol. Pgm, Indiana Univ., Indianapolis, IN 46202.

Following our initial identification of a structural defect in dopaminergic (DA) dendrites of substantia nigra pars reticulata (SNr) of *wv/+* and *wv/wv* mice (*Brain Res.* 501: 373, 1989), we used Golgi, immunocytochemical and ultrastructural techniques to further investigate this deficit. Antibodies against microtubule-associated protein 2 (MAP2), a marker for dendritic processes in nervous tissue, disclosed, in accordance with our previous observation, a substantial loss of dendrites in both *wv/+* and *wv/wv*. In Golgi preparations, the diameter of fusiform varicosities was reduced in remaining dendrites of *wv/+* by 33.6% and in *wv/wv* by 40.7%. By pre-embedding electron microscopic immunocytochemistry, 49.8% of TyroHase immunoreactive dendrites in SNr received synaptic input from unlabeled axon terminals in *+/+*, 23.7% in *wv/+*, and 9.4% in *wv/wv*. These data (i) suggest that in addition to being fewer, remaining DA dendrites of *wv/+* and *wv/wv* are aberrant in structural and most likely functional terms, (ii) strengthen the view that the dendritic DA projection of the SN represents a subcellular target of the *wv* gene and (iii) may offer insight into how the mutation hinders process outgrowth and maintenance. (Supported by USPHS RO1-NS14426, R29-NS29283 and PDP, Research & Sponsored Programs, IU).

SAGITTAL ORGANIZATION OF TYROSINE HYDROXYLASE EXPRESSION IN PURKINJE CELLS OF TOTTERING AND TOTTERING-LEANER COMPOUND HETEROZYGOUS MUTANT MICE. J.A. Heckroth and L.C. Abbott. Indiana University School of Medicine, Terre Haute Center for Med. Ed., Terre Haute, IN, 47809 and University of Illinois, Dept. of Vet. Biosci., Urbana, IL 61801.

Recent reports have demonstrated the presence of tyrosine hydroxylase (TH) and TH-mRNA in cerebellar Purkinje cells in tottering (*tg*) and leaner (*tg^{la}*) mutant mice. In the present study we report that TH-immunoreactive (IR) Purkinje cells in tottering (*tg/tg*) and tottering-leaner compound heterozygotes (*tg/tg^{la}*) are distributed in rostrocaudal stripes through all lobules of the cerebellar vermis and hemispheres. The sagittal bands of TH-IR Purkinje cells are narrow (3-5 cells wide) in the anterior lobe, but become increasingly wide in more posterior lobules. The pattern of TH expression in *tg/tg* and *tg/tg^{la}* cerebella bears striking similarity to that described for the Zebrin molecule and 5'-nucleotidase in normal mice, although the mutual identity of these patterns has not yet been confirmed by direct comparisons in these mutants. While numerous TH-IR fibers and varicosities are present in the cerebellar cortex in the mutants, the axons of the TH-IR Purkinje cells are not stained, and the cerebellar and vestibular nuclei do not contain TH-IR terminals which can be morphologically identified as originating from Purkinje cells. What functional role the products of TH activity might play within *tg* and *tg^{la}* Purkinje cells, or at Purkinje cell targets, remains to be determined. The differential expression of a mutant gene in sagittal bands of Purkinje cells is not unique to *tg* and *tg^{la}*, but the potential abnormal expression of neurotransmitter phenotype in sagittal Purkinje cell subsets deserves further investigation.

63.2

INCREASED SEROTONIN LEVELS IN THE STRIATUM OF THE WEAVER MUTANT MOUSE. E.H. Stotz, B. Ghetti, and J.R. Simon. Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

Homozygous weaver mice (*wv/wv*) and rats with 6-hydroxydopamine lesions in the substantia nigra (SN) exhibit a loss of dopamine (DA) cells in the SN and altered neurochemical markers in the striatum (STR). Rats lesioned as neonates develop a hyperinnervation of serotonin (5-HT) in the STR not seen in rats lesioned as adults. Since the weaver mutation appears at an early age, these mice were investigated to determine if they also have a striatal hyperinnervation of 5-HT by measuring the content of 5-HT along the rostro-caudal extent of the STR. In 14 month old mice there was a 60-100% increase in 5-HT on a pmoles/mg protein basis and a 15-20% decrease in protein content. Therefore, we investigated 5-HT content per section and found an increase in striatal content from 35-90% depending on the rostro-caudal section investigated. Thus, the increase in 5-HT content is not an artifact solely due to a decrease in protein content. The data for 8 month old mice mirror that in 14 month old mice. Preliminary data for 1, 2 and 3 month old mice show trends which are qualitatively similar to those seen in the older mice. (Supported by RO1 NS14426 and PO1 NS27613)

MYOBLAST TRANSFER: THE FIRST SUCCESSFUL CELL THERAPY IN TREATING MAMMALIAN GENETIC DISEASES. P.K. Law, T.G. Goodwin*, Q. Fang*, J.A. Florendo, H.J. Li*, M. Chen*, D.S. Kirby*, M.B. Deering*, J. Cornett*, T.J. Yoo, R.L. Holcomb*. Cell Therapy Research Foundation, Memphis, TN 38117.

Myoblast transfer therapy (MTT) is a cell therapy being developed for hereditary myopathies. It is a form of gene therapy that does not require the identification of the abnormal gene. Through a cell fusion process that occurs naturally during muscle development and regeneration, donor myoblasts insert full complements of normal genes into dystrophic muscle cells. Therefore, regardless of which gene is abnormal or which protein is missing, MTT has potential application for all hereditary muscle degeneration. Donor myoblasts also fuse among themselves to form normal myofibers that progressively replace the degenerative fibers. Thus, MTT replenishes lost cells and repairs degenerating cells. As such, it is the first genetic engineering procedure that has demonstrated any functional significance in treating mammalian genetic diseases.

The initial clinical trial on Duchenne muscular dystrophy (DMD) boys indicated that the myoblast-injected foot muscles produced dystrophin and showed structural and functional improvement.

Further development involves thirty DMD boys, aged 6 to 14 years, who are receiving myoblast injections in the major muscle groups of their lower limbs. Injected muscles include the gluteal extensors and flexors of the leg and the foot. Both limbs are being injected. Donor myoblasts are derived from cell culture of muscle biopsies from young males, preferably the normal father or normal brother of the subject. CsA treatment begins two days before myoblast injection and continues for three months. Three days prior to myoblast injection, and at three month intervals lasting up to nine months, the isometric dynamometry of muscle groups of the left and right lower limbs are recorded. Comparison of the muscle function before vs. after myoblast injection will determine if the procedure exerts any beneficial effect on the dystrophic muscles. (Supported by private donations)

GENETIC STUDIES OF MOTOR NEURON DEGENERATION (Mnd) IN THE MOUSE. A. Messer, J. Plummer, P. Maskin, J. M. Coffin and W. N. Frankel. Wadsworth Center for Laboratories and Research, N.Y. State Dept. of Health and Dept. of Biomed. Sci., Sch. of Public Health, SUNY, P.O. Box 509, Albany, NY 12201-0509; and Dept. of Mol. Biol., Tufts Univ. Sch. of Med., Boston, MA 02111.

The mouse mutant *Motor neuron degeneration (Mnd)*, which arose spontaneously on a C57Bl/6 background, displays an adult-onset progressive degeneration of upper and lower motoneurons, leading to spastic paralysis and premature death. While many obligate +/Mnd mice from the original stocks showed clear neuropathology, with a similar age of onset and a milder disease course than Mnd/Mnd mice, current stocks held in a semi-sterile environment and bred over several years for a very consistent age of onset in Mnd/Mnd show greatly reduced penetrance in the heterozygous state. Work therefore focuses exclusively on Mnd/Mnd at this time.

In order to map the Mnd gene, F2 progeny from a B6 Mnd/Mnd outcross to AKR were scored for neurological symptoms, then assayed for strain and chromosome-specific polymorphisms. Close linkage (5cM) of Mnd to the endogenous xenotropic murine leukemia virus fragment Xmv-26, Ank-1 and Polb on proximal chromosome 8 has been observed.

In the course of examining the F2 mice from the AKR outcross, 8 - 12% showed a very early onset (<5 months) of disease symptoms, with much more rapid progression than B6 Mnd/Mnd mice. No such acceleration has been seen in outcrosses to 5 other strains, including C3H and BALB/c. Additional breeding experiments are consistent with the existence of a timing gene, unlinked to Mnd itself, which has an early allele on the AKR background. (Supported by the ALS Association and NIH grant R35-CA44385.)

ENHANCED SENSITIVITY TO HYPOXIA-INDUCED LOSS OF SYNAPTIC TRANSMISSION IN A MOUSE MODEL OF MUSCULAR DYSTROPHY. M.F. Mehler, K.Z. Haas, J.A. Kessler and P.K. Stanton. Albert Einstein Coll. Med., Bronx, NY 10461.

Dystrophin is a member of a protein super-family that links the actin cytoskeleton to plasmalemmal glycoproteins. In neurons, dystrophin is restricted to specific somatodendritic regions and to cell populations that are particularly susceptible to hypoxic injury. To investigate whether genetic absence of dystrophin may predispose specific neuronal populations to hypoxic injury, we examined the effects of graded hypoxic insults on synaptic transmission in mdx mouse hippocampal slice preparations.

Extracellular excitatory postsynaptic potentials (e.p.s.p.s) were recorded at Schaffer collateral-commissural synapses in stratum radiatum of field CA1 in control and mdx slices incubated in dual interface recording chambers and simultaneously exposed to successive hypoxic insults (5, 8, and 15 min) by substituting N₂ for O₂. Mdx slices showed an earlier and larger irreversible loss of synaptic transmission compared to controls. 30 min after a 5 min hypoxic insult, slices from control mice exhibited 86 ± 10.8% (mean ± S.E.M.) recovery of synaptic transmission, while mdx slices averaged only 27 ± 15.8% recovery to the same hypoxic insult (n=7, p<0.05, Student's t-test). This selective vulnerability was partially ameliorated by preincubation with the anticonvulsant diphenylhydantoin (20 μM, phenytoin, DPH). Untreated mdx slices displayed partial irreversible loss of e.p.s.p. slopes by 3 min, and complete loss of synaptic transmission, after 8 min of hypoxia. In contrast, DPH-treated mdx slices exhibited nearly complete preservation of e.p.s.p. slopes after 8 min of hypoxia. These data suggest that dystrophin deficiency may predispose susceptible neurons to damage from hypoxia that could contribute to the development of cognitive deficits in dystrophin-deficient (Duchenne) patients. (supported by NIH, NIMH, the Klingenstein Fund and Health Foundation)

PROTEOLIPID PROTEIN GENE EXPRESSION IS REDUCED IN HYPOMYELINATED "Pt" MUTANT RABBIT. M. Tosic*, M. Dolivo*, K. Domanska-Janik* and J.-M. Matthieu. Lab. de Neurochimie, CHUV, 1011 Lausanne, Switzerland; * Dept. of Neurochemistry, Polish Academy of Sciences, Warsaw, Poland

Paralytic tremor (Pt) is an X-linked mutation in rabbits characterized by rapid rhythmic tremor of the body due to hypomyelination in the CNS. Few myelinated axons are surrounded by thin and abnormal myelin sheaths. The amount of myelin is reduced to about 30% to that of normal rabbits. However, the protein content of the Pt myelin is not significantly different from normal myelin. We studied the relative contribution of major myelin proteins to the myelin composition. A radioimmunoassay for myelin basic protein (MBP) showed about 30% reduction compared to controls, which corresponds to the extent of myelin reduction in the mutants. This reduction was confirmed by Western blots which showed similar reductions for other myelin proteins. Moreover, Western blots revealed a striking reduction in the concentration of the proteolipid protein (PLP). At the age of 4 weeks PLP concentration represented only about 15% of control values. This drastic reduction in PLP, the sex-linked transmission of the defect and the biochemical and morphological similarities with other PLP mutations in mice and rats, strongly indicate that the primary defect of the Pt mutant lies in an abnormal expression of the PLP gene.

BIOCHEMICAL AND MORPHOLOGICAL STUDIES IN THE CARDIAC AND SKELETAL MUSCLES OF mdx-MICE (DM): RELEVANCE AS A MODEL FOR DUCHENNE MUSCULAR DYSTROPHY (DMD).

P.L. Johnson, S.K. Bhattacharya, R.K. Handa, M.P. Gupta, T.A. Adamc*, and D.R. Shanklin*. University of Tennessee, Memphis, TN 38163.

Membrane-mediated chronic cellular degeneration plays a fundamental pathogenetic role in hereditary muscular dystrophy in DMD, CHF-146 strain dystrophic hamsters (DH) and xmd-dogs. We have shown that EICA, increased efflux of cellular enzymes (ALD, CPK and LDH), relative cardiac hypertrophy, reduced adenine nucleotides (ADN) and cellular energy charge (CEC), aberrated dystrophin distribution, dystrophic histopathology with profound cellular necrosis are associated with DMD and DH. Because of reported dystrophin anomalies in mdx-mice, we studied the EICA, plasma and cellular enzyme activities, ADN and CEC, light- and electron microscopic changes in cardiac and skeletal muscles of DM, and compared with those obtained from C57BL-+/+ normal mice (NM). Although high plasma enzymes and mild dystrophic changes were noticeable in the skeletal muscle as evidenced by EICA, reduced cellular enzymes and morphology, myocardium was spared in DM. No changes in cellular enzymes in heart, nor in ADN or CEC in skeletal muscle were found in DM. Apparent functional impairments or altered morbidity/mortality are also not present in DM. We conclude that DM does not share any of the severely involved cardiac pathology with DMD and DH. Nor does any premature death occur in DM due to compromised cardiopulmonary function and congestive heart failure, unlike DMD and DH. It seems, therefore, DH is by far a better model for the study of DMD than DM. Supported by NIH grant AR38540.

RFLP ANALYSIS OF THE DIFFERENTIAL SUSCEPTIBILITY OF THE SWR/J AND C57L/J MOUSE STRAINS TO A VIRALLY INDUCED DEMYELINATING DISEASE. Simone M. Nicholson and Roger W. Melvold*. Microbiology-Immunology Dept., Northwestern Univ. Med. School, Chicago, IL 60611

Theiler's murine encephalomyelitis virus (TMEV, a picornavirus) is a natural enteric pathogen of mice which, upon access to the central nervous system (CNS) of some strains of mice, can trigger a specific cell-mediated immune response leading to demyelination. Thus TMEV-induced demyelinating disease (TMEV-IDD) serves as an excellent model for human multiple sclerosis (MS).

The differential susceptibility among mouse strains to development of TMEV-IDD is influenced by multiple genetic loci. Three such loci have thus far been identified: *H-2D*, *Tmevd-1* and *Tmevd-2*. We are analyzing the differential susceptibility of the resistant C57L/J (and closely related C57BL/6) and the susceptible SWR/J strains, to see if additional relevant loci can be identified.

Backcross analysis indicates a role for 1 locus associated with the H-2 complex (possibly *H-2D*) and 1 locus unlinked to H-2, where a single copy of the SWR/J allele appears to be sufficient for susceptibility, even in the absence of "susceptible" H-2 genes. RFLP analyses, in recombinant-inbred strains between C57L/J and SWR/J (SWXL) and in segregating backcross animals are being done to identify the relevant non-H-2 locus.

63.10

EXPRESSION OF MHC CLASS II ANTIGENS AND MICROGLIAL RESPONSE IN TWITCHER MOUSE. M. Ohno, A. Komiyama and K. Suzuki. Dept. of Pathology, Univ. of North Carolina, Chapel Hill, NC 27599-7525.

Expression of major histocompatibility complex class II (Ia) antigens in the nervous systems has been reported in immunological and non-immunological diseases. Recently, we have observed many Ia antigens bearing cells in the brain of adult twitcher mouse, a murine model of human globoid cell leukodystrophy (GLD). For understanding of the pathological role of Ia antigen expression in GLD, we investigated patterns of the appearances of Ia antigen bearing cells and reactive microglia. Affected and normal control mice on postnatal days (P) 10 to 48 were perfused with a 2% PLP solution. Vibratome and cryostat sections from cerebrum, cerebellum, spinal cord and peripheral nerve were immunostained with monoclonal antibodies against mouse Ia antigen or Mac-1 antigen. In affected mouse, Ia antigen bearing cells were recognized in the peripheral nerve on P 10. On P 20, numerous Ia antigen bearing cells were observed in the white matter of spinal cord, brainstem, cerebellum and cerebrum. They were most numerous around P 30 and progressively declined after P 40. Ia antigens were positive on ramified microglia, rod shaped cells and macrophage-like cells in both white and gray matters. Ia positive cells were extremely rare in control mice at any age. Mac-1 positive reactive microglia and macrophage-like cells have been already recognized on P 10 in the spinal cord. They increased in number and were observed throughout the brain. Almost all of Mac-1 positive cells were reactive microglia and macrophage-like cells on P 48 when markedly reduced Ia bearing cells were observed. These results suggest that Ia expression may be suppressed in the advanced disease condition. Additionally, the intensity of microglial response and macrophage infiltration are not necessarily corresponding with Ia antigen expression. (Supported by Grants HD-03110, NS24453 and ES01104).

ABNORMAL PRODUCTION OF IL-1 BY MICROGLIA FROM TRISOMY 16 MICE. J. Yao*, J. Keri*, R. E. Taffs*, M. Oster-Grant and C. Colton. Georgetown Univ. Sch. of Med., Washington, DC, 20007; Johns Hopkins Univ. Sch. of Med., Baltimore, MD, 21218; and NIAID, NIH, Bethesda, MD, 20892. The production of interleukin-1 (IL-1) was examined in cultured microglia obtained from the cerebral cortices of trisomy 16 (Ts16) mice, an animal model for Down syndrome. IL-1 activity was measured in cultured microglia supernatants using a D10 cell proliferation assay. Unstimulated Ts16 microglia secreted significantly higher levels of IL-1 as compared to normal littermate microglia. Stimulation with lipopolysaccharide (LPS) increased IL-1 secretion in both normal and Ts16 microglia. However, IL-1 levels were significantly higher from the LPS-stimulated Ts16 microglia than from the normal littermates. Because cells from Down syndrome and Ts16 mice are known to have enhanced sensitivity to alpha/beta interferon (IFN) due to the triplicated alpha/beta receptor gene, we also studied the effect of alpha/beta IFN on IL-1 release. The results show that alpha/beta IFN did not increase IL-1 secretion by Ts16 microglia, but induced IL-1 secretion in normal littermate controls. However, even with the IFN stimulation, the overall level of IL-1 secreted in the normal littermates was still less than seen in Ts16. It appears that microglia in the Down syndrome animal model are abnormal in their IL-1 production. This abnormality may have important consequences to the development of the CNS.

ALTERATIONS IN LUMBAR MOTONEURON EXCITABILITY FOLLOWING THORACIC CONTUSION COMPARED TO HEMISECTION SPINAL CORD INJURY. Floyd J. Thompson¹, Ronald Parmer¹, Paul J. Reier^{1,2}. Depts. Neuroscience¹ and Neurosurgery², University of Florida, Gainesville, 32610.

Much interest has been focused on the basic mechanisms associated with the development of spastic hyperreflexia subsequent to spinal cord injury. We have been studying lumbar motoneuron excitability in the adult rat subsequent to contusion injury produced by weight-drop onto the exposed 8th segment of the thoracic spinal cord. Neurophysiological tests of motoneuron excitability were conducted at 6, 28, and 60 days post-injury. We have observed a progressive alteration in lumbar motoneuron excitability characterized by a loss of rate sensitive depression of the tibial monosynaptic reflex, decreased post-tetanic potentiation (PTP), decreased short latency autogenic depression (SLAD) of the monosynaptic reflex in a recovery curve at condition-test intervals < 50 msec, and no significant alteration in Renshaw inhibition. These alterations have been progressive in onset, significant in magnitude, and enduring in duration. They have collectively pointed to a loss of inhibitory control of reflex excitability. To determine how these deficits obtained from a diffuse bilateral injury compare to those derived from a specific unilateral injury, we have compared these findings in post-contusion animals to animals with hemisection of the T₈ thoracic spinal cord. The animals with hemisection injuries demonstrated unilateral loss of rate sensitive depression, PTP, and SLAD at one month post-injury. In the animals with contusion injuries, the deficits progressed in severity between 28 days and 60 days. However, in the animals with hemisection injuries, the maximal deficits were observed at 28 days. Rate sensitive depression and the loss of PTP progressed toward normal values when tested at 60 days, with no change in SLAD. Although preliminary, our conclusions from these data suggest that contusion related deficits progress in severity whereas deficits produced by hemisection progress toward normal values.

THIOPENTAL INCREASES SURVIVAL OF SPINAL CORD NEURONS AFTER PHYSICAL INJURY. G. Wang, J.H. Lucas and G.W. Gross. Center for Network Neuroscience, Department of Biological Sciences, University of North Texas, Denton, TX 76203.

Cooling at 17°C for 2h significantly increased survival of mammalian spinal cord (SC) neurons subjected to a defined physical injury: amputation of a primary dendrite 100 μm from the soma (Lucas et al., Brain Res. 517: 354, 1990). Possible mechanisms of hypothermic (HT) protection are general reduction of cell metabolism or a more specific inhibition of neuronal electrical activity. In the present study we tested whether addition of MgCl₂ (to stop synaptic activity) or thiopental (TP) increased survival of lesioned SC neurons.

Monolayer cultures (21-28 DIV) of embryonic (13-14 day) mouse SC were used for these experiments. A primary dendrite was transected from 10 neurons in each culture by a UV laser microbeam; 10 other neurons were selected to be unlesioned controls. After surgery the culture medium was replaced with medium containing 12-15 mM MgCl₂ or 200 μM TP.

At 24h survival was determined by erythrosine B. Survival in the TP group was 76% ± 5.4 (S.D.) compared to 50% ± 10.2 in the control (no TP) group (independent T test, p < 0.05). Survival in the MgCl₂ group was 37% ± 5.2 compared to 45% ± 10.4 in the control (no added MgCl₂) group. Each percentage represents the mean of 5-6 observations (cultures). The TP and HT studies suggest that reduction of cell metabolism increases the probability of SC neuron survival after physical injury.

64.2

EVALUATION OF THE CALCIUM CHANNEL ANTAGONIST NIMODIPINE ON AXONAL FUNCTION FOLLOWING EXPERIMENTAL SPINAL CORD INJURY. S.S. Haghghi, J.J. Oro*, T. Stiens*. Division of Neurosurgery, University of Missouri School of Medicine, Columbia, MO 65212.

In the present study, cortical somatosensory evoked potentials (CSEP) were recorded to evaluate whether the administration of nimodipine could improve axonal function in the cord after an acute spinal cord compression injury (SCCI). Forty rats received a 52-gm static compression injury on the cord at C7-T1 for five minutes, and were randomly allocated to one of four treatment groups. Each group was given an intravenous infusion of one of the following over two hours, commencing one hour before compression: placebo; and nimodipine at 0.5, 0.25, and 0.125 μg/kg/min (ten rats in each group).

The preinjury physiological parameters (latency, amplitude, blood pressure and heart rate) were not significantly different (p > 0.05) among the treatment groups. Immediately following the SCCI, 80% of the animals in the placebo group lost their evoked responses. All animals in this group regained CSEPs within 15 minutes after decompression. The rate of evoked potential loss for the nimodipine-treated animals at 0.5, 0.25 and 0.125 μg/kg was 100%, 30% and 50%, respectively. The rate of recovery of the responses after decompression was 20%, 80%, and 80% for 0.5, 0.25, and 0.125 μg/kg, respectively.

64.4

EFFECT OF METHYLPREDNISOLONE (MP) ON SURVIVAL OF SPINAL CORD (SC) NEURONS AFTER DENDROTOMY. L.J. Schaffer, J.H. Lucas and G.W. Gross. Center for Network Neuroscience, Dept. of Biol. Sciences, Univ. of North Texas, Denton, TX 76203.

A recent clinical study found MP significantly enhanced neurological recovery after SC injury at dosages of 30 mg/kg body weight (Bracken et al., New Eng. J. Med. 322: 1405, 1990). This dosage produces maximum plasma concentrations of 20-30 μg/ml in animals. The purpose of this study was to determine whether MP increases the probability of survival of mammalian SC neurons subjected to a defined physical injury: amputation of a primary dendrite 100 μm from the soma.

Monolayer cultures (21-28 DIV) of dissociated embryonic (13-14 day) mouse SC were used for these experiments. A UV laser microbeam was used to transect a primary dendrite from 10 neurons in each culture; 10 other neurons served as unlesioned controls. The medium of experimental cultures contained MP at concentrations ranging from 10 - 100 μg/ml.

Neuronal survival was determined 24 h after surgery by erythrosine B. Survival in the control (no MP) group was 59%. At MP concentrations of 10, 20, 30, 60 and 100 μg/ml survival was 53%, 58%, 58%, 40% and 40% respectively. Each percentage represents the avg. survival from 3-6 experiments (cultures). These data indicate that MP does not protect SC neurons subjected to physical trauma, and that concentrations greater than 30 μg/ml may decrease the probability of survival.

Supported by PHS grant NS 29683 and the Hillcrest Foundation of Dallas, TX founded by Mrs. W.W. Caruth, Sr.

64.5

EFFECTS OF THE MACROPHAGE TOXIN SILICA ON SECONDARY DAMAGE IN SPINAL CORD INJURY A.R. Blight, Center for Paralysis Res., Purdue Univ., West Lafayette, IN 47907.

A model of spinal cord trauma in guinea pigs, using lateral compression to a set thickness, produces a delayed functional loss below the injury at 1-2 days, followed by a partial recovery over several weeks, as measured using hindlimb motor behavior, vestibulospinal reflex testing, and mapping the receptive field of the cutaneous trunci muscle reflex. The role of inflammatory events in these secondary changes, was investigated with intraperitoneal injections of silica. Eleven matched pairs of animals were injured. One of each pair was selected randomly and injected with a suspension of 1.2 g of silica dust in sterile saline, immediately after injury and surgical closure. The animals survived up to 2 months from injury, then were fixed by perfusion with glutaraldehyde. Histopathology of the lesions was quantified by line sampling of myelinated axons, and measurement of all blood vessels, in plastic sections through the center of the lesion. The secondary onset of functional loss below the lesion was delayed by 1-2 days in silica treated animals with respect to controls. The number of myelinated axons at the center of the lesion 2-3 months after injury was higher in the silica treated animals, most significantly in the dorsal quadrant of the cord. Myelin sheath thickness and axon caliber distribution were not significantly different. Hypervascularity of the lesion was significantly reduced in silica treated animals. These findings support the hypothesis that macrophage activity during the first few days after injury plays a significant role in secondary tissue damage and is responsible for a proportion of long-term neurological deficits.

CHANGES IN RECURRENT INHIBITION IN PATIENTS WITH SPINAL CORD INJURY J.M. Shefner², S.A. Berman, M. Sarkarati², and R.R. Young. West Roxbury VA Medical Center, West Roxbury, MA 02132

The etiology of spasticity after spinal cord injury is unknown. One spinal circuit that may be affected involves recurrent inhibition of motor neurons via Renshaw cells. Suprasegmental influences may alter recurrent inhibition; animal studies show increased recurrent inhibition after spinal cord injury.

We studied the effects of spinal cord injury or recurrent inhibition using the conditioned H reflex technique (Pierrot-Deseligny, E., Bussel, B. *Brain Res.* 1975; 88: 105-108). A submaximal tibial nerve stimulus (S1) is presented prior to a supramaximal stimulus (S2), so that action potential collision permits an H reflex (H') to be elicited in response to S2. H' amplitude is partially a function of Renshaw cell activity.

In 10 patients, H' reflexes have been found to be absent in 6 at some time after their injury, in contrast to their uniform presence in controls. Sequential studies show reduction or disappearance of H' reflexes as spasticity increases; drugs that reduce spasticity produce reappearance of the H'. In patients who did have an H' reflex, its amplitude and the range of stimulus intensities that could elicit the reflex were both reduced as compared to controls.

We conclude that recurrent inhibition via Renshaw cell activity is increased in spinal cord injury, and that measures of recurrent inhibition may correlate with clinical measures of spasticity.

MDL 27,531 REDUCES HYPERREFLEXIA FOLLOWING CHRONIC SPINAL TRANSECTION IN RATS. J.H. Kehne, H.J. Ketteler¹, T.C. McCloskey¹, Y. Senyah¹, M. Dudley, A.M. Ogden¹, and J.M. Kane¹. Marion Merrell Dow Res. Inst., Cincinnati, OH 45215.

MDL 27,531 (4-methyl-3-methylsulfonyl-5-phenyl-4H-1,2,4-triazole), a selective antagonist of strychnine seizures (*Neurosci. Abst.* 15:1176, 1989), was tested for potential antispastic activity in a model of spinal cord injury in rats. Rats that had chronic spinal cord transections (T₈) displayed intermittent spontaneous hindlimb contractions ("hyperreflexia") which could be quantified with an automated apparatus. MDL 27,531 (5-40 mg/kg, i.p.), like the alpha₂-adrenergic agonist clonidine, decreased this hyperreflexia. Specific reflex responses produced by a rapid mechanical extension of the hindlimbs were not decreased, suggesting that the compounds did not generally disrupt reflex function. In contrast to clonidine, MDL 27,531 did not produce ataxia in normal rats, nor did it affect the cardiovascular system. MDL 27,531 had a lower side effect profile than the antispastic agents baclofen or diazepam. MDL 27,531 was inactive in a variety of *in vitro* receptor binding assays, but did enhance binding of the benzodiazepine antagonist ³H-Ro 15-1788 *in vivo* without directly elevating GABA levels. MDL 27,531 is a novel compound with potential for antispastic activity and minimal side effects compared with existing drug therapies.

64.6

POTASSIUM DEPENDENCE OF CALCIUM CHANGES IN SPINAL NEURONS IN ORGANOTYPIC CULTURE: STUDIES WITH FURA-2. M. Tymianski, C.H. Tator. University of Toronto, Ontario, Canada.

Neuronal death and dysfunction following spinal cord injury is considered to be mediated by a rise in intracellular calcium concentration ([Ca²⁺]_i). The injury process also results in large rises in extracellular potassium ([K⁺]_o). We examined the effects of a rise in [K⁺]_o on intracellular calcium in organotypically-cultured mouse spinal neurons. Cultures mounted in a microscope stage incubator were perfused with media supplemented with two concentrations of [K⁺]_o (4.5 mM and 25 mM). In some experiments, neurons were exposed to increasing concentrations of extracellular calcium [Ca²⁺]_o. Neurons were perfused for 7 minutes at each [Ca²⁺]_o. At the end of each perfusion period, [Ca²⁺]_i was measured with the fluorescent calcium indicator Fura-2. At [K⁺]_o = 4.5 mM, there was no increase in resting levels of [Ca²⁺]_i (80-100 nM) over a range of [Ca²⁺]_o, spanning 1 mM to 10 mM. However, experiments performed on neurons at [K⁺]_o = 25 mM revealed a sudden rise in [Ca²⁺]_i to levels exceeding 1000 nM after 50 minutes, irrespective of the levels of [Ca²⁺]_o in the perfusate. These results indicate that there exists a significant delay between exposure to high [K⁺]_o and a rise in [Ca²⁺]_i. This rise is unlikely to occur solely through activation of voltage-gated calcium channels by potassium-induced depolarization, as the delay implies involvement of a second-messenger system. We also show that normal neurons are not immune to secondary injury effects.

64.8

VULNERABILITY OF INJURED SPINAL CORD AXONS TO HYPOXIA M.G. Fehlings, K. Sakatani, M.R. Lee and W. Young NYU Medical Center, New York NY 10016

Traumatized spinal cord axons undergo secondary injury which may in part be due to ischemia. However, it is unknown whether injured spinal axons are more vulnerable to hypoxic/ischemic injury than normal axons. Thus, we examined the effect of hypoxia on normal and injured spinal cord axons *in vitro*. A segment of dorsal column (DC) was isolated from the thoracic cord of adult rats (n=16). The compound action potentials (CAPs) activated by bipolar supramaximal stimuli were recorded at 2 points with glass microelectrodes (1-2 MΩ). The DC segment was compressed between the microelectrodes for 15 sec. with a modified aneurysm clip (closing force = 2 g). Following recordings in oxygenated Ringer's solution, the DC was rendered hypoxic by superfusion with N₂-saturated Ringer for 1-2 hrs. After hypoxia, the preparations were superfused with oxygenated Ringer for 90 minutes.

Hypoxia at 37 °C (n=6) attenuated the CAP (p<0.05) recorded distal to the lesion (11.7 ± 5.9% of control), more than the CAP recorded proximally (36.8 ± 6.4 % of control). Maximal CAP recovery proximally (71.4 ± 11.1 %) exceeded (p<0.05) that recorded distally (38.2 ± 3.5%). At 24-27° C (n=6) hypoxia also caused greater CAP diminution (p<0.01) of the injured segment (16.1 ± 7.4% of control) than in the proximal portion (74.3 ± 6.2% of control). Oubain (0.1-1.0 mM; n=4) attenuated the CAP of injured axons more (p<0.05) than in proximal uninjured axons, mimicking the effects of hypoxia. We conclude that hypoxia affects injured axons more than uninjured axons and that inhibition of membrane bound Na⁺-K⁺-ATPase partially mimics hypoxia-induced axonal dysfunction.

64.10

NEW INSIGHTS INTO THE MECHANISM OF FORMATION OF CYSTS IN THE SPINAL CORD OF RATS AFTER SPINAL CORD INJURY. G.Guizar-Sahagun¹, I.Grijalva¹, I. Madrazo, R.Franco-Bourland¹, E.Oliva¹, A.Ibarra¹, H.Salgado¹, A.Zepeda¹, R.Barrios¹ and B.Ortega-Corona. Camina Research Center for Spinal Cord Regeneration, 14050 Mexico City, Mexico.

To characterize the process of formation and the anatomical features of post-traumatic cysts of the spinal cord (SC), 54 adult rats were subjected to graded SC contusion of the lower thoracic region. The injured zone and neighboring areas were studied by light and electron microscopy, from day 1 to 1 year after contusion. Three phases were characterized in the cyst formation: 1- NECROSIS, from the day 1 to 1-2 weeks, showing hemorrhage, thrombosis, axonal segmentation and inflammatory infiltration. 2- REPAIR, from 1-2 to 8-15 weeks, showing necrotic tissue reabsorption, revascularization, trabeculation, and delimitation between the damaged and the preserved tissues. 3- STABILITY, from 8-15 to 52 weeks, no further significant changes were observed. The cyst wall does not have a uniform structure or cell composition, and its thickness can be very variable, even in the same specimen. The characterization of stages of SC cyst formation is useful to plan strategies for their use as transplant receptacles.

