Both individuals with Down Syndrome (DS) and patients with Alzheimer's disease (AD) develop characteristic pathologic changes in their brains, including granulovacular degeneration, neurofibrillary tangles, and neuritic plaques. Within the neuritic plaques of these individuals, a 42 amino acid peptide, β-amyloid or β/A4 accumulates. This peptide is derived from a much larger precursor molecule, encoded by the gene *amyloid precursor protein* (APP). APP is located on human chromosome 21 and is overexpressed in both DS and AD individuals. In DS individuals, overexpression results in large part because of triplication of the gene; in AD, the gene does not appear to be triplicated. Mice transgenic for but a portion of the APP molecule, the last 100 amino acids at the carboxy terminal (APP-C100) display altered brain morphology (Kammersheidt et al. 1992. Proc. Natl. Acad. Sci. USA, in press).

We have begun a systematic structural analysis of various lines of these APP-C100 transgenic mice, utilizing Golgi, light, and electron microscopic methods to provide finer structural correlates to the punctate vesicular immunoreactive material observed in hippocampus in lines of these transgenic mice with highest levels of transgene expression in the brain. We have extended systematic light and electron microscopic studies to other regions of the brain, including frontal cortex, entorhinal cortex, cerebellum, and spinal cord.

LATERAL PAW PREFERENCE IN INBRED MICE N.S. Waters\* and V.H.

Denenberg Biobeh. Sci. Grad. Deg. Prog., U. Conn., Storrs, CT 06269.

We have developed a novel measure of behavioral laterality in inbred mice, the lateral paw preference (LPP) test (Waters and Denenberg, *Phys. Behav.* 50, 853). In this test a small unit, with preferred food available through two holes, is placed in the animals' cages. Each hole is most easily accessed by one paw, and the amount of food consumed from each hole is measured. We now report the results from 653 mice of 27 genotypes. Most mice were tested twice on LPP and once on the Collins' paw preference test, in which subjects reach for food from a centrally located tube, and the number of right-pawed reaches (RPE) out of 50 reaches is measured (Collins, J. Hered. 59, 9). A weak but significant bias towards the left was found on the Collins' test (\$\frac{64.6\times \text{sinistral;}}{\chi^2=4.83}, \rho<.05; \rmspace(\text{N=581}), \text{sinillar to what has been previously reported. The population bias in the LPP test was stronger and in the opposite direction, with 60.6\times dextral (\$\chi^2=29.59\$, p<.0001; \rmspace{N=653}). A Spearman correlation of 0.147 (p<.01, N=588) was found between LPP and RPE direction measures, and of 0.108 (p<.02, N=588) for magnitude of asymmetry, regardless of direction. Though significant, these correlations are small enough to be negligable. There were significant differences among the strains for magnitude of asymmetry on both measures. Using strain means, a Spearman correlation of 0.577 (p<.01, N=26) was found for the magnitude measure, while the correlation for direction was non-significant (r=0.196, p>.1). Collins has reported that magnitude of asymmetry has a genetic basis, and the strain correlation implies that this basis may be partially shared with the LPP absolute asymmetry measure, while direction of asymmetry on the two tasks is clearly under the control of different, probably epigenetic, factors. Supported, in part, by NIH grant HD20806. We wish to thank Drs. E. Eicher, L. Mobraaten, C. and R. Wimer, who generously supplied mice.

RECOMBINANT DROSOPHILA CYSTATIN AND ITS "ICELANDIC" MUTANT. M.P.Brown and L.E.Kelly\* Dept Genetics, Melbourne University, Parkville, Victoria 3052, Australia.

We aim to develop a model system in <u>Drosophila</u>

we aim to develop a model system in <u>Drosophila</u> melanogaster to investigate amyloidogenesis.

A <u>Drosophila</u> complementary DNA (cDNA), cloned and sequenced in our laboratory, has been expressed as a fusion protein which inhibits cysteine protease activity. The genetic lesion of Hereditary Cystatin-C Amyloid Angiopathy (HCCAA, formerly Hereditary Cerebral Hemorrhage with Amyloid of Icelandic type), which results in substitution of substitution of culturning for legislaring accession. substitution of glutamine for leucine in a region conserved in  $\underline{Drosophila}$  cystatin, has been reproduced in the recombinant fusion protein. This mutant fusion protein is a three-fold less potent inhibitor of cysteine protease activity than wild type fusion protein.

We postulate that defective regulation of cysteine

protease activity is responsible, directly or indirectly, for cerebral hemorrhage in HCCAA.

### 304.12

CONGENIC RECOMBINANT ANIMAL MODEL SYSTEMS: A TOP DOWN GENETIC STRATEGY TO ANALYZE QUANTITATIVE NEUROBEHAVIORAL TRAITS. C. Vadasz. Laboratory of Neurobehavioral Genetics, Nathan Kline Institute for Psychiatric Research, Orangeburg, NY 10962 and New York University Medical Center, 550 First Avenue, New York, NY. 10016

Genetically standardized inbred mouse and rat strains are highly variable in neural and behavioral traits. However, in spite of concentrated efforts, genes responsible for polygenic strain differences have not been mapped and genetic correlation between neural and behavioral traits have not been established because inbred strains and recombinant inbred strains differ at a large number of loci. We suggest, that these difficulties can be circumvented by developing Congenic Recombinant Animal Model (CRAM) systems. CRAM systems are constructed by transferring a set of genes responsible for a phenotypic strain difference to the same genetic background by a series of backcrosses to one of the parental strains with concomitant selection for the desired trait. Subsequent inbreeding results in recombinant fixation of the transferred genes. In a CRAM system the genetic background of the lines is similar, however, they carry elements of the gene set which was responsible for the original strain difference. A CRAM system, focusing on the mesotelencephalic dopamine system, is being developed in our laboratory.

A GENETIC APPROACH TO THE NEURODEVELOPMENTAL HYPOTHESIS FOR SCHIZOPHRENIA Vicente, W.G. Honer\*, D. Sidenberg, A. Bassett, F. Macciardi,

J.L. Kennedy.
Neurogenetics Section, Clarke Institute of Psychiatry, Toronto, Canada

The lack of a clear genetic etiology in schizophrenia and the large number of possible causative genes make it helpful to design strategies that select candidate genes for the disorder. Several monoclonal antibodies showing different binding affinities to schizophrenic versus control brains have been identified. One antibody, called EP10, was used to screen two cDNA expression libraries, one derived from a neuroblastoma cell line and another from human temporal cortex, in an attempt to isolate candidate genes.

Clone WH4 was isolated from the temporal cortex library. Its 381 base pairs were sequenced and WH4 was assigned to chromosome 17, close (lod score >11 by genetic linkage) to two loci involved in the development of the nervous system, the nerve growth factor receptor (NGFR) and the homeobox-2 gene cluster (HOX2@). Preliminary linkage analysis using a two gene hypothesis was conducted in an Italian schizophrenic family and has given a slight positive result (Lod score = +1.1 at theta = 0.0).

Several lines of evidence indicate that a major etiological factor in schizophrenia is a disturbance in the development of the brain. The candidate gene WH4 is located near genes implicated in brain development and displays homology with an integrin molecule. Integrins have been implicated in brain development, as well as in cell adhesion. These factors prompt us to determine the role of this gene in neurodevelopment and its possible involvement in schizophrenia.

MYOBLAST TRANSFER THERAPY( MTT) STRENGTHENS LEG MUSCLES OF DUCHENNE MUSCULAR DYSTROPHY (DMD) BOYS. P.K. Law\*. T. Goodwin, O. Fans, V. Duggirala, C. Larkin, J. Florendo, D. Kirby, M. Deering, H. Li, M. Chen, T. Yoo, J. Cornett, L. Li, A. Shirzad, T. Ouinley, and R. Holcomb, Cell Therapy Research Foundation, Memphis, TN 38117.

Therapy Research Foundation, Memphis, TN 38117. Five billion normal myoblasts were injected into each of 32 DMD boys aged 6-14 to assess the feasibility, safety and efficacy of Phase II MTT. Forty-eight i.m. injections into 22 muscles took 10 minutes under general anesthesia. Eleven boys had received 8 million myoblasts each 1 year ago in Phase I MTT. In Phase II eight of them had their myoblasts subcultured from reserves frozen 1 year ago. The remaining boys received myoblasts cultured from 1-g muscle biopsies of normal males who might or might not be histocompatible with the recipient. Cyclosporine (Cy) is administered for 6 months after MTT to facilitate donor cell survival. There has been no evidence of an adverse reaction to MTT or Cy as determined by serial laboratory evaluations including electrolytes, creatinine and urea. Objective functional tests using the KinCom Robotic Dynamometer were conducted on 13 subjects aged 6 to 13 before MTT and at 3 months after MTT. Of the 69 knee subjects aged 6 to 13 before M11 and at 3 months after M11. Of the 69 knee extensors, knee flexors, and plantar flexors tested, 43% showed mean increase of 41.3% in isometric force, 38% showed no change, and 19% showed continuous force reduction of 23.4%. The remaining subjects await the 3-month post-MTT evaluation. The results indicate that 1) MTT is safe; 2) MTT increases muscle strength in DMD: 81% of the muscles tested showed either increase in strength or did not show continuous loss of strength; 3) more than 5 billion myoblasts can be cultured from 1 g normal muscle biopsy, providing unprecedented numbers of cells for MTT; 4) myoblasts, frozen over one year, retain the ability to proliferate from 10 million to 5 billion, and to form normal myofibers; 5) injections of 5 billion myoblasts have not provoked any immunologic rejection symptoms in the Phase II subjects, eleven of whom received 8 million myoblasts in Phase I MTT a year ago; 6) it is safe to perform multiple injections of myoblasts into lower limb muscles without formation of emboli; and 7) donor cell rejection by the recipient can be prevented with Cy when properly managed. (Supported by public donations)

INTRAPAIR-DISCREPANCY IN RIDGE-COUNT OF MZ TWINS AS A MARKER OF SECOND-TRIMESTER DISTURBANCES IN FETAL-DEVELOPMENT, H. Stefan Bracha, M.D.\*, Edward Taylor, M.S.W., Ph.D., Beverly Linington, M.A., Beata Przybyla, Ph.D., Child and Adolescent Psychiatry Division, Univ. of Arkansas for Med. Sciences and Psychiatry Service, VAMC, 116A1/NLR, North Little Rock, Arkansas 72114-1706.

The second-prenatal-trimester is a critical period of neural cell migration. Fetal injuries in second-trimester are difficult to study because of a lack of obstetrical markers. The dermal anatomical feature called ridge count is a stable anthropometric measure (Bracha et al 1991, 1992) and MZ twins have nearly identical ridge count. We took advantage of the fact that prenatal insults, especially ischemias, often do not affect both MZ twins equally. Since dermal cells migrate to form ridges during the second-trimester, we hypothesized that any discrepancies in the ridge count between MZ twins may be a marker of the second-trimester injuries to one win. METHODS: 30 mothers of MZ twins completed a questionnaire about deleterious pregnancy events. We also measured intra-pair about deleterious pregnancy events. We also measured intra-pair differences in ridge count within pairs. RESULTS: The second-trimester subscale of deleterious events was the best predictor of increased intrapair differences in ridge count and accounted for 36% of variance. The third and first trimesters accounted for less than 2%. Conclusion: MZ discrepancy in ridge count may serve as a marker for prenatal events that might affect only one MZ fetus in the second-trimester. Sup. by grant MH-43537 and the U.S.-DVA

AMYLOID B PROTEIN AND AMYLOID P COMPONENT IN ALZHEIMER'S DISEASE. T. Duong\* and P. J. Acton. Terre Haute Center for Medical Education, Indiana Univ. Sch. of Med., Terre Haute, IN 47809.

The distribution of amyloid B protein (ABP) was compared to that of amyloid P component (APC) in lesions characteristic of Alzheimer's disease (AD): the amyloidotic blood vessels (ABV), senile plaques (SP) and neurofibrillary tangles (NFT). Blocks from the hippocampus and neocortical regions of AD patients and normal aged controls were collected postmortem and fixed in 4% phosphate-buffered paraformaldehyde. Cryostat sections (30  $\mu$ m thick) were processed by single- and double-antigen immunohistochemistry. ABP and APC were localized to ABV, which were mostly penetrating pial arterioles. Although the 2 proteins could be co-localized on the same vessels, their distribution did not always coincide: some portions of ABV were more immunoreactive to either ABP or APC. ABV immunoreactive only to one or the other protein were also seen. SP were labeled more often by ABP than APC antiscrum. In neocortical areas, APC-immunoreactive SP were mostly localized in superficial layers of the cortex whereas ABP-labeled SP were seen throughout the gray matter. Both ABP and APC labeled the corona and the core of SP, as well as diffuse SP in layer I. In SP double-labeled for ABP and APC, APC also labeled dystrophic neurites whereas ABP did not. APC was localized to the majority of NFT in all regions studied whereas ABP was only observed in occasional NFT in the hippocampal CA 1 region and in the layer II of the entorhinal cortex. Although occasional NFT double-labeled for ABP and APC were seen, the NFT populations labeled by ABP and APC were mostly segregated. Thus, the distribution of ABP and APC in AD lesions is not similar and this may reflect differences in their origin and /or the process leading to their incorporation in AD lesions. This work was supported by the Turken Scholarship from the Alzheimer's Disease and Related Disorders Association, Inc.

# 305.3

THE EXPRESSION OF CELL ADHESION MOLECULES IN ALZHEIMER'S DISEASE K.C. Breen & A.M. Gillian. Dept. of Pharmacology, University College, Belfield, Dublin 4, Ireland. (SPON: Brain Research

The B-Amyloid Precursor Protein (BAPP) is a membrane bound glycoprotein which has been implicated in the mediation of neural cell adhesion. This protein is abnormally degraded by protoelysis in Alzheimer's disease (AD) to the 42 amino acid BA4 polypeptide which is a major component of the characteristic amyloid plaques. It was of interest, therefore, to examine the expression of other cell adhesion molecules in AD to investigate any parallel changes.

The nerve cell adhesion molecule (NCAM) is a cell surface

The nerve cell adhesion molecule (NCAM) is a cell surface glycoprotein whose sialic acid content is developmentally regulated. Western blot analysis has demonstrated that although total brain levels of NCAM appear unaltered in AD, there is the appearance of an extra 170kd band, suggestive of altered proteolytic processing of the protein. Furthermore, there is an increase in the soluble form of NCAM in both serum and CSF.

There is also evidence of altered glycosylation in AD. While there is no reappearance of the embryonic (polysialylated) form of NCAM in AD, there is a significant decrease in brain membrane sialyltransferase levels, and also the levels of the carbohydrate adhesion epitope L2/HNK-1.

This may result in an altered neural adhesive state in AD which may alter cell-cell contact and thus contribute to the neurodegenerative process.

### 305.2

AMYLOID PRECURSOR PROTEIN(APP) IMMUNOREACTIVITY IN ALZHEIMER'S DISEASE BRAIN WITH APP 717 MUTATION. N.Nykina, K.Hashimoto, H.Mizusawa, I.Nakano, I.Kanazawa, K.Murayama\*, Department of Neurology, University of Tokyo, Japan

The amyloid core in senile plaques of Alzheimer's disease is composed of beta protein with a molecular weight of 4kD. Whether beta protein accumulation in AD is a byproduct of Alzheimer's pathology or a primary pathology has not been determined. Recent discovery of familial Alzheimer's disease which is linked to APP codon 717 mutation suggests that the beta protein accumulation is a primary pathology. It is important to clarify whether the processing of APP in those cases with the mutation is different from the processing in other cases. In this study we investigated the distribution of APP immunoreactivity in AD brains with Val-lie mutation.

Antibodies used in this study were the following:monoclonal antibody against synthetic peptide residues 45-62 of APP, polyclonal antibodies against synthetic peptide residues 666-695 of APP,beta protein, human tau protein, and ubiquitin. Tissue sections from 2 cases with the mutation and 8 cases without the mutation were examined.

APP antibodies stained neurites around senile plaques and somtimes neuronal cell bodies. Antibodies against beta protein immunostained amyloid and diffuse plaques. Antibodies against tau and antibodies against ubiquitin immunolabeled tangles and neurites around senile plaques. Those immunostainings were observed in cases with and without the mutation. We could not find any qualitative differences in those cases, suggesting that those immunoreactivities observed in this study appear in the later phase of Alzheimer's pathological cascade.

THE ROLE OF AMYLOID PRECURSOR PROTEIN (APP) IN NEURITIC OUTGROWTH AND ABERRANT SPROUTING IN ALZHEIMER'S DISEASE. E. Masliah\*. Y. Lev-Ram, M. Mallory, N. Ge, M. Ellisman, T. Saitoh. San Diego Microscopy & Imaging Resource, Dept. of Neurosciences, University of California, San Diego, La Jolla CA 92093

Previous studies have shown that APP is localized in GAP43-positive aberrant sprouting neurites in the plaque (Masliah et al, Brain Res 574:312,1992). Thus APP might by involved in neurodegeneration in Alzheimer's disease (AD) by inducing an abnormal sprouting response. In order to study the role of APP in neuritic outgrowth, we examined organotypic cultures of neonatal rat (P1) hippocampus labeled with DiI and treated with N-terminal APP fragments and amyloid B using time-lapse microscopy. In control preparations, DiI-labeled neuritic processes were imaged for 35 min and perfused with vehicle. Processes of neurons in control preps extended at rates of approximately 20 µm per hr. Experimental cultures perfused with a 100 µM amyloid ß solution (1-28, Sigma) and imaged for 35 min displayed a relative increase in fluorescence and motility. Process outgrowth was further enhanced with time. Further analysis of the presence of APP in growth cones was performed in brain sections of P1 rats, as well as organotypic culture slices. Laser-scanning confocal imaging of doubleimmunolabeled sections showed that a subpopulation of the anti-GAP43oreactive growth cones contained APP immunoreactivity in the neocortex. These fine long neuritic processes were also positive with antibodies against phosphorylated neurofilaments (SMI 312) and were GFAP negative. APP strongly immunolabeled neurons in the inner cortical layers, while GAP-43 strongly immunolabeled the neuropil surrounding them. These observations suggest a possible role for APP in neuritic outgrowth and might explain the extensive neuritic response found in plaques of AD.

LOCALIZATION OF AMYLOID PRECURSOR PROTEIN IN SELECTIVE POSTSYNAPTIC DENSITIES OF RAT CORTICAL NEURONS. <u>K. Shigematsu\*, P. L. McGeer and E. G. McGeer.</u> Kinsmen Lab. of Neurological Research, Department of Psychiatry, University of British Columbia, Vancouver, B.C. Canada V6T 1Z3

One of the hallmarks of Alzheimer pathology is extracellular deposition of amyloid which is derived from a larger glycoprotein called amyloid precursor protein (APP). Although APP is thought to be a membrane associated protein, widely distributed in various cells including neurons, its ultrastructural localization in neurons is still unclear. We now report the results of immunoelectron microscopy using three specific antibodies against different synthetic fragments of APP. All three antibodies demonstrated a localization to organelles such as the Golgi apparatus, endoplasmic reticulum and vesicular-like structures. A minor proportion of staining with all three was on selective postsynaptic membranes, whereas staining of presynaptic membranes was not observed. morphological evidence suggests that one role of APP may be in association with the function of selective synapses. (Supported by a grant from the Alzheimer Society of B.C.)

LYSOSOMAL HYDROLASES COLOCALIZE WITH β-AMYLOID IN DIFFUSE PLAQUES IN ALZHEIMER AND DOWN SYNDROME BRAIN. A.M. Cataldo. D.Hamilton, P.A. Paskevich, D.A. Mann, R.A. Nixon. McLean Hosp., Harv. Med. Sch., Belmont, MA, and Dept. of Path., Univ. of Manchester, U.K.

Our previous studies in Alzheimer Disease (AD) and Down Syndrome (DS) brains support a relationship between the presence of  $\beta$ -amyloid protein and elevated levels of lysosomal hydrolase activity. Hydrolases accumulate abnormally in neurons at risk to degenerate and are abundant in classical senile plaques (SP) of the neocortex and hippo campus. Intensely-stained neurons were often associated with classical SP. To further investigate this relationship, we studied the distribution of lysosomal hydrolases in diffuse type SP of the neocortex and cerebellum. Tissue sections from 20 AD and DS brains were analyzed immunocytochemically with antisera to cathepsin D,  $\beta$ -hexosaminidse A, and  $\beta$ -amyloid (residues 1-24). SP were identified histologically with a modified Bielschowsky stain and thioflavin S. In the cortex, diffuse SP were immunoreactive to hydrolase and  $\beta$ -amyloid antisera. These antisera colocalized in many SP. In the cerebellum, elevated amounts of hydrolase immunoreactivity were present extracellularly in most diffuse SP of the molecular layer in a similar topography to that of  $\beta$ -amyloid detected immunocytochemically. A subset of Purkinje cells in DS and AD brains were intensely hydrolase positive. In many cases, hydrolase positive diffuse SP were located in the vicinity of intensely stained dendritic arborizations of these Purkinje cells. Hydrolase-containing SP were also seen in the Purkinje cell layer. Perikarya of dying neurons are a principal source of hydrolases in many class SP; however, in diffuse SP the degeneration of different structures, such as dendrites and other cell types, may account for the association of lysosomal hydrolases with  $\beta$ -amyloid deposits.

SPECIFIC METALS AND SALTS PROMOTE OR INHIBIT B-AMYLOID DEPOSITION ONTO EXISTING PLAQUES IN ALZHEIMER DISEASE BRAIN J.R. Ghilardi, C.J. Allen, E.R. Stimson, H.V. Vinters, J.E. Maggid, P.W. Mantyh, Mol. Neurobio. Lab (151) VA Med. Cntr., Mpls., MN 55417; Dept. Pathol., UCLA, LA, CA,90024; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston,

B-Amyloid peptide (BA4), a 39–43 amino acid peptide, is the primary constituent of senile plaques and cerebrovascular deposits in Alzheimer disease (AD). Recently it has been reported that BA4 neurotoxicity is related to its aggregation state. To explore the factors which influence the deposition of BA4 onto amyloid plaques and cerebrovascular amyloid, an in vitro assay was developed using radioiodinated BA4 in conjunction with homogenates or thin sections of AD cortex. This system was used to address the effect various metals, salts, pH and temperature have on the deposition of radioiodinated BA4 onto pre-existing amyloid deposits in AD brain. The results from these experiments suggest that the presence of specific metals and salts can have pronounced effects on the ability of BA4 to deposit onto preformed amyloid deposits. These factors may be important in regulating the growth and toxicity of amyloid deposits in AD. Supported by the NIH and the VA.

STELLATE CELLS EXPRESSING APP, AMYLOID P AND LACTOFERRIN IN THE CEREBELLAR CORTEX IN ALZHEIMER AND ELDERLY CONTROL BRAINS. T. Kawamata, P. L. McGeer and A. Jakubovic\* Kinsmen Lab. of Neurol. Res., U. Brit. Columbia, Vancouver, Canada, V6T123

Amyloid deposits are frequent in the cerebellar cortex in Alzheimer disease (AD), but not in aged controls. Diffuse plaques are the most common type of amyloid deposits in the molecular layer, and emerging evidence suggests that such amorphous, largely nonfibrillary deposits may precede the appearance of altered neuritc and glial elements during development of consolidated senile plaques. We studied the distributions of APP (APP<sub>18-38</sub>, APP<sub>274-286</sub>, APP<sub>528-540</sub>, APP<sub>597-</sub> 620, and APP<sub>681-695</sub>), complement protein C4d, amyloid P component (AP) and lactoferrin (LF) in the molecular layer of the cerebellum in AD and aged controls. The antibodies to APP<sub>597-620</sub>, C4d, AP and LF stained diffuse plaques and all the antigens, except C4d, were expressed in stellate and basket cells in both AD and controls, with the staining being upregulated in AD cases. In AD some of the positive dendrites and axons were closely associated with diffuse plaques. These data suggest that diffuse plaques may derive from the neurites of stellate neurons which show upregulated expression of APP, AP and LF in the molecular layer of the cerebellum in AD.

NEUROPATHOLOGICAL STUDY OF THE BRAINS OF THREE AGED CHIMPANZEES. M. Gearing. J. Tigges and S. S. Mirra. VA Medical Center, and School of Medicine and Yerkes Regional Primate Research Center of Emory University, Atlanta, GA 30322.

While vascular amyloid and senile plaques have been described in the

While vascular amyloid and senile plaques have been described in the brains of aged mammals such as dogs, bears, and monkeys, neuropathological studies of aged great apes have been limited. We had the opportunity to examine the brains of three elderly chimpanzees: two females aged 59 and 56 and a male aged 45 years. External abnormalities were not observed in any of the brains. A battery of stains and immunohistochemical procedures revealed BA4 amyloid deposition in meningeal and cortical vessels in both females. This was particularly striking in the 59 year old. The cortex and hippocampus in this older female also displayed diffuse plaques, predominantly in a perivascular distribution, as well as rare neuritic plaques. Preliminary ultrastructural study revealed fibrillar amyloid in vessel walls, but extravascular fibrillar amyloid could not be detected in plaque-rich regions. No amyloid was found in the brain of the male. Alz-50-positive neurons were seen in all three brains in the absence of any detectable neurofibrillary tangles or immunoreactivity with Tau-1 antibody. These Alz-50 labelled neurons were rare in the male, but were more readily observed in the two females, particularly in the lateral putamen. Ubiquitin immunohistochemistry revealed scattered neurons with cytoplasmic label and "dot-like structures" in the neuropil. In summary, these findings recapitulate those described in normal elderly people and emphasize the value of aged great apes as animal models for the study of changes related to aging and Alzheimer's disease. RR-00165, AG00001, AG10130, and VA Merit Award.

# 305.10

SPECIFICITY, SENSITIVITY AND ABILITY TO QUANTIFY AMYLOID DEPOSITS IN ALZHEIMER DISEASE BRAIN USING EITHER RADIOIODINATED BA4, THIOFLAVIN S, CONGO RED OR ANTI-A4 ANTIBODIES

C.J. Allen, J.R. Ghilardi, E.R. Stimson, H.V. Vinters, M.W. Dysken\*, J.E. Maggio, P.W. Mantyh, Mol. Neurobio, Lab (151) and GRECC, VA Med. Cntr., Mpls., MN 55417; Dept. Pathol., UCLA,LA, CA, 90024; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115

The salient neuropathological feature of Alzheimer disease (AD) is the presence of a high density of amyloid plaques in the brain tissue of victims. Recent data has suggested that there is a correlation between β-amyloid peptide (βA4) deposition and the clinical severity of the dementia and that the amyloid plaques themselves are neurotoxic both *in vivo* and *in vitro*. A key tool in diagnosis of AD is the ability to visualize, characterize and quantify the amyloid deposition in AD brain. We have compared the sensitivity and specificity of 4 methods, radioiodinated βA4, thioflavin S, Congo red and anti–A4 antibodies, for their ability to label amyloid deposits in both fixed and unfixed AD brain. While each of these techniques of labeling amyloid deposits has its strengths, radioiodinated βA4 is unique in that it is highly sensitive, specific and easy to quantify. Supported by the NIH and the

SERUM, ASSOCIATION CORTEX, AND CEREBELLAR C14 CONCENTRATIONS IN ALZHEIMER'S DISEASE AND NONDEMENTED ELDERLY PATIENTS. L. Brachova\*, L.-F.

NONDEMENTED ELDERLY PATIENTS.

Lue, J. Schultz, T. El-Rashidy, and J. Rogers.

Research Institute, Sun City, AZ 85372.

Concentrations of Clq were assayed by Western blot analysis of sera, superior frontal gyrus, and cerebellar homogenates from 5 Alzheimer's disease (AD) and 5 nondemented elderly (ND) control patients. Immunoreactive serum Clq (ND) control patients. Immunoreactive serum Clc concentrations did not differ in the two groups, whereas in concentrations did not differ in the two groups, whereas in the same patients AD superior frontal gyrus exhibited five-fold more immunoreactive Clq  $(0.460 \pm 0.052 \, \mu g \, \text{Clq/mg}$  total soluble protein) than ND superior frontal gyrus  $(0.088 \pm 0.011 \, \mu g \, \text{Clq/mg}$  total soluble protein). Cerebellar concentrations from these patients averaged  $0.084 \pm 0.007 \, \mu g \, \text{Clq/mg}$  total soluble protein in AD samples and  $0.053 \pm 0.001 \, \mu g \, \text{Clq/mg}$  total soluble protein in ND samples. The significant elevation of Clq in the superior frontal gyrus of AD patients and the relative paucity of Clq in the cerebellum correlates well with the extensive AD pathology of the former structure and the relative patching of Criq in the extensive AD pathology of the former structure and the relative lack of degenerative pathology or clinical symptomatology of the latter in AD. Because  $\beta$ -amyloid is present in the AD cerebellum (albeit in a diffuse rather than compacted form), these data suggest that other factors such as complement activation may be necessary for the full expression of  $\beta$ -AP mediated neuritic damage.

# 305.13

ALZ-50 G1-IMMUNOREACTIVITY IN THE BABOON BRAIN: ENHANCED EXPRESSION IN AGING. Y. Ma. C. Anderson\* 1 E.J. Mufson, and J.H. Kordower. Dept. Neurological Sciences, Rush Presbyterian Med. Ctr. and <sup>1</sup>Dept. of Anatomy and Cell Biology, Univ. Illinois. Sch. Med., Chicago Illinois 60612

Initial studies suggested that the protein Alz-50 may be an indicator of early degenerative changes in Alzheimer's disease. Recently, Alz-50immunoreactivity has been observed in the normal human brain as well as in select nonprimate species. Therefore, we examined the expression of the Ab42, a class switch clone of the Alz-50 IgM antibody in young (age 4, 7 years old) and aged (21 and 33 year old) baboons. Baboons were perfused transcardially with 4% paraformaldehyde, their brains hemisected, and cut in the coronal plane (40 μm) on a sliding knife microtome. Only scattered Ab42-immunoreactivity was observed within thalamic and limbic structures in young baboons. In contrast, aged baboons displayed extensive Ab42-immunoreactive profiles within the neo and limbic cortices as well as subcortical structures which have been shown previously to degenerate in the aged and diseased human brain. These include the cingulate gyrus, entorhinal, and temporal neocortices, septum, the nucleus basalis, paraventricular nucleus, amygdala, and subiculum. Immunoreactivity was granular and principally localized within the peripheral portions of the cytoplasm. This age-related difference in Ab42 expression was specific since staining patterns of numerous other cytoskeletal proteins and neurotransmitter markers were similar in young and aged baboons. This study suggests that the Ab42 protein may be a marker for age-related changes in the primate central nervous system. (Supported by AG09466, AG10161, IDPH).

SOLUBLE DERIVATIVES OF APP: A POTENTIAL RELATIONSHIP TO ABNORMAL CALPAIN I ACTIVATION IN ALZHEIMER BRAIN. T. Honda, Belmont, MA. 02178; University of Massachusetts, Worcester, MA

Alzheimer amyloid precursor protein (APP) is considered to be a membrane glycoprotein. To examine the processing of APP we determined the subcellular localization of APP and quantified the proportions of APP forms in control and Alzheimer disease (AD) brain. Homogenates of prefrontal cortex were separated into four fractions: soluble, microsomal, Triton X-100 soluble and insoluble membrane fractions. Protein was analyzed by SDS-PAGE and Western Blot using a monoclonal antibody to the N-terminal domain (Boehringer-Mannheim), polyclonal antisera to APP 578-606, or the amyloid β region (1-28 and 12-28). In both control and AD samples, APP forms (100-130 kDa) were present in soluble fractions that were immunoreactive only with the antibodies which recognize the secreted domain of APP. In the course of other studies demonstrating an abnormal activation of calpain I (µCANP) in AD brain (Saito et al., these proceedings), we examined whether calpain activation was associated with alterations in the content of membrane and soluble APP forms. We observed that the concentration of soluble APP forms in brain displayed a very high inverse correlation with the degree of calpain activation (i.e., the percentage of the 76 kDa autolytically activated isoform of calpain) in AD brain (r=0.885, n=13, p <0.0001). The content of membrane-associated APP was comparable in AD and control brains and did not correlate with calpain I activation. The significance of the soluble APP correlation is unclear at present, although a relationship between calpain activity and membrane protein trafficking and processing is reasonable in view of the localization, substrate specificity and suspected biological roles of calpain I.

COMPLEMENT ACTIVATION FAILS IN DIFFUSE PLAQUES OF THE ALZHEIMER'S DISEASE CEREBELLUM. L.-F. Lue\*, and J. Rogers. Sun Health Research Institute, Sun City, Arizona 85372.

Immunohistochemistry of  $\beta$ -amyloid peptide ( $\beta$ -AP), complement proteins C4d, C3d, and C5b-9, and the HLA-DR marker LN-3 was performed on 40  $\mu$ m cerebellar sections from Alzheimer's disease performed on 40  $\mu$ m cerebellar sections from Alzneimer's alease (AD) and nondemented elderly (ND) patients. Morphologically, two major types of  $\beta$ -AP deposit were identified: a diffuse type and a compacted type. Diffuse plaques were rare and compacted plaques were absent in ND cerebella. In AD cerebella, both diffuse and compacted plaques were observed, although the former were much more abundant. C4d immunoreactivity co-localized with diffuse and compacted plaques. C3d immunoreactivity colocalized predominately with compacted plaques, but could occasionally be observed in diffuse plaques. Unequivocal C5b-9 immunoreactivity was present only in compacted plaques.

Activated microglia in the AD brain are known to express the Activated microglia in the AD brain are known to express the LN-3 antigen and to possess complement receptors. In AD cerebella, LN-3 positive microglia were consistently clustered around compacted plaques, whereas no such association was found with diffuse plaques. In the classical complement cascade, around compacted plaques, whereas no such association was found with diffuse plaques. In the classical complement cascade, formation of C4d is a relatively early step and formation of C5b-9 is the final step. These findings are therefore consistent with the hypothesis that complement activation runs to completion in the vicinity of compacted  $\beta$ -AP containing plaques, but fails to do so in the context of diffuse plaques. Since diffuse plaques greatly predominate in the AD cerebellum, these data may also help explain the relative paucity of cerebellar pathology and clinical symptomatology in AD. clinical symptomatology in AD.

COLOCALIZATION OF CHOLINESTERASES WITH AMYLOID IN SENILE PLAQUES OF AGED AND ALZHEIMER'S DISEASE PATIENTS.

P. Gómez-Ramos\* and A. Morán. Dept. Morfologia. School of U.A.M. Madrid Spain.

Medicine. U.A.M. Madrid Spain.

A sensitive modified Karnovsky-Roots protocol for Acetylcholinesterase (AChE) and Butyrylcholinesterase (BChE) (Mesulam and Morán, 1987) showed positivity for either of both enzymes in all types of senile plaques (SP) of aged and Alzheimer's brains: diffuse, classical with or without a central core and burned out SP. In addition, AChE has been ultrastructurally localized in diffuse plaques as well as in both the core and the crown of classical plaques (Gómez-Ramos et al. 1992) al, 1992).

To study the colocalization of cholinesterases with amyloid in SP the following procedures were used: a) Quantitative comparison of cholinesterase positive SP (either AChE or BChE) and these SP stained with either Thioflavine-S related sections. b) Double-procedures conbining cholinesterase histochemistry, (ACHE or BCHE) with either Thioflavine-S staining or A4 protein immunocytochemistry, in the same section. The results obtained suggest that all Thioflavin-S positive SP are also positive for at least one of both cholinesterases, whereas the Thioflavine-S negative preamyloid diffuse SP, only in some occasions were cholinesterase positives. Thus, it seems that ACHE and/or BChE colocalize with amyloid even before it acquires the B pleated configuration which leds to Thioflavin-S staining. Supported by FISS nº 90/0259. or A4 protein immunocytochemistry, in adjacent or closely related sections. b) Double-procedures combining

BETA AMYLOID DEPOSITION IN SQUIRREL MONKEYS. G. Murphy, L.S. Forno\*, L.E. DeLanney, B. Greenberg, J.W. Langston. DVA Medical Center, Palo Alto, CA 94304, California Parkinson's Foundation, San Jose, CA 95128, and The Upjohn Co., Kalamazoo, MI 49001.

Amyloid deposition in plaques and cerebral vessels was studied in two groups of squirrel monkeys of various ages. The first group consisted of control monkeys aged 3, 10, and 15-20 years, with 4 monkeys in each subgroup. The second group included 32 monkeys with a minimum age of 15 (14 controls, 18 MPTP treated). For the first group, methacam-fixed sections from the frontal and occinital pulses were reacted with anythodise to the 8 treated). For the first group, methacam-fixed sections from the frontal and occipital poles were reacted with antibodies to the β-amyloid peptide (βAP) and to the β-amyloid precursor protein (βAPP), and stained with Congo Red (CR). βAP and CR positive plaques and vessels were seen in three of the oldest animals, and diffuse βAP plaques were seen in one 10 year old, but the other animals were negative. βAPP was observed in plaque neurites in the same three old animals, but the diffuse plaques in the 10 year old had no βAPP. In the second group, formalin fixed sections old had no BAPP. In the second group, formalin-fixed sections containing cerebral cortex and forebrain subcortical structures were examined with CR and Bielschowsky stains, and with the BAP antibody. 27 of 32 animals (84%) had congophilic angiopathy, and BAP in plaques and vessels. These results suggest that as in humans, amyloid deposition is rare at younger ages, and although most older monkeys show marked Alzheimer-like amyloid pathology, considerable variation exists, and some older animals escape such changes.

PLAOUES, CYTOSKELETAL CHANGES AND CELL DEATH IN THE ALZHEIMER HYPOTHALAMUS. J.A.P. Van de Nes<sup>1,2</sup>\*, W. Kamphorst<sup>3</sup>, R. Ravid<sup>1</sup>, D.F. Swaab<sup>1</sup>. <sup>1</sup>Netherlands Institute for Brain Research; <sup>2</sup>Department of Psychiatry, Free University; <sup>3</sup>Department of Neuropathology, Free University, all in Amsterdam, The Netherlands. (Spon: ENA)

It is generally assumed that in the brains of patients with Alzheimer's disease the cytoskeletal changes are locally induced by plaques, followed by cell death. To test this hypothesis, sections from the suprachiasmatic, sexually dimorphic, paraventricular and supraoptic nuclei were stained with Alz-50 and anti-A4.

The results showed that 1) the supraoptic nucleus and the paraventricular nucleus, which do not undergo cell loss during aging or in Alzheimer's disease, did not stain for Alz-50-labelled cytoskeletal changes or anti-A4 positive plaques, thus supporting the cascade hypothesis. However, 2) cytoskeletal changes were observed in the sexually dimorphic nucleus of all Alzheimer patients but not in controls, while in this nucleus a similar decline in cell number was found during aging and in Alzheimer's disease. 3) The suprachiasmatic nucleus in Alzheimer's disease showed some cytoskeletal changes while this was not the case in the suprachiasmatic nucleus of normal subjects. In none of the patients studied was any plaque observed in the suprachiasmatic nucleus

In conclusion, the occurrence of amorphic plaques, cytoskeletal alterations and cell death seem to be independent phenomena in the hypothalamic nuclei, rather

Brain tissue was obtained from the Netherlands Brain Bank in Amsterdam (Coordinator Dr. R. Ravid)

BETA AMYLOID PROTEIN IMMUNOREACTIVE SENILE PLAQUES IN INFANTILE DOWN'S SYNDROME. Ter-Minassian M, Kowall NW, McKee AC\*. Massachusetts General Hospital. Boston. MA 02114

McKee AC\*. Massachusetts General Hospital, Boston, MA 02114 Virtually all patients with Down's syndrome develop Alzheimer's disease with aging, usually in their 4th to 6th decades. Using immunohistochemical methods and antibodies specific for beta/A4 protein (Angela and 1880,courtesy of D. Selkoe), tau 1 (courtesy of L.Binder), MAP 2 (5E2, courtesy of K.Kosik), and Alz 50 (courtesy of H.Ghanbari), in addition to modified Bietschowsky silver, Congo red and thioflavine S stains, we examined the brains of 3 infants with Down's syndrome (ages 6, 18, and 30 months) and 5 age-matched Down's syndrome (ages 6, 18, and 30 months) and 5 age-matched controls (6-30 months), mean 23 months). We found occasional silver positive, Angela and 1280 immunoreactive (imr) primitive plaques in 2 Down's infant brains (ages 18 and 30 months). The plaques were distributed in the superior frontal and transentorhinal temporal cortices, primarily in the 5th and 6th cortical layers. Congo red and thioflavine S primarily in the 5th and 6th cortical layers. Congo red and thiollavine S stains were negative. Occasional beta amyloid imr neurons and imr astroglia were also found. Beta amyloid positive plaques were not identified in the control brains. No tau positive or argyrophilic neurofibrillary tangles, neuritic threads, or abnormalities of MAP2 were found in either the Down's or control brains. Diffusely Alz 50 imr neurons and beaded fibers were scattered throughout the CA fields and subiculum of the hippocampus and in the frontal and temporal cortices of all brains. Intensely Alz 50 positive neurons were most abundant in the subcortical white matter of the hippocampus, frontal and temporal lobes. The number of Alz 50 imr neurons did not differ appreciably with age. These findings show that abnormal deposition of appreciably with age. These findings show that abnormal deposition of beta amyloid protein may begin as early as 18 months in Down's syndrome and prior to any evidence of cytoskeletal pathology.

# DEGENERATIVE DISEASE: ALZHEIMER'S-COGNITION

### 306.1

A SPECIFICALLY CONCEPTUAL PRIMING DEFICIT IN PATIENTS WITH ALZHEIMER'S DISEASE. L.A. Monti\*. J.D.E. Gabrieli, S. L. Reminger, D. A. Grosse, and R. S. Wilson. Rush Alzheimer's Disease Center, Chicago, IL 60612 and

Grosse, and R. S. Wilson. Rush Alzheimer's Disease Center, Chicago, IL 60612 and Department of Psychology, Northwestern University, Evanston, IL, 60208. Patients with Alzheimer's disease (AD) have a deficit on all explicit memory tasks (recall and recognition). In implicit memory or repetition priming (the influence of prior processing upon later reprocessing of a stimulus), AD patients have shown impaired learning on some tasks and intact learning on others. Characterization of what implicit memory processes are intact and impaired in AD has been difficult because dissociations have come from between-task comparisons, and various repetition priming tasks differ in many ways. We sought to determine whether AD patients have a specific deficit in conceptual priming by varying conceptual processing (with a depth-of-processing manipulation) in a single priming task (category-exemplar production). Subjects were 11 mildy-to-moderately demented AD patients and 10 age-matched normal control (NC) subjects. The experiment had two identical study obases followed by tests of either implicit or explicit or explicit memory. two identical study phases followed by tests of either implicit or explicit memory. In both study phases, subjects judged whether exemplars of semantic categories referred to man-made or natural objects (deep processing) or were displayed in upper or lower case (shallow processing). For the implicit test, subjects were shown the category case (shallow processing). To the impirite test, subjects were shown the category mames and asked to generate 8 exemplars of each; the measure of priming was how often study-list exemplars were provided relative to baseline. The explicit test was identical except that subjects used the category name as a cue to recall the studied exemplars. Subjects recalled more exemplars after deep than shallow processing, and exemplars. Subjects recalled more exemplars after deep than shallow processing, and the AD group recalled fewer exemplars than the NC group. On the implicit test, both groups showed repetition priming, but only the NC group showed greater priming after deep processing. The AD patients showed the normal small magnitude of priming after shallow processing. The failure of patients to show greater repetition priming after enhanced conceptual analysis in the deep processing condition indicates a specific impairment of conceptual implicit memory in AD. Supported by grants from the NIA #P01 AG09466-02 and the Illinois Department of Public Health.

INTACT CONCEPTUAL PRIMING IN A PICTURE-NAMING TASK IN PATIENTS WITH ALZHEIMER'S DISEASE. S.M. Park. J.D.E. Gabrieli\* J.R.Tinklenberg. and J.A. Yesawage. Department of Psychology, Stanford University, Stanford, CA 94305 and VA Medical Center, Palo Alto, CA 94304.

In prior studies we showed that patients with Alzheimer's disease (AD) learned normally on picture-naming priming tasks despite impaired recognition for pictures and despite impaired repetition priming on conceptually demanding tasks such as word-stem completion. One interpretation of these results is that AD patients can not demonstrate conceptual priming. To test this interpretation, we used a picture-naming task in which subjects were exposed initially to pictures or to words (labels of pictures). Word-to-picture priming is conceptual because a word and the picture that it labels are conceptually (but not perceptually) related. The subjects were 7 mildty-to-moderately demented AD patients and 4 age-matched normal control (NC) subjects. In a study phase, subjects named 20 pictures and read 20 words of common objects and animals. For the priming test, subjects named 80 pictures (20 pictures named in the study phase, 20 pictures that corresponded to the words read in the study phase, and 40 new pictures). Naming latencies were recorded. In a second study phase, and 40 new pictures, 20 pictures that corresponded to the words in the study phase, and 40 new pictures). AD patients were impaired on the recognition test (20 study phase pictures, 20 pictures that corresponded to the words in the study phase words were named most quickly; 2) new pictures were named most study phase pictures were named most quickly; 2) new pictures were named most stowly; and jo pictures were named most quickly; 2) new pictures were named most stowly; and jo pictures were named most stowly; and jo pictures were named most stowly; and jo pictures were named most stowly; and jo pictures were named most stowly; and jo pictures were named most stowly pictures. These results suggest

INTACT PRIMING PERFORMANCE IN ALZHEIMER PATIENTS ON A WORD-FRAGMENT COMPLETION TASK. D. Cahn, D. Salmon\*, W. Heindel, and N. Butters. Psychiatry and Neuroscience Depts., U.C.S.D. School of Medicine and VAMC, San Diego, CA 92161

Previous studies have found impaired stem-completion priming in Alzheimer's disease (AD) patients. Although this impairment has been attributed to a breakdown in the AD patient's semantic processing ability, impaired presemantic processes may also be mediating performance on this task. The present study investigated this issue by examining the performance of AD patients on another word completion task that is thought to be more dependent on presemantic than semantic processes. Two conditions were created so that subjects were asked to complete word fragments (i.e. A\_\_A\_\_IN for assassin) following both immediately and fifteen minutes after the presentation of the study list. A prime score was calculated by dividing the number of target fragments completed by the sum of target and distractor fragments completed. In addition, a recognition version of the task was given for both conditions. addition, a recognition version of the task was given for both conditions. As expected, AD patients performed significantly worse than elderly normal control (NC) subjects on recognition memory in both the immediate and delay conditions. Although AD patients appeared to have more rapid forgetting than the NC subjects, the interaction did not reach significance, due possibly to floor performance in the AD patients. significance, due possibly to floor performance in the AD patients. Despite impaired explicit performance, the AD patients did not differ significantly from the NC subjects on priming in either delay condition. These results suggest that AD patients can demonstrate normal priming performance when the task is dependent on presemantic rather than semantic processes. The impairment that AD patients show on the stem-completion task may indeed be attributable to an impaired ability to process the semantic component of the task.

# 306.4

SEMANTIC AND PRESEMANTIC CONTRIBUTIONS TO PRIMING IN ALZHEIMER'S DISEASE. C. Fennema-Notestine\*. W. Heindel, D. Salmon, and N. Butters. Psychology, Psychiatry and Neurosciences Depts., UCSD, La Jolla, CA 92093 and VAMC, San Diego, CA 92161.

Alzheimer's Disease (AD) patients have been found to demonstrate both impaired and preserved priming performance across a variety of tasks. We and others have suggested that the priming deficit of AD patients is due primarily to impaired semantic processing ability and that the apparent inconsistency in AD patients' priming performance is due to differences in the degree to which different priming tasks are mediated by presemantic versus semantic processes. This issue was examined in the present study by comparing AD patients' priming performance to that of amnesic patients and normal controls on both a semantic and a presemantic version of a homophone spelling bias task. In the semantic priming condition, subjects were biased against previously preferred homophone spellings by presenting the homophones orally in a semantically related context. In the perceptual priming condition, subjects' spellings were biased by presenting the homophones visually in a semantically unrelated context. As expected, amnesic patients primed normally in both the semantic and presemantic priming conditions. Interestingly, AD patients primed normally in the semantic condition, but were significantly impaired relative to controls in the presemantic priming condition. These results suggest that AD patients' impairment on the spelling bias task may be mediated by presemantic processing deficits and that, under certain conditions, AD patients can demonstrate normal semantically-based priming. Thus, the previously reported variability in AD patients' priming performance across tasks may not be attributable solely to differences in the degree to which these tasks are dependent upon semantic processes.

CHARACTERISTICS OF GAZING EYE MOVEMENT FOR DIFFERENT DEPTH TARGETS IN PATIENTS WITH ALZHEIMER'S DISEASE. K. UOMORI++. M. YAMADA+. H. YOSHIMATSU++. S. MURAKAMI+. M. EUJII+. R. FUKATSU+. N. TAKAHATA+. M. WATANABE+.\* ++ATR A&VP Res. Labs. (Kyoto, JAPAN), +Sapporo Medical College (Sapporo, JAPAN).

To clarify the stereopsis disturbance in patients with Alzheimer's disease(AD), we quantitatively analyze changes in binocular eye movement when subjects shift their gaze to different depths. The new eye movement analyzing system developed by ATR makes this analysis possible.

Subjects are patients in the early and moderate stages of AD, OND and similar-aged control subjects. Their binocular eye movement is recorded when they shift their gaze from targets faraway to targets close at hand, and vice versa. The targets are symmetrically arranged along the median plane, or asymmetrically, on opposite sides; 30 and 100 cm away from the eye. They are switched by a personal computer with a beep. The experiment is conducted in a dimly lit room with a structure capable of providing good binocular cues for depth.

In AD subjects, especially those in the moderate stage, vergence is limited and the amount of change in convergence angle decreases. They also try to focus on a target using saccadic eye movement instead of vergence. Furthermore, asymmetrical saccades are observed(where the saccadic movement amplitudes differ for each eye) even when targets are symmetrically along the median plane.

The new analyzing system will be useful in understanding visuo-spatial cognitive disturbances which are the most outstanding clinical features in early AD.

### 306.7

NAMING PERFORMANCE IN ALZHEIMER'S DISEASE IS MORE IMPAIRED IN WOMEN THAN MEN. <u>V.W. Henderson\* and J.G. Buckwalter</u>. Depts. of Neurology and Psychology, and the Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90033

Based on our preliminary observations (Buckwalter et al, JClin Exp Neuropsychol 1992;14:23), we hypothesized that women with Alzheimer's disease (AD), when compared to men, would be more impaired on language tasks but would not necessarily differ in other cognitive domains. Data were available for 259 men and 358 women enrolled in the multicenter Consortium to Establish a Registry for Alzheimer's Disease (CERAD) and who met standard criteria for "probable" AD. Dependent variables, taken from the CERAD battery, were measures of language (oral naming), visuospatial skills (line drawings), and dementia severity (the short Blessed test of orientation, memory, and concentration). Hierarchical regression analyses were done to control for potentially confounding variables, forcing in subject age, age at onset of dementia symptoms, and years of education before a dummy-coded gender variable was entered. Women with AD performed significantly worse than demented men on the language task (mean naming scores of 10.1 vs. 11.4, semipartial R = 1.2, p < 0.005), but there were no significant differences on the drawing task (semipartial R = 0.06) or in terms of severity (semipartial R = 0.01). Among 348 nondemented elderly control subjects, women scored better than men on the Blessed test after controlling for age and education (semipartial R = 0.09, p = 0.04), but there were no significant gender-associated differences on CERAD language or visuospatial measures. Although gender accounts for only a small proportion of the total variance, we conclude that naming for women with AD is more impaired than for men with this disorder.

# 306.9

THE NEUROLOGICAL CORRELATES OF MULTIPLE MEMORY SYSTEMS: [18F] FDG AND PET STUDY IN EARLY ALZHEIMER'S DISEASE. D. Perani\*. S. Bressi. S.F. Cappa. G. Vallar. M. Alberoni. F. Fazio. INB-CNR, Universities of Milano and Brescia, Scientific Institute H S Raffaele, 20132 Milano, Institute H S Raffaele, 2

Patients with Alzheimer's disease (AD) are impaired in several aspects of memory function. Severe episodic memory impairment is one of the hallmark of the disease: there are however also defects of immediate memory, semantic memory and some aspects of procedural learning. In order to define the metabolic correlates of the memory disorders in AD, we measured local cerebral metabolic rates for glucose (LCMRglc) with [18F]-FDG and PET in 18 early AD patients (mean age 64.72 +/- 8.74, disease duration 16.44 +/- 8.36 months, Mini-mental state 20 +/- 4.29). AD patients were given a neuropsychological test battery which explored short and long-term explicit memory, semantic memory, language comprehension and production, visuo-spatial processing, conceptual and abstract reasoning and implicit learning. Analysis of regions of interest, including the cortex and the main subcortical grey nuclei, was performed with ANALYZE software package (BRU/Mayo Clinic) on SUN (SPARC) workstation. The relationship between impairment of different aspects of memory function and LCMRglc was investigated with a stepwise multivariate regression analysis. The "best predictors" of cognitive variables, on the basis of their contribution to Hotelling T<sup>2</sup> value (F-to-enter p<0.05) were: for immediate memory, right parietal, left superior temporal and bilateral prefrontal areas; for episodic memory, bilateral hippocampus and cingulate cortex; for semantic memory, left cingulate, prefrontal and superior temporal cortex; for procedural memory, bilateral basal ganglia, prefrontal cortex and cerebellum.

This study indicates that, while the episodic memory impairment found in AD is secociated as in mure amesia with metabolic dysurction of the mesial temporal

This study indicates that, while the episodic memory impairment found in AD is associated, as in pure amnesia, with metabolic dysfunction of the mesial temporal cortex and its connections along Papez circuit, semantic and procedural memory defects are related to metabolic dysfunction of other neuronal networks, which include higher-order association cortices, cerebellum and basal ganglia.

A COMPUTATIONAL MODEL OF NAMING IN ALZHEIMER'S DISEASE: SEMANTIC, VISUAL AND LEXICAL FACTORS. L.J. Tippett & M.J. Farah\*. Carnegie Mellon University, Pittsburgh PA 15213.

An early and consistent sign associated with Alzheimer's Disease (AD) is difficulty naming objects. The predominant explanation of the naming deficit in AD is that it results from impaired semantic memory. However, two classes of findings seem to challenge this. First, the lower the name frequency, the less likely AD patients are to name an object, suggesting a deficit of lexical access (as opposed to semantic memory). Second, the lower the visual quality of the stimulus to be named (e.g. line drawings v. objects) the less likely AD patients are to name it, suggesting a deficit of visual perception.

The sensitivity of the AD naming deficit to lexical and visual factors is not necessarily incompatible with the semantic memory hypothesis. In parallel distributed processing systems, the different components underlying task performance are highly interactive and damage in one part of the system might therefore render the system as a whole more vulnerable to manipulations affecting the non-damaged components. We trained an interactive network to associate "visual" patterns with "semantic" and "lexical" patterns. When semantic units were lesioned, the network made disproportionate errors both to patterns trained with lower frequency, and when visual input patterns were degraded. This result shows that the hypothesis of semantic memory impairment is able to account for a variety of data on naming in AD, previously thought to challenge it.

# 306.8

DENIAL OF ILLNESS IS RELATED TO DIMINISHED FRONTAL CORTEX GLUCOSE METABOLISM IN ALZHEIMER'S DISEASE. R.P. Friedland \*, E. A. Weinstein and C.L. Grady. Section on Brain Aging and Dementia, NIA, NIH, Bethesda, MD 20892 and Alzheimer Center, University Hospitals, Cleveland, OH, 44120.

The mechanisms of denial/unawareness of illness in Alzheimer's disease (AD) are not well understood. We have found that denial/unawareness of impairment in AD is associated with confabulation, reduplicative delusions and disorientation, but is not associated with severity of illness or disease duration. Resting regional cerebral glucose metabolism was determined by positron emission tomography using (F-18) 2-fluoro-2-deoxy-D-glucose and a Scanditronix PC 1024-7B tomograph in 16 AD patients without denial/unawareness with 18 AD patients with denial/unawareness. Patients with denial/unawareness had lower rCMRglc in right (p<.01) and left (p<0.5) prefrontal and right premotor cortices (p < .01), when compared to patients without denial/unawareness. Principal components analysis showed that the denial/unawareness group had relatively fewer patients belonging to the parietotemporal hypometabolism group which is dominant in AD. These data support the view that denial of illness is a reflection of frontal cortex impairment in AD.

CELLULAR SPECIFIC PATHOLOGY ALTERS PROBABLE CORTICO-AUTONOMIC EFFERENTS IN ALZHEIMER'S DISEASE. C.C.Chu\*, G.W.Van Hoesen. A.R.Damasio. Dept. of Neurology, Univ. Iowa Coll. Med., Iowa City, IA 52242.

Brodmann's area 25 is the major component of the

Brodmann's area 25 is the major component of the ventromedial frontal cortex whose damage in humans causes defects in social behavior and decision making. Because patients with Alzheimer's disease (AD) have such defects, we investigated the integrity of area 25 in 10 brains from AD patients and in 8 brains from age-compatible controls. 50 um sections stained with Thioflavin S, Alz 50, and

50 um sections stained with Thioflavin S, Alz 50, and thionin were charted using a computer coordinated microscope. The salient findings are: (1) In area 25, there is a selective laminar distribution of neurofibrillary tangles (NFTs) involving mostly cells of layer V. (2) Layer III contains none or only a few NFTs. (3) There are more NFTs in area 25 than in adjoining areas 11 and anterior insular cortex (AI). (4) In area 11 and AI, NFTs are evenly distributed in layers III and V. Layer V pyramids in area 25 thus appears highly vulnerable in AD.

mids in area 25 thus appears highly vulnerable in AD.

In higher mammals layer V pyramidal cells in area 25 are the primary projection neurons to autonomic regulatory centers (amygdala, hypothalamus, and brainstem nuclei). Loss of pyramidal cells in layer V of area 25 would disrupt autonomic regulation, and compromise reactivation of somatic states. Elsewhere we have proposed that when this reactivation is triggered by socially significant stimuli, it plays a role in social behavior.

LONGITUDINAL ANATOMICAL AND BEHAVIORAL CHANGES IN ALZHEIMER'S DISEASE. I.P. Kesslak\*, S.F. Nagata, C.W. Cotman and O Nalcioglu, Depts Neurol, Psychobio and Radiol Sci. Univ Calif. Irvine, CA 92717. National Pepis Neurol, Psychologian Radio Sci, Oliv Cain, Irvine, CA 22717.
Alzheimer's disease (AD) is characterized by a progressive dementia and increased density of plaques, tangles and neural loss. Magnetic resonance imaging (MRI), a noninvasive, high-resolution method for quantifying longitudinal volumetric changes antemortem, has shown ventriculomegaly, cerebral, parahippocampal and hippocampal atrophy in AD. This atrophy correlates with behavioral deficits. Twelve AD patients received annual MR scans and neuropsychological evaluations. Coronal inversion recovery images were quantification from the frontal

pole of the temporal lobe to the posterior hippocampus. Neuropsychological tests included the Mini Mental State Exam (MMSE), word recall and recognition. Matched pair t-tests for brain areas and neuropsychological tests were computed to determine between year differences (Table 1). Correlations between anatomical and determine between year uniteriores (Table 1). Confeations between anatomical and psychometric measures suggest the progressive degeneration in AD impacts on behavioral function. Atrophy in the hippocampus and parahippocampal gyrus may be severe and occur early in the disease, with subsequent sequential degeneration of other brain areas contributing to increased cognitive deficits.

TABLE 1. LONGITUDINAL CHANGES IN AD BRAIN

|           | Anatomical | Behavioral Correlations |            |          |   |

# DELAY CLASSICAL CONDITIONING HAS A HIGHER SENSITIVITY FOR ALZHEIMER'S DISEASE THAN TRACE.

J.M. Coffin\* L.S. Ferrante, & D.S. Woodruff-Pak. Psych. Dept., Temple Univ. & Phil. Geriatric Cntr., Philadelphia, PA 19141.

We demonstrated the sensitivity of the 400 msec CS-US delay eyeblink classical conditioning in differentiating probable Alzheimer's disease (AD) patients from non-demented elderly control subjects. We suspected that the 750 msec CS-US trace paradigm might be even more sensitive. Two groups of patients who met NINCDS-ADRDA criteria for probable AD were conditioned in either the trace or delay paradigm, and their performance was compared to elderly control subjects. Although AD patients in each group conditioned more poorly, sensitivity in the trace paradigm was lower (54% sensitivity) than it was in the delay paradigm (95% sensitivity). Here we explored whether AD patients initially conditioned in the trace paradigm would still perform more poorly in a subsequent delay conditioning task. Following an average 4-month interval, AD patients (N=11; mean age=86.8 yrs.) were retrained in the delay paradigm (500 msec, 1 KHz, 80 dB tone CS followed after 400 msec by a 100 msec, 5 psi corneal airpuff US). Total percentage of CRs was significantly poorer in the delay paradigm (19.6) than in the initially tested trace paradigm (31.1; t=2.47; p<.05). There was no evidence of retention. The 400 msec delay paradigm is more sensitive in discriminating probable AD patients from elderly control subjects. Supported by grant IIRG-91-059 from the Alzheimer's Disease and Related Disorders Association.

# 306.15

VISION IN ALZHEIMER'S DISEASE: PREVALENCE OF DEFICIT. I.D. Mendola\*, A. Cronin-Golomb¹, S. Corkin, & I.H. Growdon Dept. of Brain and Cognitive Sciences & Clinical Research Center, MIT, Cambridge, MA 02139; <sup>1</sup>Dept. of Psychology, Boston University, Boston MA 02215.

We undertook a retrospective analysis of 12 vision tests given to 82 patients with Alzheimer's disease (AD) and 109 healthy control subjects matched for age and education. The healthy sample was used to establish a quantitative criteria for defining deficits. For each test, the criterion corresponded to the mean plus the standard deviation multiplied by a constant. The constant was obtained from the z-distribution such that p=0.01. The cut-off score obtained would be expected from only 1 control subject out of 100. When we documented the number of AD patients who performed at or worse than this cut-off score, the percentage of patients impaired varied across tests as follows: backward pattern and flash masking, 58% and 44%; low spatial frequency contrast sensitivity, 40%; mental rotation, 38%; spatial orientation, 31%; incomplete-picture recognition, 30%; color vision, 28%; stereopsis, 21%; high spatial frequency contrast sensitivity, 4%; local and global motion perception, 0%; critical flicker fusion, 0%. The distribution of impairment across tests suggests hypotheses about differential vulnerability of object, motion, and spatial vision in AD, and about the relation between visual deficits and the density of neuropathological changes in visual cortices

DIRECT FUNCTIONAL STATUS ASSESSMENT IN THE HOME ENVIRONMENT: PATIENT PERFORMANCE VERSUS CAREGIVER APPRAISAL IN AD R.A. Mulnard, and C.W. Cotman, Irvine Research Unit in Brain Aging, University of California, Irvine, CA 92717 USA.

While Alzheimer's Disease (AD) causes a protracted cognitive decline,

the impact is also significant on the individual's activities of daily living (functional capabilities) within their home environment. These functional capabilities represent important links to self esteem and functional independence of the AD victim. Historically, measurement of these daily living skills in the demented elderly has relied upon caregiver report. Data from caregivers is used as an important means to evaluate the patient in the context of clinical activities. However, the accuracy of the caregiver's appraisal of these important functions has not been systematically tested.

The advent of new instrumentation which allows a direct measurement of functional status in the demented elderly, supported this investigation. Fifteen patients diagnosed with probable or possible AD and their caregivers were visited in their home environments for the purpose of simultaneously measuring the patient's actual performance and the caregiver's appraisal of the patient's functional capabilities. The DAFS (Direct Assessment of Functional Status, Loewenstein, et al, 1989) instrument was utilized for the measurements.

Significant differences were found between the patient's actual performance and the caregiver's appraisal of performance potential in the subscales of transportation, financial skills, shopping skills and the total DAFS scores. AD patients were indeed able to perform significantly better on three of the subscales than was predicted by the caregivers. However, the caregivers were highly accurate in appraising the patients' performance on the subscales of eating and grooming.

# 306.14

COMPUTER-INTERACTIVE TASK DETECTS IMPAIRED MOTOR LEARNING IN MILDLY-DEMENTED ALZHEIMER'S DISEASE PATIENTS M.G. Baker\* W.J. Jagust. A.L. Leiman and B.R. Reed. University of California, Davis, Northern California Alzheimer's Disease Center, Berkeley, CA 94704.