64.11

SPINAL CORD INJURY IN RATS, USING A DISPLACEMENT CONTROLLED IMPACT DEVICE: EFFECTS OF NALMEFENE, U-50488H, AND YM-14673
D.L. Behrmann*, J.C. Bresnahan, M.S. Beattie, B.R. Shah* The Ohio State University, Columbus, OH 43210

A reproducible spinal cord contusion (SCC) in rats is made (spinal T9) using a displacement controlled impact device (DCID). Force and displacement transducers on the impact probe allow for immediate verification of spinal cord displacement (DSPL), time course of injury (20-23 msec), and resulting force. Varying DSPL produces tight behavioral groups with consistently predictable spinal cord lesions and degrees of incomplete neurologic deficit ranging from mild to severe. This allows for assessment of positive and negative treatment effects and of pharmacologic efficacy at different levels of neurologic deficit. Neurologic recovery is evaluated using open field walking (OFW), inclined plane (IP), grid walking (GW), and footprint analysis (FA). Percentage of tissue sparing is determined at the epicenter and by volumetric analysis of the lesion.

We used the DCID (DSPL=1.10 mm) to compare the efficacy of 3 compounds previously shown to improve behavioral outcome after acute SCC in rats: the opioid antagonist Nalmefene (NLF), which has increased activity at kappa receptors, the specific kappa agonist U-50488H (U50), and the TRH analogue, YM-14673 (YM), which has no kappa receptor binding activity in vitro. These were administered i.v. bolus or by osmotic pump over 7 days, beginning 30 min. after injury: NLF (0.1 mg/kg bolus, n=8; 3.6 mg/kg pump, n=8), U50 (10 mg/kg bolus, n=8; 71.4 mg/kg pump, n=8), YM (1 mg/kg bolus, n=8), controls (sterile water, n=8). Results indicated better OFW performance for all 3 compounds given i.v. bolus. Also, YM resulted in improved inclined plane score, a greater percentage of "grid-walkers" vs "non-grid-walkers" (also supported by FA), and sparing of fibers at the lesion epicenter. The results argue against a kappa receptor mediated mechanism of injury and suggest potential use of these compounds, especially YM, for treatment of acute spinal cord injury. Supported by NIH Grant NS10165 and Training Grant NS07291.

A NEURONAL CASCADING EFFECT: TESTING A NOVEL HYPOTHESIS IN THE ENTERIC NERVOUS SYSTEM. J.Y. Jew and T.H. Williams. Dept. of Anatomy, Univ. of Iowa, Coll. of Med., Iowa City, IA 52242.

We hypothesize that a perturbation such as an obstruction-induced distention of a segment of gut is transmitted from the intestine wall to the dorsal root ganglia (DRG). That is, there is a sequential effect, whereby changes at the second (higher) level depends on changes at the first (lower) level. We focused on a sensory pathway using the DRG as our experimental model. Male Sprague-Dawley rats (250-300 g. b.w.) were anesthetized with Nembutal (40 mg/kg b.w.), and the ileum was partially obstructed by application of a plastic cuff around the terminal ileum. Approximately 3 weeks later, control and obstructed animals were reanesthetized, and the terminal ileum was injected with the fluorescent retrograde tracer Fast Blue (FB) eight days prior to sacrifice. In DRG, the most intensely labeled cells and the greatest number of labeled cells were found at T11 and T12. In T11 DRG, the mean perikaryon area of FB-labeled neurons was 224% of control. The mechanism(s) mediating the sensory ganglion responses after a perturbation of the gut wall are not known. Our observation that only the FB-labeled DRG neurons are greatly enlarged makes it unlikely that hormones, nonspecific inflammatory substances generated in the gut, or neuron growth-promoting substances conveyed to the DRG by vascular transmission, are responsible. Consideration of other factors is also required, in particular, increased neuronal firing or transport of trophic factors, such as NGF or glial maturation factor, that may act as a regulator for the neuroplastic response in DRG neurons servicing the distended segment. In conclusion, neuronal responses to the obstruction extend beyond changes within the viscus. This is the first morphological report documenting synergistic and neuroplastic consequences of a perturbation in a sensory autonomic ganglion. We hypothesize that, with variations, this concept of a cascading or sequential effect applies to sensory ganglia servicing all viscera. Supported by grant DK38123.

REGIONAL BRAIN CONCENTRATIONS OF SODIUM AND POTASSIUM AFTER EXPERIMENTAL BRAIN INJURY. M.J. Thomas, D. Breaux, B. Nolan, D. Smith and T.K. McIntosh. CNS Injury Laboratory, Surgical Research Center, Department of Surgery, University of Connecticut Health Center, Farmington, CT 06030, USA.

Alterations in the extracellular and intracellular cation concentrations after experimental brain injury have been reported by several investigators; however, there is little known about the specific time course following brain injury. In the present study, male Sprague-Dawley rats (300-375gm) were anesthetized and subjected to a moderate (2.3-2.5atm) lateral fluid-percussion brain injury directly over the left parietal cortex. Sham-operated control (n=28) and injured animals (n=28) were sacrificed at 10min, 1, 6 and 24h post-injury, brains removed and dissected into left and right parietal cortex, left and right adjacent cortex, bilateral hippocampi and brainstem. Dissected tissue samples were weighed, extracted and analyzed for [Na⁺] and [K⁺] by flame atomic absorption spectrophotometry. At 10min post-injury, [Na⁺] increased in the left hippocampus (p<0.05). At 1h, [Na⁺] increased in injured and non-injured cortex and bilateral hippocampi, while [K⁺] decreased in the injured and left adjacent cortex (p<0.05); all cations remained increased through 24h (p<0.05). Brainstem [Na⁺] decreased at 6h and [K⁺] decreased at 1h and remained decreased through 6h (p<0.05). These prolonged alterations in regional cation concentrations may contribute to irreversible secondary injury associated with brain trauma. Supported, in part, by NIH NS26818, VA Merit Review Grant 74R, and a grant from the Brain Trauma Foundation.

U-50488H REDUCES VASCULAR PERMEABILITY AND EDEMA IN RAT SPINAL CORD INJURY. Z.X. Qu*, J. Xu, P.L. Perot* and E.L. Hogan. Depts. of Neurology and Neurosurgery, Med. Univ. of SC, Charleston, SC 29425.

Vascular injury plays a very important role in the secondary injury process of CNS trauma. It has been reported that U-50488H, a selective opioid R receptor agonist, has neuroprotective and diuresis effects. This study reports the effect of U-50488H on vascular permeability and edema in rat contusive spinal cord injury. A sensitive fluorometric method was used for the evaluation of U-50488H on extravasation of fluorescein isothiocyanate conjugated dextran (FITC-D, a macromolecular tracer). Edema was measured by dry-wet weight method in rat contusive cord with 40g-cm trauma force.

The results showed that U-50488H, 5, 10, 20 and 40 mg/kg ip at 0.5 hr before and after trauma reduced vascular permeability expressed as a vascular injury index (VII) in a dose-dependent manner. Multiple injections of U-50488H at 0.5 hr before and 0.5, 2, 8 and 22 hr after trauma also reduced VII significantly (p<0.01). The same administration of U-50488H significantly diminished edema formation. The water content in spinal cord was 71.11±0.27% compared to the control 72.47±0.22% (p<0.01). These results suggest U-50488H has a beneficial and protective effect on vascular damage in CNS trauma. Supported by NS-11066.

REDUCING BRAIN EDEMA IN EXPERIMENTAL CONCUSSIVE BRAIN INJURY WITH POSTINJURY TREATMENT BY POLYSACCHARIDE-DEFEROXAMINE. M. Tangoren*, L. Levi*, A. Wolf, R. Broadwell and B. Hedlund. Div. Neurosurgery, Univ. MD, Sch. Med., Balto., 21201.

Prophylactic administration of iron chelators, such as deferoxamine, improves outcome following several types of brain injury, probably due to free radical scavenging. Our hypothesis is that similar improvement can be achieved with a deferoxamine-polysaccharide conjugate (DFO-PSC) (Biomedical Frontiers, Minn.) after moderate fluid percussive injury in the rat. Fifteen minutes after receiving a right parasagittal 2.9 atm concussive injury (LD25), surviving rats from a group of 90 received intravenous DFO-PSC (50 mg/kg) or a similar volume of vehicle. One, 2, and 5 days postinjury, brain edema was determined in multiple cortical and deep brain regions using a gravimetric technique. Thirty-two rats received the drug, and 32 received vehicle. The difference in edema was statistically significant in all brain regions after each period postinjury. The specific gravity of the right cortical areas in the drug group on day 1 were 1.0506 (.0017) vs. control of 1.0426 (.0023), p<.001; day 2: 1.0485 (.0023) vs. 1.0424 (.0023), p<.001; day 5: 1.0491 (.0023) vs. 1.056 (.0026), p<.01. These data suggest post-injury treatment with DFO-PSC dramatically reduces concussive brain edema.

LATENCY REDUCTION OF VISUAL EVOKED RESPONSE (VER) - POSSIBLE GLUTAMATERGIC EXCITATION SECONDARY TO A FOCAL BRAIN INJURY. S. XU*, H.G. WAGNER. Lab. of Neuropathology and Neuroanatomical Sciences, NIH, NINDS, Bethesda, MD 20892

Following localized freezing injury to the cortex, we have observed calcium deposits at sites in addition to the injured area. These deposits suggest the presence of a secondary hyper-neuroexcitation which may be related to the neuro-excitotoxicity. We looked for physiological evidence of this neuroexcitation.

Electrodes were placed in the rat cranium over the visual cortex, one were later a cold probe was applied transcranially to the parietal cortex. VER to a stroboscopic flash were processed through a computer.

In the unlesioned rat the latency for the VER was about 44 ± 3 msec (Mean ± SD). Four to six hours after placement of the freeze, the latency had decreased to 40 ± msec (N = 13) (P < 0.01). The latency reached its lowest values of 37 ± 2 msec 1 to 3 days after application of the lesion. There was a little change in the unlesioned side. One week later there was a partial recovery of latency (42 ± 3 msec).

Glutamate is believed to be involved in the neuronal death after brain injury. The secondary neuronal hyperexcitation may be also glutamatergic. Further support we found in the observation that the effect of cold injury on latency or VER was reduced or abolished by application of MK-801 (3 mg/kg i.p.). And in unlesioned rats the latency of VER also reduced after topical application of L-glutamate (1mM).

Our results suggest that there is secondary neuroexcitation of the cortex adjacent to a cold lesion and it may related to glutamate.

RISES OF EXCITATORY AMINO ACIDS TO TOXIC LEVELS UPON IMPACT INJURY TO THE RAT SPINAL CORD AND THE EFFECTS OF METHYLPREDNISOLONE ON THOSE LEVELS.

D. Liu and D.J. McAadoo Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550

Release of excitatory amino acids (EAA) has been implicated in damage arising from injury to the central nervous system. These substances are neurotoxic *in vitro* at concentrations exceeding normal physiological levels in extracellular fluid. We utilized microdialysis sampling and analysis by high pressure liquid chromatography to determine whether impact injury to the rat spinal cord caused extracellular levels of EAA to reach levels that are toxic in *in vitro* experiments. *In vivo* calibration of the microdialysis fiber demonstrated that glutamate rises from 21 μ M before injury to ca. 200 μ M following injury. Parallel results for aspartate were 7 μ M to 122 μ M. Other neurotransmitter amino acids also rise dramatically in response to spinal cord injury; most non-neurotransmitter amino acids rose much less. Glutamate is strongly toxic to cultured neurons at 50-100 μ M,¹ and aspartate has comparable toxicity. Thus impact injury of the rat spinal cord raises EAA concentrations to toxic levels, adding to the evidence that those substances may contribute to secondary damage upon injury to the spinal cord. A recent clinical study² demonstrated that 30 mg/kg of methylprednisolone ameliorates the long-term deficits caused by spinal cord injury in humans. In preliminary experiments, 30 mg/kg of methylprednisolone administered to rats at the time of injury hastened the decline in excitatory amino acid levels.

Corticosterone's Mediation of Traumatic Brain Injury. D.M. Gbadebo, R.J. Hamm, B.G. Lyeth, L.W. Jenkins, J.K. Stewart, J.H. Porter. Departments of Psychology, Neurosurgery and Biology, Virginia Commonwealth University/Medical College of Virginia, Richmond, VA 23298.

Elevated corticosterone levels have been shown to exacerbate neuropathological damage produced through a variety of insults. Clinical reports indicate that following head trauma, cortisol levels are markedly elevated in patients with poor outcome. In the present experiment, adult rats were treated chronically with corticosterone acetate (15ug/ml) supplied in their drinking water. Although a mild level of injury (1.75 atm.), produced no deficits in vehicle treated animals, corticosterone treated rats displayed significant motor and cognitive deficits. The exhibited deficits did not appear to be due to serum hyperglycemia. The data demonstrate that elevated corticosterone levels potentiate deficits following traumatic brain injury. The results also suggest that elevated basal levels of corticosterone may mediate the age-related increase in vulnerability to deficits following traumatic brain injury.

REGIONAL DISTRIBUTION OF ENDOGENOUS IgG AND IgM RESEMBLES 72KD HEAT SHOCK PROTEIN EXPRESSION FOLLOWING TRAUMATIC BRAIN INJURY. H. Soares, B. Osteszeska*, K. Okiyama, and T.K. McIntosh. Surg. Research Cntr, Univ CT Health Cntr, Farmington, CT 06030.

Previous fluid percussion (FP) brain injury studies in our laboratory have demonstrated consistent patterns of blood brain barrier (BBB) breakdown in cortical, hippocampal, and thalamic regions. There exists little argument concerning the damaging consequences of hemorrhage into neural tissue. However, few studies have focused upon various "protein exudates" following acute damage to the BBB. The present study examined endogenous immunoglobulins in brain following traumatic head-injury. Anesthetized adult rats were subjected to moderate (2.2-2.4 atms) FP brain injury. Animals were sacrificed at 5 min, 2 hrs, 4 hrs, and 24 hrs post-injury (n=4/group). Sham operated animals (n=4) served as controls. Anti-rat IgG and IgM immunocytochemistry demonstrated staining of both neurons and glia in regions of trauma induced BBB breakdown. The majority of positive anti-rat IgG/IgM stained cells appeared shrunken and necrotic. However, many positive cells exhibited a more Golgi-like appearance. Positive cells were observed as late as 24 hours post-injury. The pattern of anti-rat IgG/IgM staining bore striking similarities to the pattern of 72KD heat shock protein expression after brain injury (McIntosh et al., *Neurosci Abst*, 1989). Cross-reactivity between rat and mouse immunoglobulins has been widely documented. Staining with anti-mouse IgG in our model exhibited the same patterns as the anti-rat IgG's. Care must be taken when utilizing anti-rodent immunoglobulins as secondary antibodies in rodent brain models involving breakdown of the BBB. These results indicate that endogenous immunoglobulins are present on (or in) neurons and glia following brain trauma. Supported, in part, by NS26818, a VA Merit Review grant 74R, and a grant from the Brain Trauma Foundation.

IN VITRO AND IN VIVO ANALYSIS OF TIRILAZAD MESYLATE (U-74006F) AS A HYDROXYL RADICAL (\bullet OH) SCAVENGER. J.S. Althaus, C.M. Williams*, P.K. Andrus*, P.A. Yonkers*, G.J. Fici*, E.D. Hall and P.F. VonVoigtlander. The Upjohn Company, Kalamazoo, MI 49001.

Salicylate (SA) can be used to measure \bullet OH formation because it reacts with \bullet OH *in vivo* and *in vitro* to form dihydroxybenzoate (DHBA). We tested the neuroprotectant U-74006F as a scavenger of \bullet OH based on blockade of DHBA formation during CNS injury. \bullet OH was generated *in vitro* by mixing H_2O_2 with ferrous ammonium sulfate in phosphate buffer. U-74006F was added to the mixture and then analyzed by HPLC for loss of parent and/or appearance of products. Results showed a 50% loss of U-74006F after a 1 min exposure to \bullet OH. A reaction product was identified by LC-MS which had a mass increase of 16. In other experiments, mice were given a concussive head injury, treated with vehicle or U-74006F i.v. (10 mg/kg) followed by SA i.p. (100 mg/kg) and later sacrificed. Brain DHBA was measured by HPLC-EC and brain SA by HPLC-UV. \bullet OH formation was expressed as a ratio of DHBA to SA. Results showed a 50% increase in \bullet OH after concussive injury. This increase was blocked by U-74006F. We conclude that U-74006F decreases \bullet OH formation following CNS injury possibly by a \bullet OH scavenging mechanism.

EVIDENCE OF CALPAIN ACTIVATION FOLLOWING MODERATE TRAUMATIC BRAIN INJURY (TBI). W.C. Taft, B.G. Lyeth, C. E. Dixon and R.L. Hayes. Division of Neurosurgery, University of Texas Health Science Center at Houston, Houston TX 77030 and Div. Neurosurgery, Medical College of Virginia, Richmond VA 23298.

Promising new research has indicated that neurochemical alterations mediated by muscarinic and NMDA receptors comprise crucial components of trauma pathophysiology. We have investigated the possible involvement of calpain 1, an important enzymatic intermediate of adaptive and pathological neuronal processes, in these trauma-induced neurochemical alterations. In this study, we examined the immunoreactivity of microtubule-associated protein 2 (MAP2), a principal *in situ* substrate of calpain 1, as an index of endogenous calpain 1 activity. MAP2 immunoreactivity was examined in homogenates of hippocampal and cortical tissue obtained from naive, sham-injured or fluid percussion injured animals. Rats were injured at 2.1 atm and were sacrificed 3 hours after injury. Tissue was homogenized in the presence of specific calpain inhibitors (0.1 mM leupeptin) and chelators (1 mM EGTA) to eliminate *in vitro* calpain activity and MAP2 proteolysis during tissue processing. MAP2 immunoreactivity was quantitated on nitrocellulose transfers using an anti-MAP2 monoclonal antibody. Sham injury had no effect on MAP2 levels in either cortex or hippocampus. However, TBI caused a significant decrease in both hippocampal and cortical MAP2 levels. The effect appears to be region selective since the MAP2 decrease is more pronounced in hippocampus than in cortex. The observations are consistent with *in situ* activation of calpain 1 caused by moderate TBI, and suggest that calpain proteolysis is involved in the development of TBI-induced functional deficits. Supported by NIH NS21458.

IN VITRO PROTECTION OF BOVINE BRAIN SUPERNATE PROTEINS BY EXOGENOUS HEAT SHOCK PROTEIN-70. F.A. Stevens* and D.J. Gower. University of Oklahoma Section on Neurosurgery and Department of Anatomy. Oklahoma City, OK 73190

Previous publications have demonstrated *in vivo* protection of CNS tissues following hyperthermia. Transient hyperthermia induces the synthesis of Heat Shock Proteins (HSP's). We have examined the *in vitro* effect of HSP-70 on bovine brain supernate proteins for potential protective effects.

High speed sterile supernate of bovine brain was prepared. The assay for thermo protection was carried out by heating the solution to 75° C for one hour and precipitating the coagulated proteins by centrifugation. Both bovine serum albumin (BSA) and HSP-70 were evaluated for the ability to prevent protein denaturation and precipitation following thermal stress.

Bovine HSP-70 and BSA were themselves resistant to heat denaturation. We also found that BSA was able to weakly protect the proteins in brain supernate (p=.04). HSP-70 demonstrated a stronger ability to protect brain proteins in solution (p=.001). We conclude that purified bovine HSP-70 is able to bestow thermotolerance upon a supernate of bovine brain proteins.

GM1 GANGLIOSIDE TREATMENT IN RATS WITH CORTICAL CONTUSION. R. Sutton, L. Lescaudron, X. Chen*, K. Repola* and D. Stein. Brain Research Lab., I.A.B., Rutgers University, Newark, NJ 07102.

Male rats with moderate (M-TBI) or severe (S-TBI) cortical contusion injury of the right sensorimotor cortex were treated (i.p.) with saline, GM1 (10 mg/kg) for 5 days postinjury (P-GM1), or GM1 for 3 days preinjury & 5 days postinjury (P+P-GM1). Recovery from deficits in beam-walking (BW) ability was unaffected by GM1 after S-TBI whereas BW recovery after M-TBI was worsened by P-GM1 but not P+P-GM1. The L-R forelimb wire grip time (pathologic grasp) was increased by P-GM1 and P+P-GM1 at 24 hr after M-TBI or S-TBI (compared to saline controls); deficits on this task were not present by day 8 (vs shams). A decrease in the severity of left forelimb contraflexion seen in saline controls from 24 hr to 8 days after M-TBI or S-TBI was blocked by P-GM1 and by P+P-GM1 treatment. No significant effects of treatment on additional neurological deficits (chin, tactile or visual placing, extensor rigidity, hindlimb extension) were found. Neither P-GM1 nor P+P-GM1 affected area of cortical necrosis after M-TBI or S-TBI. Supported by FIDIA and RO1NS25685.

ALCOHOL POTENTIATES BRAIN EDEMA FORMATION AFTER HEAD TRAUMA. M. Morehead, S. Murphy and H. Goldman. Department of Pharmacology, Wayne State University, Detroit, MI 48201.

In our rat model of closed-head, moderate concussion we found that acute ethanol (EtOH) intoxication exacerbated brain injury. EtOH (2.4 g/kg) in 20 ml normal saline (+5% solution) was administered intraperitoneally to male Wistar rats (330-430 g) 10 min prior to a fixed-head mechanical impact. In one set of experiments chronic epidural cannulas were cemented into the skull and intracranial pressure (ICP) was monitored for up to 7 days post-trauma. In intoxicated (blood alcohol 150 mg/dl) impacted animals, ICP rose to 23 ± 2 (SEM) mmHg at 1 hr compared to 3.8 ± 0.3 mmHg for non-impacted, non-intoxicated controls; 7.6 ± 1 mmHg for animals impacted only and 8.5 ± 2.5 mmHg for animals receiving EtOH only. By 24 hr, ICP rose to 33.6 ± 5 mmHg in the trauma + EtOH group compared to 23.6 ± 8.1 in impacted only animals and <10 mmHg in control animals or those receiving EtOH only. By 30 hr post-trauma, ICP peaked in both groups at 36.0 ± 2.4 and 31.0 ± 3.1 mmHg and fell to normal levels by 6 days. In another set of experiments regional brain permeability-capillary surface area products (rPS) were examined at 2 hr post trauma. During this time interval, rPS increased in 6 of 16 regions, including the cerebellum, hypothalamus and frontal cortex after combined exposure to both EtOH + trauma, compared to 4 of 16 regions clustered in the rostral forebrain after simple head injury. These initial experiments suggest that EtOH intoxication significantly potentiates the edema formation and brain injury that follows closed-head moderate concussion. These differences also suggest that the time available for treatment of brain edema may be much shorter when EtOH intoxication complicates head injury.

65.15

A SECOND CONCUSSIVE INSULT FOLLOWING A FLUID PERCUSSION INJURY RESULTS IN INCREASED EXPRESSION OF GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) AND THE DEVELOPMENT OF MORPHOLOGICAL DAMAGE. H. Badie, D.A. Hovda, and D.P. Becker. Div. Neurosurg., UCLA Sch. Med., Los Angeles, CA 90024-6901

Evidence now exists that following a fluid percussion (F-P) injury the brain becomes vulnerable to a second insult. To determine the morphological consequences of a second F-P injury during this period of vulnerability 25 rats were studied. Animals received two lateral F-P injuries (3.5-4.0 atm) spaced at either 1 or 2 hours, allowed to survive for 10 days and were then processed for GFAP immunohistochemistry and cresyl violet histology. Both sham and single insults were also studied for comparisons. As sampled over the cerebral cortex (in 1.04 mm² increments) the number of cells expressing GFAP was 2.9, 2.4 and 3.5 times that of normal intact animals for single, 1 hr and 2 hr double injury groups. Quantitative histological analysis revealed that there was no cell loss in animals sustaining a single injury, however in the double insult groups, there was evidence of contusions at the gray-white matter junction. Cell counts using nissl stained sections indicated that, in sham animals, cells $<35\mu\text{m}^2$ (glia) constituted only 31% of the population, however, in the double insult animals this increased up to 54% being the most evident in those animals who received their injuries only 1 hr apart. These results indicate that following a F-P injury, a second (concussive) insult increases the expression of GFAP, the development of gliosis and the formation of contusions. (UPHS RO1 NS27544).

DELETERIOUS EFFECT OF ETHANOL ON THE RECOVERY OF THE SEP AFTER SPINAL CORD INJURY. H.E. Martin, S. Katz, Dept. of Physiology and W.O. Boggan, Dept. of Psychiatry, Medical University of South Carolina, Charleston, South Carolina 29425

The objective of this study was to determine the effect of blood ethanol on recovery of electrophysiological conduction following calibrated impact trauma to the spinal cord in anesthetized rats. Conduction was evaluated by Somatic Evoked Potentials (SEP's). Sub-maximal trauma doses of 8 and 12 gm-cm were chosen which resulted in moderate recovery of untreated animals after trauma, (70 and 50% respectively, compared to pre-trauma SEP).

In the treated groups blood ethanol was increased immediately prior to trauma by a continuous IV infusion for 15 - 20 minutes of a high dose (15%) or a low dose (5%) solution of ethanol in saline. Blood samples were taken at the end of the infusion period and analyzed for % blood ethanol by either gas chromatography or by enzymatic colorimetric assay. In a previous study, the 15% solution produced a concentration of 173.8 mg% in blood, and 7.81 and 9.42 mg/gm tissue in brain and spinal cord respectively. High dose pretreatment decreased the % recovery of the SEP over a 5 hour post-trauma monitoring period. The average recovery was 50% in the 8 gm-cm group and 30% in the 12 gm-cm group. Thus, in the presence of intoxicating levels of blood ethanol, the alteration of the SEP at the 8 gm-cm trauma dose closely resembled the change seen in untreated animals following a 12 gm-cm trauma dose. In low dose pretreated groups of animals, SEP recovery was close to that observed in untreated animals suggesting a dose dependent effect of ethanol treatment.

These experiments document the deleterious effects of blood ethanol on subsequent physiological recovery from neural trauma. Subsequent experiments should be directed at further defining the mechanism by which ethanol exerts this effect in order to suggest avenues of therapy and/or prevention in intoxicated individuals with spinal cord injury resulting from accidental trauma.

65.14

HYPOTHERMIA BLUNTS ACETYLCHOLINE INCREASE IN CSF IN TRAUMATICALLY BRAIN INJURED RATS. B.G. Lyeth, J.Y. Jiang, S.E. Robinson, H. Goo, L.W. Jenkins, and R.L. Hayes. Division of Neurosurgery & Department of Pharmacology and Toxicology, Virginia Commonwealth University Richmond, Virginia 23298.

Excessive activation of muscarinic acetylcholine (ACh) receptors significantly contributes to the pathophysiological consequences of traumatic brain injury (TBI) (Lyeth et al., 1988). Moderate hypothermia (30°C) significantly reduces mortality, and motor deficits associated with TBI in the rat (Clifton et al., 1991). In order to determine whether the protective effects of hypothermia involve a decreased release of ACh, we examined the effects of moderate hypothermia (30°C) on levels of ACh and choline (Ch) in CSF following moderate (2.2 ATM) fluid percussion TBI in rats. Rats were anesthetized, intubated, and ventilated with 2% isoflurane in 70% N₂O/30% O₂ prior to TBI. Three groups were examined: sham TBI at 37°C, TBI at 37°C and TBI at 30°C. An intracisternal CSF sample was withdrawn 5 minutes after TBI. ACh and Ch were analyzed by mass fragmentography. ACh concentrations were significantly higher in 37°C TBI rats (0.21 ± 0.04 nM/ml) compared to shams (0.11 ± 0.01 nM/ml) (ANOVA, Tukey $p < .05$). In contrast, no significant changes in ACh were observed between 30°C TBI rats (0.14 ± 0.02 nM/ml) and shams. Ch concentrations were significantly higher in both 30°C (16.4 ± 1.3 nM/ml) and 37°C TBI rats (11.6 ± 1.1 nM/ml) compared to shams (3.7 ± 0.2 nM/ml) (ANOVA, Tukey $p < .05$). These results are consistent with the role of excessive muscarinic cholinergic neurotransmitter-receptor interactions in TBI pathophysiology. These results suggest that the neuroprotective effects of moderate hypothermia in TBI may be related to the inhibition of excessive release of ACh associated with injury. ADAPTATION OF THE FLUID PERCUSSION DEVICE REDUCES THE FORMATION OF CONTUSIONS IN A MODEL OF TRAUMATIC BRAIN INJURY. S. Thomas, A. Yoshino, D. A. Hovda, and D. P. Becker. Div. Neurosurg., UCLA Sch. Med., Los Angeles, CA 90024-6901

The fluid percussion (F-P) apparatus has been used to produce experimental traumatic brain injury with animals positioned at the tip of the apparatus. This type of injury has often resulted in contusions. We have adapted the F-P model by interconnecting a 20 cm, rigid polyethylene tube between the animal and the apparatus. Animals injured in this fashion typically do not exhibit morphological damage (contusion). The current study describes the physical characteristics of the pressure wave, at various levels of atmospheric pressure (atm), at the tip of the apparatus compared to those seen at the end of the extension tube. In addition, physiological and anatomical variables were measured in 20 rats who sustained an injury under these two conditions at low (3 atm) and high (5 atm) injury levels. The results indicated that at any given level of atm, the pulse at the tip of the apparatus, consisted of a single wave form lasting 20-23 msec. At the end of the tube the pulse exhibited an initial positive wave which was of the same amplitude and duration as that generated at the tip, however it was followed by an oscillating wave 4-5 times smaller than the first (2-3 peaks, 20 msec ea). In the animal studies, when the F-P was applied directly: 1) blood pressure (BP) = 40-57 mm Hg, 2) apnea time = 15-18 sec, 3) unconsciousness time = 94-294 sec. In contrast, with the extension tube 1) BP = no change, 2) apnea time = 0-1.25 sec, 3) unconsciousness time = 2-12 sec. Only animals connected directly to the apparatus exhibited contusions. The results indicate that with the extension tube the injury produced by F-P results in a concussive (diffuse) injury as opposed to a contusion (localized) injury. (UPHS RO1 NS27544).

LOW FREQUENCY VARIATIONS IN HUMAN INTRACRANIAL PRESSURE AND JUGULAR VENOUS OXYGEN SATURATION

C. F. Contant, Jr., J. D. Crouch*, C. S. Robertson*, and R. G. Grossman. Dept of Neurosurgery, Baylor College of Medicine, Houston, TX 77030

To determine if the slow variations in brain metabolism observed in animal models can be detected in indirect measurements of cerebral blood flow in humans, we have examined intracranial pressure (ICP), jugular venous oxygen saturation (SJVO2) and arterial pressure (AP) data from 10 patients.

The patients were treated at the Ben Taub General Hospital. All were comatose (GCS \leq 8) and had ICP, SJVO2 and AP catheters. Informed consent was obtained from next-of-kin. Data were collected at the bedside by a computerized monitoring system. A discrete Fast Fourier Transform (FFT) was applied to 307.2 seconds of data collected at six minute intervals. From the FFT the frequency spectrum was produced, and the portion of the spectrum from 0.00 to 0.30 Hz was plotted as a function of time.

Peaks due to respiratory variation were seen in the ICP and AP arrays, though not in the SJVO2 array. Very low frequency variation [0.0083 to 0.033 Hz (.2 to 2 cycles per minute)] was detected in all three arrays. Low frequency variations (0.033 to 0.10 Hz) that did not demonstrate a dominant frequency were characterized by changes in the spectral edges.

In five of the ten patients there was at least one period where there was a dominant wave occurring in the frequencies between 0.04 to 0.10 Hz (2.4 to 6.0 cycles per minute) and observed in all three arrays. The AP and ICP arrays were often similar, though at no time did the AP array include peaks that were not present in the ICP waves as well. We hypothesize that the variations of SJVO2 result from low frequency changes in the cerebral blood flow, and that these variations are related to the metabolic and vascular variations observed in animals.

THREE DIMENSIONAL RECONSTRUCTION OF ASTROGLIOSIS IN THE PONS FOLLOWING UNILATERAL LESION OF THE INFERIOR OLIVE

K. Ito*, R. D. Skinner, M. Morrison-Bogorad*, E. Powell, and W. S. T. Griffin. Depts. Anatomy and Pediatrics, UAMS, Little Rock, AR 72205; *Dept. Neurology, UTSWMC, Dallas, TX 75235

Glial responses to lesions of cerebrum, using a variety of techniques, including needle insertion, electrocoagulation, irradiation, or chemical substances, have been well studied. To examine the issue of local glial responses to discrete lesions of the pons, a ventral approach, using an electrolytic technique, was taken to avoid injury of the dorsal pons and involvement of cells in locations distant from the lesion side. The lesion was confined to the pyramid and regions of the inferior olivary nuclei on the right side. Survival for 24 hours post-lesion predicted greater than 90% long term survival. The astrocytic response to the lesion was reconstructed with a Biographic image analysis system. Three dimensional reconstruction revealed that astrocytes in the pons responded in both temporal and spatial modes to this unilaterally placed electrolytic lesion. The number and morphology of astrocytes were analyzed at 2, 4, 6, 10, and 24 days post-lesion (dpl) using a specific antibody that recognizes glial fibrillary acidic protein (GFAP). Reactive astrocytes, having eccentrically placed nuclei and elongated thick processes, were detected in the pons at each day examined, with the number always greater ipsilateral to the lesion. At 2 dpl, some reactive astrocytes, but most were still immature. Reactive astrocytes were most numerous and hypertrophic at 4 dpl. At and after 6 dpl, reactive astrocytes diminished in size and number. Supported by HD 14886.

66.2

THE EFFECT OF FLUID RESUSCITATION ON BRAIN TRAUMA-POTENTIATED LACTIC ACIDOSIS IN HEMORRHAGIC SHOCK.

X-Q. Yuan, C. E. Wade, G. Hanson and W. G. Rodkey. Letterman Army Institute of Research, Presidio of San Francisco, CA 94129, U.S.A.

To study the effect of fluid resuscitation on the response of blood lactate to hemorrhagic shock combined with traumatic brain injury, thirty anesthetized rats were randomly assigned to four groups: hemorrhagic shock (13.5 ml/kg/10 min, n=7) (H), hemorrhagic shock following brain trauma (fluid percussion model, 2.9 atm, 25 msec, n=7) (TH), hemorrhagic shock treated with lactated Ringer's solution (3 times shed blood volume, n=8) (HR), hemorrhagic shock following brain trauma treated with lactated Ringer's solution (n=8) (THR). Group H showed no significant changes in blood pH, HCO₃ and base excess (BE_b) after hemorrhage. In Group TH, blood pH and BE_b were significantly reduced after the hemorrhage, while in Group HR, the values of both variables were significantly raised after resuscitation. Acid-base status showed no significant difference between Groups THR and H. Group H showed a significant increase in blood lactate level after the hemorrhage. Group TH had greater elevations in blood lactate levels with a significantly higher value over Group H at 70 min (26.8 \pm 2.9 vs 18.5 \pm 1.9). However, no significant differences in blood lactate levels were found between Groups H vs HR or THR. Both brain trauma and fluid replacement increased blood pyruvate levels with marked reduction in the ratio of lactate to pyruvate levels. Our data indicate that traumatic brain injury potentiates arterial blood lactate accumulation and metabolic acidosis after hemorrhage, and infusion of lactated Ringer's solution can relieve these disturbances.

66.4

MAGNETIC RESONANCE IMAGING OF INTRACEREBRAL BLOOD IN THE RABBIT. K.H. Taber, Magnetic Resonance Center, Baylor College of Medicine, Houston, TX 77030

The evolution in appearance of experimental intracerebral hemorrhage in the anesthetized rabbit was examined during the hyperacute stage (0-4 hr). Both T2 weighted spin echo (SE) and gradient echo (GE) magnetic resonance images (MRI) were acquired on a Bruker BioSpec 2.35T magnet system before and after intracerebral injection of either normal or defibrinated blood. Following imaging subjects were sacrificed by perfusion-fixation and the brain removed for correlative histology.

The signal intensity of injected arterial blood was always hypointense in GE images. Initially, the appearance was mixed on the SE images. Areas that were isointense to brain at 15 min became hypointense by 2-4 hours. Defibrinated blood was initially isointense on both GE and SE MRI. Small areas of hypointensity developed by 2-4 hours. The lesion size was always larger on the GE images than on the SE images.

The respective appearances of normal and defibrinated blood on SE and GE MRI indicates that the clotting contributes significantly to the hypointense appearance.

66.6

QUANTITATIVE CHANGES IN MIDBRAIN AXONAL MORPHOLOGY CORRELATES WITH DEGREE OF HEAD INJURY. M.R. Park, J.B. Schweitzer, D.H. Hilton*, J.T. Robertson*. Depts. Pathology, Anatomy & Neurobiology, and Neurosurgery, Univ. Tenn., Memphis, College of Medicine, Memphis, TN 38163.

We have used cat fluid percussion injury, a well-established model of the clinicopathologic syndrome of diffuse axonal injury (DAI), to produce and calibrate clinically reproducible head injury at mild, moderate, and severe levels. We have developed a cat coma scale, verified the EEG changes that have been reported with traumatic brain injury, and quantitatively analyzed changes in axonal morphology.

Although much of the clinical literature has focused on the retraction ball as the microscopic marker of DAI, we and others have noted that axonal varicosity short of the formation of retraction balls are a more wide-spread abnormality in head trauma. Variability within individual axonal profiles has been measured and used to quantitate the degree of axonal damage at short time periods (10 hr) after injury. Both paraffin- and plastic-embedded tissue sectioned and stained with silver stains, osmium, or toluidine blue have been used to allow evaluation of longitudinally cut axons at the light-microscopic level. White matter tracts known to be implicated in the syndrome of DAI have been evaluated. These brain areas are sampled at standard levels and video images of the material captured for morphometric analysis. We have used the coefficient of variation (the standard deviation divided by the mean \times 100—a measure of the dispersion of observed values around the mean) to quantitate axonal varicosity. For example, 2900 measurements of over 200 axons in the medial longitudinal fasciculus showed mean CVs of 23%, 28%, and 35% in uninjured, moderately, and severely percussed subjects, respectively. Statistical analysis of this variability in intra-axonal diameter shows a clear and significant relationship with the severity of injury. These quantitative measurements may allow a more precise definition of the anatomic locus of clinically significant lesions.

ACUTE EFFECTS OF AXOTOMY ON THE ULTRASTRUCTURE OF CULTURED NEURONS OF THE GASTROPOD MOLLUSK, *Helisoma trivolvis*. D.G. Emery. Dept of Zoology and Genetics, Iowa State University, Ames, IA 50011.

While neurons of many arthropods and annelids can withstand axotomy injury, there is little direct evidence on the vulnerability of molluscan neurons. Neurons P1 and P5, with a length of the single native axon attached, were removed from pedal ganglia of *Helisoma* and placed in cell culture. After 24 hrs in culture, by which time the axon had developed a growth cone, the axon was transected with a glass microneedle. Viability 24 hrs. later was determined by dye exclusion. Some neurons were fixed within minutes of injury and processed for transmission electron microscopy. Neuronal death after axotomy occurred at a frequency similar to that reported for mammalian neurons in culture. Injured mammalian neurons exhibit swollen mitochondria, dilated smooth ER (SER) and Golgi bodies, and disrupted microtubules, thought to be responses to ion influx through the lesion (Emery et al., 1987, Exp. Brain Res. 67:41-51). Unlike mammalian neurons, the axons of *Helisoma* neurons contain both granular ER and SER. The mitochondria are quite small (0.1-0.2µm by ≤1µm). Within 10 minutes after axotomy dilated SER was seen in the peripheral cytoplasm of the axon stump and the perikaryon, but the mitochondria and Golgi bodies showed no effects. There also was little disruption of the microtubules in the axon stump. This may indicate a difference, compared to mammals, in the calcium homeostatic mechanisms of neurons of *Helisoma* or in the permeability of the membranes of organelles to cations. The mechanism of neuronal death after injury, in the absence of overt mitochondrial pathology, may also differ from that of mammalian neurons.

THE EFFECT OF AGING ON THE LONG-TERM DEFICITS FOLLOWING TRAUMATIC BRAIN INJURY. R. J. Hamm, D. M. Gbadebo, B. G. Lyeth, L. W. Jenkins, and R. L. Hayes, Depts. of Psychology and Neurosurgery, Medical College of Virginia, Richmond, VA 23298.

Age is one of the most important predictors of outcome following human traumatic brain injury (TBI). This study employs fluid percussion brain injury to investigate the effects of aging on long-term behavioral outcome following experimental TBI in rats. Three-month-old (n=8) and 20-month-old (n=11) rats were injured at a low level (1.7-1.8 atm) of fluid percussion brain injury. Body weight and behavioral outcome (beam balance and beam walking) were assessed for 5 days following injury. Injury did not produce significant weight loss in either age group. At the low level of injury used in this study, the 3-month-old rats did not demonstrate any significant deficits on the behavioral measures. The 20-month-old rats displayed significant beam-balance deficits on each of the 5 postinjury test days. On the beam-walking task, the 20-month-old rats had significant deficits for the first 3 postinjury days. These data demonstrate that aging is associated with increased behavioral deficits following TBI, in the absence of weight loss differences between age groups. Since the rat model of fluid percussion TBI reproduces the age-related increase in morbidity observed in cases of human TBI, the fluid percussion model should be useful for studying mechanisms responsible for the age-related increase in vulnerability to brain injury.

RECOVERY OF REFLEXES AND POSTURAL REACTIONS FOLLOWING A SEVERE TRAUMATIC BRAIN INJURY. S.J. Sullivan, J. Provost, V. MacPherson, V-L. Boulanger, M. Vanier, E. Dutil, A. Forget and G. Drouin, Concordia Univ., Hôpital du Sacré Coeur, Univ. de Montréal, Institut de réadaptation de Montréal, Montréal, Québec Canada. H3S 2J4

A severe traumatic brain injury (TBI) results in the temporary suppression of normal CNS activity immediately following the injury. We investigated the pattern of recovery of CNS activity by quantifying (using standardized protocols): the Extensor (ER) and Flexor Withdrawal (FW) reflexes of the lower limbs; Equilibrium Reactions -seated (ERS) and standing (ERST) within 1 month, and, at 3 and 6 months post-injury in 36 TBI (X GSC = 6.58) patients. Positive responses for: ER (79, 93, 95%); FW (64, 89, 92%); ERS (36, 63, 68%) and ERST (19, 48, 59%) demonstrated a hierarchical pattern in their initial recovery (<1 month). Significant (NcNemar χ^2) recovery, relative to the initial values, was observed at 6 months for all variables with FW, ERS and ERST showing meaningful ($p \leq .05$) increases by 3 months. These data indicate an early and systematic recovery of reflexes and postural reactions following a TBI. (Supported by the; SAAQ and FRSQ).

66.8

IN-VIVO LONG-TERM POTENTIATION FOLLOWING TRAUMATIC BRAIN INJURY. M.H. Ray, S.J. Goldberg, R.J. Hamm, and R.L. Hayes. Depts. of Psychology, Rehabilitation Medicine, Anatomy, and Neurosurgery, Virginia Commonwealth U., Med. Coll. of Va., Richmond, VA 23298.

We have systematically examined the effects of moderate traumatic brain injury (TBI) on the development of in-vivo long-term potentiation (LTP) in the Schaeffer collateral/CA1 pathway of the rat. These studies provide direct electrophysiological assessments of synaptic transmission in the hippocampus produced by injury. Previous research has indicated that the hippocampus, a critical area for memory, is selectively vulnerable to damage following (TBI).

In-vivo LTP development was assessed two hours following TBI. Population spikes, a measurement of summated unit spikes, were measured in the CA1 pyramidal layer in response to Schaeffer collateral stimulation. Two baseline input/output curves were obtained prior to high frequency stimulation (HFS) and repeated at 10, 30, 60, and 90 minutes following the HFS. LTP development was assessed as enhancement of population spike amplitude following HFS. LTP development was significantly suppressed in the injured group (n=8) compared to the control group (n=6) at 10 minutes ($F_{(1,12)}=5.69, p < .05$), 30 minutes ($F_{(1,12)}=10.82, p < .05$), and 60 minutes ($F_{(1,12)}=11.86, p < .05$), but not at 90 minutes following HFS.

The hippocampus is considered to be a critical brain area for memory in humans and other species. In addition, LTP is proposed to be an electrophysiological index of memory function. The findings from these experiments suggest that damage to the hippocampus may contribute to the memory deficits that accompany TBI.

METHYLPHENIDATE FACILITATES LOCOMOTOR RECOVERY AFTER UNILATERAL SENSORIMOTOR CORTEX ABLATION. A.E. Kline, M.J. Chen, D.Y. Tso-Olivas, & D.M. Feeney, Depts. of Psychology and Physiology, University of New Mexico, Albuquerque, NM 87131.

A single administration of d-amphetamine (AMPH) or its analogues phentermine and phenylpropanolamine given 24 hr after sensorimotor cortex (SMCX) ablation in the rat facilitates recovery of BW when combined with symptom-relevant experience (SRE) (CRC Critical Reviews in Neurobiol. 3(2):135-197, 1987). However, a single administration of methylphenidate (MPH) (3-15mg/kg), also an AMPH analogue, did not facilitate recovery (Neurosci. Abstr. 14:1152, 1988). Perhaps because the study employed only 3 BW trials during the period of drug action there may have been insufficient SRE for MPH to exert its effects on BW. Multiple MPH doses or increased SRE after a single dose may be required for MPH to promote recovery. At 24 hr after SMCX ablation, MPH (10 mg/kg) was given daily for 3 days using the standard BW protocol, which consists of BW trials at 1,2,3, and 6 hr post-injection. This regimen produced a significant and enduring improvement of BW ability after the third injection. A combined total of 9 BW trials were accumulated during the drug action period following the 3 doses. A second study increased SRE after a single administration of MPH by providing a BW trial every 15 min during the drug action period (1-3 hr). At 24 hr after a right SMCX ablation or sham surgery, MPH (10mg/kg) or saline was administered. A significant and enduring facilitation of BW recovery was also produced by this regimen. These studies suggest that the role of SRE during drug action is an important variable for functional recovery. Supported by U.S. Army Grant DAMD17-91-Z-1006 and DHHS 5 S06GM08139-17.

KETAMINE AND MAGNESIUM ATTENUATE MEMORY LOSS AFTER EXPERIMENTAL BRAIN INJURY. D.H. Smith, K. Okiyama and T.K. McIntosh. Surg. Research Center, Univ. of Conn. Health Center, Farmington CT 06030.

Memory dysfunction is one of the most common features following traumatic brain injury (TBI). The N-methyl-D-aspartate (NMDA) receptor has been shown to be a mediator in both memory function and secondary damage following TBI. We have previously demonstrated that antagonists acting at the NMDA receptor-associated glycine site attenuate post-TBI memory dysfunction. In the present study, we examined the ability of two non-competitive NMDA receptor antagonists ketamine (Ket) and magnesium (Mg^{++}), both individually and together, to attenuate post-TBI memory dysfunction. Male Sprague-Dawley rats (350-400g) were trained in the Morris water maze (MWM) to find a submerged platform (20 trials over 2 days) using external visual cues. 2.5 h after the final trial, animals were anesthetized (sodium pentobarbital 60mg/kg ip) and subjected to lateral fluid percussion (FP) brain injury of moderate severity (2.4 atm). Fifteen min post-injury, the animals randomly received 0.5 ml intravenous administration over 15 min of either Ket (4 mg/kg, n=9), $MgCl_2$ (35 µmol, n=9), Ket and $MgCl_2$ (identical doses) or saline (n=9). All animals were tested for memory retention at 42 hours post-injury in the MWM using a video/ computer recording unit. Animals treated with either Ket or Mg^{++} showed highly significant memory preservation compared to saline treated control animals ($p < .01$). Animals treated with combined Ket and Mg^{++} also showed highly significant memory preservation ($p < .01$), however, with no apparent additive effect. These results suggest that the NMDA receptor may play a role in post-traumatic memory dysfunction and that NMDA receptor antagonists may be potentially beneficial in the treatment of this aspect of brain injury. THE COGNITIVE ENHANCER BMY-21502 IMPROVES SPATIAL LEARNING IN BRAIN INJURED RATS. J.E. Shaw*, D.H. Smith and T.K. McIntosh. Surg. Research Center, Univ. of Conn. Health Center, Farmington CT 06030

Cognitive dysfunction is a common clinical feature of traumatic brain injury (TBI). Few drug treatments, however, have been developed to attenuate this dysfunction. We have previously shown that lateral fluid-percussion (FP) brain injury produces a profound retrograde memory deficit in rats. In the present study, we characterized changes in learning ability following FP brain injury and examined the potential modulatory effects of the cognitive enhancer, BMY-21502, on post-traumatic learning. Male Sprague-Dawley rats (340-400 g) were subjected to lateral FP brain injury of moderate severity (2.4 atm) or sham surgery (no injury). One week following brain injury, animals were trained in the Morris water maze (MWM) to find a submerged platform (20 trials over 2 days) using external visual cues. Latency (time taken to find the platform) was recorded for each trial. BMY-21502 (10mg/kg; s.c.; n=13 injured; n=11 sham) or vehicle (n=12 injured; n=10 sham) was administered 30 min prior to the start of training on both days. A highly significant impairment in learning was observed in untreated injured animals (compared to untreated sham animals, $p < 0.001$). Brain injured animals treated with BMY-21502 showed a highly significant improvement in the capacity to learn compared to injured animals treated with vehicle ($p < 0.005$). BMY-21502 did not produce significant changes in learning capacity in sham animals. These results suggest that a dysfunction in learning ability following TBI may be attenuated with the use of BMY-21502. Supported, in part, by Bristol-Myers Squibb and a grant from the Brain Trauma Foundation.

BEHAVIORAL DEFICITS FOLLOWING CORTICAL CONTUSION IN THE RAT. T. Carbery*, P. Kraemer* and S.W. Scheff. Depts. Psychology and Anatomy & Neurobiology, Univ. Kentucky, Center on Aging, Lexington, KY 40536-0230.

Little is known about the complex response of the CNS following cortical contusion. Numerous experimental models have employed different methodologies to produce brain injury resulting in a wide spectrum of clinically relevant injury. To date no single experimental model produces a complete picture of closed head injury identical to that observed in humans. An electronic controlled pneumatic impact (ECPI) model has been developed which manifests neuropathology similar to the human condition. To further develop this ECPI animal model we compared neuropathological and behavioral results after injury.

Rats were randomly assigned to one of four different treatment groups: Impact (IP), Sham, Subdural hematoma (SDH) and Anesthesia control (AC). Prior to surgical manipulation, all animals were trained and behaviorally tested for associative memory using a Pavlovian conditioned fear task. IP animals with a contusion over the posterior portion of the cortex showed a marked deficit within 24h after the injury. Sham animals, which underwent surgical manipulations without impact and SDH animals, which were subjected to a rupture of a dorsal cortical vein creating a subdural hematoma, were not significantly different from AC animals. Behavioral deficits correlated positively with the extent of neuropathology as determined from histological evaluation of cortical damage. The ECPI model appears to be extremely sensitive to both behavioral and morphological aspects of cortical contusion.

NIMODIPINE-ENHANCED RELEARNING OF 8-ARM MAZE AFTER HIPPOCAMPAL LESIONS. S. Finger, C. Nelson* and Johnny Bawa*. Psych. Dept., Washington Univ., St. Louis, MO 63130.

Rats trained in an 8-arm radial maze were given electrolytic lesions of the dorsal hippocampus or sham operations. Within 24 hours of surgery, approximately half of the rats in each groups began 14 daily oral treatments with the central calcium channel blocker, nimodipine. The untreated rats that received the larger hippocampal lesions did not relearn the maze 2-1/2 times the preoperative mean. The untreated rats that received the smaller lesions showed milder deficits. Nimodipine significantly improved the maze scores of the animals with the smaller lesions, but not the scores of the rats with large hippocampal lesions or sham operations. It was unclear whether nimodipine led to the sparing of more cells in the hippocampal region, or whether spared-but-affected cells were returning to normal modes of functioning more rapidly. These findings suggest that spared hippocampus was mediating behavior, and extend our previous findings showing that nimodipine can enhance recovery of function on higher cognitive tasks after hippocampal damage.

MUSCARINIC RECEPTOR BLOCKADE REVEALS COVERT SPATIAL MEMORY DEFICITS FOLLOWING MILD TRAUMATIC BRAIN INJURY (TBI). C.E. Dixon, T. Richardson*, W.C. Taft and R.L. Hayes. Division of Neurosurgery, University of Texas Health Science Center at Houston, Houston, TX 77030 and Division of Neurosurgery, Med. College of Va. Richmond, VA 23298.

New areas of research indicate that TBI produces receptor mediated neurochemical alterations resulting in pathological changes in neuronal function not necessarily associated with cell death (Lyeth et al, *Brain Res* 526:249-258, 1990). Hippocampal CA1 neurons appear to be the most sensitive to these neurochemical alterations. The purpose of this study was to determine whether the cholinergic system of injured rats is chronically impaired following mild TBI. We used the Morris water maze, a spatial memory task dependent on cholinergic hippocampal function to assess cognitive performance. Rats (N=8) were placed onto a foam block that was 3 cm thick. A pneumatic impactor was used to make a direct central impact (7 meters/sec) to the exposed skull under 2% isoflurane anesthesia. Water maze testing started on Day 8 post-injury. Rats were given 4 trials per day for 5 consecutive days. For each trial, latency to find a hidden platform was timed. On Day 13, rats were injected 15 min prior to being tested with a dose of scopolamine (1 mg/kg) that did not adversely affect performance in normal rats. Results showed that this magnitude of head impact acceleration produced no overt motor or maze deficits. However, scopolamine significantly increased the latency to find the platform in the injured group, but not the uninjured group. These results suggest that even mild TBI can produce increased sensitivity to disruption of cholinergically mediated memory function. These data provide addition support for the hypothesis that TBI produces pathological alterations in receptor coupled functions. These alterations may persist even in the absence of overt behavioral deficits. Supported by CDC 303547, NS21458.

66.16

RETENTION OF AN 8-ARM MAZE TASK OVER THREE RECOVERY INTERVALS FOLLOWING PREFRONTAL CORTEX LESIONS. W.L. Isaac, J.N. Freeman*, T.L. Long* and M. Fritts*. Dept. of Psychology, East Tenn. State Univ., Johnson City, TN 37614.

This study attempted to assess the influence of time from lesion of either medial or lateral frontal cortex on recovery of function. Gavin & Isaac (1986) and Isaac, Nonneman and Scheff (in prep.) found temporal limitations to recovery. Fifty male Long-Evans derived rats (30 days old) were used. They were acclimated to the test setting. The rats were then trained to visit each arm of the 8-arm maze once. A criterion of no more than 1 error/day for 2 consecutive days was set to define learning. Upon criterion, each rat received one of the lesions listed above. Testing resumed after 1 of 3 retention intervals: 12, 18 or 24 days and continued for 15 days on the maze. The lesions were histologically assessed. A repeated measures ANOVA shows a Lesion effect, a Blocks effect and a Lesion x Blocks interaction. A trend toward a retention interval effect exists. This differs from previous research that looked at the occipital and entorhinal cortices. Potential factors responsible for the absence of the recovery interval effect will be addressed.

ASTROCYTIC PROCESS REMODELLING FOLLOWING DAMAGE IN THE RAT CEREBRAL CORTEX. K.R. Isaacs, N. Hawrylak, N. Ghia*, and W.T. Greenough. Neuroscience Program, Depts. of Psych. and Cell & Struct. Biol., Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

Astrocytes in the brain exhibit morphological changes in response to mechanical damage and degeneration. These changes can impede host-transplant integration. In this study, immunohistochemical and quantitative anatomical techniques were employed to examine the amount and preferred orientation of astrocytic processes following stab wounds in the cerebral cortex.

A 23 gauge needle was lowered 3 mm into the rat cortex in order to induce a wound. The brains were processed 48h (n=2), 96h (n=3), 10 days (n=4) and 20 days (n=4) post lesion (dpl) for GFAP immunohistochemistry. GFAP positive cells with clearly recognizable soma and processes located 150 to 350 microns distant from the edge of the wound were drawn from a Zeiss microscope interfaced to an IBM computer. Control cells were drawn in the contralateral hemisphere. The process field was divided in half through the center of the soma parallel to the needle track. The hemifield oriented towards the wound and that oriented away from the wound were analyzed separately.

The percent of process length was significantly greater in the hemifield proximal to the wound compared to 1/2 of the total for control cells at both 10 and 20 dpl ($p < .01$). At 48h and 96h post lesion the trend was similar but did not reach statistical significance. Within cells at the wound site the hemifield towards the wound had more astrocytic process than that away from the wound at 96h, 10dpl and 20 dpl ($p < .05$). The overall pattern of data suggests an initial general process hypertrophy of astrocytes in the wound zone, followed by retraction of processes oriented away from the wound. TEMPORAL EXPRESSION OF GFAP IMMUNOHISTOCHEMICAL REACTIVITY IN THE SUPERIOR COLLICULUS OF ADULT RATS FOLLOWING MONOCULAR ENUCLEATION. C. Collins, N. Hawrylyk and W.T. Greenough, Beckman Inst., Neurosci. Prog., Dept. Psych. and Cell & Struct. Biol., Univ. of Illinois, Urbana 61801.

Age related changes in astrocytic responses to damage or degeneration in the nervous system may play an important role in plastic phenomena. Reactive gliosis is characterized by hypertrophy of astrocytic perikarya and processes, an increase in the number of intracellular filaments and increased immunoreactivity of glial fibrillary acidic protein (GFAP). Light microscopy was utilized to study the temporal expression of the astrocytic response to enucleation in the superior colliculus (SC) of young and middle age adult rats. Animals in the two age groups, 70-90 days and 13-17 months were unilaterally enucleated and allowed to survive 1, 2, 3, 5, 7 or 9 days. Animals were perfused intracardially with 4% paraformaldehyde and processed for GFAP immunohistochemistry.

In both age groups, at one day post-enucleation, astrocytic labelling is detectable in both colliculi. In the colliculus contralateral to the enucleation a dense GFAP reactivity was observed throughout the medialateral and dorsoventral regions, whereas the response in the ipsilateral superior colliculus appears to be distributed in patches. A similar, somewhat less intense patchy pattern of immunoreactivity was observed in non-lesioned animals. The initial response in both age groups is noticeably concentrated in the more lateral regions of the colliculi. More detailed studies of differences in the lateral geniculate nucleus (LGN) are currently in progress.

Comparison of the age related astrocytic response demonstrates that older rats reach a maximal response (day 3) in the contralateral colliculus before young adult rats (day 5). Supported by NIA AG10154.

EPILEPSY: BASIC MECHANISMS I

67.1

NEUROTROPHIC FACTORS ACCUMULATE IN THE RAT HIPPOCAMPUS FOLLOWING KAINATE-INDUCED SEIZURES. D.H. Lowenstein¹, S. Seren², M. Manthorpe³ and E.M. Longo¹, Dept. of Neurology, UCSF, San Francisco, CA(1), FIDIA Res. Lab, Padua, Italy (2), and School of Med., UCSD, La Jolla, CA(3).

Synaptic reorganization occurs in the hippocampus following various forms of seizure activity and may play a role in epileptogenesis. To characterize further the molecular basis of these changes, we measured neurotrophic activity in individual rat hippocampi harvested 1hr, 12hrs, or 7d following IP injection of 12mg/kg kainic acid (KA) and compared this to controls receiving IP saline. Serial dilutions of hippocampal extract were added to cultures of either embryologic day 8 chick dorsal root ganglia or ciliary ganglia neurons, and neuronal survival at 24hrs was measured by a colorimetric assay in which viable neurons convert a tetrazolium derivative to a blue formazan product. The extract dilution supporting 50% of the maximum NGF or CNTF-induced neuronal survival was used to quantitate the trophic units (TU)/ml of trophic activity. Hippocampi from 1hr and 12hr KA animals had no significant difference in neurotrophic activity compared to controls. However, 7d samples had a 2.9-fold increase in NGF-like activity compared to controls (57 ± 18 TU/ml, n=8 vs. 20 ± 10 TU/ml, n=4, mean \pm S.D.) and a 2.3 fold increase in CNTF-like activity (101 ± 16 TU/ml, n=8 vs. 45 ± 4 TU/ml, n=4).

These results suggest that: i) one or more neurotrophic factors accumulate in the rat hippocampus following KA-induced seizures, ii) since NGF does not support ciliary neurons in this assay, trophic factor(s) other than or in addition to NGF are present, and iii) accumulation of substantial amounts of these factors occurs after a delay of at least 12 hrs.

FACTORS INFLUENCING GRANULE CELL COLLATERAL SPROUTING IN ORGANOTYPIC CULTURES OF MOUSE HIPPOCAMPUS. B. W. Coltman*, E. Earley*, L. Alworth* and C. F. Ide, Dept. of Cell and Molecular Biology, Tulane University, New Orleans, LA 70118.

Collateral sprouting of dentate granule cell axons correlates with the development of epileptiform neural activity in rodents. Organotypic slice culture of rodent hippocampal tissue is a model system for the controlled study of sprouting *in vitro*. Organotypic rollertube cultures were prepared from hippocampal slices derived from postnatal day 7 (P7) mice. Timm's staining was utilized to assay the degree of collateral sprouting by granule cell axons. Little sprouting was present one week post-culture; by two weeks, considerable sprouting was apparent; and at three weeks, intense sprouting obscured the dentate granule cell layer. A septal to temporal gradient in the degree of sprouting was observed in a study including 8 hippocampi (59 viable cultures). Eighty-two percent of cultures from the septal region of the hippocampus showed heavy to medium sprouting compared to 71% from mid-hippocampal regions and 43% from temporal hippocampal regions. Further studies are underway which use co-cultures to assay the influence of afferent innervation on collateral sprouting of dentate granule cells.

67.2

LOCAL GENERATION OF BURST DISCHARGES IN DENTATE GRANULE CELLS ASSOCIATED WITH NMDA MEDIATED TRANSMISSION AND MOSSY FIBER SPROUTING G. Golarai, T. Sutula Neurosci. Training Prog., Univ. of Wisconsin, Madison, WI 53792

Kindling induces long-lasting enhancement of the NMDA component of the EPSP and mossy fiber (MF) sprouting in rat dentate granule cells (DGC). To investigate the role of these alterations in generation of epileptic activity in dentate gyrus (DG), intra- & extracellular recordings were obtained in DG of slices from naive and kindled rats. In both groups perforant path (PP) and hilar (H) shocks evoked an EPSP and a single spike. With block of GABA_A inhibition in kindled DGCs, PP and H shocks evoked APV sensitive population burst discharges (37/38). Normal DGCs did not burst with GABA_A blockade (0/6), but developed APV sensitive population bursts when the NMDA component of the EPSP was enhanced in 0 Mg⁺⁺, which reversed to normal upon return to normal Mg⁺⁺ medium (9/9). After enhancement of the NMDA component of the EPSP, with block of GABA_A inhibition in normal Mg⁺⁺, PP and H shocks evoked population bursts in the normal DGCs. Population bursts in normal and kindled slices were recorded in DG isolated from entorhinal cortex and hippocampus. Local circuitry in the normal DG is therefore sufficient to generate population bursts if the NMDA component of the EPSP has been enhanced. If kindling-induced MF sprouting establishes recurrent excitatory circuits, this could provide additional local excitatory drive and contribute to the generation of epileptic activity. It appears that a complex interaction of enhanced excitatory drive, diminished inhibition, and circuit reorganization plays a role in generation of epileptic activity in the DG.

67.4

HIPPOCAMPAL MOSSY FIBER OUTGROWTH IN A MUTANT WITH INHERITED SPIKE WAVE SEIZURES X. Qiao, R.S. Chafetz and J.L. Noebels, Developmental Neurogenetics Laboratory, Section of Neurophysiology, Department of Neurology and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Zinc-containing mossy fibers in the hippocampus were examined in two inherited spike-wave seizure mutants, stargazer (*stg*, Chr 15) and tottering (*tg*, Chr 8), using Timm's sulfide silver and selenium staining methods. We found increased staining in the molecular and granule cell body layers of the dentate gyrus in both adult *stg* and *tg* temporal hippocampus. The increase was far more striking in *stg* than in *tg*, corresponding to the two-fold greater seizure frequency in the *stg* mutant. Optical density measurements of staining in control (+/+) and *stg* showed no quantitative difference in the hilar region, but a mean 48% increase in the mutant granule cell body and molecular layers. In addition, we noticed an unusual pattern of diffuse fiber staining within the CA3 pyramidal cell body layer. Dicarboyanine (DiI) fluorescent dye labeling of the mossy fiber system at the hilus demonstrated the presence of individual mossy fibers in both the molecular layer of the dentate gyrus and the CA3 intrapyramidal layer in *stg*, consistent with the abnormal zinc staining pattern. A developmental study with paired *stg/stg* and +/+ mice (n= 3-5 pairs) at 5 different ages (2, 4, 8, 16 and 24 weeks) indicates that epileptic discharges begin no sooner than postnatal days 17-18, whereas the abnormal axonal outgrowth does not appear before 2 months of age. These and other data suggest that inherited 6 sec⁻¹ spike-wave discharges, like other more severe convulsive patterns of seizure activity, are sufficient to cause abnormal axon reorganization in hippocampus.

67.5

HIPPOCAMPAL CA3 PYRAMIDAL CELLS OF THE EPILEPTIC MUTANT MOUSE STARGAZER DISPLAY A DISTINCTIVE GENE-LINKED HYPEREXCITABILITY. *U. Namgun* and J.L. Noebels.* Developmental Neurogenetics Laboratory, Department of Neurology and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Hippocampal network excitability was examined *in vitro* in a single locus mutant mouse with generalized epilepsy, the stargazer (*stg/stg*, Chr15), using extracellular recordings of spontaneous interictal burst discharges in CA3 pyramidal cells activated by convulsants. Burst discharges in both control (+/+) and *stg/stg* genotypes appeared 5-10 min after elevating $[K^+]_0$ to 10 mM. Mean burst durations did not significantly differ between +/+ and *stg/stg* hippocampal slices exposed to bath applied convulsants, but mean frequency was significantly higher in *stg/stg* slices than in +/+ slices [46% increase in 10 mM $[K^+]_0$ (.35±.02 [+/+, n=109] vs .51±.03 Hz [stg, n=78] P<.01), 33% increase in 10 mM $[K^+]_0$ +10 μ M 4-AP (.52±.05 [n=20] vs .69±.04 Hz [n=16]; P<.05) and 85% increase in 10 mM $[K^+]_0$ +10 μ M PTX solutions (.27±.01 [n=10] vs .50±.08 [n=12]; P<.05). Addition of 10 μ M 4-AP to 3 mM $[K^+]_0$ solutions caused a 163% increase in burst rate for *stg/stg* slices (.08±.02 [n=7] vs .21±.05 Hz [n=6]; P<.05), but adding 10 μ M PTX to 3 mM $[K^+]_0$ solutions did not produce epileptic bursts in either genotype. These results demonstrate a clear network excitability defect in the isolated *stg* hippocampus that alters convulsant-activated burst frequency but not burst duration, a pattern exactly opposite to that observed in the tottering mutant (*tg/tg*, Chr 8) (Noebels and Rutecki, 1990, Brain Res. 524, 225). Since generalized spike-wave seizures in *stg* are identical to those seen in the hypernoradrenergic *tg* mutant, these data suggest that the two mutations initiate generalized epilepsy by altering two distinct neuronal excitability control mechanisms.

THE LETHARGIC MOUSE: A GENETIC MODEL OF ABSENCE EPILEPSY. *D.A. Hosford, S. Clark, W.A. Wilson, V. MacMillan* & Z. Cao.* Epilepsy Research Lab, Duke & V.A. Med. Ctrs., Durham, NC 27705.

The lethargic mouse, a mutant with a single-gene defect, expresses spontaneous seizures and ataxic gait (Dickie, Mouse News Lett., 1964). We characterized the behavioral, electrographic and anticonvulsant profiles of seizures in this model.