Recent evidence suggests that early in Alzheimer's disease (AD), patients exhibit a loss of declarative knowledge but retain procedural knowledge and the capacity for its acquisition. The present study sought to determine whether motor learning tasks with a strong declarative component may be abnormal in AD patients. Subjects included ten mildly-demented AD patients (MMSE ≥ 18) and ten age- and education-matched controls. On a computer, subjects made finger responses to visual stimuli presented on-screen. After training for one of seven response patterns, subjects completed trials with an escalating number of stimuli, per the Digit Span Test. This was repeated for each of the seven randomly-presented tasks of varying complexity. AD patients showed diminished maximum number of responses correct for each task, increased response times, difficulty or inability to acquire response skills on complex tasks, and deficits in the ability to shift response patterns. These results suggest that a complex motor task is sensitive in detecting abnormalities that may reflect both declarative and procedural systems.

# 306.16

BOSTON NAMING TEST ERROR ANALYSIS IN ALZHEIMER'S DISEASE. C. G. Logan\*, J. G. Buckwalter, & V. W. Henderson, Dept. of Neurol. and School of Gerontol., University of Southern California, Los Angeles, CA.

We analyzed oral responses of 30 "probable" Alzheimer's disease (AD) patients for the first 30 items of the Boston Naming Test. Errors were classified as non-responsive, perceptual, phonological, neologistic, perseverative, semantic, mixed perceptual-semantic, vague, or unrelated-other. The semantic errors were further classified as contrast coordinate, superordinate, subordinate, or circumlocutory errors. Neuropsychological measures of disease severity, attention, language, verbal fluency, memory, and constructional skills were also analyzed. Hierarchical regression analysis showed that after partialling out effects of age, duration of symptoms, education, and gender only language performance on the Token test and verbal fluency were significantly correlated with total number of errors and verbal fluency with total number missed. Language impairment on the Token test was significantly correlated with number of perseverative, neologistic and phonological errors. Constructional skills were predictive of combined perceptual and mixed semantic-perceptual errors. Impairment on an attentional task was related to number of neologisms. Measures of severity, memory, and verbal fluency were not significantly related to any errror type. These results indicate that certain domains of cognitive dysfunction are related to different patterns of errors, suggesting that anomia in AD may be multiply determined.

As reported previously, gender differences were also found in total number correct, with women scoring significantly lower than men after partialling out control variables. In particular, women gave significantly more semantic and vague errors than men, and men tended to give more mixed semantic-perceptual errors than women. [Supported by P50 AG05142 and T32 NS07149.]

Temporal Lobe Regions on Magnetic Resonance Imaging Identify Patients with Early Alzheimer's Disease. M.B. Moss'\* R. Killiany'. M.S. Albert'. T. Sandor'. J. Tieman'. & F. Jolesz'. Boston Univ. Sch. Of Med., 'Mass. Gen. Hosp. & Harvard Med. Sch., 'Brigham & Womens Hosp. & Harvard Med. Sch.

Neuropsychological and neuropathological evidence from recent studies of Alzheimer's disease (AD) has accumulated to suggest that structures within the temporal lobe may be involved early in the disease process. To assess this possibility, we examined on MRI, the volume of selective brain regions, including the hippocampus, amygdala, temporal lobe, inferior horn of the lateral ventricle and the basal forebrain, in a group of mildly impaired AD patients and a group of control subjects. Volumetric nent of the regions were taken from consecutive, serial 1.5mm thick, 3-D, T-1 weighted magnetic resonance images. An operator, blinded to group classification, manually traced on a computer screen the borders of each region. Boundaries were operationally defined based upon neuroanatomical landmarks. The total volume for each region was then reconstructed by the computer and standardized as a percentage of the total intracranial volume for each individual case. Analysis of the data revealed that the hippocampus, the inferior horn of the lateral ventricles and the temporal lobe, but not the amygdala or basal forebrain, differed significantly in volume between the two groups. In addition, a step-wise discriminant function analysis demonstrated that a linear combination of the volumes of the hippocampus and the inferior horn of the lateral ventricles differentiated 100% of the patients from the age-matched normal controls. The finding of volumetric changes in the hippocampus are consistent with findings from behavioral, neuropathological and recent MRI studies that this limbic structure is involved in the early stages of AD and, when combined with measures of the inferior horn, may ultimately provide a clinically useful tool. \*School of Medicine, Hokkaido University, Sapporo JAPAN

Visuo-spatial cognitive disfunction in one of the most prominent symptome in an early stage of Alzheimer's disease(AD) in addition to memory disturbance. The characteristic eye movements were demonstrated objectively, for the first time, using newly developed technology, the vision analyzer, during tracking the figures, following the line and copying the models. The gazing points showed disorganized and looked similar to those of Balint's syndrome. Te assumed to that normal function of various coordination system in the body are essential in order to catch an objectin fovea. Te examined therefore eye and head coordination system, which seemed most important among these coordination system.

To detect the eye movement vision analyzer(TIK939) was used Head movement is detected using a magnetic coil attached to the subject who is surrounded by an AC magnetic field (Gazing points in space, which is the summention of both head and eye moovement is calculated and superimposed on the video. We choose 10 right handed AD, Smulti infarct dementia. 10 age matched healthy controls. First.we, observed the eye movements un copying a cube when head was fixed and also was free. In the next.we instructed the subjects to catch the targets located at 25 deg. and 50 deg. in right and left direction with eye and head movements.

The result showed that a tendency of gazing point to be localized away from the model or figure became more exaggerated when head was free than that when head was fixed. And in the second experiment, all of AD looked at the targets mainly with eye movements and only limited head movements were noted compared with other dementias and controls. Our deta suggest that eye head coordination is disturbed from the early stage in AD. This may play important role in pathophysiology of visuo-spatial dysfunction in AD.

LONGITUDINAL INVESTIGATION OF EYEBLINK
CONDITIONING AND NEUROPSYCHOLOGICAL TESTS IN
DOWN'S SYNDROME ADULTS. M.Papka,\*1 D.A.Rappaport,2
E.W.Simon,2 & D.S.Woodruff-Pak1 Dept. of Psych.1, Temple Univ.,
Phil., PA 19122 & Phil. Geriatric Cntr.1, Elwyn, Inc.2, Elwyn, PA.

To date, we have applied the eyeblink conditioning paradigm to a total of 43 Down's Syndrome (DS) adults, 22 below age 35 and 21 age 35 and older. Older DS adults, who presumably have developed Alzheimer-like neuropathology, emit fewer CRs than younger DS adults (t(41)=3.29; p<.01). Eyeblink classical conditioning in Down's Syndrome adults of a mean age of 47.8 years was similar to conditioning in Alzheimer's disease patients aged in the 80s. No differences between the two age groups of DS adults were found using the Slosson Intelligence Test, the Down's Syndrome Mental Status Examination, or the Vineland Behavioral Scales. About 14 months after initial testing, longitudinal data were collected on 6 of the younger and 12 of the older DS adults. Conditioning performance was improved for both age groups (t(5)=3.16; p<.05 for young,t(11)=3.63; p<.05 for old). However, conditioning performance of older DS adults was still poorer than that of younger DS adults, (t(16)=3.05; p<.01). There were no changes in neuropsychological test performance for either age group. DS adults show evidence of retention for periods of a year, but eyeblink classical conditioning is still sensitive to the presumed Alzheimer-like neuropathology. Supported by NIMH CRC 40380 and IIRG-91-059 from the Alzheimer's Association.

Disorganized eye movements in the patients with Alzheimer's disease(AD) are observed in making trials of constructional behaviors. Constructional behavior is regarded as two functions. The one is visuo-spatial-language and the other visuo-spatial motor function. So we examined visuo-spatial set of function, visual concept, visual memory and visual cognition to detect eye movements by the vision analyzer (TKK939) when drawing and copying figures.

Subjects were 10 pre-senile onset AD and 5 multi infarct dementia as disease control and 20 age matched controls. All of cases were right handed. AD showed focal low IMP perfusion in bilateral parietal lobes, but left parietal lobe hypoperfusion were more accentrated. Clinical staging was in early stage(Sjogren's I-II). AD could understand our instruction but showed some language difficulties, constructional apraxia and some gnostic disturbances.

Gazing point trajectory gazing time and eye velocity were analyzed during drawing figures by means of verbal instruction memory and during copying a cube.

Our results showed visual concept and memory of figures and the output neuronal systems were well preserved in the early stage in AD even if they showed constructional apraxia and other gnostic disturbances and that eye movements became normalized rather by verbal instruction and memory than in copying figures.

These results indicate that visuo-spatial motor function are relatively well spared and visuo-spatial-language function might became disturbed first, especially visual cognition or vertification process of visual cognition with language which seemed to be related to left parietal pathophysiological impairment.

P300 POWER LOSS IN AGING AND ALZHEIMER'S DISEASE. J.W. Ashford\*, K.L.Coburn and K. Yamashita. Univ. Calif., Davis, VA, Martinez, CA 94553; Mercer Univ., Macon, GA.

Davis, VA, Martinez, CA 94553; Mercer Univ., Macon, GA. The amplitude of the P300 component of the auditory event related potential, recorded using an "oddball" paradigm is decreased during aging and further diminished in Alzheimer's disease (AD). Using a brain mapping approach (BioLogic Brain Atlas, with 21 electrodes, averaged reference), the P300 was recorded from 13 young normals (YN:21-41), 11 elderly normals (EN:61-80) and 23 probable AD patients (AD:63-93; NINCDS-ADRDA criteria). Peak calculations were made on the smoothed values summed across all electrodes. Average P300 peak latency - YN: 315 ms (sd+19); EN: 364 (+46); AD: 361 (+51) - was prolonged in the elderly, but not further prolonged in the demented patients. Average P300 peak amplitude - YN: 13 uv (+5.2); EN: 8.3 (+2.6); AD: 4.9 (+3.3) - showed the expected pattern of deterioration. Total power (measured by summing the squares of each wave, smoothing and integrating +2sd) revealed values - YN: 55 (+sd 38); EN: 23 (+15); AD: 8 (+7) - which showed this expected pattern more strongly. For AD with Mini-mental States >20, power = 9.0 (+11; 0-28); for MMS 10-20, power = 10 (+5; 5-19); and for MMS(10, power = 2.7 (+2; 0-5), indicating that the p300 is not obliterated early in AD, but is barely discernable in late AD.

PROPERTIES OF CHOLINESTERASES IN BRAIN WITH ALZHEIMER'S DISEASE AND COMPONENTS OF WHOLE BLOOD. C. Wright, C. Geula\*, M-M. Mesulam. Harvard Medical School, Boston, MA 02215.

Previous studies in our laboratory have shown that histochemically identified acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE) exist in the tangles and plaques of Alzheimer's disease (AD). These cholinesterases (ChEs) are best visualized at pH 6.8 and are more resistant to several ChE inhibitors than fiber and perikarya AChE, which is best seen at pH 8.0. We now show that AChE and BuChE is visualized in glial nuclei, tangles, plaques and neuropil threads; that visualization of these ChEs is susceptible to inhibition by 5-hydroxytryptophan (5-HTP, 500uM); and that visualization of fiber and perikarya AChE occurs even in the presence of 5mM 5-HTP. Glycine, tyrosine, and tyramine at 1mM have no effect on ChE visualization. S-hydroxytryptamine (5-HT) has similar effects as 5-HTP, tryptamine has a weak effect. Inhibition of AChE visualization by 5-HTP is dose-dependent, 50uM 5-HTP is required for inhibition of glial nuclei and neuropil thread AChE, while that of tangles and plaques requires 100uM and 500uM, respectively. Histochemical analysis for ChEs in whole blood smears identifies AChE and BuChE in formed elements like that found in glial nuclei and the histopathologic structures of AD. These ChEs are best visualized at pH 6.8, in comparison to pH 8.0; and their visualization is inhibitable by 5-HTP. Plasma BuChE measured by biochemical assay is also inhibitable by 5-HT and 5-HTP

These studies indicate that the histopathologic structures of AD have ChEs with properties like those of whole blood and glial cells in contrast to perikaryal and fiber AChE. This suggests that potential sources of the ChEs in the histopathological structures of AD could be glial cells or whole blood components. Alternatively, these ChEs may be produced by neural elements in altered form; or produced normally and subsequently altered by interactions with the histopathologic structures of AD. Further experiments are necessary to investigate a possible role for these ChEs in AD.

### 307.3

ALTERATIONS IN THE PHYSICAL PROPERTIES OF LEUKOCYTE MEMBRANES IN ALZHEIMER' DISEASE (AD). P.G. Antuono's, K. R. Nicholson and A. S. Bloom. Department of Neurology & Toxicology, Medical College of Wisconsin, Milwaukee, WI 53226.

Wisconsin, Milwaukee, WI 53226. Several investigators have reported changes in the fluidity of a variety of biological membranes as a result of aging and Alzheimer's Disease. We have examined leukocytes from 13 patients with probable Alzheimer Disease (NINCDS/ADRDA criteria) and 9 age matched controls. Membrane fluidity was determined by fluorescence polarization. Three fluorescent probes were used; diphenylhexatriene (DPH), which is the state of the probability of the probability of the state of the probability of the p tion. Three fluorescent probes were used; diphenylhexatriene (DPH), which primarily monitors lipid order at the hydrophobic acyl chain tail region of the membrane; TMA-DPH, which monitors lipid order at the surface head group region; and 12-anthroyloxystearic acid (12-AS), which monitors phospholipid rotations and viscosity near the membrane core. With 12-AS, significant increases in polarization were observed in leukocytes prepared from AD patients when compared to controls. Polarization values increased from 0.106 to 0.119 (pc 0.05). controls. Polarization values increased from 0.106 to 0.119 (p< 0.05). On the other hand, there were no differences between the two groups in the polarization of either DPH or TMA-DPH fluorescence. In contrast to these results, we have previously reported that the fluidity of brain membranes was increased in AD when measured using either DPH or TMA-DPH. These findings suggest that: a) physical properties of membranes in AD may be affected in both neuronal and non-neuronal tissues; b) in leukocytes, the changes appear to be due to an electric interaction of the contraction of t alteration in membrane viscosity rather than in lipid acyl chain ordering as was observed in brain. It is yet to be determined if these alterations are due to changes in membrane lipid or protein composition.

Neurotoxicity of Aluminum and Hydroxy-Aluminum Polymer on Cultured Neurons of Rat Cerebral Cortex: Tau Accumulation and Loss of Synapse. Masahiro KAWAHARA\*. Kazuvo MURAMOTO. Kazuo KOBAYASHI and Yoichiro. KURODA. Dept. of Molecular & Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience, Fuchu-city, Tokyo 183, Japan. Aluminum in drinking water has been indicated as a risk factor for Alzheimer's disease (AD) by many epidemiological surveies (Lancet, 339,713(1992)). ral-NMR spectrometry has confirmed that mononuclear aluminum (Al³+) polymerizes to form one type of hydroxy polymer ([Al₁3O₄(OH)2₄(H₂O)₁2¹+; Al13) at pH 5.0. Although Al³+ and other Alcomplexes including Al¹3 co-exist in water, their relative contributions to neurotoxicity are unknown. We applied 100µM Al³+ or Al¹3 to the cultured neurons for fat cerebral cortex at 37°C for 1h.

After 48 days, cultured neurons were stained by antibodies for tau and phosphorylated neurofilament. Al³+-intoxicated neurons were stained more densely by antibody for tau than the control. Al¹3-intoxicated cells were aggregated to form clusters, and a distinctive accumulation of tau was observed. The accumulation of tau was also observed in the case of continuous presence of Al³+ (100µM for 48 days). The clustering cells were connected by thick processes which were stained by antibodies for phosphorylated neurofilament and tau.

The effects on in vitro synapse formation between cortical neurons were investigated using multi-site fluorometry of [Ca²-). (Kuroda et

phosphorylated neurofilament and tau.

The effects on in vitro synapse formation between cortical neurons were investigated using multi-site fluorometry of [Ca<sup>2+</sup>], (Kuroda et al. Neurosci. Lett. 135,255(1992)). After 7 days, Alis-intoxicated neurons showed remarkable decrease in the frequency of [Ca<sup>2+</sup>], oscillation, which is correlated to the number of synapses, compared to Al<sup>3+</sup>-intoxicated

These results support the idea that at least a part of AD is caused by long-term accumulation of aluminum, especially aluminum polymers which are more permeable than Al3+ through the cell membrane. This work was supported in part by the Grantin-Aid for Encouragement of Young Scientists, No.03857339, from the Ministry of Education, Science and Culture of Japan.

MEMBRANE METABOLITES IN RAT FRONTAL CORTEX ARE DECREASED FOLLOWING NUCLEUS BASALIS LESIONS. T.C. Holmes\*, R.M. Nitsch, and R.J. Wurtman. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

Membrane phospholipid metabolism is abnormal in Alzheimer's

disease. Phosphatidylcholine and phosphatidylethanolamine levels per cell are decreased as are brain choline (Ch) and ethanolamine, while glycerophosphocholine (GPC) and glycerophosphoethanolamine are increased. To develop a rat model for these changes, we examined the effects on frontocortical Ch and GPC of lesioning one cholinergic nucleus basalis (nBM) with ibotenic acid (10 mg/ml in PBS, 0.5 µl). After one week, frontal cortex choline acetyltransferase (ChAT, nmol acetylcholine/µg protein/hr) activity was decreased (26%, p<0.01, n=9) on the lesioned side. Tissue Ch and GPC levels also were decreased relative to those in control tissues (Ch:16%, p<0.05,n=9; GPC: 12%, p<0.05, n=9). These data suggest that impaired cholinergic neurotransmission alters phospholipid metabolism in cholinergic target regions. Supported by NIH, NIA and CBSMCT.

α<sub>1</sub>-ADRENERGIC RECEPTOR DENSITY AND NOREPINEPHRINE LEVELS IN AGING AND ALZHEIMER'S DISEASE Z.W. Li. M. Romagnano\*, E.K. Richfield, L.M. Cousins and R.W. Hamill.

Z.W. Li. M. Romagnano\*. E.K. Richfield. L.M. Cousins and R.W. Hamill. Dept. of Neurology & Neurobiology and Anatomy, University of Rochester Medical Center, Monroe Community Hospital, Rochester, NY 14620.

The distribution and laminar density of superior temporal gyrus (STG) noradrenergic α₁ receptor was studied in postmortem human brain. Nine brains were obtained from Alzheimer's disease (AD) patients and six from aged controls. α₁ receptors were labeled with 3H-prazosin (1 nM) and nonspecific binding was determined using phentolamine (10 μM) as a blank. The laminar distribution and average density of α₁ receptors were determined using in vitro quantitative autoradiography and video densitometry based on cortical cytoarchitecture of adjacent and nearly adiacent Nissl-stained sections. The α₁ receptor brainer site was present and nearly adjacent NissI-stained sections. The c1 receptor binding site was present in all laminae. However, a heterogeneous pattern was observed. The highest densities were found in lamina I and II, while moderate densities were present in lamina III and V/VI. Lamina IV contained the lowest level of receptor binding sites. Tanima in and VIV. Lamina it contained the lowest level of receptor britishing sites.

In comparison to aged control STG, the AD group showed a significantly lower density of α1 receptor binding in lamina IV and V/VI, but not in the other laminae. Furthermore, norepinephrine (NE) levels in STG were measured in 21 AD cases and 12 control subjects using HPLC. NE levels were significantly reduced in AD brain without significant alteration in protein levels. The decrease in the NE level and  $\alpha_I$  receptor density implies that the noradrenergic system is involved in the pathophysiology of AD, and may be related to dementia symptoms. The variable decrease in laminar density of  $\alpha_1$  receptors in STG in cases of AD suggests that  $\alpha_1$ receptor loss may be heterogeneous with certain laminae showing disturbances. The exact relationship between these alterations and specific cortical function or dysfunction remains to be determined. (Supported by NIH grant AG03644).

Altered pattern of nitric oxide synthase (NADPH diaphorase) staining in the hippocampus Alzheimer brains. G. W. Rebeck\* and B. T. Hyman I

of Neurology, Mass. General Hospital, Boston, MA, 02114.

Nitric oxide (NO), a free radical neuromodulator, has been implicated in NMDA mediated excitotoxicity and in long term potentiation. We have recently shown that the number of NO synthase immunoreactive neurons is unchanged in the hippocampal formation in Alzheimer disease (AD) despite substantial overall neuronal loss. Because NO synthase NADPH diaphorase histochemistry, we used this stain to hippocampal whether the pattern of NO hippocampal examine whether the pattern of NO hippocampal innervation is affected in AD. Control individuals (n=6) showed strong terminal staining throughout the molecular layer of the dentate gyrus, with a striking band occupying the middle 1/3. In AD (n=7), the pattern of diaphorase staining in the dentate gyrus was more homogenous, with a marked loss of staining in the middle 1/3. Densitometric analysis revealed the reduction in the middle portion to be was not changed compared to CA4. The alteration in diaphorase was most striking in the most severely affected cases (Down's syndrome and familial AD). Altered innervation of neural structures by NO could contribute to neuronal vulnerability and loss in AD. Supported by NIHAG08487, and the Brookdale Foundation.

**307.7**PARVALBUMIN IMMUNOREACTIVE NEURONS IN HUMAN AMYGDALA: DISTRIBUTION IN NORMAL AGING AND REDUCTION IN ALZHEIMER'S DISEASE. D.R. Brady\* and E.J. Muſson, Lab. of Neurosci., NIA/NIH, Bethesda, MD 20892; Div. of Neurosci., Rush Med. Ctr., Chicago, II. 60612.

Antibodies to the calcium-binding protein, parvalbumin (PV), have been used previously to identify a subset of fast-firing GABAergic interneurons in the human hippocampal formation (HPF) and neocortex in normal and Alzheimer's diseased (AD) brains. Initial analyses indicated a selective, topographic loss of PV interneurons in the HPF and we have extended our analysis of limbic structures to include the amygdala. Post-mortem, paraformaldehyde fixed amygdala from normal (X=62.7, n=7) and AD (X=80.1, n=9) brains were obtained at autopsy. In normal amygdala, PV interneurons were aspiny, pleomorphic with extensive dendritic arbors and ranged from 6 to 25μm in size. PV neurons were observed almost exclusively within the corticobasal amygdaloid nuclei. The majority of PV neurons were distributed within the lateral (LT; X=321.6) and basolateral (BL; X=46.5) nuclei, and much fewer in the accessory basal, medial basal and cortical nuclei. An occasional PV neuron occupied the capsule of the central nucleus, but none were observed within the central nucleus. In AD, PV neurons displayed similar morphologies as controls. There was, however, a 49% decrease in PV neurons in the LT nucleus and a 20% reduction in the BL nucleus. The decrease in the LT nucleus is consistent with previous reports of areal decreases of greater than 50% in LT. The 20% decrease in BL nucleus in light of the 50% decrease in area, suggests a selective vulnerability of PV neurons in LT and BL nuclei in AD that may relate to their functional circuitry. ALTERATIONS OF WHITE MATTER NEURONS IN AGING AND ALZHEIMER'S DISEASE. X, Tang\* and R.E. Powers. UAB Brain Resource Program, University of Alabama at Birmingham, Birmingham, Alabama 35294

Neurons are present in white matter beneath the neocortex and many contain neuropeptides. The function of these small fusiform neurons is unclear. This study employs immunocytochemical methods with acrolien fixed human autopsy tissues (n = 20) from temporal lobe and antisera to somatostatin (SS), substance P (SP), neuropeptide Y (NPY), neurotensin (NT) and cholecystokinin (CCK). Formalin fixed human tissues were stained with antisera to Tau, the ALZ 50 antibody, as well as with silver preparations. Temporal lobe tissue from 16 young controls, 16 aged controls and 18 patients with AD were examined.

Large numbers of small fusiform neurons were stained with antisera to NPY, smaller numbers stained with antisera to SS, and SP and few were stained with antibodies to CCK or NT. In sections and few were stained with antibodies to CCK or NT. In sections from superior temporal gyrus, middle temporal gyrus and mesial temporal lobe white matter, antibodies to cytoskeletal epitopes did not stain white matter neurons in young controls, but normal appearing neurons were immunostained with antisera to Tau and the ALZ 50 antibody in aged controls and AD cases. Small circular and flame shaped neurofibrillary tangles were stained with silver preparations or immunostained with Tau and Alz 50 antisesra in white matter neurons that recembed neurofibrilegric neurons.

that resembled peptidergic neurons.

This study documents an elaborate network of small subcortical peptidergic neurons that are damaged in aging and AD.

COMPARABLE DISTRIBUTION OF SOMATOSTATIN mRNA CONTAINING NEURONS IN THE HIPPOCAMPUS IN NORMAL AGING AND ALZHEIMER'S DISEASE, <u>I. Epelbaum \* P. Doumaud</u> ASIama, C. Videau, P. Cervera°, E. Hirsch°, F. Javoy-Agid°.

U159 and °U289 INSERM, Paris, France.

Decrease in cortical and hippocampal Somatostatin (SS)

concentrations are one of the neurochemichal hallmarks Alzheimer disease (AD). Recent immunocytochemical studies concluded that the number of SS-ir neurons is maintained in AD hippocampus; thus, suggesting a metabolic defect rather than a specific cellular loss of SS-containing neurons. In this study, we used a 35S-labelled-45-mer-oligonucleotide study, we used a 3-3-1abelled-43-mer-oligonucleotide complementary to the SS coding sequence to visualize by in situ hybridization SS ARNm containing neurons in the hippocampus of age- and post mortem delay-matched AD (n=6) and controls (n=7). Labelled cells are located in all Ammonian fields. They represent 1 to 4% of the total cell number. Their distribution is similar in AD and control brains. Cells are more concentrated in the Hilus of the dentate gyrus as compared to CA1, CA2, and CA3 in which their number is equivalent. SS m RNA quantification by image analysis (Biocom RAG200) demonstrate an identical diminution (-38±3%) in all demonstrate an identical diminution (-3823%) in all hippocampal fields in AD. In summary, neurons synthetizing somatostatin are still present in AD hippocampus with an identical distribution as compared to controls but the rate of SS mRNA/cell is diminished. This implies that the minor somatostatinergic decrease observed in AD hippocampus is likely due to a metabolic defect rather than to a specific cell loss.

THE PERIRHINAL CORTEX (AREA 35) IN MAN AND ITS PATHOLOGY IN ALZHEIMER'S DISEASE. A. Solodkin  $^{*1,2}$ . G.F. Wu $^{1}$ , R.O. Kuljis $^{2}$  and G.W. Van Hoesen $^{1,2}$ . Departments of Anatomy $^{1}$  and Neurology $^{2}$ , The University

G.W. Yan rucesen. Departments of Anatomy and recuroogy, the Conversity of lowa, lowa City, IA 52242.

Brodmann's area 35 in man is a long strip of proisocortex positioned between the entorhinal periallocortex and temporal association isocortex. It lies lateral to the rhinal sulcus anteriorly, as in non-human primates, but continues posteriorly as the cortex on the medial bank of the anterior one half of the posteriorly as the cortex on the inicial bank of the anterior one half of the collateral sulcus. It is an important area from a neural systems viewpoint handling two-way traffic between the hippocampal formation and association cortices, and a functional role in memory has been documented recently in monkey behavioral

two-way traffic between the hippocampal formation and association cortices, and a functional role in memory has been documented recently in monkey behavioral investigations.

We have analized area 35 in AD and in aged compatible controls (N=45; mean autolysis time = 4.6 hrs) using cyto- and myeloarchitectonic stains (Nissl, Gallyas-myelin), histochemistry for oxidative enzymes (AChE) and for neuropathological lesions (thioflavine S) as well as immunolabeling for several neurochemicals such as glutamic acid decarboxilase (GAD), Parvalbumin (PAR), A-68 (Alz-50) and certain peptides (SP, NPY, SOM, CGRP).

AChE and GAD staining reveals a striking vertically organized distribution of neurites and cell bodies in area 35. Similar patterns are also found with PAR immunostaining but not with the peptides. Neurofibrillary tangles and dystrophic neurites as assessed with thioflavine S and Alz-50 stainings in Alzheimer's disease also showed a similar pattern of discrete vertical organization. The latter are seen most commonly in cases when the clinical signs of dementia were present for less than 5 years and proved to be a valuable tool for appreciating the extent and organization of the perirhinal cortex.

Evidence of anatomical compartmentalization outside primary sensory areas is unusual, its presence in area 35 organization may be viewed as consistent with its seemingly complex role of directing hippocampo-cortical interactions and its early destruction in Alzheimer's disease may play a prominent role in the memory impairment that characterizes this disorder. of Neurology, University of Rochester, Rochester, NY 14620
Developing new therapies for Alzheimer's disease depends on localizing the

Developing new therapies for Alzheimer's disease depends on localizing the subtypes of muscarinic receptor in brain and their presence or absence in different disease states. The binding properties of muscarinic receptors in sections of human hippocampus were examined using 0.2 and 2.0 nm [<sup>3</sup>H]-(R)-quinuclidinyl benzilate ([<sup>3</sup>H]-(R)-QNB) with and without 1.0 μM pirenzepine, AF-DX 116 and p-F-hexahydrosiladifenidol (p-F-HHSiD). Nonspecific binding was assessed using excess atropine. Tritium sensitive film was apposed to the sections for 35 days prior to development. Images were analyzed using optical density and tritium standards for calibration. Muscarinic receptor binding was compared with choline activities of the properties of the pro

for calibration. Muscarinic receptor binding was compared with choline acetyltransferase activity in the human hippocampus to determine relationships between presynaptic cholinergic markers and muscarinic receptor subtypes. Specific [<sup>3</sup>H<sub>1</sub>-(R)-QNB binding was high in the dentate gyrus, CA1-4, subiculum and entorhinal cortex. Competition studies revealed high levels of inhibition for 1 μM pirenzepine and p-F-HHSiD, and lower levels for AF-DX 116. The data indicate that muscarinic receptors present in the hippocampus are predominately M<sub>1</sub> and M<sub>3</sub> receptors. Lower levels of M<sub>2</sub> receptors were identified using AF-DX 116. The relatively high affinity of pirenzepine for muscarinic receptors in human hippocampus supports the hypothesis that M<sub>1</sub>-selective agonists might be of therapeutic value in the treatment of Alzheimer's disease. Determination of the levels of each subtype in Alzheimer's natients and in age-mached controls will be an levels of each subtype in Alzheimer's patients and in age-matched controls will be an important goal for future research. In addition, the relationship between choline acetyltransferase activity and M<sub>2</sub> receptors will be compared in various subregions of hippocampus. Supported by AG03644, NS01493 and the Ohio Department of Aging.

SYMPOSIUM. STRATEGIES FOR THE STUDY OF AMYLOIDOSIS USING ANIMAL MODELS. I.D. Buxbaum, Rockefeller Univ. & A. Goate, Washington Univ. Sch. Med. (Chairpersons); C.J. Epstein, UCSF; R.L. Neve, McLean Hosp.; D.L. Price, Johns Hopkins Univ. Sch. Med.

Abnormalities of the Alzheimer amyloid precursor protein (APP) have been implicated in the development of Alzheimer disease (AD). In this symposium, the use of animal models for understanding the relationship between APP and the underlying mechanisms of AD will be discussed.

Alison Goate will introduce APP and summarize the

recently discovered mutations in this protein which co-segregate with forms of familial AD; she will also describe strategies to target mutations to the APP gene. Trisomic and transgenic mice will be discussed as potential models for Down syndrome and AD by Charles J. Epstein. Regulation of the catabolism of APP by first and second messengers will be described by Joseph D. Buxbaum in the context of generating ransgenic animals with altered APP catabolism. Rachael L. Neve will describe neuropathology observed in transgenic mice expressing fragments of APP. Finally, Donald L. Price will present different animal models for the study of the biolance of the study of the study of the biolance of the study of the

ogy of APP and for the analysis of amyloidogenesis.

The presentations will be followed by a session to discuss the advantages and disadvantages of different strategies toward understanding Alzheimer amyloidosis.

SYMPOSIUM. CELL BIOLOGY OF THE GROWTH CONE. D.J. Goldberg, Columbia Univ. Coll. of P&S (Chairperson); M.C. Fishman, Harvard Med. Sch. & Mass. Gen. Hosp.; M.P. Sheetz, Duke Univ. Med. Ctr.; D. Bentley, Univ. of California, Berkeley

Molecular biological and video microscopic techniques have begun to yield insights into the specialized motile ending of a growing neuronal process, the growth cone. The functioning of the cytoskeleton and of signal transduction pathways in the basic behavior of the growth cone and in the modulation of this behavior by environmental cues will be discussed. After a brief introduction, the symposium will progress from the analysis of the role of a single molecule in the growth cone to the eventual consideration of the growth cone in the living animal, all the while focusing on internal events. Fishman will discuss evidence that the protein GAP-43 regulates the sensitivity of growth cone transduction and serves as an intracellular G protein activator. Sheetz will discuss experiments with VEC-DIC microscopy and optical (laser) tweezers that suggest that a membrane myosin controls the rate of elongation of filopodia and that fast axonal transport can control growth cone activity. Goldberg will talk about the potential role of tyrosine phosphorylation in regulating the specialized actin network of the growth cone as well as the subcellular mechanism of action at the growth cone of laminin, a substrate-binding promoter of neurite growth. <u>Bentley</u> will show how video microscopic observation of living growth cones making navigational decisions within the grasshopper embryo reveals how the behavior of microtubules underlies the critical role of filopodia in these decisions

### VISUAL CORTEX: THEORETICAL STUDIES

313.1

THE LONG OPEN TIME OF THE NMDA CHANNEL FACILITATES THE SELF-ORGANIZATION OF INVARIANT OBJECT RESPONSES IN CORTEX
P.A. Rhodes
The Salk Institute for Biological Studies, La Jolla, CA

Each successive area in the 'what' pathway between V1 and anterior IT seems to encode visual information about objects with increasing invariance to position and scale (Desimone et al 1984; Tanaka et al 1991). Foldiak (1991) and Stryker (1991) have proposed that to accomplish such an encoding the nervous system might link successive images of an object as it moves through the field of view. We propose that the long open time of the NMDA channel provides a mechanism to link temporally contiguous firing patterns triggered in a lower visual area as an object moves across the visual field to a more invariant pattern of activity in the subsequent higher area. In order to explore how such a system could produce invariant object coding, a computer simulation of a three-level hierarchy of neocortical areas was developed. A set of simulated 2-dimensional objects was presented to the visual field. The initial coding of form was built into a 16x16 retinotopic array of oriented edge detectors, the simulated primary visual area. Activity in this area was driven by continuous translations of the objects through the visual field, sometimes with rotation and dilation. Excitatory synaptic through the visual field, sometimes with rotation and dilation. Excitatory synaptic efficacy was mediated by a mixture of AMPA and NMDA kinetics. Feedforward synapse strengths were initiated with loose divergent retinotopy, and were allowed to self-organize, with induction of plasticity proportional to the open time of the NMDA channels. Local lateral inhibition was present. Preliminary results indicate that the long open time of the NMDA channel, coupled with Hebbian plasticity and some form of firing threshold, provides a physiological mechanism permitting the radically shifting patterns of neuronal activity in lower areas which are triggered by different retinal images of an object to become linked to an increasingly invariant pattern of activity at each successive higher area.

CORTICAL CELLS DO NOT PERFORM TEMPORAL IN-TEGRATION OF SMALL EPSP'S W. Softky and C. Koch\*, Computation and Neural Systems, California Institute of Technology Pasadena, CA 91125

Cortical cells fire almost randomly. For non-bursting cells in visual areas V1 (Knierim & Van Essen 1992) and MT (Newsome et al. 1989) of behaving macaque monkey firing at sustained rates up to 300 Hz due to visual stimuli, the rate-normalized Coefficient of Variation  $(C_V)$  of the interspike interval distribution is consistent with a completely random process (e.g.  $C_V \approx 1$ ).

This high variability cannot result from small, independent, and random EPSP's converging onto a leaky integrate-and-fire neuron. Both this and related models predict very low firing variability ( $C_V \ll 1$ ) for realistic EPSP depolarizations and membrane time constants. Independent, excitatory synaptic input to a compartmental simulation of an anatomically reconstructed layer V cat visual cortex pyramidal cell also yields  $C_V \ll 1$ , in agreement with the integrate-and-fire models but in strong disagreement with the majority of our monkey data. The simulated cell only produces highly variable firing when Hodgkin-Huxley-like currents ( $I_{Na}$  and very strong  $I_{DR}$ ) are placed on the distal basal dendrites. Now the simulated neuron acts more as a millisecond-resolution detector of dendritic spike coincidences than as a temporal integrator. Only with such fast and strong dendritic nonlinearities or with strong synchronization among individual synaptic events does our simulated cell exhibit the high variability seen in rapidly firing cortical neurons.

A SPIKING ATTRACTOR NETWORK MODEL ACCOUNTS FOR BIMODAL STATISTICS OF VISUAL CORTEX NEURONS G. C. Littlewort, D. Zipser\*, P. Perez, J. M. Fuster Cognitive Science, U.C.S.D., La Jolla, CA 92093

The interspike interval distributions of many cortical neurons, in awake animals observing their environment, is bimodal in the sense that it may be 6th but the many fortune properties. that it can be fit by the sum of two exponentials (ignoring refactory times). (Smith et al, Biophys J 5, p47, 1965; Fuster et al, Arch ital Biol 103, p159, 1965). We have extended and confirmed these observations using interspike interval distributions derived from recordings in visual cortex (V1 and IT) in awake behaving monkeys. A spiking neural network was developed to model this bimodal process. It is derived from a logistic neuron with excitatory self-connection and two stable activity levels, or attractors. This one neuron concept is extended to a network of spiking neurons, with many identical units and recurrent connections between all with many identical units and recurrent connections between all units. The logistic function now represents the probability of producing a spike. The individual units in this network are stochastic and slow firing. The number of units firing per time interval has a bimodal probability distribution. Observation of a single unit in this network provides interspike interval distributions that can be compared with experimental data. The simulated distributions match the real data. This spiking model with feedback can be analysed as a stochastic Markov process, enabling theoretical predictions of higher order correlations in the dynamics of the spike trains, that can be compared with experimental data. trains, that can be compared with experimental data.

3-D VISION AND FIGURE-GROUND SEPARATION BY VISUAL CORTEX. Grossberg, S \* ., Department of Cognitive and Neural Systems, Boston University, Boston, MA 02215.

A neural network model of 3-D visual perception and figureground separation by visual cortex is described. A unified explana-tion is given of how a 2-D image may generate a 3-D percept; how figures pop-out from cluttered backgrounds; how spatially sparse disparity cues can generate continuous surface representations at different perceived depths; how representations of occluded regions can be ent perceived depths; how representations of occluded regions can be completed and recognized without usually being seen; how occluded regions can sometimes be seen during percepts of transparency; how high spatial frequency parts of an image may appear closer than low spatial frequency parts; how sharp targets are detected better against a figure and blurred targets are detector better against a background; how low spatial frequency parts of an image may be fused while high spatial frequency parts are rivalrous; how sparse blue cones can generate vivid blue surface percepts; how 3-D neon color spreading, visual phantoms, and tissue contrast percepts are generated; how conjunctions of color-and-depth may rapidly pop-out during visual search. These explanations arise derived from an ecoduring visual search. These explanations arise derived from an ecological analysis of how monocularly viewed parts of an image inherit the appropriate depth from contiguous binocularly viewed parts, as during DaVinci stereo. The model predicts the functional role and ordering of multiple interactions within and between the blob and interblob streams of areas V1, V2, and V4. Interactions from cells representing larger scales and disparities to cells representing smaller scales and disparities are of particular importance.

A CENTER-OF-MASS MODEL PREDICTS JUDGEMENTS OF HUMAN DOT DISPLACEMENT DISCRIMINATION. Joy Hirsch\*. Dept of Ophthalmology and Visual Science, Yale University School of Medicine, New haven, CT 06510.

One of the unanswered questions in human vision is what regulates the precision of human spatial discriminations. Recently Hirsch and Mjolsness (1992) have demonstrated the success of a center-of-mass, CM, computation in predicting the accuracy of random dot displacement discriminations. Two alternative explanations may account for the success of the model: 1. the CM is the result of a visual search strategy based on uncertainty about the displacement; or 2. the CM is the result of an automatic sequential process that appreciates the dot locations and then identifies the cluster CM. These alternative explanations were tested by psychophysical measurements of dot displacement discrimination using random dot arrays that varied in shape and displacement certainty. Results of the certainty experiments support alternative 2 above. Results of the shape experiments show that location judgements are more precise when the array is round-like rather than elongated. Taken together these data suggest that a very large receptive field may "gather" the individual elements of an array and report the centroid. Further these data lead to the speculation that this "gathering field" may be shape specific.

# 313.7

CONSTRUCTIVE AND CORRELATIVE REENTRY IN THE VISUAL SYSTEM: COMPUTER SIMULATIONS AND PSYCHOPHYSICS. Q. Sporns' G. Tononi, and G.M. Edelman. The Neurosciences Institute, 1230 York Ave., New York, NY 10021.

What neural processes underlie well-known psychophysical phenomena such as the generation of form from motion and motion capture? In order to identify possible neural bases of these phenomena, we constructed a computer model simulating the organization of functionally segregated areas of the visual cortex. These areas are arranged into three parallel streams which deal with different stimulus attributes, such as form, color, and motion, and they are linked by a system of forward, backward, and lateral connections. Areas in the three streams contain simulated neurons with specialized response properties, such as selectivity to component motion, pattern motion, simultaneous color contrast, color constancy, and position-invariant discrimination of different shapes.

In the model, the process of ongoing signaling within and among these areas, called reentry, can give rise to both constructive and correlative properties. These properties are illustrated on the basis of examples taken from psychophysics. We propose that constructive properties, by means of which the activity of "higher" areas is reentered into a "lower" area of a different stream and modifies its responses to an incoming stimulus, underlie the generation of form from motion. Another consequence of such reentry is the emergence of temporal correlations in the activity of neuronal groups within a cortical area as well as between different areas (PNAS 86:7265, 88:129). This is exemplified in the model by the emergence of short-term correlations between different streams that are consistent with psychophysical capture phenomena, such as motion capture.

OPTIMIZATION ANALYSIS OF THE ORGANIZATION OF CORTICO-CORTICAL CONNECTIONS BETWEEN AREAS OF MONKEY CEREBRAL CORTEX, M.P. Young\*, Univ. Lab. of Physiology, Oxford, OXI 3PT, U.K.

The cerebral cortex is composed of many structurally and functionally distinct areas, each of which receives a large number of afferent inputs from other cortical areas and sends a large number of output projections. The cortex is thus served by a very large number of cortico-cortical connections, so that the areas and their inter-connections form a network of remarkable complexity. In fact, at least 834 projections are presently known to interconnect the 70 or so cortical areas of the Macaque, of which at least 305 projections link the 30 or so areas of the monkey visual system. Understanding the gross organization of cortical processing systems hence represents a formidable topological problem.

gross organization of collectar processing systems after type-controlled to the controlled problem. I have pursued an optimization approach to this topological problem that gives both qualitative and quantitative insight into the connectional topology of the cortical systems. The first step in the analysis is to derive a connection matrix by collating information about connections from the neuroanatomical literature. The second step is to derive by optimization a structure which best explains the variability in the connection matrix by placing areas at optimal points so that the length of connections between them is at a global manimum while the length of non-connections is at a global maximum.

The results show that the visual system is divided into a dorsal 'stream' and a ventral 'stream' with limited cross-talk, that the system is hierarchically organized, that these two streams reconverge in area 46 and in the superior temporal polysensory areas, and that the 'wiring' can be accounted for by a neighbourhood wiring rule together with 3 fascicles. The auditory system is arranged in a single hierarchy with progressively higher' stations distributed more rostrally on the superior temporal gyrus. The somatosensory system is another hierarchy, but unlike the other sensory systems, it contains the cortical motor system as a diverticulum about half way up the hierarchy. An analysis of the entire cortico-cortical network showed the limbic structures and most of the prefrontal cortical areas to be topologically closely associated, forming a 'fronto-limbic complex' to which the 'higher' areas of the sensory systems project.

DYNAMICAL CONTROL OF VISUAL ATTENTION THROUGH FEEDBACK PATHWAYS: A NETWORK MODEL. <u>K.P. Unnikrishnan\* and Janani Janakiraman</u>, GM Research Laboratories, Warren, MI 48090 and The University of Michigan, Ann Arbor, MI 48109.

Attention involves the ability of the visual system to filter out unimportant features, resolve ambiguities and enhance relevant features. Associations learned at higher brain centers play an active role in the dynamics of visual attention, possibly by affecting the processing at lower centers. A model is presented to investigate the role of feedback pathways from association cortical areas to primary visual cortex and lateral geniculate nucleus in attentional mechanisms.

In this model, visual attention is viewed as a unitary process, linking peripheral sensory relays with higher level pattern analyzers through a well established feedback loops (1,2). Previously learned associations between images affect the processing at the lower level neurons through the feedback loop. The Alopex algorithm used in our simulations can easily be carried out by known neuronal circuitry (3).

Computer simulations of the system are presented. These diffuse feedback pathways are shown to be capable of dynamically modifying tuning properties of lower level neurons and hence quicken the convergence properties of these networks. These results show how dynamic changes in the tuning properties of lower level neurons can help the visual system to focus attention rapidly. The change in tuning properties of V4 and IT neurons in the monkey has lead to the hypothesis that these changes play a role in some of the static aspects of attention (4). Our results show that this may instead be a dynamic phenomenon, helping the visual system to focus attention rapidly.

# 313.8

MODELING INTEGRATION IN THE VISUAL CORTEX G. Tononi, Q. Sporns, and G.M. Edelman\*, The Neurosciences Institute, 1230 York Ave., New York, NY 10021.

The visual system consists of multiple, anatomically segregated and functionally specialized cortical areas which are linked by a network of reciprocal connections. Although there is no evidence that these areas are coordinated by a higher order center, the visual image that we perceive seems to be unified and coherent. In an extension of our previous work, we address the problem of perceptual integration in the brain based on the notion of reentry, a process of parallel and recursive signaling along ordered anatomical connections within and among maps.

We have developed a computer model simulating nine functionally segregated visual areas organized into three streams for form, color, and motion. The model receives visual input consisting of camera images of objects of different shapes and colors. A computational strategy involving a phase variable is introduced to represent explicitly the dynamics of short-term temporal correlations among thousands of units distributed across different areas. The model solves the so-called "binding problem" through short-term correlations, which serve to link similar object features within a simulated cortical area and to bind multiple attributes of one or more objects across several areas, including a non-topographic one. Integration emerges from cooperative effects within and among the specialized areas, and it leads to a simulated foveation response, that can be used as a basis for conditioning. Reward is simulated through the activation of a saliency system that resembles diffuse projection systems in the brain. Resulting distributed synaptic changes allow the model to successfully discriminate among multiple input stimuli that require the dynamic conjunction of form, color, and location.

OPTIMIZATION ANALYSIS OF THE CONNECTIONS BETWEEN AREAS OF CAT CEREBRAL CORTEX. I.W. Scannell. M.P. Young and Colin Blakemore SPON: Brain Research Association. Univ. Lab. of Physiology, Oxford, OX1 3PT.

The cat cerebral cortex is composed of about 65 areas and is served by at least 1139

The cat cerebral cortex is composed of about 65 areas and is served by at least 1139 cortico-cortical connections. Characterizing a processing system of such complexity represents a formidable topological problem.

We collated cat cortico-cortical connection data and produced a connection matrix

We collated cat cortico-cortical connection data and produced a connection matrix which recorded the presence or absence of connections and an estimate of their density. From this we computed a topological map which best explained the variability in the connection matrix (see Young, this volume). To assess the effect of differences in the published descriptions of the density of connections we made a quantitative comparison between the 'best' map (computed from the density-coded matrix) and maps produced from two alternative matrices; in one all connection strengths were made equal, and in the other all the weak connections were discarded. The alternative solutions explained 96% of the variance of the 'best' solution, showing that possible errors in estimating the connection density did not have a major effect on the topological structure.

The results show four topological clusters of areas which correspond to the visual,

The results show four topological clusters of areas which correspond to the visual, auditory, somatosensory-motor systems and a 'fronto-limbic' complex. The cat visual system is divided into two streams by virtue of its connectivity with non-visual areas. One stream, containing area 7, the anterior ectosylvian sulcus and the oculomotor areas passes towards the somatosensory-motor system. The other, containing areas PS, 20b and EPp, passes towards the auditory system. Unlike in the monkey, the visual streams do not project densely to the fronto-limbic complex. The auditory system is also a 2-streamed hierarchy. The dorsal auditory areas project more heavily to the dorsal fronto-limbic areas and the ventral auditory areas to the ventral fronto-limbic areas. The somatosensory-motor system is a single hierarchy as in the monkey. The primary motor cortex is closely associated with SI, SII and area 5, and the premotor cortex is closely associated with area 5 and SIV. The higher auditory and somatosensory areas have strong connections with the fronto-limbic complex which is the system most distant from the sensory periphery. A COMPUTATIONAL STUDY OF CORTICAL HYPERCOLUMNS AND THE TOPOLOGY OF RANDOM ORIENTATION MAPS Eric L. Schwartz and Alan Rojer\*, Computational Neuroscience Lab., NYU Med. Ctr. 550 1 st Ave. NY 10016 and Dept. Computer Science, Courant Institute of Mathematical Sciences,

Smoothing a random pattern of orientations causes the appearance of orientation similar to the hypercolumn pattern of monkey visual cortex, and to the "pinwheels" that have been recently observed in cat area 18. The generic presence of such patterns in continuous random orientation maps is a consequence of a basic topological theorem (non-retraction of  $R^2 \rightarrow S^1$ ), as illustrated with computer simulations and animation. Several of the qualitative features of cortical hypercolumn patterns, including the features of the "puff-extra puff" structure of monkey V-1, are evident in our simulations. The principle conclusion of this work is that any measurement procedure, such as optical dye recording, 2-deoxyglucose, or multi-unit recording, which has a measurement resolution in the range of 100µ to 200µ, is insufficient to establish the detailed structure of cortical hypercolumns, and may in fact artifactually produce such hypercolumn structure out of random orientation noise. Consequently, methods such as optical dye recording are not a reliable indicator of these patterns. Since single unit recording has never unambiguously established the structure of the hypercolumn pattern, our current knowledge of this fundamental feature of cortical architecture is called into serious question. And, given a reliable future demonstration of the details of the hypercolumn pattern, it must be remembered that there is no physiological, developmental, or computational mechanism that need be invoked to produce them. They are noise patterns, whose production is a by-product of the definition and the topology of orientation maps

COMPUTER RECONSTRUCTION FROM 2DG SERIAL SECTIONS OF THE TOPOGRAPHIC MAP OF MACAQUE VISUAL CORTEX David Roser Amar Munsif, Thomas D. Albright, and Eric L. Schwartz\* Comptl. Neuro. Lab., NYU Med. Ctr. 550 1 st Ave. NY 10016, Dept. Comp. Sci., Courant Inst. of Math. Sciences, NYU, and Salk Inst., P.O.Box 85800, San Diego, CA.

We present a quantitative two dimensional estimate of the Macaque V-1 topographic map, the cortical magnification factor, and, for the first time, an estimate of the error in the measured map function. Autoradiograms of coronal sections obtained after 2DG was administered and a stimulus pattern was presented to a paralyzed monkey, were reconstructed into a 3D model of the cortex. This 3D numerical model was then flattened into a 2D model, which was fit with a conformal map using the Nelder simplex algorithm. The fitted map function determined the (small) error in eye position of the paralyzed monkey, and allowed us to com pute cortical magnification factor through numerical differentiation. The conformal (locally isotropic) maps generated for two monkeys are in quantitative and qualitative agreement with the experimentally determined V-1 topographic map. The generated maps are in turn similar to the complex log map, which provides a good approximation to the topographic map of Macaque V-1, as suggested in ea-lier work. Cortical magnification factor derived from these maps is in good agreement with the previous work of the labs of Dow and Van Essen, but is in significant disagreement with the recent measurements of Tootel et al(JNS,6(1989). However, we found that these latter measurements, when corrected for errors introduced by the large step size used in their derivation, are in agreement with our data and other recent estimates. The computer software that was used to perform the 3D reconstructions and 2D flattening has recently been made available to interested workers under support of the System Development Foundation and the NIMH. # INGESTIVE BEHAVIOR: SALT APPETITE AND FOOD INTAKE

### 314.1

SODIUM APPETITE IN THE SHAM DRINKING RAT AFTER CHORDA TYMPANI

1 h 35.3±2.8 9.5±2.3 10.7±2.4 6.2±1.1 2 h 46.0±3.4 13.1±2.8 11.9±2.9 9.8±1.6 These results strongly suggest that Information provided by the CT is critically important to the strong motivational properties of NaCl after Na\* depletion. This information is likely to be based on signals in the CT which correspond to activity generated by Na\* transport through channels in taste buds specifically blocked by the diuretic amilioride.

Support: NIH DK39180 (SPF), DC00248 (ILB) & Training Grant T2HD07391.

# 314.3

EVIDENCE THAT VISCERAL INPUT SENSING REDUCED VASCULAR PRESSURE AND VOLUME FACILITATES ANGIOTENSIN-INDUCED SALT APPETITE. R.L. Thunhorst\* and .K. Johnson. Dept. of Psychology and Pharmacology and the Combined ac administration of the diuretic, furosemide (10

mg/kg) with a low dose of the angiotensin-converting enzyme (ACE) inhibitor, captopril (5 mg/kg), that blocks ACE only in peripheral tissues, rapidly induced ingestion of 0.3 M NaCl solution and water (>4 ml of each in 2 hrs). This treatment increases renin secretion by reducing fluid volume and by interrupting the negative-feedback k involving angiotensin ii (ANG II; Fitts, D.A. & Masson, D.B., Behav, Neurosci., 1989, v.103), and we have found that it reduces me arterial pressure (MAP) as well, thereby presumably unloading both cardiopulmonary and arterial baroreceptors. Centrally-formed ANG (via unblocked brain ACE) partially mediates ingestion in this protocol because intakes were abolished after blockade of the reninangiotensin system with a greater dose of captopril (100 mg/kg), that blocks brain ACE as well as peripheral ACE, or with the AT1 receptor blocker, Losartan (DuP 753; 5 or 20 mg/kg, sc). Furthermore, unloading of cardiopulmonary and arterial baroreceptors in this protocol likely facilitates the action of centrally-acting ANG, because central infusions of ANG II (15 or 30 ng/hr) rapidly elicited substantial saline intakes only after fluid volume and MAP were reduced by treatment with furosemide and high dose captopril. Therefore, withdrawal of signals from vascular volume and pressure receptors facilitates salt intake to centrally-acting anglotensin. Supported by NIH grants HL44546 and HL14388.

RENIN-ANGIOTENSIN SYSTEM (RAS) BLOCKADE DURING PREWEARLING DEVELOPMENT PRODUCES LONG-TERM INCREASES IN WATER INTAKE IN RATS. R. Kirby\*, M, Henry, A Alt. C. Novak, A. Revelz and A. Johnson. Dept. of Psychology and the Cardiovascular Center, Univ. of Iowa, Iowa City, IA 52242. The present study examined the influence of RAS blockade during the late preweaning period, when a rat pup initially begins to ingest fluids other than the dam's milk, on the intake of water and hypertonic NaCl solution during the postweaning period. Wistar-Kyoto (WKY) and spontaneously hypertensive rat (SHR) pups were administered losartan potassium (10 mg/kg s.c.), an anglotensin il type ceptor antagonist, daily from postnatal day (PD) 11 through 20 On PD22 animals were weaned to individual cages and intakes of tap water and a 0.3M NaCl solution were monitored daily. Blockade of the RAS produced elevated water intakes through at least 50 days of age, no change in saline intake, and blunted body weight developmen between PD16 and PD18. To determine if the effects on body weight development were related to the increased water intake, a second study was conducted using the technique of artificial rearing. WKY pups were implanted with gastric catheters on PD11 and infused with a control diet or a diet containing losartan (approximately 10 mg/kg) until PD20. Pups were then weaned to metabolism cages from the artificial rearing procedure and daily measures of water and NaCl intake recorded. Biockade of the RAS increased water intake and urine output. However, there was no effect of losartan treatment on body weight development when intake was fixed using the artificial rearing procedure. These data indicate that RAS activity during the preweanling period has lasting influences on body fluid metabolism.

Angiotensin II Participates In Sodium Intake and C-Fos Immunoreactivity In A Rapid Salt Appetite Paradigm. M. Z. Cicha, A. M. Zardetto-Smith\*, R. L. Thunhorst, and A. K. Johnson, Depts. of Psychology, Pharmacology and the Cardiovascular Center University of Iowa, Iowa City, IA 52242.

Administration of angiotensin elicits salt intake and induces c-fos immunoreactivity (fos-IR) in forebrain areas associated with body fluid homeostasis. In this study, we employed fos-IR as a neuronal marker for areas participating in the behavioral response to sodium depletion, that is, salt appetite. The protocol used in this study produces high levels of circulating angiotensin, and tests were performed to examine produces might event of cucuating anglorism, and tests were performed to examine the contribution of angiotensin to sodium intake. Rats were given furosemide so (Furo, 10 mg/kg) followed 5 min later by either a low dose of captopril so (Lo Cap, 5 mg/kg), which blocks only peripheral converting enzyme, or a high dose of Cap (Hi Cap, 100 mg/kg), which blocks both central and peripheral converting enzyme. Additional animals received DuPont 753, a specific ATI receptor blocker sc (DuP, 10 mg/kg). Two hr later, animals were euthanized and the brains processed using the avidin-biotin technique for fos-IR. Another series of animals received the same treatments, but were allowed access to water and 0.3 M saline to assess intakes. treatments, but were allowed access to water and 0.3 M saline to assess intakes. Rats receiving the Furo/Lo Cap combination consumed both saline and water. Rats receiving the Furo/Lo Cap combinations drank neither water nor saline. Rats receiving the Furo/Lo Cap combinations drank neither water nor saline. Rats receiving the Furo/Lo Cap combination demonstrated the heaviest fos-IR within the organum vasculosum of the lamina terminalis (OVLT), median preoptic nucleus (MnPO), subfornical organ (SFO), supraoptic (SON) and paraventricular (PVN) nuclei. Fos-IR was greatly reduced in the OVLT, MnPO, SFO, PVN and SON in rats receiving Furo/Hi Cap or Furo/Lo Cap/DuP treatments. The results show that fos-IR expression is high in areas implicated in the control of body fluid homeostasis following procedures which generate salt appetite, and that the intake and fos-IR expression produced by this protocol depend at least in part on AT1 receptors.

Supported by NIH grants HL44546 and HL14388.

C-FOS EXPRESSION INDUCED IN THE CIRCUMVENTRICULAR ORGANS OF THE LAMINA TERMINALIS BY CIRCULATING ANGIOTENSIN II IN RATS. M.J. McKinley, E. Badoer, R.S. Weisinger, B.J. Oldfield\*. Howard Florey Institute of Experimental Physiology and Medicine, University of Melbourne, Parkville, Vic, Australia 3052.

Thirst and a centrally-mediated pressor response are some of the physiological effects of circulating angiotensin II (ANG II) thought to be mediated by an action of ANG II on cerebral sites, such as the subfornical organ (SFO), organum vasculosum laminae terminalis (OVLT) or area postrema (AP). The aim of the present experiments was to determine whether blood-borne ANG II induced neurons in these regions to increase Fos production. Fos was detected immunohistochemically. Intravenous (IV) ANG II (0.5-5µp/h for 1.5-2h, n=6) in conscious rats induced Fos-immunoreactivity (Fos-IR) in the SFO and OVLT and, to a lesser extent, in the AP, whereas IV isotonic saline (n=4) did not. IV phenylephrine (0.1mg/kg/h for 2h, n=4) which produced a pressor response (~40mmHg) increased Fos-IR in the AP, but not in the SFO or OVLT. Sodium depletion for 2h resulting from furosemide treatment (20mg/kg ip, n=4), which elevates endogenous ANG II levels in blood, increased Fos-IR in the SFO, OVLT and AP. This effect was inhibited in the SFO and OVLT but not in the AP by angiotensin converting enzyme inhibitors. These data support the view that both the SFO and OVLT are sites at which blood-borne ANG II exerts its central actions, whereas Fos-IR induced in the AP in these experiments is not necessarily due to direct actions of circulating ANG II on AP neurons. II on AP neurons.

### 314.7

INTRADUODENAL GLUCOSE ENHANCES INHIBITION OF SHAM FEEDING BY CCK-8. J.E. Cox\*, Dept. Psychol., Univ. Alabama-Birmingham, Birmingham, AL 35294.

Impairment of runway performance by cholecystokinin octapeptide (CCK-8) is potentiated by duodenal infusion of 30% sucrose (Behav. Brain Res 38:35-44). The purpose of the research described here was to determine whether this effect generalizes to sham feeding when the infusate is glucose, at concentrations lower than that used previously. Adult, male Sprague-Dawley rats (N = 9) sham fed 30% sucrose for 30 min beginning 10 min after intraperitoneal injection of 1 ug/kg CCK-8 or normal saline. Throughout each test, each rat received duodenal infusion of 0.3 M or 0.6 M glucose or saline at 0.388 ml/min or no infusion. A subset (N=5) of the rats underwent additional tests with infusate concentrations of 0.375 M and 0.45 M. Sham feeding was significantly reduced by 1 ug/kg CCK-8 when given in conjunction with glucose, at all concentrations (P's < .05). By contrast, in the absence of duodenal infusions, CCK-8 was without effect. On tests with duodenal saline infusions, CCK-8 was effective only in conjunction with the highest concentration, 0.6 M. Thus, these results demonstrate that (1) a dose of CCK-8 by itself ineffective in reducing sham feeding can be rendered effective by concurrent duodenal infusion of glucose; (2) glucose concentrations at least as low as 0.3 M are sufficient to produce this potentiation; and (3) glucose appears to be more effective in this regard

STEROID RECEPTORS (TYPE I AND II) IN THE PARAVENTRICULAR NUCLEUS (PVN) MODULATE NUTRIENT INTAKE. D.L. Tempel\*, T. Kim. and S.F. Leibowitz, Rockefeller Univ. N.Y. N.Y. 10021.

Adrenalectomy (ADX) suppresses carbohydrate and fat intake over the 24hr period in the rat. At the start of the dark feeding cycle, the primary effect of ADX is a strong and selective suppression of carbohydrate intake. Subcutaneous (sc) as well as PVN administration of corticosterone (CORT) selectively restores carbohydrate ingestion in ADX rats at this time of the feeding cycle. The present studies, using specific steroid receptor agonists and antagonists, examined the steroid receptor subtype, the type I or type II, which mediates the selective effect of CORT on carbohydrate ingestion at dark onset. Results indicate that in male ADX rats, fed pure macronutrient diets, sc or PVN administration of CORT or the type II agonist RU362 selectively stimulates carbohydrate ingestion at dark onset, (+5.4 and +7.3 Kcak respectively, p < 0.05). In contrast, the type I agonist aldosterone (ALDO) predominantly stimulates fat intake in both sham (+4.5 Kcals; p < 0.05) and ADX (+4.0 Kcals, p <0.05) rats. Blockade of PVN type II receptors with the selective antagonist RU486 abolished the carbohydrate-stimulatory effect of both CORT and RU362 but had no effect on the fat-stimulatory effect of ALDO. Conversely, type I steroid receptor blockade with RU318 antagonized ALDO-induced fat intake, while leaving CORT and RU362-induced carbohydrate intake unaffected. In addition, a role for these receptors in mediating natural feeding behavior is suggested by results demonstrating that RU486, in the PVN of adrenal-intact rats, strongly inhibits spontaneous carbohydrate ingestion at dark onset, while RU318 inhibits natural fat intake. These data suggest that PVN type I receptors may be involved in modulating fat ingestion, while PVN type II receptors are important in controlling carbohydrate ingestion specifically at the onset of the dark feeding cycle.

GUSTATORY EXPERIENCE ALTERS TYROSINE PHOSPHORYLATION IN RAT CORTEX. K. Rosenblum, N. Meiri, Y. Hadari, Y. Zick and Y. Dudai\*, Weizmann Institute of Science, Rehovot 76100, Israel

We are investigating short- and long-term experience-dependent modifications in rat cortici that subserve chemical senses. Recently, we have reported that protein synthesis in gustatory cortex is necessary for the formation of long-term taste memory (Rosenblum et al. Soc. Neurosci. Abst. 17: 660 and in press). In the present study, we have quantified fast alterations in tyrosine phosphorylation of cortical proteins following gustatory experience. Adult male rats were placed on a partial fluid-deprivation schedule (20 ml water allowed only during 10 minutes per day, with food pellets ad libitum). On the day of the experiment, the rats were divided into 4 groups: group 1 was presented with 20 ml water, group 2 with 20 ml 0.1% saccharin solution, group 3 with saccharin followed by an i.p. injection of LiCl (0.15 M, 2% body weight), and group 4 with neither water nor saccharin. The rostral insular cortex (which contains the gustatory saccharm. The rostral insular cortex (which contains the gustatory cortex) was immediately removed, homogenized, and subjected to SDS-PAGE followed by Western immunoblotting with an anti-phosphotyrosine antibody. A set of phosphoproteins was detected in the MW range of 35-180 kD. Significant differences were found among the experimental groups in the level of tyrosine phosphorylation of several proteins, especially those of MW 110 and 180 kD. The level of tyrosine phosphorylation in rats that drank saccharin was higher than in those that drank water. Phosphorylation was highest in the LiCI treated rats and lowest in those that did not drink at all. Gustatory experience can thus induce fast alterations in tyrosine phosphorylation in brain. (Supported by a grant from the Whitehall Foundation.)