Using stocks from Jackson Labs we colonized congenically wild mice (+/+): all progeny of C57Bl/6Jei females X C3H/HeSnJ males) and lethargic mice (lh/lh: 25% of progeny of lh/+ X lh/+). Bipolar recording electrodes were stereotaxically implanted bilaterally into 7-week mice (n = 32). Over 80% of lh/lh but no +/+ or lh/+ mice exhibited bilaterally synchronous bursts (mean duration 1.4 sec; range 0.4 - 3.0 sec) of 6 Hz spike-wave discharges with a mean frequency of 127/hr (range 43 - 239/hr). Bursts were accompanied by behavioral arrest but no clonic activity, similar to early results of J. Noebels (Adv. Neurol. 44, 1986). Ethosuximide blocked seizures in a dose-dependent manner that was maximal (99%) at 400 mg/kg i.p. (n = 6 mice; mean serum level = 47 μ g/ml by HPLC). Phenytoin had no effect on seizure frequency (n = 6 mice) even at 40 mg/kg i.p. (mean serum level = 21 μ g/ml). Taken together, these data strongly argue that seizures in lethargic mice resemble those of absence epilepsy.

Hypotheses that GABA_B receptors contribute to burst-firing in absence epilepsy (Crunelli, TINS 14, 1991) led us to test a GABA_B antagonist on seizure frequency. In preliminary studies, CGP 35348 (100 mg/kg i.p.) totally suppressed seizures for more than 60 min after a brief period of torpor. These findings, similar to results from rat models of absence epilepsy (O.C. Snead III, personal communication), suggest that GABA_B receptors contribute to seizures in lethargic mice. The enhanced GABA_A drive observed in lethargic brain slices strengthens this possibility (S. Clark, Soc. Neurosci. Abstr. 17, 1991). The lethargic mouse is a powerful model in which to examine pathologic mechanisms of absence epilepsy.

67.9

TRIAZOLOBENZODIAZEPINE-BASED ANTAGONISM OF PLATELET-ACTIVATING FACTOR AND INDUCTION OF fos EXPRESSION IN HUMAN SH-SY5Y NEUROBLASTOMA CELLS. *J.P. Doucet,^{1,2} V.L. Marcheselli,¹ & N.G. Bazan.^{1,2}* ¹LSU Eye Center & Neuroscience Center; ²Department of Biochemistry and Molecular Biology, LSU Medical Ctr., New Orleans, LA 70112.

The anxiolytic triazolobenzodiazepines alprazolam and triazolam are potent antagonists of platelet-activating factor (PAF) activity (*Science* 226:1454,1984). Two triazolobenzodiazepine-based PAF antagonists, BN50726 and BN50739, promote metabolic recovery of posts ischemic canine brain (*J Neurochem* 56:311,1991). We previously showed that BN50726 and BN50739 displace PAF from high-affinity, intracellular binding sites in rat brain (*J Biol Chem* 266:9140,1990). The related antagonist BN50730 has the highest affinity for these sites (*Trans Am Soc Neurochem* 22:187,1991), and BN50730 decreases hippocampal and cortical fos expression evoked by a single electroconvulsive shock (*Soc Neurosci Abs* 16:629,1990), suggesting that PAF may mediate the primary genomic response to seizure. In SH-SY5Y cells, PAF stimulation of the fos promoter region requires the Ca²⁺/cAMP-response element (*J Neurosci Res* 24:558,1989), and the corresponding induction of fos expression is abolished by equimolar concentrations of the ginkgolide PAF antagonist BN52021. Here we show that, in serum-deprived SH-SY5Y culture, a 30-min, 1 μ M-pretreatment with either triazolam or BN50730 is insufficient to suppress equimolar PAF-evoked fos expression. In addition, induction of fos by Ca²⁺-dependent, K⁺ depolarization of SH-SY5Y cells is likewise resistant to triazolobenzodiazepine-based PAF antagonism. These results are consistent with the insufficiency of triazolobenzodiazepines to antagonize PAF-evoked Ca²⁺ influx in neural hybrid cells (*Science* 240:1792,1988) and suggest exclusivity of triazolobenzodiazepine-based PAF antagonism and expression of intracellular PAF-binding sites for mature, nonproliferating neuronal cells. (Supported by NINDS NS23002).

EVIDENCE FOR ENHANCED GABA_B-MEDIATED INHIBITION IN HIPPOCAMPAL SLICES FROM LETHARGIC MICE, A GENETIC MODEL OF ABSENCE EPILEPSY. *S. Clark, R. A. Morrisett, W. A. Wilson, D. A. Hosford.* Deps. of Pharmacology and Medicine (Neurology), Duke University & the Veterans Administration Medical Centers, Durham, NC 27705

The lethargic mouse is a genetic model of absence epilepsy which exhibits 6 Hz spike-wave discharges that are blocked by ethosuximide and by the GABA_B antagonist CGP 35348 (Hosford et al., Soc. Neurosci., Abstr. 17, 1991 & Am. Epilepsy Soc., 1991). Since it has been hypothesized that GABA_A currents may play a role in the generation of bursts during absence seizures (Crunelli, TINS 14, 1991), we investigated the strength of GABA_B-mediated inhibition of synaptic potentials in brain slices from lethargic and age-matched control mice.

We utilized paired (200 ms) stimulus protocols and the 6,7-dinitroquinoline-2,3-dione/picrotoxin (DNQX/PTX) model (10 μ M each) to pharmacologically isolate NMDA receptor-mediated population synaptic potentials as an indirect measure of post-synaptic GABA_B-mediated responses (Morrisett et al., Neuroscience, 1991). At 200 ms, the second stimuli occurs at the peak of the GABA_B IPSP. The resulting responses were recorded in str. radiatum and in str. pyramidale of area CA1 of the hippocampus. In slices from lethargic mice, GABA_B-mediated inhibition of the NMDA EPSP was enhanced and was maximal at 200 ms. In control mice, this paired pulse inhibition of the NMDA EPSP was not readily apparent.

We conclude that enhanced GABA_B-mediated responses exist in the hippocampus of a genetic mouse model of absence seizures.

C-FOS PROTEIN-LIKE IMMUNOREACTIVITY IS DEPENDENT ON AGE AND METHOD OF SEIZURE INDUCTION. *F.E. Jensen, I.R. Firkusny*, and G.D. Mower.* Dept. of Neurology, Children's Hosp. and Harvard Med. Sch., Boston, MA 02115.

Administration of the convulsant, pentylenetetrazol (PTZ), results in widespread c-fos protein-like immunoreactivity in the adult rat. We compared fos immunoreactivity in adult rats to 10 d.o. (P10) rats at 2 and 4 hours after PTZ induced generalized convulsions (GC). At both ages, the amygdala, hypothalamus, and pyriform cortex appeared most sensitive to seizures, staining earlier and after less severe seizures than dentate gyrus (DG) and hippocampus (HI). Fos immunoreactivity occurred earlier in adults (2hrs) than in the P10 rats (4hrs). The distribution of immunoreactive cells was generally similar between the ages, except that cortical staining was present in layer II in the adults and layer VI of the P10 rats.

The response to another convulsant, flurothyl, was tested at 2, 4, and 6 hours after seizures (GC) in the two age groups. At both ages, the distribution was similar to that induced by PTZ. However, the time course was shorter than PTZ in the adults, with staining present at 2 hours and absent by 4 and 6 hours. For the P10 rats, staining was most prominent at 2 hours, but persisted in layer VI of the cortex at both 4 and 6 hours.

Because we have previously shown that acute global hypoxia (3%O₂) results in seizures in young rats (P10) but not in adults, we examined fos immunoreactivity at 2, 4 and 6 hours after hypoxia induced seizures in P10 rats. The distribution and time course was different from both PTZ and flurothyl. No immunoreactivity was present until 4 hours after hypoxia, and the DG, HI, and layer II of cortex were highly stained, with only moderate staining of the amygdala and pyriform cortex. These data suggest that there are differences in the pathways activated by PTZ, flurothyl, and hypoxia induced seizures, and that these are also dependent on age.

67.10

STIMULATION OF HIPPOCAMPAL CYCLOPHILIN EXPRESSION FOLLOWING LIMBIC SEIZURES. *G.L. Yount, C.M. Gall¹ and J.D. White,* Div. Endocrinology, Dept. Medicine and Dept. Neurobiology and Behavior, SUNY, Stony Brook, NY 11794 and ¹Dept. Anatomy and Neurobiology, Univ. Cal., Irvine, CA 92717

Previous studies have shown that generalized limbic seizures, induced by unilateral focal electrolytic lesion of the hippocampal dentate gyrus hilus, lead to dramatically increased expression of neuropeptide (enkephalin, dynorphin, neurotensin Y), transcriptional regulatory protein (c-fos, c-jun, NGFIA) and growth factor (NGF, BDNF) mRNAs by dentate gyrus granule cells. In the present study, the influence of hilus lesion (HL)-induced seizures on the abundance of mRNA coding for cyclophilin in rat hippocampus was analyzed. Cyclophilin (peptidyl-prolyl *cis-trans* isomerase) is found in almost every cell in the body. In the rat brain, cyclophilin mRNA is expressed at comparatively high levels in the cerebral cortex and hippocampus. By nuclease protection analysis a significant increase in cyclophilin mRNA content was observed in the dentate gyrus following HL-induced seizures. The increase began 6 hours post-HL, reached a maximum (2.5-fold) at 12 hours post-HL and returned to control values by 48 hours post-HL. Cyclophilin mRNA levels remain stable in the cerebral cortex throughout the same time course. Thus, increased cyclophilin expression is a component of the complex genomic response of hippocampal neurons to recurrent seizure and may be required for the sequelae of neurochemical events induced in these cells. (ADAMHA MH00801, NIH NS26748)

C-FOS INDUCTION AND AUDIOGENIC SEIZURES: MAPPING CELLS INVOLVED IN BOTH INDUCTIVE AND SEIZURE-PRECIPIATING EVENTS. M.G. Pierson and A.M. Snyder-Keller. Wadsworth Center for Labs and Research, New York State Dept. Health, Albany, NY 12201.

Rats normally resistant to audiogenic seizures can be made susceptible by exposing them to an intense noise during a critical period during development. We are studying c-fos induction within cells of auditory nuclei in relation to both the inductive noise exposure and the audiogenic seizures that occur in response to subsequent noise exposure. Four hr after noise exposure at 14 days, fos-immunoreactive cells were present in a discrete zone within the central nucleus of the inferior colliculus (IC). At longer intervals after noise exposure, numerous fos-immunoreactive cells were seen in dorsal and external cortices of the IC. These two patterns of c-fos induction could be differentially altered by pretreating animals with the NMDA antagonist MK-801, which promotes the development of audiogenic seizure susceptibility. Audiogenic seizures that occur in response to a subsequent noise exposure resulted in dense fos immunoreactivity in the IC as well as afferent and efferent auditory nuclei. By restricting either the inductive or the seizure-precipitating noise exposure to one ear, we have been able to demonstrate that widespread c-fos induction occurs only in previously "sensitized" lobes of the IC. The pattern and extent of fos immunoreactivity correlated well with observed seizure behaviors. Fos immunocytochemistry offers a simple anatomical approach towards identifying the sites of epileptogenesis in this model of developmental epilepsy. Supported by the Epilepsy Foundation of America.

MATURATIONAL DIFFERENCES IN GENE EXPRESSION OF GABA-A $\alpha 1$ RECEPTOR SUBUNIT IN RAT SUBSTANTIA NIGRA. E.F. Sperber, D.E. Pellegrini-Giampietro, L.K. Friedman, R.S. Zukin and S.L. Moshé. Departments of Neurology, Neuroscience and Pediatrics, Albert Einstein College of Medicine, NYC, NY.

Actions of GABA are mediated predominantly through the GABA-A receptor, a member of the large family of ion-channel forming receptors. Functional studies in oocytes and transfected cell lines indicate that the native GABA-A receptor is a heterooligomer comprised of α , β , γ , δ or ϵ subunits. GABA receptors in the substantia nigra (SN) are implicated in the control of seizures. Effects of GABA-A agonists infused in the rat SN are age-specific; in 15-day old pups, GABA-A agonists are proconvulsant whereas in adults they are anticonvulsant. The present study was undertaken to determine whether a developmental regulation in the gene expression of the GABA-A $\alpha 1$ subunit in the SN may play a role in the age-specific effects of GABA-A agonists on seizures. *In situ* hybridization was used to measure the GABA-A $\alpha 1$ subunit mRNA in 15-day old and adult rats. Nigral sections were hybridized with a 35 S-labelled riboprobe directed against the $\alpha 1$ subunit mRNA. Resolution at the cellular level was obtained by use of emulsion-dipped sections. In the adult SN, $\alpha 1$ mRNA was expressed at high levels in the pars reticulata and at low levels in the pars compacta. A similar pars reticulata/pars compacta pattern was observed in the pup SN, but there was a decrease in grains/neuron ratio. These results suggest that ontogenetic alterations in the nigral GABA-A $\alpha 1$ subunit may contribute to developmental differences in seizure suppression.

67.15

ABNORMALITIES IN BRAIN SEROTONIN UPTAKE AND STEADY STATE CONCENTRATION IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR). M.A. Stalnack, J.W. Dailey, P.C. Jobe, and R.A. Browning. Dept. of Physiology, Southern Illinois Univ. Sch. of Med., Carbondale, IL 62901; and Dept. of Basic Sciences, Univ. of Illinois Sch. of Med., Peoria, IL 61656.

Neurochemical deficiencies in brain serotonin (5-HT) and norepinephrine (NE) play a role in determining seizure predisposition of the GEPR. Previous studies have shown a parallel decrement in NE steady state levels, high affinity NE uptake, and dopamine β -hydroxylase activity in the GEPR suggesting a reduction in the NE terminal fields in the GEPR. To further evaluate the nature of the 5-HT deficit in GEPRs, regional steady state concentration and high affinity uptake were measured by reverse phase HPLC in age matched, male, severe seizure GEPRs (GEPR-9s) and seizure-resistant controls (SRCs). Regional brain 5-HT levels were found to be significantly reduced in the GEPR-9 cortex, caudate nucleus, amygdala, septum, hippocampus, and corpora quadrigemina when compared to SRCs, while the hypothalamus displayed a nonsignificant ($P=0.06$) reduction. No differences in 5-HT content between GEPR-9s and SRCs were observed in the thalamus, midbrain reticular formation, cerebellum, or pons medulla. 5-Hydroxyindoleacetic acid (5-HIAA) was significantly reduced in the cortex of GEPR-9s, but not in any of the other regions examined. Fluoxetine-sensitive high affinity uptake of 3 H-5-HT into crude synaptosomes was reduced in the GEPR-9 hippocampus. However, no difference in 5-HT uptake was observed in the amygdala, hypothalamus, thalamus, midbrain reticular formation, or corpora quadrigemina between GEPR-9s and SRCs. These findings contrast with the parallel decrement in presynaptic NE markers in GEPR-9s, and suggest that the mechanism(s) responsible for the reduced 5-HT levels in GEPR-9s may be different from that responsible for the NE deficit.

67.12

EFFECT OF MK801 ON DISTRIBUTION OF FOS IMMUNOREACTIVITY FOLLOWING STIMULATION OF THE ANGULAR BUNDLE. L. M. GRIMES, C. L. MITCHELL AND M. I. BARNES*. LMIN/NIEHS/NIH, Research Triangle Park, NC 27709

Continuous stimulation of the angular bundle (CSAB) for 45 min. uniformly produces status epilepticus in rats. We previously reported that such stimulation results in widespread induction of fos immunoreactivity (Mitchell et al. Neurosci. Abs., 16:348, 1990). The purpose of the present study was to determine the effect of MK801 on convulsive behavior and expression of fos under CSAB for 45 min. In animals given saline followed in 1 hr. by 45 min. CSAB, fos was expressed in widespread areas of the brain. MK801, 1 mg/kg, given 1 hr. prior to CSAB prevented the status epilepticus associated with 45 min. of CSAB. Also, fos was expressed in several limbic areas not expressed in the saline plus CSAB group. However, whereas fos was expressed in the saline plus CSAB group in the striatum and brain regions interconnected with it, these regions did not express fos in the MK801 plus CSAB group. These findings suggest that status epilepticus is associated with expression of fos in striatum and its interconnected areas. In addition, those areas known to be most sensitive to cell death following status epilepticus were seen to express fos immunoreactivity in the MK801 plus CSAB group but not the saline plus CSAB group.

67.14

The immunocytochemical pattern of heat shock protein 72kDa induction following seizures induced from prepiriform cortex. Shinichi Shimosaka*, Yuen So, Roger P. Simon, Department of Neurology, UCSF.

To study the vulnerability of neuronal regions to seizures emanating from deep pre-piriform cortex, we performed microinjections of bicuculline (294-1764 pMOL, 0.3 μ l per injection) into the area tempestus (AT) of 14 rats. Cell injury was assessed after 72 hours in two ways: 1) immunocytochemical localization of a monoclonal antibody to the non-constitutive 72kDa heat shock protein (hsp72) as a marker of stress, 2) cells failing to exclude an acid dye (acid fuchsin) as an indicator of neuronal death. AT bicuculline injection resulted in 10-86 min of sustained epileptiform EEG discharges. Hsp72 induction was seen only in animals with greater than 20 minutes of electrographic status epilepticus.

Hsp72 was first observed in the ipsilateral amygdaloid complex and the ipsilateral dorsal medial thalamus. With greater than 60 min of status, bilateral amygdaloid and thalamic staining for hsp72 occurred. Acid fuchsin staining was seen in these same cell groups, with frank necrosis occurring in the piriform cortex adjacent to the amygdala. Four control animals received bicuculline infusions into the subarachnoid space resulting in a different pattern of hsp72 expression occurring after 3-10 min. of sustained epileptiform discharges: parietal cortex, hippocampus, dorsal medial and ventral thalamic nuclei.

These results suggest that the dorsal amygdala and dorsal medial thalamus have selective functional interconnections with deep pre-piriform cortex and that neuronal death occurs at these regions from electrographic status epilepticus of greater than 20-60 minute duration emanating from AT.

67.16

AMINO ACIDS IN SUBSTANTIA NIGRA: INTRACEREBRAL MICRODIALYSIS IN GENETICALLY EPILEPSY-PRONE RATS. M.C. Doretto, R. Burger, N. Garcia-Cairasco and P.C. Jobe. Univ. of Illinois College of Medicine at Peoria and Faculty of Medicine of Ribeirao Preto, SP, Brazil.

Previous studies have shown that GABA transmission plays an important role in audiogenic seizure regulation. Excitatory amino acids may also participate in seizure regulation as evidenced by the fact that bilateral microinjections of NMDA receptor antagonists in substantia nigra (SN) block or reduce seizure severity in the severe seizure genetically epilepsy-prone rats (GEPR-9s). Accordingly, we undertook a microdialysis study of K^+ stimulated release of amino acids in the SN of GEPR-9s and non-epileptic controls. A 1 mm U-shaped probe was inserted into the SN of awake and freely moving rats (seven GEPR-9s and four non-epileptic controls), and used to perfuse a 100mM K^+ solution for 2h. Four 30 μ l samples were collected prior to high K^+ stimulation (basal release), during 100mM K^+ perfusion, and post- K^+ infusion. After pre-column derivatization with phenylisothiocyanate, levels of aspartic (ASP) and glutamic (GLU) acids, glycine (GLY), taurine (TAU) and GABA were measured by reversed phase high performance liquid chromatography. Two hours after the initiation of high K^+ infusion, the percent increases relative to basal were, for non-epileptic controls, 35%, 74%, 68%, 847% and 283% respectively for ASP, GLU, GLY, TAU and GABA. Corresponding increases for GEPR-9s were 14%, 10%, 41%, 505% and 123% respectively. GABA release in GEPR-9s was significantly less than in non-epileptic controls ($p<0.05$) throughout the K^+ stimulation period. The amino acid release for ASP, GLU, GLY and TAU was not statistically different between GEPR-9s and non-epileptic controls. These results may suggest that GABAergic mechanisms and associated nigral efferents play a role in the seizure susceptibility observed in GEPR-9s.

67.17

NORADRENERGIC REGULATION OF FOREBRAIN AND BRAINSTEM SEIZURES IN NON-EPILEPTIC AND GENETICALLY EPILEPSY-PRONE RATS (GEPRS).

P.K. Mishra, A.F. Bettendorf*, R.L. Burger*, J.W. Dailey, M.K. Eldadah, C. Wang, B.A. Browning and P.C. Jobe. Univ. of Illinois College of Medicine at Peoria and SIU School of Medicine, Carbondale, IL.

The role of norepinephrine in regulating brainstem seizures has been well documented. These seizures are characterized by running/bouncing clonus, and tonic extensor convulsions. Such evidence comes partially from studies with genetic models of epilepsy which are characterized by innate noradrenergic deficits and from selective lesioning of noradrenergic neurons and/or pathways. The present study was conducted to evaluate whether forebrain seizures, characterized by facial and forelimb clonus, are regulated by norepinephrine. Accordingly, one hundred female Sprague-Dawley rats (49-55 day old) and sixty moderate seizure genetically epilepsy-prone rats (GEP-3s) were either injected with 50 mg/kg ip of DSP-4 (N-(2-chloroethyl)-N-2-bromobenzylamine, Sigma) or vehicle. Three weeks later, these animals were tested for facial and forelimb clonus threshold via corneal electrode stimulation. Three days after the initial corneal electroshock, these animals were tested for brainstem seizure intensity using supramaximal electroshock (150 mA) delivered through ear clip electrodes. Two days after the supramaximal electroshock, animals were sacrificed and the extent of norepinephrine depletion was assessed in 9 brain areas. Widespread norepinephrine deficits were detected in the brain areas innervated by locus ceruleus in the DSP-4 treated animals. Also, the facial and forelimb clonus thresholds (convulsive current, I_{50}) in these animals were significantly reduced below control (vehicle) values as indicated by the Litchfield and Wilcoxon test. Brainstem seizures were facilitated as indicated by increased hindlimb extension-flexion ratios in the drug-treated animals. These observations provide additional support for the noradrenergic hypothesis of seizure regulation of brainstem and forebrain seizures. The evidence also strengthens the concept that the innate noradrenergic deficits, localized both in rostral and caudal portion of the GEP-3 brain contribute to seizure predisposition. Supported in part by NIH grant # NS22672.

EXCITATORY AMINO ACIDS: GABA IMBALANCE IN GENETICALLY

EPILEPSY PRONE BALB/c MICE IS PYRIDOXINE REVERSIBLE. S.

Dolina, J. Peeling, G. Sutherland, N. Pillay, S. Zalcman, A. Greenberg. University of Manitoba, Winnipeg, MB R3E 0V9

Neurotransmitter amino acid levels were determined by ¹H-NMR spectroscopy in the brain tissue of selectively bred epilepsy-prone (EP) and epilepsy-resistant (ER) substrains of BALB/c mice. Higher levels of excitatory amino acids (EAA), glutamate and aspartate, and higher ratio of EAA/GABA were observed in the cerebellum, hippocampus, cortex and brain stem of EP compared to ER animals. The EAA/GABA imbalance was corrected by pyridoxine (100 mg/L in drinking water) given to EP mice prenatally and throughout their lifespan, and was found to be region- and sex-specific. The combination of lower GABA level and EAA excess produced the severe glutamate/GABA imbalance in the hippocampus and cerebellum in EP (9.67 ± 0.36) vs ER (7.61 ± 0.13) females. These indices in both regions were reversed in pyridoxine-treated EP females. Pyridoxone treatment of EP males increased GABA and led to a decrease in EAA/GABA ratio in the cerebellum. The GABA deficiency which produced a higher glutamate/GABA ratio in the cortex of EP females (8.65 ± 0.07) compared with ER (6.6 ± 0.43) was not correctable by pyridoxine. In contrast, EAA levels and EAA/GABA ratios in the cortex and brain stem of EP males were pyridoxine reversible. Pyridoxine-dependent enzyme(s) of the glutamate system are currently under study in the EP animals. (Supported by the R.J. Reynolds Corp.)

EPILEPSY: ANIMAL MODELS I

NEUROPROTECTION FROM EXCITOTOXIC DAMAGE IN A RAT MODEL OF STATUS EPILEPTICUS. L.P. Penix*, F. Mansouri*, A.M. Morin and C.G. Wasterlain. Epilepsy and Neurology Research Labs, VAMC, Sepulveda, CA and Brain Research Institute, UCLA.

The rat model of Status Epilepticus (SE) described by Sloviter produces a pattern of hippocampal damage similar to that observed in human patients with Temporal Lobe Epilepsy and SE. In this model, there is a loss of recurrent inhibition in response to paired pulses given 40msec apart at stimulation frequencies greater than 1 Hz. The loss of recurrent inhibition is a result of death of hilar interneurons. We have used this model of 24 hour stimulation of the perforant path in rats to test the ability of NMDA and non-NMDA antagonists to prevent loss of neurons and recurrent inhibition. After 24 hours of intermittent 20 Hz stimulation of the perforant path, untreated animals had 52.9 ± 15.8 % reduction of hilar interneurons on the side of stimulation compared to the unstimulated side and 100.9 ± 4.9 % loss of recurrent inhibition at the 4 Hz stimulation rate. Animals treated with a constant infusion of 120 µg/kg/hr of the non-competitive NMDA antagonist MK-801 had 20.7 ± 28.3 % reduction of hilar interneurons with 53.4 ± 44.3 % loss of recurrent inhibition. Preliminary results on two animals given a constant infusion of the non-NMDA antagonist NBQX (1 mg/kg/hr) showed no protection against loss of recurrent inhibition but did show only 19.4 ± 7.9 % loss of hilar interneurons. These data suggest a selective protection of subpopulations of interneurons by NMDA and non-NMDA antagonists, with the NMDA blocker protecting interneurons involved in paired pulse inhibition.

67.18

MONOAMINERGIC AND AUDITORY INDICES IN NON-AUDIOGENIC SEIZURE (AGS) SUSCEPTIBLE GENETICALLY EPILEPSY-PRONE RATS (GEPRS). C.E. Reigel, K.D. Bell*, M.E. Randall, C.L. Faingold. Dept. of Pharmacol., Texas Tech Univ. Health Sci. Ctr., Lubbock, TX 79430, Dept. Basic Sci., Univ. of Ill. Col. of Med. at Peoria, Peoria, IL 61656 and Dept. Pharmacol., South. Ill. Univ. Sch. of Med., Springfield, IL 62708

The GEP-9 was developed from Sprague-Dawley (SD) rats through selective breeding for AGS susceptibility. Nearly all of the members of the current GEP-9 colony exhibit full tonic extensor convulsions when sound stimulated, reflecting over 25 generations of inbreeding for this trait. The highly consistent AGS responsiveness of the GEP-9 has allowed pathophysiological studies of the etiology of epilepsy. AGS susceptibility in the GEP-9 has been characterized by and is believed to be mediated through widespread deficits in central noradrenergic and serotonergic function as well as peripheral hearing deficits.

In a similar manner, those rare GEP-9s who are not AGS susceptible represent a unique opportunity to study the pathophysiology of epilepsy. Over a 6 month period, 7 non-AGS susceptible GEP-9s were identified during normal colony AGS screening. AGS susceptible littermates and non-AGS susceptible SD rats served as 2 control groups. Both AGS susceptible and non-AGS susceptible GEP-9s were determined to possess peripheral hearing impairment as compared to SD rats. Regional monoamine content was determined in all groups. Both AGS susceptible and non-AGS susceptible littermates were found to possess characteristic regional deficits in norepinephrine (NE) and serotonin as compared to SD rats with one notable exception. Non-AGS susceptible GEP-9s did not possess a deficit in midbrain NE content. These results suggest a deficiency in NE at the level of the midbrain is critical for the expression of AGS susceptibility in the GEP-9.

68.2

THE INFLUENCE OF NEONATAL HYPOXIA ON ELECTROCONVULSIVE SHOCK SEIZURES IN RATS. C.T.

Lombroso,¹ C.D. Applegate,² F.E. Jensen,¹ J.L. Burchfiel,² I. Firkusny¹ and G.M. Samoriski.² The Children's Hospital,¹ Boston, MA 02115 and Univer. of Rochester Sch. of Med.,² Rochester, NY 14642.

Neonatal hypoxia, but not anoxia, produces an acute ictal event in immature rats (F.E. Jensen, et al., *Ann. Neurol.*, v. 29, 1991), and results in an increased susceptibility to pentylenetetrazol- (PTZ) and fluorothyl-induced seizures in adulthood. In this study we examined the effects of neonatal hypoxia on susceptibility to corneal electroconvulsive shock (ECS) stimulation as adults.

At post natal day 10, male, Long Evans hooded rats were exposed to a 3% O₂ environment until heart rate decreased to 30% of basal. This procedure is acutely epileptogenic in rats of this age. Rats were tested for susceptibility to ECS-induced seizures at 60 days of age. ECS stimulation was delivered via corneal electrodes using a Grass S-48 stimulator (150 V, low impedance output) and consisted of a 400 ms train of 15 ms square waves at 400 Hz.

No differences in ECS-induced seizure manifestations were observed between hypoxic and non-hypoxic littermate controls. Thus, neonatal hypoxia increases susceptibility to generalized seizures in the PTZ and fluorothyl models but not in the ECS model. Results indicate the importance of evaluating the effects of neonatal hypoxic or other insults using multiple seizure models. We are currently assessing the effects of neonatal hypoxia on susceptibility to kindled seizures.

DEVELOPMENT OF VOLTAGE SENSITIVE CALCIUM CHANNEL TYPES OF AUDIOGENIC SEIZURE MICE. M.L. Smart, M.S. Esplin, C.L. Mouritsen, D.M. Woodbury, M.J. Litzinger Depts. of Pediatrics, Physiology, and Biology, Univ. of Utah, SLC, UT.

Development of voltage sensitive calcium channel (VSCC) types mark a critical period in Swiss Webster mouse neurodevelopment (Grover et al., 1990, Litzinger et al., 1990). Omega conotoxin (w-CgTx), believed to mark the presynaptic N type VSCC and PN-200, a 1,4 - Dihydropyridine, believed to mark the L type VSCC, show a rapid increase in binding on postnatal days 10 to 15. This time period corresponds to a "critical period" noted by Himwich, 1962, which signal the activation of electrocortical maturation.

Susceptibility of the DBA/2J mice to seizure is greatest at juvenile ages (days 16-21) and dissipates thereafter. This study compared the development of VSCC types in these audiogenic seizure mice. W-CgTx binding was done in whole brain from DBA/2J mice and shows a gradual increase between postnatal day 0 and day 7, and then plateaus between day 8 and day 16 (Esplin et al., 1991, Litzinger et al., 1991). Preliminary binding data with PN200 in the same frozen whole brain samples show a gradual increase between day 3 and day 13. These results suggest a developmental difference between VSCC types in DBA/2J mice. Perhaps this developmental difference underlies the basic mechanism of audiogenic seizures. This work was sponsored by NICHD K08 00886-02.

KINDLING-LIKE EFFECTS OF A PENICILLIN-INDUCED AMYGDALINE EPILEPTIC FOCUS DURING 23 H RECORDINGS IN FREELY MOVING CATS. A. Fernández-Guardiola, A. Martínez*, R. Fernández-Mas*, R. Gutiérrez. Inst. Mex. Psiquiatría, México 14370, D.F.

The topical application of penicillin to the amygdala induces focal discharges. The amygdaline penicillin focus is a useful model of "massed kindling". Two cats were implanted with a 16-channel cortical isometric matrix. Two were implanted for conventional sleep recordings and 4 had electrodes in both amygdalae and frontal cortices. All of them had a cannula implanted into left amygdala for penicillin delivery (50-100 IU). EEG mapping showed an early ipsilateral frontal propagation followed by a contralateral frontal activation. These progressive EEG manifestations were concomitant to behavioral changes resembling kindling stages within 5 h. Twenty four hour sleep recordings, starting at 8:30 AM, one hour before penicillin delivery, revealed dose-dependent REM latency augmentation, though the percentage of SWS and REM was unaffected. Amygdaline spiking was noticeably facilitated during SWS. As PGO activity appeared during REM, amygdaline and interictal cortical spiking were diminished or even suppressed. The consolidation of amygdaline penicillin epileptogenesis requires time for the involvement of distant structures responsible for the kindling-like behavioral manifestations since interictal spiking is present in areas distant from the primary focus. 1. Gloor et al., EEG clin. Neurophysiol. 43: 79-94, 1977.

IDENTIFICATION OF A HYDROPHOBIC DOMAIN ON VOLTAGE-GATED SODIUM CHANNELS LABELLED BY ³H-PHENYTOIN. J. Francis, L. Spero and W. M. Burnham. Department of Pharmacology, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

Electrophysiological studies suggest that phenytoin (PHT) limits repetitive neuronal firing via selective inhibition of voltage-gated sodium flux. Pharmacological studies, however, have failed to reveal a significant biochemical action of the drug within the therapeutic concentration range (1-10 μ M). We previously reported the existence of a specific and saturable ³H-PHT binding site with a K_d of approximately 5 μ M. We here report that the ³H-PHT binding site is a hydrophobic domain on the voltage-gated sodium channel, related to, but distinct from, the alkaloid toxin binding domain labelled by ³H-batrachotoxin A 20- α -benzoate (³H-BTX-B). Specific ³H-PHT binding in neocortical synaptosomes at 22°C reveals a single population of sites with an K_d of 1.7 μ M and a B_{max} of 5.5 pmol/mg protein. This specific ³H-PHT binding is inhibited by ligands specific for the hydrophobic neurotoxin site 2 on the sodium channel, with a rank order of inhibition similar to that previously reported for inhibition of the binding of ³H-BTX-B. Scatchard analysis indicates these interactions to be allosteric and non-competitive. Other anticonvulsant ligands which compete with the ³H-PHT site include mephenytoin, ethotoin, phenobarbital and carbamazepine. These interactions are also allosteric in nature and occur at supra-therapeutic concentrations. It is concluded that the ³H-PHT binding site lies on the voltage-gated sodium channel. Since the K_d for binding to this site falls within phenytoin's clinical concentration, it is proposed that phenytoin exerts its anticonvulsant effects by binding to this specific channel domain.

68.4

SODIUM VALPROATE EFFECT ON ETHANOL WITHDRAWAL IS MEDIATED BY ENDOGENOUS ETHANOL. F. Poldrugo, I. Bykov* and S. Ostrovsky*. Alcohol Research Group, Univ. of Trieste, 34100 Italy; Inst. of Biochemistry, BSSR Acad. Sci., Grodno 230009 USSR

Sodium valproate (SV) is known to be useful in the treatment of the ethanol withdrawal syndrome (EWS) in humans, but its mechanism of action is unclear.

The drug interferes with the enzymes involved in catabolism of gamma-hydroxy-butyric acid (GHB), which in turn is competitively inhibited by ethanol (E) since both substances are degraded by alcohol dehydrogenase (ADH). A possible effect of SV in the treatment of EWS is thus via a change in E catabolism.