REPEATED MORPHINE IN NUCLEUS ACCUMBENS: CONDITIONING AND SENSITIZATION OF FEEDING. <u>V.P. Bakshi\*</u>, A.E. Kelley and S.M. Fleming. Dept. of Psychology, Northeastern University, Boston, MA. 02115.

Acute administration of opioids into the nucleus accumbens (N.Acc.) results in hyperphagia in rats. The present study was conducted to investigate the effect on feeding of multiple opiate injections into this region. On all test days, behavior in sated rats was rated every 10 min for a 2 min period over a total of 4 h immediately following infusion. Food intake and spillage were calculated at the end of each session. Two experiments were completed. In the first, animals were given repeated littered between the second of the seco session. Two experiments were completed, in the first, animals were given repeated bilitateral infusions of either saline or morphine ( $10 \, \mu g/0.5 \, \mu$ ) into N.Acc. and then challenged with a saline and mock infusion (injector tips were lowered but no solution was delivered). Animals that had received multiple morphine injections exhibited a marked increase in food intake and feeding score in response to both the saline challenge and the mock injection, compared with pre-morphine saline levels. This conditioned feeding effect was present up to 18 d after the final morphine infusion. Repeated morphine administration also resulted in sensitization of feeding; a progressive and robust increase in food intake was noted with successive injections. a progressive and robust increase in tool make was noted with successive injections. Multiple saline injections had no behavioral effects. In order to examine the involvement of opiate receptors in these phenomena, a second experiment was conducted in which rats were given repeated injections of either morphine (5  $\mu$ g/0, 5  $\mu$ l) or a mixture of agonist and antagonist [(5  $\mu$ g morphine + 5  $\mu$ g methyl naloxonium)/1.0  $\mu$ l] followed by a mock infusion. Again, rats that had received multiple morphine injections showed both conditioned and sensitized food intake and multiple morphine injections showed both conditioned and sensitized food intake and feeding. However, co-administration of the opiate antagonist blocked the development of both effects. Interestingly, all conditioned feeding was immediate in onset whereas the acute morphine effect occurred after a delay of approximately 120 min. Results suggest that repeated stimulation of opiate receptors within the N.Acc. leads to a heightened ability of cues (i.e.-the injection procedure) associated with morphine presentation to elicit hyperphagia. This finding may have important implications for understanding disorders of impulse control, and in particular, compulsive eating.

DOPAMINE IN THE PERIFORNICAL HYPOTHALAMUS ATTENUATES NEUROPEPTIDE Y-INDUCED FEEDING. E.R. Gillard\*, D.O. Dang & B.G. Stanley, Depts. Neuroscience & Psychology, University of California, Riverside, CA 92521.

Mapping studies suggest that the perifornical hypothalamus (PFH) is a primary locus for both the feeding stimulatory effect of neuropeptide Y (NPY) and the anorectic effect of catecholamines (CA), suggesting that NPY and CA may interact antagonistically To investigate this, amphetamine (AMPH) was injected through indwelling guide cannulas into the PFH of satiated adult male rats 5 min prior to injection of NPY (78 pmol/0.3  $\mu$ l) and food intake was measured 1, 2, and 4 hrs later. Amphetamine (50-400 nmol) dose-dependently reduced NPY feeding, usually eliminating it at the higher doses. The receptors mediating this effect were investigated by sequential injection of CA antagonists, AMPH, and NPY into the PFH. Neither the α- nor β-adrenergic antagonists phentolamine or propranolol (100 nmol) significantly affected AMPH anorexia. In contrast, haloperidol (5 nmol) abolished the AMPH suppression of NPY feeding, suggesting that dopamine (DA) mediates the AMPH effect. To examine this, epinephrine (EPI) and DA (25-200 nmol) were tested for suppression of NPY-induced feeding. While EPI had no significant effect, DA at the maximally effective dose (50 nmol) significantly reduced the feeding response by 33% or more. These findings provide convergent evidence for antagonistic interactions between endogenous DA and NPY in the control of eating behavior.

ROLE OF AMYGDALOID CATECHOLAMINES IN FEEDING:A MICRO-DIALYSIS STUDY IN FREELY MOVING RATS. L. Lenard, A. Hajnal, Z. Karadi, I. Abraham, I. Vida, A. Czurko & T. R. Scott\* European Neuroscience Association) Institute of

Physiology, Pecs Univ. Med. School, Pecs, H-7643 Hungary The amygdala (AMY) is innervated by dopaminergic (DA) elements of the mesolimbic system and by noradrenergic (NA) terminals of the coerular-medullary NA cell groups. Our previous data based on different neurotoxic treatments of the AMY showed that a relative DA deficit caused body weight loss and hypophagia, while hyperhagia and weight increase occurred after a relative decrease of NA level. In the present experiments microdialysis probes were implanted into the medial or central part of the AMY and catecholamines (CAs) and their metabolites were determined by HPLC. Measurements were made after food deprivation or satiation and after insulin or glucose challenges Deprivation was followed by a sharp decline in L-DOPA, NA and DOPAC levels while a significant increase occurred in the extracellular DA content. These changes reversed to initial values after satiation. No significant change of 5-HIAA level was observed after deprivation. changes to those seen after deprivation were observed following insulin challenges, while glucose treatments led to similar response patterns observed after satiation. results provide additional support for the role of AMY CA systems in the regulation of feeding and demonstrate that hunger and satiety states are accompanied by opposite changes of AMY CAs and their metabolites.

### 314.12

LATERAL HYPOTHALAMIC INJECTION OF GLUTAMATE ELICTS EATING IN RATS. Stanley, B.G., Ha, L.H., Spears, L.C. Depts. Neurosci. & Psych., Univ. California, Riverside, CA 92521.

While lateral hypothalamic (LH) control of eating behavior has been suggested by extensive lesion, electrophysiological, and biochemical data, there is little evidence to specify the neurotransmitters mediating its effects. Glutamate (GLU) is a likely candidate, as it is localized within the LH and has pervasive excitatory effects on neurons there (van den Pol, J. Neurosci., 11, 1991, 2087). To test this, GLU was injected, through indwelling guide cannulas, directly into the LH of satiated adult male rats, and food intake was measured 1, 2, and 4 hrs later. Glutamate (300 to 900 nmol/0.3 µl artificial CSF) produced dose-dependent increases in eating (means of 3.7 to 5.2 gm) only within the first hr of injection. To determine the locus of this effect, GLU was injected into anatomical sites bracketing the LH. In contrast to the eatingstimulatory effect in the LH, injections < 1.5 mm anterior, posterior, medial, lateral, or dorsal to this site were ineffective. Finally, as a first step in determining the receptor subtypes mediating the eating response, injections of kainate (KA), NMDA, and AMPA, prototypical agonists of these subtypes, were tested. Although all three agonists produced significant eating, KA was particularly effective. The threshold dose was 0.33 nmol, and at > 1.0 nmol KA consistently elicited mean increases of over 9 gm within 1 hr of injection. These findings suggest that glutamate in the LH may be a neurotransmitter in neuronal systems mediating eating behavior.

IMPLICIT MEMORY FOR REPRESENTATIONAL AND NOVEL VISUAL MATERIALS IN PATIENTS WITH ALZHEIMER'S DISEASE. J.D.E. Gabrieli. S. L. Reminger, D.A. Grosse, and R. S. Wilson'. Rush Alzheimer's Disease Center, Chicago, It. 60208.

Patients with Alzheimer's Disease Center, Chicago, It. 60208.

Patients with Alzheimer's disease (AD) have impaired explicit memory, but intact implicit memory (i.e., repetition priming or the influence of prior processing upon the reprocessing of a stimulus) on some tasks in which they see words or pictures. The pictures in those studies were representational drawings of real objects known premorbidly by the AD patients. The present study examined whether AD patients could show implicit memory for novel visual stimuli. Nine early-stage AD patients and 10 normal control (NC) subjects saw drawings of real objects and novel nonobjects with object-like appearances (from Kroll and Potter, 1994). There were two identical study phases followed by tests of implicit or explicit memory. In both study phases, subjects performed an object decision task in which they saw 20 objects and 20 nonobjects and had to decide whether each drawing was that of an object or a nonobject. In the implicit test, subjects performed the same task with the 40 previously-seen and 40 baseline drawings. In the explicit test, subjects performed a yes/no recognition task with 40 previously seen drawings and 40 folis. All responses were vocal, and response latencies and accuracies were recorded. In the explicit test, subjects recognized objects more accurately than nonobjects, and AD patients were impaired for recognizing both kinds of drawings. In the implicit test, AD patients were impaired for recognizing both kinds of drawings. In the implicit test, AD patients were impaired for recognizing both kinds of drawings. In the implicit test, AD patients were impaired for recognizing both kinds of drawings. In the implicit test, AD patients were impaired to recognizing both kinds of drawings. In the implicit test, AD patients were pe

### 315.2

DIMENSIONALITY OF THE SEMANTIC SPACE IN ALZHEIMER'S DISEASE PATIENTS. A. S. Chan, N. Butters \*, D. P. Salmon and K. A. McGuire. Depts. of Psychiatry and Neurosciences, Univ. of Cal., San Diego, CA 92093 and VA Medical Center, San Diego, CA 92161.

The organization of semantic memory in Alzheimer's disease (AD) patients was investigated by a triadic comparison task in which subjects chose, among three concepts, the two that are most alike. A multidimensional scaling statistic was used to analyze the proximity data, resulting in a three-dimensional cognitive map for each subject. The cognitive maps, indicating the attributes and the saliency of those features that were used by subjects in categorizing concepts, were compared by discriminant analysis. The results suggest that the structure of semantic memory in AD patients is significantly different than that of NC subjects in two ways. First, AD patients are less consistent in utilizing the attributes of concepts. Second, AD patients focus primarily on concrete conceptual information (size), whereas NC subjects stress abstract conceptual knowledge (domesticity). The performance of AD patients was highly consistent over two sessions within a week. These results not only support the notion that AD patients are characterized by knowledge deterioration, but also suggest that the semantic memory in AD patients may undergo a structural alteration.

DISTRIBUTED NEURAL NETWORK UNDERLYING MUSICAL SIGHT-READING AND PIANO PERFORMANCE. J. Sergent\*, B. MacDonald and S. Terriah. Cognitive Neuroscience Laboratory, Montreal Neurological Institute, McGill University, Montreal, Canada.

Music is a message comprising combinatory acoustical patterns and, like speech, is governed by rules of grammar and syntax, has both an expressive and a receptive side, is made of sounds that can be translated into print, and involves fine motor activity for its production. However, a musical phrase does not convey the same sort of information a verbal sentence does; it evokes feelings and emotions rather than referring to entities in the world; musical notation is grahically, symbolically, and functionally different from the alphabetic writing system. These similarities and differences between the musical and verbal languages may explain why aphasia and amusia are sometimes, but not consistently, associated following brain damage. With the use of MRI and PET measurement of cerebral blood flow, the functional neuroanatomy of musical sight-reading and keyboard performance was studied in ten professional pianists. By comparing through the subtraction method the intensity and spatial pattern of cerebral activation associated with different experimental conditions, the results indicated that reading musical notations and translating these notations into movement patterns on a keyboard produced activation of cerebral areas distinct from, but adjacent to, those underlying corresponding verbal operations.

CROSS-MODAL ASSOCIATIONS AND THE HUMAN AMYGDALA. F.K.D.Nahm\*1,2,A.R.Damasio<sup>2,3</sup>,D.Tranel<sup>3</sup>,H.Damasio<sup>3</sup>. Univ. of California, San Diego<sup>1</sup>, The Salk Institute<sup>2</sup>, and Univ. of Iowa College of Medicine<sup>3</sup>.

It has been suggested that damage to the amygdaloid complex of non-human primates impairs tactile-visual cross-modal recognition (CMR). Investigations as to the role of the human amygdala in CMR as well as crossmodal matching (CMM) have been inconclusive. Here we report our attempt to clarify this question by studying two patients: SM-046 who has bilateral damage circumscribed to the amygdala and no damage to the hippocampal formation; and patient Boswell, whose damage in both temporal lobes includes ventral and mesial inferotemporal cortex, amygdala, hippocampus and interconnecting cortices. An Arc-Circle test was used to assess cross-modal matching and cross-modal recognition -- the CMR task included a 60-second delay between sample and match.

Patient SM-046 was not impaired on tactile-visual (T-V) or visual-tactile (V-T) versions of the CMR and CMM tasks as compared to IQ, gender and age-matched controls. Patient Boswell was also intact on the T-V and V-T versions of the CMM task. Taken together, the data indicate that the human amygdala is not involved in either the acquisition or recall of cross-modal associations between perceptually "equivalent" basic stimulus properties. However, since both patients have defects in learning and recalling knowledge which requires integration of higher-order perceptions and internal values (affect and emotion), we suggest that the cross-modal role of the human amygdala may be restricted to associations at this more complex level.

DEFECTIVE ESTIMATE OF FUTURE PUNISHMENT IN PATIENTS WITH

DEFECTIVE ESTIMATE OF FUTURE PUNISHMENT IN PATIENTS WITH PREFRONTAL DAMAGE AND IMPAIRED SOCIAL DECISION-MAKING. A. Bechara\*, S.W. Anderson, H. Damasio, and A.R. Damasio, Dept. of Neurology, Univ. of Iowa, Iowa City, IA 52242.

Damage to some prefrontal cortices in humans results in impaired decision-making and planning which is most marked in the social realm. It has been proposed that a possible cause of the defect is a failure to re-enact somatic states that would mark (overtly or covertly) negative future consequences of a selected option. Unable to estimate the prospect and magnitude of future punishment, the patients' behavior becomes governed by the presence of immediate reward. As part of a program to test this hypothesis, we developed a card game task, in which the goal was to maximize profit on a loan of play money, and in which response selection was guided by various schedules of immediate reward and future punishment. Subjects were asked to choose one card at a time, from one of four decks; choosing a card was always followed by an immediate reward of play money, but the amount was higher in some decks than in others; at unpredictable card was always followed by an immediate reward of play money, but the amount was higher in some decks than in others; at unpredictable points in each deck, choosing a card was followed by money loss, which was greater in the high reward decks than in the low reward ones. The task cannot be solved by mental computation, and relies instead on the ability to develop an estimate of which decks are less risky. Subjects were required to make 100 choices. Control subjects learned to select the most advantageous card decks after about 30 trials. By contrast, EVR (a prototypic patient with "acquired sociopathy" following prefrontal damage and who has superior memory and intellect) persistently selected alternatives which yielded high immediate rewards but brought larger future losses. The results are compatible with the hypothesis that EVR-like patients are defective in their ability to evaluate future risk, independent of their otherwise intact intellectual status. intellectual status Supported by NINDS PO1 NS19632.

PERCEPTUAL "FILLING IN" PHENOMENA IN PHANTOM LIMBS. V. S. Ramachandran, M. Stewart, D. Rogers-Ramachandran. Brain & Perception Lab, Psychology Department, UCSD, La Jolla, CA

We studied localization of sensations in a patient whose left arm had been amputated 8 cms above the elbow 4 weeks prior to testing. The patient experienced a "telescoped" phantom hand. We found that: a) A drop of warm water placed on his left cheek or 5 cms above the amputation line caused his phantom hand to feel warm. Water at room temperature was ineffective. Also, a pinprick 5 cm above the amputation line was felt as a distinct pinprick on an individual digit. Thus it would appear that the mislocalization can be *modality specific*. b) We used a Q-tip to study localization of touch. Remarkably, stimuli applied to points remote from the stump were mislocalized to the phantom hand. Furthermore, the distribution of such points was not random -- they appeared to be <u>clustered</u> on the lower left side of the face and there was a surprisingly precise point-to-point "mapping" between points on the face and specific digits (e.g., cheek to thumb; philtrum to index finger; chin to pinkie). It remains to be seen whether philtrum to index linger; chin to pinkie). It remains to be seen whether this clustering is a general finding or unique to this patient. Sensations from the neck, axilla, trunk, tongue, and contralateral arm were never mislocalized but there was a single point on the contralateral face that elicited referred sensations. c) A second "map" was found on the arm 3 cm above the amputation line with the pinkie represented laterally and thumb medially. The extreme rapidity of functional reorganization (4 weeks) suggests that it is probably subcortical in origin and may be related to the observations of Pons et al (Science, 1991). The word "switching" or "disinhibition" might be more appropriate.

# 315.9

CONSEQUENCES OF ORIENTING IN SOMATIC SPACE: A REACTION TIME STUDY. G. Tassinari, D. Campara, G. Berlucchi\*. Istituto di Fisiologia Umana, Università di Verona, I-37134 Verona, Italy It is known that covert orienting to spatial locations can be studied by asking normal subjects to detect targets presented in cued or uncued positions. Cues may either provide valid information about the spatial location of the targets or not. Many previous studies have shown that simple visuomotor reaction time (RT) is lengthened when the target is preceded by a non-informative visual cue on the same side of fixation, as compared to RT to opposite cues and targets. This result has been interpreted as a consequence of inhibition of motor reactions triggered by the cue: subjects are requested to suppress the natural overt orienting towards the cue, so that their general motor set is still affected by this directional vetoing command when the target comes from the same side. In the present experiment, we wanted to learn whether this directional constraint in motor readiness extends to the somatosensory modality by asking subjects to respond by a manual key-pressing to the second of two identical stimuli, delivered to the skin of either the same or opposite shoulders. Non noxious electrical stimulation, 4 msec in duration and about .15mA in intensity, was applied through surface electrodes. Ipsilateral or contralateral stimuli were randomly presented at four different stimulus onset asynchronies (SOA: 335, 850, 1750 and 4250 msec). RTs to ipsilateral combinations were significantly slower than RTs to contralateral combinations at the first three SOAs. A control experiment with the same two electrodes placed on either left or right shoulder at discriminable distances showed that lengthening of ipsilateral responses does

not depend on local adaptation but is a true consequence of a lateral unbalance. We conclude that a directional bias of orienting is present also in the somatic space.

PERCEPTUAL FILLING IN OF SCOTOMAS OF CORTICAL AND RETINAL ORIGIN. D. Rogers-Ramachandran\* V. S. Ramachandran, H. Damasio. UCSD and Iowa College of Medicine.

We studied perceptual "filling in" in two patients who had small

(6°) parafoveal scotomas caused by right occipital pole damage. We found that: a) A 3° gap in a vertical line was "completed" across the scotoma but the process took 6 seconds. b) when the two halves of the vertical line were misaligned horizontally by 2° they were seen to move vividly towards each other and become collinear before completion occurred. A similar effect occurred with horizontal lines but over much smaller misalignments (<0.5°). c) When viewing dynamic 2-D noise composed of red dots, one of the patients (R.D.) reported that the red color seemed to bleed into the scotoma first so that it was filled in with red for several seconds before being filled in that it was filled in with red for several seconds before being filled in with the noise. d) Coarse checkerboards were completed more readily than fine checkerboards. e) If the corner of a square or arc of a circle fell on the scotoma it was "filled in" (even when physically deleted from the stimulus). This effect cannot be observed in the natural bind spot. f) R.D. also reported that when the perceptually completed vertical line was switched off, he continued to see a persisting "phantom" of the filled-in portion of the line inside his scotoma for about 7 seconds.

None of these effects (except c) were ever observed in two

patients with identical scotomas caused by retinal lesions. We suggest that these intriguing filling in effects may be mediated by the kinds of dynamic reorganization of receptive fields that occur when lesions are made in the retina or in area 17.

INDEPENDENT TEMPORAL FACTORS UNDERLYING COGNITIVE PROCESSES. N.v.Steinbüchel, E.Pöppel\*, B.Hiltbrunner. Institut für Medizinische Psychologie, Universität München, Germany and Ciba-Geigy, Basel, Switzerland.

Previous studies have indicated that cognitive processes are quantized on two different levels, i.e. in the 40 Hz and the 0.3

quantized on two different levels, i.e. in the 40 Hz and the 0.3 Hz domain. These quantizations may reflect automatic binding operations and logistical constraints of central information processing. Independent of these automatic timing mechanisms, three different components of processing, reflecting different tasks could now be identified. This conclusion is derived from experiments on single and choice reaction time to auditory and visual stimuli, personal tapping tempo, high speed tapping and sensorimotor synchronization, performed with 36 subjects. With a principle component analysis, it was found that central decision timing, programming of movement times and repetitive timing represent different central timing algorithms. If choice reaction time is decomposed in its central decision component and motor execution, independent factors can be identified. An equivalent observation can be made studying sensorimotor coordination when a sequence of auditory stimuli has to be synchronized with motor responses. Interestingly, fast tapping and a preselected tempo (personal tapping tempo) appear to reflect the same mechanism of dynamic timing.

# 315.10

LATERALIZATION OF FRONTAL LOBE FUNCTIONS AND HANDEDNESS. K.Podell and E.Goldberg\*, Medical College of PA, Philadelphia, PA 19129

Prior research failed to establish a strong relationship between cognitive measures of hemispheric specialization and handedness. We present the first evidence, to our knowledge, for a robust relationship between handedness and functional lateralization of the frontal lobes in males. We developed a task measuring cognitive bias along the set maintenance (SM)/set shifting (SS) continuum. Low score indicates extreme SM bias, and high score extreme SS bias. Opposite performance patterns emerged when the task was given to right- and nonright-handed males (RHM and NRHM) with left and right frontal lesions (LFL and RFL). RHM with RFL (N=8) and NRHM with LFL (N=3) had low scores (SM bias); and RHM with LFL (N=5) and NRHM with RFL (N=1) had high scores (SS bias). Healthy controls and patients with posterior lesions, both right- and nonright-handed, had intermediate scores.

MEMORY FOR SPATIAL LOCATIONS AND SENTENCES IN DATA-BASED. AND KNOWLEDGE-BASED MEMORY SYSTEMS IN HYPOXIC SUBJECTS. R.O. Hopkins\* and R.P. Kesner, Department of Psychology, University of Utah, Salt Lake City, Utah 84112.

Subjects who have experienced a hypoxic episode and college student control subjects were tested for memory of temporal distance information using sentences and spatial locations. Using analogous procedures it was possible to assess memory for temporal distances in both the data-based and knowledge-based memory systems. Memory for knowledge-based information was assessed by the presentation of 8 words that were organized into syntactically and semantically correct sentences and 8 X's that formed a specific spatial pattern. Memory for data-based information was assessed by the presentation of 8 words that were organized into nonsense sentences and 8 X's that formed a random spatial pattern. During the study phase subjects 8 X's that formed a random spatial pattern. During the study phase subjects were presented with a list of 8 items which were presented on a computer screen, one at a time, for a duration of 5 seconds. During the test phase subjects were presented with either 2 words or 2 spatial locations (X's) that had occurred in the study phase. Subjects were asked to choose the item that occurred earlier in the sequence. Temporal distance was determined by the number of items that occurred in the study phase between the two test items. Choices occurred across temporal distances of 0, 2, 4 and 6, with 8 observations for each temporal distance. Results indicate that hypoxic ooservations for each temporal distance. Hesults indicate that hypoxic subjects were impaired across all distances for new data-based information for both the sentences and spatial locations. However, hypoxic subjects performed similar to control subjects for all distances in the knowledge-based sentences and spatial locations tasks. The results suggest that hypoxic subjects can remember knowledge-based information, but have a difficult time remembering new data-based information.

### 315.13

THE ABSENCE OF CONTEXTUAL INTERFERENCE IN THE MNEMONIC PERFORMANCE OF AMNESICS. Elizabeth A. Phelps\*, William Hirst, Craig

PERFORMANCE OF AMMESICS. <u>Elizabeth A. Phelps\*. William Hirst. Craig</u>
Piers. Stephen Hartman. Bradford Richards. and Bruce T. Volpe. Center for
Neural Science, New York Univ., N.Y., N.Y. 10003
Studies on experimental animals suggest that the hippocampus may be
necessary for forming relations between multiple cues (Eichenbaum et al.,
1991, Sutherland & Rudy, 1989), such as contextual cues present during
learning. The extension of this hypothesis to human hippocampal function,
suggests that changes in context should differentially effect the mnemonic
performance of amnesics and normal control subjects. Two studies examined amnesic subjects, however, were not effected by the change in context and their recognition performance is superior to their cued recall performance. Both

RIGHT HEMISPHERE COGNITION DOES NOT REQUIRE RIGHT HEMISPHERE LANGUAGE. J.E. Bogen\* and D.L. Van Lancker. Depts. of Neurosurgery an Neurology, Univ. of So. Calif., Los Angeles, CA 90033.

t has been asserted (Gazzaniga, 1983 and 1987) that the disconnected right hemisphere without language [in right handers] is cognitively inferior chimpanzee or even a monkey. Related is the even stronger claim (Edelman, 1989) that human consciousness requires language. These claims are contradicted by a wealth of evidence. Examples are presented from split-brain subjects, patients rendered aphasic by large left hemisphere lesions, apnasic by large left nemisphere lesions and from two patients hemispherectomized in adulthood after customary development as right-handers. A relevant videotape will be available in the video viewing

whether this is the case. Amnesics and controls were shown a picture of a family and learned a list of facts about this family. Subjects were then shown two pictures, one of the same family and one of a new family. For each picture the subjects were asked to learn a new set of facts about the family, some of which were semantically related to the previous facts. For the related facts paired with the old family, reinstating the old context improved the mnemonic performance of both amnesics and controls, although amnesics seem to benefit somewhat more than controls. For the related facts paired with the new damily, control subjects showed interference in the misleading context of a different family. Amnesic subjects performed similarly on related and unrelated facts paired with the new subjects performed on study the control subjects replicated a finding that normal subjects can perform better on tests of cued recall than recognition, when the context of the recognition task is drastically different than the original learning context (Thompson & Tulving, 1972). The of these studies suggest that while amnesics can use cues present in the testing context to aid mnemonic performance, they have access to these cues only when specifically reinstated and, as a result, do not show the same mnemonic intererence control subjects demonstrate when presented a misleading context during testing.

RESPONSES OF SLOWLY ADAPTING AFFERENT FIBRES IN THE MONKEY TO SPHERICALLY CURVED STIMULI. A.W. Goodwin\*, A.S. Browning and H.E. Wheat. Dept. of Anatomy, University of Melbourne, Parkville Vic 3052, Australia.

Neural recordings from monkeys and corresponding psychophysical experiments in humans were used to investigate the role of cutaneous mechanoreceptors in determining the shape of contacted objects. Stimuli consisted of spherically curved segments of different radii presented passively to an immobilized fingerpad. Humans were able to scale for contact force or for curvature, and could discriminate changes in curvature of about 10%. Responses were recorded from single slowly adapting afferent fibers (SAs) in the median nerves of anesthetized monkeys. The stimulus parameters that were controlled were the curvature of the surface, the applied contact force, and the position of the stimulus in the fiber's receptive field.

Responses of SAs increased when the curvature of the surface applied to the center of the receptive field increased, or when the contact force increased. Changing the position of the stimulus in the receptive field also changed the response. The profile of response, as a function of position, reflected the shape of the stimulus, being more peaked and greater in magnitude for more curved surfaces and broader and lower in magnitude for less curved surfaces. Although the stimulus parameters (curvature and contact force) are confounded in individual fibre responses, the profiles of activity across the SA population provide information about each parameter.

WHISKERS, BARREL FIELDS, AND SENSORY MOTOR PERFORMANCE OF RATS

M. Glickstein\*, I. Kralj-Hans, B. Mercier, T. Onyirioha, G. Wynn Dept. of Anatomy & Developmental Biology, University College London, Gower Street, London WC1E 6BT.

Normal rats quickly learned to run rapidly along a one meter straight runway for a food reward. The runway contains a gap along its course whose width can be varied and whose position is not predictable. The animals were reinforced if and only if they ran faster than a pre-set and continously adjusted time. Shaving the large mystacial whiskers abolished the animal's ability to traverse a 14 cm gap successfully when tested in the dark but not in the light. Running was not affected by shorter gaps in either the dark or light. In most animals tested to date bilateral lesions of the barrel fields or unilateral lesions combined with ipsilateral whisker shaving impaired or abolished performance in the dark. Control lesions which spared the most lateral barrels had no effect on performance in the light or dark. Animals with barrel field lesions can sometimes recover successful performance by detecting the leading edge of the gap and jumping maximally. Our anatomical evidence suggests that an efferent pathway from the barrel fields to the cerebellum by way of the pontine nuclei may play a critical role in this simple behaviour. We are currently studying the effects of blocking the efferent pathway to the cerebellum by interrupting corticopontine fibres from the barrel field in the basis pedunculi.

RECEPTIVE FIELD PROPERTIES OF IPSILATERAL TRIGEMINOTHALAMIC NEURONS IN CATS. Jin Y. Ro. Norman F. Capra, and Revers Donga\*. Dept. of Physiology, University of Maryland Dental School, Baltimore MD 21201.

This study describes the distribution, receptive field properties, and antidromic latencies of neurons thought to project to the ipsilateral ventroposteromedial nucleus (VPM) of the thalamus. Previous anatomical studies showed that most of these cells are located in or near the dorsal part of the principal sensory nucleus. In 4 pentobarbital anesthetized cats, each VPM was stimulated in alternate fashion, while recording extracellular responses from the rostral brainstem. Neurons responding with a short-fixed latency to thalamic stimulation were tentatively classified as trigeminothalamic cells. This classification was supported by the ability of these cells to follow high frequencies of thalamic stimulation. The receptive fields of all antidromically activated cells were mapped using natural stimuli such as blowing, brushing, light pressure, pinch, and stretching the jaw. Twenty four trigeminothalamic neurons were identified. Of these, 15 were activated by antidromic stimulation of the ipsilateral thalamus. The mean antidromic latency of these neurons was 0.9 msec. Most neurons were low threshold and had relatively discrete ipsilateral intraoral receptive fields including tongue, palate, and periodontal tissues. However cells with other recentive field characteristics were identified, including one with convergent properties and one that responded to ramp and hold stretches of the jaw. Ipsilateral projection neurons tended to be more medially situated above the trigeminal motor nucleus than contralaterally projecting neurons. These results are consistent with anatomical data reporting the distribution of primary afferent fibers to this region. The more rostral uncrossed projections and the decussating projections from more caudal regions of the trigeminal sensory nuclei provide the oral cavity with significant bilateral representation in more rostral parts of the neuraxis. Supported by DE06027.

ANALYSIS OF DENDRITES FROM INTRACELLULARLY FILLED THALAMO-CORTICAL PROJECTION (TCP) NEURONS IN THE SOMATOSENSORY THALAMUS OF THE CAT. L.A. Havton and P.T. Ohara\* Dept of Anatomy, UCSF, San Francisco, CA 94143. USA

Standard techniques were used to record receptive fields and label TCP neurons using glass micropipettes containing 4% HRP or 2% Neurobiotin in adult cats anaesthetized with sodium pentobarbitol. The animals were perfused with aldehyde fixatives and 50 µm coronal sections were cut through the thalamus. Labeled cells were located in the VPL or VPM and responded to the normal range of non-nociceptive stimuli

Quantitative analysis of physiologically characterized neurons at the light microscope level suggests that non-nociceptive somatosensory TCP neurons form a homogenous population. 52 dendrites from 5 neurons were fully reconstructed and quantitatively analyzed at the light microscope level. The dendrites ranged in size from  $404\mu m^2$  to  $14,733\mu m^2$  (mean  $4140\mu m^2$ , SD 3400) and in number of dendritic end points from 1 to 29 (mean 8.8, SD 6.9). There was also a positive correlation between primary dendritic diameter and total dendrite size.

The pronounced variation in the morphology of individual dendrites suggests that the more stereotyped structure of individual TCP neurons results from a combination of dendrites with different features.

UNITARY THALAMOCORTICAL SYNAPTIC CURRENTS EVOKED IN LAYER IV CELLS OF NEONATAL MOUSE BARREL CORTEX BY CHEMICAL STIMULATION OF THE THALAMUS IN VITRO. A. Agmon\*, R.A. Warren, L. Yang and E.G. Jones. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA

We have recently described whole-cell thalamocortical synaptic currents recorded in layer IV neurons of developing mouse barrel cortex, elicited by electrical stimulation of the ventrobasal nucleus of the thalamus (VB) (Agmon and O'Dowd, J. Neurophysiol., in press). However many important issues require data on unitary events, i.e. synaptic responses to activation of individual thalamocortical axons. We have modified our methods in order to evoke and record such events. Tight-seal whole-cell recordings were achieved in layer IV neurons, and the precise region of VB giving rise to monosynaptic excitatory currents (EPSC's) was mapped by electrical stimulation. Small quantities of glutamate (1mM in 0.9% saline) were then pressure-ejected in the mapped region. Responses were dose-dependent and varied from sporadic unitary events to massive excitatory synaptic barrages. Some of the resolved unitary events showed a voltage-dependency typical of NMDA receptor-mediated currents. Ongoing experiments are aimed at providing a detailed characterization of these unitary synaptic inputs. The morphology of the thalamocortical axons involved is being studied by focal injections of Di-I into the mapped locus in VB at the end of the recording session. Supported by BOA-Giannini Foundation and by NS21377.

STAINING FOR CALCIUM BINDING PROTEINS REVEALS WHISKER-RELATED PATTERNS, FUNCTIONALLY DISTINCT CELL GROUPS AND PLASTICITY IN TRIGEMINAL (V) NUCLEI. N. Hobart, M.F. Jacquin\*, C.A. Bennett-Clarke, R.W. Rhoades & N.L. Chiaia Dept. Anatomy & Neurobiology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104; Dept. Anatomy, Med. Coll. of Ohio, Toledo, OH 43699.

Calbindin (CA) and parvalbumin (PA) immunostaining and retrograde tracing were used to define the targets of V brainstem cells that stain for these 2 proteins in adult rats. Large #s of PA+ cells occurred in V nucleus principalis (PrV) and they were arranged in a whisker-related pattern. Almost all of these cells projected to thalamus. In interpolaris (SpI), large #s of small-medium cells were PA + in a whisker-like pattern. None of these cells had long-range targets, but many projected to PrV. SpI also had many large CA+ cells; most projected to thalamus or colliculus; some also projected to PrV. In caudalis (SpC), PA + cells occurred in inner lamina II, and in layers III+IV where they formed whisker patterns; none had long-range targets. Large #s of CA+ cells occurred throughout lamina II in SpC, with smaller #s in layers I and III-V; a small % projected to thalamus. Thus, PA and CA identify 2 functionally distinct cell groups in V nuclei and the PA cells are somatotopically patterned in PrV, SpI and SpC. PA and CA also distinguish 2 cell groups in superficial dorsal horn. In 7 adults with infraorbital nerve section at birth, PA+ cells were not arranged in a whisker-related pattern and their #s were reduced by the following %s in PrV, SpI, SpC layers III+IV, and I+II, respectively: 20±14, 35±13, 29±21, 0 (mean±SD). CA+ cell #s were reduced in SpI and SpC I+II by 26+21 and 0%. Thus, V inputs are necessary for patterning PA+ cells as well as the survival of some PA+ and CA+ V neurons. A RETICULO-RETICULAR COMMISSURAL PATHWAY IN THE RAT THALAMUS

Spreafico.

Dept. of Neurophysiology, Neurological Institute "C. Besta",

The thalamic reticular nucleus (RTN) is known to extensively project to the ipsilateral dorsal thalamic nuclei. A few previous studies reported that RTN as well as other ventral thalamic structures send commissural projections to the contralateral thalamus (Rinvik, 1984; Nakamura and Kawamura, 1988). The present investigation was undertaken to ascertain whether commissural connections exist between the RTN of the two sides of the set halams. of the rat thalamus. Different tracing techniques were employed in deeply anesthetized adult rats: the retrograde transport of WGAapoHRP-gold, combined with GABA immunocytochemistry, and the anterograde transport of biocytin. After WGAapoHRP-gold injections in the rostral pole of RTN, retrogradely labeled neurons were present in the contralateral rostral pole of RTN, concentrated in its medial part. After WGAapoHRPgold injections in the caudal RTN, retrogradely labeled neuons were present in the contralateral ventromedial part of the caudal RTN, close to the border with the zona incerta. Anterograde tracing findings confirmed the retrograde labeling data: after iontophoretic biocytin injections in the rostral pole of RTN, anterogradely labeled axons and terminals were detected in the medial part of the contralateral rostral pole of RTN, as well as in the contralateral anteromedial and anteroventral thalamic nuclei. The present study suggests that RTN could provide a channel for interthalamic connectivity. Further experiments are in progress to ascertain the quantitative relevance of these thalamic commissural pathways.

CORTICOTHALAMIC SYNAPTIC CURRENTS IN NEURONS OF THE VENTROBASAL NUCLEUS OF THE DEVELOPING MOUSE THALAMUS STUDIED IN VITRO. R.A. Warren, A. Agmon, M. Spitzer, and E.G. Jones. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA92717.

The corticothalamic projections form one of the major inputs to the dorsal thalamus. They provide both direct excitatory to the dorsal thalamus. input, and indirect inhibitory input via the reticular thalamic nucleus (RTN). It is thus possible to study both the excitatory and inhibitory influences of the corticothalamic projections on ventrobasal nucleus (VB) relay neurons. We have studied the synaptic inputs evoked in thalamic relay neurons by electrical stimulation of the corticothalamic pathway at different postnatal ages. Whole-cell recordings were performed in a mouse slice preparation with preserved corticothalamic connectivity. Synaptic currents were evoked in VB neurons as early as postnatal day 4 by electrical stimulation in deep layer VI, white matter or internal capsule. Both excitatory and inhibitory synaptic currents were recorded. Inhibitory inputs were often trains of relatively large all-or-none events. These probably originated in RTN neurons since in rodents, VB is virtually devoid of GABAergic interneurons and RTN is the only source of GABAergic inhibition. The electrophysiological and pharmacological characteristics of these responses are currently under investigation. Supported by NS22317 and FRSQ of

EPICORTICAL POTENTIALS EVOKED IN GRANULAR AND PERIGRANULAR SOMATOSENSORY CORTEX OF THE RAT BY CONTRALATERAL ELECTRICAL STIMULATION JOSEPH KITHAS, SHI DI and DANIEL S. BARTH\* Department of cychology, University of Colorado, Boulder, CO 80309-0345 (U.S.A)

In a previous report from our laboratory, stimulation of individual vibrissa was demonstrated to produce epicortical potentials localized to the functionally defined vibrissa/barrel field in the rat. This work utilized electrocorticographic mapping and numerical analysis capable of resolving individual cortical columns. The present experiment extended these methods to study the

influence of transcallosal input on the somatosensory evoked potential complex. While recording from an 8x8 microelectrode array covering a 3.8 x 3.8 mm<sup>2</sup> area of the right vibrissa/barrel field, a similar array was used for electrical stimulation of a homologous region in the left hemisphere. The spatial patterns of potentials evoked by contralateral electrical stimulation and by mechanical stimulation of contralateral vibrissae were compared to cytochrome oxidase stained tangential sections of somatosensory cortex

Our results indicate that while contralateral whisker stimulation activates populations of cells confined to the anatomically defined barrel field of primary somatosensory cortex, potentials evoked transcallosally by electrical stimulation are more widely distributed and suggest a major input to perigranular cortex posterior and lateral to the barrel field.

ABNORMAL SOMATOSENSORY CORTICAL ORGANIZATION AND CORTICAL PLASTICITY IN HUMANS REVEALED BY MAGNETOENCEPHALOGRAPHY

A. Mogilner\*, J.A.I. Grossman, U. Ribary, F. Lado, J. Volkmann, M. Joliot and R.R. Llinás Center for Neuromagnetism, Department of Physiology and Biophysics and Institute of Reconstructive Plastic Surgery, NYU Medical Center, NY 10016

Institute of reconstructive raisets surgery, NTO institute a tenter, NT 10010

A 14-channel neuromagnetic recording system was used to record and map magnetic evoked responses to vibratory stimulation of the digits in both normal subjects and in a number of patients with injuries and/or congenital malformations of the hand. In 5 normal subjects studied, the fingers of the hand were represented in a somatotopic order superiomedially along the postcentral gyrus (area 3b), with the little finger and the thumb separated by a two-point average distance of 10.6±1.3 mm (mean ± SEM), with the little finger consistently superior to the thumb on the gyrus. In threa 1.52M, with the little finger consistently superior to the thumb on the gyrus. In three of the five normal subjects, all, five fingers were studied, and the average distance between adjacent fingers was found to be 4.2 ±0.4 mm. We have reported previously (Mogilner et al, Soc. Neurosci. Abstr. 1991) a case of homotransplant of innervated skin from the et at, 50c. Neurosci. Abstr. 1991) a case of nonotranspiant of inherivated skill from the ring finger to the thumb, without displacement of somatosensory perception. The functional interdigital distance (thumb-ring finger) following surgery, 0.2 mm, was significantly smaller than both the patient's own other interfinger distances (10.6 mm, p=.0016), and the control group's interfinger distances (p=.0326, one-tailed *t*-test), indicating no cortical reorganization in accordance with cognitive findings. Two subjects with syndactyly (digit fusion) were also studied. In one subject with bilateral syndactyly, both hand areas were abnormal – the thumb-little distances, right: 1.6 mm, left: 1.1 mm, were significantly smaller than controls (p=0.026 and 0.023,1-tailed ttest). The other patient, with unilateral syndactyly, underwent surgical separation of the digits. The pre-operative organization was grossly abnormal and non-somatotopic (thumb-little distance: 2.4 mm p= 035, little finger located below all fingers except thumb). One month following digit separation, the thumb-little distance had increased to 10.5 mm, and the little finger's location shifted significantly ( $\Theta$ =3.8° p=.018). This result indicates the presence of plasticity in the adult somatosensory cortex and its correlation to the new post-surgical functionality.

A PET STUDY IN HUMAN SUBJECTS TO LOCALIZE BRAIN STRUCTURES INVOLVED IN THE SOMATOSENSORY DISCRIMINATION OF TACTILE "ROUGHNESS".

B.T. O'Sullivan, P.E. Roland. R. Kawashima, B. Gulyas\*. Lab. for Brain Res. and PET, Karolinska Institute; S10401, Stockholm, SWEDEN.

The regional cerebral blood flow (rCBF) was measured with 15O-butanol and Positron Emission Tomography (PET) in 10 healthy subjects performing a two-alternative forced choice discrimination of roughness using pairs of standardized stimuli (Roland and Mortensen, Brain Res. Rev.12:1-42, 1987). There was a total of 4 activation runs for each subject, consisting of 2 roughness discriminations, a similar task to discriminate length of pairs of similar smooth cylinders, and a control trial which required exploratory finger movements only, without a specific stimulus to feel. Mean subtraction images were computed using the computerized adjustable brain atlas of Bohm and Greitz (1986) and areas of significant blood flow change were identified. Both the roughness and the length discrimination tasks activated cortical fields in the contralateral post-central gyrus and supramarginal gyrus, including the anterior and posterior lip of the post-central gyrus but not extending to the superior or inferior lip of the intraparietal sulcus. These areas were interpreted as being somatosensory association areas engaged in the discrimination and perception of roughness and tactile length. The length discrimination task activated in addition, parts of the angular gyrus bilaterally and several regions in the superior and middle frontal gyri bilaterally.

DEVELOPMENTAL. REGULATION OF PLASTICITY SOMATOSENSORY CORTEX OF KITTENS. S.L. Juliano, D.E. Eslin, R. Code, R. Sonty\*. Dept. Anatomy, Cell Biol., & Neurosci., USUHS, Bethesda, MD 2089:

This lab has previously shown that amputation of a single digit (DA) in adult cats causes expansion of stimulus-evoked metabolic activity in the somatosensory cortex (SSC) following stimulation to an adjacent digit. To test the idea that developmental mechanisms may affect the ability of the cortex to reorganize, DAs were performed on kittens 2, 4 or 6 weeks of age. After unilateral amputation of digit 2, animals survived until they were 3-4 months of age. At this time, a 2deoxyglucose (2DG) experiment was conducted, stimulating digit 3 bilaterally. Digitized maps of metabolic activity reveal that the DA at all ages causes substantial reorganization in the activity pattern. For the animals that received a DA at 6 wks of age, the expanded pattern was like that found in the adult, demonstrating a distribution that was similar to, but larger than, the pattern evoked in the normal hemisphere. When the DAs were conducted at 2 or 4 wks of age, the characteristics of the activity evoked by stimulation to the digit adjacent to the amputation were substantially different from that evoked in the adult or in the 6 wk animal. The metabolic activity pattern contralateral to the DA was severely disorganized compared to that found on the normal side. Rather than occurring as an expanded version of the normal distribution, the evoked activity was located in numerous small foci that covered an expanded cortical territory. Even though these numerous foci were widespread within the SSC, the actual area included in the individual spots was similar to, or only slightly larger than, the cortical area demonstrating increased 2DG uptake on the normal side. Activity patterns evoked in hemispheres contralateral to a DA in adults or 6 wk old treated animals cover about 2 times the cortical area in the normal hemisphere. The disorganized pattern after a DA in young animals may reflect functional and anatomical substrates that are present during development of the cerebral cortex. Supported by NS24014.

ACTIVITY-DEPENDENT CHANGES OF GLUTAMATE-IMMUNOREACTIVITY IN THE SOMATIC SENSORY CORTEX OF MONKEYS FOLLOWING PERIPHERAL AND CENTRAL MANIPULATIONS OF SOMATOSENSORY

PERIPHERAL AND CENTRAL MANIPULATIONS OF SOMATOSENSORY INPUT. A. Minellis. I. Danielsson. J. Hahm. T.P. Pons\* and F. Contis. "Institute of Human Physiology, University of Ancona, Via Ranieri, I-60131 Ancona (Italy), and Laboratory of Neuropsychology, N.I.M.H., Bethesda, MD 20892 (USA)
Previous studies using electrophysiological techniques demonstrated that the adult brain possesses a remarkable capacity for changes in cortical maps in response to experimental perturbations of the sensory input, but little effort has been made to identify the molecular mechanisms underlying this phenomenon. Since the regulation and expression of neurotransmitters and neuromodulators occurs in an activitydependent manner, such changes could provide a mechanism that might account for

alterations in sensory maps following central or peripheral perturbations.

In the present experiments, five monkeys were used to determine whether changes in glutamate (Glu) activity were correlated with presence or lack of cortical reorganization guitamate (Citi) activity were correlated with presence or tack of cortical reorganization seen in operated animals. Four animals had the three nerves innervating the hand cut and tied, while a fifth animal had the cortical hand representation in SI ablated. Six to eight weeks later, the five animals were perfused transcardially and sections from the spinal cord, dorsal column nuclei, ventroposterior thalamus and the first (SI) and second (SII) somatic sensory cortex were processed for Glu-immunocytochemistry. In the animals with nerve cuts, the pattern of Glu-immunoreactivity in the dorsal horn of the spinal cord, in the dorsal column nuclei, and in the ventrobasal thalamus, and in SI appeared as in unoperated animals. By contrast, the hand representation in SII contained appeared as in unperaeut animals. By comman, the hard representation in SII commented regions with a normal distribution of Glu-positive neurons alternating with regions devoid of Glu-positive neurons. Electrophysiological experiments conducted in the same animals revealed reorganization in SI but not in SII. In the animal with the SI ablation, Glu-immunoreactivity appeared normal throughout SII, and recordings indicate complete reorganization in SII. These results suggest that i) the reduction of Glu levels may contribute to the elimination of SII neural activity after peripheral nerve cuts; and ii) a correlation exists between the presence or absence of map reorganization and Glu levels.

EFFECTS OF 5HT MONOAMINE UPTAKE BLOCKERS AND 5HT1A AGONISTS ON SPONTANEOUS FIRING RATE OF PREFRONTAL CORTICAL NEURONS. A. Ceci\*, A. Baschirotto and F. Borsini. Boehringer Ingelheim Italia S.p.A. Milan, Italy.

In the present study we have determined the effects of two 5HT monoamine uptake blockers (fluoxetine and imipramine) and two 5HT1a agonists (buspirone and 8OH-DPAT) on spontaneous extracellular activity of 43 neurons within prefrontal cortex (PFC). The rats were anaesthetised with chloral hydrate and only one cell for rat was tested. The drugs were administered i.v. at logarithmic doses. Fluoxetine increased the basal firing rate in dose-dependent manner, dose-range 0.1-1000  $\mu$ g/kg, with 53% maximum excitatory effect at 1000  $\mu$ g/kg. Imipramine, at the doses of 1 up to 300  $\mu$ g/kg, induced an excitation of basal firing rate; the maximum excitatory effect was 30% at 3 and 10  $\mu$ g/kg; raising the dose up to 1000  $\mu$ g/kg, an attenuation of the effect was detected. Buspirone produced a dose-related, 0.1-30  $\mu$ g/kg, excitatory effect on basal firing rate, 54% maximum effect at the dose of 30  $\mu$ g/kg; increasing the dosage up to 1000  $\mu$ g/kg a clear attenuation of the excitatory effect was noted. 80H-DPAT elicited a dose-dependent bimodal effect, which was characterized by an activation of PFC neurons at low doses 0.1-10  $\mu$ g/kg, followed by an inhibition of basal firing rate with higher doses, 30-300  $\mu$ g/kg. The basal firing rate between vehicle and drugs was not statistically different. The results are discussed in the terms of preferentially pre-or post-sinaptically activity of the two uptake blockers and the two 5HT1a agonists.

ORIGINS OF SEROTONERGIC AFFERENTS TO THE HYPOGLOSSAL NUCLEUS. S. Manaker\* and L. I. Tischler, Pulmonary and Critical Care Division, Department of Medicine and Center for Sleep and Respiratory Neurobiology, University of Pennsylvania, Philadelphia, PA 19104.

Hypoglossal motoneurons alter their firing rates in response to serotonin (5HT), and the hypoglossal nucleus (Mo12) is densely innervated by 5HT terminals. While several brainstem regions that contain 5HT also project to the Mo12, which of these contributes 5HT afferents to the Mo12 remains to be determined. Fluorogold (FG; 20 nl) was injected into the Mo12 of anesthetized rats, who survived 10 days. After dextran/saline perfusion and paraformaldehyde fixation, the brainstem was removed and frozen. Sections (32 µ) were cut through the entire brainstem, and the FG injection site examined. In cases with the FG injection site restricted to the Mo12, every 6th section was processed for 5HT immunofluorescence (rabbit anti-5HT, 1:2000; Texas Red-conjugated goat anti-rabbit, 1:400). Retrograde labeling by FG was observed in all sources of Mo12 afferents, while 5HT immunoreactivity was present in all major groupings of 5HT somata. Double labeled cells were observed primarily in the nuclei raphe pallidus and obscurus, with fewer double labeled cells in the caudal nucleus raphe magnus and the parapyramidal nucleus. No double labeled neurons were noted in other groupings of 5HT somata, including the rostral nucleus raphe magnus, the dorsal and median raphe nuclei, and the locus coeruleus and laterodorsal tegmental nucleus. These observations suggest that the 5HT innervation of the Mo12 originates exclusively from the caudal raphe and parapyramidal nuclei. (Supported by SCOR HL-42236)

DEX-FENFLURAMINE WHEN ADMINISTERED ORALLY IN DOSES IN CONSIDERABLE EXCESS OF THE HUMAN THERAPEUTIC DOSE PRODUCES NO ULTRASTRUCTURAL OR AXONAL TRANSPORT CHANGES IN RAPHE SEROTONERGIC NEURONS OF THE RAT. M. Kalia\*Popartment of Pharmacology and Neurosurgery, Jefferson Medical College, Philadelphia PA 19107.

We have previously reported that the observed reduction in immunocytochemically labeled nerve fibers in the rat cortex following both short- and long-term oral treatment with dex-fenfluramine (D-FF) is dose dependent and rapidly reversible (Kalia, M., Brain Res. '91), indicating that the loss of immunoreactivity (IR) is merely a function of the loss of serotonin from the nerve terminals as a result of the therapeutic action of the drug (a 5-HT uptake inhibitor and 5-HT releaser). The present study was conducted to confirm this conclusion by using two other indicators of neuronal integrity electronmicroscopy and the ability of the neuron to transport and accumulate retrogradely transported material. The retrograde transport of cholera-toxin horseradish peroxidase (CTHRP) combined with 5-HT IR was used to examine the functional status of rat cortical serotonergic networks following oral D-FF administration (8 & 16 mg/kg/day) for 4 or 21 days. The animals survived 3 - 5 weeks after cessation of the treatment before the entire cortex was injected with 400 µl of CTHRP under nembutal anesthesia. Following a 3 day survival, the animals were perfused and the brain stem was processed for double-labeling using HRP histochemistry and 5-HT IR (Rye et al. '85). No differences were seen between D-FF treated animals and pair-fed controls. Quantitative analysis was performed with a Bioquant Meg IV image analysis system. Electronmicroscopic examination of 5-HT labeled neurons in D-FF treated animals showed normal morphology. These results indicate that short- and long-term treatment with D-FF does not produce functional or morphological changes in brain serotonergic neurons. (Supported by IRIS).

EFFECTS OF 5-HT<sub>1A</sub> AND 5-HT<sub>1B</sub> AGONISTS ON FOREBRAIN 5-HT SYNTHESIS AFTER LOCAL APPLICATION INTO THE MEDIAN RAPHE OR THE NUCLEUS ACCUMBENS IN THE RAT. <u>V. Hillegaart<sup>1+</sup>. A Wijkström<sup>2</sup> and S. Ahlenius<sup>1</sup>. Department of <sup>1</sup>Behavioural Pharmacology and <sup>2</sup>Bioanalysis, Astra Arcus AB, S-151-85 Södertälje, Sweden.</u>

In a previous study, it was shown that the local application of the 5-HTIA agonist 8 OH DPAT into the median raphe produced a statistically significant decrease in the nucleus accumbens 5 HT synthesis, as estimated by the 5-HTP accumulation in rats pretreated with the 5-HTP decarboxylase inhibitor NSD-1015 (100 mg/kg IP). In the present series of experiments, the effects of 8-OH-DPAT on 5-HT synthesis in the nucleus accumbens was examined after local application of the compound in the same forebrain area (0.5 and 5.0 ug). There were no effects on forebrain 5-HT synthesis, however, after local application of 8-OH-DPAT in the vicinity of terminal serotonergic autoreceptors, presumed to be of the 5-HT<sub>1B</sub> subtype. Control 5-HTP accumulation: 1.50±0.27 (mean SD, n=4). The corresponding values after 8-OH-DPAT (0.5 and 5 ug) were 1.47 $\pm$ 0.12 and 1.35±0.28, respectively. In order to test the functional coupling of such receptors, nucleus accumbens 5-HTP accumulation was measured after local application of the 5-HT<sub>1B</sub> receptor agonist CP-93129 into this forebrain area. Preliminary observations, however, suggest that also this compound lacks effects in the nucleus accumbens after local application into this brain area. CP-93129 (1 and 10 ug) 5-HTP accumulation: 1.42±0.14 and 1.57±0.40, respectively. Together, these observations demonstrate that forebrain 5-HT synthesis is regulated by somato dendritc 5HT1A autoreceptors, whereas the functional coupling of terminal 5-HT1B receptors in the nucleus accumbens could not be demonstrated in the present test system.

SEROTONINERGIC AND CHOLINERGIC CONCERT ACTIONS ON ENTORHINAL CORTEX LAYER II NEURONS: AN IN VITRO STUDY. R. Klink' and A. Alonso. Montreal Neurological Institute and McGill University, Montreal, QC, Canada H3A 2B4.

Entorhinal cortex (EC) layer II, a key element in the learning and memory functions of the neocortical-hippocampal circuitry, receives dense acetylcholine (ACh) and serotonin (5-HT) innervation. Both 5-HT and ACh act in concert in cognitive functions. We reported last year on the cholinergic modulation of EC layer II neurons intrinsic excitability (Alonso and Klink, 1991). By means of intracellular recording in rat brain slices we have now extended the analysis to the effects of 5-HT. Bath application (30-60s) of 5-HT (10-30µM) triggered on EC layer II stellate cells a large (50%) increase in membrane conductance frequently associated with a moderate (1-4mV) membrane depolarization which persisted for relatively long periods (>10 min), 5-HT also largely increased (100%) the frequency of both the Na-dependent rhythmic subthreshold oscillations characteristic of these cells (6-12Hz in control) and the repetitive bursting activity (spike "clustering") (13Hz in control) that they develop upon moderate d.c. depolarization. Concomitantly, in the presence of 5HT the intraburst firing frequency increased to about 40 Hz and the bursting activity tended to become more rhythmic. The 5HT-induced depolarizing response is consistent with mediation via 5-HT3 receptors which are present in high concentrations in the EC. As the above-described 5-HT actions largely oppose those of ACh, the interplay between cholinergic and serotoninergic systems in the modulation of EC layer II neurons intrinsic oscillations may be of great significance for understanding the interactions of both systems in learning and other cognitive aspects of hippocampal function.

# 317.6

EFFECT OF STRESS ON SEROTONIN TRANSMISSION IN THE PREFRONTAL CORTEX AND INTERACTIONS TRYPTOPHAN, DIAZEPAM AND BUSPIRONE; A MICRODIALYSIS STUDY. E. Carboni\*, C. Cadoni, G.L. Tanda, and G. Di Chiara. Department of Toxicology, University of Cagliari, Italy It has been widely reported that serotonin (5-HT) metabolism is increased by stress although generally 5-HT concentrations have not been affected. We use here the transversal dialysis for detecting tryptophan (Try), 5-HT, and 5-hydroxyindoleacetic acid (5-HIAA) in the prefrontal cortex of freely moving rats. Restraint stress, obtained by taping the rat hind legs for 40 min., increases 5-HT output by 90 %, over basal values, without changing levels of Try and of 5-HIAA. Immobilization for 40 min., causes an increase in 5-HT output by 125 % over basal values affecting also levels of Try and 5-HIAA that were increased respectively by about 250 % and 50 % over basal values. The administration of systemic Try (100 mg/Kg i.p.) just before the application of stress potentiated only serotonin release induced by immobilization. The pretreatment with both diazepam (1 mg/Kg i.p.) and buspirone (1 mg/Kg s.c.) antagonizes the increase in serotonin release induced by both restraint and immobilization.

These results indicate that: a) 5-HT release is affected by plasma and brain Try availability; b) 5-HT in the prefrontal cortex plays an active role in emotional behavior; c) diazepam and buspirone, drugs with anxiolitic properties might interact with stress via 5-HT transmission.

THE BLOOD-BRAIN BARRIER TRANSPORT OF L-TRP MEASURED AT STEADY-STATE IN RAT. M. Diksic\*, A. Takada, and A. Giedde. Department of Neurology and Neurosurgery, McGill University, Montreal Neurological Institute, Montreal, Canada

The purpose of this study was to establish which fraction of the plasma Trp interchanges with brain Trp under a steady-state. In the past, the bloodbrain barrier (BBB) transport of L-Trp was measured under non-steady state conditions. Total plasma Trp was used for data analysis, although a large fraction of Trp is known to be bound to plasma proteins. Six groups of three Wistar rats (190-200 g) were catheterized with femoral vein and artery catheters under anesthesia, allowed to awaken, and injected (i.p.; constant volume) about 2 h later with saline, (control) or 20, 50, 100, 200, 300 and 400 mg/kg of L-Trp methyl ester. One hour after injection of the L-Trp seter, rats were infused with a mixture of L- $\{^3H\}$ Trp (40  $\mu$ Ci) and  $\{^{14}C\}$ butanol (10  $\mu$ Ci) into the femoral vein for 22 sec. Rats were decapitated 20 seconds after the beginning of the tracer infusion, the brain removed and homogenized for radioactivity determination. Arterial blood was collected from the arterial catheter designed to yield about 1 g of blood in 20 sec. The PS product (not corrected for protein binding) was highly correlated with the free plasma fraction of Trp (p < 0.001). From the relationship between the PS and the plasma free Trp concentration, an apparent K<sub>m</sub> of 27  $\pm$  11  $\mu$ M, a V<sub>max</sub> of 6.3  $\pm$  1.6 nmol/g/min, and a diffusion constant of 0.136  $\pm$  0.006 ml/g/min were estimated by non-linear least square. The of 360 mol/ml and  $K_D$  of 81  $\pm$  10  $\mu$ M. Under steady-state conditions the plasma free Trp fraction is the one functionally communicating with the brain. The simple diffusion of Trp was higher than previously measured. The V<sub>max</sub> is far above the requirements of the brain for Trp.

### 317.9

EFFECTS OF MAO INHIBITORS ON EXTRACELLULAR 5-HT IN THE RAPHE NUCLEI AND FRONTAL CORTEX OF RAT BRAIN. "IN VIVO" MICRODIALYSIS STUDIES IN THE AWAKE RAT. F. Artigas, P. Celada, N.

The net effects of MAO inhibitors on aminergic neurotransmission are still poorly known. Electrophysiological results suggest a potentiation of 5-HT transmission via a desensitization of 5-HT autoreceptors. We have examined the actions of MAO inhibitors on the brain extracellular compartment of 5-HT in frontal cortex and dorsal+median raphe nuclei. Previous studies indicate that the raphe nuclei may be a preferential target for the action of antidepressant drugs. Locally applied, clorgyline (CLG), brofaromine (BRF, a reversible inhibitor of MAO-A) and tranylcypromine (TCP) induce dose-related increases of extracellular 5-HT that were more important in the raphe nuclei. Depreny (DEP) was without effect in both areas at specific doses. Systemically administered, TCP (15 mg/kg) induced huge increases of extracellular 5-HT in the raphe nuclei (60-fold) and frontal cortex (10-fold) while increasing tissue 5-HT by 6-fold. However, CLG and BRF did not increase dialysate 5-HT at doses that inhibited MAO-A by more than 95% and increased tissue 5-HT (CLG) by 4-fold. Extracellular 5-HT increased after a two step inhibition of MAO: in animals pretreated with clorgyline (10 mg/kg) or deprenyl (2.5 mg/kg) the administration of deprenyl or clorgyline (respectively) led to large (ca. 10-fold) and significant increases of extracellular 5-HT after the administration of the second MAO inhibitor. These results show that the complete inhibition of MAO-A and the concurrent increase of intracellular 5-HT do not result in an increase of the 5-HT output, probably because the increase of tissue 5-HT occurs in a non-releasable compartment (e.g. glial cells).

SEROTONIN SUPPRESSES EPILEPTIFORM BURSTS IN RAT CA1 NEURONS. D. Salgado\* and K. A. Alkadhi. Department of Pharmacology, University of Houston, Houston, TX 77204-5515

Serotonin can evoke multiple responses via activation of the various 5-HT receptor subtypes. In the CA1 region of the hippocampus, where a high density of 5-HT<sub>1A</sub> receptors are present, serotonin causes an inhibitory response. Previous studies on whole animal preparations done by other investigators suggest that serotonin may be involved in the inhibition of seizure activity. Further, it has been shown that the Genetically Epilepsy Prone Rats are deficient in brain serotonin content. The purpose of this study was to assess the role of 5-HT in bicuculline-induced epileptiform bursts using the rat brain slice preparation. All experiments employed conventional techniques for intracellular recording from CA1 neurons of the hippocampus. Serotonin (20  $\mu$ M, n=5) suppressed the bicuculline evoked response. Further, serotonin (20  $\mu$ M) caused a marked hyperpolarization (control: -73.9 $\pm$ 1.5 mV; after 5-HT: -82.7 $\pm$ 2.3 mV, n=7) accompanied by a decrease in input resistance (control: 52.5 $\pm$ 6.1 M $\Omega$ ; after 5-HT: 31.7 $\pm$ 4.9 M $\Omega$ , n=4). The selective 5-HT<sub>1A</sub> agonist 8-OH-DPAT (20 μM) mimicked the effects of serotonin. These preliminary results suggest that serotonin may play a significant role in the inhibition of epileptiform activity and

that this should be further investigated focusing specifically on the

inhibitory action mediated via the 5-HT1A subtype.

CLONING AND EXPRESSION OF GLYCINE, TAURINE/β-ALANINE, AND TWO GABA TRANSPORTERS. N. Nelson, Q.-R. Liu, B. Lopez-Corcuera, S. Mandiyan, H. Nelson, and J.L. Noebels\*. Dept. of Gene Regulation, Roche Institute of Molecular Biology, Nutley, NJ 07110 and Developmental Neurogenetics Laboratory, Baylor College of Medicine, Houston, TX, 77030

Neurotransmission in the CNS is terminated by a rapid reaccumulation of neurotransmitters into presynaptic terminals by transporters. We have isolated cDNA clones from a mouse brain library encoding the sodium dependent, high affinity GABA transporter (GABAT2), a second GABA transporter, a glycine transporter and a taurine/β-alanine transporter. All four transporters share similar amino acid sequences and membrane topography. Xenopus oocytes injected with synthetic RNAs from the cDNA clones revealed that the glycine transporter is specific for glycine transport. No other amino acid could be transported by it, nor did they inhibit glycine uptake into oocytes. The taurine transporter takes up  $\beta$ -alanine at about 5-fold lower affinity than taurine. The two GABA anamine at about 5-told lower animity than cauline. The two GABA transporters differ in their pharmacology as well as their Km for GABA. The tissue distributions of those transporters are under study by Northern blot analysis and at the cellular level. In situ hybridization of the 35S-labelled antisense mRNA for the high affinity GABA transporter in mouse brain showed a clear pattern of high expression in neocortex, hippocampal pyramidal cell layer, habenular, periventricular and suprachiasmatic nuclei, zona incerta and cerebellar Purkinje cells. Neither hippocampal nor cerebellar granule cell populations were clearly positive, and there was trace expression over white matter tracts containing oligodendroglia. These transporters directly regulate inhibitory synaptic transmission, and in the case of glycine, may indirectly regulate NMDA receptor-mediated excitatory amino acid signalling in the CNS.

# 318.2

LITHIUM POTENTIATES CHOLINERGIC PRESYNAPTIC INHIBITION OF GLUTAMINERGIC, BUT NOT GABAERGIC TRANSMISSION. G.A. Cohen\* and D.V. Madison. Dept of Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA 94305-5426.

We have previously reported that acute bath application of a therapeutically

relevant level (2mM) of LiCl strongly potentiates carbachol-induced (1uM) presynaptic inhibition of excitatory transmission in rat hippocampal slices, while LiCl alone only slightly reduces excitatory transmission (Cohen, et al., Neuroscience Abstracts, 1990). Our present experiments center on comparing presynaptic modulatory interactions of these two agents in glutaminergic and GABAergic transmission, and on elucidating the biochemical mechanisms of these effects.

It has been shown that carbachol inhibits both polysynaptic and monosynaptic evoked IPSPs (Cohen, et al., Neuroscience Abstracts, 1991). LiCl (2mM) had a slight inhibitory effect on poly- and mono-synaptic IPSPs. However, LiCl markedly potentiated cholinergic inhibition (carb, 1uM) of polysynaptic IPSPs, but did not potentiate cholinergic inhibition of monosynaptic IPSPs. Since polysynaptic IPSPs differ from monosynaptic IPSPs in that they involve the glutaminergic activation of

affer from monosynaptic IFSFs in that they involve the glutaminergic activation of a GABAergic synapse, our results suggest that lithium interacts with cholinergic inhibition at glutaminergic, but not GABAergic, presynaptic terminals. Bath application of myo-inositol (5-10mM) did not affect the inhibition of the EPSP induced by carb (1uM), LiCl (2mM), or carb + LiCl. This suggests that the interaction of acutely administrated LiCl with carb is not mediated by a depletion of myo-inositol. We are currently pursuing the signal transduction mechanism involved in presynaptic inhibition induced by carbachol and lithium.

PRESYNAPTIC FACILITATION OF GLUTAMATE EXOCYTOSIS MAY BE SUSTAINED BY ACTIVATION OF A PROTEIN KINASE CASCADE. <u>D.M. Terrian¹</u>, <u>D.K. Ways²</u>, <u>R.V. Dorman³³ and D.A. Zetts¹</u>. Depts. ¹Anatomy and ²Medicine, East Carolina University School of Medicine, Greenville, NC 27858. ³Dept. Biological Sciences, Kent State Univ., Kent, OH 48504.

Hippocampal mossy fiber (MF) nerve endings contain multiple protein kinase C (PKC) isoforms and the activation of PKC significantly increases the K\*-evoked release of both glutamate and dynorphin B (Terrian et al., Hippocampus 1:303-314, 1991). Here, we report that the persistent activation of PKC leads to a delayed and and sustained enhancement of the K\*-evoked release of endogenous glutamate but not dynorphin B from isolated hippocampal MF synaptosomes. The K+-evoked release of glutamate was found to be selectively enhanced when MF synaptosomes were preincubated with the PKC activator 46-phorbol 12,13-dibutyrate (PDBu) for 15 min, extensively washed with a PDBu-free medium and depolarized. Three lines of evidence indicate that the sustained enhancement of glutamate release observed under this condition may be due to the activation of a phosphorylation cascade that is no longer directly dependent on continued PKC phosphotransferase activity. First, the evoked release of glutamate was desensitized to the potentiating effects of PDBu after a 15 min exposure to the phorbol ester. Second, the potentiation of glutamate release persisted throughout the course of PDBu-induced downregulation of the α, δ, γ, ε and ζ PKC isoforms. Third, preincubation of MF synaptosomes with PDBu lead to an increase in the basal, PKC-independent, phosphorylation of two endogenous substrates with molecular weights of 45 and 50 kDa. It is concluded that the PKC second messenger system generates a signal, that may be subsequently propagated by the activation of a protein kinase cascade, that is sufficient to enhance K\*-evoked release of glutamate from hippocampal MF synaptosomes. However, it is postulated that the generation of this signal is not sufficient to raise the bulk level of cytosolic free calcium and, therefore, the release of dynorphin B is not affected. REGULATION OF SPONTANEOUS GABA RELEASE IN THE HIPPOCAMPUS. Y. A. Doze\* and D. V. Madison. Department of Molecular & Cellular Physiology, Beckman Center, Stanford Univ. School of Medicine, Stanford, CA 94305-5426.

Synaptic inhibition in the hippocampus arises primarily from GABA-containing interneurons. We have been examing the effects of various neurotransmitters (e.g., epinephrine and baclofen) and changes in extracellular potassium on the spontaneous release of GABA from inhibitory interneurons in the rat hippocampus using whole cell patch-clamp recording techniques.

Epinephrine (1-10 μM) caused a marked increase in both the frequency and amplitude of monosynaptic, action potential-dependent, spontaneous GABAergic inhibitory postsynaptic currents (IPSCs) recorded in CA1 pyramidal neurons in rat hippocampal slices (recorded with KCl and QX-222 in the electrode, and CNQX/APV in the ACSF to monosynaptically isolate action potential-dependent GABA release). In contrast, baclofen (1-10 μM) reduced the frequency and amplitude of these action potential-evoked IPSCs. Interestingly, neither epinephrine or baclofen affected the frequency and amplitude of miniature, action potential-independent, GABA-mediated IPSCs (recorded with KCl and QX-222 in the electrode, and CNQX/APV and TTX in the ACSF to block action potential-dependent release).

Changes in the extracellular potassium level also caused marked changes in the frequency and amplitude of monosynaptic, action potential-dependent, spontaneous IPSCs. Increasing the extracellular potassium caused a large increase in both the frequency and amplitude of these IPSCs. Decreasing the extracellular potassium resulted in a reduction in the frequency and amplitude of these events. Changes in extracellular potassium also caused changes in the frequency of miniature, action potential-independent, GABA-mediated IPSCs, but did not affect their amplitude.

STUDIES ON DYNAMIN FUNCTION IN DROSOPHILA. K.S. Krishnan.S. Rao. A. van der Bilek@.R. B. Kelly#\*. and M. Ramaswami # Molecular Biology Unit, Tata Institute of Fundamental Research, Colaba, Bombay 400005, India; @ Division of Biology, Caltech, Pasadena, CA 91125; # U.C S F., Dept of Biochemistry and Biophysics, San Francisco, CA 94143-0554

We have used <u>Drosophila</u> genetics and molecular biology to study the role of dynamin in the nervous system. Multiple subforms of dynamin are encoded by the <u>shibire</u> gene of <u>Drosophila</u>. Several mutant alleles of <u>shibire</u> induce reversible, temperature-dependent paralysis due to a conditional block in synaptic-vesicle recycling. When developing <u>shibire</u> files are pulsed to high temperatures during varied developmental stages, varying, but remarkably specific defects are observed in diverse tissues. These defects might result from the blockage of endocytosis-dependent, or perhaps microtubule-dependent developmental processes. In an attempt to understand the diverse roles of dynamin in <u>Drosophila</u>, we have isolated a collection of intragenic revertants of the temperature-dependent paralysis induced by the <u>shibire</u> 152 mutation. All of the revertants appear to restore partial (but not complete) activity to the dynamin forms required for synaptic-vesicle recycling. We are examining these alleles for suppression of other <u>shibire</u> phenotypes. We expect that the sequence of the revertant alleles will also offer some insights into the structure of dynamin; towards this end we will shortly be presented.

MONOSIALOGANGLIOSIDE (GM1) ENHANCES GLUTAMATERGIC TRANSMISSION IN RAT HIPPOCAMPAL SLICES. P. Miu\* and K. Krnjević. Anaesthesia Research Dept. McGill University, 3655 Drummond St., Montréal, Canada, H3G 1Y6.

GM1 can be found abundantly in mammalian nerve terminals, where it may modulate transmitter release. Indeed, GM1 enhances excitatory inputs while suppressing the inhibitory inputs to CA1 cells (Miu and Krnjević, 1991, Can. J. Physiol. Pharmacol., 69:Axxii).

To isolate the excitatory and inhibitory PSPs, we perfused rat hippocampal slices with ACSF containing either bicuculline (10  $\mu$ M) or kynurenic acid (2 mM) respectively. In addition, spontaneous EPSPs were also measured in the presence of TTX from CA3 cells, where the excitatory mossy synapses are close to the soma.

In CA1 neurons, GM1 enhanced both the frequency and peak amplitude of the spontaneous, TTX- and kynurenate-sensitive EPSPs. In the presence of TTX, GM1 also increased the frequency and peak amplitude of spontaneous EPSPs in CA3 cells, suggesting a direct action on mossy fibre terminals. Monosynaptic IPSPs evoked in the presence of kynurenic acid, however, were not altered by GM1. Hence, these observations suggest that GM1 a) selectively facilitates the excitatory component of the neural circuitry by increasing excitatory transmitter release, b) has little direct effect on inhibitory synapses, c) but depresses the firing of inhibitory interneurons.

SMALL FUSION PORES PASS LITTLE LIPID. F.W. Tse\* & W. Almers. Dept. Physiol & Biophysics U of Washington Seafle WA 98195

Physiol. & Biophysics, U. of Washington, Seattle, WA 98195.

We voltage-clamped 3T3 fibroblasts expressing HA (the fusion protein of the infuenza virus) while they fused to single human red blood cells (RBC). The electrical conductance of the cell-cell connection (fusion pore) was calculated from the membrane capacitance (C) measured with a lock-in amplifier (26 - 28 °C). The RBC membrane was loaded with a fluorescent lipid (DilC1g(5)) so that movement of lipid into the fibroblast could be detected with an image intensifier and later analyzed digitally. When HA was activated by acidification of the external medium, a small but abrupt increase in C was seen 27 - 159 s later, indicating the opening of the fusion pore. Over the next 2 - 300 s, the pore conductance (g) increased from <0.5 nS to >1 - 2 nS. In 12 cells, we calculated the rate constants of lipid flux from segments of data in which the average value of g could be also calulated as a function of time. Lipid flux was clearly seen when g was >1 - 2 nS, but not when g was <0.5 nS. Flux appears to require that g exceeds a minimum value. This is not expected if the pore is made of mobile lipid, in which case flux should rise as the square root of g. Instead, our data suggest that (1) either the initial fusion pore (<0.5 nS) is proteinaceous, or the lipids in it are essentially immobile (perhaps due to interactions with proteins), and (2) the fusion pore dilates with the addition of lipids. Supported by GM-39520.

KINETICS AND SIZE OF CHOLESTEROL LATERAL DOMAINS IN BRAIN SYNAPTOSOMES: MODIFICATION BY SPHINGOMYELINASE AND EFFECTS ON CYTOSOLIC CALCIUM. A. M. Rao, U. Igbavboa, M. Semotuk and W.G. Wood\*, VA Medical Center, GRECC, and Dept. of Pharmacology, Univ. of Minnesota, School of Medicine, Minneapolis, MN 55417.
Cholesterol domains have been well-studied in non-neuronal membranes. The

purpose of these experiments was to determine if: 1) exchangeable and non-exchangeable cholesterol domains or pools were present in brain synaptosomal membranes; 2) effects of sphingomyelin on cholesterol domains; and 3) cholesterol domains and calcium uptake and cytosolic calcium in synaptosomes. Cholesterol domains were determined using cholesterol exchange between radiolabeled small unilamellar vesicles and mouse synaptosomes. In some experiments, synaptosomes were treated with sphingomyelinase (Staphylococcus aureus), that has previously been shown to alter membrane cholesterol in non-neuronal membranes. Calcium uptake and  $[Ca^{2+}]_i$  were measured using Fura-2. The size of the exchangeable pool of synaptosomal membrane cholesterol was approximately 50% of total membrane cholesterol when measured at 37°C. The  $t_{1/2}$  of cholesterol exchange at 37°C in cholesterol when measured at  $37^{\circ}$ C. The  $1_{1/2}$  of cholesterol exchange at  $37^{\circ}$ C in synaptosomes was approximately 9 hr. Temperature-induced changes in membrane fluidity significantly reduced the size of the exchangeable pool and significantly increased the  $1_{1/2}$  of cholesterol exchange. Sphingomyelinase treatment of synaptosomes significantly increased the  $1_{1/2}$  of cholesterol exchange but did not modify the exchangeable pool of cholesterol. Calcium uptake into synaptosomes was significantly increased in sphingomyelinase-treated synaptosomes. Cholesterol domains can be described in neuronal tissue and the size and kinetics of those domains were altered by temperature-induced changes in fluidity and hydrolysis of sphingomyclin, that also increased Ca<sup>2+</sup> uptake. Supported in part by the Dept. of VA and NIAAA 07292 (WGW).

THE COMBINED EFFECTS OF AGE AND HALOTHANE ON TRANSMITTER RELEASE AT THE NEUROMUSCULAR JUNCTION: M.D. Sokoll\*, B. Bhattacharvya, K. Tsen and L.R. Davies. Department of Anesthesiology, University of Iowa College of Medicine, Iowa City, IA 52242

It is now well documented that increasing age into the geriatric range is associated with a decrease in anesthetic requirement. We wished to examine the possible relationships between age and anesthetic at the neuromuscular junction

METHODS: The phrenic nerve-cut diaphragm muscle preparation of the rat was METHODS: In pricinc nerve-cut diapriagm music preparation of the rat was used. The preparation was placed in a bath (volume 3 ml). Miniature endplate currents MEPC's and endplate currents EPC's were recorded with a two microelectrode voltage clamp. MEPC's and EPC's (0.4 and 40 Hz) were recorded before and during the application of halothane (1 and 2%). MEPC's and EPC's were analyzed for amplitude and time constant of decay (tau). Quantum content of EPC's was calculated by the direct method. Rats aged 6, 18-20 and 30-33 months were

RESULTS: Membrane potential related changes in MEPC amplitude and tau were similar in all groups of rats. Quantum content of the EPC's (0.4Hz) was greater in the young animals (52 vs 44 for 6 and 30 month animals). Halothane decreased the amplitude and tau of both MEPC's and EPC's. Quantum content of EPC's elicited at amplitude and use of both mether's and EPC'S. Quantum content of EPC'S educated to 0.4Hz was decreased following the application of halothane. The decrease was greater in the older animals. The percentage of rundown of the EPC was similar in all groups and was not altered by the application of anesthetic.

DISCUSSION: Transmitter output at the neuromuscular junction is decreased in

older rats. The anesthetic induced decrease is greater in the older animals. The process of mobilization of transmitter in the nerve terminal (relative to EPC#1) appears to be unaltered by either age or the anesthetic halothane. If anesthetics have similar actions in the CNS these may be related to the mechanism of anesthetic

NEUROSTEROIDS CAN BE SYNTHESIZED IN SPECIFIC REGIONS OF THE RAT BRAIN BY ADRENAL STEROIDOGENIC ENZYMES. S. H. Mellon and C. F. Deschepper\*, Dept. of Ob, Gyn & Repro Sci, Dept. of Physiology, and The Metabolic Research Unit, Univ. of Calif, San Francisco, CA 94143

Neurosteroids are steroids that are made in and act on neural tissues in an auto/paracrine fashion, as opposed to adrenal and gonadal steroids that can act on the CNS in an endocrine fashion. All glandular All glandular steroidogenesis is initiated by P450scc which converts cholesterol (Chol) to pregnenolone (Preg). Rat neonatal forebrain glial cells mimic adrenal steroidogenesis by converting <sup>3</sup>H mevalonolactone to <sup>3</sup>H Chol, <sup>3</sup>H Preg, and <sup>3</sup>H 20-OH Preg. Although undetectable by RNase protection assays, RNA-based PCR detected mRNAs for P450scc and P450c11β (11β hydroxylase), but not for P450c17 (17α hydroxylase) or P450c11AS (aldosterone synthase) in primary cultures of neonatal forebrain glial cells. Thus the rat brain contains some, but not all, of the steroidogenic enzymes found in glandular endocrine tissues. Both P450scc and P450c11 $\beta$  mRNAs were found in the amygdala, hippocampus and midbrain and were most abundant in the cortex of both male and female rats, but P450c11β mRNA was more abundant in the female than male hippocampus. P450scc mRNA is found in Type-1 astrocytes of primary glial cultures. P450scc protein is almost as abundant in Type-1 astrocytes as in adrenal Y-1 cells, while P450scc mRNA is about 103-104 less abundant, suggesting that the protein is very stable in the brain. Thus the synthesis of classic (e.g. glucocorticoids and progestins) and nonclassic (e.g. allopregnanolone) neuorsteroids can be regulated *in situ* in the brain, and do not require extra-neural substrates

MATERNAL ADRENALECTOMY ELEVATES POMC mRNA, BUT NOT CRF mRNA IN MALE OFFSPRING. E. Redei\*, LF. Li, I. Halasz, and F. Aird. Department of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

The role of maternal glucocorticoids on the integrity of the hypothalamic-pituitary-adrenal function of offspring was investigated. Dams were adrenalectomized or shamadrenalectomized on day 12 of gestation. Pups were crosswere subjected to intermittent footshock stress (7 shocks in 15 sec, 0.2 mA). Pups were decapitated immediately before (t=0), and 5, 20 and 40 min post-stress. Basal ACTH levels were significantly higher in offspring of adrenalectomized dams (ADX) compared to the sham group The ACTH stress-response and basal corticosterone levels did not differ between the groups, but the immediate corticosterone response to stress (t=5 min) was significantly higher in the ADX group. Hypothalamic CRF mRNA and glucocorticoid receptor (GR) mRNA levels were not affected by maternal adrenalectomy. In the anterior pituitary, however, POMC mRNA was dramatically (p=0.008) increased, and a trend of increased GR mRNA was seen, in offspring of adrenalectomized dams. These results suggest that expression of the POMC gene, but not the CRF gene, is sensitive to glucocorticoid regulation prenatally. Supported in part by MH45862 and AA07389.

ELEVATED BLOOD CORTICOSTERONE LEVELS IN NEUROLOGIC MUTANT MICE LURCHER AND STAGGERER. F. Frederic, T. Chautard, C. Oliver, E. Wollman, N. Delhaye-Bouchaud and J. Mariani\*. Inst.Neurosc. Univ. P. & M. Curie, Paris, INSERM U. 297, Marseille and Inst. G. Roussy, Villejuif, France

We reported recently an hyperproduction of interleukin-1 (IL-1) by the peripheral macrophages of the cerebellar mutant mice lurcher and staggerer. As IL-1 causes increased ACTH synthesis by the pituitary and consequently increased blood levels of corticosterone (CS) and thymic hypoplasia in mice, we investigated if an IL-1-dependent increased in plasma CS, might be responsible for the thymic hypoplasia also observed

We measured the plasma CS levels of 7±1 week-old mutants and matched controls, at 10 a.m. or 5 p.m., either at rest or after a stress consisting of a change in the housing conditions during increasing periods of time. At 5 p.m, we found a marked increase of nearly 100% of the resting CS levels in the plasma of staggerer and lurcher as compared with controls. At 10 a.m, the CS levels were 100% higher in staggerer, but not in lurcher. Both mutants were more reactive to stress than controls, and at any period of the nycthemeral cycle. The over-reaction was also of the 100% range after 15 min of stress. Both sexes were reactive and females had higher levels than males. Plasmatic CS increase after i.p. injections of exogenous (L-1α was similar in mutants and in controls. The hyperreactivity of the lurcher mutant to an adaptative stress was not suppressed by pretreatment by the IL-1 receptor antagonist protein, suggesting that this abnormality is IL-1-independent in *lurcher*. Whatever its origin, currently under investigation, the high plasma CS level of staggerer and lurcher may play a role in the thymic hypoplasia of these mutants

THE EFFECTS OF CHRONIC COLD EXPOSURE ON DIURNAL CORTICOSTERONE AND ALDOSTERONE RHYTHMS IN SPRAGUE-DAWLEY RATS. M.E. Bligh, S.A. Bhagwat, J.R. Thomas, and T.W. Castonguay\*. Dept of Human Nutrition and Food Systems, Univ. Maryland, College Park, MD 20742 & Naval Medical Research Inst., Bethesda, MD 20814.

Chronic cold exposure increases plasma corticosterone (CORT) to maximal levels after approximately 7d. CORT levels then approach baseline concentrations observed at ambient (23°C) temperatures. Aldosterone (ALDO) release is also stimulated by cold exposure. The purpose of this study was to investigate the effects of chronic cold exposure on CORT and ALDO diurnal rhythms. Thirteen male Sprague-Dawley rats were individually housed, adapted to a 12/12 light/dark cycle (lights on 0900h) and provided with Purina Chow and water ad lib. Rats were housed at 23°C. On the 7th d tail blood samples were obtained every 4 h for 24 h beginning at 0900h. Blood samples were centrifuged, and plasma CORT and ALDO were measured via RIA. Laboratory temperature was then decreased to 4°C. On the 7th and 14th d of cold exposure, blood was sampled every 4 h as Cold exposure resulted in elevated levels of CORT at 0900h after both 7 and 14 d of exposure (p < .05). At 1300h and 0500h levels were elevated only after 7 d of cold exposure (p < .05). Aldo was significantly elevated at all time periods after 7 d of cold exposure, but after 14 d were only elevated at 0900h, 1300h, and 2100h (p<.05). Peak CORT levels occurred at 1700h (180.5 $\pm$ 16.8 ng/ml) at 23°C and 2100h at 7 and 14 d at 4°C (202.2±16.4 and 190.7±16.4 ng/ml, respectively). Peak ALDO occurred at 2100h at 23°C (257.9 + 21.3 pg/ml), and 7d (431.9±21.2 pg/ml) and 14d (398.4±21.2 pg/ml)at 4°C. Results suggest that CORT and ALDO pg/ini) and Pd (3934-E21.2 pg/ini) at V. Results aggest that CoVR and Alzo are released by different mechanisms throughout the day/night cycle and that cold stimulates ALDO release by a different mechanism than that stimulating CORT release. (Supported in part by NIH grant ... DK42446 and a grant from Maryland Agricultural Experiment Station Competitive Grants Program).

MR AND GR SYNERGISTICALLY CONTROL ACTH AT THE PEAK OF THE DIURNAL RHYTHM. M. J. Bradbury\*, S.F. Akana, §J.P. Herman and M.F.Dallman, U. California-San Francisco, 94143-0444 and §U. Kentucky-Lexington, 40536-0084.

Adrenalectomized (ADX) rats have high plasma ACTH in the absence of corticosterone(B). Sensitivity of inhibition of ACTH by free plasma B is high in the morning (IC50 0.7 nM) and lower in the evening (IC50 3.7 nM). The reported K<sub>D</sub>s morning (IC50 0.7 nM) and lower in the evening (IC50 3.7 nM). The reported Kps for B with type I (MR) and type II (GR) receptors are 0.5 and 2.5 nM, respectively, suggesting that B on MR controls AM ACTH and that B on GR alone, or in conjunction with MR controls PM ACTH. To find out whether, in the evening, the efficacy of GR occupancy on ACTH is affected by MR occupancy, we implanted rats with low doses of B (relative MR agonist) and dexamethasone (relative GR agonist), alone or in combination at the time of ADX. The plasma ACTH and total plasma B 5 days after surgery, 2 hours BEFORE lights out are shown below in bold (n=5 or 6). In combination, rats with 15% B and 2.5µg dex/day had lower ACTH than ADX rats (\*\*). However, alone these doses did not lower ACTH. 15% B and 2.5µg dex/day lone did not inhibit expression of AVP mRNA in the parvocellular rats (\*\*). However, alone these doses did not lower ACTH. 15% B and 2.5µg dex/day alone did not inhibit expression of AVP mRNA in the parvocellular paraventricular nucleus (PVN); however, CRF mRNA tended to be reduced by both. We conclude that 1) the control of plasma ACTH at the peak of the diumar hythm by GR requires the full occupation of MR, an effect initiated outside of the PVN and 2) the level of CRF mRNA in this paradigm does not predict plasma ACTH.

HEMORRHAGE-INDUCED c-fos PROTEIN EXPRESSION IN RELATION TO

HEMORKHAGE-INDUCED e-Jos PROTEIN EXPRESSION IN RELATION TO HPA AXIS ACTIVITY. K.V. Thrivikraman\* and P.M. Plotsky. Clayton Fndn. Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Mapping of e-Jos protein expression was used to identify neural circuits activated by controlled venous hemorrhage (HEM; 14 ml blood/kgBW over 3 min) in awake male rats. In one group shed blood was retransfused at 10 min (HR), while in the second group blood was not retransfused (HN). A third group of time controls did not sustain blood loss (CON). Plasma ACTH and corticosterone (B) levels in sequential blood samples were determined by RIA. Groups of rats were perfused immediately before or at 30 min intervals after HEM. Coronal 30 µm frozen immediately before or at 30 min intervals after HEM. Coronal 30 µm frozen sections of the brain were cut and immunostained for nuclear c-fos protein. Some sections were also stained for cytoplasmic corticotropin releasing factor (CRF). HEM elicited time-dependent increases in plasma ACTH and B. In HR rats, ACTH decreased towards prestimulus values after retransfusion. In contrast, both ACTH and B peaked by 30 min in HN rats, then plasma ACTH decreased whereas B remained elevated. Following HEM, c-fos protein was initially visualized in the nucleus of the solitary tract (NTS; A2), a primary hemodynamic sensitive region of the brainstem. At 60 min, c-fos immunostaining was observed in cells of the hypothalamic paraventricular (PVN) and supraoptic (SON) nuclei. The number of Fos-positive cells in each of these regions was greater in HN rats than in HR rats platerestingly at 150 min post-HEM c-fos expression was noted in limbic area (e.g. Interestingly, at 150 min post-HEM c-fos expression was noted in limbic areas (e.g. central nucleus of the amygdala, bed nucleus of the stria terminalis, hippocampal central nucleus of the amygodala, bed nucleus of the stria terminans, inppocampate CA3 region) of HN rats but was absent in the HR rats. Nuclear c-fos protein staining was co-localized with cytoplasmic CRF immunostaining in the central nucleus of the amygdala as well as in the PVN. These studies complement mapping of hemodynamically sensitive CNS pathways by other techniques and provide new insights into the sequele of their activation. Furthermore, these studies have identified neural circuits potentially involved in stimulus-dependent activation and modulation of hypothalamic-pituitary-adrenal function.

CHRONIC ANTIDEPRESSANT DRUG (AD) TREATMENT ATTENUATES HYPOTHALAMIC-PITUITARY-ADRENOCORTICAL (HPA) ACTIVITY IN THE RAT. J.M.H.M. Reul' and F. Holsboer. Max-Planck-Institute of Psychiatry, Clinical Institute, Dept. Neuroendocrinology, 8000 Munich 40, Germany.

In major depressive illness a defective HPA regulation is often observed, exemplified by increased basal HPA activity and an altered responsiveness in neuroendocrine challenge tests. We have hypothesized that a deterioration of HPA homeostasis may be an etiological factor in this mental disease. Recently, we have embarked on a study to investigate the effects of AD (i.c. amitriptyline) on the HPA system in order to gain insight in the mechanism of action of these drugs.

In rats, 5 weeks of amitriptyline treatment resulted in decreased basal levels of ACTH and corticosterone as well as a decreased adrenal weight. A decline in adrenal weight was not apparent after 2 weeks of AD treatment and no effects were found on body weight. In addition, AD treatment resulted in time-dependent and dose-dependent changes in brain corticosteroid receptor concentrations. As compared to controls, hippocampal mineralocorticoid receptor (MR) levels were elevated by 40-70% after 2 and 5 weeks of treatment. At 7 weeks, the increments in MR were largely diminished. Hypothalamic gluccocrticoid receptor (GR) levels were increased by 20-25% at 5 weeks of treatment, but not at 2 or 7 weeks. We interpret these data as providing evidence for the notion that chronic AD treatment results in an attenuation of HPA activity. We postulate, in view of the role of MR and GR in HPA regulation, that AD-induced changes in brain corticosteroid receptor capacity may underlie the attenuation of HPA activity. receptor activity.

SYNERGISTIC POSITIVE TRANSCRIPTIONAL REGULATION OF THE HUMAN CORTICOTROPIN-RELEASING HORMONE GENE BY CAMP AND DEPOLARIZATION. H. Guardiola-Diaz\* and A.F. Seasholtz. Mental Health Research Institute and Deptartment of Biological Chemistry, University of Michigan, Ann Arbor, MI 48109

Michigan, Ann Arbor, MI 48109

Neuronal gene expression can be regulated by synaptic activity and membrane depolarization. The transduction of signals from neurotransmitter receptors and ion channels on the cell membrane to the genome involves activation of several second messenger systems that often interact. In this study we investigate the mechanisms involved in the regulation of the human corticotropin-releasing hormone (hCRH) gene by depolarization. Pc-12 cells are transiently transfected with the hCRHCAT1 construct containing 663 bp of 5° flanking DNA and 127 bp of 5° UTR fused to the bacterial CAT gene. This construct is positively regulated by cAMP (10-15 fold) via a cAMP-responsive element (CRE) located 220 to 227 bp 5° to the mRNA cap site. Potassium-mediated depolarization (55mM) results in a synergistic upregulation of hCRHCAT1 activity from forskolin-activated levels in Pc-12 cells. The hCRH sequence between -231 and -179 bp (including the hCRH CRE) confers the positive cAMP regulation and the depolarization-mediated synergistic upregulation of forskolin-activated CAT activity to a heterologous promoter, consistent with previous reports that the CRE mediates regulation by depolarization for the human proenkaphalin and c-fos genes. However, the effects promoter, consistent with previous reports that the CRE mediates regulation by depolarization for the human proenkaphalin and c-fos genes. However, the effects of verapamil and Bay-K 8644 on the synergy between cAMP and depolarization are significantly different between hCRHCAT and enkephalin-CAT reporter plasmids. These findings suggest that an equivalent stimult can trigger multiple intracellular cascades that may act independently on different genes, having the same ultimate positive transcriptional effect. These independent transduction steps may be targets for regulation and could explain the specificity in induction of neural genes. (Supported by a NARSAD Young Investigator Award and NIH grant DK42730 to A.F.S.)

HIGH FREQUENCY OF HOMOLOGOUS RECOMBINATION AT THE MOUSE POMC GENE LOCUS IN EMBRYONIC STEM CELLS. M.A. Japón, M. Rubinstein and Malcolm J. Low\*. Vollum Institute for Advanced Biomedical Research.

Rubinstein and Malcolm J. Low\*. Vollum Institute for Advanced Biomedical Research, Oregon Health Sciences University, Portland, OR 97201.

Propiomelanocortin (POMC) generates a diverse family of peptides including ACTH, α-MSH and β-endorphin that may function as hormones, mitogens or neurotransmitters. To characterize the physiological role of individual POMC peptides in development and the unique contribution of β-endorphin to the total opioid activity of the brain we disrupted the entire POMC gene or selectively mutated β-endorphin coding sequences by homologous recombination in embryonic stem (ES) cells. The gene replacement vector POMCXX3 contains a 9.8 kb fragment of murine POMC genomic DNA. 0.5 kb of coding sequences were deleted at the 3' end of the third exon abrogating the production of any bioactive POMC peptides and replaced by a neomycin resistance gene (neo). To screen for homologous recombination events using the positive and negative selection method, a herpes simplex virus thymidine kinase gene resistance gene (neo). To screen for homologous recombination events using the positive and negative selection method, a herpes simplex virus thymidine kinase gene (kle) was inserted at the 5' end of the mouse POMC gene fragment. Both neo and tk cassettes (kindly provided by Dr. P. Soriano) are under the transcriptional control of the phosphoglycerate kinase-1 promoter. The construction POMCX\*4 is similar to the one described above but instead of having the 0.5 kb deletion, a single base was inserted in the codon for the N-terminal tyrosine of  $\beta$ -endorphin converting it to a premature termination codon (TAC to TAA). AB1 ES cells, grown on y-irradiated SNL76/7 mouse fibroblasts (cell lines generously provided by Dr. A. Bradley), were electroporated in the presence of 25 µg of linearized plasmid. Double selection with 300 µg/ml G418 and 2 µM gancyclovir resulted in a two to three fold enrichment over G418 alone. Five positive clones per construction were detected by PCR from 150 double resistant colonies. Southern blot analysis using different probes revealed, in each case, that 4 clones had a single targeted event with the predicted restriction map. Thus, we obtained homologous recombination at the mouse POMC locus with a relatively high frequency of 1/30. Transgenic mice derived from these clones will be used to study the neuroendocrine physiology of the mammalian stress response and the role of  $\beta$ the neuroendocrine physiology of the mammalian stress response and the role of  $\beta$ -endorphin in the development of the CNS and the hypothalamic-pituitary axis.

# 319.10

EVIDENCE AGAINST CHANGES IN CORTICOTROPH CRH RECEPTORS IN DEPRESSED PATIENTS. Elizabeth A. Young\*, Huda Akil, Roger F. Haskett, and Stanley J. Watson. Department of Psychiatry and Mental Health Research Institute, University of Michigan Medical Center, Ann Arbor, MI 48109, U.S.A.

Previous studies by a number have investigators have documented a decreased ACTH and  $\beta$ -lipotropin/ $\beta$ -endorphin ( $\beta$ -End) response to ovine corticotropin releasing hormone (oCRH) in depressed patients. Since depressed patients demonstrate higher plasma cortisol concentrations at the time of oCRH challenge, it is difficult to determine if the decreased ACTH response is due to enhanced negative feedback of cortisol on ACTH release or an alteration in CRH receptors in depressed patients. To evaluate release of an anteration in CNR receptors in depressed patients. To evaluate the response to oCRH in an "open feedback loop" system, we administered metyrapone, 750 mg, at 4 p.m. and 7:30 pm, followed by administration of 0.3µg/kg oCRH at 8 p.m. in 10 normal controls and 10 depressed patients. Administration of metyrapone at this time in the circadian rhythm clamped plasma cortisol concentrations to less than 2 µg/dl but did not result in rebound ACTH or  $\beta$ -End secretion. In control subjects, metyrapone administration produced a 90% blockade of the cortisol response as well as a 2-fold greater β-End response compared to administration of the same dose of oCRH without metyrapone. The 10 depressed patients and their matched controls demonstrated identical  $\beta$ -End response (integrated response for controls=319 $\pm$ 63, for patients=325 $\pm$ 86) and cortisol response (integrated response for controls=162 $\pm$ 38, for patients=215 $\pm$ 58) to oCRH following metyrapone pretreatment. These data confirm that corticotroph CRH receptors are normal in depressed patients, and that cortisol feedback plays an essential role in the abnormal ACTH and  $\beta$ -End response to oCRH in depressed patients.

EFFECTS OF RENAL DENERVATION AND REINNERVATION ON GANGLIONIC GENE EXPRESSION OF NEUROTRANSMITTER PROTEINS AND c-fos. T.L. Krukoff\* and Y. Zheng. Dept. of Anatomy & Cell Biol., Fac. of Medicine, Univ. of Alberta, Edmonton, Canada T6G 2H7.

The molecular basis for the reno-renal reflex was studied in paravertebral ganglia (PG, T11 to L2) and the celiac-mesenteric (CM) plexus following kidney denervation to show changes in mRNAs encoding tyrosine hydroxylase (TH), neuropeptide Y (NPY), and c-fos. For TH and NPY, tissues were removed at 4, 14, 21, and 56 days after denervation of the left kidney; for c-fos they were removed at 1 and 4 hours after denervation and Northern blot analyses were carried out. Compared to control animals, levels of TH mRNA in the left PG and the CM plexus were decreased at 4 and 14 days, elevated at 21 days, and similar to controls at 56 days. In the right PG, TH mRNA levels were increased at 4 and 14 days, decreased from this level at 21 days, and similar to controls at 56 days. Changes in c-fos mRNA levels were present only at 1 hour after denervation and paralleled those described for TH. No changes in NPY mRNA were found in any of the ganglia at any stage in

We conclude that kidney denervation leads to acute and chronic decreases in ipsilateral ganglionic levels of c-fos and TH mRNAs, respectively, and that levels of TH mRNA return to normal only after reinnervation is known to occur. Furthermore, increases in c-fos and TH mRNA in the contralateral PG, likely induced by the reno-renal reflex, show that the changes have an early onset and that they continue to operate until the compromised kidney is reinner-

Supported by the Medical Research Council of Canada.

SPINAL MECHANISMS UNDERLYING THE SYMPATHOEXCITATORY EFFECTS OF RAPHE PALLIDUS NEURONS. S.F. Morrison\* Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Raphe pallidus stimulation elicits a long-latency excitatory potential in rat sympathetic nerves. This excitation appears to be mediated by raphe pallidus neurons which project to the thoracic spinal cord with slowly conducting axons. In the present study, characteristics which distinguish serotonergic neurons in other raphe nuclei were examined for these raphe pallidus neurons. The conduction velocities of the spinal axons of raphe pallidus neurons ranged from 0.4 to 0.8 m/s. The frequency with which such neurons were found to be spontaneously active was increased in unanesthetized, decerebrate rats in comparison to those anesthetized with urethane/chloralose. The rate of discharge of raphe pallidus neurons was slow (< 5Hz), and often characterized by very regular interspike intervals. Their activity was not synchronized to the cardiac cycle and was not altered by stimulation of the baroreceptor reflex during large increases in arterial pressure. Their activity was, however, completely inhibited following intravenous administration (4 g/kg) of 8-OH-DPAT, a 5-HT<sub>IA</sub> receptor agonist. These results, similar to those in the cat (Brain Res. 477:172-182, 1989), suggest that sympathoexcitatory, raphe pallidus neurons are serotonergic. However, the additional finding that the long-latency excitation of splanchnic sympathetic preganglionic neurons following raphe pallidus stimulation was blocked by iontophoretic application of the glutamate receptor antagonist, kynurenic acid, indicates that the sympathoexcitatory effects mediated by raphe pallidus neurons are dependent on the activation of excitatory amino acid receptors in the intermediolateral nucleus. (Supported by HL 47196)

# 320.5

PARTICIPATION OF NMDA AND NON-NMDA RECEPTORS IN BAROREFLEX SIGNAL TRANSDUCTION IN NUCLEUS TRACTUS SOLITARII (NTS) OF RATS. H. Ohta\* and W.T. Talman, Department of Neurology, The University of Iowa and VAMC, Iowa City, IA 52242

Excitatory amino acids (EAA) may be important neurotransmitters released from baroreceptor nerve terminals in the NTS. EAA receptors have been categorized by their major agonists as NMDA and non-NMDA receptors. Although, microinjection of EAA agonists into NTS produces depressor and bradycardiac responses similar to those induced by activation of the baroreflex, studies of the effect on the baroreflex of antagonists injected into NTS have been inconsistent. The present study is designed to determine if NMDA or non-NMDA receptors are involved in the baroreflex at the level of NTS. Baroreflex responses elicited by iv administration of phenylephrine and nitroprusside were tested before and after bilateral microinjection into NTS of MK801 (1 nmol) or DNQX (20 pmol) in rats anesthetized with chloralose. Activity of the baroreflex was assessed by sigmoidal curve fitting. Both MK801 and DNQX produced increases in arterial pressure and heart rate. The gain of the baroreflex expressed by the average slope of the reflex curve was similarly reduced by each antagonist: Before

After -2.32 ± 0.30 -1.38 ± 0.30\* DNOX -2.57 ± 0.25 -1.22 ± 0.25\*

\* p<0.05, comparison between before and after.

These results suggest that both NMDA and non-NMDA receptors are involved in baroreflex transmission in NTS. Support: VA Merit Review and Clin. Investigator(WTT), and NIH HL32205 and HL14388.

ROLE OF SPINAL NMDA RECEPTORS IN THE REGULATION OF SYMPATHETIC NERVE ACTIVITY AND CONTROL OF ARTERIAL PRESSURE. Frank J. Gordon\* Dept. of Pharmacology Emory University School of Medicine, Atlanta, GA 30322

Rats were anesthetized with urethane, paralyzed and artificially ventilated. The NMDA receptor antagonist D-2-amino-7-phosphonoheptanoic acid (D-AP7; 100 mmol/10 ul) was delivered to the spinal cord via an intrathecal (IT) catheter. The rostral ventrolateral medulla (RVLM) was electrically stimulated (0.5 msec pulses, 100 uA) and sympathetic nerve activity (SNA) was recorded from the lumbar Paired-pulse stimulation of the RVLM (150 trials) produced bimodal averaged sympathetic evoked potentials (total duration < 200 msec) that were little affected by IT D-AP7. However, in the same animals, IT D-AP7 virtually eliminated the sustained sympathoexcitation and pressor responses produced by 10 sec trains of RVLM stimulation. In other animals, 1500 msec stimulus trains (50 Hz) were delivered to the RVLM and sympathetic potentials were recorded. IT D-AP7 had little effect on the initial (100-200 msec) increase in SNA, but SNA rapidly diminished and could not be sustained for the remainder of the stimulus train. Additionally, blockade of spinal NMDA receptors had little effect on the baroreflex-mediated periodicity of SNA locked to the cardiac cycle, but abolished reflex-mediated increases in SNA evoked by lowering arterial pressure for 1-2 min with i.v. nitroprusside. These data indicate that synaptic activation of NMDA receptors in the spinal cord is necessary to support sustained increases in SNA that are required to elevate peripheral arterial blood pressure. ELECTRICAL STIMULATION OF HINDLIMB AFFERENT FIBRES INHIBITS CAROTID SINUS BARORECEPTOR NEURONES IN THE CAT NUCLEUS TRACTUS SOLITARIUS (NTS). S.E. McMahon, P.N. McWilliam\*, J. Robertson & J.C. Kaye. Cardiovascular Studies, University of Leeds, Leeds, U.K.

Kaye. Cardiovascular Studies, University of Leeds, Leeds, U.K. Hindlimb contraction produces an inhibition of the cardiac vagal component of the baroreceptor reflex and a rapid cardiac acceleration mediated by a withdrawal of vagal tone. These effects could be mediated by an inhibition of neurones in the baroreceptor reflex pathway. Experiments were designed to investigate whether baroreceptor neurones in the NTS are inhibited by electrical stimulation of hindlimb afferents in chloralose anaesthetized cats. Extracellular recordings were chloralose anaesthetized cats. Extracellular recordings were made from single neurones in the NTS that were activated by stimulation of the carotid sinus nerve. The evoked activity in 22/25 carotid sinus neurones was significantly inhibited by only a single or twin pulse to the ipsilateral peroneal nerve. In the majority of cases the inhibition was mediated by stimulation of group III afferent fibres only, although a small proportion also showed some degree of inhibition by groups I and II fibres. When the ipsilateral isolated carotid sinus was distended these neurones responded with bursts of firing, indicating that they were baroreceptor neurones. In a high proportion of these neurones the inhibition was antagonized by ionophoresis of the GABA antagonist bicuculline. Therefore, baroreceptor neurones in the NTS can be inhibited by peroneal nerve stimulation and this inhibition is mediated at least in part by GABA. This inhibitory mechanism maybe involved in mediating the cardiovascular response to exercise.

# 320.6

MECHANISMS OF PRESSOR AND BRADYCARDIC RESPONSES PRODUCED BY MICROINJECTION OF L-GLUTAMATE (L-GLU) INTO THE NUCLEUS TRACTUS SOLITARII (NTS) OF CONSCIOUS RATS. B.H.Machado\* and K.Colombari. Dept. of Physiology, School of Medicine of Ribeirão Preto, 14.049, Ribeirão Preto, Brazil.

Microinjection of L-GLU (5nMoles/100nl) into the NTS of conscious rats (n=7) produced pressor (+37±4 mmHg) and bradycardic responses (-114±12 bpm). The pressor and bradycardic responses were sequentially blocked by prazosin (1mg/Kg,i.v.) (+7±3 mmHg and -116±8 bpm) and methyl-atropine (1mg/Kg,i.v.) (+8±4 mmHg and 0±0 bpm), respectively. Microinjection of L-GLU into the NTS after the blockade of glutamatergic receptors with kynurenic acid (10nMoles/100nl) (n=12) produced increase of pressure (+26±3 mmHg) and almost abolished the bradycardic response (-10±3 bpm). The results shown that L-GLU into the NTS produced increase of pressure and bradycardic preprocess with its pressure. and bradycardic response, which is not reflex in origin. The data on the pressor response suggest that L-GLU into the NTS is not involved in the reflex inhibition of efferent sympathetic activity, while the bradycardic response to L-GLU seems to be mediated by glutamatergic receptors. (Supported by FAPESP).

ARE ANGIOTENSIN II AND SUBSTANCE P RECEPTORS ON MEDIAL NTS NEURONS PRE- OR POSTSYNAPTICT K. L. Barnes.\* L. Qu and A. J. McQueeney. Dept. of Brain & Vascular Research, Research Institute, Cleveland Clinic Foundation, Cleveland, OH 44195-5286.

Cleveland Clinic Foundation, Cleveland, OH 44195-5286.

We previously discovered a group of medial nucleus tractus solitarii (nTS) neurons that are excited by both angiotensin (Ang) II and substance P (SP), and that Ang II releases SP from medulla slices. Vagal deafferentation suggested that some Ang II receptors in the nTS are presynaptic on vagal afferent fibers, while SP receptors are postsynaptic on intrinsic nTS neurons. Thus the cardiovascular effects of Ang II in the medial nTS might be mediated by Ang II-induced release of SP from vagal afferents. To determine the pre- or postsynaptic location of receptors that mediate the excitation of medial nTS neurons by Ang II or SP, we tested the capacity of each peptide to activate nTS neurons before and after blockade of synaptic transmission in the in vitro rat medulla slice. Blockade of synaptic transmission by low Ca<sup>++</sup> artificial cerebrospinal fluid (aCSF; 0.2 mM Ca<sup>++</sup>, 5 mM Mg<sup>++</sup>) was verified by elimination of short latency spikes evoked by solitary tract stimulation, but not postsynaptic activation of the neuron by Leglutamate. Ang II-induced excitation was prevented in 12 of 26 medial nTS neurons when synaptic transmission in the slice was blocked. In contrast, low Ca<sup>++</sup> aCSF failed to prevent excitation by SP in 25 SP-responsive cells. In 11 of 20 neurons excited by both peptides, low Ca<sup>++</sup> aCSF blocked excitation by Ang II but not by SP; 9 cells continued to respond to both peptides. These findings suggest that a substantial proportion of nTS neurons excited by both Ang II and SP have presynaptic Ang II receptors and postsynaptic SP receptors, and may be the neuronal substrate for mediation of the cardiovascular effects of Ang II in the medial nTS via release of SP. NEUROTENSIN PROJECTIONS FROM NUCLEUS OF THE SOLITARY TRACT TO NUCLEUS AMBIGUUS. J. Ciriello\* S. Roder and V. Badhwar. Department of Physiology, University of Western Ontario, London, Canada, N6A SC1

We have previously shown that microinjections of neurotensin (NT) into the nucleus ambiguus (AMB) region in spinal animals elicit a vagal bradycardia. However, the sites of origin of the NT pathways to AMB are not known. In this study, experiments were done to investigate whether neurons in the nucleus of the solitary tract (NTS) containing NT innervate AMB in the rat, using the retrograde tracer Fluorogold (FG; 2%) and the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L; 2.5%) in combination with NT immunohistochemistry. FG (20-30nl) injections overlapping the AMB region resulted in retrogradely labelled neurons in NTS. Neurons within the caudal aspects of the dorsolateral (dl) subnucleus of NTS labelled with FG were found to contain NT immunoreactivity. Iontophoretic PHA-L injections within the dlNTS resulted in dense fiber and presumptive terminal labelling in the region of AMB. Using the double labelling immunofluorescence technique for identification of PHA-L and NT, a moderate number of PHA-L/NT fibers were found in and around the AMB. These data suggest that NT pathways from NTS maybe involved in controlling vagal cardiomotor neuronal activity and that these pathways likely function as central components of the baroreceptor reflex arc. INNERVATION OF CARDIOMOTOR REGIONS OF THE NUCLEUS AMBIGUUS (AMB) BY DESCENDING PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS (PVH)-OXYTOCIN (OXY) CONTAINING FIBRES. E.T. Kiriakopoulos\*, J. Ciriello and M.M. Caverson. Depts. of Anatomy and Physiology, Univ. of Western Ontario, London, Ontario N6A 5C1.

We have previously shown that approximately 5% of PVH neurons projecting to cardiomotor regions of AMB contain OXY. We have also shown that microinjections of OXY into AMB inhibit vagal cardiomotor neurons (VCN). However, it remains equivocal whether PVH-OXY fibres innervate vagal motor neurons (VMN) in AMB. The present study was done to provide a description of the relationship of PVH-OXY fibres to VMN in AMB. Experiments were done in pentobarbital anesthetized male Sprague Dawley rats. Phaseolus vulgaris leucoagglutinin (PHA-L; 2.5%), was iontophoresed into PVH. In the same animals the retrograde tracer Fluorogold (2%) was injected into the cervical vagus nerve to retrogradely label VMN. After 7-14 days the rats were perfused transcardially and forebrain and brainstem sections were processed for the identification of PHA-L and OXY using the double labelling immunofluorescence technique (Vecta). Fibres and presumptive nerve terminals double labelled with PHA-L and OXY were seen throughout the AMB cell column in the compact and external subdivisions. The projections were most dense at intermediate levels of the AMB, from the level of obex to 1.0 mm rostral to obex. PHA-L/OXY immunoreactivity was closely associated with VMN in the external formation of AMB, the principle site of VCN in AMB. These data support the suggestion that PVH-OXY neurons provide an input to cardiomotor regions of AMB and represent the anatomical substrate by which OXY may influence VCN function. SOMATIC AFFERENT (SA) INPUTS TO CELLS IN THE NUCLEUS OF THE TRACTUS SOLITARIUS (NTS). S. W. Mifflin\*, Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX. 78284-7764
Anatomical studies have shown that NTS neurons receive

Anatomical studies have shown that NTS neurons receive mono- and poly-synaptic inputs from SA fibers. To examine the integration of SA inputs within the NTS, intracellular recordings were obtained from 14 cells which responded to sciatic nerve (ScN) stimulation in pentobarbital anesthetized, mechanically ventilated and paralyzed cats. Cells responded to single pulse ScN stimulation (500uA, 1.0ms) with an EPSP (n=9; latencies = 7.3-21.8ms) or an EPSP/IPSP (n=5; latencies = 9.1-19.8ms). None of these PSPs exhibited the characteristics of a monosynaptic input. Higher intensity or train ScN stimulation (3-5 pulses, 20ms interval) evoked a longer latency (140-310ms) depolarization in 6 cells. A variety of sensory modalities were represented as cells were activated by manual flexion of the hindlimb (n=4), squeezing of skeletal muscle (n=3), lightly touching the skin (n=2), or pinching the skin (n=4). One cell was activated by both manual flexion of the hindlimb and pinching the skin (n=2), or manual flexion of the hindlimb and pinching the skin (n=2), or an EPSP/IPSP (n=2). SA inputs to NTS neurons might provide a substrate for SA interactions with visceral afferent (e.g. baroreceptor and chemoreceptor) reflexes and might contribute to the reflex responses observed during activation of SA fibers. (Supported by NIH HL-36080)

EFFECT OF MICROINJECTION OF OPIATE PEPTIDES INTO NUCLEUS AMBIGUUS ON HEART RATE, T. X. Zhang and J. Ciriello, Department of Physiology University of Western Ontario, London, Canada N6A 5C1

F8F amide (NFF), leu-enkephalin (l-ENK) and met-enkephalin (m-ENK) like immunoreactivity has been demonstrated in the region of nucleus ambiguus (AMB) that is known to contain vagal cardiomotor neurons in the rat. In this study, the effect of microinjection of opiate peptides into AMB on heart rate was investigated. Experiments were done in alpha-chloralose anesthetized and artificially ventilated male wistar rats that had their spinal cord cut at the level of  $C_2$ . Microinjections of 20 nl (50 pmol) of NFF into AMB elicited a bradycardia response (-61.4  $\pm$  14.4 bpm) that was not significantly attenuated 5 and 60 min. after the administration of naloxone (10 mg/kg, i.v.) (-41.8  $\pm$  6.3 and -42.7  $\pm$  7.7 bpm, respectively). Microinjections of 20 nl (200 pmol) of I-ENK or m-ENK into AMB also elicited decreases in heart rate of -13.7  $\pm$  1.6 and -23.6 ± 3.7 bpm, respectively. However, these bradycardic responses were blocked by the administration of naloxone. Microinjections of 20 nl (200 pmol) of 1-ENK or m-ENK 5 min after the administration of naloxone elicited an increase in heart rate (+13.6  $\pm$  2.3 and +19.8  $\pm$  0.4 bpm, respectively). The responses to microinjection of I-ENK returned to control after 60 min. In addition, it was found that the decrease in heart rate elicited by a 20 nl injection containing 200 pmol of NFF (-76.5  $\pm$  16.3 bpm) was significantly larger than those obtained at the same dosage of l-ENK and m-ENK. Taken together, these data suggest that AMB vagal cardiomotor neurons have receptors that are activated by NFF, 1-ENK and m-ENK. These results also suggest that NFF activates receptors different to those of the other opiate peptides. (Supported by the MRC of Canada).

INCREASED TRH GENE EXPRESSION IN MEDULLARY RAPHE NUCLEI BY HYPOTHYROIDISM: IMPLICATION IN THE REGULATION OF VAGAL OUTFLOW TO THE HEART. H. Yang\*, V. Wu, G. Ohning and Y. Taché. CURE/VA Wadsworth Medical Center, Dept. of Medicine and Brain Research Institute, UCLA, Los Angeles, CA 90073.

Hypo- or hyper-thyroidism is accompanied with changes in vagal activity. TRH acts in medullary neurons projecting to the vagus to stimulate vagal activity. Using Northern blot analysis we found that thyroidectomy (Tx) increases medullary TRH gene expression in rats (Gastroenterology, 102:A767,1992). Tx decreased total Tx serum levels (nmol/l) from 35±4 (control, n=5) to 9±1 (one week post Tx, n=5, P<0.05) and throughout the first 5 weeks in rats. TRH mRNA signal in brainstem was significantly increased by 70% (one week) or 2-3 fold (3-5 week) after Tx (n=3,4,4.4) compared with sham operated rats (n=9). This effect was reversed by daily injection of Tx (4  $\mu$ g/100 g, ip) in Tx rats. Rats with sham operation or Tx (30-40 days after the surgery) were fasted overnight and anesthetized with urethane. Heart rate (HR, beats/min) was measured by a olygraph through a PE-90 cannula inserted into the cervical artery. Basal HR was 377±25 and 282±7 (P<0.05) in sham operated and Tx rats respectively. Gastric distension performed by flushing the stomach with 10 ml saline reduces HR from 261±9 to 171±22 (P<0.05) for 4-6 seconds in Tx rats but not in control group. Kainic acid (96 ng/30 nl) injected into the raphe pallidus, where TRH mRNA neurons are located, reduced HR by 34% (P<0.01) in Tx rats at 5-15 min post injection period. In control group, HR was not changed. Bilateral microinjection of TRH polyclonal antibody (24  $\mu$ g/100 nl/side) into the nucleus ambiguus which sends parasympathetic projections to the heart and contains TRH immunoreactive terminals, prevented the decrease in HR in Tx rats. These results suggest that hypothyroid state enhanced medullary TRH gene expression and TRH activity in the nucleus ambiguus which may account for the bradycardia and enhanced vago-vagal reflex.

NITRIC OXIDE MEDIATES COMPONENTS OF NMDA AND GP120 NEUROTOXICITIES IN PRIMARY STRIATAL CULTURES. V.L. Dawson\*, T.M. Dawson, G.R. Uhl, S.H. Snyder, Lab. Mol. Neurobiol., ARC/NIDA, & Depts.

Neuroscience and Neurology, Johns Hopkins School of Medicine, Box 5180, Baltimore, MD. 21224.

Nitric oxide (NO) mediation of NMDA toxicity in primary neuronal cultures from cerebral cortex and hippocampal slices is supported by studies utilizing NO synthesis inhibitors, NO releasers, and inactivators. We now document roles for NO in neuronal death induced in primary striatal neuronal cultures by NMDA and the HIV coat protein, GP120. In cultures assessed 24 hr following a 5 min exposure to either NMDA (300 μM) or GP120 (100 fM), 60% of neurons fail to exclude trypan blue; fewer than 5% of control cells stain. More than 60% of NMDA toxicity and 50% of toxicity due to GP120 is prevented when NO synthesis inhibitors or inactivators are coapplied to the cells; this blockade is reversible by excess substrate. More modest roles for non-NMDA receptors and voltage-dependent calcium channels in GP120 toxicity were supported by 30-40% reductions in toxicity by NBQX and nifedipine, respectively. These results document important roles for NO, as well as non-NMDA components, in mediating GP120 neurotoxicity. If such mechanisms apply in vivo, drugs blocking NO synthesis might slow progression of HIV encephalopathy.

CHRONIC GLUTAMATE TOXICITY IN MOTOR NEURONS FROM ORGANOTYPIC SPINAL CORD CULTURES. RW Kuncl\*, Lin Jin, and JD Rothstein. Johns Hopkins University, Dept Neurology, Baltimore, MD 21205.

The pathogenesis of motor neuron death in amyotrophic lateral sclerosis (ALS), is unknown. ALS has been characterized neurochemically by a derangement in the control of neurotransmitter glutamate metabolism: CSF levels of glutamate and aspartate are elevated and their high affinity transporter is defective in brain and spinal cord. Inefficient glutamate transport, and subsequent chronic increase in extracellular glutamate, could be responsible for motor neuron death. To test the hypothesis that chronic defects in glutamate uptake can produce motor neuron toxicity, we developed a tissue culture model employing organotypic rat spinal cord maintained with chronic inhibition of glutamate uptake. Slices (300 μm) of lumbar spinal cord from 8-14 day old rat pups were cultured on Millicell membranes. Using this method, organotypic cultures could be maintained with good morphology for greater than 60 days. Chronic inhibition of glutamate uptake was produced by culturing tissue in the presence of threohydroxyaspartate (THA) or pyrrolidine dicarboxylic acid (PDC), both specific inhibitors of glutamate transport. THA produced chronic elevation of glutamate in the medium and produced motor neuron toxicity after 25-30 days in culture using 100 µM THA, and after 18 days using 500 µM THA, as determined by assay of tissue choline acetyltransferase (ChAT) activity and by histological analysis of one micron plastic sections. PDC produced similar results. Motor neuron toxicity was completely blocked by the non-NMDA antagonists CNOX and NBQX (10-50 μM), but not by the NMDA antagonists MK-801 and CPP (10-50 μM). Tetrodotoxin blocked THA mediated toxicity, suggesting that presynaptic release was required for cell death. This model demonstrates that the chronic loss of glutamate transport in ALS can produce motor neuron degeneration and that, in organotypic cultures, motor neurons appear to be susceptible to non-NMDA mediated glutamate toxicity.

NMDA RECEPTOR-INDUCED MEMBRANE FLUIDITY CHANGES MAY MODULATE CALCIUM INFLUX IN CORTICAL NEURONS L.L. Dugan\*, V.M.G. Bruno, S.M. Amagasu, D.W. Choi, and R.G. Giffard Depts of Anesthesia and Endocrinology, Gerontology, and Metabolism, Stanford University School of Medicine, Stanford, CA 94305; Dept. of Neurology, Washington Univ., St. Louis, MO 63110

Arachidonic acid is released from cortical neurons following N-methyl-D-aspartate (NMDA) receptor stimulation, and has recently been shown to alter NMDA calcium currents (Miller et. al. 1992 Nature 355:722). Transient alteration of the lipid environment is a possible mechanism for We have documented significantly increased membrane this effect. fluidity following 10 minute exposure of cortical neuronal cultures to 500 µM NMDA. Fluorescence anisotropy (r) was decreased by 7% in the NMDA treated samples (n=6, p<0.05), indicating a more fluid, less restricted membrane environment for the receptor. In preliminary experiments, 45Ca accumulation was increased in cultures pretreated with arachidonic acid (200 µM) or with another polyunsaturated fatty acid, 22:6  $(200\mu M)$ , and this increase was not seen when  $50\mu M$  diacylglycerol (diolein) was included in the preincubation. The samples treated with arachidonic acid or 22:6 were more fluid than samples exposed to NMDA alone, an effect which was normalized by the co-incubation with diacylglycerol. These results indicate that NMDA receptor stimulation can alter the physical state of the membrane, and that NMDA-induced fluidity changes could be responsible for subsequent augmentation of calcium current after initial stimulation.

NITRIC OXIDE SYNTHASE: NMDA AND THE IMMUNO-SUPPRESSANT, FK-506, MODULATE PHOSPHORYLATION, FUNCTION AND NEUROTOXICITY T.M. Dawson.\* 1 J. P. Steiner. 1 V.L. Dawson. 2 G.R. Uhl 1.2 and S.H. Snyder 1 Depts. Neurosci. & Neurol., Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205 & 2Lab. Mol. Neurobiol., ARC/NIDA, Baltimore, MD 21224.

Potential modulation by NMDA of the phosphoprotein nitric oxide synthase (NOS) is of interest due to the central role of NO in NMDA mediated neurotoxicity. Phosphorylation can be modulated by NMDA receptor-mediated calcium fluxes through activation of the calcium-dependent phosphatase, calcineurin. Since phosphorylation can influence the function of many brain proteins, we have examined possible roles for NMDA induced calcium-modulated phosphorylation of NOS. In primary cerebral cortical cultures, NMDA stimulated formation of cGMP via activation of NOS is completely attenuated by 100 nM FK-506, a potent immunosuppressant that interacts with immunophilins to inhibit calcineurin. In contrast, FK-506 fails to inhibit cGMP elevations by NO releasers. Nearly all of the toxicity induced by a 5 min exposure to 500 µM NMDA, assessed 24 hr later by trypan blue exclusion, can be blocked by coapplication 100 nM FK-506. Attenuation of NMDA toxicity by FK-506 occurs in a dose dependent manner with protection occurring with concentrations of FK-506 as low as 100 pM. These results suggest a central role for NOS phosphorylation in mechanisms of NO-mediated NMDA toxicity. If such mechanisms apply in vivo, clinically-useful drugs like FK-506 which may inhibit NOS dephosphorylation could alter NO-mediated mechanisms implicated in excitotoxic and neurodegenerative disorders.

IMPAIRED MITOCHONDRIAL METABOLISM REFLECTS THE STRIATAL PATHOLOGY IN HUNTINGTON'S DISEASE. Robert J. Ferrante\*. Neil W. Kowall. Emmanuel Brouillet. and M. Flint Beal. Massachusetts General Hospital. Harvard Medical School, Boston, MA 02114

General Hospital, Harvard Medical School, Boston, MA 02114

A recent hypothesis in Huntington's disease (HD) suggests that abnormalities in the electron chain may secondarily lead to slow excitotoxic neuronal death by making neurons more vulnerable to endogenous glutamate. The striatal pathology of HD is characterized by relentless neuronal loss and astrogliosis, with selective involvement of spiny projection neurons. Dysmorphic proliferative changes are an early marker of neuronal dysfunction in HD. The systemic administration of the succinate ubiquinol oxidoreductase (Complex II) inhibitor, 3-nitropropionic acid, resulted in specific bilateral striatal lesions in rodents. Combined Nissl/NADPH-diaphorase stains demonstrated differential sparing of aspin neurons, while GFAP immunochemistry identified marked gliosis. The severity of the pathology was dose dependent. The lesion loci were primarily within the rostral dorso-lateral aspect of the striatum. Golgi staining of lesioned striata identified proliferative dysmorphic alterations in spiny striatal neurons. Antisera against neural cell adhesion molecule and microtubule-associated protein 18, markers of neurite outgrowth, were increased throughout the lesion site in both the neuropil and surviving neurons. These alterations resemble the pattern of neuronal degeneration observed in HD and strengthen the possibility that there may be a primary defect in mitochondrial energy metabolism in this disorder.

THE PUTATIVE ESSENTIAL NUTRIENT PQQ PROTECTS AGAINST NEURONAL DAMAGE IN AN IN VIVO STROKE MODEL. G. Gardner¹\*, P.M. Gallop¹, E. Aizenman², P.A. Rosenberg¹ and F.E. Jensen¹. ¹Children's Hospital and Harvard Medical School, Boston, MA 02115, and ²Dept. Physiology, University of Pittsburgh Medical School, Pittsburgh, PA 15261.