Experiments were performed in Sprague-Dawley rats receiving SV in acute or chronic doses (100-400 mg/kg), and in rats in EWS after chronic E intoxication. Endogenous ethanol (EE) was measured by gas-liquid chromatography.

Both acute and chronic administration of SV increased the EE level in animal brain, plasma and liver and the use of SV prolonged the time of E elimination during EWS.

The results suggest that the suppressive SV effect on EWS in animal and humans may be mediated through a direct effect on EE concentrations in brain and an indirect effect on E catabolism in the liver because of a relationship with the metabolism of GHB.

Voltage Sensitive Dye Maps Differential Patterns of Seizure Spread. D.S. Sacks and R.M. Dasheiff. Dept. of Veteran Affairs, VAMC, University Dr., Pgh, Pa, 15240 and Univ. of Pittsburgh Epilepsy Center.

It is our hypothesis that unique spatial and temporal patterns of polarization throughout the brain reflect the underlying neural circuits activated by different seizures. The voltage sensitive dye di-*O*-C(2)-5 and computerized image analysis was used to histologically map the *in vivo* electrical activity of these neural circuits during drug induced seizures in awake animals (Soc. Neurosci. Abstr., 16: 1335, 1990). The rats received one of four treatments prior to dye injection: 1) i.p. Kainic Acid (KA) 12 mg/kg in saline; 2) i.p. saline; 3) intrajugular bicuculline (BIC) 0.25 mg/kg in DMSO; or 4) intrajugular DMSO. EEG activity was recorded via hippocampal and subdural electrodes and the dye injection timed to coincide with seizure activity.

The present study indicates that both agents produced depolarization relative to their specific controls. However, each drug produced qualitatively different patterns of neural activity. In our technique, dye concentration reflects the relative depolarization of neural tissues in such a way that lower dye concentration indicates greater depolarization. The dye concentration in the KA animals was Thalamus > Limbic > Brainstem > Cortex while the BIC animals showed a different pattern of Cortex > Limbic > Thalamus > Brainstem. These results demonstrate that the seizure circuits are activated differentially, in keeping with work using other techniques. Further spatial and temporal analysis will provide insight into seizure pathophysiology.

ARE THERE C-14, 2-DEOXYGLUCOSE CORRELATES OF THE EPILEPTOGENESIS PRODUCED BY COBALT IMPLANTS? R.M. Cooper and G. Van Ostrand*. Behavioural Neuroscience Research Group, Dept. of Psychology, University of Calgary, Calgary, Alberta, Canada T2N 1N4.

The 2-DG autoradiographic technique, which permits assessment of functional activity throughout the brain, could be used to determine how well anti-convulsants target ictal sites and to answer other questions of interest to epileptologists. Our findings with cobalt rod (.5 x 1.0 mm) implants in rat cortex suggest that correlates do exist: (1) Both cobalt and copper are toxic to tissue, but only cobalt is epileptogenic and only cobalt produced a ring of elevated 2-DG uptake around the implant site. (2) Cortical elevation in glucose metabolism peaked at 9 d after implant and disappeared around 21 d, mirroring the reported EEG and behavioral seizure time course for large cobalt implants. (3) The literature also indicates that secondary foci, presumably a reflection of retrograde and anterograde axonal transport of cobalt ions, may occur. In this connection we observed 2-DG "hot spots" in the LGN of rats with area 17 cobalt implants. (4) Finally, cobalt-induced elevations in 2-DG uptake were erased or attenuated by sodium pentobarbital anesthesia suggesting that the abnormal activity is affected by an anticonvulsant. Our findings point to a useful 2-DG marker of the excessive neuronal activity associated with brain cobalt implants.

ISOGUVACINE SUPPRESSION INDUCES LONG-LASTING EPILEPTOGENIC CHANGES IN THE RAT. S. Brailowsky and T. Montiel*, Instituto de Fisiología Celular, U.N.A.M., México 04510 D.F., Mexico.

Since the original description of an epileptogenic withdrawal syndrome induced by cessation of chronic (7 days) intracortical GABA infusion in photosensitive baboons, the phenomenon has been confirmed in non-epileptic baboons and rats and both in cortical and limbic structures. This "GABA-withdrawal syndrome (GWS)" represents a new model of partial status epilepticus.

We have also found that baclofen, a GABA_B receptor agonist, induces paroxysmal activity at the cortical injection site. In this report, we have induced a GWS-like phenomenon through semi-acute (2 hs) intracortical infusion of isoguvacine, a GABA_A receptor agonist. The behavioural and EEG effects of this agent are more pronounced than those of GABA itself during infusion suggesting an accumulation at the injection site. Cessation of drug infusion induces an epileptogenic process comparable to the GWS both in latency, duration and morphology. We conclude that the GWS is a GABA_A receptor-dependent phenomenon.

CYTOCHEMICAL DETERMINATION OF ALUMINUM IN MOTOR CORTEX OF RECIPIENT CATS IMPLANTED WITH ALUMINA CREAM EPILEPTOGENIC FOCUS. A. Feria-Velasco, I. De la Rosa*, M. Velasco and F. Velasco, Exptl. Path. Div., Unidad Invest. Biomed. Octe., I.M.S.S.; Dept. Morphology, Univ. Autónoma de Guadalajara; Guadalajara, Jal., and Unidad Invest. Biomed. Centro Méd. Nal., I.M.S.S. México, D.F.

Focal motor epilepsy is induced in cats by intracranial injection of alumina cream (AC), obtaining a constant model with a latent, convulsive and remission stages. Progressive reduction in thickness and cellularity in motor cortex (MCx) adjacent to AC deposit is seen with preferential loss of inhibitory GABAergic neurons. In this work, the role of free aluminum in the events sequence of the model was explored. For this, the AC focus of implanted cats obtained at latent, convulsive and remission stages were transplanted beneath the MCx of intact recipient cats. Electrocorticographic (ECG) recordings and motor behavior were analyzed in donors and recipients, up to 100 days after AC implantation. A semiquantitative study of aluminum in MCx adjacent to the epileptogenic focus was done by means of aurine tricarbonylic acid stain and Bielschowsky technique, and by a qualitative X-ray spectrometric study (EDAX) for aluminum in a scanning electron microscope. A progressive reduction in amount of non-phagocytosed alumina gel at the center of epileptogenic foci, and reduction of aluminum identified by the histochemical techniques and EDAX study, were seen in recipient cats when implanted with foci obtained from donors at latent, convulsive, and remission stages, respectively. Data correlate well with ECG recordings in recipient cats, in which a classical pattern was seen when latent stage-focus was implanted; moderate number of abnormal spikes with occasional convulsions were seen when a convulsive stage-focus was implanted; and few abnormal spikes with no convulsions were seen when a remission stage-focus was implanted. It is concluded that the amount of GABAergic interneurons destroyed in the MCx adjacent to AC deposits is proportionally related to the amount of free aluminum diffusing from the AC epileptogenic focus.

AUDIOGENIC SEIZURE SEVERITY IN THYROID-DEFICIENT RATS INCREASES AFTER NOREPINEPHRINE DEPLETION. D.L. Patrick Patra, C. Wang, R.A. Browning and C.L. Faingold, Depts. Pharmacol., Physiol. Southern IL Univ. School of Medicine, Springfield, Carbondale, IL 62794.

Neonatal thyroid deficient (THX) rats and genetically epilepsy-prone rats (GEPR-9s) both display audiogenic seizures (AGS) and significant hearing deficits. GEPR-9s are transiently thyroid deficient during development. THX rats exhibit submaximal AGS with wild running and clonus, while GEPR-9s display maximal AGS with tonic hindlimb extension (TLE). Brain norepinephrine (NE) deficits are an important determinant of AGS severity in GEPR substrains. This study examined regional brain NE levels and AGS severity in THX rats before and after depletion of NE using N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine (DSP-4, 50 mg/kg, ip). Thyroid hormone levels in normal neonatal rats were depleted using propylthiouracil (0.0075% postnatal day 0-19). AGS severity was evaluated before and after DSP-4 according to the scale (0-9) of Jobe using a bell (122 dB SPL, for 60 sec or until AGS onset). One week following AGS testing the brains of THX rats were removed and NE levels were subsequently evaluated using HPLC. THX rats exhibit a median AGS score of 2, and NE levels were not different from normal rats. Two weeks following DSP-4, AGS severity scores were significantly increased (median = 5) with 25% of THX rats (N=12) exhibiting TLE. THX rats displayed significantly decreased NE (but not dopamine) levels in all brain areas examined 3 weeks following DSP-4. THX rats exhibited a smaller degree of NE depletion, and AGS severity (median score = 3) was also reduced 3 months after DSP-4 treatment, suggesting recovery from both effects occurs in parallel. Thus, NE deficits are not observed in AGS-susceptible THX rats, but depletion of NE increases AGS severity in THX rats, further supporting the critical role of brain NE in determining AGS severity. (NIH NS 21281)

CORTICAL AND SUBCORTICAL PROPAGATION OF AN AMYGDALINE PENICILLIN EPILEPTIC FOCUS IN "ACUTE" AND FREELY MOVING CATS. R.Gutiérrez, A. Martínez*, R. Fernández-Mas*, A. Fernández Guardiola. Inst. Mex. Psiquiatría, México 14370, D.F.

In order to explore whether an amygdaline chemical epileptic focus follows the same cortical propagation pattern than the electrical kindling, we carried out subcortical recordings and cortical mapping in cats with an amygdaline penicillin focus. Fifteen cats were used: 11 for "acute" and 4 for "chronic" experiments. Penicillin (50-5000 IU) was delivered through a cannula implanted in the left amygdala. Six animals were prepared as encéphale isolé and 5 were anaesthetized with urethane. Two "acute" and 2 chronic cats were epidurally implanted with a 16-channel isometric matrix (10-20 international) for monopolar EEG recordings and subsequent brain mapping. The interhemispheric transfer was conducted mainly through stria terminalis (ST) and pericommisural fibers (PCF) and in a lesser extent by corpus callosum. Spikes appeared also in Habenula and Septum. The shortest latencies were evident in ST, PCF and ipsilateral prefrontal cortex. The AM spiking projection was more evident in the insular and ectosylvian posterior cortices, bilaterally in the frontal regions and an activation of the contralateral temporal lobe appeared towards the end of the AM spiking activity. The electrical and the behavioral manifestations were asymmetrical throughout the experiment. We conclude that the induction of a penicillin amygdaline focus is a model of "massed kindling". The secondary epileptogenic site is in the prefrontal cortices.

BRAINSTEM RETICULAR FORMATION UNIT ACTIVITY DURING ETHANOL INTOXICATION AND WITHDRAWAL ASSOCIATED WITH AUDIOGENIC SEIZURES. A. Riaz and C.L. Faingold, Dept. Pharmacology, Southern IL Univ. School of Medicine, Springfield, IL 62794.

Ethanol withdrawal (ETX) in normal rats induces susceptibility to audiogenic seizures (AGS). Previous studies support an important role of the brainstem reticular formation (RF) in AGS. The present study examined effects of ethanol treatment (ET+) and ETX on single neuron responses using microwire electrodes implanted into the pontine RF. Ethanol was given intragastrically (9-15g/kg/day) for 4 days. Neuronal responses to AGS-inducing stimuli (12kHz tone bursts) were recorded in awake rats before ET+ (control), during ET+ and during ETX. The mean evoked activity during ET+ was significantly decreased from control and significantly increased in ETX at all intensities. The degree of response "habituation", occurring with increasing repetition rates was measured as % of firing at 1/2sec. Before ET+, mean firing was decreased from 1/2sec response rate to 74.5±7% (at 1/sec) and to 49.5±5.3% (at 2/sec). During ET+, habituation was intensified to 49.3±11.5% (mean at 1/sec) and to 30.5±10% (at 2/sec). During ETX, mean habituation was decreased at 1/sec (79.5±9.2%) and at 2/sec (85.4±13.8%), indicating that RF neuronal habituation is augmented during ET+ and reduced during ETX. During ET+ spontaneous firing of RF neurons was decreased (10.8±4% of control) but markedly increased during ETX (229±67.3%). Ethanol affects the actions of GABA and excitant amino acids (EAAs). Microinjection of GABA agonists or EAA antagonists into the RF blocks AGS during ETX. During ET+, increased GABAergic and decreased EAA transmission may mediate reduced RF firing. ETX may lead to hyperexcitability due to rebound changes in amino acid transmission. Thus, increased RF excitation and reduced inhibition may play a role in AGS susceptibility during ETX. (NIH NS 21281)

CHRONIC SEIZURES IN JUVENILE WISTAR-FURTH RATS FOLLOWING SYSTEMIC ADMINISTRATION OF KAINIC ACID. G.T. Golden, P.F. Reyes, G.C. Smith* and T.N. Ferraro, DVAMC, Coatesville, PA 19320 and Thomas Jefferson Univ., Phila., PA 19107.

Wistar-Furth (WF) rats are exceptionally sensitive to the convulsant effect of systemic kainic acid (KA) (Neuroreport, 2,141-144, 1991). Sixteen male juvenile (36-37 days old) WF rats were given KA 10 mg/kg, sc and observed for seizure activity. Seven age-matched male WF rats served as controls. Animals had food and water intakes and body weights recorded for seven days prior to KA and for 100 days after. Animals were placed in an activity monitor each week. Mortality (usually 80% at this age and dose) was minimized by administering 10cc lactated ringer's solution sc, six hours after KA and for the first five days post-KA and by providing cookie mash and sucrose-powdered rat chow until body weight stabilized. One animal died in status 3h19m post-KA, 15 animals survived both the acute and chronic phase. Over the next 100 days 53% (8/15) of surviving animals were observed having multiple spontaneous behavioral seizures. Spontaneous seizures were first observed at 12 days post-KA and could be observed in some animals until termination of the experiment at 100 days post-KA (137 days old). Spontaneous seizures consisted of staring, facial and abdominal myoclonic jerks, running-bouncing seizures, and major clonic seizures ranged from 15 sec to 90 sec in duration. Results indicate that KA treated juvenile rats show chronic spontaneous, recurrent seizure activity as adults. Supported by VA funds & NIA grant #5301AG0814802.

68.15

HISTOLOGICAL AND IMMUNOHISTOCHEMICAL CHANGES IN HIPPOCAMPUS AND PREPIFORM CORTEX OF WISTAR-FURTH RATS WITH CHRONIC KAINIC ACID INDUCED SEIZURES. P.F. Reyes, G.T. Golden, G.C. Smith* and T.N. Ferraro. Neurology and Pharmacology, Thomas Jefferson Univ., Phila., PA and DVAMC, Coatesville, PA 19320.

Sixteen adult male Wistar-Furth rats with kainic acid (KA)-induced seizures, and seven normal age- and sex-matched controls were utilized in this study. Seizures were induced by injection of KA (10mg/kg, sc) between 36-37 days of age. All KA animals demonstrated behavioral seizures and status epilepticus during the four hr observation period following KA. More than half of the KA treated animals were observed having multiple spontaneous behavioral seizures over the next 100 days. Seizures appeared spontaneous since they could not be elicited by visual, auditory, or tactile stimulation. Animals were sacrificed 136-137 days of age, and selected brain sections were prepared and stained with H&E, LFB-CV, and silver impregnation and reacted with antibodies to GFAP. The KA group showed varying degrees of neuronal loss, reactive gliosis, and astrocytic Rosenthal fiber formation in the CA1 and CA3 segments of the hippocampus, and neuronal loss in the prepiriform cortex. The presence of observed seizures correlated directly with the severity of hippocampal alterations; Rosenthal fibers were the best indicator of neuro-glial damage in the hippocampus. Supported by NIA grant #5301A0814802 and VA funds.

A FLEXIBLE PERFORATED MICROELECTRODE ARRAY FOR EXTENDED NEURAL RECORDINGS. B.C. Wheeler, S.A. Boppert* and C.S. Wallace. Beckman Institute, University of Illinois at Urbana-Champaign, Urbana, IL, USA 61801.

A flexible and perforated 32-element planar microelectrode array has been fabricated for measuring evoked potentials in brain slices or from any brain or ganglion surface. Electrodes are spaced 200 μ m apart in a 4 x 8 array and are sandwiched between layers of insulating polyimide. The polyimide was etched by wet chemical and reactive ion etchants with the results compared. In addition to etching holes through the polyimide to expose recording sites 15 μ m in diameter, perforations surrounding the electrodes were etched through both layers. The perforations allow increased circulation of artificial cerebrospinal fluid to the recording surface of the tissue and, hence, increased viability. Evoked potentials were recorded from rat hippocampal slices to demonstrate the functionality of the 32 simultaneously recording, spatially distributed electrodes. Individual spikes and EPSPs were recorded over time to determine the slice viability. Comparisons between perforated and nonperforated arrays showed an average increase of 10 hr to the viability of the slice while using the perforated array. The flexible nature of the array allows shaping to contoured tissue surfaces while still permitting adequate circulation of fluids by way of the perforations.

FACILITATION OF SENSORY EVOKED POTENTIALS: CHANGES WITH KINDLING OF HIPPOCAMPUS AND AMYGDALA IN GUINEA PIGS. Arnold Lidsky, NYS Basic Research, Staten Island, NY 10314

Kindling as a model of epileptogenesis and neural plasticity, extensively studied in the rat, cat and rabbit emphasizes EEG afterdischarges (AD) and generalized seizure development. These observations are here extended to guinea pigs receiving daily kindling for up to 150 days in either dorsal or ventral hippocampus, the amygdala, or parietal cortex, with serial testing of visual (VEP) and auditory (AEP) evoked potentials at 14 and 30 day intervals. Changes in EP morphology persisted for at least 2 months following termination of kindling. ADs were longest for hippocampal animals and shortest for cortical controls (C), with progressive prolongations in all groups. VEP components occurring between 40 and 150 msec after light flashes were both faster and larger in limbic-kindled animals within 30 days and reached plateaus at 60-90 days of kindling, while earlier components showed no significant changes. C animals showed paradoxical prolongation of the N3 component of the VEP. AEP latencies decreased in all kindled animals with amplitudes remaining constant in hippocampal-, and decreasing in both cortical and amygdala-kindled guinea pigs. Thus focal kindling, rarely manifesting in tonic-clonic convulsions in these hippocampal animals, altered specific remote sensory conduction in guinea pigs, with longterm consequences including hypersensitivity to peripheral sensory input.

68.16

HYPERREACTIVITY IN RATS WITH SEIZURE-INDUCED BRAIN DAMAGE: ROLE OF NUCLEUS ACCUMBENS. S.L. Hartgraves, M. S. Tristan*, M. L. Williams*, S. A. Miller, and M. R. Murphy, University of Texas Health Sciences Center at San Antonio, Texas, 78284; Armstrong Laboratory, Brooks AFB, Texas, 78235.

Organophosphate (OP)-induced seizures in rats result in hyperreactivity to physical stimuli and an exaggerated locomotor response to stimulant drugs such as d-amphetamine (d-Amph) and caffeine (Caff). Extensive damage to the limbic system is present in these animals, and may underlie this heightened sensitivity to stimulants. The objective of this study is to assess this hyperreactivity by measuring drug-induced locomotor activity, before and after 6-hydroxydopamine (6-OHDA) lesions of the nucleus accumbens (NAS). HPLC will be used to measure catecholamines in the NAS at study completion.

Rats exhibiting seizures and weight loss following injections of the highly toxic OP soman, were screened for responses to 1.5 mg/kg d-Amph and 20 mg/kg Caff. Those showing 2-3 fold increases in locomotor activity (compared to controls), as well as control animals, underwent additional 6-OHDA/sham lesions of the NAS, to examine its role in stimulant-induced exaggerated responses.

Animals with dopamine depletions in the NAS greater than 65% showed reduced responses to both d-Amph and Caff. This information is examined in light of reports showing different neural substrates for d-Amph and Caff-induced locomotor activation (Swerdlow et al., 1986).

68.18

MECHANISM OF GAMMA-BUTYROLACTONE (GBL)-INDUCED ACTIVATION OF TYROSINE HYDROXYLASE (TH) IN DOPAMINERGIC NERVE TERMINALS. S.M. Lasley and M.C. Green*. Dept. of Basic Sci., U. Illinois Coll. of Med., Peoria, IL 61656

GBL is metabolized *in vivo* to gamma-hydroxybutyrate (GHB) and GBL-treated rats have been proposed as a model of generalized absence seizures. GBL derivatives have been shown to be active at the GABA_A receptor-Cl⁻ channel, but the parent drug has also been employed to test the autoreceptor activity of dopamine (DA) agonists *in vivo* by virtue of its blockade of DA neuronal impulse flow and elevation of synaptic TH activity. Male Long-Evans hooded rats were utilized at 85-100 days of age to examine the time course and activation of TH by GBL employing multiple approaches. Conversion of ³H-tyrosine by TH isolated from caudate-putamen of rats receiving 750 mg/kg i.p. GBL reached maximal values by 30 min post-injection and remained at this level until 90 min. In combination with a decarboxylase inhibitor, GBL produced a 2.3-fold increase in striatal L-DOPA content at this dose and time after administration. However, direct measurement of the increase in striatal enzyme activity in GBL-treated rats by the tritium release method observed no more than a 60-70% activation. Kinetic analyses of the change in TH activity as a function of 6-MPH₄ concentration employing nonlinear regression found that the GBL-induced activation was due primarily to a doubling of the maximal velocity of the enzyme form with high affinity for the cofactor. In contrast, a 1.0 mg/kg i.p. dose of haloperidol caused a 2.4-fold increase in V_{max} of the high affinity form 2 hr after administration. These results suggest that the GBL effects on DA neurons may be a significant behavioral component of the GHB model of generalized absence seizures. (Supported by ES04359 and the Children's Miracle Network)

CHOLINERGIC STIMULATION OF THE VENTROPOSTERIOR THALAMIC NUCLEUS INDUCES LIMBIC SEIZURES: BEHAVIORAL, ECoG, AND METABOLIC CORRELATES. S. Mraovitch*, Y. Calando*, P.J. Goadsby+, J. Seylaz*. *Laboratoire de Recherches Cérébrovasculaires, CNRS UA 641, Université Paris VII, Paris (France). + Department of Neurology, The Prince Henry Hospital, Sydney, Australia.

It has recently been demonstrated that cessation of chronic unilateral infusion of GABA into the somatomotor cortex in rats induces focal epileptic spikes ("GABA withdrawal syndrome"; GWS) and marked increase in local cerebral glucose utilization (LCGU) in the ipsilateral ventroposterior thalamic nucleus (VP). Since the VP is a site of termination of cholinergic afferents originating in the upper brain stem we sought to determine whether neurons within the VP were the origin of the thalamo-cortical activation which is thought to trigger the GWS epileptic manifestation.

Wistar rats (300-350g) were used in the experiments. Carbachol (CCh, 10 μ g in 100nl) was stereotactically injected unilaterally into the VP via a glass micropipette to determine behavioral and ECoG changes. ICGU was studied by quantitative 2-DG analysis in anesthetized (alpha-chloralose), paralyzed (d-tubocurarine) and artificially ventilated rats.

CCh injection into the VP (n=7) caused behavioral alterations (wet dog shakes) and the ECoG (n=15) bilateral bursts of paroxysmal discharge with a latency of 25-30min. LCGU was markedly increased in CCh-injected rats (n=4) in ipsilateral dorsal (+259 \pm 39%), postero-ventral CA3 (+226 \pm 13%) and CA3 (+247 \pm 9%) hippocampal fields, the lateral septum (+122 \pm 47%); Mann-Whitney test, p < 0.05.

We conclude that activation of the VP cholinergic receptors induced behavioral, ECoG and marked metabolic alteration in the hippocampus and the lateral septum, known to be associated with limbic seizures. Further research

SYMPOSIUM. THE BASAL GANGLIA IN THE '90S: WEDDING THE NEURAL SYSTEM TO CELLULAR AND MOLECULAR MECHANISMS. C. Gerfen, NIMH (Chairperson); R. Albin, Univ. Michigan; L. Mink, Washington Univ.; P. Bolam*, Oxford Univ.; C. Wilson, and J. Surmeier, Univ. Tennessee, Memphis.

The basal ganglia presents a considerable challenge to relating neuroanatomical organization to behavioral function. This symposium will present clinical, electrophysiological, neuroanatomical and molecular studies that together offer a new view of basal ganglia function. The synthesis of these studies suggest that the basal ganglia transforms excitatory inputs from the cerebral cortex into a delicately balanced opposition in the activity of the two major outputs systems of the striatum. The mechanisms of this balanced opposition will be discussed at the systems level, as well as at the cellular and molecular levels. Roger Albin will introduce the concept of the balanced opposition of striatal output systems as this mechanism relates to the spectrum of clinical disorders associated with basal ganglia disease. John Mink will describe single unit recording studies of internal globus pallidus activity in relationship to voluntary limb movements of monkeys. Paul Bolam will describe ultrastructural studies of the synaptic organization of the inputs to neurons that are recorded from by Mink, to provide a morphologic basis to the pattern of physiologic activity. Charles Wilson will describe intracellular neurophysiological studies of the mechanisms of integration of corticostriatal inputs by the major output neuron of the striatum, the medium spiny neuron. Jim Surmeier will describe application of patch-clamp techniques to acutely dissociated striatal neurons to study the modulation by acetylcholine muscarinic and dopamine receptors of potassium and sodium conductances. C. Gerfen will describe in situ hybridization histochemical studies that demonstrate the differential modulation through D1 and D2 dopamine receptors of striatonigral and striatopallidal output neurons.

SYMPOSIUM: REGULATION OF ION CHANNELS. L.K. Kaczmarek, Yale U (Chairperson); R.A. Frizzell*, Univ. of Alabama; K-W Yau, Johns Hopkins Univ.; R. MacKinnon*, Harvard Univ.; B. Ganetzky, Univ. of Wisconsin.

In the last four years, the molecular identity of a variety of ion channels has been revealed. Studies with these channels are beginning to identify discrete regions of the proteins that form part of the ion pore itself. Other regions and components of the channel proteins allow their activity to be regulated by protein kinases or cyclic nucleotides. Moreover, new types of ion channels are being discovered, based on the existence of conserved regions that are required for ion channel function and selectivity. The symposium will use examples of channels found in both neuronal and neuronal cells to illustrate these approaches.

The first part of the symposium will discuss how ion channel are regulated by protein kinases and cyclic nucleotides. These presentations will use two examples; i) chloride channels in epithelial cells, where a genetic defect in the response to protein kinases has led to the identification of a regulatory protein (R.A. Frizzell) and ii) new insights into the function of cation channels that are gated by changes in cyclic nucleotides (K.-W. Yau). The second part of the symposium will focus on potassium channels. It will describe experiments showing that one short segment of the Shaker family of channels determines drug sensitivities and plays a major role in ion permeation (R. MacKinnon). The final presentation (B. Ganetzky) will show how this knowledge combined with genetic studies, is bringing about the identification of new classes of potassium channels.

VISUAL CORTEX: STRIATE CORTEX

73.1

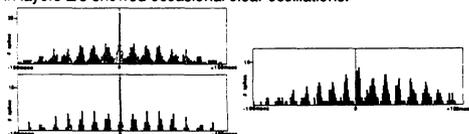

AN *IN VIVO* WHOLE-CELL PATCH STUDY OF THE LINEARITY OF IPSP-EPSP INTERACTIONS IN CAT VISUAL CORTEX D. Ferster and B. Jagadeesh, Department of Neurobiology, Northwestern University, Evanston, IL 60208.

Postsynaptic inhibition operates by two distinct mechanisms, hyperpolarization and shunting of excitatory postsynaptic currents (EPSCs). The predominant inhibitory mechanism determines the arithmetic operation—addition or multiplication—that synapses perform during neuronal computations (PNAS 80, 2799). Hyperpolarizing IPSPs interact linearly with EPSPs; the positive and negative synaptic currents sum to produce a net change in membrane potential. Shunting synapses interact nonlinearly with EPSPs; the shunting-induced increase in membrane conductance reduces the size of EPSPs by a constant fraction. We have searched for shunting inhibition by measuring the effect of visual stimuli on the size of small, electrically-evoked test EPSPs in cortical neurons.

Intracellular current-clamp records were obtained from neurons in anesthetized adult cats with the whole-cell patch method (J. Neurosci. Methods 30:203). A bar of light was passed across each cell's receptive field at the same time that a monosynaptic test EPSP was generated by electrical stimulation of the lateral geniculate nucleus. Decreases in test-EPSP size were evoked by stimuli of the preferred orientation, but the decreases were not caused by shunting. They occurred only during periods of visually-evoked depolarization, and were presumably caused by reduction in the driving force on EPSCs that accompanied the depolarization. Visually-evoked hyperpolarizing IPSPs were accompanied by a slight increase in test-EPSP size. Stimuli of the null orientation caused no significant change in test-EPSP size. We conclude that for inhibition evoked by the simple natural stimuli employed here, the predominant inhibitory mechanism is hyperpolarization, rather than shunting.

73.3

VISUALLY-EVOKED OSCILLATIONS IN MONKEY STRIATE CORTEX. M.S. Livingstone, Dept. Neurobiology Harvard Med. School, Boston MA 02115. Two- and three-electrode recordings from 11 recording sessions from halothane-anesthetized squirrel monkeys were analyzed for interneuronal correlations in firing and for oscillatory firing patterns, as described in the cat by Gray and Singer (PNAS 86:1698, 1989). Many neurons did show oscillatory firing, but only in response to visual stimuli. The oscillations were correlated between cells in the same orientation column, within and between layers, but not between cells of different orientation selectivity. The oscillations were faster than was observed in the cat—50 to 90 Hz. Some of the cells showed oscillation frequencies near 60 Hz, but this does not appear to be an artifact of the refresh rate of our TV monitor, because these cells showed the same oscillation frequencies to a constant light source. The periods of oscillatory firing lasted only 40 to 100 msec even when the entire visual response was much longer. More than half the cells in layers 4C α and 4B showed striking oscillatory firing at some time during most responses, and about 20% of the cells in layers 2/3 showed occasional clear oscillations.

(Left) autocorrelograms from two cells recorded simultaneously in deep layer 3 (top) and layer 2. The crosscorrelogram (right) shows that the oscillations in the two cells were correlated, with the layer 2 cell lagging the layer 3 cell by 4 msec. 73.2

VISUALLY-EVOKED OSCILLATIONS OF MEMBRANE POTENTIAL IN NEURONS OF CAT AREA 17. †B. Jagadeesh, †D. Ferster and *C. Gray. †Neurobiology Dept., Northwestern University, Evanston, IL 60208 and *The Salk Institute, La Jolla, CA 92186.

Extracellularly-recorded single unit and field potential activity in visual cortex exhibit 30-60 Hz oscillatory responses to specific visual stimulation (PNAS 86:1698). Intracellular records obtained *in vivo* from neurons in cat area 17 using the whole-cell patch technique (J. Neurosci. Methods 30:203) showed oscillations of neuronal membrane potentials similar to previously observed extracellular oscillations.

Intracellular oscillations resemble those seen extracellularly in the following properties: 1) The membrane potential, like the local field potential, oscillates at frequencies between 30 and 60 Hz in response to optimal visual stimuli, with amplitudes of up to 10 mV; 2) The oscillations are smaller in layer 4 simple cells, which receive monosynaptic excitation from the LGN, than in complex cells with polysynaptic geniculate input. 3) Oscillations with the greatest amplitude are evoked by stimuli of the preferred orientation of the cell, as defined by slow EPSP responses; 4) The exact frequency of the oscillation is variable from moment to moment. 5) The onset latency, frequency and duration and phase of the oscillations vary slightly from trial to trial. 6) The average frequency of the oscillations varies little with stimulus orientation. 7) Spike activity is synchronized with the depolarizing phase of the oscillation in membrane potential.

The oscillations do not arise solely from neuronal electrical properties. In some cells, depolarizing current pulses did evoke oscillatory responses, but not of the frequencies or amplitudes characteristic of visually-evoked oscillations, suggesting that in these neurons, membrane potential oscillations reflect rhythmic changes in synaptic input.

73.4

ON OSCILLATING NEURONAL RESPONSES IN MONKEY VISUAL CORTEX. M.P. Young¹, K. Tanaka², S. Yamane³. 1: University Laboratory of Physiology, Parks Rd., Oxford, OX1 3PT, U.K. 2: Frontier Research Program, RIKEN, Saitama, Japan. 3: Division of Neuroscience, ETL, Tsukuba, Japan.

We recorded multi-unit activity (MUA) and local field potentials (LFP) in areas V1 and MT, and MUA from the inferotemporal cortex (IT) of monkeys (*Macaca fuscata*). Recordings in all areas were made under conditions of anaesthesia as close as possible to those in studies of oscillating responses in the cat (e.g. Gray et al 1989, Nature 338:334). In addition, we recorded MUA in the IT of behaving monkeys while the monkeys performed a face discrimination task (see Yamane et al 1988, Exp. Brain Res. 73:209).

In areas V1 and MT, LFP power spectra showed broad band increases (1-100Hz) in amplitude on stimulation by swept optimally-oriented light bars, and not a shift in power from low to mid-frequency, as has been reported in the cat. MUA autocorrelograms (ACGs), classified by fitting Gabor functions, showed oscillations mainly in the alpha range. MUA ACGs from IT in the anaesthetized monkey showed no oscillations, when stimulated by images previously determined to be effective. MUA ACGs from IT in the behaving monkey showed only one oscillating response, with a frequency of 44Hz. The very low incidence in the monkey of oscillating responses in the 30-70Hz range (1 in 424 recordings) suggests that such oscillations are unlikely to serve a function in the monkey, and that there may be a species difference between monkey and cat in the dynamics of neural activity in the visual cortex.

We used a method very similar to that of Engel et al (1990) (Eur. J. Neuro. 2:588) to classify ACGs as oscillating. We found that this and related methods may have led to Type I error by failing to take account of badness of fit between Gabor functions and their ACGs, and by Gabor functions 'ringing' in response to short phasic phenomena which could be consistent with activity in other than the oscillatory domain. In the present data, these problems, if uncorrected, would have led to overestimation of the incidence of oscillation by between 54% and 100%.

CHARACTERISTICS OF TEMPORAL FREQUENCY TUNING OF NEURONS IN MACAQUE V1

M.J. Hawken, R.M. Shapley, D.H. Grosop, Center for Neural Science, New York University, 6 Washington Pl., New York, NY 10003.