We have previously shown that the soluble redox cofactor pyrroloquinoline quinone (PQQ) blocks NMDA receptor mediated cell damage in cortical cultures. This protection in vitro appears to be caused by direct oxidation of the redox modulatory site on the NMDA receptor. In the present study, we investigated the effects of PQQ pretreatment on neuronal damage in an in vivo model of stroke employing a combination of bilateral carotid ligation and hypoxia in immature rats aged postnatal day (P) 7-9. Three to 4 hours after bilateral carotid ligation, rats were treated with either PQQ (10mg/kg i.p.) (n=19) or vehicle (n=14) 30 min before exposure to hypoxia (10% O<sub>2</sub> for 30 min or 8% O<sub>2</sub> for 25 min). After 48 hours of recovery, the animals were sacrificed and transcardially perfused with 4% paraformaldehyde in PBS. The brains were serially sectioned and stained with cresyl violet. A blinded light microscopic analysis was performed for each of the 2 hypoxic conditions (10%O2 - moderate, and 8%O2 - severe) to compare PQQ-treated animals with vehicle-treated littermate controls. In 17/19 matched pairs, the infarct size in the PQQ-treated animal was significantly smaller than the control, and in 2/19 pairs the infarct was judged as the same for the PQQ- and vehicle-treated animals. These data show a significant effect of PQQ treatment in reducing stroke size compared to vehicle-treated controls (p < 0.001). In addition, the PQQ-treated animals did not show any behavioral side effects at the dose used in this study.

THIAZIDE DIURETICS REVERSIBLY BLOCK POSTSYNAPTIC GLUTAMATE RECEPTOR DESENSITIZATION IN RAT HIPPOCAMPAL NEURONS. K.A. Yamada\*. Deptartments of Pediatrics and Neurology, Washington University School of Medicine, St. Louis, MO 63110

Recently we reported that diazoxide (DZ), a benzthiadiazide drug, reversibly blocked rapid, postsynaptic glutamate (GLU) desensitization in rat hippocampal neurons and thereby enhanced non-NMDA mediated glutamatergic synaptic responses (Yamada and Rothman, J. Physiol., in press). Thiazide diuretics are also benzthiadiazide drugs. These experiments were performed to determine if drugs chemically similar to DZ also block GLU desensitization, using voltage-clamp recording from cultured rat hippocampal neurons and rapid, whole-cell application of quisqualate (QA). QA currents were increased by cyclothiazide (CYZ), by droflumethazide, trichlormethiazide, hydrochlorothiazide, bendroflumethazide, trichlormethiazide, did not increase QA currents, nor did and DZ. Benzthiazide and chlorothiazide did not increase QA currents, nor did chemically similar non-thiazide drugs quinethazone, chlorthalidone, metolazone, or sulfadiazine. CYZ was the most potent, virtually eliminating desensitization at micromolar concentrations. The steady-state QA current was increased 10-15 fold and the peak QA current 3 fold by  $10\text{-}100\mu\text{M}$  CYZ, with EC<sub>50</sub>s of  $0.3\mu\text{M}$  and  $2\mu\text{M}$ respectively. In addition, 10µM CYZ potentiated spontaneous miniature excitatory postsynaptic currents (mEPSCs). In conclusion, certain benzthiadiazide drugs ("neuroactive thiazides") potently block GLU desensitization. CYZ's effects upon mEPSCs is similar to that observed for DZ on evoked EPSCs, and indicates that these drugs also affect responses produced by synapticly released GLU at synaptic GLU receptors. The activity of several chemically related drugs, and the apparent high affinity, concentration-dependent effect of CYZ suggests that these drugs may act at a novel modulatory site that regulates desensitization of non-NMDA receptors and modulates glutamatergic synapses. (Supported by NIH grant NS01443)

# 321.9

NEUROTOXICOLOGICAL EVIDENCE FOR A NOVEL BENZODIAZEPINE SITE WITHIN THE NON-NMDA GLUTAMATE RECEPTOR COMPLEX JW Olney\*, MT Price, CF Zorumski, K Yamada, Washington University, St. Louis, MO 63110 Non-NMDA glutamate receptors typically are responsive to either quisqualate (Quis) or kainic acid (KA), but when these agonists are continuously applied, the response to Quis is rapidly desensitizing and to KA is non-desensitizing. Recently a diuretic drug, cyclothiazide, was shown to convert the Quis response to a KA-like non-desensitizing response (Yamada, NS Abst, 1992). Tarnawa et al have described a benzodiazepine, GYKI 52466 (GY), with muscle relaxant properties and apparent antagonist activity at the non-NMDA receptor. In the present experiments, the neurotoxic responses to Quis and KA in the isolated chick embryo retina were blocked by GY at concentrations of 25 μM and 75 μM respectively, whereas the neurotoxic action of NMDA was not blocked by Gy at concentrations up to 250 μM. The neuroprotective action of GY was non-competitive and could not be overcome by 10-fold increases in the concentration of Quis or KA. Against simulated ischemia (oxygen/glucose deprivation), neither the NMDA antagonist MK-801 (1 μM) nor GY (50 - 200 μM) provided more than equivocal protection, but when the two agents were combined (MK-801 at 1 μM + GY at 50-200 μM), they provided complete protection. The antagonist action of GY against Quis neurotoxicity was counteracted by cyclothiazide, and the mechanism of this interaction was competitive in that the action of cyclothiazide was easily overridden by increasing the concentration of GY. These findings, together with those in a companion study (Zorumski et al., NS Abst, 1992), suggest that the non-NMDA receptor ion channel complex may contain a previously unsuspected benzodiazepine recognition site where GY acts to facilitate the desensitizing properties of this receptor and cyclothiazide, a structurally similar molecule, exerts an opposing action. This putative recognition is treat neu

MEMANTINE, A CLINICALLY-TOLERATED NMDA OPEN-CHANNEL BLOCKER, PREVENTS HIV COAT PROTEIN-INDUCED NEURONAL INJURY IN VITRO AND IN VIVO. Stuart A. Lipton\* and Frances E. Jensen. Depts. of Neurology, Children's Hospital, Beth Israel Hospital, Brigham & Women's Hospital, Massachusetts General Hospital, and Program in Neuroscience Meneral Medical School Reston Med 02115 Neuroscience, Harvard Medical School, Boston, MA 02115

Studies on mixed neuronal-glial cultures from rodent brain and retina suggest that at least part of the neurological manifestations of AIDS may stem from neuronal injury mediated indirectly by the HIV-1 coat protein gp120 (reviewed in *Trends in Neurosci.* 1992;15:75-79). Concurrent activation of NMDA receptors is necessary for gp120 to induce neuronal damage, and NMDA antagonists or  $Ca^{2+}$  channel antagonists can ameliorate this injury *in vitro*. In the present study, stereotactic injection of gp120 (5-10 pmoles, n=5), but not control glycoprotein, into rat pup cortex produced a focal lesion by 2-10 d consisting of foamy macrophages and neuronal damage. Memantine, a drug that blocks NMDA receptor-operated ion channels, was studied for possible protective effects both *in vitro* and *in vivo*. Memantine, a more potent congener of the anti-viral drug amantadine, has been employed clinically as an anti-Parkinsonian agent in Europe for over ten years with the rapeutic levels of 2-12  $\mu$ M. In rat retinal cultures, 2  $\mu$ M memantine prevented gp120 (20 pM)-induced injury of identified ganglion cells. In prevented gp120 (20 ptv)-induced injury of identified garginon cents. In the *in vivo* gp120 rat model, either nimodipine (400  $\mu$ g/kg, ip, n=3) or memantine (20  $\mu$ g/kg, ip, n=2) was protective. Taken together, these data suggest that memantine, like nimodipine, has therapeutic potential as a channel antagonist capable of ameliorating neuronal injury associated with exposure to gp120.

DESENSITIZATION CHANGES THE PHARMACOLOGY OF GLUTAMATE NEUROTOXICITY. A.M. Moudy, K.A. Yamada and S.M. Rothman\* Departments of Neurology and Anatomy and Neurobiology, Washington University Medical School, St. Louis, MO 63110

In a variety of experimental paradigms, glutamate (Glu) neurotoxicity is largely mediated by activation of NMDA receptors. Even prolonged exposure of cultured hippocampal neurons to Glu is tolerated if NMDA antagonists are present. We have recently shown that some hiszides can dramatically diminish rapid Glu desensitization in voltage-clamp experiments. We now demonstrate that in the presence of these compounds, Glu toxicity is antagonized by an AMPA/kainate antagonist, CNQX.

When cultured hippocampal neurons were exposed to 500 μM Glu for either .5 or 18 hours, over 90% of the cells died. Addition of 10 μM MK-801, an NMDA antagonist increased survival to about 70%. Addition of either 500 μM diazoxide or 10 μM cyclothiazide diminished survival to less than 20%. Addition of 20-50 μM CNQX increased survival back to at least 70%. Neither thiazide was toxic in the absence of Glu. Thiazides which failed to potentiate Glu currents in voltage-clamp experiments had no effect on Glu toxicity. The organic calcium channel antagonists nifedipine and nimodipine did not duplicate the CNQX effect.

In voltage-clamp experiments, CNQX reduced cyclothiazide-enhanced Glu currents, but did not reduce steady-state Glu currents below control values. We also used the calcium-sensitive dye fura-2 to measure the effect of cyclothiazide did not elevate Ca, above the peak level produced by Glu + MK-801 when added during exposure to the latter substances. Neurons exposed to Glu while incubating in cyclothiazide + MK-801 did not have higher Ca, than cells exposed to Glu in MK-801 alone.

These experiments indicate that desensitization dramatically reduces the toxicity of Glu and that there are circumstances when Glu toxicity can be blocked by AMPA/kainate antagonists. These results offer a potential explanation for r

ELECTROPHYSIOLOGICAL EVIDENCE FOR A BENZODIAZEPINE SITE WITHIN THE NON-NMDA GLUTAMATE RECEPTOR COMPLEX C.F. Zorumski\*, K. Yamada, S. Mennerick, & J.W. Olney, Depts. of Psychiatry and Pediatrics, Washington Univ. Medical School, St. Louis MO 63110

The non-NMDA class of glutamate receptors desensitize rapidly when activated by quisqualate (Quis) or AMPA but not when activated by kainate Certain lectins, aniracetam and thiazide derivatives inhibit this desensitization, but agents augmenting desensitization have not been described. GYKI 52466 (GY) is a novel benzodiazepine (BDZ) which is reported to be an antagonist at non-NMDA receptors. We have investigated the actions of GY on amino acid-gated currents in cultured postnatal rat hippocampal neurons using whole-cell voltage clamp recordings.

At concentrations > 1μM, GY non-competitively inhibits currents gated by KA and Quis with an EC<sub>so</sub> against KA of 14μM. The EC<sub>so</sub> for the competitive non-NMDA antagonist, CNQX, is 2µM. When coapplied with KA, GY depresses steady-state currents to a greater extent than peak responses, imparting a desensitizing appearance to the normally nondesensitizing KA current. GY also depresses KA/AMPA responses when applied before the agonist. The effects of GY are weakly voltage-dependent with no effect on the KA equilibrium potential. GY does not alter currents gated by NMDA or GABA. The effects of GY can be overcome by cyclothiazide (CYZ), an agent which inhibits non-NMDA receptor desensitization. GY and CYZ appear to interact competitively suggesting a shared site of action. These observations suggest that desensitization of non-NMDA receptors can be modulated by drugs acting at a novel BDZ site.

MPP+ INDUCES NEURONAL DEGENERATION IN THE SUBSTANTIA NIGRA PARS COMPACTA BY AN EXCITOTOXIC MECHANISM

Rachana Srivastava, Emmanuel Brouillet, Elsdon Storey\*, Flint Beal and Bradley T. Hyman. Neurology General Hospital, Boston, MA 02114. Service, Mass.

The neurotoxic effect of MPTP on dopaminergic neurons is mediated by l-methyl-4-phenylpyridinium (MPP') which is accumulated by the dopamine uptake system. The mechanism by which MPP+ results in neuronal death may be due to its ability to bind to complex I, which inhibits mitochondrial energy metabolism, and may lead to secondary excitotoxic neuronal death. In the present study we examined neuronal cell death in the substantia nigra (SNc) following intrastriatal injection of 90 nmol of MPP\*. Histologic evaluation of the SNc at 1 week showed ipsilateral Histologic evaluation of the SNc at I week showed ipsilateral gliosis. Quantitative cell counts showed a 75% loss of SNc neurons, a 67% decrease in SNc volume, and a 26% decrease in neuronal density. Prior decortication significantly (p<.01) protected against these changes, and there was no significant decrease in either neuronal number or density (n=3). Administration of MK-801 for 48 hours by Alzet pump at a dose of 1.2 mg/kg/h also significantly protected against MPP+ induced neuronal loss in the SNc (p<0.05) (n=3). results show that MPP+ induces neuronal degeneration in the SNc by an NMDA receptor mediated excitotoxic process. Supported by the Parkinson's Foundation.

DIAZEPAM WITHDRAWAL MODULATED BY GLUTAMATE ANTAGONISTS.

K.G. Steppuhn, H.H. Schneider, D.N. Stephens and L. Turski\*, Res. Labs of Schering AG, 1000 Berlin 65. Germany.

Schering AG, 1000 Berlin 65, Germany.

Long term treatment leads to tolerance to and dependence on benzodiazepines. Adult NMRI mice, 25-30 g in weight, withdrawn from chronic treatment with diazepam (15 mg/kg/day for 12 days) showed a time related evolution of anxiety, muscle rigidity and seizures between days 4 and 21 after discontinuation of diazepam intake. A period between withdrawal days 1 and 3 was symptom-free. During this "silent phase" the susceptibility of mice to quisqualate and kainate seizures, and the magnitude of monosynaptic reflexes mediated by non-N-methyl-D-aspartate (NMDA) mechanisms, were enhanced. In apparent contrast, the "active phase" of withdrawal, between days 4 and 21, was characterized by an increased susceptibility of mice to NMDA seizures and enhanced magnitude of NMDA dependent polysynaptic reflexes. Treatment of mice with the NMDA antagonist CPP (3-((+)-2-carboxypiperazine-4yl)-propyl-1-phosphonate; 1 mg/kg/day) during chronic administration of diazepam prevented the evolution of tolerance and dependence. The AMPA antagonist NBOX (2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo(F)quinoxaline; 10 mg/kg/h), but not the NMDA antagonist CPP (10 mg/kg/h) prevented or markedly reduced the evolution of withdrawal symptoms when administered by means of osmotic mini-pumps during the withdrawal days 1 to 3 "silent phase"). In mice subjected to NBQX treatment during the first three withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal days, no muscle rigidity or seizures, and little anxiety were observed up to withdrawal

TRIAZOLAM IS A MAXIMALLY EFFICACIOUS ALLOSTERIC MODULATOR IN A BROAD SPECTRUM OF STRUCTURALLY DIFFERENT RECOMBINANT GABAA RECEPTORS. L. Ducic. G. Puia, G. Mereu\*, S. Vicini and E. Costa. FGIN, Georgetown University, Washington DC.

Tolerance, sedation, ethanol potentiation and ataxia are unwanted side effects of diazepam and other benzodiazepines (BZD), used in the treatment of anxiety disorders. With triazolam (Halcion) a sleep inducing triazolobenzodiazepine also psychotic symptoms, fast tolerance, amnesia, syncope and paranoid behavior have been reported (Oswald, I., 1991 Lancet, 338:516). In order to elucidate the reason for these severe side effects of triazolam, we compared the facilitatory efficacy of triazolam, diazepam, and other benzodiazepines of GABA induced Cl<sup>-</sup> currents on native and recombinant GABAA receptors. Using the patch clamp technique we employed whole-cell recordings of GABA-activated Cl- currents in human kidney tumoral cells transiently transfected with cDNAs encoding for various molecular forms of  $\alpha$ ,  $\beta$  and  $\gamma$  subunits of the GABAA receptors. Triazolam (10  $\mu$ M) applied to various recombinant GABAA receptors showed a greater efficacy (T-test p<0.05) on receptors including α1β1γ1, α1β1γ2 and α1β1γ3 subunits, whereas diaz (10 μM) was more efficacious only on GABAA receptors assembled with α3β1γ2. We also found that the same concentration of triazolam (10 µM) is the most efficacious (142 ± 8 %, mean ± SD, n=14 cells) in α1β1γ1 subunit containing receptors when compared with similar concentrations of clonazepam (69  $\pm$  10 % n=6), zolpidem  $(58 \pm 20 \%, n=8)$ , alpidem  $(49 \pm 10 \%, n=10)$  and bretazenil  $(50 \pm 12 \%, n=10)$ . It seems possible to infer that the triazolam greater efficacy and broad spectrum of action on various molecular forms of GABAA receptors expressed in vivo (Wisden et al., 1992 J. Neurosci., 12:1043) may account for the peculiarities and severity of its side effects.

ADRENALECTOMY POTENTIATES BEHAVIORAL DEPENDENCE TO ALCOHOL AND INDUCED CORTICAL HYPERVASCULARIZATION IN MALE RATS. Ph. DE WITTE\* and F. LAMBLIN. Lab. Psychobiology Univ. of Louvain, Louvain-la-Neuve, Belgium.

Adrenalectomized and sham-operated rats were exposed to

Adrenalectomized and sham-operated rats were exposed to chronic alcoholization using an inhalation procedure. After sejourning 4 weeks into the alcoholization chamber, rats were placed in an apparatus for motility detection and then submitted to a free-choice paradigm (water vs a 10% (v/v) ethanol solution). Another group of experimental rats were perfused with a nuclear emulsion allowing to reveal the cortical vascularization. No differences were observed between adrenalectomized and sham-operated animals in the motility recording for 20 hr after withdrawal of alcohol inhalation. The sham-operated rats presented an alcohol induced behavioral preference towards alcohol lasting 10 days following chronic alcoholization by inhalation while the adrenalectomized rats preferred the alcoholized beverage (mean of 25 ml/day 10% alcohol vs 10 ml/day water) until we sacrificed the rats, i.e. 75 days after withdrawal of inhalated alcohol. As regards the microvascularization of the frontal cortex, alcoholized adrenalectomized rats displayed significant enhanced cortical microvascular network when compared to alcoholized sham-rats. These data show thus that intact adrenals protect animals to behavioral dependence towards alcohol while alcohol impairs the adrenal response.

DEVELOPMENT OF TOLERANCE AND WITHDRAWAL TO THE ACTION OF FULL AND PARTIAL ALLOSTERIC MODULATORS OF GABA, RECEPTORS.

J. Auta, H. Alho¹ and A. Guidotti\*. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Med. School, Washington, DC 20007 and ¹ Dept. of Biomed. Sci., Univ. of Tampere, 33101 Tampere, Finland.

Rats receiving protracted daily doses of full (diazepam and alprazolam) and partial (clonazepam and bretazenii) allosteric modulators of GABA<sub>A</sub> receptors were tested for tolerance and withdrawal response. The brain content of DBI, the putative ligand of mitochondrial DBI receptors (MDR) was also studied. Benzodiazepines (BZs) were administered by oral gavage three times daily in anticonvulsant doses equipotent to 33 µmol/kg of diazepam. Doses of drugs were progressively increased by 50% every 4 days. After 21 days of treatment, rats allowed an 18 hrs drug free period, were challenged with single, anticonvulsant oral doses of the respective drugs and tolerance tested by seizures elicited with bicuculline infusion. Protracted treatment with diazepam and alprazolam but not clonazepam or bretazenii showed tolerance to the anticonvulsant effect of these drugs. For withdrawal response, rats were left free of drugs for 24 hrs after protracted treatment and then challenged with flumazenil (16.5 µmol/kg, i.v.) before behavioral tests with the Vogel paradigm. Protracted treatment with diazepam but not bretazenii showed a withdrawal effect characterized by an increased sensitivity to the behavioral inhibition of electric shock. Immunohistochemical estimation of DBI-LI content with DBI-antiserum in the cerebellum of rats receiving protracted diazepam and alprazolam, but not bretazenil or clonazepam, revealed a significant (2-3 fold) increase DBI-LI in the Bergmann glial which is not correlated with an increase GFAP-LI.

It can be inferred that tolerance and withdrawal effects that occurs with full but not partial allosteric modulators of GABA $_{\Lambda}$  receptors may be associated with an elevated glial content of DBI. This increase may mediate glial MDRs stimulation and thereby elicit neurosteroid biosynthesis; which may account for the GABA $_{\Lambda}$  receptor desensitization that occurs after protracted treatment with diazepam and alprazolam.

STRUCTURAL CHANGES OF THALAMO-CORTICAL CIRCUITS IN A RAT FOETAL ALCOHOL SYNDROME D. Minclacchi(\*), A. Granato(#), M. Santarelli and A. Sbriccoll Lab of Exp. Neurol., Inst. of Anatomy(#), Catholic University, 00168 Rome, Italy.

Prenatal exposure to ethanol is able to affect the normal development of the cortex in rats. Here we analyze the organization of thalamo-cortical circuits in adult animals exposed to ethanol during prenatal development.

Pregnant rats were given intragastric administrations of ethanol during the third week of gestation. Offsprings underwent either cortical (frontal areas Fr2 and CG1-CG3) or thalamic injections of WGA-HRP.

Results obtained from animals prenatally exposed to ethanol were compared with those from control cases, a) in the frontal cortex of animals prenatally exposed to ethanol a strong reduction of anterograde labeling was present as consequence of contraction of the thalamic-recipient layers, b) Densitometric analysis of the thalamus revealed a considerable reduction of the non-cellular labeling in offsprings of alcohol-dependent rats. c) The overall pattern of retrograde labeling was similar in both offsprings of alcohol-dependent rats and control cases.

We observed major structural changes of the normal organization of thalamo-frontal circuits in animals prenatally exposed to ethanol. The damage seems to involve specifically the terminal arborizations of both thalamo-cortical and cortico-thalamic fibers, sparing apparently their parent cell bodies.

These modifications could represent structural bases for some of the behavioural impairments observed in the human foetal alcohol syndrome.

GENETIC DIFFERENCES IN THE EFFECTS OF ETHANOL: THEIR RELA-TION TO INHIBITORY AND EXCITATORY BRAIN NEUROTRANSMITTERS S. Liljequist, Dept of Drug Dependence Research, Karolinska Institute, PO Box 60500, S-10401 Stockholm, Sweden. Behavioral effects of ethanol were examined in CBA, C57,

Behavioral effects of ethanol were examined in CBA, C57, and BALB mice. In BALB animals, increasing doses of ethanol had a biphasic action on locomotor activity (stimulation followed by inhibition) whereas only inhibition was seen in C57 and CBA mice. Ethanol produced a similar dose-dependent and preferential increase in the DOPAC/DA (dopamine) ratio in the limbic forebrain as compared to striatum in all animals suggesting no direct relationship between ethanol-produced enhancement of DA release and ethanol-induced locomotor stimulation. C57, and especially CBA mice were more sensitive to the sedative actions (sleep time) of ethanol than BALB mice. CBA mice were more sensitive to the CBA make were more sensitive to the convulsant effects of the GABA antagonist picrotoxin whereas no such differences were noted after administration of the specific GABA receptor antagonist bicuculline. In receptor binding studies the modulation of 3H-flunitrazepam binding by GABA and pentobarbital was similar in the forebrain of CBA and C57 mice. Further behavioral studies revealed that CBA mice differed in their response to non-competitive and competitive NMDA receptor antagonists as compared to C57 and BALB mice. In summary, these data suggest that genotypic differences are present in the GABA and glutamate receptor systems and that a complex interplay between various inhibitory and excitatory neurotransmitter systems may determine the pharmacologic profile of ethanol.

ETHANOL CAUSES INHIBITION OF GRANULE CELLS AND THE DEVELOPMENT OF ACUTE TOLERANCE IN CEREBELLAR SLICES. C.Huang\*, C.-F.Hsiao and R.Huang. Univ. Missouri-Kansas City, Kansas City, MO 64110.

Ethanol (0.3-1.2g/kg, IV) caused severe inhibition of cerebellar granule cells in the cat. To determine whether this inhibition was due to the primary effects of ethanol on afferent structures or from direct ethanol actions on the cerebellar cortex, we have investigated the consequences of ethanol on cerebellar granule cells in brain slices. Cerebella from 35-day old rats were cut into sagittal sections. Single granule cells and granule cell clusters were recorded with tungsten or glass microelectrodes. Ethanol concentrations were varied from 5-50mM. Ethanol at 10mM was the lowest concentration which inhibited the spontaneous discharges of granule cells. Ethanol from 20-50mM produced a near-complete inhibition on some granule cells but had little or no effect on other granule cells or Purkinje cells. Inhibition or recovery took place in 2min or as soon as the control solution in the recording chamber was replaced by the ethanol solution or vice versa. In some granule cells, acute tolerance developed within 30-45min so that there was a significant recovery of spontaneous activity even when ethanol was present. We concluded that ethanol had a direct effect on the cerebellar cortex and that rapid development of tolerance occurred. (supported by PHS AA07643)

OPIATE SUPPRESSION OF THE PROESTRUS LUTEINIZING HORMONE SURGE IN RATS PRENATALLY EXPOSED TO ETHANOL. <u>L.R. Nelson\*</u>, <u>R. Poland. S Tritt. A.N. Taylor</u>. Depts. of OB/GYN, Anatomy & Cell Biology, and Psychiatry, UCLA and West LA VAMC, Los Angeles, CA 90024. Work in our laboratory has shown that adult, female, Sprague-Dawley rats, prenatally exposed to ethanol, have altered endocrinological and behavioral responses to opiate administration and to stress. For example, when these rats are either exceeding the intermittent footbook or receive morphise, they have greater equations.

Work in our laboratory has shown that adult, female, Sprague-Dawley rats, prenatally exposed to ethanot, have altered endocrinological and behavioral responses to opiate administration and to stress. For example, when these rats are either stressed with intermittent footshock or receive morphine, they have greater elevations in plasma corticosterone and ACTH than do control rats. Since the pituitary release of luteinizing hormone (LH) is known to be depressed by both stress and opiates, we assessed the effect of opiates on the proestrus LH surge in these rats. Timed-pregnant Sprague-Dawley dams were randomly assigned to three groups: Control (N), fetal ethanol-exposed (FAE), or pair-fed (PF). The ethanol dams were fed a liquid diet containing 5% w/v ethanol from gestational day 8 to delivery. With this regimen ethanol consumption averages 11-13g/kg/day and results in maternal blood alcohol levels of between 80 - 120 mg/dl. The pair-fed dams were given an isocaloric liquid diet without ethanol. Female pups were reared in group cages with the following light cycle: on-5500h; off-1900h. Testing was begun at approximately 120 days of age. Vaginal smears were checked in the morning across several cycles to determine the day of proestrus. On the morning of proestrus, rats were smeared and weighed. At 1400h morphine sulfate 10 mg/kg (MS) or saline was administred intraperitoneally (IP). At 1800h, blood was rapidly obtained by cardiac puncture under light halothane anesthesia. Compared to the N and PF groups, FAE rats had significantly lower LH levels following MS, and FAE rats had the largest decrement (72.5%) compared to N (40%) and PF (50%). Thus, in this paradigm, FAE rats again demonstrate a potentiated response to MS. In addition, we suggest that the IP saline injection is a significant stressor and as such, depresses the LH levels in FAE rats.

THE EFFECTS OF TWO ETHANOL DOSES ON EEG ACTIVITY IN MALES AT RISK FOR ALCOHOLISM. <u>H.L. Cohen, B. Porjess, and H. Begleiter</u>, Neurodynamics Lab., SUNY HIS EL. Cir., Blyin, Brooklyn, N.Y. 1120.

The present investigation examined the effects of placebo ( P ), low dose ( LD ) and high dose (HD) ethanol on EEG activity in adult males at high risk for the development of alcoholism (HR, N = 21,  $\overline{X}$  = 22.8 yrs ) and in matched, low risk ( LR, N = 21,  $\overline{X}$  = 22.8 yrs ) and in matched, low risk ( LR, N = 21,  $\overline{X}$  = 22.7 yrs ) controls. Only one condition ( P, LD, or HD ) was presented each day and condition order was randomized. For each subject, both blood alcohol level(s) (BAL) measured via breathalyzer, and EEG activity, using the entire 10/20 International System, were recorded prior to and at intervals of ca. 35, 70, 105 and 140 minutes after P, LD or HD administration. The Fast Fourier Transform (FFT) was used to calculate power spectral densities ( PSD ). Measures of relative area under the power spectral curve were obtained for each of the following frequency bands: slow alpha ( SA, 7.5 - 10 Hz ), fast alpha ( FA, 10.5 - 13.0 Hz ), slow beta ( SB, 13.5 - 19.5 Hz ) and fast beta ( FB, 20 - 26 Hz ) at electrodes: F3, F4, C3, C4, P3, P4, O1 and O2. The results of repeated measures MANOVA conducted on the normalized relative area values revealed significant changes in SA activity at each electrode examined. Risk Group differences in SA activity were obtained at F3, F4 and P4, and were due to the differential effects of ethanol rather than to baseline differences in SA activity, Risk Group differences were also observed in the relationship between SA activity and the phases of the blood alcohol curve. HR had significantly greater increases during the ascending phase ( acute sensitization ) and significantly greater increases during the descending phase ( acute tolerance).

CORRELATION BETWEEN IMMEDIATE EARLY GENE INDUCTION AND THE PERSISTENCE OF LTP. W.C. Abraham<sup>2</sup>. J. Demmer<sup>2</sup>, S.E. Mason<sup>1</sup>, P. Lawlor<sup>3</sup>, J. Williams<sup>2</sup>, M. Dragunow<sup>3</sup>, and W.P. Tate<sup>2</sup>. Depts of Psychology<sup>1</sup> and Biochemistry<sup>2</sup>, Univ. of Otago, Dunedin and Dept. of Pharmacology<sup>3</sup>, Univ. Auckland Medical School, Auckland, New Zealand.

Levels of immediate early gene (IEG) induction were correlated with the persistence of LTP across a number of tetanization protocols. Groups of awake rats, which had been chronically implanted with stimulating and recording electrodes in the perforant path and dentate hilus, respectively, were separately tested for LTP persistence (over days or weeks), IEG mRNA levels (20 min post-tetanization) using Northern blots, and IEG protein levels (2 h post-tetanization) using immunohistochemistry. Varying the number of stimulus trains (400 Hz) from 10-50 (on one day) resulted in a gradual increase in the persistence of LTP. The frequency distribution of decay time constants was bimodal, however, with maxima at 5.8 d (LTP2) and 30.7 d (LTP3). LTP was not as long lasting when 10 trains were delivered on consecutive days, compared to the same number of total trains given on one day. The IEGs zif/268, c-jun, jun-B, jun-D and Fos-related proteins all showed gradual increases in mRNA and protein levels as the number of trains given on one day was increased. Zif/268 was the major responding gene after 10 trains, however, and was the only IEG showing repeated responses on consecutive days of stimulation. These results suggest that the pattern and degree of IEG expression influences the stabilization and subsequent maintenance of LTP over days or weeks.

EVIDENCE FOR THE TRANSLOCATION OF PKC ISOZYMES BY PHORBOL ESTERS AND DURING THE INDUCTION PHASE OF LTP. Xiaolan Jiang\*, Paul Osten and Todd C. Sacktor (SUNY-Brooklyn, NY, 11203)

Protein kinase C has been implicated in both induction and

Protein kinase C has been implicated in both induction and maintenance of LTP because many of the agents that inhibit PKC block LTP and because activators of the enzyme, such as phorbol esters, mimic the potentiation. To investigate the roles of PKC and the individual isozymes of the kinase in synaptic regulation, all known isozymes were assayed simultaneously by Western blot in rat hippocampal slices following conditions that enhance synaptic strength. Phorbol esters, at a dose (5 µM) that causes synaptic enhancement, translocated to membrane all isozymes of PKC in concert, a shift in subcellular distribution associated with the enzyme's activation. A brief high-frequency tetanus to Schaffer collaterals, which in parallel experiments induced LTP in 85% of healthy slices, was also tested. One min after tetanus, a translocation of several isozymes similar to that seen with phorbol esters was observed in CA1. Multiple isozymes of PKC, therefore, may be important in the short-term regulation of synaptic strength induced by synaptic activity. In the accompanying abstract evidence is presented for a role for a single isozyme in LTP maintenance.

EVIDENCE FOR A CONSTITUTIVELY ACTIVE FORM OF THE ζ ISOZYME OF PKC IN LTP MAINTENANCE. <u>Paul</u> Osten\* and Todd C. Sacktor (SUNY-Brooklyn, NY, 11203)

Osten\* and Todd C. Sacktor (SUNY-Brooklyn, NY, 11203)

Protein kinasse appear to play roles in both induction and maintenance of LTP in the hippocampus, but the relationship and transition between these two phases is not understood. Protein kinase C (PKC) may be activated or modified following an initial translocation to membrane, resulting in a persistent phosphorylation that could contribute to maintenance. These modifications could include permanent insertion into membrane or proteolytic cleavage of the enzyme's regulatory domain, resulting in a constitutively active form of the enzyme. The analysis of PKC, however, is complicated by the heterogeneity of PKC isozymes, each of which may have a distinct role in neuronal function. We used carboxy-terminal antibodies to examine simultaneously by Western blot the known PKC gene family in CA1 of the rat hippocampus following tetanic stimulation of Schaffer collaterals that produced LTP. While most of the isozymes were downregulated 30 min following tetanization, the  $\zeta$  isozyme appeared to undergo limited proteolysis to a fragment that by molecular weight would be a constitutively active kinase, not regulated by transitory second messengers. This change may contribute to a mechanism for the maintenance of LTP.

# 323.5

LTP-ASSOCIATED PERSISTENT PKC ACTIVATION DETECTED USING A SELECTIVE PEPTIDE SUBSTRATE DERIVED FROM THE SEQUENCE OF NEUROGRANIN AND NEUROMODULIN S.J.Chen\*, E.Klann, and J.D.Sweatt.

NEUROGRANIN AND NEUROMODULIN S.-J.Chen\*. E.Klann, and J.D.Sweat. Division of Neuroscience, Baylor College of Medicine, Houston, Texas 77030.

We have previously observed that the maintenance phase of long-term potentiation (LTP) is associated with an NMDA-receptor dependent persistent kinase activation. Indirect evidence using an inhibitor peptide of PKC suggested the kinase persistently activated in LTP was protein kinase C (PKC). As an additional test for the presence of persistently activated PKC, we developed a selective PKC substrate peptide, neurograini(28.43) (NG(28.43)), and determined the phosphorylation of NG(28.43) in homogenates from control and LTP slices. The synthetic peptide has a sequence (AAKIQASFRGHMARKK) corresponding to the PKC phosphorylation site of native neurograinin (also known as RC3) and has a high degree of sequence homology to neuromodulin (GAP43/F1/B50). NG(28.43) was phosphorylated by purified PKC and PKM with a K<sub>m</sub> of about 150 nM and the phosphorylation was sensitive to inhibitor by the selective PKC inhibitor peptide PKC(19.36). No significant phosphorylation of NG(28.43) by cAMP-dependent protein kinase or CaM kinase II could be detected. Substituting the Phe35 residue with Ala resulted in a dramatic decrease in affinity (K<sub>m</sub> 150 μM), indicating a crucial role of the sequence "SFR" in the binding of substrate to PKC. Substituting the Ser<sup>34</sup> residue with Ala generated a PKC inhibitor peptide with Ki of 25 μM. NG(28.43) was phosphorylated in hippocampal homogenates in the presence of EGTA and addition of calcium and lipid cofactors greatly stimulated the phosphorylation of NG(28.43) we observed an LTP-associated increase (207±51% of control, n=9) in the phosphorylation of NG(28.43) in homogenates of area CA1 of hippocampus. The increased activity was expressed in the presence of EGTA, indicating an increase in calcium-independent PKC activity. The increased NG(28.43) phosphorylation was blocked by the addition of PKC is persistently activated in the maintenance phase of LTP

PKC(19-13) AND CAMKII(273-302) GIVEN TOGETHER INTRACELLULARLY TO THE POSTSYNAPTIC NEURON SYNERGISTICALLY BLOCK LTP IN HIPPOCAMAPAL CA1 REGION. T.P.Feng\*and J.H.Wanq. Shanghai Institute of Physiology, Chinese Academy of Sciences, Shanghai 200031, China

Shanghai 200031, China
Inhibition of postsynaptic protein kinase C (PKC) before or after the tetanus has been shown to block the induction or to arrest the maintenance of LTP in rat hippocampal CA1 region respectively (Wang and Feng, PNAS in press). We now report, first, that the specific inhibitor of Ca<sup>2+</sup>/calmodulin dependent kinase II (CaMKII), CaMKII(273-302), given intracellularly to the postsynaptic neuron before or after the tetanus can likewise block the induction or arrest the maintenance of LTP respectively, and, second, that the specific inhibitor of PKC, PKC(19-31), and CaMKII(273-302) given together strikingly reinforce each other in the production of the inhibitory effects on LTP. This provides direct evidence that both the induction and the maintenance of LTP in the hippocampal CA1 region involve the joint activity of PKC and CaMKII in the postsynaptic neuron. [We thank Drs. Richard Tsien and Howard Schulman for the supply of CaMKII(273-302)]

PERSISTENT PKC ACTIVATION IN THE MAINTENANCE PHASE OF NMDA RECEPTOR-INDEPENDENT LTP (LTP<sub>K</sub>). C. M. Powell', D. Johnston, & J. D. Sweatt, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The use of N-methyl-D-aspartate (NMDA) receptor antagonist D,L-2-amino-5-phosphonovaleric acid (APV) has categorized LTP into two types: NMDA receptor-dependent (NMDA-R-dep) LTP and NMDA receptor-independent (NMDA-R-indep) LTP. We are interested in identifying potential molecular mechanisms for the maintenance of NMDA-R-indep LTP. LTP was elicited in area CA1 of intact rat hippocampal slices, in the presence of 50  $\mu$ M APV, by application of 25 mM tetraethylammonium (TEA) for 10 min plus low frequency stimulation (0.05 Hz) of Schaffer-collaterals (LTP  $_{\rm K}$ : Aniksztejn & Ben-Ari, Nature 349; 67-9). Population synaptic responses (pEPSPs) were potentiated during the 45 min period following TEA washout (pEPSP slope at 45 min 170  $\pm$  12% of baseline, n=14). Slices were frozen and the region between the electrodes was microdissected. Kinase activity was assayed using a peptide substrate selective for protein kinase C (PKC), neurograninze-43. A significant increase in basal (Ca²+-independent) PKC activity was observed with LTP  $_{\rm K}$  (269  $\pm$  74% of control, p<0.05). This increase in basal PKC activity was blocked by addition of the selective PKC inhibitor peptide PKC  $_{\rm (19-30)}$  (5  $\mu$ M) to in vitro reactions (control 0.39  $\pm$  0.01 pmol/min/ $\mu$ g, LTP  $_{\rm K}$  0.37  $\pm$  0.08 pmol/min/ $\mu$ g, n=6). No change in Ca²+/PS/DAG-stimulated PKC activity was observed (control 2.77  $\pm$  0.34 pmol/min/ $\mu$ g, LTP  $_{\rm K}$  3.24  $\pm$  0.34 pmol/min/ $\mu$ g, n=9). These results suggest persistent PKC activation as a mechanism for the maintenance of this form of NMDA-R-indep LTP. As persistent PKC activation has previously been described in NMDA-R-dep LTP (Klann et al., JBC 266; 24253-6), these two forms of LTP, distinct in their induction mechanisms, may converge on a common biochemical pathway in their maintenance phases. (MH44754)

CHARACTERIZATION OF LTP-ASSOCIATED PERSISTENT PROTEIN KINASE ACTIVATION USING NEUROGRANIN<sub>(28-43)</sub>, A NOVEL SELECTIVE PEPTIDE SUBSTRATE FOR PKC. E. Klann\*, S.-J. Chen and J.D. Sweau. Division of Neuroscience. Baylor College of Medicine. Houston, Texas, 77030.

Division of Neuroscience, Baylor College of Medicine, Houston, Texas, 77030.

We have previously described a Ca<sup>2+</sup>-independent, persistent activation of PKC to be associated with the maintenance phase of LTP. To investigate the mechanism(s) underlying this phenomenon, we used a selective peptide substrate for PKC, neurogranin(28-43), as an exogenous substrate to assay PKC activity. LTP of the Schaffer collateral input into area CA1 of rat hippocampal slices was studied. Slices were frozen, dissected, and homogenized at various time points after the final tetanic stimulation. We detected an increase in Ca<sup>2+</sup>-independent (basal) PKC activity of animutes after tetanus (203±28% of control, n=13). This persistent increase in PKC activity was inhibited by the NMDA receptor antogonist APV (50 μM; 113±12% of control, n=4). Control and LTP homogenates (45 min time point) were centrifuged at 133,000 g for 60 minutes and separated into pellet and soluble fractions. We detected a significant increase in basal PKC activity in the soluble fraction (177±38% of control, n=6). In contrast, no significant increase in the pellet fraction was observed. Control and LTP homogenates were also assayed 45 sec, 2 min, 5 min, 15 min, and 90 min following the final tetanus. We detected significant increases in basal PKC activity at 2 min (161±24% of control, n=10) and 5 min (184±35% of control, n=10). This finding was not observed at other time points. PKC activity (assayed in the presence of Ca<sup>2+</sup>, phosphatidylserine and oleoylacylglycerol, 174±18% of control, n=10). This finding was not observed at other time points, indicating the possibility of different mechanisms of PKC activation at different time points after tetanus. Obegin to address this question, we performed Western blots for PKC using control and LTP homogenates at the 45 minute time point and observed an LTP-associated decrease in PKC immunoreactivity (77±7% of control, n=4). These data are consistent with a post-translational modification of PKC at later time points. S

MICE MUTANT FOR THE ALPHA CA/CALMODULIN KINASE II HAVE IMPAIRED LTP AND PLACE- LEARNING. Alcino J. Silva, Yanyan Wang@ Richard Paylor\*, Jeanne Wehner\*, Charles Stevens@ and Susumu Tonegawa.

\*HHMI and Biology Depart., MIT, Cambridge, MA 02139. @ Salk Institute, La Jolla, CA 92037. #IBG, University of Colorado, Boulder, Co 80309. We have created mice lacking the alpha Ca/calmodulin

kinase II (aCAMKII), a major synaptic kinase. Field potential as well as whole cell recordings in the CA1 region suggest that these mutant mice have severely deficient LTP, but normal neurotransmission. Furthermore, the ratio of NMDA to non-NMDA components, as well as the voltage dependence of the NMDA receptor are not affected in the mutant mice. Hence, these mice are an ideal model to study the behavior implications of normal synaptic transmission but deficient LTP. Mice lacking this kinase cannot learn the precise location of a hidden platform within the Morris maze, a sensitive task of hippocampal function. Behavioral analysis shows that the learning deficit is specific, and that it is not due to a motor impairment, a lack of motivation, an inability to see distal cues or recognize that they are relevant to solving the tests. Our results demonstrate that aCAMKII is essential for place-learning, and they strongly support the hypothesis that LTP is an electrophysiological phenomena underlying some forms of learning.

RECOMBINANT VACCINIA VIRUS INFECTION OF SELECTED TARGETS IN THE HIPPOCAMPAL SLICE AND LTP. D.L. Petti: & R. Malinow. Neuroscience Program & Physiology and Rionbysis Dept. Lipix of Iowa

Neuroscience Program & Physiology and Biophysics Dept., Univ. of Iowa. LTP is triggered postsynaptically in CAI hippocampus but the mechanisms underlying its expression remain unclear. Here we describe a new technique that allows expression of recombinant proteins in anatomically selected neuronal populations, while maintaining intact synaptic circuitry and function. A vaccinia virus carrying a gene for ß-galactosidase (ß-gal) was used to infect selected neuronal populations in the rat hippocampal slice. Following extracellular application of virus in the CA3 or CA1 pyramidal cell body layer the slices are incubated overnight to obtain optimal expression of the gene product. ß-gal expression was confirmed by light microscopy after fixing, staining with X-gal, and xylene clearing of the slices. Robust X-gal staining is confined to presynaptic (CA3) or postsynaptic (CA1) injection sites, showing that there is no trans-synaptic infection during the incubation period. Individual cells stain in the apical and basal dendrites as well as a perinuclear ring. Cryostat sections (20µm) made from infected slices show that virtually 100% of the cells in the injected region are infected. Serial sections show uniform infection throughout the thickness of the slice.

We tested the effects of infection and overnight incubation on synaptic transmis-

We tested the effects of infection and overnight incubation on synaptic transmission and LTP. Whole-cell recordings from an infected region with the in vivorallourescent 8-gal marker CMFDG in the pipette confirmed the viability of infected cells. Synaptic transmission and LTP in infected cells were indistinguishable from control recordings. In other experiments, a pathway originating from an infected Subiculum pathway. Subsequent histological processing revealed strong X-gal staining in the stimulated CA3 region. These control experiments show the feasibility of this technique. We are currently generating recombinant constructs to modify selected protein kinase activities to test their role in the presynaptic terminal.

LTP-INDUCING TETANIC STIMULATION CAUSES A NITRIC OXIDE-MEDIATED INCREASE IN cGMP IN HIPPOCAMPAL AREA CA1. <u>D.M.</u> <u>Chetkovich\* and J.D. Sweatl.</u> Div. Neurosci., Baylor Col. Med., Houston, TX 77030

Recent reports have suggested that nitric oxide (NO) may be necessary as a "retrograde messenger" traveling from the postsynaptic to the presynaptic cell in the induction of LTP. Hemoglobin, which absorbs NO in the extracellular space, and NO synthase inhibitors have been shown to block LTP. In light of these findings, we have undertaken a biochemical approach to determine if NO is a transcellular messenger in LTP. One known target of NO action is soluble guanyly leyclase (GC); NO activates GC, leading to production of cGMP. We measured cGMP levels in area CA1 following LTP-inducing high-frequency stimulation (HFS, 100 Hz, 3x1 sec). We found that HFS in area CA1 leads to an increase in cGMP levels (control: 35±.01; HFS: 44±.03 pmol cGMP/ mg protein, n=8, p<.01). This increase was augmented in the presence of the phosphodiesterase inhibitor IBMX (control: 249+.12; HFS: 5.82±.18 pmol cGMP/mg protein, n=7,p<.001), indicating an effect of HFS on cGMP synthesis rather than degradation. Competitive inhibitors of NO synthase, N-methyl-l-arginine and 1-nitroarginine, both blocked the increase in cGMP seen with HFS. The effects of both inhibitors were reversed by 1 mM arginine. Hemoglobin markedly attenuated the increase in cGMP seen with HFS, suggesting that NO can cross cell membranes to affect changes on GC. Taken together, these data implicate NO as the mediator of the increases in cGMP caused by HFS. Part of the increases in cGMP was NMDA receptor-dependent, as the NMDA receptor-antagonist APV (100 μM) attenuated the increase in cGMP observed with HFS. No-mediated increases in cGMP was observed with HFS in the presence of 500 μM APV, 100 μM CNQX and 100 μM AP3, indicating that some production of NO may be occuring presynaptically, or postsynaptically via stimulation of non-glutamate receptors. In summary, these data support a role for NO as a transcellular effector in LTP, as well as implicate the cGMP pathway in the induction of LTP.

A POTENTIAL ROLE FOR AN ADP-RIBOSYLTRANSFERASE (ADPRT) IN HIPPOCAMPAL LONG-TERM POTENTIATION (LTP). E.M. Schuman, M.K. Meffert, H. Schulman, and D.V. Madison, Dept. of Molecular & Cellular Physiology and Dept. of Pharmacology, Stanford School of Medicine, Stanford, CA 04305

Previous studies have strongly suggested that nitric oxide (NO) production is necessary for the production of LTP in the CA1 region of the hippocampus. However, the molecular target(s) of NO and the mechanisms by which NO brings about synaptic potentiation remain to be elucidated. We have begun to examine these questions by asking if either of two established NO targets, a soluble guanylyl cyclase and a cytosolic mono-ADPRT, plays a role in the production of LTP. In initial studies we have examined whether a membrane permeant analog of cGMP in conjunction with strong presynaptic activity is sufficient to enhance transmission. Tetanic stimulation in the presence of APV (50 μM) and dibutyrl cGMP (100 μM) failed to potentiate synaptic transmission, although LTP could be elicited in the same pathway following wash-out of both agents. In addition, an inhibitor of cGMP-dependent protein kinase, H-8, applied extracellularly before tetanic stimulation failed to reduce LTP. Conversely, extracellular application of three different inhibitors of ADPRT, nicotinamide (NIC; 1 mM), luminol (LUM; 200 μM), and vitamin K (100 μM) were extremely effective blockers of LTP. We attribute the actions of these agents to inhibition of a mono- rather than poly-ADPRT since benzamide (100 μM; LSop poly-ADPRT = 22 μM) did not block LTP. Also, in preliminary experiments postsynaptic injection of NIC did not prevent tetanus-induced LTP of one synaptic pathway, although subsequent bath application of NIC blocked LTP in a second pathway, suggesting that the critical site of ADPRT activity may be in the presynaptic neuron. Finally, in homogenized CA1 tissue incubated with (<sup>32</sup>P)NAD+, the NO donor sodium nitroprusside (SNP; 300 μM) increased the ADP-ribosylation of ~45 kD and ~116 kD protein(s) and induced the ribosylation of a ~40 kD protein(s). The SNP-induced ribosylation of these proteins was blocked by NIC and LUM at the same concentrations that were effective in blocking LTP.

ROLE OF NITRIC OXIDE IN NMDA-RECEPTOR MEDIATED NEUROTRANSMITTER RELEASE IN HIPPOCAMPUS

P. R. Montague\*+#,C. D. Gancayco#,R. B. Marchase#,M. J. Friedlander#, Neurobiology Research Center# University of Alabama at Birmingham, Birmingham, AL 35294. Computational Neurobiology Lab\*, The Salk Institute. Nitric oxide (NO) has been implicated as a rapid, diffusible messenger re-

Nitric oxide (NO) has been implicated as a rapid, diffusible messenger required for the induction of long-term potentiation (LTP). The synthetic enzyme for NO (NOS) is localized in some hippocampal neurons and is activated by increased levels of intracellular calcium subsequent to NMDA receptor activation. We investigated whether NO can link postsynaptic NMDA receptor activation to changes in neurotransmitter release using synaptosomes from hippocampi of anesthetized adult guinea pigs. The ability of the synaptosomes to release preloaded radiolabeled neurotransmitter (^3H-D-aspartate or ^3H-L-norepinephrine) and endogenous neurotransmitter (-F.glutamate) was evaluated by scintillation counting and luminometry, respectively. NMDA (100 uM) caused a large release of neurotransmitter: 60% of available glutamate and aspartate; 20% of available norepinephrine. Release of all three neurotransmitters was blocked in calcium free media and by the NMDA receptor antagonist 5-amino-phosphonovalerate (AP5). Release was also blocked if the synaptosomes were exposed to the competitive blockers of NOS,  $N^G$ -monomethyl-L-arginine (100  $\mu$ M) or  $N^G$ -nitro-L-arginine (100  $\mu$ M); the D-enantiomers did not block release. Moreover, extrasynaptosomal hemoglobin (Hb-20  $\mu$ M) blocked the NMDA effect. The NOS block was reversible (via 1 mM L-arginine application) and did not effect neurotransmitter release subsequent to K+ depolarization. Thus, NO may serve to link NMDA receptor activation to changes in neurotransmitter release from both presynaptic glutamatergic and catecholaminergic terminals in a local volume of tissue.

NEUROTENSIN INDUCES SUSTAINED RHYTHMIC BURSTING ACTIVITY AND IS INTERNALIZED IN BASAL FOREBRAIN CHOLINERGIC NEURONS. A. Alonso, M.P. Faure and A. Beaudet. Montreal Neurological Institute and McGill University, Montreal, QC, Canada H3A 2B4.

The cholinergic cells of the basal forebrain (BF) play an important role in the control of limbic and neo-cortical activity. Recent evidence indicates that most of these neurons are endowed with neurotensin (NT) receptors Moreover, ICV application of NT has an awakening effect and enhances EEG theta activity (Latell et al, Peptides, 1989). In the present study we have investigated by intracellular recording in guinea-pig brain slices the effects of NT on the intrinsic excitability of BF (substantia innominata-horizontal limb of the diagonal band) neurons identified as cholinergic by a) their electrophysiological characteristics (Khateb et al, Soc. Neurosci. Abstr., 1992) and b) their ability to internalize NT (Faure et al, Soc. Neurosci. Abstr., 1992). The most salient electrophysiological characteristic of most of these neurons is their ability to generate a Ca-dependent low-threshold burst that can usually repeat 2-4 times when the cells are depolarized from their resting potential (close to -70 mV) to about -60 mV. Bath application of NT or fluorescein-labeled NT (NT-FTC) (1-100nM) caused a depolarization associated with a decrease in membrane conductance and triggered the development of a sustained rhythmic bursting activity (0.5-3Hz) with a The depolarizing and robust enhancement of individual burst events. oscillatory-inducing actions of NT persisted in the presence of TTX. Furthermore, confocal examination of NT-FTC responsive neurons that were intracellularly injected with biocytin revealed that they had internalized the neuropeptide as assessed by double fluorescence labeling. These data demonstrate a potent and direct neuromodulatory action of NT on the intrinsic excitability of BF cholinergic neurons suggesting that the peptide may thereby play a major role in the BF-mediated control of cortical arousal.

INTERNALIZATION OF NEUROTENSIN IN BASAL FOREBRAIN CHOLINERGIC NEURONS: A CONFOCAL MICROSCOPIC ANALYSIS. M-P. Faure\*, A.Alonso, K.Leonard and A.Beaudet. Montreal Neurol Inst., McGill Univ.Montreal, Canada.

We have previously demonstrated an extensive association of specific high affinity neutotensin (NT) binding sites with acetylcholinesterase positive neurons in both rat and human basal forebrain. Furthermore, hybrid cells derived from medial septal cholinergic neurons were found to bind and internalize exogenous NT. To test the hypothesis that NT is similarly internalized in basal forebrain cholinergic neurons themselves, we have resorted to a fluorescein thiocarbamyl conjugate of NT (FTC-NT) shown to exert the same electrophysiological effects as unlabeled NT (Alonso et al, Soc. Neurosc. Abst.1992) and to retain high binding affinity for brain NT receptors. Slices (350µm thick) of guinea pig basal forebrain, maintained at 35°C in oxygenated Ringer, were preloaded with 100nM FTC-NT for 3 min, superfused with Ringer for 15,30,60 and 120 additionnal min, fixed with 4% paraformaldehyde and sectionned at 50µm for choline acetyltranferase (ChAT) immunostaining. Confocal laser microscopic (CLSM, Leica) examination of 25 optical sections taken at 0.25µm intervals showed intense specific intracellular FTC-NT labeling at all wash-out times. The labeling pattern was initially diffuse and predominantly dendritic, becoming more granular and perikarial with time. At 120 min the label was mainly confined to the perinuclear area within endosome-like particules. Treatment with 0.2% triton for 15 min did not affect this pattern, confirming the intracellular localization of the label. Merged confocal images of perikarial FTC-NT and ChAT-Texas red immunofluorescence indicated that the label had been selectively internalized within ACh neurons. These results confirm the selective association of NT receptors with basal forebrain cholinergic neurons and demonstrate the existence of a somatodendritic internalization of the peptide within these cells.

PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP) FACILITATES THE INDUCTION OF TYROSINE HYDROXYLASE (TH) BY NICOTINE IN BOVINE ADRENAL CHROMAFFIN CELLS (BAC). R.A. Rius, A.M. Szekely\*, A. Guidotti, E. Costa. Fidia-Georgetown Institute for the Neurosciences, Georgetown University, School of Medicine, Washington, DC 20007.

PACAP is a novel peptide present with VIP in cholinergic neurons (Reg. Pept. 37: 287, 1992). Thus, PACAP, similar to VIP, might be a good candidate for acting as a cotransmitter of acetylcholine in the cascade of events operative in the transsynaptic induction of TH gene expression. The present study was designed to investigate whether nicotine and PACAP are study was useful to investigate whether income and FACAF are cotransmitters in TH induction. In BAC, PACAP (10<sup>10</sup> to 10<sup>7</sup>M) produced a dose-dependent increase of TH Vmax when measured after 48 hrs of treatment. This effect was preceded by an increase in TH mRNA content that starts after 2 hrs and peaks at 12 hrs. A significant induction (35%) in TH was already observed with 5x10<sup>-10</sup>M PACAP and maximal increase (3 fold) was observed with 10<sup>-7</sup>M PACAP. VIP and forskolin also induced TH in BAC, however, they were 3-4 orders of magnitude less potent and VIP also less efficacious. In BAC, TH can be induced after a short (20 minutes) pulse of exposure to PACAP. The potency of PACAP was increased in presence of the phosphodiesterase inhibitor HL 725 (trequinsin 10<sup>-5</sup>M) indicating a role for cAMP in the TH induction by PACAP. In addition to increasing cAMP, PACAP increased the expression of several immediate early genes including cfos and jun-B. Nicotine (10 M) applied for 48 hrs produced a modest increase (20-30%) in TH. Moreover, in the presence of nicotine, the action of PACAP or VIP in TH induction was facilitated. It remains to be studied whether PACAP and VIP facilitates TH induction triggered by splanchnic nerve stimulation.

IN SITU HYBRIDIZATION ANALYSIS OF PREPROTACHYKININ mRNAs IN DISCRETE AREAS OF THE RAT BRAIN: AN INVOLVEMENT OF TACHYKININS IN DIFFERENT NATRIOREXIGENIC TREATMENTS. P. Pompei, A.M. Magarinos\*, J. Angulo and B. McEwen, Lab. of Neuroendocrinology, the Rockefeller University, New York, NY 10021.

Previous studies have shown that the bed nucleus of the stria terminalis (BNST) plays a major role as a site of action for the inhibitory effect of intracerebroventricularly (icv) injected tachykinins (Tks) on salt appetite. This investigation examined the presence and abundance of preprotachykinin (PPT) A-gene mRNA transcripts in BNST and in the caudate-putamen (CP) of sodium depleted (DEP) (furosemide-induced natriuresis) and adrenalectomized (ADX) rats. In situ hydridization with synthetic oligodeoxyribonucleotide probes specific for PPT A-gene was used. Quantitative analysis revealed dispersed PPT A labelled cells in sections from rat CP and BNST. Furthermore, the concentration of PPT A mRNAs in the ventral CP was denser than in the dorsal CP. The intensity of silver grains in both regions of the brain was greater in DEP than in control animals. On the other hand, both CP and BNST showed a markedly lower level of PPT A mRNAs in ADX rather than sham operated rats

These findings, in relation to the enhanced PPT gene expression in CP and BNST of <u>DEP</u> rats, are provocative expecially in light of the antinatriorexigenic effect of these peptides and they also extend previous functional considerations on the primary role that Tks exert on sodium homeostasis. (Supported by MH 43787).

INFUSION OF OXYTOCIN ANTAGONISTS INTO THE VTA OR MPOA BLOCKS THE POSTPARTUM ONSET OF MATERNAL BEHAVIOR. <u>Cort A. Pedersen\*, Jack D. Caldwell and Gail Ayers</u>. Dept. of Psychiatry, BDRC, Neurobiology Curriculum, The University of North Carolina School of Medicine, Chapel Hill, NC 27599-7160.

We have recently reported a significant increase in oxytocin (OT) binding at parturition in the ventral tegmental area (VTA) and the medial preoptic area (MPOA). We have, therefore, tested whether antagonism of OT in these sites blocks the onset of maternal behavior (MB) occurring at parturition. Primiparous rats received either PPTPO (a specific OT antagonist), a specific V<sub>1</sub> antagonist (1ug/0.25ul/side) or NS bilaterally into the VTA region, OTA (another OT antagonist) or NS bilaterally into the MPOA (0.25ug/0.25ul/side) or PPTPO (2ug/2ul), OTA (0.5ug/2ul) or NS into the lateral cerebral ventricles after delivery of the first pup, 1 hr later, 15 and 40 min after delivery of the last pup. Each pup was removed from its mother's cage after it was delivered and licked clean of blood and birth fluids. 40 min after delivery of the final pup and immediately following the last central infusion, 8 of their offspring were returned to each rat and behavioral observations were conducted over a 30 min period. Among animals receiving PPTPO into the VTA only 1/10 retrieved pups or crouched in a nursing posture >1100 sec (p<.05 compared to other treatments). ICV administration of PPTPO or OTA had no significant effect on MB. The VTA and MPOA appear to be sites of endogenous OT activation of MB. Supported by HD25255 and MH33127.

COMPARISON OF PITUITARY ADENYLATE CYCLASE-ACTIVATING POLYPEPTIDE (PACAP) AND ACETYLCHOLINE (ACh) IN STIMULATING CATECHOLAMINE (CA) SECRETION FROM RAT ADRENAL GLAND. Xie Guo, John Haycock and Arun R. Wakade\*. Dept. Pharmacol. Wayne State Univ., Detroit, MI & \*Dept. Biochem. Molec. Biol., Louisiana State Univ. Med. Ctr., New Orleans, LA

The role of vasoactive intestinal polypeptide (VIP) as a non-cholinergic neurotransmitter is well-established in rat adrenal medulla. PACAP is a new member of the VIP/secretin/glucagon family having 68% homology with VIP in the N-terminal 28 amino acid residues. High-affinity receptors for PACAP are present in the rat adrenal medulla, and we have previously demonstrated that stimulation of splanchnic nerves releases PACAP from perfused rat adrenal gland (basal, 47  $\pm$  15 pg; stimulated, 130  $\pm$  40 pg). Here we compared the stimulatory actions of PACAP and ACh on secretion of epinephrine (EPI) and norepinephrine (NE). CA secretion was increased by as little as 1-3 nM PACAP as opposed to 2-3  $\mu$ M ACh. Secretions of CA upto 250 ng/4 min were produced by 1  $\mu$ M PACAP whereas 30  $\mu$ M ACh was required to produce similar increases. Different proportions of the CAs were released in response to 7:1 for PACAP as ACh. The ratio of EPI to NE was 4:1 for ACh but increased to 7:1 for PACAP. CA secretion returned to basal levels within 5 min after treatment with 30  $\mu$ M ACh whereas the secretory response to 10 nM PACAP continued for over 30 min after removal of PACAP. Omission of Ga²+ (plus 1 mM EGTA) prevented the increases in CA secretion produced by either ACh or PACAP, and removal of Ca secretion produced by PACAP. These date indicate that PACAP and VIP could both function as non-cholinergic transmitters in splanchnic nerve/chromaffin cell synapses.

NEUROPEPTIDE K (NPK) STIMULATES GH RELEASE IN THE RAT. V. Rettori, L. Debeljuk, M.C. Aguila, A. Bartke and S.M. McCann\*. Dept. of Physiology, UT Southwestern Medical Center, Dallas, Texas 75235.

NPK is a 36-amino acid peptide synthesized within the precursor polypeptide \$\mathbb{E}-preprotachykinin \$A\$, which contains neurokinin \$A\$ (NKA) as a \$C\$-terminal decapeptide. To evaluate the possible role of NPK on \$G\$H secretion, it was microinjected into the third cerebral ventricle (3V) of conscious, freely moving, ovariectomized rats. Blood samples were taken from previously implanted external jugular catheters. NPK (0.5  $\mu g/3$   $\mu l$  saline (0.9% NaCl)) significantly increased plasma levels of \$G\$H beginning at 70 min, reaching a peak at 90 min and declining until 120 min as compared to 0 time and saline-injected controls. To elucidate the site of action of NPK, anterior pituitaries from male rats were incubated for 2 hrs in the presence of NPK (10^9 to 10^7M). None of the doses used modified the release of \$G\$H. Therefore, we studied the effect of NPK (10^8-10^7M) on somatostatin release from mediobasal hypothalami (MBH) in vitro. There was no significant effect of NPK on somatostatin release. We conclude that the stimulatory action of NPK on \$G\$H release is at the hypothalamic level probably mediated by \$G\$H release. The delay in the effect suggests that NPK may be converted to an active fragment; however, this fragment is not NKA since it was inactive at equivalent in vivo doses (supported by DK40994).

EFFECTS OF AN OXYTOCIN-ANTAGONIST (OT-A) ON SUCKLING-INDUCED RELEASE OF OXYTOCIN (OT) INTO THE SUPRAOPTIC NUCLEUS (SON) AND BLOOD. I. Neumann  $^1_{\rm R}$ , Landgraf  $^1_{\rm L}$ , E. Koehler  $^2_{\rm L}$ , J.A. Russell  $^3_{\rm L}$  and J. Summy-Long  $^2_{\rm L}$ . Univ. of Leipzig, Germany  $^1_{\rm L}$  M.S. Hershey Med. Ctr., Hershey, PA  $^2_{\rm L}$ , Univ. of Edinburgh, U.K.  $^3_{\rm L}$ .

OT released within the SON during suckling may stimulate release of more OT within the nucleus as well as into blood. To examine this, the SON area of conscious lactating rats was microdialyzed (MD) with artificial CSF (aCSF, 3.9 ul/min) on 2 days, collecting 30-min samples before, during and after suckling. On day 1 vehicle (1.5 ul) was infused adjacent to the MD probe 5 min before returning the pups. This was repeated on day 2 except half the rats received OT-A (50 ng/1.5 ul). On day 1, OT (pg/30 min;Risem;n9,10) in dialysates increased (P<0.05) during suckling in vehicle (0.5+0.1 vs 2.0+0.4) and OT-A (0.6+0.1 vs 2.8+1.0) groups. On day 2, however, suckling elevated (P<0.05) OT in dialysates only from rats given vehicle (0.6+0.1 vs 2.2+0.4) but not OT-A (0.9+0.2 vs 1.1+0.2). On day 3, OT-A did not alter intranuclear release of OT by MD of 1M NaCl in aCSF. In other studies, OT-A (50 ng/1 ul) infused into both SONs before suckling lowered (P<0.02; vs vehicle) plasma OT (15.3+1.5 vs 29.6+5.2 pg/ml) and weight gain of the litters (1.6+0.9 vs 5.8+1.2 g). These data indicate a receptor-mediated, positive feedback of OT on it's own release in the SON to facilitate OT secretion into blood during suckling. Funded by VW-Stiftung (1/67301) and ROJHD 25498.

SENSITIVITY OF THE NEUROTENSIN RESPONSE OF RAT SUBSTANTIA NIGRA NEURONES  $IN\ VITRO$  TO TOXINS AND ION CHANNEL BLOCKERS

K.D.Keegan, G.N.Woodruff and R.D.Pinnock\*.

Parke-Davis Neuroscience Research Centre, Addenbrookes Hospital Site, Hills Road, Cambridge CB2 2QB

Two populations of neurones were observed in the substantia nigra, pars compacta. Of 1 group of neurones, 38 responded to neurotensin (0.1-1.0µM) with a depolarization and increase in firing rate. The response to NT was dose dependent and lasted for between 3 and 15 mins. The depolarizing effects of NT persisted in the presence of TTX. Current voltage relationships determined under current and voltage champ conditions showed an increase in membrane resistance occurred during the NT response. The effects of NT persisted in the presence of high magnesium, cobalt and manganese although in the presence of high magnesium, cobalt and response was reduced. Addition of apamin (1µM) and charybdotoxin (300nM) had no blocking action on the NT response although the input resistance of the neurone increased slightly after five minutes exposure to these agents. Addition of 30Oµm barium (n=3) or replacement of potassium with cacsium (n=3) blocked the NT response. The effect of all these agents was fully reversible on washout. 100-3OOnM \( \alpha \)-dendrotoxin caused a partial block of the NT response which washed out. The results of the present study suggest that the depolarizing response to NT is mediated via a postsynaptic receptor on a subpopulation of dopamine sensitive neurones in the substantia nigra. The ability of either barium, replacement of potassium with cacsium or a-dendrotoxin to reduce or abolish the NT response suggests a potassium conductance is involved in the depolarising response.

IMMUNONEUTRALISATION OF NEUROPEPTIDE Y REDUCES FAST-INDUCED FEEDING IN THE RAT - EVIDENCE OF A PHYSIOLOGICAL ROLE IN FEEDING BEHAVIOUR. P.D. Lambert, J.P.H. Wilding, S.G. Gilbey, E. Comoy, C. Bohuon and S.R. Bloom, (SPON: Brain Research Association) Endocrine Dept., Hammersmith Hosp., London, U.K. \*Institute Gustave-Roussy, Paris. France.

Central administration of NPY produces a robust feeding response in the rat, and raised levels of hypothalamic NPY and NPY mRNA have been shown following food deprivation and in animal models of obesity and diabetes. These observations suggest that NPY may have a physiological role in feeding. However, the important question is whether or not changes in the level of endogenous, central NPY mediate changes in feeding. We therefore investigated the effects of intracerebroventricular injection of a monoclonal antibody to NPY (NPYAb), prepared from mouse ascites, on NPY-induced and fast-induced feeding. We also studied the feeding response to central injections of NPY and NPYAb in streptozotocin-induced diabetic rats. All studies were of crossover design comparing the effects of NPYAb with an antibody to chloraquine which had been prepared in the same way and had no affinity for NPY. Intracerebroventricular pretreatment with NPYAb (5ul) reduced NPY-induced feeding by 74±6% (p<0.001, n=6). Pretreatment with NPYAb 10 minutes before 24 hour fasted animals were presented with food reduced their food intake by  $29 \pm 6\%$  (p<0.02, n=9). NPY-induced (2.4nmols) food intake in diabetic animals was 52 ± 10% lower than seen in controls (p < 0.04, n = 6). The food intake of diabetic animals following a 24 hour fast could not be reduced by central injection of NPYAb. These data suggest a significant, physiological role for NPY in the control of feeding after food deprivation in the rat. There was reduced sensitivity to the central effect of NPY on feeding in animals with insulin-deficient diabetes, suggesting that the NPY system is excessively stimulated in this model.

REGULATION OF PEPTIDES AND PEPTIDYLGLYCINE  $\alpha$ -AMIDATING MONOXYGENASE (PAM) ACTIVITY IN THE PITUITARY AND BRAIN OF HIBERNATING GROUND SQUIRRELS. G.P. Mueller. T.A. Ford. T.L. Stanton and A.L. Beckman\*. Uniformed Services University of the Health Sciences, Bethesda, MD 20814 and California State University, Long Beach, CA 90840.

Morphine physical dependence is significantly reduced in the hibernating state of the ground squirrel, Citellus lateralis. This effect may be mediated by changes in endogenous beta-endorphin  $(\beta\text{-END})$  and cholecystokinin octapeptide (CCK-8) systems, which have reciprocal influences on opiate analgesia in awake rodents. To investigate this, we examined the effects of hibernation on: (1) levels of pituitary  $\beta\text{-END}$  and brain CCK-8 and (2) the activity of PAM, the enzyme that catalyzes formation of bioactive  $\alpha\text{-amidated}$  CCK-8. We observed that the concentration of  $\beta\text{-END}$  in the pituitary anterior (AL) and neurointermediate (NIL) lobes, and CCK-8 in cerebral cortex, was decreased by 50% (p<0.05) compared to non-hibernating animals. Conversely, hibernation was associated with a nearly 2-fold increase in the activity of PAM (membrane bound and soluble) in the AL, due to an increase in the V\_max (no apparent change in K\_m). PAM activity in the NIL and cerebral cortex, however, was not altered by hibernation, indicating that different mechanisms control PAM activity in these tissues. Thus, hibernation differentially alters neuropeptides and processing enzymes involved in analgesia. Changes in the balance of these systems may contribute to the hibernation-related reduction in morphine dependence.

NEUROPEPTIDE AND NE EFFECTS IN PGE2-SENSITIVE mPOA HEAT GAIN SITES OF THE RAT. <u>C.W. Simpson\* and G.E. Resch.</u> Schl. Biol. Sci., Univ. Missouri at Kansas City, Kansas City MO 64108.

In previous reports we presented data supporting neurochemical differentiation of adjacent PGE2-sensitive mPOA sites in which a variety of neurotransmitters and ligands elicited colonic temperature (Tc) increases in ketamine anesthetized rats and hamsters. In this report these investigations have been extended to evaluate effects of four peptides ( $\alpha$ -MSH, AVP,  $\beta$ -End, and NPY) and NE in unanesthetized rats. Each was injected in 1ul volumes into previously identified PGE<sub>2</sub>-sites as previously described. Each peptide elicted a change in Tc: α-MSH, β-End, and NPY increased Tc 0.49° to 0.80°C; and AVP decreased Tc -0.8°C. Each value represents the mean of values measured in 7 to 9 rats. To the best of our knowledge, this is the first demonstration of AVP induced hypothermia in contrast to other reported attenuations from a febrile state. There may be an expanded role for AVP beyond antipyresis. Threshold doses determined for each peptide:  $\alpha$ -MSH and NPY,  $10^{-12}$ gm; AVP and  $\beta$ -End,  $10^{-6}$ gm. The threshold dose for NE was 10<sup>-8</sup>gm. Data from NE injections were consistent with the reports of others, showing primarily decreases and some increases in Tc. Similarly for the peptides instances of opposite responses occurred. Such response patterns are consistent with site differences reported by Boulant in vitro, and Beckman in vivo and consistent with different routes of administration (icv vs tissue injections) reported by Lipton. These data indicate these peptides modify Tc at these PGE<sub>2</sub>sensitive mPOA heat gain sites. In addition the data imply that several parameters may modify the expression of responses to any given ligand; eg. fever, internal/external heat load, and anesthesia. AVP attenuates fever but did not induce hypothermia in the ventral septal area. Internal heat load blocked heat gain pathways but this did not occur in normo- and hypothermic animals. Finally, NE did not elicit a fall in Tc in ketamine anesthatized rats but did in the unanesthetized rat. Supported by AFOSR 870295.

L-365,260, A CCK<sub>B</sub> ANTAGONIST, BLOCKS CCK-4-PANIC J. Bradwein\*, D. Koszycki, A. Couetoux duTertre, H. van Megen, J. den Boer, H. Westenberg, C. Karkanias, J. Haigh.McGill Univ., Montreal, Canada; Univ. of Utrecht, The Netherlands; Merck Sharp & Dohme, USA and UK.

CCK-4, a CCK<sub>B</sub> receptor agonist, induces panic attacks in panic disorder (PD) and normals. This study investigated the effects of pre-treatment with L-365,260, a CCK<sub>B</sub> antagonist, on CCK-4-panic in PD. Patients were treated with L-365,260 (10 or 50 mg PO) or placebo 90 mins before 20 ug of CCK-4 I.V.. 24 patients were entered; 3 were challenged once and 21 were challenged twice in a double blind, incomplete block design. The panic rate after CCK-4 was: 13/15 (placebo), 5/15 (10 mg), and 0/15 (50 mg); (P <.01 for 10 mg and 50 mg against placebo). The adjusted mean (±5D) sum intensity scores on the Panic Symptom Scale were 37.2±15.6 (placebo), 25.7±16.3 (10 mg) and 12.4±15.9 (50 mg). Differences between 50 mg and placebo were statistically significant (P<.01) and differences between 10 mg and placebo approached significance (P=.07). These data demonstrate that L-365,260 can block CCK-4-panic. The clinical efficacy of this CCK<sub>B</sub> antagonist in PD warrants investigation.

BOMBESIN-LIKE PEPTIDES (BLP) ARE ENDOGENOUS REGULATORS OF FERTILIZATION OF OVUM BY SPERM: EXPRESSION OF LIGANDS AND RECEPTORS IN TESTES AND THEIR ROLE IN FERTILIZATION. S.R. Nagalla, S.Vijayaraghavan, K.Li, A. Archibong, D.P.Wolf, E.R.Spindel\* Div of Neurosci, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Bombesin-like peptides are important neurotransmitters, paracrine hormones and autocrine growth factors. The best characterized mammalian BLP is gastrin-releasing peptide (GRP) which is widely distributed in brain, GI tract and lung. Here we report evidence for a potentially important role of a BLP to effect fertilization through regulation of the acrosome reaction in primate sperm. RNA blot analysis showed the presence of GRP and GRP receptor mRNA in rhesus testes at levels higher than we have previously observed in any normal adult tissues. In situ hybridization localized the GRP mRNA to the spermatogenic cells in the seminiferous tubules. Sequence analysis of partial cDNAs isolated from a rhesus cDNA testes library showed high homology with the 3'-end of the human GRP mRNA though PCR suggests that the 5'-end of the mRNA may be different. As a necessary part of successful fertilization, sperm undergo an exocytic process called the acrosome reaction. Concentrations of GRP as low as 1 nM significantly stimulated the acrosome reaction (AR) of both human and monkey sperm. The stimulation of the AR by GRP could be blocked by the bombesin antagonist [D-Phe<sup>6</sup>] bombesin (6-13) propylamide (D-Phe<sup>6</sup>Bn) which is selective for the GRP-preferring bombesin receptor subtype. D-Phe<sup>6</sup>Bn also blocked the AR induced by progesterone another known mediator of the AR. Finally, D-Phe<sup>6</sup>Bn blocked the *in vitro* fertilization of monkey ovum by monkey sperm. Thus a BLP, most likely GRP itself, plays an essential role in fertilization. This suggests that appropriate bombesin antagonists may have utility for *in vitro* fertilization procedures and that appropriate bombesin antagonists may have potential as contraceptive agents.

TRANSLATION AND PROCESSING OF AMYLOID PRECURSOR PROTEIN ARE DIFFERENT IN RAT CORTICAL NEURONS, ASTROCYTES AND MICROCLIAL CELLS. LeBlanc AC\*, Xue R, Gambetti, P, Inst. Pathol. Case Western Reserve U. Cleveland, OH 44106

Translational and post-translational regulation of amyloid precursor protein (APP) gene expression was studied in primary cultures of rat cerebral cortex neurons, astrocytes and microglia as well as in cultures of whole cerebral cortex by pulse-chase experiments. Detergent soluble (cytosolic and membrane-associated proteins) and detergent insoluble cellular proteins (cytoskeleton and nuclei fraction) as well as secreted proteins were immunoprecipitated with antibodies to various regions of the APP. The rate of synthesis of detergent soluble cellular APP was different in the various cell types. The most abundant synthesis was found in astrocytes despite their relatively low levels of APP mRNA. Chase experiments after 60 min. pulses, revealed that the half-life of detergent soluble APP also differed in each cell type. In addition, longer pulse times of 6 hours followed by chase, revealed a pool of detergent soluble APP which appear to be very stable and were detectable even after a 24 hour chase. Secretion was more rapid in mixed cerebral cortex cultures compared with isolated cells but slowed down considerably with time in vitro. The detergent insoluble cellular proteins are also being investigated. The results of these experiments emphasize differences in the rate of translation, distribution and post-translational processing of the APP among the main cell types of the CNS. SEARCH FOR MUTATIONS IN THE β-AMYLOID PRECURSOR PROTEIN (βAPP) BY DENATURING GRADIENT GEL ELECTROPHORESIS (DGGE). M.B. Podlisny\*, B.L. Ostaszewski, E. Abrams¹, D.R. Tolan², D.L. Salker, Harrad Madical School, MITL and Begin Linia?

D.J. Selkoe. Harvard Medical School, MIT¹ and Boston Univ.², Boston, MA. Missense mutations in βAPP discovered in a few kindreds with familial Alzheimer's disease (FAD) have provided the first specific molecular cause of AD. Because FAD is a common, multi-ethnic autosomal dominant disorder, it is likely that additional point mutations (or other defects) in the βAPP gene will be found in some other FAD families. We have established a sensitive and efficient procedure for screening large numbers of putative FAD subjects for βAPP mutations that utilizes DGGE. Exonic segments of genomic DNA are amplified by PCR using primers designed by computer simulation to encompass a single DNA melting domain; one primer is joined to a GC-clamp. Any mutations in the amplified exonic fragments should be detected with >98% efficiency (Sheffield et al., PNAS 86:232, 1989). Fragments are electrophoresed on polyacrylamide gels containing a gradient of urea/formamide denaturant dictated by the individual melting characteristics of each exonic segment. Gels of positive control DNA from an HCHWA-Dutch patient with the βAPP693 mutation and an FAD patient with the βAPP717 mutation always showed the expected 2 heterodimers and 1 or 2 homodimers of double-stranded DNA. As positive controls for those exons in which no DNA from human and monkey. These species differ by 1-4 bases in most βAPP exons, and these substitutions are readily detectable in our DGGE system. Analysis to date on βAPP exons 16 and 17 (comprising β/A4) and exon 18 (carboxyl terminus) in 51 AD subjects having 1 or more first degree relatives with a history of AD have not revealed any base substitutions. The age of onset in these putative familial cases range from 44 - 83 years, but most are >65 yr old. We are currently extending our DGGE analysis to other βAPP exons and infrequent cause of AD.

# ALZHEIMER'S β/A, PROTEIN FORMS A FORMATE ESTER WITH SERINE-26 IN CONCENTRATED FORMIC ACID. W.E. Klunk, MD, PhD\*, C. Xu, PhD, and J.W. Pettegrew, MD.

Lab. of Neurophysics, Univ. of Pittsburgh, WPIC, Pittsburgh, PA 15261 Deposition of  $\beta/A_4$  may play an role in the pathogenesis of AD and has been the subject of intense investigation. The insoluble nature of this peptide has hampered work in this area and has necessitated the use of harsh chemical methods of solubilization. A common method was the use of concentrated formic acid. We have previously reported that this technique covalently modifies the peptide (Klunk et al. J. Neurochem. 54: 2050-2056; 1990). In this study, we use a combination of one- and two-dimensional <sup>1</sup>H NMR techniques to show that the modification occurs via formation of a formic acid ester of a serine residue in the peptide. One dimensional NMR comparison of the formylated and native peptide shows the appearance of a singlet at 8.3 ppm, consistent with a formate proton. After sequential assignment of all peaks by two-dimensional NMR, it was clearly seen that the only major changes in chemical shift occurred at the lone serine in the peptide fragment studied. Relayed COSY experiments showed a cross peak between the formate proton and the serine beta protons, further demonstrating the nature of this covalent attachment. This data, combined with our previous study, conclusively demonstrates that dissolution of  $\beta/A_4$  in concentrated formic acid results in covalent modification of this peptide through formic acid esterification of a serine residue and makes this procedure unsuitable for many studies.

THE ~11.4 KD COOH-TERMINAL APP DERIVATIVE IN TRANSFECTED 293 CELLS HAS THE AMYLOID B-PROTEIN AT ITS AMINO TERMINUS. <u>I.</u> Cheung', M. Shoji, J. Ghizo'', S. Estus. T. Golde, S. Gandy''', P. Greengard''', B. Frangione'', and S. G. Younkin. Case Western Reserve University, Cleveland, OH 44106; "NY Univ. NY, NY 10012; "'The Rockefeller University, NY, NY

The 39-43 residue amyloid ß protein (βAP) deposited in Alzheimer's disease is derived from membrane-associated glycoproteins referred to as the amyloid ß protein precursor (APP). Using antisera to the COOH-terminus of the APP, we previously isolated a set of 8-12 kD proteins from human brain and embryonic kidney 293 cells, employed augmentation after transfection and pulse chase studies to show that all of the proteins in this set are authentic APP derivatives, and performed epitope mapping to obtain strong evidence that the largest (~11.4 and ~11.8 kD) proteins in this set are authentic APP derivatives, and performed epitope mapping to obtain strong evidence that the largest (~11.4 and ~11.8 kD) proteins in this set are potentially amyloidogenic COOH-terminal derivatives that have the entire BAP at or near their NH2-terminus (Estus et al., Science, 255,726,1992). To better identify the cleavage that produces the ~11.4 kD βAP-bearing derivative, we radiolabelled 293 cells transfected with a βAPP<sub>695</sub> expression construct with <sup>35</sup>S-Met and <sup>3</sup>H-Phe, immunoprecipitated with 369 (anti-βAPP<sub>645-694</sub>), separated the radiolabeled proteins by 10/16% tristricine SDS/PAGE, transferred to immobilon, and sequenced. To validate this method, the major ~8.7 kD COOH-terminal derivative isolated with the ~11.4 kD fragment was sequenced, shown to begin at βAP<sub>17</sub> as previously reported (Esch et al., Science 248, 1122,1990), and <sup>3</sup>H Phe and <sup>35</sup>S-Met were recovered only at the appropriate cycles. Although only a small fraction of the cpm in the isolated 11.4 kD protein were recovered in the sequination of the cpm in the isolated 11.4 kD protein were recovered in the sequination of the cpm in the solated 11.4 kD protein were recovered in the sequination of the cpm in the solated 11.4 kD protein were recovered in the sequination of the cpm in the solated 11.4 kD protein were recovered in the sequination of the cpm in the solated 11.4 kD protein were recovered in the sequination of the cpm in the solated 11.4 kD protein were rec

B/A4 FROM DIFFUSE PLAQUE AMYLOID IS CLOSELY SIMILAR TO COMPACTED PLAQUE AMYLOID. S.J. Frucht, D.A. Teplow, D.I. Selkoe, E.H. Koo\*. Harvard Medical School and Brigham and Women's Hospital, Boston, MA

Diffuse \( \beta\)-amyloid plaques are believed to be an early stage in senile plaque evolution. We have biochemically characterized diffuse plaques from cerebellum in AD cases and from cortices of AD and aged individuals with abundant diffuse plaques but lacking senile plaques or significant vascular amyloid. On centrifugation, diffuse plaque material requires much higher speeds to pellet than compacted cores and fractionates differently on sucrose density gradients. In a slot blot immunoassay, diffuse plaque amyloid and isolated compacted amyloid cores are virtually identical as regards to their sensitivities to a variety of proteases and chaotropic agents. Following SDS extraction and formic acid solubilization, cortical and cerebellar diffuse plaque amyloid migrates as a '4 kDa doublet. Moreover, partially purified diffuse plaque amyloid reacts specifically with a variety of \( \beta\)/A4 antibodies. Homogenates from AD cases with both diffuse and compacted plaques show the same '4 kDa doublet and a prominent '16 kDa tetrameric form. Whereas a tetrameric form of \( \beta\)/A4 is occasionally detected in the diffuse plaque material, we have been unable to demonstrate longer APP-derived fragments using antibodies directed to regions N- or C-terminal to the \( \beta\)/A4 domain. Our results to date suggest that although diffuse plaques are morphologically different from senile plaques, their biochemical properties and major amyloid protein species are closely similar.

SITE PROTECTED, CATIONIZED MONOCLONAL ANTIBODY AGAINST BETA AMYLOID AS A POTENTIAL DIAGNOSTIC IMAGING TECHNIQUE FOR ALZHEIMER'S DISEASE. U. Bickel, V.M.-Y. Lee, J.O. Trojanowski, and W.M. Pardridge\*. Departments of Medicine and Neurology and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA, 90024, and The University of Pennsylvania School of Medicine, Philadelphia, PA, 19104. While cerebrovascular amyloid and senile plaques containing beta amyloid ( $\beta$ A4) are widely accepted as the most consistent morphological markers of senile dementia of Alzheimer's type (SDAT), the only positive ante mortem diagnosis available to date is by brain binosy. One annoach

While cerebrovascular amyloid and senile plaques containing beta amyloid ( $\beta A4$ ) are widely accepted as the most consistent morphological markers of senile dementia of Alzheimer's type (SDAT), the only positive ante mortem diagnosis available to date is by brain biopsy. One approach to a diagnostic test for cerebral amyloid would be the application of radiolabeled antibodies and an imaging technique such as single photon emission tomography. However, it is first necessary to enable the antibody to pass through the blood-brain barrier, which generally is intact in SDAT. Cationization has recently been shown to profoundly enhance brain uptake of immunoglobulin G (Triguero et al, P.N.A.S. 86, 4761, 1989).

In the present study, a well-defined monoclonal antibody, AMY33 (Stern et al, Am. J. Pathol. 134:973, 1989), raised against a synthetic \( \beta A4 \) peptide, was used. AMY33 IgG was affinity purified from mouse ascites on protein G-Sepharose. Site protected cationization in the presence of a molar excess of synthetic \( \beta A4 \) was performed using hexamethylenediamine and carbodi-imide, followed by gel chromatographic purification at acid pH to remove \( \beta A4 \) peptide. Isoelectric focusing proved that the pI of cationized AMY33 was shifted from 7 to 9. Retained affinity of the cationized antibody to \( \beta A4 \) peptide was demonstrated with ELISA. In immunocytochemistry on SDAT brain sections the modified antibody still recognized cerebrovascular and plaque amyloid. \( \frac{12}{1} - 1 \) labeled cationized AMY33 is taken up by isolated bovine brain capillaries in vitro and can now be evaluated in vivo for its ability to detect amyloid deposits.

LAMINAR AND SIZE DISTRIBUTION OF SENILE PLAQUES IN AD, CRITICAL CORONARY ARTERY DISEASE (cCAD) AND NORMAL CONTROLS.

D. Larry Sparks\* and Huaichen Liu. UKMC Lexington KY 40536-0230

D. Larry Sparks\* and Huaichen Liu. UKMC Lexington KY 40536-0230
We have previously reported the enhanced prevalence of senile plaques
(SP) in non-demented individuals with cCAD compared to age-matched nondemented non-heart disease (non-HD) controls. Furthermore, we have found
an age-related increase in the occurrence of SP in both cCAD and non-HD
individuals, although it is shifted to younger ages in cCAD by approximately 40
years. The youngest cCAD patient exhibiting cortical SP was 26 years of age.
Previous studies in AD patients have shown increased numbers of SP in
superficial layers of cortex (I-III) compared to deep layers (IV-VI) with larger SP
being found in layers II,III and V. We have investigated the density, and size
and laminar distribution of SP in young and old AD, cCAD and non-HD subjects.
Utilizing automated image analysis (Kontron) and manual counting methods we
have accessed SP in frontal pole stained by the Bielschowsky method from 12 have accessed SP in frontal pole stained by the Bielschowsky method from 12 AD, 12 cCAD and 11 non-HD individuals. All of the individuals investigated exhibited SP in frontal pole, which predicated their selection. In each case, three columns of non-overlaping images perpendicular to both the pia and the white matter were analyzed for the full thickness of the cortical mantle. Each individual Kontron image measured 537.9 µm in width by 616.4 µm in depth.

individual Kontron image measured 537.9  $\mu$ m in width by 616.4  $\mu$ m in depth. An age-related decrease in the depth of the cortex was found in the cCAD and non-HD subjects, and SP tended to be larger in the young cCAD and non-HD subjects. Except for the increased number of SP in AD (p < 0.001), there were no significant differences among the elderly groups. In the younger groups, SP density in cCAD was between AD and non-HD. In all three groups, SP density was greatest in the superficial cortical layers, predominently layers II and III. SP size was determined between 200 (the lower limit cut off) and 10200  $\mu$ m<sup>2</sup> in 500  $\mu$ m<sup>2</sup> increments, where >90% of the SP were between 200 and 2700 µm² in all groups and in all layers of cortex. Increased numbers of large SP in cCAD and non-HD may reflect the prevalence of the diffuse form.

ALZHEIMER AMYLOID PRECURSOR PROTEIN CAN BE RELEASED FROM HIPPOCAMPAL SLICES IN VITRO. Steven A. Farber, Roger M. Nitsch and Richard J. Wurtman. Dept. of Brain and Cognitive Sciences, M.I.T. Cambridge, MA 02139, and Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Abnormal processing of the amyloid precursor protein (APP) is a central event in the formation of the amyloid deposits in Alzheimer's disease brain. APP is a membrane glycoprotein which can either be secreted or internalized and degraded by lysosomal proteolysis. We have shown that APP secretion in transfected cell lines is stimulated by activation of cellsurface neurotransmitter receptors (Nitsch, R.M. et al., this meeting). To examine the physiological relevance of this finding, we tested the examine the physiological relevance of this intollig, we tested they hypothesis that APP processing can be affected by neuronal activity. Hippocampal slices from adult rats (6-8 months) were prepared at 4°C, and equilibrated in specially designed superfusion chambers (50min, 37°C) with oxygenated artificial CSF (0.8ml/min). The slices were then stimulated electrically (30Hz, 0.5A/cm², 1ms pulse duration) for 50min; APP in the superfusate was purified using ultrafiltration and dialysis, and measured by densitometric Western blot analysis (mAb 22C11). Electrical stimulation caused a significant 2-fold increase in APP release (p<0.01, n=10 rats per group) as compared to unstimulated controls in parallel chambers. This increase in APP release was proportionate to stimulation frequency in the range of 0, 10, 20, and 30 Hz. These data show for the first time that APP is released from hippocampus *in vitro*, and that release can be increased by neuronal depolarization. They thus suggest that APP processing in the brain is regulated by neuronal activity. Supported by NIMH, NIA and the Center of Brain Sciences and Metabolism Charitable Trust.

ULTRASTRUCTURAL LOCALIZATION OF COMPLEMENT PROTEINS TO NEURONAL MEMBRANES AND \$-ANYLOID PEPTIDE CONTAINING ALZHEIMER'S DISEASE PATHOLOGY. S.D. Webster\*, L.-F. Lue, M. McKinley, and J. Rogers. Health Research Institute, Sun City, Arizona 85351.

At the light microscopic level, proteins of the classical complement pathway have been demonstrated to co-localize with neuritic plaques, neurofibrillary tangles, and neuropil with neuritic plaques, neurofibrillary tangles, and neuropil threads in Alzheimer's disease (AD) brain tissue. However, ultrastructural studies are important in demonstrating a functional role of complement cytolytic processes in AD pathogenesis. AD and control brain tissue was processed according to standard immunocytochemical techniques for Clectron microscopic examination, and antibodies recognizing Clq, C3d, C4d, and C5b-9 (the membrane attack complex) were visualized by colloidal gold labelling. Complement immunoreactivity was observed at sites of AD pathology on elements with the ultrastructural characteristics of meetings. elements with the ultrastructural characteristics of myelinated and nonmyelinated neuronal processes, many of which had degenerative morphology. These findings may be relevant to degenerative morphology. the generalized neuronal and neuritic loss characteristic of AD.

TRANSMITTER- AND PHF-IMMUNOLABELED DYSTROPHIC NEURITES ARE NOT SEEN IN OTHER NEURODEGENERATIVE DISEASES EXCEPT IN THE PRESENCE OF  $\beta$ -AMYLOID DEPOSITION. W.C. Benzing, E.J. Mufson and D.M. Armstrong. FGIN, Georgetown Univ., Washington, D.C. 20007 and Rush, Prob, St. Luke Med. Ctr., Chicago, II. 60612.

We sought to determine whether the dystrophic neurites which we observed

related to senile plaques in patients with Alzheimer's disease (AD) were in fact unique to AD or whether they were characteristic of a more generalized process of neurodegeneration. To accomplish this, we examined the brains of cases with Parkinson's disease (PD), PD with concurrent AD (PD-AD), PD that were demented but not with concurrent AD (PD-DEM), Huntington's disease (HD), and Pick's disease and compared these various cases to normal controls and AD cases using antibodies directed against tyrosine hydroxylase, substance P, neurotensin somatostatin, amyloid- $\beta$  protein (A $\beta$ P), and paired helical filaments.

Additionally, all tissue sections were counterstained with thioflavine-S. Inclusive within our tissue sections was the basal ganglia, basal forebrain, amygdala, entorhinal, temporal, and insular cortices. Within these various brain regions we found that immunolabeled dystrophic neurites, characteristic of AD, were seen only in regions where  $A\beta P$  deposition was present. These observations held true even in areas known to display severe degenerative changes such as the caudate in the HD cases and the temporal cortex in the Pick's, as well as severe afferent degeneration such as the caudate and putamen in all three PD groups. While these findings did not rule out that other forms of neuritic degeneration were accompanying the degeneration seen in these latter diseases, it did suggest that the enlarged immunolabeled neurites so frequently observed in AD brains are unique to regions of senile plaque formation and probably are forming in response to ßamyloid deposition.

HIGH CONCENTRATIONS OF ALUMINUM OR IRON PROMOTE AGGREGATION OF HUMAN B-AMYLOID

P.W. Mantyh, J.R. Ghilardi, C.J. Allen, E.R. Stimson, J.E. Maggio , Mol. Neurobio. Lab (151) VA Med. Cntr., Mpls., MN 55417; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115

The salient pathological feature of Alzheimer disease (AD) is the presence of a high density of amyloid plaques in the brain tissue of victims. The plaques are predominantly composed of human B-amyloid peptide (BA4), a 40-mer whose neurotoxicity may be related to its aggregation. Aluminum is a proposed risk factor in the etiology of AD, but the mechanism by which aluminum or other metals exert their effects remain unclear. Radioiodinated human BA4 was used to assess the effects metals had in inhibiting or promoting ßA4 aggregation. Whereas 0.001M calcium, cobalt, copper, manganese or EDTA had no effect on BA4 aggregation, at the same concentration, aluminum and iron strongly promote BA4 aggregation. These results demonstrate that high concentrations of aluminum and iron promote BA4 aggregation, and suggests a mechanism by which aluminum and iron may play a role in the pathogenesis of AD. Supported by the NIH and the VA.

COMPLEMENT CASCADE INHIBITORS IN ALZHEIMER'S

COMPLEMENT CASCADE INHIBITORS IN ALZHEIMER'S DISEASE. I. Schultz\* L.-F. Lue, L. Brachova, J. Rogers, and W.H. Civin. Sun Health Research Institute, Sun City, AZ 85372.

We and others have reported profuse expression of classical pathway complement proteins in Alzheimer's disease (AD) but not nondemented elderly (ND) brain. These proteins are highly co-localized with  $\beta$ -amyloid peptide ( $\beta$ -AP) containing AD pathology. We have also demonstrated that  $\beta$ -AP may be pathology. We have also demonstrated that  $\beta$ -AP may be capable of activating the classical pathway directly, without the usual mediation of Ig. In the periphery, non-Ig mediated complement activation by isolated peptides is handled by Cl inhibitor (Cl INH). Utilizing Western blot analysis, ELISA, and immunohistochemical techniques we have determined that Cl INH levels do not differ in AD and ND patient sera, and that Cl INH is not present in brain. The absence of Cl INH in AD brain would strongly favor non-Ig mediated complement activation by  $\beta$ -AP. as well as activation by serum amyloid P, another protein would strongly lavor non-ig mediated composition.  $\beta$ -AP, as well as activation by serum anyloid P, another protein known to be co-localized with AD pathology and known to activate complement without Ig mediation. Once complement activate complement without ig mediation. Once complement activation has occurred, cells under attack may increase expression of complement inhibitory mechanisms. Our studies show that C4 binding protein, which mediates one such mechanism, is immunohistochemically co-localized with neuritic plaques, neurofibrillary tangles, and neuropil threads in the AD party of the complement of the co brain. These studies therefore may help explain how  $\beta$ -AP is able to activate complement in the AD brain without Ig mediation, as well as provide evidence that such activation is of sufficient pathologic significance as to warrant the mounting of complement cascade inhibitory mechanisms.

Reduced Levels of Secreted Amyloid  $\beta$ -Protein

Precursor in CSF of Pathologically Confirmed Alzheimer's Disease Patients

Reduced Levels of Secreted Amyloid β-Protein Precursor in CSF of Pathologically Confirmed Alzheimer's Disease Patients. Wagner, S.L.¹, Read, S.L.², Van Nostrand, W.E.³, Cunningham, D.D.³, Peskind, E.⁴, Davis, K.L.², Perl, D.⁵, Ryan, T.⁵, Ghetti, B.⁴, Benson, M.D.⁴, Farlow, M.⁶ and Vinters, H.V.²

'Department of Pathology, UCLA Medical Center, Los Angeles, CA.

Pathologically, Alzheimer's disease (AD) is characterized by deposition of amyloidotic material in both the cerebral vasculature and bearenchyma of the brain. Using a highly specific monoclonal antibody (mApp2-1) raised against native human PN-2, which cross-reacts with all secreted AβPP in seven patients diagnosed as probable AD who have since expired and were pathologically confirmed as having AD. In addition, we analyzed CSF for secreted AβPP levels in four live probable AD patients who were neuropathologically confirmed as having AD in addition, we analyzed CSF for secreted AβPP levels in three individuals with a single amino acid substitution (Phe for Val) in the transmembrane domain of the AβPP. All patients who were clinically symptomatic for AD and histopathologically shown to contain senile plaques in conjunction with moderate to severe cerebral amyloid angiopathy (CAA) had at least two to three fold lower secreted AβPP levels in three individuals with a single way to the secreted AβPP levels in the CSF (x=0.7 ± 0.4 μg/ml) Han did then on-AD control patients (x=3.5 ± 0.4 μg/ml) AD patients either without or with only sparse CAA had slightly h

ALZHEIMER AMYLOID PRECURSOR FORMS AND A4/B PROTEIN IN MICROVESSELS ISOLATED FROM HUMAN BRAIN. R. N. Kalaria\*, S. N. Kroon and I. Lieberburg. Dept. of Neurology, CWRU Sch Med, Cleveland, OH 44106 & Athena Neurosciences, S. San Francisco, CA 94080. The amyloid A4/B protein involved in Alzheimer's disease and Down

syndrome is derived from a membrane associated precursor protein (APP). It is not known how amyloid deposits in the vasculature which is commonly involved in the pathology of these diseases. It is also not clear whether vascular APP processing is independent from that in senile plaques. To address these issues, we have used relatively simple in vitro studies employing immunochemical methods on isolated cerebral microvessel (CMV) fractions containing mainly capillaries obtained postmortem from cortex of AD subjects and aged controls. Using antibodies to various domains of APP and to ß protein we found that the full length APP and its smaller fragments and B protein are readily detectable in solubilized fractions of CMV from AD subjects. Immunocytochemical studies on isolated CMV preparations showed anti-B protein reactive deposits along the vessel length. However, larger vessels with smooth muscle showed typical concentric deposits described previously. To demonstrate the localization of  $\beta$  protein deposits and whether they could be removed by digesting the basement membrane (BM), we pretreated CMV with collagenase (0.1-1%; 1 hr at 37°C). These treatments showed that ß protein immunoreactivity was largely removed, however, there was distinct appearance of a 5-6 kD fragment evident with antibodies to the carboxyl terminal of APP containing the ß protein domain. These experiments suggest that the vascular BM is inherently involved in amyloid deposition and that in addition to larger arterioles with smooth muscle cerebral capillaries readily metabolize APP and also contain amyloid deposits.

EVIDENCE FOR IN VITRO AND IN VIVO REGULATION OF CYTOKINES BY THYROTROPIN RELEASING HORMONE (TRH).

D.V. Harbour\*, M.Jyoti, W.L.Kang. Dept HBC&G, UTMB, Galveston, TX 77550.

We studied effects of TRH on the release of Interferon (IFN) gramma and Interlowkin (IL) 22

We studied effects of TRH on the release of Interferon (IFN)-gamma and Interleukin (IL)-2. IL-2 and IFN- were significantly increased by human PBLs and Molt 4 T-cells after treatment with TRH but not mock alone. Both effects could be abbrogated by pretreatment with antisera to IFN-. The mRNA levels for IL-2 rose 2-4 fold after 4-6 hours TRH treatment then declined. The TRH induced IFN had antiviral activity of up to  $100 \text{ U/}\mu\text{L}$ . To test the in vivo relevance of this data, we performed in vivo TRH induction tests on Balb/c mice. The mice were normal (N). The mice were normal (HY) Balb/c mice. Balb/c mice. The mice were normal (N), hypothyroid (HO), hyperthyroid (HY) or thymectomized [TMX (lowered T cell number)]. The TSH RIA levels verified that the TRH tests were working. Spleen mRNA levels for IL-2 from the HO mice was stable and 2-3 fold higher than N; but, HY mRNA was less than half of the N mRNA level. Immunofluorescent (IF) studies correlated with  $\underline{\text{in}}$   $\underline{\text{vivo}}$  serum levels. Monoclonal abs to IL-2 and IFN- , showed a significant reduction of IL-2, and IFN- from N spleen cells from time 0 to 60 minutes. The HO mice showed very high basal levels of IL-2 and IFN- and declined after treatment with TRH. The HY mice showed no IF. minutes.

INTERLEUKIN-18 INDUCES THE RELEASE HYDROXYINDOLEACETIC ACID (5-HIAA) FROM THE HYPOTHALAMUS IN VIVO P.S. Mohankumar, S. Thyagarajan and S.K. Ouadri\*. Neuroendocrine Research Laboratory, Kansas State University, Manhattan, KS 66506.

Interleukin-1ß (IL-1ß), a lymphokine, stimulates the release of hypothalamic and pituitary hormones. The mechanism of this action is not clear. There is evidence that the effects of IL-1B on the neuroendocrine system are mediated through neurotransmitters. We have shown before that IL-1B stimulates the release of norepinephrine and dopamine from the hypothalamus (HT) both in vitro and in vivo. Recently, it has been reported that interleukin increases the extracellular levels of 5-HIAA in the HT. Except for this study, there are no reports on the effects of IL-1B on the indoleamine metabolism. In the present study, we investigated the effects of IL-1B on the release of 5-HIAA from the arcuateventromedial area (ARC-VMN) of the HT using push-pull perfusion technique. Push-pull cannulae were implanted stereotaxically in the ARC-VMN of adult male The hypothalamic nuclei were infused through the cannulae with 100 ng, 50 ng, 25 ng of IL-18 or the vehicle (PBS-BSA). The perfusate samples were analyzed for 5-HIAA using HPLC. There were no differences in the pre-treatment release of 5-HIAA among the various groups. In the groups treated with 100 ng and 50 ng of IL-1B, the average release of 5-HIAA during the post-treatment period increased significantly (220% and 47% respectively) compared to the pre-treatment release (p<0.001). There was no significant change in the release of 5-HIAA in the control and 25 ng IL-1ß treated groups in the post-treatment period. In the group treated with 100 ng of IL-18, 5-HIAA release increased significantly within 25 minutes and continued to increase even after 325 minutes (p<0.05). In the 50 ng IL-18 treated group 5-HIAA release increased within 25 minutes (14%) but decreased the pre-treatment levels within 50 minutes (p<0.05). This data suggest that IL-1ß has significant effects on the indoleamine metabolism of the hypothalamus.

### 326.2

MORPHINE ATTENUATES INTERLEUKIN-1 ACTIVATION OF C-FOS EXPRESSION IN THE RAT HYPOTHALAMUS. S.L. Chang 1\*, T.T. Taol, J. Zadina<sup>3</sup> and J. Thompson<sup>2</sup>. Dept. of Physiology, Dept. of MIP, Louisiana State Univ. Med. Ctr., JVA Med. Ctr. and Tulane Med. Center, New Orleans, LA. 70119. Interleukin-1 (IL-1) is now known to be synthesized by

neuronal cells. IL-1 receptors have been shown to occur throughout the rat brain. Several studies have suggested overlapping effects of opioid and IL-1 in CNS. In the present studies, we examined IL-l regulation of c-FoS expression; morphine attenuates this regulation. The c-fos mRNA concentration of rat hypothalamus was elevated  $^{\sim}$  100% (p  $^{<}$ 0.05) 30 min after direct intracerebroventricular (ICV) injection of IL-l $\alpha$  (200 ng) and returned to near the control level 60 min after the injection. In a parallel study, the cannulated rats were grouped randomly to receive either IL- $1\alpha$  (200 ng), IL- $1\beta$  (200 ng), control vehicle (100 mM Tris pH 7.6, 1% BSA) or nothing through cannulation for 3 hrs. At the end of treatment, the rats were perfused for immunocytochemistry of FOS protein. The FOS immunoreactivity was markedly increased by both IL-l $\alpha$  and IL-l $\beta$  in the paraventricular nucleus (PVN) and arcuate nucleus (ARC) of the hypothalamus. In a second parallel study, chronic morphine pelleting appeared to prevent  $IL-l\alpha$  activation of c-fos mRNA in the hypothalamus. These data suggest that CNS action of IL-1 on the hypothalamuspituitary adrenal axis may work through the regulation of FOS protein and morphine exposure attenuates this regula-tion.

## 326.4

EXCITATORY AMINO ACID INVOLVEMENT IN THE INTERLEUKIN 18 AND TACHYKININ-INDUCED EFFECTS ON LH RELEASE IN CASTRATED MALE RATS. J.J. Bonavera, S.P. Kalra and P.S. Kalra\*, Department of Obstetrics and Gynecology, University of Florida College of Medicine, Gainesville, FL 32610 Evidence suggests that cytokines and tachykinins may interact to

modulate neuroendocrine responses. Interleukin-1β (IL-1β) and the tachykinin, neuropeptide K (NPK), have been shown to markedly suppress LH release in gonadectomized rats. Since N-methyl-D-aspartic acid (NMDA) is excitatory to LH secretion, we tested the hypothesis that IL-1β and NPK-induced LH suppression may be due to diminution in the action of this excitatory signal. Adult male rats were castrated and implanted with permanent indwelling cannulae in the third cerebral ventricle. Two weeks later rats were injected with either saline (control, 3 μl), IL-1β (100 ng/3μl saline) or NPK (2.5 nmol/3 μl saline) intracerebroventricularly at time '0' min. Each of these treatments was followed by four iv injections of NMDA (5 mg/kg body wt.) or saline at 0, 30, 60 and 90 mins. Blood samples were withdrawn for LH analysis at different intervals from an indwelling intra-atrial cannula for 120 mins. NMDA treatment alone did not alter LH levels in control castrated rats, whereas both IL-1\$ and NPK markedly suppressed LH release starting at 70 and 30 mins post-injection, respectively. Treatment of IL-1β- and NPKinjected rats with NMDA completely prevented this LH suppression. These results are suggestive of a commonality of neural pathways in the inhibitory effects of hypothalamic cytokines and tachykinins involving an excitatory NMDA receptor. (Supported by NIH HD 11362).

TWENTY-FOUR-HOUR CIRCADIAN RHYTHMS OF CIRCULATING INTERLEUKIN-1a IN HEALTHY FEMALE VOLUNTEERS. J. Licinio\*. M. Wong. M. Altemus. L. Tamarkin. P.W. Gold. Clinical Neuroendocrinology Branch, NIMH Intramural Research Program, Bldg. 10/3S231, Bethesda, MD 20892.

Interleukin-1a (IL-1a) is pleiotropic cytokine released by various cells in response to inflammation and stress. Even though it is widely known that IL-1a acts locally at multiple sites, including the brain, it is still uncertain whether IL- $1\alpha$  is a classical hormone, circulating systemically. We have tried to elucidate this point by measuring circadian rhythms of IL- $1\alpha$  plasma levels. **Methods:** 6 female healthy volunteers (ages 18-35) were admitted to the NIH Clinical Center for 48 hours. After one night acclimatization, we conducted a 24-hour blood collection at 15min intervals. Plasma was assayed by enzyme-linked immunoassay (Assay Research, Inc., College Park, MD), with a limit of detection of 25 pg/ml (intra-assay C.V.=7%, inter-assay C.V.=17%). Results: All subjects had detectable levels of IL-1α through the 24-hour period. A pulse analysis reveals that IL-1α levels seem to have discrete peaks and circadian variation. The integrated 24-hour IL-1α levels were 3.11.7±0.65 (mean±SEM) µg.ml-1.24-hours-1, with a range of 4.40 (1.55 min., 5.95, max.). Implications: Our data show that IL-1 $\alpha$  is present in the systemic circulation throughout the 24-hour period in healthy females. IL-1a levels exhibit circadian variation, which suggests that this cytokine may be a classical hormone, being secreted in the blood stream, and acting at distant sites, possibly as a key element in the modulation of the response to stress and to inflammation. The source of systemic IL-1a remains to be determined.

KINETIC ANALYSIS OF ADHESION-MOLECULE EXPRESSION IN THE CNS OF EAE MICE. J.M. Dopp 1 and J.A. Olschowka2, Depts. of Microbiology and Immunology<sup>1</sup>, and Neurobiology and Anatomy<sup>2</sup>, University of Rochester School of Medicine and Dentistry, Rochester, NY, 14642.

NN, 14642. Leukocyte migration into the murine CNS increases dramatically during the course of experimental allergic encephalomyelitis (EAE). Leukocytes extravasate out of the bloodstream and into the CNS parenchyma, initiating an inflammatory cascade which leads to paralysis. Extravasation is facilitated by leukocyte expression of adhesion molecules which bind to counterpart ligands on CNS vascular endothelial cells (CVECs). We used immunocytochemistry to analyze leukocyte and CVEC adhesion-molecule expression during EAE. SWXJ mice (n = 3) were injected twice s.c. with an emulsion containing 5 mg CNS homogenate in adjuvant, and thrice i.v. with 3.3 X 10<sup>8</sup> heat-killed Pertussis bacteria. Control mice received identical injections lacking CNS homogenate. 8, 11, and 14 days later, mice were perfused with 4% PF, and sections from brain, spleen, and spinal cord were stained for intercellular adhesion molecule-1 (ICAM-1), and leukocyte-endothelial cell adhesion molecule-1 (LECAM-1), and leukocyte markers.

leukocyte-endothelial cell adhesion molecule-1 (LECAM-1), and leukocyte markers.

A low constitutive level of CVEC ICAM-1 expression in major CNS vessels was upregulated on days 11 and 14 in EAE mice. ICAM-1 was also expressed by CVECs of smaller capillaries and la+/GFAP-1 glial cells in EAE mice. LECAM-1 expression by neutrophils in the choroid plexus of control mice was faint and scattered at all timepoints, while EAE mice showed foct of intensely-staining neutrophils in the choroid plexus, as well as perivascular staining around major vessels on all days. ICAM-1 and LECAM-1 expression preceded clinical symptoms and was likely integral in initiating CNS inflammation. Ongoing experiments involve the analysis of additional adhesion molecules, cell markers, and cytokines using this model.

Supported by PHS grant NS29400.

THE ESTABLISHMENT OF A LATENT HSV-1 INFECTION IN THE CENTRAL NERVOUS SYSTEM REQUIRES A FUNCTIONAL IMMUNE RESPONSE. G. A. Lewandowski<sup>1\*</sup> D. Lo<sup>2</sup> and F. E. Bloom <sup>1</sup>. Departments of <sup>1</sup>Neuropharmacology

and <sup>2</sup>Immunology, The Scripps Research Institute, La Jolla, CA 92037.
Following intra-ocular injection, HSV-1 (strains F and KOS) enters the CNS through classical visual synaptic connections to the lateral geniculate and superior colliculus. After infecting neurons in these primary ocular targets, strain F established a latent infection by 6-7 days post-infection, while the KOS strain invariably produced lethal infections. Through immunohistochemical analysis of the CNS using antibodies to antigens including HSV-1, CD4, CD8, Mac-1, F480 and 1-CNS using antibodies to antigens including HSV-1, CD4, CD8, Mac-1, F480 and I-E (MHC class II), we have found that the response of the CNS to the presence of HSV-1 includes and goes beyond a general inflammatory response. The inflammatory response is characterized by the infiltration of macrophages and activation of resident microglia in the regions of virus infection. In addition, following either KOS or F infection of the CNS, CD4+ and CD8+ lymphocytes were specifically recruited to the sites of viral infection. While MHC class II protein synthesis was induced in antigen presenting cells during both the productive (KOS) and latent (F) infections, a striking difference in the I-E antigen expression was observed. In the KOS viral infection centers the MHC class II antigen was primarily expressed in the cvtoolsam/funcleus of the microplia and macrophages. By constract expressed in the cytoplasm/nucleus of the microglia and macrophages. By constrast, during the establishment of a latent infection the MHC class II antigen was expressed at the cell surface of the antigen presenting cells. These data suggest that the antigen presentation step in the immune response is interrupted during a KOS infection, but not during the F infection. Thus, it is quite likely that the full cascade of the T-cell mediated immune response to virus is require to establish a latent viral infection in neuronal cells.

TRANSGENIC EXPRESSION OF IFN-7 IN MURINE CNS. T. Renno, J. Antel\*, R. Sekaly and T. Owens. Montreal Neurol. Inst. and IRCM, McGill Univ., Montreal, Canada H3A 2B4. IFN-γ has been implicated in the induction of diabetes and EAE

in mice. To determine the effect of IFN-y expression in the CNS, we have produced (C3H X C57BL/6) transgenic mice using a DNA construct that contained mouse IFN-y cDNA, with the MBP promoter. This promoter had been shown to direct expression to oligodendrocytes in vivo. Transfection of our construct into an oligodendrocytes (11 WW). Haustection of our constitute time an oligodendrocyte cell line induced secretion of biologically active IFN-\(\gamma\). Of eight transgenic founders, only one showed IFN-\(\gamma\) RNA expression in the CNS. IFN-\(\gamma\) message was expressed in the CNS at levels comparable to those found in mice with severe EAE, whereas CNS from non-transgenic littermates showed no IFN-\(\gamma\) message. Expression in the spinal cord was significantly higher than in the brain. Expression of IFN-y in non-CNS tissue was comparable to that in normal mice. Mice from this transgenic comparable to that in normal mice. Mice from this transgenic line have been observed for several months and have not revealed neurological symptoms even at peak ages for EAE susceptibility or for development of IFN-γ-induced diabetes, neither has histological evaluation of CNS tissue showed significant abnormalities. Therefore, unlike studies in which IFN-γ was transgenically expressed in the pancreas, transgenic expression of IFN-γ in the CNS was not sufficient to produce autoimmune disease. We are currently backcrossing our mice to the EAE-susceptible strain, SJL/J, and also generating homozygous transgenics, to further define the role of IFN-γ in neurological autoimmune disease. neurological autoimmune disease.

### 326.8

CD4 EXPRESSION IN MOUSE AND HUMAN BRAIN. B. Pessac\*, B. Omri, F. Alliot, P. Crisanti, M.C. Marty, I. Rutin, and A. Privat. Centre de Biologie Cellulaire C.N.R.S., 67 rue Maurice Günsbourg, 94205 IVRY cedex, FRANCE.

FRANCE.

CD4 and its mouse equivalent L3T4 are members of the immunoglobulin gene superfamily expressed on the surface of most thymocytes and of a subset of T lymphocytes. We have observed, in the developing and adult mouse brain, a 55 kD molecule indistinguishable in Western blots and in 2D immunoelectrofocusing from the humus L3T4 molecule. In young SCID mice, the L3T4 thymus L3T4 molecule. In young SCID mice, the L3T4 protein is not detected in thymus, but is clearly present in brain. In situ hybridization and immunocytochemical experiments show that the full length L3T4 transcript and the L374 protein are expressed coordinately in neurons throughout the brain and in distinct neural structures including hippocampus, cerebellum and olfactory bulb. In addition, L3T4 immunoreactivity is present in brain small vessel walls, ependymal cells and choroid plexus. We are currently investigating the presence of the CD4 protein in warious regions of post-mortem human brain samples. Western blot show a 55 kD protein immunoreactive to a novel CD4 monoclonal antibody (a gift from A.Bernard, Nice, France) in extracts of distinct human brains. Current immunocytochemical experiments suggest CD4 expression in astrocytes as well as in neurons. (This work was supported by grants from CNRS and ARNS).

PERIPHERAL METABOLIC AND ENDOCRINE RESPONSES INDUCED BY CENTRALLY ADMINISTERED INTERLEUKIN-18 IN THE RAT. R.D. Stith, L. Templer and R.W. Blair\*. Dept. Physiology and Biophysics, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

This study was based on the hypothesis that centrally-acting interleukin- $1\beta$ (IL1) affects peripheral carbohydrate metabolism. Sprague-Dawley rats (275-400 g) were administered 1 uL of IL1 or sterile PBS via a 3rd ventricle cannula. Core body temperature (Tc) was constantly monitored and blood samples were obtained over 360 min from awake, freely moving rats via a jugular cannula implanted two days prior, liver tissue was obtained at the time of death. Peak Tc  $(39.6^{\circ}, 39.3^{\circ}, \text{ and } 38.2^{\circ}; \text{ control}=37.6^{\circ})$  and plasma corticosterone (cort) levels (685, 666, 682 ng/ml; >300% of control) were measured after 15, 25, and 50 ng IL1, respectively. Plasma glucose was elevated in a dose-related manner: the peak of the response (100-105 mg/dL; 125% of control) was earlier (300 min @ 15 ng and 120 min @ 50 ng) and its duration was longer with increasing doses. Hepatic glycogen content was diminished to 50% of control by 15 ng, 40% of control by 25 ng IL1, and to 70% of control by 50 ng. The plasma insulin response to 15 ng IL1 (from 25 uU/ml to 80 uU/ml) paralleled the increase in plasma glucose. After 25 and 50 ng, however, plasma insulin levels remained at control basal levels in the face of elevated plasma glucose. No significant changes in plasma glucagon were observed. When the same doses of IL1 were injected iv, no changes in Tc or plasma cort were found. These data reveal that in addition to fever, anorexia, somnolence, etc., central IL1 induces changes in peripheral metabolism.

INHIBITION OF INTERLEUKIN-1-INDUCED CORTICOTROPIN-RELEASING FACTOR SECRETION BY ALPHA-MELANOCYTE-STIMULATING HORMONE IN <u>VITRO</u>. <u>K. Lyson\*and S.M. McCann</u>. Department of Physiology, UT Southwestern Medical Center, Dallas, TX 75235-9040.

Interleukin-1 (IL-1) and interleukin-6 (IL-6) are potent stimulators of corticotropin-releasing factor (CRF) release from the hypothalamus, which can be responsible for the immunosuppressive effects of centrally administered cytokines. Since we demonstrated that alpha-melanocyte-stimulating hormone ( $\alpha\text{-MSH}$ ), an antipyretic compound in cytokine-mediated fever, could inhibit IL-6-induced CRF release from medial basal hypothalamus (MBH), we examined if such  $\alpha\text{-MSH}$  action applies also to IL-1-induced CRF release. After 60 min preincubation in Krebs-Ringer bicarbonate buffer (KRB), MBHs were incubated for 30 min with KRB or IL-1 and/or  $\alpha\text{-MSH}$  (10<sup>-15</sup> - 10<sup>-11</sup>M). CRF release into the incubation medium was measured by RIA. As reported previously, none of the  $\alpha\text{-MSH}$  concentrations used changed basal CRF release significantly. IL-1 evoked a bell-shaped, dose-dependent increased CRF secretion with a maximal effective dose of 10<sup>-15</sup>M (p<0.025), 100 times lower than that of IL-6, which was significantly suppressed, in a dose-dependent fashion, by  $\alpha\text{-MSH}$  at concentrations of 10<sup>-14</sup> and 10<sup>1-3</sup>M, with the maximal inhibitory effect at 10<sup>-13</sup>M  $\alpha\text{-MSH}$  (p<0.001). The results show that  $\alpha\text{-MSH}$  is a potent inhibitor of IL-1-induced CRF release from the hypothalamus in vitro, which provides another evidence for the central antagonistic action of  $\alpha\text{-MSH}$  against cytokines.

### GENESIS OF NEURONS AND GLIA II

### 327.1

IDENTIFICATION OF A CHICKEN ACHAETE-SCUTE HOMOLOG EXPRESSED IN BRAIN AND RETINA. <u>C.L.Jasoni, M.B. Walker, and T.A.Reh\*</u>. Department of Biological Structure, University of Washington, Seattle, WA 98195.

The achaete-scute genes of Drosophila melanogaster are members of the basic helix-loop-helix (bHLH) family of transcription factors, mammalian members of which include the c-myc proto-oncogene, several muscle determination genes, and mammalian achaete-scute homologs (MASH)-1 and -2. The achaete-scute complex genes, and presumably their vertebrate counterparts, are believed to play a role in the specification of neuronal identity. We employed a degenerate polymerase chain reaction (PCR) strategy to identify a chicken achaete-scute homolog (CASH-1). Fully degenerate PCR primers were designed based on conserved amino acid residues in the basic region and second helix of the bHLH motif. PCR, of random hexamer reverse transcribed total RNA extracted from stage 24 retina, yielded a single band of ≈140bp. Sequence analysis revealed the PCR fragment to be 88% identical to MASH-1 at the nucleotide level and 100% identical at the deduced amino acid level. Northern blot analysis, using cloned CASH-1 PCR fragment as a probe, revealed the presence of an mRNA of 1.4kb. CASH-1 mRNA is expressed in all CNS regions examined forebrain, midbrain, hindbrain, and retina but not in liver and heart. CASH-1 mRNA is expressed from embryonic day 3.5 through E8.5. The pattern and timing of expression of CASH-1 is similar to that found for MASH-1, and the high degree of sequence conservation between MASH-1 and CASH-1, suggests that these molecules have important functions in early neural development. Supported by NSF BNS-9110676.

## 327.3

Cell cycle-specific expression of the neuronal phenotype in an immortal hypothalamic cell line. <u>V. Quiñones-Jenab.</u>, S. Meiners, M. Marone, and H. M. Geller. UMDNJ-Robert Wood Johnson Medical School and The Graduate School, Rutgers University, Piscataway, NJ 08854

The tsV1 cells were derived by infecting E14 mouse hypothalamic cells with a replication defective retroviral construct containing the SV40 tsA58 large T antigen (T-ag). This cell line contains cells with two different morphologies: the vast majority of cells are flat and stellate; and a smaller number are phase-bright, process-bearinground cells. The tsV1 cells express astrocyte-specific markers including: GFAP, S100, and tenascin. When the tsV1 cells enter the mitotic phase of their cell cycle, the flat cells become phasebright and round and in some cases extend process. These cells have condensed chromosomes and also express many typical neuronal proteins, such as: neurofilament (NF) 200, NF-160, NF-68, tau, microtubule associated protein 2 (MAP2), GAP-43, and neuron-Other cells with similar morphology during specific enclase. mitosis, such as HeLa and C6 cell lines, did not express any of these neuronal markers. This would suggest that the tsV1 cell line may be a neuro-glial precursor expressing different phenotypes during the cell cycle. Alternately, these proteins may have a functional role in mitosis. We believe that this system is a good model to understand the control of cell fate, mitosis and maturation of hypothalamic glial and neuronal cells. Supported in part by NIH PO1 NS 21469.

### 327.2

ANALYSIS OF A DROSOPHILA GENE CLUSTER EXPRESSED DURING CNS DEVELOPMENT S.D.Zhang. D.Mellerick-Dressler. H.Gainer \* W.Odenwald and J.Kassis \* Lab. of Neurochemistry, NINDS, NIH and \* Ctr. for Biologics Evaluation and Research, FDA, Bethesda, MD 20892

Enhancer-detection screening has led to the discovery of two closely spaced Drosophila genes, *castor* and *pollux*, that are expressed in the developing CNS. The two genes, separated by 99 bp, are located at the chromosomal subdivision 83c and are transcribed in converging directions.

castor encodes a putative transcription factor containing an acidic domain, multiple homopolymeric amino acid stretches and four linked TFIIIA like zinc fingers. Its expression is restricted to a subset of CNS neuroblasts and to ventral midline glial precursor cells during the intermediate stages of neurogenesis. The expression pattern of the segmentation gene engrailed is altered in the CNS of castor null mutant embryos, suggesting that castor is required for the proper differentiation of a subset of neuronal precursor cells.

DNA sequence analysis of *pollux* indicates that it encodes a leucine-rich protein, containing a putative leucine zipper motif. *pollux* transcripts are detected in oocyte nurse cells and are ubiquitous in early embryos. Late in embryonic development, *pollux* is expressed in CNS neurons. The analysis of *pollux* mutants will be reported.

## 327.4

IMMORTALIZED STRIATAL AND MESENCEPHALIC CELLS EXPRESS D2-DOPAMINE RECEPTORS AND GAD<sub>67</sub>. D. C. Chugani\*, J. Segovia, A. J. Tobin, M. Mahmoudi, H. Roseboro, UCLA Departments of Radiological Sciences and Biology and The Brain Research Institute Los Angeles, CA 90024

Brain Research Institute, Los Angeles, CA 90024
We have produced reversibly immortalized cells from embryonic day 10 rat mesencephalon and striatum using a retroviral vector containing the genes for temperature sensitive large T antigen of SV40 and neomycin resistance (G418) (obtained from R. McKay, MIT). Following selection in G418, surviving cells were cloned by dilution and grown at 33°C. At 39°C the cells stopped dividing, but displayed fibroblast-like morphology. Addition of bFGF, BDNF or NT3 together with IBMX and db-cAMP resulted in differentiation of cells into neuron-like morphology. Cell lines expressing neuronal morphology were screened under different growth conditions by both immunocytochemistry and PCR for brain cell markers and for neurotransmitter receptors and synthetic enzymes. We have identified six cell lines that express the neuron specific immunochemical markers, neuron specific enolase and neurofilament 68. These cells were screened by PCR for the D2 dopamine receptor and the GABA synthetic enzyme GAD<sub>67</sub>. Three cell lines expressing neuron specific markers were found to contain mRNA for the D2 dopamine receptor and 2 of the cell lines, in addition, contained mRNA for GAD<sub>67</sub>. These cell lines, now provide us with a valuable tool for the study of regulation of the D2 receptor and GAD in response to pharmacological treatments. HUMAN GAP43: MULTIPLE 5'UNTRANSLATED REGIONS AND DISTINCT REGULATION IN NEUROBLASTOMA CELL LINES: E Örtoft\* C Betsholtz, S Påhlman and U Hammerling, Dept of Pathology, University Hospital, S-751 85 Uppsala, Sweden.

The neuronal protein GAP43 is preferentially located in growth cone membranes of the elongating exon. Northern analysis revealed two GAP43 bybridizing bands of 1.4 kb.

analysis revealed two GAP43 hybridizing bands of 1.4 kb and 1.6 kb in human neuroblastoma cell lines. The temporal expression of the two clusters of GAP43 mRNA differed during phorbolester-induced neuronal maturation of SH-SY5Y and LA-N-5 neuroblastoma cells. cDNA clones, encompassing ord LA-N-2 neuroplastoma ceils. CDNA clones, encompassing overlapping stretches of the GAP43 transcribed regions, were isolated from SH-SY5Y cells. No heterogeneity was found in the open reading frame. A genomic clone of circa 1050 bp, overlapping the major transcription initiation sites, was also isolated. By RNase protection several GAP43 transcript species were identified, and two clusters of the least transcript species. of cap sites located circa 200 bp apart were found. The region 5 of the coding sequence was devoid of appropriately positioned consensus TATA- or CAAT-motifs. It is concluded that the synthesis of the larger GAP43 species is explained by alternative initiation of transcription.