We have measured the temporal frequency tuning of neurons in different layers of Macaque V1 using both chromatic and achromatic sine wave grating stimuli under mid-photopic conditions. In these experiments we were particularly concerned with the measurements of the full range of frequency response and with measurement of integration time. These measurements were made in order to compare the transformation that occurs between the LGN and cells in different layers of the striate cortex. Unlike the transformation that occurs between cat LGN and cortex where there seems to be significant attenuation of high temporal frequency, in monkey V1 a number of cells show responses to temporal frequencies up to 40 to 50 Hz. The integration time, derived from the slope of the response phase versus temporal frequency, was as short as 40 msec in some cortical cells. This value is close to that measured in Macaque LGN neurons.

73.7

RESPONSES OF SINGLE UNITS IN MACAQUE V1 TO MOVING PATTERNS.

Vincent P. Ferrera and John H. R. Maunsell

Dept. of Physiology and Ctr. for Visual Science, Univ. of Rochester, Rochester, NY 14642.

Several lines of psychophysical and physiological evidence suggest that motion processing is broken down into two stages: initial sampling by linear "component" direction selective units, followed by integration across different directions by "pattern" motion units. Movshon and his collaborators have obtained physiological evidence that the component stage is carried out in area V1, and that pattern motion processing occurs in area MT. However, their analysis leaves a significant proportion of the cells unclassified as either component or pattern direction selective. In order to examine potential contributions of these unclassified neurons, we recorded from 48 single units in area V1 of alert macaque monkeys trained to fixate a small spot while stimuli were presented at eccentric locations in the visual field. Direction tuning curves were obtained using cosine gratings and patterns that consisted of the sum of two gratings with different orientations ("plaids.") We confirmed the result that most cells in V1 are component direction selective, although a small number are clearly pattern direction selective. Furthermore, about one-fifth of the cells have good orientation tuning for gratings and plaids, but their tuning curves for plaids are inconsistent with either the component or pattern prediction, which puts them in the unclassified category. The difference in response of these cells to the two different stimuli may be due to the operation of oriented inhibitory mechanisms whose orientation preference is orthogonal to that of the cell's excitatory drive. We have constructed a model which demonstrates that units with such inhibition could be used in a network which computes pattern motion. We conclude that many neurons in V1 carry signals which may contribute to pattern motion processing.

PATHWAYS IN THE VISUAL CORTEX REVEALED BY RECEPTIVE FIELD MAPPING OF CORRELATED DISCHARGE. G.M. Ghose*, J. Ohzawa, and R.D. Freeman. Biophysics and Neurobiology Groups, University of California, Berkeley, CA, 94720.

Cross correlation analysis of the discharge activity from two neurons has been used to infer neural interactions in a large number of preparations. One limitation in interpreting correlated activity is that it can arise as a result of a single shared common input or because of the temporal superposition of many different neural interactions.

In order to identify pathways leading to pairs of neurons within the cat's visual cortex, we constructed receptive field maps of correlated discharge. Correlated discharges that originate from different pathways are expected to have different latencies or spatial profiles reflecting the underlying inputs. Extracellular activity from pairs of cells was recorded during the presentation of random sequences of small bright and dark bars flashed in and around the two receptive fields. Reverse correlation of spike pairs is used to reveal the spatiotemporal stimulus selectivity of correlated discharge.

For most of the cell pairs studied, multiple features are observed in the spatiotemporal response maps of correlated discharge. These "receptive fields" of correlated discharge can be classified on the basis of their latencies. Single regions whose peak precedes the response peak of each member cell by about 20-50 ms. are associated with nearly synchronous correlated discharge. Response peaks which follow the responses of member cells by 50-90 ms. include cases of asynchronous discharge, with interspike intervals between the two neurons as large as 100 ms. Unlike the early responses, more than half of these late responses are elicited by stimuli presented outside of the classical receptive fields of the two cells.

These results suggest a two stage sequence of stimulus-evoked discharge in the visual cortex. Synchronous geniculate inputs invoke primary cortical responses. Secondary responses, often consisting of asynchronous discharge between cortical neurons, reflect intracortical and extra-receptive field feedback. (EY01175)

ANOMALOUS RESPONSES IN V1 TO ANOMALOUS CONTOURS?

D.H. Grosop, R.M. Shapley & M.J. Hawken, Center for Neural Science, New York University, New York, NY 10003.

Von der Heydt & Peterhans (1989) investigated the responses of monkey V1 neurons to abutting line gratings which were drifted parallel to the grating bars. They asked whether V1 responses signaled the orientation of the perceived anomalous ("illusory") contour on the boundary between two abutting gratings, or the orientation of the inducing bars in the gratings. V1 neurons always responded more when the bars were at the cell's preferred orientation. Thus, they concluded that V1 cells are not directly involved in the signalling of anomalous contours.

Testing orientation-selective neurons in monkey V1, we have recorded responses to drifting patterns made up of an abutting pair of sine gratings offset in spatial phase but equal in frequency, contrast and color. A range of speeds, colors and spatial frequencies was used. Responses were averaged, synchronized to the passage of the texture boundary across the receptive field. When the bars making up the patches are perpendicular to the cell's preferred orientation, and the drift direction is parallel to the bars, only a weak response is expected according to most receptive field models. But we found that some cells respond more vigorously to the boundary of the patch--an anomalous contour--than one would expect from their responses to full-field temporally modulated gratings. Support: NEI EY-1472 (RS), EY-8300 (MH), and a NRSA (DG).

REVERSIBLE INACTIVATION OF FUNCTIONALLY CHARACTERIZED SITES IN CAT VISUAL CORTEX: EFFECTS ON ORIENTATION TUNING AND DIRECTIONAL SELECTIVITY. J. M. Crook, Z. F. Kisvárdy and U. T. Eysel. Dept. of Neurophysiology, Faculty of Medicine, Ruhr University of Bochum, W-4630 Bochum, Germany.

Iontophoresis of GABA was used to reversibly inactivate small sites of defined orientation and directional specificity at a horizontal distance of some 500-700µm from single cells recorded in area 18 of cat visual cortex, and the effects on orientation and directional selectivity studied. Inactivation of sites where the preferred orientations differed by 45° or more from that of a recorded cell (cross orientations) caused substantial broadening of orientation tuning in some two-thirds of cells. Broadening of tuning always reflected an increase in response to non-optimal orientations, but typically occurred in the absence of a marked increase in response to the optimum. Application of GABA at sites where the preferred orientations were within 22.5° of that of a recorded cell (iso orientations) rarely affected orientation tuning, but often modified directional specificity due to an increase in response to the direction of motion preferred by cells at the inactivation sites; the result was either an increase or a decrease in directional selectivity depending on the relative direction preference at the recording and inactivation sites. All GABA-induced effects had a short time course and were reversible. The results provide evidence for a contribution of cross-orientation inhibition to orientation tuning and of iso-orientation inhibition to directional selectivity.

V1 RESPONSES TO TWO-SURFACE TRANSPARENT AND NON-TRANSPARENT MOTION. Ning Qian, Richard Andersen and Edward Adelson. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

It is well known that a pattern composed of two sets of random dots moving across each other produces a perception of motion transparency while a counterphase grating consist of two identical sine wave gratings drifting in opposite directions does not. We recorded from the directional selective V1 cells of a behaving macaque monkey using these two types of two-surface patterns together with their corresponding one-surface patterns (i. e., a single moving random dot or sine wave pattern). We first compared a cell's response to a one-surface pattern moving in its preferred direction with its response to the corresponding two-surface pattern having one component moving in the preferred direction and the other in the antipreferred direction. This allowed us to determine the amount of antipreferred direction inhibition. We then compared this inhibitory effect between the random dot patterns and the counterphase gratings. We found that most cells showed similar amount of inhibition among these two types of patterns. Furthermore, for the majority of the cells this inhibitory effect was weak. This result suggests that cells appear to detect the component moving in their preferred directions regardless of whether the two-surface pattern is perceptually transparent or not. Thus the perception of transparent motion must be processed at a stage beyond V1. We have also generated some other two-surface patterns that are perceptually either transparent (e. g., randomly spaced line patterns) or non-transparent (e. g., equally spaced line and paired random dot patterns). Using Adelson-Bergen model of motion detection, we found through computer simulations that the presence or the absence of motion transparency in these patterns can be predicted by the amount of locally unbalanced motion energies in opposite directions and that V1 cells are rather similar to the unidirectional motion energy detectors. We are currently testing whether MT neurons respond differently to transparent and non-transparent patterns.

73.11

A MODEL OF DIRECTION-SELECTIVITY IN VISUAL CORTEX WITH MASSIVE EXCITATORY FEEDBACK. H.H. Suarez, C. Koch & R.J. Douglas. CNS, Caltech, Pasadena, and Department of Physiology, University of Cape Town Medical School, South Africa.

The model consists of two populations of cortical neurons. One population is excitatory and represents the pyramidal neurons, and the other is inhibitory and represents smooth cells. Each cell has two compartments: the soma, and a dendritic cylinder. The pyramidal somata contain seven ionic currents that obey Hodgkin-Huxley-like dynamics, including calcium-dependent adaptation. The synaptic connections within this network are consistent with the canonical microcircuit (Douglas and Martin, 1990): the major part of the excitatory input to cortical cells is derived from other cortical cells, and only a minor part (20%) is derived from geniculate input. Visual input from the geniculate is simulated by a detailed model of X-cells (Victor, 1987). Inhibition is supplied only by intracortical neurons. In the null direction, the weak geniculate excitation is vetoed by simultaneous cortical inhibition. However, in the preferred direction, cortical inhibition is delayed and so the weak geniculate input is amplified by the excitatory cortico-cortical connections (Douglas and Martin, 1991). In this model, single cells show only small increases in input conductance (< 30% relative to control) in the null direction. These changes are consistent with *in vivo* intracellular recordings (Douglas et al., 1988). Despite the strong excitatory feedback connections, the neural responses are graded with stimulus contrast because adaptation restricts the discharge of the pyramidal cells.

73.12

STEREOSCOPIC RESPONSES IN MACAQUE VISUAL CORTEX: EFFECTS OF LUMINANCE AND COLOR. G.F. Poggio and C.E. Connor. The Bard Laboratories, Dept. of Neuroscience, Johns Hopkins University, Baltimore, MD 21205.

Depth perception is degraded for chromatic stimuli under conditions of isoluminance. To evaluate the neural mechanisms underlying the phenomenon, we have analyzed the response of disparity-selective neurons in V1, V2 and V3 complex of the visual cortex of the alert rhesus monkey performing a fixation/detection task, during presentation of behaviorally irrelevant dynamic random-dot stereopatterns (RDS) of different contrast but constant average luminance, and of solid-figure stereograms (SFS). Typically, the stereo response was unaffected by luminance contrast of chromatic SFS (e.g. red bar on green background), whereas the response to monochromatic SFS (e.g. red on red) was predictably smaller the lower the luminance contrast. The response to red/green RDS, on the other hand, was commonly reduced at lower contrasts, though only seldom abolished at or near isoluminance. For some neurons, the magnitude of the stereo response was uniformly strong at all contrast conditions in which one of the two colors of the RDS was brighter (usually green > red), and it became significantly smaller when the contrast reversed. Finally, a few neurons gave equal responses to chromatic RDS irrespective of the contrast between red and green components. No relations were observed between types of disparity selectivity (tuned or near/far) and contrast effects. The results indicate that both brightness and chromatic signals may contribute to the magnitude of the stereo response, and have different interactive effects depending on the spatial configuration of the visual pattern. (Grant EY02966).

FORMATION AND SPECIFICITY OF SYNAPSES I**74.1**

THE ROLES OF THE SYNAPTIC BASAL LAMINA AND OF INNERVATION IN DIRECTING THE ACCUMULATION OF A SYNAPTIC MOLECULE, mAb 3B6 Antigen, IN REGENERATING SKELETAL MUSCLES. S. Rotshenker, H. Sugarman and A. Dunaevsky-Hutt. Dept. of Anatomy, Hebrew Univ. Med. Sch. Jerusalem, Israel.

MAb 3B6 antigen, a molecule concentrated at endplate / junctional regions and myotendinous junctions in innervated muscles, appears in denervated muscles in restricted perijunctional areas that are continuous with and centered on endplates. In 86% to 90% of denervated regenerating myofibres, mAb 3B6 antigen was preferentially localised at former junctional and perijunctional regions. In innervated muscles, this colocalization was 97% to 99%. A peri-junctional distribution of the antigen was present in 85.9% of denervated regenerating myofibres compared to 50.5% of innervated ones. MAb 3B6 antigen was detected in the cytoplasm of most denervated regenerating myofibres but in none of the innervated ones. These results indicate that the basal lamina directs the preferential accumulation of mAb 3B6 antigen at original synaptic sites whereas innervation down regulates its overall production and presence in perijunctional regions.

cDNA THAT ENCODES AGRIN. K.W.K. Tsim, M.A. Ruegg, G. Escher, S. Kröger and U.J. McMahan. Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

We have for the first time isolated a cDNA that encodes a protein which, based on sequence homology, antigenicity, and activity is agrin, a basal lamina molecule that induces cultured myotubes to form on their surface aggregates of acetylcholine receptors (AChRs). The full-length agrin cDNA is 8,045 nucleotides long and contains an open reading frame encoding a protein of 1,917 amino acids with a calculated M_r of 206,695. The deduced protein has four potential N-glycosylation sites and several repeated regions containing motifs that are similar to those in other proteins: 8 cysteine-rich repeats similar to repeats in laminin and s-laminin, 6 cysteine-rich repeats similar to EGF-repeats and 9 cysteine-rich repeats similar to the active domain of the Kazal family of protease inhibitors. Expression studies reveal that agrin can be distinguished from agrin-related proteins in the CNS by its having an 11 amino acid stretch absent from agrin-related proteins and that this stretch is required for AChR-aggregating activity. Polymerase chain reaction studies on RNA from the marine ray CNS reveal that this stretch is conserved in agrin across species, as expected. Similar studies show that fractions of chick spinal cord enriched in motor neurons are enriched in agrin transcripts while fractions enriched in non-motor neurons are enriched in the transcripts of agrin-related proteins. Altogether, these findings support the hypothesis that agrin is synthesized by motor neurons and mediates the motor neuron and basal lamina-induced aggregation of AChRs at the neuromuscular junction in skeletal muscle.

74.2

AGRIN SYNTHESIZED BY MOTOR NEURONS INDUCES MYOTUBES TO AGGREGATE AChRs AT NEUROMUSCULAR JUNCTIONS IN CULTURE. Noreen E. Reist, Michael J. Werle, and U.J. McMahan. Dept. of Neurobiology, Stanford University, Stanford, CA 94305.

During development, motor neurons provide molecules that induce myotubes to aggregate acetylcholine receptors (AChRs) at developing neuromuscular junctions. Several lines of evidence have led to the hypothesis that the inductive molecule is agrin, a protein that causes cultured myotubes to form aggregates of AChRs. We have generated anti-agrin sera that inhibit the aggregating activity of agrin on cultured myotubes. These sera stain the neuromuscular junctions in chick but not rat muscles, indicating that they recognize agrin in a species specific manner. To test the ability of the anti-agrin antibodies to inhibit motor neuron induced AChR aggregation, we cocultured chick motor neurons with chick myotubes or chick motor neurons with rat myotubes in the presence of the anti-agrin IgGs. In both types of culture the number of AChR aggregates on the myotubes at and near neuromuscular contacts was markedly lower than in similar cultures grown in presence of preimmune or normal IgGs. On the other hand, the anti-agrin IgG had no effect on the number of AChR aggregates induced on chick myotubes by rat motor neurons. These experiments provide the most direct evidence to date that agrin synthesized by motor neurons mediates the formation of AChR aggregates at developing neuromuscular junctions.

74.4

AGRIN IS A MEMBER OF A GROUP OF MOLECULES HAVING HIGH STRUCTURAL SIMILARITY BUT DIFFERING IN FUNCTION. M.A. Ruegg, K.W.K. Tsim, S.E. Horton*, S. Kröger, and U.J. McMahan. Dept. of Neurobiology, Stanford University, Stanford, CA 94305

We used a 4.7 kb cDNA encoding the region of chicken agrin that is active in aggregating acetylcholine receptors (AChRs) on cultured myotubes to isolate from chicken libraries two homologous cDNAs that encode agrin-related proteins (ARPs). The cDNA for one of the proteins (ARP-1) was from a brain library (E13) and the cDNA for the other (ARP-2) was from a muscle library (E13); both were nearly the same length as the agrin cDNA. The coding regions of the cDNAs for the ARPs were identical to that of agrin except that a 33 base pair (bp) stretch was missing from that of ARP-1 and both the 33 bp and a 12 bp stretch were absent from that for ARP-2. Transfecting the ARP cDNAs into COS cells resulted in the synthesis of proteins recognized by anti-agrin antibodies but inactive in the AChR-aggregation assay on myotubes. Thus, the proteins encoded by the ARP cDNAs were greater than 99% identical to agrin in their amino acid composition but they lacked agrin's activity. Transfection of hybrids between the agrin cDNA and ARP cDNAs showed that the lack of activity in ARPs was owing specifically to the absence of the inserts; accordingly, both the 33 and the 12 bp inserts are required for agrin's AChR aggregating activity. Northern blot analysis indicates that the full length message for the ARPs is similar to that of agrin. Southern blot analysis on genomic DNA revealed that agrin and the ARP transcripts are derived from a single copy gene. Altogether, our findings demonstrate for the first time that agrin is a member of a protein family in which one (agrin) is capable of aggregating AChR on cultured muscle cells and some (ARPs) are not and that agrin and ARPs are generated by alternative mRNA splicing.

74.5

FOCALLY APPLIED AGRIN INDUCES THE FORMATION OF ACHR AGGREGATES AT SITES OF AGRIN-MYOTUBE INTERACTION. S. Krüger, M.A. Ruegg, K.W.K. Tsim and U.J. McMahan

Dept. of Neurobiology, Stanford University, CA 94305-5401.

Several lines of evidence have led to the hypothesis that agrin mediates the motoneuron- and basal lamina (BL)-induced aggregation of AChRs in developing and regenerating skeletal muscles. The hypothesis predicts that the aggregates form at or near the site where agrin interacts with the myofiber. Accordingly we devised a way to apply agrin focally to cultured myotubes and determined the distance between the site of application and the induced AChR aggregates. COS-7 cells, transfected with a construct of a partial agrin cDNA that encodes the active region, were seeded at low density onto a sheet of BL isolated from the chick retina. Agrin secreted by the COS cells adhered tightly to the BL in the vicinity of the cells. Myoblasts seeded onto the BL sheets after removal of the COS cells formed myotubes some of which were directly apposed to the agrin patches. By differential staining of the agrin patches and AChR aggregates we observed that agrin-induced AChR aggregates were coextensive with the agrin patches, even where the patches were only 5µm in diameter. We conclude that agrin induces the formation of AChR aggregates at or very near the site where it interacts with cultured myotubes. By transfecting a number of different cDNA constructs, we identified a stretch of approximately 100 amino acids that is required for binding the secreted agrin to the BL sheets.

74.7

EXTRACTS ENRICHED IN BASAL LAMINA PROTEINS INDUCE MOTOR NEURONS TO FORM PRESYNAPTIC SPECIALIZATIONS IN THEIR NEURITES. M.J. Werle, Z.O. Obeso*, and U.J. McMahan. Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305

Molecules stably bound to synaptic basal lamina at neuromuscular junctions direct the formation of presynaptic specializations in regenerating axon terminals. The specializations include enlargements (varicosities) of the terminal which have a high concentration of synaptic vesicles and active zones. We have found that basal lamina fractions of the synapse-rich electric organ of *Torpedo* induce motor neurons to form varicosities, having high concentrations of vesicles, in their neurites. The active molecules migrate on gel filtration columns along with standards having a molecular mass of 15-30 kDa. Treatment of the extracts with trypsin or heat destroys the activity indicating that the active molecules are proteinaceous. Monoclonal antibodies that immunoprecipitate the activity recognize molecules highly concentrated at the neuromuscular junctions of *Torpedo* and frog as well as the innervated surface of the *Torpedo* electric organ. Altogether, our findings raise the possibility that the active protein(s) mediate(s) the basal lamina-induced formation of some, perhaps all, of the presynaptic apparatus in regenerating axon terminals and that it is the counter part of agrin, the protein thought to mediate the basal lamina induced formation of postsynaptic apparatus in regenerating muscles.

74.9

CHARACTERIZATION OF A PUTATIVE AGRIN RECEPTOR FROM TORPEDO ELECTRIC ORGAN. J.R. Fallon, J-Y. Ma* and M.A. Nastuk. Worcester Fdn. Exper. Biol., Shrewsbury, MA. 01545

Agrin is a component of the synaptic basal lamina that is likely to play a central role in orchestrating postsynaptic differentiation at the neuromuscular junction. However, little is known about how agrin interacts with the cell surface, or of the nature of its membrane receptor. Here we have used membrane preparations from the synapse-rich *Torpedo* electric organ (TEO) to characterize the cell surface receptor for agrin. TEO membrane fractions bind soluble agrin as judged by immunofluorescence microscopy, RIA, and absorption of bioactive agrin from solution. Binding measured by all three assays requires calcium and is abolished by pretreatment of the membranes with trypsin. Agrin binds selectively to TEO membrane fractions enriched in synaptic components: membranes from non-synaptic regions of electric organ or from *Torpedo* liver show low or undetectable levels of agrin binding. Agrin binding to TEO membranes is unaffected by removal of peripheral membrane proteins by alkaline treatment. The putative agrin receptor from TEO membranes can be solubilized in non-ionic detergent with retention of calcium sensitive binding, and can be separated from the AChR by gel filtration chromatography. We are currently using affinity methods to identify and purify this receptor. The high affinity, saturable, and calcium dependent agrin binding of this integral membrane protein, coupled with its localization to synaptic membranes, strongly suggest that the molecule characterized here represents the cell surface receptor that mediates agrin-induced AChR clustering. Support by ACS, March of Dimes and HD 23924.

TRANSCRIPTS RECOGNIZED BY PROBES FOR AGRIN/AGRIN-RELATED mRNA IN MOTOR NEURONS ARE DEVELOPMENTALLY REGULATED. G. Escher, K. Tsim, S. Horton*, & U.J. McMahan. Department of Neurobiology, Stanford CA 94305-5401.

RNA probes that recognize transcripts for both agrin and agrin-related proteins strongly label by *in situ* hybridizations motor neurons and certain nuclei, laminae and ganglia throughout the nervous system. As part of a study aimed at determining the functional role of these proteins and how they are regulated, we used *in situ* hybridization methods to examine in chick lumbosacral motor neurons the level of expression of the transcripts at different times during development. The earliest day that elevated levels of agrin/agrin-related transcripts were detected was E5, the day at which the motor neurons are beginning to form functional neuromuscular junctions. From E7 to E13, when there is an exponential increase in the formation of neuromuscular contacts, levels of agrin/agrin-related mRNA became markedly increased. By one month after hatching, when neuromuscular junction formation is nearly complete, the level of transcripts is greatly reduced, but above background. The correlation between increased levels of agrin/agrin-related transcripts and the period of neuromuscular synapse formation is consistent with the hypothesis that agrin mediates the motor neuron-induced aggregation of AChRs on myofibers at the developing neuromuscular junction.

NEURONALLY DERIVED AGRIN-LIKE MOLECULES APPEAR EARLY AT EMBRYONIC FROG NERVE-MUSCLE SYNAPSES IN CULTURE. M.W. Cohen and E.W. Godfrey. Dept. of Physiology, McGill Univ., Montreal, Que. and Dept. of Cellular Biology & Anatomy, Medical College of Wisconsin, Milwaukee, WI.

If agrin or a closely related molecule is the neural agent which causes aggregation of acetylcholine receptors (AChRs) during nerve-muscle synaptogenesis, agrin-like molecules derived from the neuron should be present at the synapse from the onset of AChR aggregation. This prediction was tested in cultures of spinal cord (SC) and myotomal muscle (M) cells derived from embryos of *Xenopus laevis* (X) and *Rana pipiens* (R). Using anti-agrin antibodies which are reactive in both species, we observed immunostain at AChR aggregates along all four combinations of nerve-muscle contact, and even at the smallest (<0.5 µm) and most distal aggregates along early (<8 hr) SC_X-M_X contacts. In contrast, there was little if any stain at AChR aggregates on non-innervated M_X and M_R cells in the same cultures. Furthermore, an anti-agrin antibody which is reactive in R but not in X stained sites of aggregated AChRs along SC_R-M_R and SC_R-M_X contacts but not along SC_X-M_X and SC_X-M_R contacts. These results provide the most direct evidence to date that neuronally derived agrin-like molecules are present at embryonic nerve-muscle synapses from the onset of AChR aggregation.

DUAL REGULATION OF C-FOS TRANSCRIPTION BY CALCIUM AND CYCLIC AMP IN PRIMARY CULTURES OF CORTICOSTRIATAL NEURONS. F.M. Vaccarino, H.N. Le*, E.J. Nestler. Dept. of Psychiatry, Yale University, New Haven, CT 06508.

NMDA receptor agonists increased the level of c-fos mRNA in neuronal monolayers from rat cerebral cortex and striatum; this increase appeared to be dependent on a transmembrane calcium influx and on the activation of protein kinase C (PKC). Activators of adenylate cyclase, such as vasoactive intestinal peptide (VIP) and dopamine D₁ receptor agonists, also increased c-fos mRNA; this action was mimicked by forskolin and by lipophilic analogs of cAMP and was mostly independent of extracellular calcium. To define the DNA elements responsible for the calcium/PKC- and the cAMP-regulated c-fos transcriptional activation, we performed transient transfection experiments of c-fos promoter constructs. Primary cultures of corticostriatal neurons were transfected with chimeric constructs carrying deletion mutants of the c-fos promoter fused to the bacterial gene for chloramphenicol acetyltransferase (CAT). A plasmid carrying the β -galactosidase gene was co-transfected to provide an internal control for transfection efficiency. Different varieties of neurons stained for β -galactosidase by histochemistry, while glial cells were unstained. The induction of CAT by different c-fos promoter constructs after cell stimulation by agents specific for the calcium/PKC or for the cAMP second messenger pathways will be discussed.

Acknowledgements: We thank M.Z. Gilman for providing c-fos constructs. This work was supported by a NARSAD grant to F.M.V.

MONITORING INTRACELLULAR CYCLIC NUCLEOTIDES IN LIVING NEURONS WITH DIRECTLY CYCLIC NUCLEOTIDE-GATED CHANNELS FROM OLFACTORY RECEPTOR CELLS. R.H. Kramer. Ctr. for Neuro. and Behav., Columbia Univ., New York, NY 10032

Vertebrate olfactory receptor cells contain cation channels that are directly activated by cAMP and cGMP. Here it is shown that these channels can be used as cyclic nucleotide detectors in other cell types. The receptive portion of dissociated catfish olfactory receptor cells (dendrite and cilia) was sucked into a patch pipette (~1 μ m tip diam.). After forming a gigohm seal, the cell was passed through the air/water interface, disintegrating the soma and exposing an extensive inside-out "patch" containing hundreds of channels. Calibration of cyclic nucleotide sensitivity revealed identical $K_{1/2}$'s of activation for cAMP and cGMP (about 2 μ M), with a detectable current appearing at concentrations as low as 0.1 μ M. The cyclic nucleotide-gated current did not desensitize, and was unaffected by cAMP-dependent protein kinase, GTP- γ -S, IP₃, and internal Ca ions (at -50 mV). Hence the channels are reliable selective indicators of cyclic nucleotides.

After calibration, a patch pipette containing the channels was inserted into an intact living neuron in the subesophageal ganglion of the land snail *Helix*. A microelectrode in the neuron was used to monitor and control voltage. Application of 20 μ M 5-HT, which modulates ionic currents and broadens action potentials, elicited an inward current in the detector patch, equivalent to increasing cyclic nucleotide concentration to 1 μ M. Activation and recovery of the detector current was rapid (<10 sec). Repeated 5-HT applications resulted in a diminished neuronal response and a diminished detector current, indicating that desensitization occurs at the level of cyclic nucleotide concentration.

SECOND MESSENGER SYSTEMS ACTIVATED BY ODORANTS IN PRIMARY CULTURES OF OLFACTORY RECEPTOR NEURONS. G.V. Ronnett, D.J. Parfitt, L.D. Hester and S.H. Snyder. Departments of Neurology and Neuroscience, Johns Hopkins University School of Medicine, 725 N. Wolfe Street, Baltimore, MD 21205.

We have previously described a method for primary culture of rat neonatal olfactory receptor neurons in which odorants elicit rapid, transient elevations in intracellular cAMP levels and adenyl cyclase (AC) activity (Ronnett et al., 88:2366-2369, 1991). The degree of elevation is both odorant and concentration dependent, showing activity for some odorants at sub-nanomolar concentrations. This odorant sensitive AC activation is entirely calcium-dependent, with maximal activation between 10-100 μ M free calcium. Odorants cause an even more rapid increase in production of inositol phosphates. To investigate a possible inter-dependence of these two signalling pathways, the ability of odorants to induce calcium flux in cultured cells as well as the ability of calmodulin inhibitors to prevent cyclase activation were studied. The complex interactions suggested by these experimental results may have implications for other receptor systems.

75.2

INTERACTION OF CYCLIC AMP AND PHOSPHOINOSITIDE SECOND MESSENGER SYSTEMS. B.W. Rigatti, M. Smith*, J.J. Mann. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

The interaction of second messenger systems in neurons is a critical aspect of cellular function under normal conditions or pathological states. We therefore studied the effects of phytohemagglutinin (PHA) and beta-adrenergic receptor stimulation on the cyclic AMP (cAMP) and the phosphoinositide (PI) second messenger systems in lymphocytes obtained from normal human venous blood.

Phytohemagglutinin (PHA) stimulation of PI turnover was 5.07 ± 2.7 times unstimulated controls ($p < 0.05$). The beta-adrenergic receptor agonist, isoproterenol (ISO) alone, did not alter PI turnover in comparison to the control. The combination of PHA and ISO stimulated PI turnover 3.54 ± 2.04 times unstimulated controls. The addition of ISO did not depress PI turnover to PHA compared to the PI response to PHA alone ($p > 0.20$).

PHA did not alter cAMP levels (8.8 ± 2.2 pmol/ 10^6 cells) in comparison with unstimulated controls (9.0 ± 1.6 pmol/ 10^6 cells). ISO alone stimulated cAMP formation 2.5 times over both PHA treated cells and controls, producing levels of 22.1 ± 2.7 pmol/ 10^6 cells. The combination of PHA and ISO stimulated cAMP levels to 2.7 times those of the PHA treated cells or controls, producing levels of 23.8 ± 2.7 pmol/ 10^6 cells.

These experiments suggest that the elevation of cyclic AMP levels by the beta-adrenergic receptor agonist, ISO, did not inhibit PHA activation of PI turnover. Similarly, PHA activation of PI turnover failed to alter beta-adrenergic generation of cyclic AMP. We conclude that in the lymphocyte there is no inhibitory effect on PI turnover by the cAMP second messenger system, and that the PI second messenger system has no effect on the cyclic AMP system. Future studies should examine neuron and other cell systems to determine where similar constraints on second messenger cross-talk are present. This work was supported by MH40695.

OLFACTORY RECEPTOR NEURONS EXPRESS COMPONENTS OF TWO DISTINCT SECOND MESSENGER SYSTEMS: INSP₃ AND THE G-PROTEIN GOLF. A.M. Cunningham*, G.V. Ronnett, P.B. Manis, R.R. Reed and S.H. Snyder. Dept of Molecular Biology and Genetics and Dept of Neuroscience, The Howard Hughes Medical Institute, The Johns Hopkins University Sch. of Med., Baltimore, MD 21205.

Odorant-induced signal transduction occurs in the specialized cilia of olfactory sensory neurons. Many lines of evidence indicate this process is mediated at least in part by a G-protein coupled cascade which utilizes cAMP as an intracellular second messenger. The recent description of a multigene family encoding olfactory specific seven transmembrane domain proteins, putative odorant receptors, strengthens this hypothesis [Buck & Axel, 1991]. Recently, InSP₃ has been shown to dynamically increase in cilia preparations in response to some odorants [Boekhoff et al., 1990] raising the possibility that the two pathways may function, perhaps interactively, in odorant detection.

Utilizing the previously described technique for primary culture of neonatal rat olfactory neurons [Ronnett et al., 1991] we varied the culture conditions to enrich for a particular neuronal class based on phenotype - designated ORN-1. These small bipolar cells were easily distinguishable morphologically from other neuronal types present. PCR analysis of the cultures indicated mRNAs for Golf and the olfactory cyclic nucleotide-activated channel were present in low abundance. In contrast, InSP₃ receptor and NGFR mRNAs were abundant. These findings were confirmed by Northern analysis. Immunocytochemistry revealed that ORN-1 cells expressed Golf, OMP and other proteins known to be enriched in olfactory neurons but were negative for GFAP and other non-neuronal markers. ORN-1 cells were also immunoreactive for synaptophysin, N-CAM and InSP₃ receptor. Preliminary electrophysiological studies showed the cells generated action potentials in response to depolarizing current pulses and had appropriate inward and outward currents. Double labeling immunofluorescence confirmed that all ORN-1 cells identified in culture expressed both Golf and InSP₃ receptor. Similar analysis of adult olfactory neuroepithelium by confocal microscopy showed Golf and InSP₃ receptor colocalized to the cilia, although InSP₃ receptor had a less restricted distribution than Golf, being also present in the dendritic process of the neuron. Binding studies on cilia preparations confirmed specific InSP₃ binding activity. Colocalization of the two components, InSP₃ receptor and Golf, in the same sensory neuron presents intriguing opportunities for interaction of the two signaling pathways, including the possibility that some olfactory receptors directly activate both cascades.

SECOND MESSENGER RESPONSES OF THE CHICK RETINAL MELATONIN RECEPTOR. J.T. Laitinen¹⁾ and J.M. Saavedra²⁾. 1) Dept Physiol, Univ Kuopio, SF-70211 Kuopio, Finland and 2) Sect Pharmacol, Lab Clin Sci, NIMH, Bethesda, MD 20892.

We have recently localized the chick retinal melatonin (MT) receptor to the inner plexiform layer (Brain Res. 1990,528,349). This site shows GTP modulation of agonist binding and thus resembles the mammalian MT receptor. The present studies were aimed to clarify MT signal transduction pathways in the chick retina.