### 327.7

HIGH CONCENTRATIONS OF MORPHINE INHIBIT PURKINJE CELL MORPHOGENESIS AND SURVIVAL IN ORGANOTYPIC CULTURES OF THE MOUSE CEREBELLUM. K.F. Hauser\*. Dept. of Anat. and Neurobiol., Univ. Kentucky Sch. of Med., Lexington, KY 40536-0084.

To determine whether opiates can intrinsically affect neuronal maturation in the cerebellum, the effects of morphine on Purkinje cell numbers and dendritic differentiation were examined in developing cerebellar explant cultures Monoclonal antibodies against calbindin-D<sub>28k</sub>, a cell-type-specific marker that labels the axon, soma, and dendrites of Purkinje cells, were used to immunolocalize Purkinje cells in permeabilized, whole-mount explants. Opiatedependent changes in the maturation of calbindin-D<sub>28k</sub>-immunoreactive Purkinje cells were examined in paired, symmetrical (right versus left) organotypic cultures isolated from 1- and 7-day-old cerebella from thirty-six male ICR mice. One explant from each pair was continuously exposed to 10 µM morphine, 10 µM morphine plus 30 μM (\_)-naloxone, or 30 μM (\_)-naloxone alone for 7-10 days in vitro, while the other explant served as a control. Purkinje cells were categorized as immature or mature depending on whether they had primary dendrites. In explants derived from 1-day-old mice, continuous morphine treatment significantly reduced the number of immature Purkinje cells and decreased the total dendritic length of mature Purkinje cells. Both effects were completely blocked by concomitant treatment with naloxone. This suggests that the cellular response to morphine was not a result of generalized toxicity but mediated through specific id receptors. Morphine treatment did not affect the number or dendritic length of Purkinje cells in explants derived from 7-day-old mice. Collectively, the results suggest that at high concentrations opiates can inhibit Purkinje cell morphogenesis and survival in a selective, age-dependent manner. These effects are likely to be mediated through a direct action on endogenous opioid systems within developing cerebellar cultures. Supported by NIDA grant DA 06204

## 327.9

DEVELOPMENTAL PROFILE OF GFAP IN THE RAT BRAIN: INCREASED REGIONAL GFAP FOLLOWING PRENATAL EXPOSURE TO METHYLAZOXYMETHANOL. E. S. Goldey<sup>1</sup>, S. Barone, Jr.<sup>2</sup>, K. M. Crofton<sup>1</sup> and J. P. O'Callaghan\*1. 1 Neurotoxicology Division, U.S. Environmental Protection Agency and <sup>2</sup> ManTech Technologies, RTP, NC 27711.

Reactive gliosis, as evidenced by qualitative and quantitative increases in glial fibrillary acidic protein (GFAP), is a universal response to neural damage of the adult CNS. This same response only rarely has been demonstrated following damage to the fetal or neonatal CNS. Here we examined: 1) the ontogenetic profile of GFAI immunoreactivity and content in specific regions of rat brain from birth to adultho and 2) the temporal and regional profile of GFAP immunoreactivity and content following prenatal exposure to the developmental neurotoxicant methylazoxymeth (MAM). Rats were given a single i.p. injection of saline or MAM (30 mg/kg) on day 15 of gestation. GFAP content was determined in nine brain regions collected from pups on each of postnatal days (PND) 1, 4, 10, 21, and 84. GFAP concentrations increased throughout brain development and reached near adult levels by PND 21. A consistent regional GFAP concentration gradient was revealed (high to low concentration): brain stem > hippocampus > cerebellum = olfactory bulbs = diencephalon = mesencephalon > cerebral cortex > striatum. MAM exposure caused significantly elevated GFAP concentrations compared to controls only in the cortex and hippocampus, regions previously demonstrated to be extensively damaged b MAM. GFAP was significantly elevated in the rostral half of the cortex on PND 1, and by PND 4 rostral cortex, caudal cortex and hippocampus all showed significantly elevated GFAP concentrations relative to controls. In addition, GFAP co were significantly elevated in the cortex samples collected from mature (PND 84) MAM-treated animals. These results provide a profile of the developmental increase. n GFAP in specific brain regions and indicate that neurotoxicant exposure of the fetal CNS induces a rapid and long-lasting elevation of GFAP in the damaged brain regions

A NEW METHOD FOR CULTURING ORGANOTYPIC CEREBELLAR SLICES: MATURATION, GROWTH AND NEURONAL MAPPING USING IMMUNOPEROXIDASE METHOD. D.K. Racker\*, D.J. LaPorte, P.E. Hockberger and J.C. Houk, Dept. of Physiology, Northwestern Univ. Medical School, Chicago, IL 6061

A simplified method for culturing organotypic cerebellar slices (OTCS) is described utilizing glass coverslips and 12 well culture plates, as opposed to collagen gels or plasma clots and Maximow chambers (Seils, Rev. Neurosci., 4:329-3423, 1979) or roller tubes (Gahwiler, Neurosci. Methods, 4:329-342,1981).

Cerebelli of postnatal day 1 Sprague-Dawley rats were parasagitally sectioned into 1 mm segments (Microblades, Fine Science Tools) with the choroid plexus attached. Excised crebelli and slices were kept cold throughout the procedure (Cryoplate, Streck Industries). Slices were allowed to recover in cold medium [40% fetal calf serum, 30% Hanks solution, 30% Dulbecco's modified Eagles medium, 1 mM L-glutamine, 6.6 g/L glucose, 26 mM NaHC03, 10 mM Hepes, 0.2 units/ml insulin and 1% 6.6 g/L glucose, 26 mM NaHCO3, 10 mM Hepes, 0.2 units/m1 insulin and 1% antibiotic antimycotic (Sigma)] for 30 min, then washed in fresh medium, plated into separate wells containing 1 ml medium and pretreated coverslips, incubated at 37 °C with 95% humidity and 7% CO2 and fed once weekly in medium without antibiotics. Coverslips (Gold seal, VWR) were scrubbed (Microclean, Cole Palmer), acid etched, and coated with 0.5 mg/ml polylysine (PL) or with PL and 10 µg/ml laminin or 50 µg/ml fibronectin. Organogenesis was evaluated in live and 4% paraformaldyhyde fixed OTCS at 1.5, 2, 3, 4 and 5 weeks in vitro and compared to perfuse-fixed frozed foxed frozed fixed fixe sections of age-related littermates. Immunoreactivity specific for: Purkinje cells (PC, mono- and polyclonal calbindin, Sigma and S. Christakos); PCs and Deep cerebellar nuclei (DCN) neurons (302, S. Hockfield); Golgi cells and DCN (303, S. Hockfield); neuron specific enolase and astrocytes (NSE and GFAP, Dako) was visualized using the LSAB kit (Dako) along with Thionin for Nissl and Holmes stain for myelin.

Temporal development of cell types and myelination followed closely that in vivo.

OTCSs thinned so that individual neurons were visible by direct observation and could be photograhed throughout the culture period. The choroid plexus was a topographical marker for the caudal cerebellar and DCN regions. Supported by NIH NS17489

### 327.8

OPIATES DO NOT AFFECT ASTROCYTE DEATH IN DEVELOPING MIXED-GLIAL CULTURES. J.A. Gurwell\* and K.F. Hauser. Dept. Anat and Neurobiol., Univ. Kentucky Sch. of Med., Lexington, KY 40536-0084.

Opiates reduce the number of cells in mixed-glial cultures in part by inhibiting the rate of proliferation of type 1 astrocytes. High concentrations (1 µM) of morphine, however, cause a complete cessation in the net production of cells, despite continued DNA synthesis, suggesting that morphine is killing cells. To determine whether morphine affects glial survival, dissociated mixed-glial cultures of ICR mouse cerebra were maintained in DMEM with 10% fetal calf serum and continuously exposed to 1 µM morphine, 1 µM morphine plus 3 µM naloxone, or 3 µM naloxone alone. Cell death was assessed using fluorescent markers for living (calcein AM) and dead (ethidium homodimer) cells (Live/Dead Viability/Cytotoxicity Assay, Molecular Probes Inc., Eugene, OR) at 3, 5, and 7 days in vitro. After a 40 min. incubation, live cells fluoresced green (an indication of esterase activity), whereas the nuclei of dead cells fluoresced red. Cell counts indicated that there was a significant loss of cells in all treatment groups. However, opiate treatment did not affect the number of dying cells compared to control values at 3, 5, or 7 days in vitro. Thus, the rate of cell death was always similar in control and treated cultures. When the identity of the dying cells was investigated by combining the Live/Dead Assay with immunocytochemical markers for astrocytes (GFAP) and bipotential O-2A glial progenitors (A2B5), GFAP+ type 1 astrocytes were not found to be dying, whereas 1-4% of the A2B5+ cells were dying (per 40 min. labeling period) at varying times in vitro. These and previous findings suggest that opiates decrease the number of type 1 astrocytes solely by inhibiting proliferation and not by altering their survival. The loss of O-2A progenitors occurs irrespective of opiate treatment and reflects the development dynamics occurring in these cultures. Supported by NIDA grant DA 06204.

ASTROCYTES EXPRESS GABA, NSE AND EARLY GLIAL IMMUNOREACTIVITIES AFTER ISCHEMIC- OR LESION-INDUCED INJURY IN THE ADULT FOREBRAIN, R.C.S.LIN\* AND D.F.MATESIC. Department of Physiology and Biophysics, Hahnemann University, Philadelphia PA 19102 and Department of Pediatrics and Human Development, Michigan State University, East Lansing, MI 48824

Transformation of normal astrocytes to reactive astrocytes after injury in the adult brain is a well-known phenomenum. Recently, we have shown that reactive astrocytes express GABA but not its synthesizing enzyme-glutamic acid decarboxylase (GAD) immunoreactivity in the gerbil forebrain after transient ischemia. The expression of GABA immunoreactivity in reactive astrocytes begins around 4-7 days and lasts for 3 months after ischemia. Using a double immunofluorescent method, we have found that these cells are not only immunoreactive to GABA but also to GFAP or vimentin, confirming their glial identity.

identity.

Previous in vitro tissue culture studies have shown that 02A progenitor cells are immunoreactive to GABA but not GAD. This raises the question of whether reactive astrocytes in the adult brain may re-express fetal trait(s) of astrocytes after injury. To further elucidate the phenotype of astrocytes after injury in the adult brain, we made lesions in the forebrain using either transient ischemia or thermal lesions as our experimental models. We then used a panel of antibodies including A2BS (a marker for 02A progenitors and type 2 astrocytes) and neuron specific enolase (NSE; a marker for neurons) to study the identity of reactive astrocytes. Using immunofluorescent techniques, we found that reactive astrocytes immunostained with GABA are also immunohistochemically labeled with NSE, A2B5 or GalC. These preliminary results further support the notion that reactive astrocytes in the adult brain can re-express fetal trait(s) of undifferentiated glial cells after injury. The functional significance of the aberrant expression of GABA and NSE immunoreactivity by astrocytes will be further investigated with physiological and pharmocological approaches.

MET-ENKEPHALIN IMMUNOREACTIVITY IN HIPPOCAMPAL ASTROCYTES FOLLOWING BILATERAL DENTATE GRANULE CELL LESIONS. L. Thai\*. C. Mitchell, M. Barns, and J.S. Hong. Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599; LMIN, NIEHS/NIH, Research Triangle Park, NC 27709.

In the primary hippocampal culture system, proenkephalin and its bioactive peptides are present in the type I astrocytes in great abundance. Hauser et al., (1987) suggested that enkephalin secreted from glial cells may suppress cell growth. Up to this time, however, enkephalin has not been localized within glial cells in the hippocampus. The purpose of this study was to examine whether enkephalin peptides are present in glial cells within injured or regenerative areas. Colchicine was injected bilaterally into the hippocampus to selectively degenerate dentate granule cells. Met-enkephalin immunoreactivity was determined by using antibodies against Met-enkephalin in two-week and two-month post-lesion animals. As revealed by glial filament acetic protein (GFAP) antibody staining, glial cells were found in higher number in the lesioned hippocampi at the two-week compared to the two-month time point. Met-enkephalin immuno- reactivity correlated positively with the GFAP labeling. A shrinkage of the hippocampi was also observed in the two-month post-lesion animals. The emergence of Met-enkephalin in glial cells following colchicine lesion suggests a possible role of Met-enkephalin for regulating glial cell growth in injured brain regions.

### 327.13

DISCRETE BRAIN LESIONS PROMOTE NEUROGENESIS IN ADULT RING DOVES -- A POSSIBLE MECHANISM UNDERLYING BEHAVIOR RECOVERY?

C. Ling\*, M. Chaiken and M.-F. Cheng. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102

Brain lesions are known to induce reactive gliogenesis throughout life. However, there have been no reports about the relationship between brain lesions and neuro-genesis in higher vertebrates. It was thought that neurogenesis stops after birth in birds and mammals Studies of songbirds have revealed that neurogenesis occurs in adult birds, and we have recently demonstrated that neurogenesis persists throughout life in ring doves. In this study we explore the effects of brain lesions on neurogenesis and the relationship between lesion-induced neurogenesis and behavioral recovery in adult doves. Twenty doves received electrolytic lesions in the Nucleus Taeniae (avian Amygdala) of the telencephalon, and then received daily [3H]thymidine injections for seven days, starting 2 days after lesioning. The birds were sacrificed 2 months after the last injection. The courting and mating behavior of these birds was observed before and after electrolytic lesions or sham lesions. We found that discrete brain lesions promote neurogenesis -- the number of new neurons per brain section was doubled, and new neurons concentrated around the lesion site. Changes in courtship behaviors after lesioning were correlated with the time course of neurogenesis.

## 327.15

DEVELOPMENT OF PERIPHERAL SPINAL PROJECTIONS: EPIGENETIC INFLUENCES ON THE EXPRESSION OF SPINAL NEUROTRANSMITTERS.

N. Leblanc, G. Audet, R. Marchand and E. Philippe\*. Centre de recherche en Neurobiologie, Univ. Laval, Québec, Canada, G11 1Z4.

During the development of a neuronal population, the microenvironment may play a major role in initiating and maintaining the expression of phenotypes such as γ-aminobutyric acid (GABA) and dopamine. In order to determine what factors could induce expression of these transmitters in spinal motoneurons, we will verify at what embryonic stage the efferent contacts are established as well as the stage at which these motoneurons are contacted by the peripheral, propriospinal and supraspinal afferences.

the stage at which these motoneurons are contacted by the peripheral, propriospinal and supraspinal afferences.

Dil crystals (a fluorescent tracer) deposited in the leg of embryonic chicken fixed at different stages, allows us to study the development of the peripheral sensitive and motor projections.

When Dil crystals are implanted at E4.5, fluorescence is visible at the lombo-sacral level in the dorsal and ventral roots, the motoneurons and the spinal ganglions. An oval longitudinal bundle is observed, on transverse sections, in the white substance of the dorsal horn. This bundle extends to adjacent segments. At later stages (E5, E6), the bundle is broader and subdivided, suggesting an increase in the number of axons. At theses stages we also notice that Dil is progressively seen in small nervous fibres of the intermedio-lateral region of the grey substance.

region of the grey substance.

Knowing that the expression of various phenotypes is initiated at these embryonic stages, it would be interesting to determine if the initiation of the contacts described above have an influence on the appearance of GABA and dopamine in the spinal neurons. (Supported by l'Association de l'ataxie de Friedrich and the F.R.S.Q.)

LESION-ENHANCED NEURONAL INCORPORATION D.G. Herrera\*, M. Skup, A. Ribeiro-da-Silva and A.C. Cuello. McGill University, Department of Pharmacology, 3655 Drummond Street, Montréal, Québec, Canada H3G 1Y6.

We investigated whether spontaneous or lesion-induced neuronal reproduction may occur in the adult rats by using two markers of cell division: tritiated thymidine (3H-Thy) and bromodeoxyuridine (BrdUrd). Experiments were performed on both control (i.e. unoperated), and fimbria-fornix (FF) transected animals. One hundread twenty nanograms (100 µCi) of 3H-Thy or one hundread micrograms of BrdUrd were administered intracerebroventricularly immediately after FF transection. Ten days or 1 month after onset of administration, brains were fixed and processed for autoradiography (3H-Thy) or immunocytochemistry (BrdUrd). Light and electron microscopic studies revealed that 3H-Thy and BrdUrd were incorporated into the nuclei of neuron-like cells localised predominantly in the granular cell layer of the dentate gyrus (DG) of the hippocampal formation. Most of the neuron-like cells analyzed by E.M. proved to be neurons. Unilateral FF lesion enhanced the incorporation of both markers into neuron-like cells in DG. This was more evident one month after the lesion. These results suggest that under certain conditions DNA synthesis in the adult mammalian brain may be stimulated. (Funded by the Medical Research Council of Canada and the Centres of Excellence Network for Neural Regeneration and Functional Recovery).

IN VITRONEUROGENESIS BY MULTIPOTENTIAL PRECURSOR CELLS OF THE ADULT AVIAN BRAIN S. A. Goldman\* 1. A. Zukhar\* 1, T. Mikawa\* Depts. of 
1Neurology and 2Cell Biology, Cornell Univ. Medical College, NYC, NY 10021.

The adult songbird brain generates neurons throughout life, from stem cells located in the forebrain ventricular zone. We previously found that explants derived from one such region, the vocal control nucleus HVC, continue to generate neurons in vitro when cultured under relatively low serum conditions. This paradigm has allowed us to study the ontogeny of the new adult neurons, by using retroviral-mediated insertion of lacZinto cultured HVC ventricular zone cells, followed by an analysis of the progeny generated in vitro. Presumptive HVc vertricular zone from 3-7 day old canaries was dissociated into low-serum media, plated upon laminin, and then exposed to the lacZ-bearing retrovirus CXL. After fixation 6 days later, clonally-derived cells were identified by  $\beta$ -galactosidase expression. Single ventricular zone cells yielded clusters of co-derived neurons and radial cells, whose identities were confirmed by immunolocalization of MAP-2 and vimentin, respectively. Among 301 β-galactosidase+ clones examined, 19 included neurons; of these, none contained more than 1 neuron (median 4 cells/cluster, range 1-6 cells). Several clones included both MAP-2+ neurons and vimentin/mAb 3A7+ ependymoglia and radial cells (mAb 3A7 courtesy of V. Lemmon). These results suggest the in vitro division of single lacZ-infected precursors, and the asymmetric differentiation of their progeny into both neurons and non-neuronal siblings. The newly produced neurons and radial guide cells of the postnatal avian brain may thus arise from a common, pluripotential stem cell, capable of generating both neurons and their substrate cells. The multipotentiality of these stem cells suggests that adult neurogenesis may be restricted not only by a humoral inhibition of precursor cell mitosis, but also by a diversion of daughter cell phenotype into non-neuronal lineages.

## 327.16

A TEMPORAL RELATIONSHIP BETWEEN NEURO-GENESIS AND NEURONAL DEATH IN THE HIGH VOCAL CENTER OF THE ADULT CANARY BRAIN.

Kim\*. S. Kasparian & F. Nottebohm, The Rockefeller University Field Research Center, Millbrook, NY 12545.

The high vocal center (HVC) in songbirds continues to receive new neurons in adulthood (Goldman & Nottebohm, 1983). In canaries, neurogenesis is coupled to neuron loss (Alvarez-Buylla et al., 1990; Kim & Nottebohm, 1901). Havasar Lista is because the second to the control of the control o & Nottebohm, 1991). However, little is known about the extent to which neuron production and death vary throughout the year --- information necessary to understand how adult neuronal replacement is regulated. We used <sup>3</sup>H-thymidine to quantify neurogenesis and pyknotic cell counts to measure cell death at monthly intervals for a period of 1 year. Adult male canaries (15-28 months old) received 4 days of 3H-thymidine injections as described elsewhere (Kirn & Nottebohm, 1991). Birds (n=2-5/ month) were sacrificed 27 days later. Brains were processed for autoradiography and counterstained with cresyl violet. <sup>3</sup>H-labelled neurons and pyknotic cells were found in HVC at all times. Sept. and Feb. showed the highest incorporation rates of new neurons. Pyknotic cell densities were also highest in Sept. and in Jan.-Feb. In additional birds injected in RA (robustus archistriatalis) with fluorogold (FL) in Oct.-Feb. or in May (3-5 birds / group), 54% of pyknotic cells in HVC were FL-labelled and therefore were degenerating RA-projecting HVC neurons. Collectively, these results show that adult neurogenesis and neuronal death are temporally related. Testosterone levels drop sharply prior to the observed peaks in HVC neuronal turnover (Nottebohm et al., 1987). There may be a relationship between neurogenesis, neuron death and endocrine state. (Supported by NIH #MH18343 & NS29843)

GENERATION AND MOVEMENT OF CELLS IN THE DEVELOPING FROG Dept. of Anatomy, Kirksville CEREBELLUM. N.J. Uray\*. College of Osteo. Med., Kirksville, MO 63501

Normally developing and thyroxine-induced (100 ppm) metamorphosing bullfrog tadpoles were used in this study Routine histological sections and  $^3H$ -thymidine  $(10\mu\text{Ci/g})$ autoradiograms of brains were examined to analyze cerebellar cell generation and movement using the method devised by Rüdeberg

The most useful data came from the thyroxine-induced metamorphosing animals. In these specimens, Rüdeberg's migrations A,  $A_1$  and B could be clearly detected and demarcated. Analysis of the composition and cell movement of migration B, however, is difficult and complicated. In the frog, cells which are homologous to the deep cerebellar nuclei of mammals are mostly ventral to the cerebellar plate, and a distinct migration layer (nuclear transitory zone of Altman and Bayer) is not present in the cerebellar plate, nor does a transposition of these cells and Purkinje cells (cortical transitory zone) occur as described in the rat. Migration B, however, can be subdivided into two separate zones, the superficial one being composed of Purkinje cells and a deep one, formed by small cells whose identity is not clearly understood. Overall, cerebellar formation in the frog has many similarities to the process observed in mammals, but appears to be more simple and less organized. Supported by NIAAA Grant AA97537.

### 327.19

SEGMENT SPECIFIC CELL DEATH IN THE PROGENY OF HOMOLOGOUS NEUROBLASTS IN THE GRASSHOPPER. Karen J. Thompson and Melody V.S. Siegler.\* Dept. of Biology, Emory Univ., Atlanta GA 30322

The median neuroblasts (MNBs) in grasshoppers are identified neuronal stem cells. Each segment of the embryonic ventral nerve cord has a posterior MNB which gives rise to a midline group of neurons. The number of MNB progeny differs between segments. In the metathoracic segment (T3), about 95 neural progeny from the MNB survive embryonic development, whereas in the next posterior segment, the first abdominal (A1), only about 60 neural progeny survive. Segment specific patterns of development account for these differences in neuronal number. In T3, the MNB arises at 29% of embryogenesis and dies at 78%, whereas in A1, the MNB arises at 30% and dies at 73%. In T3, the number of MNB progeny increases at a steady rate, with about 10 cells being added to the midline group per 5% of embryogenesis until 70%. Between 70% and 80%, growth tapers off: although the T3 MNB continues to divide, cell death occurs at the same time, specifically removing the last born progeny. By contrast, in A1, the number of MNB progeny increases in two distinct phases, one from 30% to 45% and the other from 60% to 75%, again at the rate of 10 cells per 5%. Between the two phases, the population is stable: the A1 MNB continues to divide, but cell death occurs coincidentally with the effect of removing cells advice, but cell death occurs coincidentally with the effect of removing cells from the population at the same rate they are being added. Cell death specifically removes earlier bom progeny in A1. Thus, the lifespan of the MNB, and the timing and magnitude of cell death among its progeny, differ between the T3 and A1 segments, and result in differences in the number and composition by cell type of the midline groups of T3 and A1.

BIRTH AND FATE OF B & C NEURONS AND GLIA IN BULLFROG SYMPATHETIC GANGLIA. WD Stofer\* and JP Horn Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Times of origin of sympathetic neurons and glia in paravertebral ganglia 9 & 10 of the bullfrog were determined by injecting tadpoles repeatedly with 5'-bromodeoxyuridine (BRDU) for 1 - 6 developmental stages between III and XXI. Our goal was to determine whether the stages between III and AAI. Our goal was to determine whether the birthdates of sympathetic neurons were related to their subsequent fates as cutaneous B cells or vasomotor C cells. After allowing BRDU-injected tadpoles to enter late metamorphic stages (XX-XXV), the ganglia were double-immunostatined for BRDU and neuropeptide Y (NPY) using distinct black and brown HRP reaction products. BRDU was localized in nuclei of labeled neurons and glia. NPY was localized was tocalized inducted or tabeled therefore and gala. Not was tocalized in perinuclear cytoplasm of C neurons. Cell counts showed that at least 21% of ganglionic neurons are born during tadpole stages and that neurogenesis ceases during early foot stages (XII-XIV), a time coinciding with the onset of NPY expression. By contrast, the labeling of non-neuronal satellite cells with BRDU was most common during that total stages. Transporting of their brighted to about belief of the later tadpole stages. Irrespective of their birthdates, about half of the BRDU-labeled neurons were also positive for NPY. This proportion of

NPY-positive neurons is indistinguishable from that in adult ganglia.

The results show that: i) early tadpole ganglia contain neuronal and glial precursors, ii) birthdates are different for neurons and glia in this system, and iii) birthdates are not determinants for phenotypic subclasses of sympathetic neurons.

RETINAL AFFERENTS AFFECT MITOTIC ACTIVITY AND CELL DEATH IN THE DEVELOPING OPTIC LOBES OF THE MOTH, MANDUCA

IN THE DEVELOPING OPTIC LOBES OF THE MOTH, MANDUCA SEXTA. S.A. Monsma\* and R. Booker. Section of Neurobiology and Behavior, Cornell University, Ithaca NY 14853.

The two outer optic ganglia of holometabolous insects, the lamina and the medulla, are produced during metamorphosis from a single structure, the outer optic anlage (OOA). Neuroblasts (Nbs) in the OOA undergo asymmetric divisions to yield an Nb and a ganglion mother cell (GMC); the GMCs divide symmetrically to yield two ganglion cells. Medulla ganglion cells are produced by Nbs and GMCs in the medial half of the OOA, while lamina ganglion cells are produced by Nbs and GMCs in the distal half. lamina ganglion cells are produced by Nbs and GMCs in the distal half. Cell death is apparent in the developing medulla cortex as well as in the lamina cortex, usually in a zone adjacent to the OAA.

To examine the influence of retinal afferents on mitotic activity and cell death, we sectioned the optic nerve on one side at pupation, leaving the contralateral side as the unoperated control. Denervation did not affect the mitotic activity of the medulla Nbs, GMCs, or the lamina Nbs. However, the mitotic activity of lamina Nbs, GMCs, or the lamina Nbs. However, the mitotic activity of lamina GMCs was completely abolished within 24 hr of denervation. Further growth of the lamina was completely blocked, and an ectopic population of lamina GMCs built up. These ectopic GMCs degenerated 1-2 d before the OAA degenerated.

Cell death in the already-present lamina continued for up to 3 d after denervation. Cell death in the medulla continued at a normal rate until 6 d after denervation. Thereafter, cell death in the medulla cortex climbed to approximately twice the level of the control side, and remained elevated until ~2 d after the OAA degenerated. These results suggest that retinal afferents can influence both mitotic activity of precursors and cell death.

## DEVELOPMENT OF NEUROTRANSMITTER SYSTEMS: CATECHOLAMINES AND NEUROPEPTIDES

PRENATAL EXPOSURE TO DESIPRAMINE CHANGES THE DEVELOPMENT OF BETA RECEPTORS IN RAT CORTEX X.-K. Gao. A. J. Friedhoff and K. A. Bonnet\* Millhauser Lab., N.Y.U.Sch. Med., New York, N.Y. 10016
Prenatal exposure to desipramine (DMI) at 10 or 25 mg/kg was effected via pregnant rat dams, in drinking water, at gestation days (GD) 7-13. DMI at 10 mg/kg caused a significant decrease in 3H-dihyrdroalprenolol (3H-DHA) binding sites in brain cortex of the 14 day old offspring, and later postnatal increase in 3H-DHA binding sites in 28 and 56 day old offspring. DMI at 25 mg/kg caused a significant increase in 3H-DHA binding sites in 7 day old offspring. Since fetal brain begins to show uptake of NE at presynaptic sites at GD18, the effect of DMI may not involve direct presynaptic effects of fetal brain. We observed a dose-dependent increase in NE in blood serum of observed a dose-dependent increase in NE in blood serum of pregnant mothers during and after treatment with DMI. Since different doses of DMI have differential effects on the development of brain b-receptors, mothers' indirect effects on fetus does not explain the differential effects of DMI. This suggests that prenatal exposure to DMI may have a direct effect on postsynaptic programmatic development in fetal brain.

## 328.2

EFFECTS OF PERINATAL EXPOSURE TO COCAINE ON [3H]YM-09151-2 BINDING IN ADULT RAT BRAIN <u>D.L. Dow-Edwards\*</u>, <u>B. Landwehrmeyer</u>, <u>and J.M. Palacios</u>, Lab. of Cerebral Metabolism, Dept. of Pharmacology, SUNY-Brooklyn, NY and Sandoz Pharma Ltd., Basel, Switzerland.

Previous studies from this lab have shown that perinatal exposure to cocaine results in alterations in brain glucose metabolism which can be identified in adult male and female rats (e.g. Dev. Brain Research 42:137, 1988). Since many of the regions affected are rich in dopaminergic projections, we examined the brains of similarly treated rats for the concentrations of dopamine receptors. For the present study, rat pups were injected with either cocaine HCl at 50mg/kg/day or vehicle during postnatal days 1-10 or 11-20. At 60 days of age, rats were sacrificed and the brains processed for autoratiography. processed for autoradiography. Sections were incubated for 30 min at RT with 1nM [3H] YM-09151-2 (New England Nuclear), a ligand with high specificity for the D2 receptor. Sections were apposed to [3H] hyperfilm for 2 weeks along with [3H] standards from Amersham. Computerized image analysis using the Loats Imaging System shows that the alterations in YM-09151-2 binding produced by cocaine depend upon the period of drug exposure and the gender of the animal. From these data as well as the data of others, one can conclude that developmental exposure to cocaine has long term effects on the function of central dopamine

DEVELOPMENT OF HUMAN BRAIN DOPAMINE D, RECEPTORS. JR. Atashi<sup>1</sup>, C.P. Lawler<sup>1,2,4</sup>, C.A. Mathis<sup>5</sup>, R.B. Mailman<sup>1,2,3,4</sup> and J.H. Gilmore<sup>1,2,4</sup>. Curriculum in Neurobiology<sup>1</sup>, Departments of Psychiatry<sup>2</sup> and Pharmacology<sup>3</sup>, and the Brain and Development Research Center<sup>4</sup>, University of North Carolina, Chapel Hill, NC, 27514-7250 and Department of Radiology, University of Pittsburgh<sup>5</sup>, Pittsburgh PA, 15213.

Alterations in the development of dopamine neurotransmission have been hypothesized to play a role in the pathogenesis of several neuropsychiatric disorders. The present studies examined several aspects of development and localization of dopamine D<sub>2</sub> receptors in post-mortem human brain tissue, using quantitative receptor autoradiography with the selective D<sub>2</sub> benzamide ligand [12³1]-epidepride. Time course studies were conducted at ambient temperature. In tissue from both adult and infant brain, maximal binding was reached by ca. 2.5 hr, and remained relatively stable for at least another 10 hr. Preliminary saturation analyses using non-linear regression have been completed in post-mortem brain from one infant (3 mo old, 24 hr post-mortem interval) and one adult brain (53 yr, 16 hr post-mortem interval). The densities of [12³1]-epidepride receptors were not significantly different either between the caudate and putamen, or between the adult and infant. On the other hand, in this experiment the K<sub>D</sub> was significantly higher in both adult regions compared to the same regions in the infant. In the caudate, D<sub>2</sub> receptors were found to be present in a heterogeneous pattern of density, with areas of low D<sub>2</sub> binding corresponding to acetylcholinesterase-poor zones as defined by histochemistry in adjacent sections. This pattern was present in adult caudate, as well as at six weeks, three months, four months, and four years age. This pattern appeared in a distint medial-lateral gradient in adult, but was less defined in the younger subjects relative to the adult. These studies provide further evidence that [12³1]-epidepride appears to be a useful ligand to study the localization of D<sub>2</sub> receptor development in human brain. These data also suggest that D<sub>2</sub> receptors undergo significant and specific changes in localization during development.

TRANSITORY DETECTION OF DOPAMINE IMMUNOREACTIVITY IN DIFFERENCIATING NEURONS OF EMBRYONIC AND LARVAL LOBSTERS. L. Cournil\* and M. Moulins. Lab. Physiol. Neurobiol. Comp., Université de Bordeaux I et CNRS, Arcachon, 33120, France.

We were aiming to understand the timing and mechanisms involved in the selection of neurotransmitter phenotypes in the developing nervous system of *Homarus gammarus*. Dopamine and its rate limiting enzyme, tyrosine hydroxylase, are widely distributed in the adult lobster nervous system and can be readily vizualized immunocytochemically.

To trace the development of dopamine containing neurons in embryos and larvae, whole animals at various developmental

To trace the development of dopamine containing neurons in embryos and larvae, whole animals at various developmental stages were fixed, embedded in paraffin, and sectioned prior to staining. The adult pattern of dopamine staining appears progressively from 50% development, and once differentiated, most dopamine- containing neurons are maintained throughout subsequent ontogeny of the embryonic lobster. However an intense immunoreactivity which can be detected early in the embryonic neurons of the suboesophageal ganglion and stomatogastric nervous system (innervating pericardial muscles and foregut muscles respectively), has disappeared by the adult stage. We are currently investigating this phenomenon to determine (1) whether it is due to cell death in the adult or to the transitory expression of dopamine by still surviving neurons, and (2) its possible significance for the development of target muscles.

## 328.7

INDUCTION OF NADPH DIAPHORASE ACTIVITY IN CULTURED PRINCIPAL NEURONS OF THE SUPERIOR CERVICAL GANGLION (SCG) OF THE POSTNATAL RAT.

P.B. Senatus. M.D. Johnson and D.D. Potter\*. Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

In adult rat neurons, reduced nicotinamide adenine dinucleotide phosphate diaphorase activity (NADPH-DA) has been correlated with the presence of neuronal nitric oxide (NO) synthase (e.g. Hope et al., 1991). Principal neurons of the SCG have been reported to be unreactive (e.g. Grozdanovich et al, 1992), and we have confirmed this finding using NADPH diaphorase histochemistry in 40 um thick frozen sections of SCG's from adult and postnatal Long Evans rats of both sexes. However, sympathetic neurons dissociated from postnatal SCG's became visibly reactive for NADPH-DA after a few days in culture (less than 1% at the time of plating; about 80% after 1 week), and the reactivity was strongly enhanced if 5% adult rat serum was present in the culture medium. Neurons containing NADPH-DA retained immunoreactivity for tyrosine hydroxylase.

About 80% of postnatal SCG principal neurons co-microcultured with dissociated hippocampal cells develop cholinergic function in the first three weeks in culture (Johnson and Potter, 1989). Although most co-microcultured SCG neurons became visibly reactive for NADPH-DA, no correlation was found between NADPH-DA and cholinergic function when synaptic function was assayed using intracellular electrophysiological methods. These data indicate that NADPH-DA can be induced in sympathetic neurons, and raise the possibility that expression of NO synthase can be regulated in the nervous system. EFFECTS OF ADULT AND NEONATAL HEMIDECORTICATION ON MUSCARINIC AND D2 RECEPTOR BINDING IN THE CAT NEOSTRIATUM A. Ebrahim \$ K.J. Tatsukawa \$\frac{A}{2}, L.D. Loopuijt \$\frac{A}{2}, S. Chen \$\frac{5}{4}, D.A. Hovda \$\frac{1}{4}, J.R. Villablanca \$\frac{A}{4}, H.T. Chugani\* \$\frac{5}{2}\$ UCLA School of Medicine. This study examined the influence of hemidecortication performed at two

This study examined the influence of hemidecortication performed at two different developmental stages on D2 receptors and muscarinic binding in the cat neostriatum. Receptors were measured in the lateral, intermediate and medial caudate, putamen and accumbens nuclei (at rostral and caudal levels) by means of quantitative autoradiography. Tissue was incubated using 1nM [3H]spiperone in the presence of 10µm ketanserin for D2 receptor binding, and in 2nM [3H]quinuclidinyl benzilate for muscarinic receptor binding. Three groups of animals were used: cats hemidecorticated in adulthood (AH, N=3) or at 8-13 day old (NH, N=4) and intact controls (C, N=4).

old (NH, N=4) and intact controls (C, N=4).

The muscarinic receptor binding showed no differences between the 3 groups and no right vs. left asymmetries within each group [ipsilateral/left: anterior lateral caudate: NH 622.8 (range 620.5-625.2), AH 650.8 (range 442.1-908.1), C 527.2 (range 4930.5-63.1) fmol/mg tissue; contralateral/right: NH 632.9 (range 597.9-667.8), AH 628.5 (range 412.0-754.4), C 585.8 (range 548.4-654.5) fmol/mg tissue]. Dopamine D2 receptor binding also showed no differences between the three groups with one exception; in NH the density in the anterior (lateral) caudate and putamen was higher ipsilaterally compared to C (ipsilateral/left NH 86.4 (range 32.3-75.8), C 38.2 (range 20.0-0.2) fmol/mg tissue. These findings indicate that the deafferentation of the caudate-putamen has no influence on the density of the muscarinic receptors, but results in an increase of D2 receptor binding in parts of caudate and putamen in the NH. Since the increase does not occur in AH, this reflects a permanent change due to plasticity in early development and may represent part of the D2 binding that is not functionally coupled to inhibition of acetylcholine release. Grants USPHS HD-05958,HD-04612, 2P01-NS15654-13.

LONGTERM ALTERATIONS IN NEUROTRANSMITTER BIOSYNTHETIC ENZYMES IN RESPONSE TO NEURONAL INJURY. M. Weiser', H. Baker, T. Wessel and T.H. Joh Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605

Alterations in the levels of neurotransmitter biosynthetic enzymes are a concomitant of many neurodegenerative disorders. To determine the longterm alterations in the levels of neurotransmitter biosynthetic enzymes in response to axotomy, a microknife lesion was placed in either: (1) the posterolateral hypothalamus transecting the axons of both the dopaminergic neurons in the substantia nigra pars compacta (SNc) and the noradrenergic neurons in the locus ceruleus (LC); or (2) more rostrally in the anterior forebrain severing the axons of cholinergic neurons in the horizontal limb of the diagonal band (HLDB). At timepoints from 7 days to 6 weeks, the changes in the mRNA and protein levels for tyrosine hydroxylase (TH) and choline acetyltransferase (ChAT) were examined in Sprague-Dawley rats by in situ hybridization and immunohistochemistry. Following unilateral axotomy, TH mRNA and protein levels in the LC were reduced at 14 days and returned to controls levels by 28 days. In contrast, TH mRNA and protein levels in the SNc were irreversibly decreased in a majority of the remaining neurons at both 14 days and 6 weeks. However, a few neurons in the SNc had normal or high levels of TH mRNA. In comparison, in the HLDB, while ChAT mRNA levels increased at 7 days following axonal transection, ChAT protein levels were reduced below control values. Both ChAT protein and mRNA levels were reduced to at least 40% of control values at 6 weeks. These data suggest that the neuronal response to axotomy is phenotype specific and may depend on the axonal arborization pattern of a neuron. Supported by MH44043 and AG08702.

## 328.8

NEUROPEPTIDE EXPRESSION BY SYMPATHETIC NEUROBLASTS. S. Tyrrell\* and S. C. Landis. Dept. of Neurosciences, Case Western Reserve University, Cleveland, OH 44106.

University, Cleveland, OH 44106.

During development, neurotransmitters and their synthetic enzymes are not normally expressed until after neuroblasts have undergone their final division. One exception is the expression of adrenergic properties, tyrosine hydroxylase (TH) and catecholamine histofluorescence, by sympathodarenal (SA) precursors and the neural crest cells that colonize the gut. Since many sympathetic neurons contain neuropeptides as well as catecholamines, we examined embryonic sympathetic ganglia containing SA precursor cells for the presence of neuropeptide Y (NPY) and vasoactive intestinal peptide (VIP). At embryonic day (E)11.5, TH immunoreactivity (-IR) was present in the developing superior cervical (SCG) and stellate ganglia but neuropeptide-IR was undetectable. One day later, at E12.5 when only a small number of sympathetic neurons have undergone their final division, virtually all TH-IR cells contained low levels of NPY-IR. The intensity of immunoreactivity increased uniformly over the next two days of gestation. VIP-IR first appeared in approximately one-third of the TH-IR cells in the stellate ganglion at E 14.5 but was not evident in the SCG at any age. Localization of peptide mRNAs by in situ hybridization at E14.5, during the peak of neurogenesis, revealed uniform binding of the NPY mRNA probe throughout the SCG and stellate and of the VIP mRNA probe throughout the stellate ganglion, suggesting that many cells in the embryonic ganglia synthesize NPY and VIP. To confirm that neuroblasts contain neuropeptide-IR, we injected pregnant rats with the thymidine analogue BrdU on gestational day 14 and removed sympathetic ganglia were triple labeled using TH, BrdU, and NPY or VIP antisera. At E14, many cells exhibited -IR for NPY as well as TH and BrdU. In addition, some cells at E14 contained VIP, TH and BrdU. Sympathetic neuroblasts contain neuropeptides as well as catecholamines, thus, these precursors express multiple aspects of the mature sympathetic phenotype.

NEUROPEPTIDE Y IMMUNOREACTIVITY IN CAT CORPUS CALLOSUM AXONS DURING DEVELOPMENT. S.-L. Ding\* and A.J. Elberger. Dept. of Anatomy and Neurobiology, The University of Tennessee Memphis, College of Medicine, Memphis TN 38163. It has been demonstrated that many transitory corpus callosum (CC) connections exist throughout visual cortex during normal development in the cat (Elberger, Soc. Neurosci. Abstr. 16:495), but little is known about the chemical nature of CC connections in the developing cat brain. In 100 µm thick coronal sections from normal cats postnatal day (PND) 2 to adult, CC axons were identified immunocytochemically with an antiserum (Incstar) against Neuropeptide Y (NPY) using a biotin-avidin substrate. The density of NPY\* CC axons increased slightly in postnatal weeks (PNW) 1-2, remained stable in PNW 3-4, and decreased gradually during PNW 5-7. From PNW 8 to adult the density of NPY\* CC axons was stable below what existed at PND 2. The highest and lowest densities of NPY\* CC axons occurred at PNW 3-4 and PNW 8 to adult, respectively. Therefore, at least 2 types of NPY\* CC axons (i.e., transitory and permanent) exist in the developing cat brain. The majority of transitory NPY\* CC axons, existing until PNW 7, are present while cortical development in the cat.

Many previous studies of CC development show a gradual postnatal decline in the extent of connectivity. However, in PNW 1-2 several NPY\* CC axons had growth cones located around the CC midline, suggesting that subsets of CC connections may have different developmental timetables. The simultaneous trends of growth and elimination among different subsets of CC axons show the CC to be a complex, dynamic structure. Support by State of Tenn. Neuroscience Center of Excellence (SLD) and NIH grant EY08466 (AJE).

#### 328.11

SOMATOSTATIN EXPRESSION AND PLASTICITY IN THE PICEON VISUAL SYSTEM. <sup>1</sup>G.Fontanesi, <sup>3</sup>G.Traina, <sup>2</sup>M.Molnar and <sup>3</sup>P.Bagnoli\*. <sup>1</sup>Dept.of Physiology and Biochemistry, Pisa Univ., 2 VANC, West LA, Los Angeles, CA and 3 Dept. of Environmental Sci. Univ. of Tuscia. Viterbo. Italy.

The pigeon visual system serves as useful model for studying neurotransmitter expression and maturation since its delayed maturation offers the possibility of a persisting plasticity into postnatal life. We have used the mouse monoclonal antibody S8 (provided by the Canada Regulatory Peptide Group) to map the distribution of somatostatin-immunoreactivity (SS-ir) during development and in adults with unilateral and bilateral retina ablation. Protocols for animal use are in compliance with NIH guidelines. The adult retina contains significant amount of SS-ir. A prominent population of amacrine cells are present in the INL and diffusely arborize in the IPL. Developmental changes include modifications in the density of cell bodies and processes. The adult pattern coincides with the onset of light-driven activity. SS-ir is present in the optic tectum, the n.of the basal optic root, the visual Wulst and the ectostriatum. The chemical differentiation of SS-positive neurons is characterized by drastic variations in their numerical density and their total number as determined by quantitative analysis. Incoming retinal fibers play a role in regulating SS expression since the final distribution of SS-ir is altered by unilateral and bilateral retina removal. Our results demonstrate that developing visual neurons transiently express SS in association with their retention of plasticity into postnatal life.

## 328.13

A Cell Type-Specific Enhancer within the FMRFamide Neuropeptide Gene Promoter of Drosophila. Paul H. Taghert\*, Dusan Zitnan and Marie Roberts., Dept. of Anat. and Neurobiol., Washington Univ. Sch. Med., 660 S. Euclid Ave., St. Louis, MO, 63110.

We have used lacZ reporter gene constructs to study the promoter and enhancer regions of the Drosophila FMRFamide neuropeptide gene in germ line transformants. FMRFamide is normally expressed in ~60 diverse neurons of the larval central nervous system that represent ~15 distinct cell types. We reported last year that an 8 kilobase FMRFamide DNA fragment (including 5 kilobases of 5 upstream sequence) was sufficient to produce lacZ expression in a pattern that minicked nearly all spatial aspects of the normal pattern. This result indicates that the cell-specific regulation of FMRFamide expression is largely generated by used lacZ reporter scriptional mechanisms. We have extended this analysis by testing smaller transcriptional mechanisms. We have extended this analysis by testing smaller DNA fragments in a variety of vector constructs. Reporter gene expression was lost from selected cell types when smaller fragments were tested: sequences between -5000 bp and -4500 bp were necessary for expression by the interneuronal SE2 cells; sequences between -922 and -162 were necessary for expression by the SP4, Tv and OL2 neurons. Expression in the other ~11 cell types that normally express FMRFamide was correlated with inclusion of sequences near the transcription start site and/or within the single intron. A 300 sequences near the transcription start site analog within me single intro. A 300 bp fragment (490 to -162) displayed cell type-specific enhancer activity: when placed adjacent to a heterologous promoter, it directed *lacZ* expression in the OL2 visual system neurons exclusively. This fragment contains 4 regions that display sequence conservation between different species of *Drosophila*; one such fragment contains both an E box and an octamer motif. These results suggest that, in the mature nervous system, the complex pattern of *FMRFamilae* neuropeptide gene expression derives from the activity of cell type-specific enhancers that are broadly distributed within the vicinity of the gene and that are independently regulated.

TISSUE DISTRIBUTION OF DIFFERENT VIP TRANSCRIPTS AS DETECTED BY RT-PCR. A. Orosz1, J.A. Waschek2 and D.V. Agoston1 <sup>1</sup>Laboratory of Developmental Neurobiology, NICHD, National Institutes of Health, Bethesda, MD 20892 and <sup>2</sup>N.P.I, UCLA, Los Angeles, CA 90024 Vasoactive Intestinal Peptide (VIP) is a 28 amino acid long peptide

neurotransmitter with broad physiological effects (reviewed by Waschek, 1992). Among the several functions of VIP, the neurotransmitter, the neuromodulator but also the autocrine trophic function have been demonstrated. The expression of the VIP gene is regulated by neuronal activity during development in the CNS and by soluble factors released from target tissues in the PNS. The expression of some neuropeptide genes, including preproenkephalin, is not restricted to the nervous system; enkephalin transcripts are temporarily present in various tissues during organogenesis. Here we report, that using reverse transcription followed by PCR amplification (RT-PCR) with primers specific to different parts of the VIP-gene, we were able to detect distinct sizes of VIP transcripts in various tissues. Total RNA, derived from tissues dissected from mice of various age were reverse transcribed and PCR amplified. dsDNA fragments were separated on agarose gel, transcribed and PCR amplified. asDNA fragments were separated on agarose get, stained with ethicium bromide and transferred to Nytrane membranes for Southern-hydridization. The expected size of message was found in the cerebral cortex and various parts of the CNS, but not in the cerebellum. Various parts of the gastrointestinal tract also contained the correct size of message, but the adrenals, kidney, liver, skeletal muscle, heart, lung, thymus, eyes, lymph nodes were negative. The uterus and the spleen expressed a much larger size of VIP message. whereas in mesenterium both, the normal and extended forms, were detected. The extended form of VIP-message in the spleen is seemed to be more abundant than that of the neuronal form present cerebral cortex. Using the sequence information available on the mouse VIP cDNA, we hypothesize, that the extended form of VIP-message in certain tissues can be generated either by alternative splicing or different transcriptional initiation. This extended form of transcript may encode a distinct molecular form of VIP with a yet unknown function.

DEVELOPMENTAL DISSOCIATION OF R15 NEUROPEPTIDES IN APLYSIA. M.W. Cooper A. Ljunggren, L.H.Dickert & T.J.Carew., Dept. Psychol. and Biol., Yale Univ. New Haven, Ct. 06520.

IN APL YSIA. M.W. Cooper. A. Ljunggren. L.H.Dickert & T.J.Carew\*. Dept. Psychol. and Biol., Yale Univ. New Haven, Ct. 06520.

The R15 gene in Aplysia encodes two alternatively spliced mRNAs, R15-1 and R15-2 (Buck et al., 1987). The peptides encoded by these mRNAs are expressed differently in individual neurons: The R15α1 peptide (encoded by the R15-2 mRNA) is expressed in cell R15 in the abdominal ganglion; this cell is thought to be involved in homeostasis (Kupfermann & Weiss, 1976). Another peptide, R15α2 (encoded by the R15-1 mRNA) is expressed in a number of neurons in the abdominal, pedal and cerebral ganglia (Alevizos et al., 1991). These neurons are thought to comprise part of a neural circuit also involved in homeostatic regulation (Koester, 1991).

To gain insights into the functional significance of the alternative splicing of the R15 mRNAs, we examined the expression of the R15 peptides during development using antibodies specific for the R15α1 and R15α2 neuropeptides (Ab I and Ab I/II respectively). Ab I labels only R15α1, while AbI/III labels both R15α1 and R15α2 (Alevizos et al., 1991). We found that AbI labeled R15 as early as juvenile stage 10; labeling continued to adulthood. R15 was the only cell labeled with Ab I at any stage. AbI/II also labeled R15 as early as juvenile stage 10; labeling continued to adulthood. R15 was the only cell labeled with Ab I at any stage. AbI/II also labeled with Ab I/II until 3-4 weeks later (in stage E12). At that time labeling appeared (1) in clusters of pedal cells, (2) in a pair of cells in the cerebral ganglion, and (3) in an oval shaped cell (L40) in the abdominal ganglion. Several weeks later (stage L12), Ab I/II labeling appeared in identified cell RBHE, as well as other neurons, in the abdominal ganglion.

Our data show that the R15α1 peptide is synthesized exclusively by R15 very early in juvenile development. Other cells synthesize only R15α2, and begin expression of this peptide at a later time, suggesting the hypothesis that two peptides resulting fr

LOSS OF CHAT- AND NGF RECEPTOR-IMMUNOREACTIVE

LOSS OF CHAT- AND NGF RECEPTOR-IMMUNOREACTIVE BASAL FOREBRAIN NEURONS FOLLOWING EXCITOXIC HIPPOCAMPAL LESIONS IN THE DEVELOPING RAT. M.A. Burke-Watson<sup>6</sup>. E.I. Mufson <sup>1</sup> B.H. Wainer <sup>2</sup> and J.H. Kordower <sup>1</sup>, Dept. of Anatomy and Cell Biology; Univ. Illinois Sch. Med., 1 Dept. of Neurological Sciences, Rush Presbyterian Med Ctr., 2 Dept. of Pharmacology, Univ. Chicago Sch. Med., Chicago, IL. 60612 USA. Adult cholinergic septal/diagonal band neurons persist following elimination of growth factor-producing target neurons within the hippocampus (Sofroniew et al., Science, 247: 338-342, 1990; Kordower et al., Exp. Neurol., in press). To determine whether the sustained viability of these neurons is the result of target contact, postnatal day 7 (PN7) rat pups received injections of ibotenic acid into the hippocampus (10 μg/ul; 1 μl injection) and were sacrificed 4 weeks later. As seen previously in adult rats, no reductions in ChAT-immunoreactive neurons were observed within the septum pisilateral to the lesion (T(7)=1-97; p>.05). In contrast, PN7-lesioned rats displayed a 28% decrease in ChAT-immunoreactive neurons within the ipsilateral vertical limb of the diagonal band (VLDB) relative to the contralateral side (T(7)=8.41; p<.0001). Similar results were obtained on adjacent sections immunoreacted for the p75 NGF receptor. To assess the extent of septal/diagonal band connectivity within the hippocampus at this time point in development, intact rat pups were injected at PN7 with fluorogold (2%; 0.2 μl) and sacrificed 48h later. Numerous neurons were retrogradely labeled within the Septum. In contrast, only a few magnocellular neurons were retrogradely labeled within the VLDB. This suggests that trophic factor-producing target neurons may be required for basal forebrain viability during the development of afferent fiber innervation. (AG09466, NS25985).

ULTRASTRUCTURAL THREE DIMENSIONAL RECONSTRUCTION OF CORTICAL ChAT IMMUNOREACTIVE VARICOSITIES: EFFECTS OF LESION, GMI AND/OR NGF TREATMENT L. Garofalo.\* A. Ribeiro-da-Silva and A.C. Cuello, Dept. Pharmacology, McGill University, Montréal, Québec,

NGF treatment preserves cholinergic fiber length and produces a significant hypertrophy of cortical presynaptic terminals in layer V of the remaining rat cortex adjacent to a lesion site (PNAS 89, 2639-2643, 1992). We further studied whether adjacent to a lestion site (PNAS 89, 2039-2043, 1992). We further studied whether such effects could be potentiated by the monosialoganglioside GM1. Adult male Wistar rats were cortically lesioned and treated as previously described (PNAS 86,2056-2060,1989). Thirty days post-lesion, the rats were processed for ChAT mmunocytochemical electron microscopic quantitative analysis. A total of 96 varicosities per group were automatically detected and measured by an image analysis system (Quantimet 920). In control unoperated rats the mean cross sectional analysis system (Quantumet 920). In control unoperated rats the mean cross sectional area of layer V cortical ChAT immunoreactive (ChAT-IR) varicosities was 0.223 ± 0.013 µm². Confirming previous results, a remarkable shrinkage (40%) of these boutons was noted in lesion vehicle treated rats while, NGF treatment significantly augmented bouton area 20% above control values. This cholinergic terminal augmented outour area 20% above control values. Inis choinergic terminal hypertrophy was even more dramatic (52% above control values) in rats treated with both GM1 and NGF. By contrast, GM1 treatment alone failed to prevent bouton shrinkage in lesioned rats. Furthermore, a higher percentage of boutons with synaptic contacts were noted in NGF and NGF/GM1 treated lesioned rats. Three to four contacts were noted in NGF and NGF/GM1 treated lesioned rats. Three to four representative ChAT-IR cortical varicosities from each group were then examined serially and reconstructed by image analysis in order to quantify bouton volume and synaptic area. The effect of NGF and its potentiation by GM1 was more apparent here, where an increase in bouton volume of 110% and 154% respectively, above control values was observed. A trend towards an increase in synaptic area per varicosity in NGF and NGF/GM1 treated lesioned animals was also noted. The results suggest that NGF can significantly alter presynaptic terminal fields and synaptic connections in the fully differentiated CNS; effects which can be potentiated by the monosialoganglioside GM1. Supported by MRC (Canada) and the Canadian Network of Centres of Excellence for Neural Repair and Functional Recovery.

CHRONIC NGF TREATMENT ENHANCES MUSCARINIC M1 RECEPTOR FUNCTION IN ADULT RATS FOLLOWING PARTIAL FIMBRIAL TRANSECTIONS. F. Hefti, D.M. Araujo, and P.A. Lapchak. USC, Andrus Ger. Ctr., Los Angeles, CA, 90089-0191.

Effects of chronic recombinant human (rh) NGF treatment (icv, 1.0 µg qod for 21 days) on hippocampal muscarinic receptor densities and muscarinic receptor-linked second messenger systems were determined in adult rats 21 days following fimbrial transections. First, quantitative autoradiographic analysis of muscarinic receptors was carried out using [Hipirenzepine for M1 receptors and [HiA-DX 384 for M2 receptors. Partial fimbrial transections did not alter the density of the M1 or M2 receptor population in the dorsal or ventral hippocampus and there was no effect of chronic rhNGF treatment. In contrast, in animals receiving full fimbrial transections which by themselves did not alter muscarinic receptor density, thNGF treatment increased the density of M1 and M2 receptors in the CA1 region by 35%. Secondly, we determined the effect of chronic rhNGF on muscarinic receptor-mediated second messenger production in rats receiving partial fimbrial transections. The muscarinic M1-receptor mediated response, oxotremorine-induced IP, production by hippocampal slices was increased by 61% on the lesioned side of animals treated with a control protein. Chronic NGF treatment prevented the lesion-induced supersensitivity of M1 muscarinic receptors. In rhNGF-treated animals IP, production was similar to values on unlesioned control sides. Neither fimbrial transections nor NGF treatment altered oxotremorine-induced changes in hippo-campal CGMP levels. The findings of the present study suggest that rhNGF-induced enhancement of presynaptic cholinergic function(s) translate into functional changes at the level of postsynaptic hippocampal muscarinic receptors.

NGF RESTORES THE AREA OF CHAT-POSITIVE CORTICAL FIBERS IN NBM-LESIONED RATS WITHOUT AFFECTING CHOLINERGIC INTER-NEURONS. Ad J. Dekker\* and Leon J. Thal, Dept. Neurosciences, UCSD and Dept. Neurology, VAMC, San Diego, CA92161.

Rats received bilateral lesions of the nucleus basalis magnocellularis (NBM) by infusion of ibotenic acid (28 nmol in 2 injections per side). Two weeks after the lesion, osmotic minipumps were implanted that released 10 µg NGF or 0.3 µg Cytochrome-C per day through intraventricular cannulas. Treatment lasted for 6 weeks. Coronal sections of the frontal neocortex were stained for choline acetyltransferase (ChAT). The number of cortical neurons showing ChAT immunoreactivity was enhanced in lesioned animals (+42%), but was not further increased by NGF (+35%). The cross-area of the neurons was not affected by either the lesion or treatment with NGF. However, lesions of the NBM reduced the area of ChAT-positive fibers by 55%, while treatment with NGF restored the area to 95% of control. These results suggest that NGF restores cholineraic innervation to the cortex from remaining NBM neurons. rather than stimulating compensation by local interneurons.

### 329.4

CORTICAL DEVASCULARIZING LESION MODEL IN PRIMATES: LONG TERM EFFECT OF HUMAN RECOMBINANT NERVE AND GROWTH FACTOR MONOSIALOGANGLIOSIDE TREATMENT. P. Liberini\*1, E.P. Pioro1, D. Maysinger1, F.D. Ervin2 and A.C. Cuello<sup>1</sup>. Dept. of Pharmacology & Therapeutics<sup>1</sup>, and Dept. of Psychiatry<sup>2</sup>, McGill University, Montreal, P.Q., Canada, H3G 1Y6.

In the present study, the cortical devascularizing lesion model well established in rat has been reproduced in nonhuman primate (Coercopithecus aethiops). Thirty adult male monkeys randomly divided in four groups underwent surgeries and treatment with recombinant human nerve growth factor (rhNGF) alone or in combination with the monosialoganglioside GM1 (sham operated [7], lesioned/vehicle-treated [7], lesioned/rhNGF-treated [8], lesioned/rhNGF+GM1treated [8]). After a 6-months survival the animals were processed either for biochemistry (Choline acetyltransferase - ChAT - assay) nunocytochemistry (ChAT and NGF-receptor immunostainig). In lesioned/vehicle-treated monkeys the nucleus basalis of Meynert (nbM) underwent retrograde degeneration. ChAT activity significantly (p<0.05) decreased to 69  $\pm 5\%$  of sham operated value. The morphometrical analysis revealed a significant shrinkage of ChAT immunoreactive (IR) neurons in the intermediate region of the nbM (61  $\pm$ 1.4% of sham operated cell size, p < 0.01). The reported decrease of ChAT activity was fully prevented with the administration of rhNGF alone or in combination with GM1. However, the shrinkage of nbM ChAT IR neurons was fully prevented only in animals receiving both rhNGF and GM1 (89  $\pm$  3.6% of sham operated cell size, p>0.05). (Supported by the Medical Research Council of Canada, the Centres of Excellence Network for Neural Regeneration and Functional Recovery and Fidia Research Labs).

## 329.6

DEATH OF SEPTAL CHOLINERGIC NEURONS FOLLOWING ABLATION OF TARGET NEURONS IN NEONATAL RATS. J.D. Cooper\* and M.V. Sofroniew. Department of Anatomy, University of Cambridge, Cambridge, U.K. Following ablation of their target hippocampal neurons in adult or aged animals, the cholinergic neurons of the septal region do not die, but nearly in an attorbind state. These observations extract the state of the septal region of the target.

aged animals, the chorning in reutons of the separation is a suggest that arget-but persist in an atrophied state. These observations suggest that target-derived neurotrophins do not precisely regulate neuronal survival in the adult CNS, but influence neuronal structural and chemical phenotype. To investigate the effect of target ablation in the *developing* CNS, the hippocampus was excitotoxically ablated in anaesthetised 9 day old Wistar rat pups. After aspiration of the overlying cortex the exposed hippocampus was injected into 4 sites with NMDA or vehicle. After 28 days animals were perfused and the extent of the lesion and its effect upon afferent septal neurons assessed histologically. Injections of NMDA resulted in the ablation of over 90% of hippocampal tissue. Comparable lesions in adults abolish NGF and BDNF mRNA Comparable lesions in adults abolish NGF and BDNF mRNA production and lower septal NGF levels. In lesioned neonates, the number of septal neurons stained for ChAT or the low affinity neurotrophin receptor (p75NGFR) declined significantly by over 65%, as compared with a 30% decline in vehicle injected animals (which showed some hippocampal damage). These findings indicate that developing cholinergic neurons are lost from the septum in the absence of their learner neurons. This observations expects that terrest derived. target neurons. This observation suggests that target-derived neurotrophins regulate septal cholinergic neuronal survival during early post-natal development.

AMELIORATION OF SEPTAL CHOLINERGIC NEURONAL DEGENERATION AFTER NERVE GROWTH FACTOR DEPRIVATION BY CYTOKINE-ACTIVATED ASTROCYTES. K. YOSHIDA\*, M. SAGOH, H. WAKAMOTO,T. YAZAKI, M. OTANI, S. TOYA and F. H. GAGE†: Dept. of Neurosurg., Keio Univ., Shinjuku-ku, Tokyo 160, Japan; †Dept. of Neurosci., UCSD, La Jolla, CA 92193.

Nerve growth factor (NGF) synthesis and secretion from astrocytes is cooperatively regulated by various cytokines including fibroblast growth factors, interleukin- $1\beta$  (IL- $1\beta$ ), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) [Yoshida and Gage: 1991, 1992]. The present study was performed to determine the effect of NGF produced by cytokine-activated astrocytes on NGFdeprived septal neurons in vitro. Enzymatically dissociated septal neurons from E-16 rat fetuses were grown on monolayered astrocytes obtained from neonatal rat hippocampi in a serum-free defined medium. Effects of the various combinations of IL-1 $\beta$ , TNF- $\alpha$  and TGF-β1 on septal cholinergic neurons cocultured with astrocytes were examined. A combination of IL-1 $\beta$  and TNF- $\alpha$  increased cholineacetyltransferase (CAT) activity via NGF produced by astrocytes. NGF-treated septal cholinergic neurons were found to degenerate following NGF deprivation. However, a combination of IL-1\beta and TNF- $\alpha$  significantly reduced the degeneration of NGF-deprived septal cholinergic neurons by activating astrocytes. The cytokines, which regulate NGF synthesis and secretion in astrocytes, are considered to play an important role in neuronal regeneration following brain injury.

EXPRESSION OF NEUROTROPHIN AND TRK mRNA IN ALS AND AXOTOMIZED RAT SPINAL CORD AND PERIPHERAL TISSUE. J. L. Seeburger\*. T.C. Cope, and J.E. Springer, Departments of Neurology (JLS and JES) and Physiology and Biophysics (TCC and JES), Hahnemann University School of Medicine, Philadelphia, PA 19102.