In the presence of 1 mM IBMX, forskolin (FSK) caused a 50-fold increase in cAMP accumulation (EC_{50} 10 μ M). At higher doses, FSK also increased cGMP levels. MT had modest inhibitory effects on basal and FSK-stimulated cAMP levels, as well as on basal cGMP levels. In our hands, cholinergic stimulation elicited a 3-fold increase in retinal IP₃ accumulation. MT had no effect on internal phosphoinositide metabolism. In chick retinal membranes, MT failed to affect Na⁺/K⁺-ATPase activity suggesting no direct interaction with this pump. However, a modest inhibition of ouabain sensitive Rb⁺-uptake was observed.

We conclude that multiple second messenger systems could be affected by MT receptor activation in the chick retina.

PHOSPHORYLCHOLINE-STIMULATED PROLACTIN RELEASE: A NOVEL SECOND MESSENGER SYSTEM. W.D. Jarvis¹ and R.M. MacLeod, Departments of Neuroscience¹ and Medicine, University of Virginia Health Sciences Center, Charlottesville, Virginia 22908.

Receptor-activated catalysis of choline-linked phospholipids occurs in both transformed and normal cell types, including anterior pituitary cells, through multiple enzymatic routes. Most notable are phospholipase C-mediated cleavages of choline-linked phosphatides and sphingomyelins to yield a complex spectrum of diglycerides and ceramides. These lipid messengers are widely known to act as both positive and negative effectors of various isoforms of protein kinase C; more obscure, however, is the biological relevance of phosphorylcholine (PCho), the obligatory co-product of these reactions.

We have evaluated the potential effector activity of PCho in modulating prolactin release. Primary cultures of normal female rat anterior pituitary cells were incubated with PCho at varying concentrations (0.001-10 μ M) for varying intervals (15-120 min) in serum-free RPMI-1640 medium. Exposure to PCho for 30 min resulted in significant ($p < 0.01$) increases (226%) in prolactin release, but was without effect on growth hormone release; free choline and pyrophosphate were ineffective in modifying prolactin release, as were free and phosphorylated headgroup compounds of other phospholipid species. The response to PCho proved to be concentration-related, exhibiting an EC₅₀ of approximately 720 nM, and was abolished by co-exposure to dopamine (500 nM) or somatostatin (250 nM). A similar ability of PCho to elicit hormone release was also demonstrated in transformed pituitary cells such as the GH₃ mammosomatotrophic cell line and the dopamine-sensitive MMQ subclone of the 7315a lactotrophic tumor cells. We conclude from these observations that PCho acts as a cellular effector molecule and participates in receptor-activated prolactin release from normal and transformed pituitary cells. Supported by NIH grant CA-07535.

FREE ARACHIDONIC ACID LEVELS CONTROL GLUTAMATE UPTAKE RATE IN NEURONS AND ASTROCYTES. A. Volterra, D. Trotti, P. Cassutti¹, C. Tromba² & G. Racagni. Ctr. Neuropharmacology & Inst. Pharmacol. Sci., Univ. Milan, ¹Farmitalia Carlo Erba, Milan, Italy.

High-affinity glutamate (GLUT) uptake systems on neuronal terminals and astrocytes control GLUT clearance and synaptic availability. Arachidonic acid (AA) is released at GLUT synapses upon NMDA receptors stimulation. Using both synaptosomes and cultured astrocytes from rat cerebral cortex, we find that AA (1-50 μ M) reduces GLUT uptake rate up to 50% in a rapid and reversible manner. Polyunsaturated fatty acids, but not 12-lipoxygenase metabolites mimic AA effect. Potent inhibition is seen also with the PLA₂ activator melittin (0.2 μ g/ml) and the AA reacylation blocker thimerosal (100 μ M). In prelabelled astrocytes the two agents at these concentrations increase basal ³H-AA extracellular accumulation by 1-2 fold. Albumin, a free fatty acid-binding protein, enhances basal GLUT uptake and prevents inhibition by melittin, thimerosal and AA. These data indicate that neuronal and glial GLUT transport systems are highly sensitive to changes in free AA levels. Therefore, uptake inhibition seems a relevant mechanism underlying AA-induced potentiation of GLUT synapses.

CATALYTIC SUBUNITS OF APLYSIA NEURONAL cAMP-DEPENDENT KINASE WITH NOVEL AMINO TERMINI. S. Reuschausen¹, E. Lee², B. Walker³ and H. Bayley. Worcester Foundation for Experimental Biology, Shrewsbury MA, 01545. Lab of Neurobiology, NIH, Bethesda, MD, 20892.

cAMP-dependent protein kinase (PKA) is involved in synaptic plasticity in *Aplysia californica*. Two forms of PKA catalytic (C) subunits generated by mutually exclusive use of two internal exon cassettes (A1 and A2) have been demonstrated in *Aplysia* neurons. Two additional subunits with alternative N-termini, N1 and N2, are derived from two exons and spliced in combination with either of the internal cassettes generating four distinct C isoforms. The N1 terminus is homologous to termini previously sequenced in several species and includes a signal for myristylation. The N2 terminus is 21 amino acid residues longer than N1 and has homology with the non myristylated yeast C-subunit, TPK1. Nuclease protection experiments suggest that exon N1 is transcribed from a contiguous promoter region with multiple initiation sites. Exon N2 is upstream from N1 indicating that N2 transcripts arise via alternate promoter use. Quantitative nuclease protection experiments suggest that promoter choice and alternative splicing of the internal cassettes are independent of one another. Transcripts derived from N1 and N2 are of about equal abundance in the nervous system, while A1 containing transcripts are about three times as abundant as those containing A2. N2 polypeptides, enriched from *Aplysia* extracts, autophosphorylate and can phosphorylate the synthetic peptide substrate, kemptide. These data support the view that subtleties in *Aplysia* neuronal PKA activity arises from a complex array of regulatory and catalytic subunits that generate multiple holoenzyme forms with different substrate specificities, regulation and subcellular localization.

CORTICOSTERONE DEPENDENCE AND TIME COURSE FOR RESPONSIVENESS OF MEDIAL PREOPTIC AREA (mPOA) NEURONS TO PGE₂. G.E. Resch. Univ. of Missouri-Kansas City, MO 64108.

Corticosterone (B) restores cold tolerance in adrenalectomized (Adx) rats following whole body hormone replacement. A previous report from this laboratory demonstrated restoration of cold tolerance following replacement of compound B in the mPOA at doses that were not effective when administered subcutaneously. Adx rats exposed to -4°C for up to 2 hrs. showed a 3.2 \pm 0.4°C (mean \pm SEM) fall in Tc. PGE₂ and B were microinjected into awake unrestrained female Sprague Dawley rats (200-250 gm) using a 29 ga injector inserted through a guide tube implanted into the mPOA 7.5 mm below bregma and 0.5 mm lateral to the midline. All injections were unilateral. Tc was monitored with a YSI telethermometer. PGE₂ microinjection into previously identified mPOA PGE₂ sensitive sites elicits a rise in colonic temperature (Tc) in the intact rat but not in the Adx rat. Replacement of B in the mPOA at low doses (100 ng 2X/d) for five days restored the Tc responses to PGE₂. Replacement of B into PGE₂ sensitive sites of the mPOA for 2 hrs., 2 days, or four days had no effect on cold tolerance or PGE₂ elicited responses. Restoration of cold tolerance and PGE₂ responsiveness in Adx rats occurred between days 4 and 6 of hormone replacement. This time course is similar to the restoration of cold tolerance after whole body B replacement. Replacement of B unilaterally in ADX rats restored cold tolerance and Tc response after PGE₂ microinjection to 84% and 82% of normal, respectively. The data indicate that cold tolerance involves neuronal responsiveness to PGE₂ and further that B effects on cold tolerance are at least partially accounted for by B effects on PGE₂ responsiveness of mPOA neurons.

75.10

SYNAPTIC MEMBRANE G-PROTEINS ARE COMPLEXED WITH TUBULIN *IN SITU*. Kun Yan and Mark M. Rasenick. Department of Physiology and Biophysics and the Committee on Neuroscience, University of Illinois College of Medicine P.O. Box 6998 Chicago, IL 60680

Adenylyl cyclase in membranes prepared from C6 glioma cells is activated by GppNHP, an hydrolysis-resistant GTP analog. In saponin-permeable C6 cells, where adenylyl cyclase is coupled tightly to the β adrenergic receptor, GppNHP is without effect in the absence of a β receptor agonist. Despite this, dimeric tubulin liganded with GppNHP, bypasses the receptor to stimulate adenylyl cyclase. Experiments using the photoactivatable GTP analog, azidoamidilo GTP (AAGTP) suggest that the mechanism for this involves direct guanine nucleotide transfer from tubulin to the stimulatory G-protein (G_s). Similar experiments with cerebral cortex membranes show tubulin-GppNHP-mediated inhibition of adenylyl cyclase and the transfer of nucleotide from tubulin to G₁₂. Although both cerebral cortex membrane and C6 glioma membrane have G_s, only the former has G₁₁. Since tubulin binds to G_s and G₁₁ with a higher affinity than to G₀, G₁, G₁₂, and G₁₃, the lack of G₁₁ in C6 membrane is a likely explanation for the stimulation of adenylyl cyclase by tubulin in C6 cells. In the cerebral cortex synaptic membrane, quantitative immunoblotting suggests that 6% of the total protein (integral and peripheral) is tubulin. Co-immunoprecipitation studies indicate that nearly 90% of the synaptic membrane G_s exists in preformed complexes with membrane tubulin. This is true for only about 8% of the total G₁₁. This tight association of tubulin-G_s in the cerebral cortex membrane renders tubulin added to synaptic membranes free to interact with G₁₁, ultimately inhibiting adenylyl cyclase. Given the preformed G_s-tubulin complexes in the membrane, it is plausible that tubulin is involved in the stimulation of neural adenylyl cyclase, especially in response to neurotransmitters which are coupled, primarily, to other second messenger systems.

75.12

CHARACTERIZATION OF 12-LIPOXYGENASE IN APLYSIA NERVOUS TISSUE. A. Thekkuvetttil*, D.J. Steel, M. Abe*, J.H. Schwartz and S.J. Feinmark. Depts. of Pharmacology, Pathology, Center for Neurobiology and Behavior, and Howard Hughes Medical Institute, Columbia University, NY, NY, 10037

Studies on *Aplysia* neurons show that 12-lipoxygenase (LO) metabolites modulate ion channel function. The synthesis and significance of these products in vertebrate nervous systems is the subject of current debate. Stereochemical analysis of the *Aplysia* 12-LO product shows that the isomer formed is 12(S)-HETE, confirming that the process is enzymatic. We are currently localizing and purifying *Aplysia* 12-LO. In contrast to mammalian LO, which are primarily soluble, most of the *Aplysia* 12-LO activity is particulate. Like mammalian leukocyte 12-LO, the invertebrate enzyme apparently loses activity during the reaction, possibly because of enzyme inactivation during catalysis. Our results indicate that the spectrum of arachidonic acid metabolites in neurons and the sheath around ganglia are quantitatively different and differentially affected by Ca²⁺. The sheath serves as a neurohemal organ, receiving and distributing hormones. It is tempting to speculate that 12-LO metabolites may regulate these processes.

76.1

OPTIC AXONS ARE ATTRACTED BY WOUNDS IN ORGAN CULTURED EMBRYONIC CHICK EYES. W. Halfter, Dept. of Neurobiology, Anatomy and Cell Science, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

In order to study the response of growing axons to lesions in the developing nervous system, a wound healing paradigm was devised in organ-cultured embryonic chick eyes. The eyes, consisting of retina and lens, were incubated in culture medium after removing pieces from the E4 to E7 retinal tissue (wound diameter between 100-200µm). Within minutes after lesioning, the inner limiting membrane sealed the wound edges, and after a further 10 hrs, the wound area was reduced to 50% of its original size. The wound was completely closed after 24 hrs in culture. Histological studies showed that the wound closure was not accomplished by cell migration or cell proliferation, but most likely by a contraction of extracellular matrix fibrils of the vitreous body that connected the wound margins. Staining of the specimens with silver, vital dyes or axon-specific antibodies showed that axons from an area of 300 µm around the wound were headed toward the center of the closing wound. The axons left the optic fiber layer at the wound center and formed a neuroma at the ventricular side of the retina, showing a pattern and concentration of nerve fibers similar to that seen at the optic nerve head, the natural convergence point for axons in the retina. The studies suggest that either the mechanics of wound closure or factors secreted at the wound margins attract the growing retinal axons. The navigation of retinal axons toward the wound site in a pattern similar to that seen at the optic disc suggests that the same or a similar axon guiding mechanism operates in both cases.

76.3

AXONAL PLASTICITY IN CROSS-FACIAL NERVE GRAFTING J.K. Terzis, M.D., M. Hamilton, and M. Slater EVMS, MRC, Norfolk, VA. 23507

Facial paralysis is an extremely debilitating disorder. This project seeks to elucidate the mechanisms underlining the regenerating fibers which mediate the success or failure of CFNG.

Work to date has yielded the following results: The establishment of a strong experimental CFNG model in the rat. We have developed a two Stage Cross-Facial procedure in the rat similar to that used in humans. The Saphenous n. is used as the graft, tunneled across the face, and coapted to the donor (L) facial n. (Stage I). Three months later (Stage II) the distal coaptations are made on the contralateral (R) side: Group B; non-connectivity, Group C; correct targets (facial), Group D; foreign target connectivity. The normal anatomy will serve as the control group (A). Three months after stage II, animals are photographed, in vivo nerve stimulations are performed, and all relevant muscles and the graft are harvested for end-plate and axon counts.

Quantitation of end-plate and axon counts have proven that facial and non-facial target muscles became reinnervated. Evaluation of the morphological and electrical data in this model will provide a scientific rationale to guide CFNG procedures.

MONOCLONAL ANTIBODY DELINEATES A SUBSET OF OPTIC NERVE FIBERS IN XENOPUS. S. Hoskins, G. Kirchbaumer*, and D. Eastzer*, Biology Dept., City College of CUNY, New York NY 10031.

We are using a monoclonal antibody approach to define molecules whose distribution might differentially mark subsets of retinal ganglion cells or their axons, and perhaps play a role in guiding axons to proper CNS targets.

Gro1 was generated in mice tolerized over a 4 day neonatal period with membrane preparations from thalamus of premetamorphic tadpoles. Beginning at postnatal day 16, the mice were immunized with membrane prepared from ipsilateral thalamus and optic tract of one-eyed frogs or metamorphosing tadpoles. Fusions were carried out by standard methods during the tenth postnatal week, and supernatants screened on methanol fixed sections of fresh-frozen brain. Gro1 staining is visualized using HRP-coupled secondary antibodies.

Gro1 staining is found on optic, olfactory and vomeronasal nerves, beginning by premetamorphic stage 50 and persisting postmetamorphically. In the central retina, gro1 immunoreactivity is found in a small number of ganglion cells interspersed with unstained cells. Stained cells are not seen in peripheral retina. Near the eye, gro1 positive fibers are seen throughout the optic nerve. Near the brain, immunopositive fibers lie primarily ventrally and at the periphery of the nerve. In the optic chiasm, gro1 positive fibers are found ventrally. In the brain, gro1 positive fibers innervate both thalamic and tectal targets, but thalamic innervation is quite sparse.

Gro1 appears to define an epitope shared by a subset of ganglion cells whose axons segregate in the tadpole optic nerve and chiasm. The retinal locations of gro1 positive ganglion cells and the staining patterns in brain suggest that gro1 expression may correlate with CNS destination.

Supported by NIH NS 25042 and NSF BNS 8616730.

A MIDLINE NEURONAL POPULATION IS PRESENT AT THE MAMMALIAN OPTIC CHIASM DURING EARLY RETINAL GANGLION CELL AXON INGROWTH. L. Feng* & D. W. Sretavan, Lab. of Neurobiology, Rockefeller University, New York, NY. 10021

Specific retinal ganglion cell (RGC) axon routing at the mammalian optic chiasm is established during embryonic development as axons from nasal retina project specifically into the contralateral optic tract while a population of RGCs in temporal retina send axons ipsilaterally.

Examination of the neuroepithelial region of the future optic chiasm prior to arrival of retinal axons revealed a population of MAP-2 immunoreactive cells with neuronal-like arborization patterns. These neurons were distributed on the ventral surface of the brain as a striking inverted V-shaped band pointing anteriorly. Individual neurons had multiple processes some of which pointed towards the midline while others ran along the approximate course of the future optic tract. The first retinal axons entering the chiasm grew in close association with the processes of these neurons to turn into one or the other optic tract but did not penetrate posteriorly through this neuronal population. Both ingrowing retinal axons and processes of chiasm neurons at this stage expressed the cell surface molecule L1. With arrival of later retinal axons, the inverted "V" shape pattern was lost and the chiasm neurons were instead distributed as a flattened band straddling the midline with retinal axons crossing the midline directly anterior to them.

The early presence of these neurons prior to retinal axon arrival, their strategic location at the chiasm and the growth of the earliest retinal axons among their processes raise the possibility that these midline neurons influence the navigation of retinal axons at this pathway branch point during embryonic development.

76.4

THE FIRST PATHWAY OF THE RAT NEOCORTEX IS CONSTRUCTED BY THE THALAMOCORTICAL AND CORTICOTHALAMIC PIONEER AXONS. R. Erzurumlu and S. Jhaveri, M.I.T., Cambridge, MA, 02139.

We have studied the emergence of corticofugal and corticopetal projections in fetal rats. Various combinations of tracers Dil and DiA were placed in the neocortex, dorsal thalamus and midbrain tegmentum, of embryonic (E14-19) rats.

The first axonal profiles seen in the neocortical mantle on E14 are those of preplate (PP) neurons. These axons are located superficially and do not appear to be directed towards the future site of the internal capsule. On E15, cortical plate (CP) is first seen encouched in the ventrolateral PP splitting it into a superficial marginal zone (MZ) and subplate (SP). Concurrently a group of pioneer axons, tipped with large, forking growth cones cascade ventrally over the dorsal striatum. These axons arise from immature, pyramidal-shaped neurons situated in the lower border of the CP, with their apical dendrites branching in the MZ. Corticofugal neurons accumulate along a lateromedial gradient, closely following the progression of the CP in this dimension. None of these cells are back-labeled from the dorsal thalamus on E15. Tracer placements in the dorsal thalamus reveal a second front of pioneer axons ascending towards their corticofugal counterparts. Double labeling experiments show that complex growth cones of both pioneer fronts embrace in the striatum. On E16 the two pioneer systems pass one another and head towards their final targets. Within the intermediate zone of the neocortex, thalamocortical axons fasciculate along a lateromedial gradient just beneath corticofugal axons. At this age, tegmental pioneer axons are situated at the base of the striatum. On E17 thalamic and cortical projection cells can be back-labeled from their respective target zones. This is also the time when tegmental axons are first seen in the developing neocortex. We conclude that: 1) The CP emerges prior to arrival of corticopetal projections; 2) both corticothalamic and thalamocortical axons bridge the pathway between the thalamus and neocortex; 3) The first afferent system to arrive in the neocortex is from the dorsal thalamus. ALTERED AXONAL TRAJECTORIES IN FAS AND NAC MUTANTS OF *DROSOPHILA MELANOGASTER*. K.E. Whitlock and J. Palka, Dept. of Zoology, University of Washington, Seattle, WA 98195.

The wing of *Drosophila* has several classes of readily identifiable sensory receptors. The neurons associated with these receptors arise in the periphery and grow centrally to make connections in the central nervous system (CNS). The morphology of their central terminations was studied by staining the axons with DiI (Molecular Probes) and light reacting with DAB to yield permanent preparations. The preparations were then drawn with a camera lucida and analyzed for tract pattern and degree of branching.

There are several distinct axonal tracts and areas of branching in the CNS of wild type flies to which specific sensory receptors on the wing project. Several of the *fasciclin (fas)* mutants as well as the *neurally altered carbohydrate (nac)* mutant display altered axonal trajectories in the CNS when compared to wild-type flies and controls with similar genetic backgrounds. One phenotype seen in both *fas II* mutants and *fas I; fas III* double mutants is extra branching within the normal tract pattern. A second phenotype observed is the reduction or complete loss of one of the tracts apparently due to the axons shifting to a neighboring tract. This was seen in *fas III* and in the most extreme form in *nac* flies. The finding that *fas* and *nac* mutants display altered axonal trajectories in the CNS implies that the cell surface molecules encoded or affected by these genes are important in the regulation of pathway choice.

Mutants were further analyzed by labelling developing neurons in the periphery using anti-HRP. Both misrouting of normally present axons and the appearance of ectopic neurons in the wing were observed.

Finally, the behavior of the mutants was studied using a phototaxis test to assess sensory-motor function on a gross level. Several of the *fasciclin* mutants and the *nac* mutant display aberrant phototaxis, but the cause of this altered behavior could not be assigned to any observed structural defect. This research was supported by a NIH Traineeship (KEW) and NINDS Research Grant R01-NS07778 (JP).

SOMITE REMOVAL DISRUPTS THE DISTRIBUTION OF TENASCIN AND THE PATTERN OF PERIPHERAL NERVE PROJECTIONS. J. W. Yip and Y. P. L. Yip*. Dept. of Physiology, University of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

The relationship between the hexabrachion extracellular matrix molecule tenascin and the outgrowth of peripheral nerves was examined in normal and somite-removed chick embryos using double immunofluorescent staining. Cryostat sections of normal and experimental embryos at different stages of development were stained with EC/8 antibody against intermediate filaments in neuronal processes and with a polyclonal antibody against tenascin. In the normal embryo, the outgrowth of peripheral nerves follows a tenascin rich pathway restricted to the anterior half of the somite. Indeed, spinal nerves at the brachial levels follow a tenascin rich girdle into the limb. With time, tenascin disappears along neuronal pathways and is found only to surround peripheral nerves.

To examine whether tenascin along nerve pathways is produced by somitic cells, and whether the somite is involved in the growth and guidance of peripheral nerves, segments of newly formed somites or the segmental plate of Stages 13-14 (48-53 h) embryos were unilaterally removed. Somite removal disrupts the segmental organization of peripheral nerves. Moreover, somite removal causes a reduction of tenascin along and surrounding peripheral nerve pathways, suggesting that tenascin is produced, at least in part, by somitic cells. In addition, preliminary results indicate that segmentally specific patterns of sympathetic preganglionic projections are altered in somite-removed embryos.

These results indicate that somites are important in the organization of peripheral nerves and that tenascin may be involved in this process.

EXPRESSION OF SV-40 T-ANTIGEN IN GnRH NEURONS INHIBITS ORGANIZATION OF TERMINALS IN THE MEDIAN EMINENCE IN TRANSGENIC MICE. R.I. Weiner, K.K. Thind, J.J. Windle¹*, P.L. Mellon¹* and P.C. Goldsmith. Reproductive Endocrinology Center, Univ. Calif., San Francisco, CA 94143 and ¹Salk Institute, La Jolla, CA 92037.

Transgenic mice were made which express a hybrid gene consisting of 2 kb of the GnRH promoter/enhancer fused to the coding region of the potent transforming oncogene, SV40 T antigen (Tag). All adult mice expressing the transgene were infertile and had infantile gonads and accessory sex organs. The anterior pituitary of these animals immunostained weakly for LH compared to normal controls. Although cell bodies and processes of GnRH neurons were immunostained in the preoptic area, no terminals were observed in the external layer of the median eminence (ELME). This lack of organization at the neurohemal junction occurred exclusively for GnRH endings, since both the tuberoinfundibular dopaminergic and vasopressin neurosecretory systems showed their characteristic organization. In a developmental study, animals were sacrificed on embryonic days (E) 12-20. We confirmed earlier work in controls showing fusiform GnRH neurons migrating towards the cribiform plate along the nervus terminalis prior to E16. In transgenic mice neurons were rounded, but still were capable of migrating into the brain. By E16 GnRH neurons were moving ventrocaudally into the preoptic area, where both immunopositive cell bodies and neuronal processes were observed. GnRH cell lines (GT1) derived from a tumor in these transgenic mice send out extensive neurites which form numerous contacts with processes and perikarya of adjacent cells. We conclude that GnRH-Tag transgenic mice are infertile due to a specific developmental defect preventing extension and organization of GnRH axonal endings in the ELME, thereby preventing GnRH from reaching the anterior pituitary. Supported by NIH grants HD08924 (R.W.) and HD20377 (P.M.).

AN INCREASE IN INTERNAL FREE CALCIUM CONCENTRATION COINCIDES WITH TWO DIFFERENT GROWTH CONE BEHAVIORS. Stephen J. Moorman and Richard L. Hume. Department of Biology, The University of Michigan, Ann Arbor, Michigan 48109.

In vitro, sympathetic preganglionic growth cones fasciculate on motor neuron neurites, collapse after contact with the cell bodies and neurites of dorsal root ganglion neurons (DRG), and grow across the cell bodies and neurites of sympathetic ganglion neurons (SYM). All of these cell types might potentially be encountered by a growing preganglionic axon *in vivo*. These cell-type specific responses suggest that contact mediated recognition might be sufficient for growth to and interaction with appropriate targets.

We have performed experiments aimed at elucidating the cellular mechanisms that underlie these growth cone behaviors. We have monitored internal free calcium concentration ($[Ca_i]$) in growth cones and neurites, using FURA-2, during the cell-specific interactions. In our standard culture conditions, preganglionic growth cones and neurites that had grown out of explants showed spontaneous, low level fluctuations in $[Ca_i]$. These low level fluctuations were independent of growth cone contact with any other neurons. Following contact with the neurites of DRG, preganglionic growth cones showed rapid 5-6 fold increases in $[Ca_i]$ followed by oscillations of $[Ca_i]$ between resting level and the maximum level seen upon initial contact. These $[Ca_i]$ oscillations continued for several minutes, and by 4-6 minutes after contact the growth cone collapsed. Following contact with the neurites of SYM, the preganglionic growth cones also showed a transient 5-6 fold increase in $[Ca_i]$. However, within a few seconds the $[Ca_i]$ returned to baseline. No persistent large excursions from baseline $[Ca_i]$ were detected as the growth cone continued to grow. Although both crossing and collapse are accompanied by an initial increase in $[Ca_i]$, it remains possible that different temporal patterns of change in $[Ca_i]$ may underlie specific growth cone behaviors. (Supported by the American Paralysis Assoc. and N.I.H.)

A DYNAMIC VIEW OF NEURULATION AND NEURAL CREST MIGRATION IN NORMAL CHICK EMBRYOS USING 16 MM TIME-LAPSE HIGH-DEFINITION PHOTOMICROSCOPY. T. Jaskoll, G. Greenberg* and M. Melnick*. University of Southern California School of Dentistry, Los Angeles, CA 90089.

The dynamic process of neural tube formation and neural crest migration in live, unstained cultured White Leghorn avian embryos, H.H. stages 8-11, was investigated by time-lapse cinematography using a new prototype high-definition light microscope which greatly enhances resolution, sharpness and depth of field. These studies provide previously unobserved details of neural apposition and fusion. During development neural tube closure in the trunk region markedly differs from that observed in the head. The cephalic neural folds slowly elevate, then rapidly touch and appose. They gradually "zip-up" in the anterior and posterior direction. In the trunk region where the neuroepithelium bulges adjacent to the somites, the edges of the folds pulsate and forcefully make contact at these bulging regions; the intersomatic epithelia retract, remain open and then slowly close. Between the open folds only a few bridging cells were seen, probably representing the sites of initial cell adhesion that had been stretched during epithelial retraction. Through focusing into the embryos revealed a meshwork of synchronously pulsating neural crest cells below the epithelial surface. The *in vivo* crest cell migration pattern was investigated. Selected embryos were fixed in paraformaldehyde, stained with antibodies to cell adhesion molecules (N-CAM) and processed for whole mounts. N-CAM was observed on the leading edges of the open neuroepithelia; the loss of N-CAM was associated with tube apposition. Supported by NIH DE07006.

77.1

NEUROPROTECTIVE EFFECTS OF GM1 GANGLIOSIDE TREATMENT AFTER FOCAL CEREBRAL ISCHEMIA IN RATS. S. Mazzari, A. Lazzaro*, M.S. Seren, T. Koga*, N. Schiavo*, R. Zanoni*, and A. Leon. Fidia Research Labs, 35031 Abano Terme, Italy.

Systemic GM1 treatment exerts beneficial effects in different models of cerebral ischemia (Karpiaik S.E., Mahadik S.P., Wakade C.G. CRC Crit. Rev. Neurobiol. 5, 221, 1990). We now report GM1 effects following MCAo in rats according to Tamura A. et al. (J. Cereb. Blood Flow Metab. 1, 53, 1981). GM1 was administered (30mg/kg) immediately after MCAo (i.v.) and then once a day (i.m.). As shown in table I, 7 days after MCAo, striatal alterations such as decrease of choline acetyltransferase (ChAT) activity, dopamine (DA) content (percentage reduction versus contralateral), and brain infarcted area were reduced by GM1 treatment.

Table I.	ChAT activity	[DA]	infarcted area
Saline (n=8)	-49.7±5.2	-76.6±2.2	32.8±2.9
GM1 (n=8)	-35.6±3.5**	-60.3±3.5**	23.1±3.7*

** p<0.01 *p<0.05

These findings provide further evidence that GM1 treatment, likely via its RADA action (Manev H. et al. Faseb J. 4, 2789, 1990), results in lasting neuroprotection after cerebral ischemia.

ISCHEMIA, HYPOGLYCEMIA AND KINDLING INCREASE BRAIN LEVELS OF mRNAs FOR NEUROTROPHIC FACTORS J. Bengzon¹*, Z. Kokaia¹*, P. Ernfors², M.L. Smith³*, R. Ekman⁴, B.K. Siesjö³, H. Persson² and O. Lindvall¹*

¹ Restorative Neurology Unit, University Hospital, S-22185 Lund, Sweden; ² Dept. of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institute, S-10401 Stockholm, Sweden; ³ Laboratory of Experimental Brain Research, University Hospital, S-22185 Lund, Sweden, ⁴ Dept. of Psychiatry and Neurochemistry, Medical Center, S:t Lars Hospital, S-22009 Lund, Sweden

Expression of mRNA for nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and hippocampus-derived neurotrophic factor/neurotrophin-3 (HDNF/NT-3) was studied using *in situ* hybridization after 2 and 10 min forebrain ischemia induced by bilateral carotid artery occlusion plus a lowering of blood pressure, after 1 and 30 min of insulin-induced hypoglycemia and after hippocampal kindling. *In situ* hybridization was performed using alpha-³⁵S-d(ATP)₃-end labeled 50-mer oligonucleotide probes.

Two min forebrain ischemia induced marked increases in BDNF and NGF mRNA in dentate gyrus granule cells. The increase was detectable 30 min after the insult and maximal levels were seen after 2 hrs. At 2 hrs there was also an increase in BDNF mRNA in the piriform cortex. At 24 hrs NGF and BDNF mRNAs had essentially returned to baseline. One min hypoglycemia induced similar patterns of increased expression of BDNF and NGF mRNAs as those seen after 2 min ischemia. Less pronounced increases were observed after 10 min ischemia and 30 min hypoglycemia. Two hrs after focal kindled seizures, increases in BDNF and NGF mRNA were confined to the dentate gyrus. Generalized seizures gave rise to increases in more widespread regions including the hippocampal CA1-CA3 region, amygdala, and the piriform and parietal cortices. HDNF/NT-3 mRNA was not affected in either of the three experimental paradigms. The increased mRNAs for neurotrophins and the presumed increases in the factors themselves could possibly play a role in protecting neurons from seizure-, ischemia- and hypoglycemia-induced damage.

77.3

DIFFERENTIAL REGULATION OF AMPA RECEPTOR SPICE VARIANTS IN THE CA1 REGION FOLLOWING ISCHEMIA. H. Monyer (1), B. Nelligård (2), P.H. Seeburg (1) and T. Wieloch (2). (1) Center for Molecular Biology Heidelberg, F.R.G., and (2) Lab. for Experimental Brain Res. Lund, Sweden.

Recent molecular cloning studies have shown that four related high affinity AMPA receptors GluR-A, -B, -C, and -D exist in two versions (Flip and Flop) which arise from alternative splicing. A difference of only a few amino acids (9 to 11) preceding the predicted fourth transmembrane region imparts distinct properties on AMPA- and glutamate-elicited currents. The cell specificity of these alternatively spliced mRNAs is particularly evident in the hippocampus: both variants are expressed in the CA1 pyramidal cells whereas in the CA3 area there is a conspicuous lack of Flop mRNAs. The CA1 region is particularly vulnerable to cerebral ischemia and the development of neuronal necrosis can be mitigated by AMPA receptor blockade. Thus the question arises whether ischemia may produce a switch in channel composition.

In this study we analyzed the Flip/Flop expression pattern in the hippocampus following ischemia. Reversible cerebral ischemia of 10 minutes duration in a rat model was induced by bilateral common artery occlusion with combined hypotension. An upregulation of Flop mRNAs with a concomitant downregulation of the Flip variants can be documented in the CA1 region one hour following a transient ischemic episode with no noticeable changes in the CA3 region at this time point. There is no evidence for changes of several other control mRNAs (map2, GABA_A receptor $\alpha 2$ subunit) which are also expressed in this brain area. 24 hours following ischemia both Flip and Flop mRNAs are downregulated in the CA1 pyramidal neurons.

77.5

EFFECTS OF LOW CALCIUM AND NMDA ANTAGONIST ON ATP DURING "ISCHEMIA" IN THE RAT HIPPOCAMPAL SLICE. D. Lobner and P. Lipton. Dept. of Physiol., Univ. of Wisconsin, Madison, WI 53706.

Exposure to 0 Ca buffer or 1mM ketamine allows recovery of synaptic transmission measured 60 minutes after a 5 minute period of "ischemia" (anoxia plus 0 glucose). The effects of these treatments on ATP levels in the CA1 region during ischemia were studied.

	ATP (% of pre-ischemia normal)				% recovery of population spike
	Pre-ischemia	1'	2.5'	5'	
Normal	100±4	92±3	46±4	13±1	0
20' 0 Ca	116±11	47±8	16±3	17±4	93±11
TTX	98±3	89±3	67±2	29±2	
20' 0Ca/TTX	93±3	81±3	55±3	16±1	
Ketamine	92±4	81±7	55±3	14±3	100±8

1) ATP falls far more rapidly in the 0 Ca buffer. This effect is greatly attenuated by TTX (tetrodotoxin), suggesting it is due to enhancement of ischemic sodium entry by the 0 Ca buffer.

2) Transmission recovers fully after 0 Ca ischemia although ATP falls more quickly than it does in normal buffer. Thus, during ischemia, reducing intracellular calcium is more important than maintaining ATP levels for protecting against transmission damage.

3) The NMDA antagonist ketamine also allows full recovery of synaptic transmission. It has no effect on ATP fall but has been shown to decrease calcium influx during ischemia.

4) Further investigation will include studying whether maintaining ATP during 0 Ca provides protection against longer ischemic periods.

77.7

ASTROCYTIC CELL DEATH SECONDARY TO COMBINED GLUCOSE-OXYGEN DEPRIVATION IS DEPENDENT ON EXTRACELLULAR CALCIUM. SE Haun, EJ Murphy, CM Bates, and LA Horrocks. Depts. of Pediatrics and Medical Biochemistry, The Ohio State University, Columbus, OH 43210.

Extracellular calcium has been proposed to play a major role in the pathophysiology of cerebral ischemia. To test this hypothesis, we studied the effect of removing extracellular calcium on the rate of cell death in primary cultures of rat cortical astrocytes exposed to combined glucose-oxygen deprivation ("ischemia"). "Ischemia" was created by placing cell cultures in an anaerobic incubator and replacing media with glucose-free buffer that had been equilibrated with 85% N₂, 10% H₂, and 5% CO₂. Cell death was quantitated by lactate dehydrogenase (LDH) efflux. Standard buffers (+ Ca²⁺) contained 1.8 mM calcium whereas calcium-free buffers (- Ca²⁺) contained no added calcium and 25 μ M EGTA. Control buffers contained 30 mM glucose. Four groups (n=6 each group) were studied: 1) Ischemia + Ca²⁺, 2) Ischemia - Ca²⁺, 3) Control + Ca²⁺, and 4) Control - Ca²⁺. Aliquots of buffer were removed for LDH measurement after 12 and 24 hours of exposure to experimental conditions. LDH efflux (expressed as percent of total LDH) was 2 to 3 fold higher in the Ischemia + Ca²⁺ group (58.1 ± 2.4 vs. 19.1 ± 1.1 at 12 hr; 80.2 ± 1.5 vs. 30.3 ± 2.5 at 24 hr; mean ± SEM) as compared to the Ischemia - Ca²⁺ group. The Control - Ca²⁺ group had much higher LDH efflux (6.3 ± 0.5 vs. 0.0 ± 0.0 at 12 hr; 14.6 ± 0.8 vs. 0.9 ± 0.3 at 24 hr; mean ± SEM) than the Control + Ca²⁺ group. This study supports a role for extracellular calcium in the pathophysiology of cerebral ischemia.

77.4

NEURONAL DEATH INDUCED BY ENERGY DEPLETION PROCEED INDEPENDENTLY OF CYTOSOLIC CALCIUM CONCENTRATION M. Nedergaard and M. Khayata. Dept. of Neurology and Neuroscience, Cornell Univ. Med. College, 1300 York Avenue, New York, NY 10021

Cytosolic calcium ([Ca²⁺]_i) increases during neuronal death. However, it is unclear whether this antecedent increase in [Ca²⁺]_i is necessary for the initiation or maintenance of those processes leading to death, or rather follows cellular injury. We examined the temporal relationship of calcium influx to neuronal death following lethal energy depletion *in vitro*. Cultures were prepared from E16 rat forebrain; after 14 days *in vitro*, [Ca²⁺]_i was measured in single neurons loaded with Fluo-3, using a laser scan confocal microscope (MRC-600, BioRad). Neuronal death was defined by propidium iodide (PI) entry. Dual-emission imaging with an excitation of 414 nm permitted simultaneous detection of [Ca²⁺]_i (emission 540 nm) and PI uptake (emission 620). Superfusion with both the glycolytic inhibitor iodoacetate (0.2 mM) and the electron transport inhibitor rotenone (10 μ M), resulted in ATP content falling to undetectable levels in less than 5 min. Superfusion of iodoacetate and rotenone induced a slow steady increase of [Ca²⁺]_i among neurons, with a 5-fold increase in [Ca²⁺]_i occurring within 5 min (n=11). This increase in [Ca²⁺]_i did not occur when calcium (3 mM) was exchanged for 50 mM EGTA (n=6), a treatment which resulted in [Ca²⁺]_i levels remaining at or below resting values during energy depletion. Nevertheless, PI uptake occurred within 44±12 min in calcium-free media, analogous to the 47±11 min latency noted among neurons incubated in 3 mM CaCl₂. Population studies measuring the release of intracellular LDH similarly failed to reveal any dependence of cellular viability upon the extracellular calcium levels. Thus, cultured embryonic neurons die within 30-90 minutes following energy depletion, by a process which can proceed independently of [Ca²⁺]_i.

77.6

RELATIONSHIP OF PRESENCE OF THE CALCIUM-BINDING PROTEIN PARVALBUMIN IN GABAergic INTERNEURONS AND THEIR SURVIVAL AFTER TRANSIENT GLOBAL ISCHEMIA. C. Nitsch* (SPON: European Neuroscience Association) Section of Neuroanatomy, Anatomy Institute of the University, CH-4056, Basel, Switzerland.

Transient global ischemia in gerbils (*Meriones unguiculatus*) causes delayed neuronal cell death in the hippocampus thought to be triggered by a glutamate-receptor mediated lethal calcium influx. The degeneration involves the pyramidal neurons of the CA1 sector, but spares local GABAergic interneurons. The hypothesis that the calcium-binding protein parvalbumin (PV) might protect a subpopulation of GABAergic neurons (Nitsch et al, *Neurosci. Lett.* 103: 263, 1989) was challenged by Freund et al (*Exp. Brain Res.* 83: 55, 1990) in a rat model. Therefore, a quantitative study was performed in male gerbils subjected to bilateral occlusion of the common carotid arteries for 7 min under halothane anesthesia. Serial sagittal vibratome sections were stained for PV- (Celio et al, *Cell Calcium* 9: 81, 1988) and for GABA-immunoreactivity, and collected in 3 groups (controls, short survival for up to 14 days, and long survival up to 77 days). Three representative sections were analyzed per animal. Both, in the short and long survival group there was a significant increase in the number of PV-containing neurons in the CA1 sector, whereas no change was found in CA3 sector and dentate gyrus. We conclude that in gerbils PV-containing GABAergic neurons resist ischemia-induced nerve cell death and that in vulnerable areas they even increase PV-synthesis resulting in visualization of PV in neurons where it is below detection limit in controls. However, PV is not a prerequisite for neuronal survival: the GABAergic neurons in stratum lacunosum-moleculare which do not contain PV are also resistant against ischemia induced nerve cell death.

77.8

AGE-DEPENDENT SENSITIVITY TO ANOXIA: NEWBORN RAT HIPPOCAMPAL NEURONS HAVE A LONGER LATENCY AND SMALLER Ca²⁺ RISE THAN ADULT. J. E. Friedman and G. G. Haddad. Sec. of Respiratory Medicine, Dept. Pediatrics, Yale Univ. Sch. of Med., New Haven, CT 06510.

In vivo and *in vitro* studies have shown that hypoxia-induced synaptic release of glutamate with the subsequent opening of NMDA channels and entry of Na⁺ and Ca²⁺ are responsible for neuronal degeneration. Since in these models the direct effect of hypoxia cannot be distinguished from that of glutamate, we investigated the effect of O₂ deprivation on freshly dissociated rat hippocampal CA1 neurons. We monitored changes in free Ca²⁺ using Fluo-3 and a Laser Scanning Confocal Microscope. Anoxia was achieved by saturating the perfusing buffer with N₂ + 1-2mM Na₂S₂O₄, an oxygen scavenger. PO₂ reached 0 within 30 sec of switching perfusate. These studies were performed in neonatal (1-8d) and adult (>22d) rats. The experimental protocol consisted of (1) baseline (10 min, oxygenated Krebs buffer), (2) anoxia (10 min) and (3) reoxygenation. A significant rise in intracellular free Ca²⁺, as demonstrated by increased fluorescence, was observed in all cases. The percent maximum fluorescence change for adults was 40.4±7.2 (n=9), while that of neonates was 23.3±8 (n=6). The latency in onset of the rise in calcium was 1.9±0.3 min for adults (n=15) and 13.2±1.3 min for neonates (n=5). CoCl₂ (1mM) added to both the oxygenated and nitrogenated buffers reduced the baseline fluorescence by approximately 40% but failed to halt the observed rise in Ca²⁺, albeit the amplitudes were reduced: 26.5±5.7 (n=4) for adults and 7±2.8 (n=4) for neonates. When extracellular calcium was replaced with cobalt, adult neurons exhibited a 7.7% rise. Latency was not affected. We conclude that in direct response to anoxia (a) the rise in Ca²⁺ is mostly of extracellular origin and (b) the pattern and magnitude of change in Ca²⁺ in adults is different from that of neonates.

77.9

CALCIUM INDEPENDENCY OF ANOXIA-INDUCED ³(H) ASPARTATE RELEASE IN HIPPOCAMPAL SLICES. L. Annunziato, S. Amoroso*, S.L. Sensi* and G.F. Di Renzo*, Section of Pharmacology, Department of Human Communication Sciences, 2nd School of Medicine, University of Naples, Via S. Pansini 5, 80131 Naples, ITALY.

When energy production is impaired in the brain, as a consequence of anoxia, hypoglycaemia or ischemia, a massive release of glutamate and aspartate occurs in the extracellular space. Evidence has been provided that this presynaptic release of excitatory amino acids is involved in post-anoxic cell death. At the present time the mechanism by which glutamate and aspartate are released during anoxia, is not clearly identified. In the present study we investigated the mechanisms involved in presynaptic release of aspartate induced by anoxia in hippocampal slices. Ischemic conditions have been mimicked (1) by replacing the normal O₂-equilibrated medium by N₂ equilibrated (95% N₂-5% CO₂) glucose free solution or (2) by using oligomycin + 2-deoxyglucose in a glucose free medium. Both these treatment increased aspartate release. This presynaptic release induced by anoxia was completely independent from extracellular calcium since neither Ca⁺⁺ chelation by EGTA, nor inorganic calcium entry blocker (2mM La⁺⁺⁺, 300 μM gadolinium) and organic calcium entry blockers (10 μM verapamil, 10 μM nimodipine) prevented anoxia-induced aspartate release. These results suggest that anoxia-induced aspartate release might be due to the reversal of the Na⁺-cotransport system of aspartate, as a consequence of the decay in Na⁺-electrochemical gradient due to the decreased activity of the Na⁺-K⁺ ATPase. Supported by C.N.R. 883416 grant to Lucio Annunziato.

CYCLOHEXIMIDE ATTENUATES ISCHEMIC DAMAGE TO CA1 HIPPOCAMPAL NEURONS IN RATS T. Mima*, I. Halaby, D. Levy, and W. Pulsinelli, Dept. of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021

Protein synthesis inhibitors have been reported to reduce selective ischemic necrosis of CA1 hippocampal neurons (Shigeno et al. Neurosci Lett, 1990; Goto et al. Brain Res, 1990). To test whether this neuroprotective response is based on the degree of protein synthesis inhibition or other mechanisms peculiar to the drugs, we examined the effects of several protein synthesis inhibitors including actinomycin-D. Male Wistar rats were subjected to 10 minutes of 4-vessel occlusion ischemia (Pulsinelli W, Duffy T. J Neurochem, 1983). Sublethal doses of each inhibitor were injected subcutaneously either 1 hr before or immediately after ischemia. The animals were perfusion-fixed 5 days later. The grade of ischemic injury to hippocampus was quantified blindly on a scale of 0-3 (0 = normal brain, 3 = more than 75% of CA1 neurons damaged).

	Mean Grade CA1 Damage			
	Dose (mg/kg)	Vehicle (n=6)	Pre-Rx (n=6)	Post-Rx (n=6)
Cycloheximide	2.5	2.9±0.2	1.9±0.7*	2.8±0.3
Anisomycin	5.0	2.4±0.8	2.5±0.7	2.7±0.7
Actinomycin-D	0.2	2.3±0.8	2.8±0.3	3.0±0.0

The selected dose of these drugs inhibits protein synthesis for at least 4 hours. However, only pre-ischemic treatment with cycloheximide significantly reduced CA1 damage (*p < 0.001). The results suggest that inhibition of 'specific proteins' might differ with each inhibitor or that cycloheximide may be neuroprotective via some other mechanism.

77.10

PREINCUBATION WITH CREATINE PREVENTS ANOXIC DAMAGE IN RAT HIPPOCAMPAL SLICES AND AUGMENTS THE EFFECTS OF NMDA RECEPTOR ANTAGONISTS. A. J. Carter and R. E. Müller*, Dept. of Pharmacology, Boehringer Ingelheim, 6507 Ingelheim, Germany.

We have investigated the relationship between energy metabolism, anoxic damage and NMDA-receptor antagonism in vitro. Anoxic damage was assessed by measuring protein synthesis in rat hippocampal slices with [¹⁴C]-lysine. The levels of energy metabolites - phosphocreatine (PCR), creatine, AMP, ADP and ATP - were measured by ion-exchange HPLC. Protein synthesis and the levels of PCR and ATP were reduced after 20 min anoxia. Preincubation with creatine dose-dependently (0.03 - 3 mmol/L) increased the levels of PCR and prevented the impairment of protein synthesis. Creatine did not influence baseline rates of protein synthesis under normoxic conditions or the levels of ATP. Incubation with β-guanidinobutyric acid, a synthetic analogue of creatine which cannot be phosphorylated, did not prevent anoxia-induced impairment of protein synthesis and did not enhance the levels of PCR or ATP. Incubation with an NMDA antagonist also did not significantly prevent the impairment of protein synthesis. Incubation with a combination of both creatine and an NMDA antagonist provided complete protection. These results indicate that energy depletion is a major factor which is responsible for anoxic damage in this model.

77.12

CALPAIN AND CALPASTATIN IN CEREBRAL ISCHEMIA. K. Ostwald, P. Andiné*, H. Hagberg*, E. Nilsson* and J.-O. Karlsson*, Institute of Neurobiology, PO Box 33031, 400 33 Göteborg, Sweden.

In one project we studied the effects of in vitro ischemia on the total levels of calpain and calpastatin and their distribution between the membrane and the cytosolic fraction. We found that incubation of brain homogenates at different pH resulted in a transfer of calpains from the cytoplasmic compartment to the membranes when pH was lowered from 6 to 5. Incubations of bisected brains in saline at 39°C for 1.5 h resulted in decreased μ-calpain activity in the cytosol and increased hydrophobicity of the remaining cytosolic m-calpain activity.

Our second project involved a model for transient cerebral ischemia in 7-day postnatal rats (unilateral occlusion of the common carotid artery combined with hypoxia, 7.7 % for 2 h). The arterial occlusion per se does not affect the cerebral blood flow whereas the hypoxia inflicts ischemic damage in widespread regions of the hemisphere on the side of the ligature, leaving the other hemisphere virtually unaffected. Compared with control animals, we found a bilateral 20% decrease in Ca-activated proteolysis in the cytosolic fraction after a two hour ischemic attack followed by 30 min of reperfusion. After 20 hours of reperfusion the level of Ca-activated proteolysis was practically restored. We also found a decrease in calpastatin activity in the membrane fraction of the ischemic hemisphere after one hour of reperfusion. This might indicate an increase in proteolytic activity in the membrane fraction during ischemia.

IMMUNOHISTOCHEMICAL STAINING OF THE DEVELOPING TELEOST RETINA: IS GABA A PIONEERING SUBSTANCE FOR RODS? M.M. Hagedorn and R.D. Fernald*, Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403 and *Department of Psychology, Stanford University, Stanford, CA 94305

Vertebrate retinal development consists of sequential production of specific cell phenotypes, beginning with cone photoreceptors and concluding with rods. We have analyzed cell proliferation and neurogenesis in the developing teleost retina. In particular, we have analyzed the late addition of rod photoreceptors using immunostaining.

Cones can be distinguished at day 4, followed shortly by putative rod precursors at day 4.5 (Hagedorn and Fernald, 1991). Approximately 12-20 hrs later, these late added cells first show reactivity to opsin and by Day 6 rod photoreceptors in the central retina have a mature morphology. Vimentin-positive radial fibers are widely distributed throughout the embryonic retina from Day 4-Day 6 and on Day 7, the first vimentin-positive Müller cells were observed.

Concomitant with rod neurogenesis is the production of GABA by the horizontal cells. Horizontal cells completely cover the embryonic retina in a grid-like pattern by Day 5, therefore differentiation of the horizontal cells is not coupled with GABA production. In adults, only horizontal cells close to the margin produce GABA. In other vertebrate retinas, GABA activity in horizontal cells appears early in embryogenesis and then disappears (Redburn, 1987) and is considered a pioneering or tropic substance. In H. burtoni, the GABAergic activity of the horizontal cells appears at the onset of rod neurogenesis and is maintained only in the margin of the adult retina. GABA may play some role in stimulating the genesis of rod photoreceptors.

DEVELOPMENT OF TYROSINE HYDROXYLASE-IMMUNOREACTIVE CELLS IN THE RODENT RETINA. D.K. Wu* and C.L. Cepko, Department of Genetics, Harvard Medical School, Boston, MA 02115.

The appearance and development of tyrosine hydroxylase immunoreactive (THIR) cells were studied in whole mounts of developing rat and mouse retinas. Previous studies have shown that THIR cells appear around postnatal day 2. Using a more sensitive method of staining, THIR cells were first detected around embryonic day 19 at the peripheral temporal margin of the rat retinas. By postnatal day 5, TH positive cells were found across the entire retina. The 'early' THIR cells are small unipolar neurons with large nuclei and very little cytoplasm. Presumably, they are the class II THIR cells. Class I THIR cells which have larger cell bodies and often exhibit two primary dendrites appear between postnatal day 5 and day 7. However, with the same staining method, the earliest THIR cells in mouse retinas were detected at postnatal day 4. The lack of THIR cells at earlier developmental ages supports the hypothesis that the class II THIR are not present in the mouse retina.

MECHANISMS MEDIATING CAT RETINAL GANGLION CELL DEVELOPMENT. S.J. Ault, K.G. Thompson, Y. Zhou, A.G. Leventhal. Anat. Dept. U. of Utah Med. Sch., Salt Lake City, UT 84132

We examined the morphologies and distributions of α cells in regions of mature cat retina selectively depleted of β cells due to unilateral visual cortex lesions at birth. As a result of this procedure, α cells close to the area centralis in β cell-poor regions grew to be abnormally large; this size increase was greater in temporal than in nasal retina. In contrast, in more peripheral regions depleted of β cells, α cells were smaller than normal. In fact, the normal central to peripheral α cell size gradient was absent in the β cell-poor hemiretinae even though α cells retained their normal central to peripheral density gradient and were distributed normally in a 'mosaic-like pattern'. It may be that central and peripheral α cells are affected differently because the number of afferents which are made available as a result of β cell loss is sufficient in central but not peripheral retina to compensate for the loss of axon collaterals to the thalamus. Similar mechanisms may explain the differences observed between nasal and temporal retina since, following cortical ablation, nasal α cells, which project to layers A and C of the LGN, should lose more axon collaterals than do temporal ones, which project only to layer A₁. We suggest that 1) ganglion cell size depends upon intraretinal interactions which are not class specific since the elimination of one class of cell affects the size of another, 2) trophic support from target nuclei via axon collaterals may also be involved, and 3) the development of the normal territorial distribution of α cells is class specific since it develops whether or not β cells are present.

EXPRESSION OF AN AXONAL GROWTH ASSOCIATED PROTEIN, GAP-43, IN DEVELOPING RETINA. L.S. Honig, D.T. Hess, J.H.P. Skene and C.J. Shatz. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

To study molecular correlates of retinal development in the cat, particularly at those stages when activity-dependent retinogeniculate segregation occurs, we have examined the pattern of expression of GAP-43, an axonally transported growth-associated phosphoprotein. In situ hybridization (ISH) using antisense riboprobe for GAP-43 mRNA at E28 reveals high signal in the forming ganglion cell layer distributed in a central-to-peripheral gradient. Between E43-E57, signal remains high, but is present throughout the retinal ganglion cell (RGC) layer. From E57 to postnatal day P27, signal in the RGC layer decreases overall, but high signal persists in scattered large cells, presumably alpha cells based on their size, distribution and late maturation. This same population of 18-30 μ m diameter cells stains with monoclonal antibody [9-1E12: D.J. Schreyer] to GAP-43. At early fetal ages, there is little signal in other retinal layers, but at E57 and later, clear ISH signal is also present in the inner nuclear layer. This signal may be in amacrine cell bodies, hence correlating with the prominent immunostaining observed for GAP-43 within the inner plexiform layer - the terminating fiber zone of amacrine cell processes. Thus, transcription of GAP-43 mRNA is an early feature of postmitotic retinal neurons, and its expression is consistent with the idea that both ganglion and amacrine cells use GAP-43 in the process of axonal growth, and that amacrine cells may continue to express GAP-43 postnatally. Supported by Dana Fellowship (LSH), NIH EY06012 (DTH), EY07397 (JHPS), and NSF BNS8919508 (CJS) grants.

SPONTANEOUS CORRELATED BURSTING ACTIVITY OF RETINAL GANGLION CELLS IS UNIQUE TO THE PERIOD OF AXONAL SEGREGATION IN THE LGN. R.O.L. Wong, M. Meister* and C.J. Shatz. Dept. Neurobiology, Stanford Univ., Stanford, CA 94305.

In the ferret visual system, the axonal inputs of retinal ganglion cells segregate into eye-specific layers in the lateral geniculate nucleus (LGN) between postnatal days P3 and P21. Using a multielectrode array to simultaneously record action potentials from many neurons in the neonatal ferret retina, we recently reported spontaneous waves of activity travelling across the ganglion cell layer, resulting in locally correlated bursts of action potentials in neighbouring cells. The developmental time course of this activity pattern has now been determined more accurately. From P4 to P22, neurons fired rhythmic bursts, 2-8 secs in duration. The interburst intervals were 40-90s for P4-15 but decreased to 15-30s by P22. The waves propagated at about 110 μ m/s throughout this period. By P30, the wave-like activity disappeared; most cells fired in irregular, asynchronous bursts. Cells in the adult retina fired continuously in darkness, at rates of 2-30 Hz. To establish the identity of the bursting cells, single cells were recorded *in vitro* before being intracellularly dye-filled to reveal their dendritic morphology. Both alpha- and beta-like ganglion cells, known to project to the LGN, fired in regular bursts up to P23 and developed non-rhythmic activity by P30. Thus, the periodic wave-like activity pattern of ganglion cells appears to be unique to the period of axonal segregation and is likely to facilitate this process.

RETINAL GANGLION CELLS WITHIN THE PRIMATE FOVEA. Kirk G. Thompson, Steven J. Ault, Audie G. Leventhal. Anat. Dept., Univ. of Utah Sch. of Med., Salt Lake City, UT 84132

HRP labeled retinal ganglion cells within and around the foveal pit were studied in new world (*Saimiri sciureus*) and old world (*Macaca fascicularis*) monkeys. Most cells within the foveal pit resembled peripheral B type (midjet) ganglion cells; their cell body and dendritic field areas were, respectively, 4 and 15 times larger than those of cells in the foveal slope. Around the edge of the foveal pit, the cell body and dendritic field areas of the cells were, respectively, 2 and 4 times larger than those of cells in the foveal slope. The primary dendrites of ganglion cells in the foveal pit arborized in the IPL within the foveal pit and were on average three times longer than those of cells in the foveal slope. These long primary dendrites were randomly oriented with respect to the center of the foveal pit. In contrast, the primary dendrites of ganglion cells around the edge of the foveal pit encircled the foveal pit and arborized in the IPL at the inner edge of the foveal slope. More peripherally, the proximal dendrites of retinal ganglion cells tended to be oriented toward the center of the foveal pit. In all areas studied, the initial segment of the ganglion cell's axon strongly tended to be on the opposite side of the cell body from its proximal dendrite. Our results suggest that retinal ganglion cell morphology is in large part determined by extrinsic factors such as the density of neighboring cells and the position and density of their afferents. The coverage of the foveal pit by the dendritic fields of retinal ganglion cells may provide the anatomical basis for the clinical phenomenon of macular sparing.

DEVELOPMENT OF MEMBRANE CURRENTS IN DISSOCIATED RETINAL GANGLION CELLS OF THE CAT. I. Skaliotis, L.C. Liets*, R.P. Scobey and L.M. Chalupa. Depts of Psychology and Neurology, Neurobiology Graduate Group and Center for Neurobiology, University of California, Davis, CA 95616.

We are investigating the development of membrane excitability in retinal ganglion cells (RGCs) during the period of axonal pathfinding and the establishment of synapses at central targets. Isolated neurons are obtained after enzymatic treatment of the retinae and are kept in suspension at 10°C for up to three days after eye removal. RGCs are identified by retrograde labeling with rhodamine beads previously injected into the optic tracts and subcortical targets. Voltage-clamp recordings are obtained with the whole-cell patch clamp recording technique. Membrane currents are determined during a series of depolarizing voltage steps from a holding potential of -70mV. Peak inward current amplitudes, normalized for differences in membrane area, are found to increase with fetal age. The Na current is pharmacologically isolated for study of the channel kinetics. Results to date indicate that the increase in inward current is primarily due to an increase in the number of Na channels rather than a change in channel properties. The development of specific membrane currents in relation to the onset of impulse activity is being assessed.

ALDEHYDE DEHYDROGENASE IN THE DORSAL RETINA. U.C. Dräger, P. McCaffery and P. Tempst*. Departments of Neurobiology and Genetics, Harvard Medical School, Boston, MA 02115.

In a search for factors in positional determination of the retina we compared proteins from different parts of embryonic mouse retinae by subcellular fractionation and high-resolution protein gel analysis. The cytosolic fractions contained a 53kD protein that was much more abundant in dorsal than ventral retina. Nitrocellulose blots of this protein from 150 dorsal and ventral retina halves were digested with trypsin, and microsequencing of the resulting peptide fragments by Edman degradation identified it as an aldehyde dehydrogenase (AHD). Sections of embryonic mice labeled with AHD antisera showed the first expression of the enzyme early on embryonic day 9 (E9) in the dorsal part of the eye vesicle and in the adjacent surface ectoderm. The labeled surface ectoderm gives rise to the lens and the cornea, which continued to be brightly labeled up to adulthood. In the neural retina of all ages, from eye-cup stage to adult, AHD expression was very high in a dorsal zone comprising about one-third of retinal area, and levels in ventral retina were much lower. In addition, axons and their growth cones emerging from ganglion cells in the dorsal retina were brightly labeled during the axon outgrowth phase, which lasts from E12.5 up to a few days after birth. While in the embryo the enzyme was expressed in undifferentiated stem cells and in neurons, in the adult mouse retina it was mainly present in Müller glial cells, indicating that it is the spatial localization rather than the cell type which matters for the expression of the enzyme.

THE DORSAL RETINA CONTAINS AN ALDEHYDE DEHYDROGENASE THAT CONVERTS RETINALDEHYDE TO RETINOIC ACID. P. McCaffery, M.-O. Lee*, G. Lara*, N. E. Sladek* and U.C. Dräger. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115, and Dept. of Pharmacology, University of Minnesota Medical School, Minneapolis, MN 55455.

A 53kD protein present in much higher amounts in dorsal than ventral embryonic mouse retina was identified as an aldehyde dehydrogenase (AHD). AHD's represent a group of enzymes which have in common the capacity of NAD-dependent dehydrogenation of aldehydes to carboxylic acids, but which differ in subcellular localizations, and physical and catalytic properties. The AHD from embryonic retina was found to be a cytosolic isoform with preference for aliphatic substrates and basic isoelectric point. In these characteristics it resembled AHD-2, the isozyme that accounts for over 90% of NAD-dependent capacity for retinoic acid synthesis in adult mouse liver. Comparison of embryonic AHD with AHD-2 purified from adult liver by isoelectric focussing gel analysis confirmed their identity. Homogenates of embryonic retinas showed NAD-dependent retinoic acid synthesis from retinaldehyde as detected by high-pressure liquid chromatography. In this *in vitro* test the synthetic capacity for retinoic acid in dorsal retina was about 15 times higher than in ventral retina. Whether AHD-2 is responsible for retinoic acid synthesis in the embryonic eye *in vivo*, and what fraction it contributes to the total retinoic acid content, remains to be determined. CHARACTERIZATION OF A NOVEL CNS PROTEOGLYCAN: DISTRIBUTION IN THE ADULT RAT RETINA AND OPTIC NERVE. D.J. Bidanset, R.C. Williams and E.E. Geisert, Jr. Department of Cell Biology, Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, Alabama 35294.

A novel CNS-specific glycoprotein containing sulfated polyglucosamine side chains is identified by a monoclonal antibody TED15. The antibody recognizes a carbohydrate epitope that is removed from the core protein by keratanase digestion. The relative molecular weight of the glycoprotein is not altered following heparinase, heparitinase or chondroitinase ABC digestions. By immunoblot analysis, the TED15 antigen is differentially distributed in the CNS, being present in the optic nerve but absent from the retina. In the optic nerve the TED15 antigen appears to be associated with astrocytes, while in the retina no labeling of astrocytes or Muller cells is observed. The TED15 antigen is found in the CNS of monkey, cat, ferret, rat and chicken, but is absent in gold fish, frog and medicinal leech. The tissue and species distribution of the TED15 antigen indicates that it has a unique function in the maturation of mammalian and avian CNS, and suggests that it may play a role in the lack of long tract axonal regeneration. DEGENERATIVE AND REGENERATIVE RESPONSES OF AXOTOMIZED RABBIT RETINAL GANGLION CELLS.

E. Famiglietti, S. Sharpe* and G. Thurlow*. Dept. Anat. and Lions' Sight Ctr., Univ. Calgary, Calgary, AB, Canada T2N 4N1.

Retinal ganglion cells (GCs), like other central mammalian neurons, exhibit abortive attempts at regeneration following axonal damage. We are developing a model of GC regeneration in rabbit retina, supported initially by peripheral nerve grafting (PNG) directly through the sclera and retina, in order to provide an established source of trophic factors, as well as a more favorable environment for axonal regeneration. The range of rabbit GC types are especially well characterized, and we may thus be able to determine specifically which of the rabbit's well-characterized GC types can be rescued with normal inputs intact. GC survival at 2 months is up to 30% at the retinal perimeter and less centrally. Of the central surviving GCs, a few hundred cells, distributed mostly near the PNG, are larger than normal, hyperchromatic (c+) and some are lobulated in contour. Some very large, round, hypochromatic (c-) GCs exhibit several features of "chromatolysis". Without optic nerve crush, GC loss in the segment of retina containing GCs axotomized by the PNG insertion is still massive, leaving less than 100 cells at 4 months. Most are very large (1,000 μm^2 or more) and c+. At 6 and 9 months reduced silver staining reveals similar cells with axons entering the graft. Most have at least some normal dendrites and a typical axon, but many also exhibit 1 or 2 convoluted processes branching in the inner and occasionally the outer plexiform layers. A few completely normal cells are present at 9 months, mainly in peripheral retina.

A NEW VISUAL SYSTEM MUTATION: ACHIASMATIC DOGS WITH CONGENITAL NYSTAGMUS. Robert W. Williams, Preston E. Garraghty, and Dan Goldowitz University of Tennessee, College of Medicine, Memphis, TN and Vanderbilt University, Nashville, TN.

A mutation has been identified in a family of black Belgian sheepdogs in which the entire retinal projection extends back into the ipsilateral optic tract. Tight inbreeding over three generations indicates that the mutation is an autosomal recessive with complete penetrance. The pattern of misrouting of optic axons is opposite that seen in albinos and other *c* locus mutants in which an excess of fibers cross at the chiasm. All achiasmatic mutants have a persistent horizontal nystagmus. The pendular eye movements are conjugate and are associated with head tilt and head oscillation. This behavioral complex is remarkably similar to that seen in some human albinos, and in both cases is probably related to disparities among sensory and motor maps.

The eye and fundus of mutants are normal, but in several cases, the optic papilla is abnormally small. With the exception of the chiasm, necropsy cases and MRI scans do not reveal any obvious central abnormalities. The callosum is intact and the hypothalamus and 3rd ventricle appear normal. Although we have not yet studied the lateral geniculate nucleus, we predict marked abnormalities in lamination.

The achiasmatic mutation may prove valuable as an animal model for human congenital nystagmus. It may also prove useful for developmental studies of axonal pathfinding in mammalian CNS and for studies of the generation, integration, and plasticity of sensory and motor maps.

We thank Drs. John Cummings, Alexander de Lahunta, John Hathcock, and Susan Tieman for their generous help in getting this project started. We especially thank Mary Young for her extraordinary efforts in breeding these dogs. Supported by NEI R01-6627.

PEPTIDES: RECEPTORS I

79.1

MOLECULAR CLONING AND CHARACTERIZATION OF THE GENES CODING FOR THE RECEPTORS FOR HUMAN GASTRIN-RELEASING PEPTIDE (GRP) AND NEUROMEDIN B (NMB). E. Giladi¹, M. Daly², S.L. Naylor², and E.R. Spindel¹. ¹Div of Neurosci, Oregon Rgl Primate Res Ctr, Beaverton, OR 97006, ²Dept of Cellular and Structural Biol, U Texas Health Sciences Ctr, San Antonio, TX 78284

Bombesin-like peptides are potent growth factors, neurotransmitters and paracrine hormones. GRP and NMB are the two characterized mammalian bombesin-like peptides and pharmacologically distinct receptors for these peptides exist. Previously we have reported the cloning of the mouse GRP receptor by means of expression in *Xenopus* oocytes and the cloning of a rat NMB receptor from an esophageal cDNA library. Sequence analysis revealed these receptors belonged to the 7-membrane spanning domain, G protein-linked receptor superfamily. Now to facilitate the study of the physiologic and pathologic roles of bombesin-like peptides in human systems, we have cloned the genes encoding their receptors. The human genes were isolated by screening an EMBL3 library with the respective rodent receptor cDNAs. Sequence analysis showed high homology between the rodent and human forms. Unlike the adrenergic receptors, introns separate in part the hydrophobic membrane spanning domains. Somatic cell hybrids were screened by polymerase chain reaction to localize the chromosomes encoding these genes. The GRP receptor was localized to the X chromosome between p11 and q11 while the NMB receptor was localized to chromosome 6 between q21 and q4ter. Southern blot analysis indicated that both these genes are single copy genes. Northern blot analysis showed highest levels of NMB receptor mRNA levels in esophagus, duodenum and antrum. Whether NMB, like GRP is localized only in neurons in the GI tract remains to be determined. Analysis of the promoter regions of the genes will allow determination of how these genes are regulated.