Peripheral nerve crush or transection in adult experimental animals results in the

Peripheral nerve crush or transection in adult experimental animals results in the increased expression of nerve growth factor receptor (p75NGFR) mRNA in spinal cord alpha motoneurons and NGF mRNA in peripheral nerve and muscle. We recently found increased expression of p75NGFR and NGF mRNA in postmortem ALS spinal cord motoneurons and muscle, respectively. We propose that the increase in p75NGFR expression in ALS spinal cord may be associated with compensatory growth responses in minimally or unaffected alpha motoneurons.

Recent evidence has supported the involvement of membrane receptor tyrosine kinase (trk) molecules in high affinity neurotrophin binding associated with biological activity. To determine if alpha motoneurons are potentially responsive to target-derived neurotrophins, we have begun to examine the expression of trkA and trkB mRNA in ALS spinal cord and spinal cord from rats receiving sciatic nerve damage. We hypothesize that if neurotrophins are involved in compensatory growth responses in ALS and/or experimental animals, alterations in trkA and/or trkB should be observed. Peripheral nerve axotomy is a well studied procedure for analyzing events associated with muscle denervation and reinnervation. Also, there is substantial associated with muscle denervation and reinnervation. Also, there is substantial evidence demonstrating compensatory growth responses of motoneurons in patients with ALS. We have used cRNA probes in conjunction with in situ hybridization to with ALS. We have used cRNA probes in conjunction with in situ hybridization to localize cells in ALS and rat spinal cord sections that may express triAA or trkB mRNA. In addition, a nuclease protection assay was used to analyze the levels of NGF and BDNF mRNA in skeletal muscle and peripheral nerve samples from ALS patients and nerve-transected animals. Although no neurotrophic effects of NGF on alpha motoneurons have been documented, it is possible that NGF and/or other neurotrophins could play a role in compensatory growth events associated with motorneuron sprouting and reinnervation. Supported by PHS grants AG-08969, NS-30248, and the Philadelphia ALS Association (JES).

NEUROTROPHIN AND trk TYROSINE KINASE RECEPTOR mrna expression in kindling is dependent on seizure DURATION. Z. Kokaia<sup>1</sup>, I. Bengzon <sup>1</sup>, P. Emfors<sup>2</sup>, M. Kokaia<sup>1</sup>, G. Leanza\*<sup>3</sup>, O. Nilsson<sup>3</sup>, H. Persson<sup>2</sup> and O. Lindvall<sup>1</sup>.

<sup>1</sup>Restorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden; <sup>2</sup>Department of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institute, S-104 01 Stockholm, Sweden; <sup>3</sup>Department of Medical Cell Research, University of Lund, S-223 62 Lund, Sweden.

Medical Cell Research, University of Lund, S-223 62 Lund, Sweden. Expression of mRNAs for nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) and the tyrosine kinase receptors trkA, trkB and trkC has been studied using in situ hybridization in the rat brain 2 h after kindling-induced seizures. Epileptiform activity produced by hippocampal stimulation (once daily) and exceeding 70 s increased BDNF, NGF, trkB and trkC mRNA expression in the dentate granule cells irrespective of seizure grade. BDNF mRNA levels were also elevated bilaterally in the CA1-CA3 regions, amygdala and the piriform, entorhinal, perirhinal, retrosplenial and temporal cortices after generalized seizures. The magnitude of the increases was similar throughout kindling development and in the fully kindled brain. TrkA mRNA levels were unchanged after situres [Internet price] of the hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for injection of 6 hydroxydoxpanine or a bilateral [imprice] for inj seizures. Intraventricular injection of 6-hydroxydopamine or a bilateral fimbria-fornix lesion did not alter seizure-evoked mRNA levels for the neurotrophins or the *trk* testion did not after seizure-evoked mRNA levels for the neurotrophins or the trix receptors, but increased the number of animals with elevated levels in dentate granule cells after the first stimulation, probably due to a prolongation of seizure activity. Both in sham-operated and fimbria-fornix lesioned rats seizure activity caused a significant reduction of NT-3 mRNA levels in dentate granule cells. The results indicate that the induction of BDNF mRNA is an "all-or-none" type of response and demandant on sainuse durition but not the grade of individual designation. dependent on seizure duration but not the grade of kindling development. Changes of BDNF, NGF, NT-3 and *trkB* and *trkC* were observed concomitantly in the dentate gyrus, which suggests, that seizure activity triggers a cascade of genomic events in dentate granule cells, probably regulated via the same mechanism.

Differential Actions of Neurotrophins in the Locus Coeruleus and Basal Forebrain. W.J. Friedman\*, C.F. Ibáñez<sup>1</sup>, F. Hallböök<sup>1</sup>, H. Persson<sup>1</sup>, L.D. Cain, C.F. Dreyfus, and I.B. Black. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, 675 Hoes Lane, Piscataway, NJ 08854, USA, and <sup>1</sup>Department of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institute, Box 60400, \$10401 Stockholm, Sweden

We have compared different neurotrophins in the regulation of reuronal survival and function using dissociated embryonic cell cultures from two brain regions, the basal forebrain (BF) and locus coeruleus (LC). In the BF, nerve growth factor (NGF) increased choline acetyl transferase (ChAT) activity, but did not influence cholinergic cell survival. In contrast to NGF, BDNF, NT-3, and the novel neurotrophin, NT-4, all increased ChAT activity and cholinergic cell survival.

We also examined embryonic locus coeruleus (LC) neurons in culture. LC neurons are unresponsive to NGF. In contrast, NT-3 and NT-4 elicited significant increases in survival of noradrenergic LC neurons, the first demonstration of trophic effects in this critical brain region. Identification of factors supporting coeruleal and basal forebrain neuronal survival may provide insight into degeneration of these disparate structures in disorders such as Alzheimer's disease. Supported by NIH grants NS 10259 and HD 23315-05, and DA 05132.

### 329.10

DE NOVO EXPRESSION OF THE p75 NGF RECEPTOR FOLLOWING HYPOGLOSSAL NERVE TRANSECTION IN NONHUMAN PRIMATES. C. Del Rosario, K. Bankiewicz\*1, E.J. Mufson, and J.H. Kordower, Dept. of Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago Ill. and ISurgical Neurology Branch, NIH.

Few examples of trophic factor-mediated neuronal plasticity exist in

the primate brain. In nonprimates, transection of peripheral nerve segments have been demonstrated to induce a *de novo* synthesis of the p75 receptor for nerve growth factor (NGFr). As part of a larger study in our laboratory, Cebus and Rhesus monkeys received complete unilateral transections of the hypoglossal nerve as it courses across the carotid bifurcation. We examined the immunohistochemical expression of NGFr within the hypoglossal nucleus in these monkeys which were sacrificed 1 (n=1), 4 (n=2), 10 (n=2), and 14 (n=1) weeks after surgery. They were compared to monkeys treated identically except for surgery. They were compared to monkeys ucated themselly except to sparing the hypoglossal nerve (operated controls; n=4) and unoperated controls (n=2). The hypoglossal nucleus was devoid of NGFr-immunoreactivity (NGFr-ir) in both control groups. In contrast, all monkeys undergoing hypoglossal nerve transection displayed robust NGFr-ir within neurons of the hypoglossal nucleus ipsilateral to the lesion. Interestingly, the contralateral hypoglossal nucleus also display a few NGFr-ir neurons. These effects were consistent at each time point examined except for a decrease in the number of NGFr-ir neurons in the monkey sacrificed 14 weeks post lesion. The *de novo* expression of other trophic factors are currently being investigated in this nonhuman primate model system. (NS25985).

## 329.12

ADRENALECTOMY DISRUPTS ASPECTS OF NEUROTROPHIN EXPRESSION IN HIPPOCAMPUS. J.C. Lauterborn\* and C.M. Gall, Dept. of Anatomy & Neurobiology, Univ. of California, Irvine CA. 92717.

Glucocorticoids have been shown to regulate the expression of nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF) in hippocampus but cellular localization of these changes have not been investigated. Further, it has not been determined if glucocriticolds affect neurotrophin-3 (NT-3) expression. Using *in situ* hybridization affect neurotrophin-3 (NT-3) expression. Using *in situ* hybridization and <sup>35</sup>-labeled cRNA probes, the effect of adrenalectomy (ADX) on levels of mRNA coding for NT-3, BDNF, and NGF in rat hippocampus was evaluated by film densitometry. Rats were adrenalectomized and killed 10-14 days later with paired controls. NT-3 cRNA hybridization in control rats was dense in CA2 stratum pyramidale and in the dentate gyrus stratum granulosum. Following ADX, NT-3 cRNA hybridization was decreased in CA2 stratum pyramidale to 10-20% of control levels. In stratum granulosum, NT-3 cRNA hybridization was only slightly decreased to ≈80% of control levels. In contrast, in stratum granulosum hybridization to NGF mRNA was markedly decreased to ≈30% of control levels. Hybridization to BDNF mRNA in CA3 stratum pyramidale and in stratum granulosum was unaffected by ADX: in both pyramidale and in stratum granulosum was unaffected by ADX; in both control and ADX rats these lamina were heavily labeled. These results indicate that within hippocampus basal expression of some neurotrophins by particular cell types (e.g., NT-3 in CA2 pyramidale cells) is largely dependent upon corticosteroids, whereas other aspects of neurotrophin expression are not glucocorticoid dependent. Supported by NS26748 to C.M.G.

SEIZURE-INDUCED CHANGES IN NEUROTROPHIN mRNA EXPRESSION ARE NOT DISRUPTED BY ADRENALECTOMY. C.M. Gall\* and J.C. Lauterborn. Dept of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

Recurrent limbic seizures cause different changes in the expression of mRNAs for nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) in hippocampus and cortex, including increases in NGF mRNA and decreases in NT-3 mRNA occurring after the period of seizure activity. In the present study, the involvement of glucocorticoids in these effects was assessed by quantitative in situ hybridization. Seizure-producing hilus lesions were placed in untreated rats and rats adrenalectomized (ADX) 10 days earlier. In both groups, seizures caused a marked increase in BDNF mRNA throughout the granule and pyramidal cell layers of hippocampus and in both superficial and deep layers of cortex that peaked by 12 hrs and had largely declined by 24 hrs postlesion. In control and ADX rats, NGF mRNA in stratum granulosum rapidly increased over 8-fold by 6 hrs postlesion, declined to near control levels by 12 hrs, and then increased to a second peak at 24 hrs. In both groups, neocortical NGF mRNA was markedly increased 12-24 hrs postlesion. Seizures decreased NT-3 mRNA in hippocampal stratum granulosum to virtually undetectable levels by 12 and 24 hrs postlesion in both control and ADX rats. Thus, although adrenalectomy alone reduces basal levels of NGF mRNA and virtually eliminates NT-3 mRNA expression in some forebrain neurons, this manipulation does not significantly disrupt the pattern of changes in neurotrophin expression induced by limbic seizures in the hilus lesion paradigm. Supported by NS26748 to C.M.G.

TROPHIC FACTOR PREVENTION OF DIABETIC NEUROPATHY IN A STREPTOZOCIN RAT MODEL. S. C. Apfel', J. C. Arezzo, M. Brownlee, M. Moran, P. K. Barnecott, and J. A. Kessler. Albert Einstein College of Medicine, Bronx, New York 10461

Peripheral neuropathy is a common debilitating complication of diabetic mellitus. Typically a combination of sensory, motor, and autonomic nerves may be affected. This broad spectrum of neuronal involvement suggests that administration of any one neurotrophic factor may provide inadequate protection. We have established a model of diabetic neuropathy in streptozocin treated rats using a combination of behavioral, biochemical and electrophysiological techniques to document abnormal nerve function. In a series of trials we have tested the ability of several neurotrophic factors including nerve growth factor (NGF), ciliary neurotrophic factor (CNTF), and Org 2766 to prevent the manifestations of neuropathy seen in our model. NGF prevented behavioral and biochemical manifestations of a small fiber neuropathy, but failed to fully prevent slowing of nerve conduction velocity. CNTF had striking effects on sensory neuropeptide and electrophysiology, but failed to prevent the diabetes-induced changes. No one agent prevented all the diabetic changes. Ultimately the ideal therapy may involve using combinations of trophic factors.

## 329.17

SERUM LEVELS OF NGF IN ADULT RATS FOLLOWING SUBCUTANEOUS INFUSION OF NGF. M.A. Tria, B. Figliomeni, M. Fusco, N. Schiavo, S. Cereser, P. Marini, F. Fogarolo and G. Vantini. Fidia Research Labs, Abano Terme, Italy.

Sympathetic and sensory neurons retain responsiveness to NGF and/or NGF-like molecules throughout their lifetimes. Dysfunctions in trophic factor availability may thus have a pathophysiological role in neuropathies involving these neurons. In this regard, studies concerning NGF and related molecules may open new concepts for treatment of peripheral neuropathies including the possible use of NGF itself as a therapeutic agent. Here we have evaluated NGF levels in serum of rats receiving a continuous subcutaneous infusion of NGF (3-30µg/day, for 2-4 weeks) via osmotic minipumps (Alzet, model 2002). Fairly stable levels of NGF in serum were attained within a few days following pump implantation. The apparent steady-state serum NGF levels showed progressive increments as a function of NGF infusion rate. The serum concentrations of NGF obtained were in the picomolar range, and are therefore compatible with the administered trophic factor having a physiological/pharmacological role exerted via interaction with high-affinity receptors (KD about 10pM) (see Figliomeni et al., this meeting).

#### 329 14

MODULATION OF LOW-AFFINITY NGF RECEPTOR IN ADULT SPINAL MOTONEURONS AFTER TRAUMATIC AND NON TRAUMATIC LESIONS OF THE PERIPHERAL NERVE M.Rende, C.Provenzano and G.De Renzis\* Inst. of Human Anatomy, UCSC, Rome, Italy

Adult rat spinal motoneurons (SMN) express low-affinity NGF receptor (LNGFR) after their axotomy (cut or crush). We have analyzed the modulation and the time-course of LNGFR expression in lumbar SMN following (a)traumatic injures of the sciatic nerve that allow a regeneration delayed relative to crush (implantation of a silicone chamber, repeated crushes and delayed repair of a ligated nerve);(b)toxic or metabolic injures without any direct trauma of the nerve (experimental diabetogenesis, Botulinum and Bungarotoxin intoxication, 2,5-Hexanedione intoxication) and (c) block of the axoplasmatic transport by topical applications of Vincristine combined with a nerve crush. The results we present are consistent with the idea that (1)LNGFR immunoreactivity in adult SMN is a specific marker for SMN that are attending an axonal outgrowth and not a generic signal of cellular damage; (2) LNGFR expression in these SMN is related and strict parallel the outgrowth process time-frame and (3) the signal/s that trigger and sustain this expression are retrogradely transported from the periphery. Supported by a Telethon-Italy grant.

#### 329.16

SYSTEMIC NGF AFFECTS NGF RECEPTOR EXPRESSION IN DORSAL ROOT GANGLIA (DRG) OF DIABETIC RAT. B. Figliomeni, C. Panozzo, G. Vantini\*, F. Biasiolo, R. Rubini C. Triban and F. Di Gregorio. Fidia Research Labs, Abano Terme, Italy.

Sensory and sympathetic neurons, known to be continually dependent on NGF and/or NGF-like molecules, are adversely affected at an early stage in diabetes mellitus. A diabetes-induced altered synthesis and/or an impaired signal transduction mechanism of these trophic factors may well underlie the clinical symptoms of diabetic neuropathy. To gain further insights into this problem, Northerm blot analysis was used to evaluate the levels of mRNA encoding the low-affinity NGF receptor (pTsNGFR) in L4 and L5 DRG of streptozotocin-induced diabetic rat, receiving a continuous subcutaneous infusion of NGF or the corresponding vehicle via osmotic minipumps (Alzet, model 2002). Diabetic rats showed a progressive decrease of mRNA pT5NGFR levels in DRG which was counteracted by NGF treatment. These data support the notion that diabetic sensory neurons remain responsive to NGF, suggesting that NGF itself may rapresent a therapeutic agent in diabetic neuropathy.

## 329.18

TREATMENT WITH ACETYL-L-CARNITINE (ALCAR) ELEVATES NGF LEVELS IN THE CNS OF AGED RATS. G. Taglialatela\*. D. Navarra, R. Cruciani, M.T. Ramacci, L. Angelucci<sup>1</sup>. Institute for Research on Senescence, Sigma Tau, Pomezia, Rome; <sup>1</sup>Institute of Pharmacology II, La Sapienza Univ. of Rome, Italy.

Some age-related impairments of the CNS in senescent rats, which may be due to reduction of neurotrophic support to neurons, are prevented by chronic treatment with ALCAR. Also, ALCAR potentiates NGF action on PC12 cells and prevents the reduction of NGF receptors in the CNS of aged rats. On the basis of these findings, a study was carried out on the effects of an 8-day treatment with ALCAR (200 mg/kg i.p.) on the NGF levels in the various brain structures of adult and aged rats. Although no differences were found between adult and aged control rats, a significant increase of NGF levels in hippocampus and basal forebrain of the aged rats only was observed following treatment with ALCAR. ALCAR did not affect the NGF levels in frontal cortex and cerebellum. These data are suggestive of a strategy of possible therapeutical relevance to increase NGF content in those CNS areas that are impaired in aged subjects, especially in the light of previous findings of an i.c.v. treatment with NGF rescuing atrophic cholinergic neurons of the basal forebrain and septum in aged rats.

329 19

CORRELATION OF PHARMACOLOGICAL INDUCTION OF NGF IN VIVO AND IN VITRO. J. L. Vaught\*. M.E. Lewis, M.S. Saporito, H. Wilcox, K. Clopton-Hardpence and S. Carswell. Cephalon, Inc., 145 Brandywine Parkway, West Chester, PA 19380.

Work from several laboratories has shown that NGF can be induced by

Work from several laboratories has shown that NGF can be induced by structurally diverse compounds in various types of primary and established cell lines, as well as in the CNS. To examine whether induction of NGF in cell culture has predictive value for *in vivo* activity, we compared the effects of 4-methylcatechol and 1,25 dihydroxy-vitamin D3 on NGF mRNA expression in mouse fibroblast L929 cells and in rat hippocampus after ICV injection. NGF mRNA was analyzed by Northern blot analysis in L929 cells and RNase protection in rat brain (see accompanying abstracts by Carswell et al. and Saporito et al.). Doseresponse studies indicated a similar relative potency in both systems. Similar efficacies were also observed, with each compound stimulating NGF RNA levels between 2- and 4-fold both *in vivo* and *in vitro*. Time course studies of induction using maximally-inducing doses revealed comparable kinetics in cell culture and *in vivo*. In both models, peak levels of induction were observed between 4 and 8 hours after treatment with either compound, but by 24 hours these levels had returned to baseline with 4-methylcatechol and were sustained with 1,25 dihydroxy-vitamin D3. Taken together, the results indicate that NGF induction in L929 cells can be used with at least some classes of compounds to predict both qualitative and quantitative parameters of activity in the brain.

### 329.21

MULTIPLE CELLULAR PATHWAYS OF INDUCTION OF NGF BY 1,25 DIHYDROXYVITAMIN D3, TPA, SERUM, AND 4-METHYLCATECHOL. S. Carswell\*, H. Wilcox, K. Clopton-Hartpence, M.S. Saporito, M.E. Lewis, and J.L. Vaught. Cephalon, Inc., 145 Brandywine Parkway, West Chester, PA 19380. In an effort to characterize the mechanisms underlying the regulation of NCS.

In an effort to characterize the mechanisms underlying the regulation of NGF expression, we recently showed that isoproterenol, 4-methylcatechol and serum induce NGF by distinct pathways in mouse L929 cells (Carswell et al., *Mol. Brain Res.*, in press). These investigations have now been extended to compare the mechanisms by which the phorbol ester TPA, 4-methylcatechol, serum, and 1,25-dihydroxyvitamin D3 stimulate NGF synthesis. Various combinations of these compounds at maximally-inducing concentrations (50 ng/ml TPA, 50 µM 4-methylcatechol, 10% serum, and 10 nM 1,25 dihydroxyvitamin D3) revealed additive effects on secreted NGF levels from L929 cells. Each of these compounds has been shown previously to induce NGF mRNA, and preliminary data suggest that the additivity observed in NGF protein can be accounted for by commensurate changes in NGF mRNA levels. The goal of this work is now to identify molecular and cellular parameters which discriminate these differing mechanisms. Studies measuring the effects of these compounds on NGF mRNA stability and rate of transcription initiation are in progress, as well as experiments using various metabolic inhibitors. In parallel work, we are testing whether these results can be replicated in the CNS (see abstracts by Saporito et al. and Vaught et al.).

MOLECULAR MECHANISMS OF NERVE GROWTH FACTOR INDUCTION BY 4-METHYLCATECHOL. E. K. Hoffman. M. S. Saporito, H. M. Wilcox, K. C. Hartpence, M. E. Lewis\* and S. Carswell. Cephalon, Inc., 145 Brandywine Parkway, West Chester, PA 19380. Nerve growth factor (NGF) has been proposed as a candidate for use as a therapeutic in the treatment of Alzheimer's disease (AD) due to its

Nerve growth factor (NGF) has been proposed as a candidate for use as a therapeutic in the treatment of Alzheimer's disease (AD) due to its actions as a neurotrophic agent for basal forebrain cholinergic neurons. Augmentation of endogenous levels of NGF by compounds capable of crossing the blood-brain barrier may provide a novel alternative therapeutic strategy. To test the feasibility of this approach, we have been studying the induction of NGF expression by the catecholamine derivative 4-methylcatechol (4-MC). Treatment of mouse L929 fibroblasts with 75 uM 4-MC results in a 2- to 3-fold induction of NGF protein and RNA levels. Similiarly, ICV injection of 4-MC into adult rat brain leads to an elevation of hippocampal NGF RNA levels. These findings suggest that NGF induction by 4-MC may be mediated at the level of transcription. To address this possibility, we have analyzed the effect of 4-MC on the NGF promoter region by using the bacterial chloramphenicol acetyltransferase (CAT) gene fused to NGF promoter deletion fragments as a reporter system in transient expression assays. Further, we have studied the effect of 4-MC on the initiation and stability of the endogenous NGF mRNA transcripts. The results of these studies indicate that the induction of NGF by 4-MC is complex, and likely involves the participation of multiple mechanisms which together lead to an overall enhancement of NGF levels.

### 329.22

PHARMACOLOGICAL INDUCTION OF NERVE GROWTH FACTOR mRNA IN ADULT RAT BRAIN. M.S. Saporito\*. K.C. Hartpence. E.M Reilly. E. Robbins. C. Steffler. H. M. Wilcox. J.L. Vaught. M.E. Lewis and S. Carswell. Cephalon, Inc. 145 Brandywine Parkway, West Chester, PA 19380.

West Chester, PA 19380.

Nerve growth factor (NGF) may be an effective treatment for Alzheimer's disease based on its ability to maintain cholinergic neurons in animal models of neurodegeneration. However, NGF does not cross the blood-brain barrier making direct administration into the brain the only viable means of delivery. An alternative approach is to upregulate NGF gene expression in the CNS. In the present study, compounds shown to induce NGF in other systems were assessed for their ability to induce NGF in at CNS. Rats were injected ICV with test compounds and sacrificed between 4 and 24 hrs after injection. NGF mRNA levels were quantified by an RNAse protection assay. Interleukin-16, 4-methy catechol and 1,25 dihydroxyvitamin D3 all induced NGF mRNA in the hippocampus and cortex by 2 to 4 fold after administration to anesthetized rats. Dexamethasone, which reduces NGF levels in L929 cells, increased NGF mRNA in these two brain regions. Induction of NGF mRNA was dose-dependent, with interleukin-1B and 1,25 dihydroxyvitamin D3 being the most potent. Peak levels of NGF mRNA occurred between 4 and 8 hrs after injection, and the duration of NGF induction was dependent on the dose and the compound administered. These studies demonstrate induction of NGF mRNA in adult rat brain following administration of structurally diverse compounds. Additional studies are focused on determining if these compounds induce NGF to a sufficient level to increase cholinergic function and other NGF-mediated responses.

## DEVELOPMENT OF CEREBRAL CORTEX AND LIMBIC SYSTEM I

EFFECT OF DEPLETION OF LAYER IV ON DORSAL LATERAL GENICULATE CELL NUMBER AND INGROWTH OF GENICULO-CORTICAL AXONS. T.-U. Woo\*. J. K. Niederer. and B. L. Finlay. Biopsychology Laboratory, Cornell University, Ithaca, New York 14853. Previous studies have shown that ablation of the dorsal lateral geniculate nucleus (dLGN) leads to the disappearance of layer IV in visual cortex in the

Previous studies have shown that ablation of the dorsal lateral geniculate nucleus (dLGN) leads to the disappearance of layer IV in visual cortex in the hamster, suggesting a crucial role of the thalamus in specifying or maintaining neurons with stellate morphology. To further explore the trophic relationship of the two structures, we depleted layer IV using the mitotic inhibitor methylazoxymethanol (MAM) and evaluated the effect of this depletion on the dLGN and the pattern of innervation of geniculocortical afferents.

MGN and the pattern of innervation of geniculocortical afferents.

MAM was injected into pregnant hamsters (20 mg/Kg) on embryonic day
14 when the major population of layer IV neurons are generated but after the
generation of dLGN. The absolute number of cells in layer IV was reduced by
approximately 60%. Examination of brains of animals treated with MAM and
labeled with bromodeoxyuridine (BrdU) showed depression of mitosis lasting at
most 33 hours after MAM injections. The volume (normal:0.163±0.006 mm<sup>3</sup>,
n=2; MAM:0.160±0.014mm<sup>3</sup>, n=3), neuronal density (normal:129,700±290
/mm<sup>3</sup>; MAM: 142,000±7,700/mm<sup>3</sup>) and number (normal:20,800±600;
MAM:22,700±1,600) of the dLGN of postnatal day 20 animals were not changed
significantly by this manipulation. Thalamocortical projections, assessed with
HRP, terminated in the dorsal aspect of the remaining cortex with less dense
arborizations. There was no compensatory increase in density of terminals in the

subplate and layer VI.

Our results have demonstrated that thalamic neurons show surprising independence of layer IV neurons for their survival; this could be due to the fact that stellate neurons are not the sole targets for thalamocortical afferents. Studies in progress are examining thalamocortical axonal development after MAM treatment with the fluorescent axon tracer, DiI.

Supported by NIH Grant R01 NS19245.

## 330.2

STAGE-SPECIFIC PRODUCTION OF FIBRONECTIN IN NEOCORTICAL DEVELOPMENT: EVIDENCE FOR SYNTHESIS BY BOTH NEURONS AND GLIA. A.L. Pearlman\*, T.J. Broekelmann, J.A. McDonald¹, and A.M. Sheppard. Depts. of Cell Biol., Neurol. and Med., Washington Univ. Sch. of Med., St. Louis, MO 63110, and Mayo Clinic¹, Scottsdale, AZ 85259

The distribution of immunolabeling for fibronectin (FN) changes rapidly during

The distribution of immunolabeling for fibronectin (FN) changes rapidly during early development of the cerebral cortex, but FN remains closely associated with both radial glia and preplate/subplate neurons throughout its transient period of expression (Stewart and Pearlman, 1987; Chun and Shatz, 1988; Sheppard et al., 1991). In the present study, we used in situ hybridization with a riboprobe generated from a partial cDNA for human FN (Kormblihtt et al., 1985) to analyze FN production in the neocortex of the embryonic mouse (E11-E16). FN mRNA is evident in two different locations at temporally distinct stages. Before the first postmitotic neurons form the preplate, FN mRNA levels are highest deep in the proliferative epithelium of the ventricular zone, then decrease substanially as the preplate forms. A second stage of FN production begins with the emergence of the cortical plate, when FN mRNA is prominent in the upper intermediate zone and subplate. To identify the cellular sources of FN, we used brefeldin A to block protein secretion by cortical cells in culture, then double-immunolabeled the cells with antibodies to FN and to cell-type specific intermediate filaments. Both neurons, identified with antibodies to neurofilaments, and glia, identified with MAb RC1, produce FN in culture. Taken together, our findings suggest that FN is produced first by cells of the neuroepithelium, the most mature of which are radial glia. The later production appears to be by migrating neurons in the upper intermediate zone, and perhaps by the more mature neurons of the subplate as well.

EXPRESSION OF TWO CHONDROITIN SULFATE PROTEOGLYCAN CORE PROTEINS IN THE SUBPLATE PATHWAY OF EARLY CORTICAL AFFERENTS. B. Miller\*, A.M. Sheppard and A. L. Pearlman, Depts. of Cell Biology and Neurology, Washington Univ. Sch. of Med., St. Louis, MÖ 63110.

In prior studies we demonstrated that chondroitin sulfate proteoglycans (CSPGs), immunolabeled with antibodies to their glycosaminoglycan side chains, are prominent in the extracellular matrix (ECM) of the marginal zone and subplate in the developing neocortex of the mouse (Sheppard et al., J. Neurosci.11:3928, 1991), and that thalamic afferents travel directly through the CSPG-rich subplate, while cortical efferents cross it (Bicknese et al., Neurosci. Abst., 1991). To identify the CSPGs present in these locations, we used monoclonal antibodies to the core protein of selected CSPGs to immunolabel cortex in the developing rat and mouse. Immunolabeling for two brain-derived core proteins, 1D1 and 3F8 (245kD and 400kD; Rauch et al., J. Biol. Chem., 266:14785, 1991; provided by R. Margolis) appears in the subplate as it forms and before thalamic afferents arrive Labeling for 1D1 is both more prominent and more restricted spatially than 3F8, which is also faintly evident in the ventricular zone. Immunolabeling for both 1D1 and 3F8 subsequently appears in the layers of the cortex as they mature Immunolabeling for NG2 (300kD, provided by W.B. Stallcup) is restricted to blood vessels and presumptive 02A precursor cells, and 2D6, an antibody to a basement membrane CSPG (150kD; provided by J.R. Couchman) labels only blood vessels. Thus, two CSPG core proteins identifiable in developing corter (1D1 and 3F8) are components of the subplate associated extracellular matrix that may form a pathway for thalamocortical axons. In contrast, the distribution of the other core proteins we have examined does not suggest a role in the formation of axonal pathways or layers in early cortical development.

### 330.5

BOW ARE THALAMOCORTICAL AXONS GUIDED IN THE REELER MOUSE? Zoltán Molnár\* and Colin Blakemore. Univ. Lab. of Physiology, Parks Road, Oxford, OX1 3PT, UK.

In Reeler mouse, where the layers of the cortex are inverted, thalamic axons nevertheless innervate the correct cortical regions (see Caviness et al., Cerebral Cort, 1988, 7, 59). We examined early projections in Reeler, using carbocyanine dyes to trace axons in fixed tissue, viewed by conventional and confocal microscopy. The formation of the preplate, outgrowth of an array of topographically ordered, descending, corticofugal pioneer axons, the synchronous growth of pioneer thalamic axons through the primitive internal capsule and their tangential distribution over the scaffold of corticofugal fibres, all occur indistinguishably in Reeler and normal animals. By the time thalamic axons arrive under their target areas (El5 for occipital cortex), the cortical plate itself has started to form. In Reeler, the plate forms under the 'superplate' cells, whose pioneer axons come to lie in oblique fascicles, running through the thickening plate. In normal mice, most thalamic axons accumulate in the subplate below. By contrast, in Reeler, thalamic axons run up diagonally in fascicles through the plate, to gather and wait over the 'superplate' cells above. The puzzling appearance of thalamic fibres in adult Reeler, looping up to layer 1 before ending lower in the cortex, is explained by those axons following precisely the same algorithm of development as in the normal animal, but in relation to the displaced cells of the 'superplate'. Our findings support the hypothesis that early postmitotic cells play a crucial role in guiding and holding thalamic axons (Shatz et al. and Blakemore & Molnar, Cold Spring Harb Symp Quant Biol, 1990, 55: 469 and 491). We thank André Goffinet for providing Reeler specimens and the Wellocome Trust, the MRC and the Human Frontier Science Program for support.

## 330.7

AFFERENTS TO PREPLATE NEURONS IN EMBRYONIC MOUSE CORTEX. J.E. Crandall\*, L.C. Hassinger and J. Bonaccorso. E.K. Shriver Center, Waltham, MA 02254 and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

We have been studying the differentiation of early generated neurons that form the preplate and the development of their afferents in normal and replace parts of the control of their afferents in normal content of their afferents.

and reeler mutant mouse cortex (Crandall et al., Dev. Brain Res., 1986, 28:127). We are determining when and where synaptic contacts reach different morphologic types of preplate neurons by photoconverting the fluorescent lipophilic dye, Dil, into reaction product appropriate for electron microscopy. Embryos from timed-pregnant B6C3 mice were perfused intracardially with mixed aldehydes. Crystals of Dil were placed into one of three potential sources of cortical afferents: brainstem, thalamus and cortex. After brains were stored at 37°C for 1-3 weeks, 50-100 µm thick sections were cut with a Vibratome and fluorescently labeled cells and fibers were photoconverted to an electron dense DAB reaction product according to Sandell &Masland (1988). At E13 we have not as yet detected thalamic or brainstem fibers that contact preplate cells. However, both medial and lateral cortical areas send relatively long fibers within the preplate and outer regions of the intermediate zone to adjacent cortical areas. Labeled preplate neurons and their processes present good membrane preservation. To date, labeled cortical fibers occasionally tipped with growth cones contact preplate cells but do not yet show synaptic specializations. By extending the findings of others on embryonic rat cortex to embryonic mice, we can take advantage of the genetic mutant reeler to determine the effect of cell position on afferent ingrowth. Supported by MR Core Grant HD-04147 and the Dept. of Mental Retardation of the Commonwealth of Massachusetts (Contract: 1002-20023-SC).

GROWING CORTICOTHALAMIC AND THALAMOCORTICAL AXONS INTERDIGITATE IN A RESTRICTED PORTION OF THE FORMING INTERNAL CAPSULE. A.R. Bicknese\* and A.L. Pearlman, Depts. of Neurol. Peds., and Cell Biol., Washington Univ. Sch. of Med., St. Louis, MO 63110

Axons from preplate/subplate cells, some destined for the thalamus, are the first to leave the developing neocortex, while axons from the thalamus are the first to arrive. In prior studies from this laboratory, we established that afferents travel within the chondroitin sulfate proteoglycan (CSPG)-rich subplate once they reach the neocortex, while efferents cross the subplate and leave in the intermediate zone which contains much less CSPG (Bicknese et al., Soc. Neurosci, Abst., 1991) Here we examine the relationship of these two sets of fibers to each other and to CSPG as they form the internal capsule. We used single and double labeling with Dil and DiA to trace axons in fixed embryonic mice, and an antibody to the glycosaminoglycan side chains to label CSPG. Cortical efferents leave the cerebral wall in a broad front, traveling through a zone of moderate CSPG immunolabeling until they reach the striatum, which contains little CSPG. Axons leaving the thalamus also travel through a zone containing moderate CSPG, then cross through the striatum in very close proximity to striatal neurons to meet the efferents on the other side. Cortical axons interdigitate with thalamic axons that have crossed the striatum, but the two pathways separate on the cortical side of the interdigitation. Both afferents and efferents subsequently form bundles, suggesting that later arriving axons fasciculate selectively with earlier axons of the ne type. Thus axons have several potential guidance cues available to bridge the gap between thalamus and cortex, including selective responsiveness to extracellular matrix molecules, interactions with striatal neurons, and fasciculation with other axons of the same type. If interdigitation of dissimilar axons (e.g. efferents on afferents) is a guidance mechanism, it is only operative over a restricted segment of the axonal trajectory.

### 330.6

GENICULOCORTICAL AXON INGROWTH & MORPHOGENESIS OF CORTICAL NEURONS IN RAT AUDITORY AND VISUAL CORTICES. G.H. Kageyama\*. M.Beilstein. L. Hoang. S. Catalano. J. Yu. & R.T. Robertson. Dept. Anat. & Neurobiol., Univ. of Calif., Irvine, CA 92717.

The temporal relation between the development of the basilar dendrites of cortical pyramidal cells (PC) and ingrowth geniculocortical (GC) axons was examined in the auditory and visual cortices of prefixed neonatal (E17-P7) rat brains. Laminar identity of labeled PCs was revealed with bisbenzimide. Dil placed in the MGN or LGN for 2+ weeks at 37°C resulted in labeling of developing medial and lateral GC axons, respectively. Although ingrowing medial GC axons reach the intermediate zone and subplate (SP) in auditory medial GC axons reach the intermediate zone and subplate (SP) in auditory cortex one day earlier than lateral GC axons to visual cortex, the timing of their ingrowth into the developing cortical layers was more closely synchonized, so that both medial and lateral GC axons grow into SP on E17-E18, deep VI on E19, middle VI on E20, superficial VI on E21, layer VO e22/P0, the deep half of the cell dense cortical plate (CP, future layer IV) on P1. Layer IV formed on P2. The GC axons grow continuously into the developing deep cortical layers without "waiting" as was previously described for thalamocortical axons growing into S1 (Catalano et al, 91). Golgi-like staining of cortical neurons with DiI revealed that apical dendrites developed well in advance of basar dendrites. Dendrites of SP neurons were already present on E17. The basal dendrites of layer VI, V, IV, and III PCs developed in the same inside-out order of cortical neurogenesis, migration, and settling, closely coinciding with GC ingrowth. Basal dendrites of VI PCs began forming on E18-20, those of V PCs on E20-21, those of IV PCs on P1, and those of III PCs on P2-3. The results indicate that developing GC axons may influence the elaboration of basal dendrites as each laminar cohort axons may influence the elaboration of basal dendrites as each laminar cohort of PCs begins to differentiate subjacent to the cell dense CP. It is possible that GC axons may also play an important role in cortical histogenesis and/or topographic specification. Supported by NSF 87-08515 and NIH NS 25674.

## 330.8

SYNAPTOPHYSIN IMMUNOHISTOCHEMISTRY REVEALS INSIDE-OUT PATTERN OF EARLY SYNAPTOGENESIS IN FERRET CEREBRAL CORTEX. T. Voigt, A. D. de Lima, M. Beckmann. Max-Planck-Institut für Entwicklungsbiologie 7400 Tübingen, Germany Synaptogenesis in the ferret cerebral cortex was examined from the day of birth to adulthood with an antibody against synaptophysin at the light and electron microscopic level. Due to the premature birth of ferrets, the generation of cells destined to the upper cortical layers and their subsequent migration to their final positions in the cortical plate are largely postnatal events. Throughout the newborn ferret cerebral cortex, a high amount of synaptophysin immunoreactivity was present within the marginal zone and subplate region. Staining was also conspicuous within the forming cortical plate. The typical layering pattern of synaptophysin immunoreactivity in the developing cortical plate correlated with the migration pattern of cortical neurons. The synaptic density was lowest directly below the marginal zone where the youngest neurons just stopped their migration. Below this zone the density of the synaptic staining increased gradually towards lower (and older) cortical plate layers. As the cortex expanded, the synaptophysin immunoreactivity pattern closely followed the expansion, suggesting that synapses were formed in a given layer shortly after the cells migrating to this layer reached their final position. As soon as cell migration had finished, the entire cortical plate contained dense synaptophysin immunoreactivity, in a pattern similar to that observed in the adult animal. At any given time, rostral and lateral regions of the cerebral cortex were more advanced in their development than caudal and dorsal regions. Electron microscopic examination of synaptophysin immunoreactivity seen in the light microscope. In conclusion, early synaptogenesis in the developing ferret cerebral cortex is predetermined by neurogenesis and closely follows its inside-out pattern as well as the rostrocaudal

POSTNATAL DEVELOPMENT OF THALAMOCORTICAL AFFERENT 'PATCHES" IN AUDITORY NEOCORTEX. R.K. de Venecia\* and N.T McMullen. Department of Anatomy, University of Arizona College of Medicine, Tucson, AZ 85724

Thalamic afferents to rabbit auditory neocortex were labeled with biocytin iontophoretically injected into the medial geniculate body (MGB) at successive postnatal ages. Immunohistochemical methods were used to visualize biocytin-labeled axons in 100 um thick serial coronal sections. Selected axons were serially reconstructed using a computer microscope. In young adults, focal biocytin injections within the MGB labeled two to five 'patches" of thalamocortical axons along the dorsal-ventral tonotopic axis within the auditory cortex. Thalamocortical patches approximately 500 um in width arose from the convergence of numerous fine axons (< 1 um diameter) studded with varicosities. The patches were elongated (up to 2 mm) in the anterior-posterior axis, parallel to isofrequency contours. We report that patches are evident as early as postnatal day (PD) 3, almost four days prior to the onset of hearing. At PD-3, axons entered the cortical plate tangentially and gave rise to branches which radiated to the full width of the cortical plate and extended into lamina I. Growth cone-like structures were usually observed at the termination of axons at this age, but appeared less frequently at older ages. By the second postnatal week, axonal arbors had shifted to a predominantly vertical orientation and were characterized by repeated dichotomous branching in laminae III and IV. During the third postnatal week, there was a progressive redistribution of axons from upper cortical week, there was a progressive redistribution of axons from upper cortical layers to lamina III/IV. By PD-21, thalamic axons terminated in 3 zones: lamina VI, lamina III-IV, and lamina I, with terminal branches most densely distributed in III/IV. The major changes in axonal orientation and redistribution of terminal branches at later ages suggests significant afferent remodelling during postnatal development. (Supported by NIH and ADCRC).

## 330.11

DEVELOPMENT OF BASAL FOREBRAIN PROJECTIONS TO CEREBRAL CORTEX: EFFECTS OF IMMUNOTOXIN INDUCED CHOLINERGIC LESIONS AS VISUALIZED BY ACHE AND DII STUDIES CHOLINERGIC LESIONS AS VISUALIZED BY AChE AND DII STUDIES IN RATS. K.A. Gallardo<sup>1</sup>, R.T. Robertson<sup>1</sup>, R.G. Wiley<sup>3</sup>, and J.Yu\*<sup>2</sup>. Depts. of Anatomy and Neurobiology<sup>1</sup> & Physical Medicine and Rehabilitation<sup>2</sup>, University of California, Irvine, CA 92717; Lab. of Experimental Neurology<sup>3</sup>, DVAMC, Nashville, TN 37212. We are studying the development of basal forebrain (BFB) projections to cerebral cortex to determine the timecourse of the ingrowth of these projections, and to determine the possible role of cholinergic afferents in cortical development.

In the present studies we attempted to selectively lesion the NGE-sensitive

cortical development.

In the present studies we attempted to selectively lesion the NGF-sensitive cholinergic neurons of the basal forebrain in infant Sprague-Dawley rats. Intraventricular injections of 130 to 400 ng of the immunotoxin 192-1gG saporin were made in animals at postnatal day 0 (PND-0) through PND-4. The 192-1gG saporin is an antibody against the low affinity NGF receptor, as described (Wiley et al. Brain Research 562: 149-153, 1991). Following survival periods that varied from 2-10 days, the brains of aldehyde perfused animals were processed for AChE histochemistry. Other brains received placements of DiI into cerebral cortex or the diagonal band of Broca.

Preliminary results show a loss of AChE positive axons in all layers of cerebral cortex and of hippocampus. Decrease in AChE positive axons was evident as early as 2 days after injection and appeared to become more severe with longer survival periods. AChE positive neurons in thalamus appeared not to be affected. Retrograde labeling of BFB neurons following DiI placements in cortex was reduced in treated animals. Fewer neurons were labeled, relative to controls, and some labeled neurons appeared atrophic. These results indicate that basal forebrain cholinergic neurons may be selectively eliminated during development by the use of the 192-1gG saporin antibody.

## 330.13

POSTNATAL EXPRESSION OF  $\alpha 7$  NEURONAL NICOTINIC RECEPTOR mRNA IN RAT SENSORY CORTEX AND THALAMUS. R.S. Broide\* and F.M. Leslie. Dept. of Pharmacology, Univ. of California, Irvine, CA 92717

Sensory areas of the rat neocortex are differentially innervated by thalamic afferents that appear to play a critical role in the determination of cell fate within these regions.  $\alpha$ -Bungarotoxin, which is used extensively to study nicotinic these regions.  $\alpha$ -bungarous, which is used extensively to study incomine receptors at the neuromuscular junction, exhibits a unique, transient developmental binding pattern within areas of sensory cortex, which peaks at postnatal day ten. Recent studies indicate that, in the CNS, the toxin binds to the  $\alpha$ 7 subunit of the neuronal nicotinic receptor and have suggested that this binding site may be involved in the formation of neural connections. It is thus important to determine whether this site is found on thalamic terminals or on their cortical targets during the early stages of synaptogenesis. The distribution their Context algest uning the early stages of synaphogenesis. The unstandard of  $\alpha$ -bungarotoxin binding sites in adult rat brain. However, the developmental appearance of the message has yet to be characterized. We have used in situ hybridization and receptor binding methodolgy to compare the distribution of  $\alpha$ 7 message to that of α-bungarotoxin binding sites in postnatal rat brain. In somatosensory cortex, at postnatal day ten, mRNA distribution delineated barrel columns, similar to the posmata day ten, mkNA distribution. mRNA was most apparent in layers II-III, IV, deep V, and superficial VI, but was present at lower levels in layers of superficial V, deep VI and the subplate. Visual and auditory cortex also showed a high correlation between mRNA and binding site distribution. Within the thalamic nuclei innervating these regions, the ventroposterior medial and lateral geniculate nuclei, but not the medial geniculate, were densely labeled with both markers. Therefore, the of subunit may be localized both pre and post-synaptically in somatosensory and visual cortex, but only present post-synaptically in auditory cortex. This suggests a putative role for this site in the formation of thalamocortical synapses. Supported by PHS grant #DC00450

#### 330.10

SIMILARITY IN THE PROPORTION OF GABA(+) NEURONS IN 3 AREAS OF THE RAT CEREBRAL CORTEX. C. Beaulieu\* and C. Crevier. Département de pathologie, Université de Montréal, Montréal, (Qué) CANADA, H3C 3J7

The numerical density  $(N_V)$  and the number of neurons beneath 1mm<sup>2</sup> of cortical surface (N<sub>C</sub>) were estimated in individual laminae of the monocular segment of visual area (OC1M), the somatosensory barrelfield, and a frontal area (FR1) of the rat cerebral cortex by using the disector method. GABA(+) neurons were identified with a postembedding method on semithin sections

For the total cortical depth, the N<sub>V</sub> and the N<sub>C</sub> for both GABA(+) and the overall population of neurons were significantly different in the 3 areas. Since the variation in the N<sub>V</sub> and in the N<sub>C</sub> of GABA(+) neurons among the cortical areas followed a pattern similar to that of the overall population, the proportion of GABA(+) neurons remained similar (15%). It thus appears that when more neurons are added to a cortical area, the basic cortical circuit retains the same proportion of inhibitory neurons. Furthermore, differences found in the N<sub>C</sub> for the 2 neuronal populations were due to significant changes of their numbers in layer IV, the main recipient lamina of thalamic axons.

Even though the proportion of GABA(+) neurons was similar in the 3 examined areas of the rat cerebral cortex, it remained lower than that previously found in areas of the cat or monkey cortex in which GABA(+) neurons represented 20-25% of all cortical neurons

DISTRIBUTION OF ACETYLCHOLINESTERASE IN THE DEVELOPING VISUAL CORTEX IN NEONATALLY HEMIDECORTICATE RATS. M. Vinette. D. Boire M. Ptito\*, F. Leporé, J.-P. Guillemot. Dépt. de Psychologie, Université de Montréal et Dépt de Kinanthropologie, Univ. du Québec à Montréal, Canada. The primary visual cortex (17) in neonatally hemidecorticate rats was examined in order to investigate the morphological and neurochemical development of the remaining cortex. In normal development, primary sensory cortices display a transient pattern of acetylcholinesterase (AChE) during the second and third postnatal weeks. Areal and laminar distributions of transient AChE correspond to the distribution of genicule-cortical axons (Robertson, 1988). It has been proposed that transient AChE

distributions of transient AChE correspond to the distribution of geniculo-cortical axons (Robertson, 1988). It has been proposed that transient AChE may play a morphogenic role in the development of these projections (Kristt, 1979, Robertson, 1987).

Wistar rats received a right hemidecortication at postnatal day (PND) 4 and were sacrificed at 3 days interval until PND 27 and in adulthood. Brains were processed for AChE histochemistry and compared to age-matched controls. Results show no apparent modification in the areal and laminar distribution of AChE during the development of visual cortex following hemidecortication. The transient expression of AChE remains confined to layer IV and deep layer III, layer I and layer VI, and its time-course comparable to controls. This suggests that hemidecortication does not affect the time-course nor the distribution of geniculo-cortical projections. (Supported by FCAR and NSERC) (Supported by FCAR and NSERC)

UNIQUE DEPLOYMENT OF 02 and β ADRENERGIC RECEPTORS IN THE SUBPLATE AND INTERMEDIATE ZONE OF DEVELOPING PRIMATE CEREBRUM M.S. Lidow and P. Rakic Section of Neurobiology Yale University,

CEREBRUM M.S. Lidow\*and P. Rakic Section of Neurobiology Yale University, School of Medicine, New Haven, CT 06510

Quantitative receptor autoradiography was used to study the emergence and distribution of adrenergic, dopaminergic, scrotonergic, cholinergic, GABAergic and excitatory amino acid receptors in the cerebral wall of developing rhesus monkeys ranging in age from 65th embryonic day (E65) to two postnatal months. During the entire period examined, the majority of neurotransmitter receptors were localized in the cortical plate with little or no presence in the subjacent strata. The notable exception were α2 and β adrenergic sites which were transiently abundant in the embryonic subplate and intermediate zone. The α2 receptors were labeled with [³H]-and [¹²¹][clonidine, and the specificity of binding was assured by its complete displacement with 100μM noradrenaline. This binding was also displaceable with 100μM noradrenaline. From the earliest age studied, α2 sites were present in the cortical layer I and throughout the subplate and intermediate zone with the highest density (ranging from 43 to 17 fmol/mm³ depending on embryonic age) found in three narrow, clearly delineated bands situated close to the cerebral ventricle. On the other hand, β receptors were seen in the entire cortical plate, the subplate and in a other hand, β receptors were seen in the entire cortical plate, the subplate and in a separate band situated near the cerebral ventricle (where their density reached 24 separate band situated near the cerebral ventricle (where their density reached 24 fmol/mm³ at E115). After birth, the density of  $\alpha 2$  and  $\beta$  receptors below the cortex declined rapidly and by the 2nd month, the densities of these sites in the white matter were below detection by the methodology employed. In contrast to  $\alpha 2$  and  $\beta$  receptors, at sites, labeled with  $^{14}\mathrm{Hprazosin}$ , were present exclusively in the cortical plate during the entire developmental period studied. The high density of  $\alpha 2$  and  $\beta$  adrenergic receptors in subcortical embryonic zones suggest their unique role in modulation, maintenance, transfer and/or elimination of transient neurons and afferents in the embryonic subplate zone. AMINO ACID NEUROTRANSMITTERS REGULATE THE PROLIFERATION OF NEOCORTICAL PROGENITORS.
Joseph J. Lo Turco\* & Arnold R. Kriegstein.
Dept. of Genetics, Harvard Medical School,
Boston, MA 02115, & Dept. of Neurobiology, Yale
Univ. Sch. of Med., New Haven, CT 06510.
Cell to cell interactions are thought to direct the proliferation and differentiation of neocortical cells. It is critical, therefore, to specifically identify how immature cortical cells interact with each other and with their environments. Using patch-clamp techniques we found that dividing cells in the ventricular zone of developing rat neocortex express functional GABA receptors and kainate receptors. To test the hypothesis that activation of these receptors influences the proliferation of cortical progenitors, we determined the effects of GABA and glutamate agonists and antagonists on the incorporation of [H3]thymidine incorporation in E16 and E19 explants, but failed to affect younger (E14) explants, but failed to affect younger (E14) explants, but failed to affect younger (E14) explants. The decreased (H3]thymidine incorporation could be blocked by the antagonists BMI and CNQX. In fact, antagonists to GABA or kainate receptors increased (H3]thymidine incorporation in E16 explants. The effects of the antagonists indicate that endogenous amino acid receptor agonists act to decrease the proliferation of cortical progenitors. Such regulation may operate as a feedback control mechanism between differentiating cells and dividing cells in developing neocortex.

EFFECTS OF LOW-DOSES OF TONIZING RADIATION ON DEVELOPING EFFECTS OF LOW-DOSES OF IONIZING RADIATION ON DEVELOPING RAT CEREBRAL CORTEX, WITH SPECIAL REFFERENCE TO NEURONAL MIGRATION AND EXPRESSION OF N-CAM. S.Fushiki\*, K.Matsushita, A.Yoshiki and W.J.Schull. Dept.of Dynamic Pathol., Res.Inst.for Neurol.Diseases & Geriatrics, Kyoto Pref.Univ.Med., Kyoto 602, Japan, 'Univ. Texas Graduate School of Biomed.Sci., Houston, Texas 77225, U.S.A. To elucidate the effects of low-doses of ionizing radiation of first investigated the pattern of mirration

radiation we first investigated the pattern of migration of cortical neurons in the fetal rat brain that was irradiated in utero. The cells were labeled with <sup>3</sup>Hthymidine at E16. The doses of cobalt gamma rays were 5,10,15 and  $20{\rm cGy}$ . The number of heavily labeled cells within each zone of the cortex was counted in autoradiographic sections and analyzed in relation to dose. Secondly, molecular changes appearing in the fetal cortex after irradiation were immunohistochemically examined with antibodies for N-CAM, L1, MAPs and neurofilaments. Our studies indicate that 1) exposure to doses of 15cGy significantly slows neuronal migration without increasing cell death, and 2) exposure to doses of 15-20cGy results in decreased immunoreactivities of N-CAM in the matrix cell zone. These observations may suggest a presumptive role of N-CAM in cortical histogenesis. (supported in part by a grant from the Atomic Energy Control Board of

NMDA AND NON-NMDA RECEPTOR-MEDIATED SYNAPTIC POTENTIALS IN IMMATURE (PO-8) RAT NEOCORTICAL NEURONS. B.W. Connors. H.G. Kim. and K. Fox, Dept. of Neuroscience, Brown University, RI 02912.

The most dynamic phase of synaptic development in rat

neocortex occurs during the early postnatal period. However, the physiology of the earliest synapses has not been well characterized. Whole-cell current- and voltage-clamp recordings were obtained from developing neurons (P0 to P8) in slices of rat parietal neocortex. Input resistances were 500 M $\Omega$  to 2 G $\Omega$ , and resting membrane potentials were -40 to -60 mV. Glutamate antagonists hyperpolarized the cells and increased input resistance, suggesting tonic receptor activation at rest. Stimulating the subplate region with single shocks at 1 min<sup>-1</sup> evoked excitatory postsynaptic events from animals as young as PO. EPSPs were quite variable, often lasted over hundreds of msec, and sometimes occurred repetitively following a single stimulus. They were blocked by TTX and reversed polarity around 0 mV. Synaptic currents were carried by both NMDA- and nonNMDA-specific channels, as judged by relative sensitivities to APV, CNQX and glycine, and the nonlinearity of I-V curves. Unlike mature neurons, NMDA currents predominated in most young neurons. We did not observe any inhibitory inputs before P6. Biocytin-staining showed that EPSPs were obtained from small pyramidal neurons and other immature cell types in the cortical plate and Cajal-Retzius cells in layer I. The presence of large, prolonged NMDA receptor-mediated

currents could have significant developmental consequences.

GLUTAMATE REGULATION OF GENE EXPRESSION IN DEVELOPING CORTICAL NEURONS. A. Ghosh and M. E. Greenberg, Dept. of Microbiology and Molecular Genetics, Harvard Medical School, Boston, MA 02115

The molecular pathways by which glutamate receptor activation affects the formation of appropriate synaptic connections in the developing cortex are not understood. To begin to understand how stimulation of glutamate receptors can lead to long term adaptive changes in cortical neurons, we have initiated experiments to examine whether glutamate stimulation can affect the expression of (i) transcription factors (such as c-fos) that can potentially regulate downstream gene expression, and (ii) neurotrophic factors and their receptors since it has been proposed that the formation of appropriate synaptic connections may involve an activity-dependent competition for trophic factors.

Experiments were performed on E18 rat cortex cultures (5 to 15 days in-vitro). Cells were stimulated for 10 minutes with 10 μM I-glutamate in the presence of 1 μM TTX (to prevent trans-synaptic stimulation), following which kynurenic acid (1mM) was added to the medium to prevent further receptor activation. To examine the pharmocology of receptor activated gene expression, various receptor blockers were added to the medium 5 minutes prior to stimulation. 1 hour after stimulation RNA was extracted for Northern analysis. Our initial experiments indicate that RNA was extracted for Northern analysis. Our initial experiments indicate that glutamate stimulation leads to a robust increase in c-fos expression. This increase is almost completely blocked by the NMDA receptor antagonist APV (100 µM), but is not significantly affected by the non-NMDA receptor blocker CNQX (40 µM). Furthermore, the glutamate induced expression of c-fos is not significantly attenuated by the L-type calcium channel blocker Nifedipine (5µM). Of the molecules that may be involved in neurotrophic interactions, BDNF and its putative receptor, trk-B, are expressed in our cultures. We have found that BDNF mRNA levels are also enhanced that the transport of the control of the intercent of the control of the intercent of the control of the intercent of the control of the control of the intercent of the control by glutamate stimulation. This increase, as in the case of c-fos, is specifically APV sensitive. Our observations suggest that NMDA receptor activation is likely to be required for the expression of rapidly induced transcription factors and also for the regulation of neurotrophic factors such as BDNF in developing cortical neurons. A METHOD FOR ABLATING DISCRETE CELL TYPES IN VIVO; A MEANS FOR BLOCKING CELL-CELL INTERACTIONS IN DEVELOPING CIRCUITS. S.A. Nirenberg, D.M. Fekete\* and C.L. Cepko, Dept. of Genetics, Harvard Med. Sch., Boston, MA 02115.

The development of a neural circuit involves a complex series of cell-cell interactions. One approach to unravelling these interactions is to systematically ablate discrete classes of cells from the circuit as is to systematically ablate discrete classes of cells, one can determine its role(s) in development. In addition, by ablating an individual cell class at different times during development, one can examine separately the different roles it may play at sequential stages (e.g., regulating proliferation, cell fate, neurite guidance). We describe a technique for ablating discrete classes of cells in vivo or in tissue slices. The targeted class of cells is first engineered to express the slices. The targeted class of cells is first engineered to express the gene for the enzyme B-galactosidase. This is achieved by generating transgenic animals in which the B-gal gene is regulated by a cell type-specific promoter. The cells are then selectively labelled with a photoactivatable dye by applying a B-galactosidase substrate that releases the dye when enzyratically cleaved. The dye-labelled cells are then photoablated. This approach differs from other ablation methods that have been applied to vertebrates in that it can be used on a broad range of cell types, and a given cell type can be ablated at a broad range of cell types, and a given cell type can be ablated at different developmental times, or in the adult. We demonstrate the use of this technique *in vivo* on several cell types in the mouse retina and cerebral cortex, as well as in the zebrafish embryo.

BICOMMISSURAL NEURONS IN THE CORTEX OF DEVELOPING HAMSTERS. C. Hedin-Pereira, D. Uziel and R. Lent. Instituto de Biofísica Carlos Chagas Filho, U.F.R.J., 21941 Rio de Janeiro, Brazil.

In the course of a study on the development of callosal axons originating in dorsal sectors of neocortex, we noticed the existence of some callosal fibers extending long within the white matter into the anterior commissure (AC). To clarify the origin of this bicommissural projection, two series of experiments were done in hamster pups aged P2 through P9 (P1 = day of birth). In the first series, fixed brains were bisected along the midplane, and crystals of DiI and DiA were placed one into each transected commissure, to test for the presence of doubly-labeled bicommissural cells. In the second series a piece of ventromedial forebrain was disected out of one hemisphere exposing the AC for Dil placement, to label AC fibers extending into the callosum (CC), and thus test for the presence of bicommissural neurons in the opposite dorsal cortex. In both cases the brains were cut coronally several months after tracer placement, and all sections were examined, charted, and photographed under a fluorescence microscope coupled to a microcomputer. A few doubly-labeled neurons were found in the lateral transition cortex in most P5 and P7 brains, after tracer placement in both commissures. On P9, however, only a single doubly-labeled cell was found in one of the brains. No labeled neurons were found in the opposite dorsal cortex after tracer placement in the AC. We concluded that a group of cells in the lateral cortex extend a branched axon that grows transiently through both the CC and the AC

PARTICLE-MEDIATED GENE TRANSFER AND EXPRESSION IN

PARTICLE-MEDIATED GENE TRANSFER AND EXPRESSION IN RAT BRAIN TISSUES. N.-S. Yang. S.S. Jiao. L. Cheng. F. Siegel\* and J. Wolff. Agracetus, Inc., Middleton, WI 53562 & Depts. of Pediatrics & Medical Genetics, Waisman Center, University of Wisconsin, Madison, WI 53705.

We have previously demonstrated Accell M particle-mediated gene delivery process provides a useful means for transduction of various cell types in culture. Here we evaluated application to both fetal and adult rat brain cells. Using a CMVL gene as a reporter, we obtained high levels of transient gene expression in primary culture of fetal brain cells. Reduced but significant levels were also detected in adult brain cell cultures. Both neurons and glia cells were transduced using this technique. The transient gene expression level obtained with the Accell technology was found to be at least 100-fold higher than those obtained with three other tested gene transfer methods. The relative strengths of four cellular and seven viral promoters were evaluated in these cultures. Ex-vivo transduced fetal brain cells were transplanted into adult host rat brains. In vivo expression of transgenes was observed for up to two months, including detection of CMVL activity in the grafts and of human growth hormone (hGH) released into the cerebrospinal fluid (CSF) of host brains. We thus suggest that the Accell technology of particle bombardment can be employed as an effective method for ex vivo gene transfer into brain tissue. Implications and the current limitations of this technology for gene therapy of certain neurological diseases will be discussed. discussed.

SPINAL IMPLANTS OF CELLS GENETICALLY MODIFIED TO PRODUCE ENKEPHALIN REDUCE NOCICEPTIVE SENSITIVITY IN HOST MICE.

H. Wu\*, S. C. McLoon and G. L. Wilcox, Department of Pharmacology and Department of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

Minneapolis, MN 55455. The aim of the current study was to determine whether AtT-20/hENK cells, an AtT-20 cell line transfected with a proenkephalin gene, implanted around mouse spinal cord would produce an antinociceptive effect. 100,000 cells in 5  $\mu$ l of medium were injected into mouse lumbar subarachnoid space. Control animals were injected with medium alone. The animals' response to thermal nociceptive stimuli was tested by tail flick and hot plate assays. The mouse spinal cords were also examined histologically for the presence of implanted cells. Three days after implantation, mice were treated with an intrathecal injection of isoproterenol to stimulate origid release from the cell implants. Expresseroes treating days of the produced does not simplate origid release from the cell implants. Expresseroes treating or the cell implants is provinced and the produced does not simplate origid release from the cell implants. implantation, mice were treated with an intrathecal injection of isoproterenol to stimulate opioid release from the cell implants. Soproterenol produced dose-related antinociception only in the mice with cell implants. Sections of spinal cords from these animals processed for enkephalin immunohistochemistry revealed the presence of enkephalin positive cells surrounding the cord. The broad spectrum opioid antagonist naloxone, but not the μ opioid antagonist β-funaltrexamine, blocked the antinociceptive effect of the implanted cells. This would suggest that the entinociceptive effect of the implanted cells. This would suggest that the antinociceptive effect of the implanted cells. This would suggest that the antinociceptive effect of these genetically modified cells was mediated through  $\delta$  opioid receptors. Enkephalin is generally believed to act via  $\delta$  opioid receptors, further implying that enkephalins released by the implanted cells were responsible for the observed effect. By 7 days post-implantation, enkephalin positive cells were still present around the spinal cord in the cell-implanted animals. Intrathecal injection of the  $\delta$  opioid agonist, DPDPE, resulted in a reduced antinociceptive effect in mice with cell implants as compared with the control group. This suggests that the chronic release of enkephalins from the implanted cells produced  $\delta$  opioid receptor tolerance. These results show that cells genetically modified to secrete enkephalin, when implanted adiagent to the spinal cord can release enkephalins both enkephalin, when implanted adjacent to the spinal cord, can release enkephalins both tonically and acutely under adrenergic stimulation and can reduce pain sensitivity. (DA-01933 to GLW and EY-05371, EY-09537 and EY-07133 to SCM).

A POSSIBLE THERAPEUTIC APPLICATION OF CELL LINES ENGINEERED TO PRODUCE GABA. J. Segovia". L.J. Fisher', A. Sandrasagra', C.H.J. Ruppert', B. Anton', C.J. Evans', F.H. Gage' and A.J. Tobin<sup>1,3,4</sup>. Departments of <sup>1</sup>Biology and <sup>2</sup>Psychiatry and Biobehavioral Sciences, <sup>3</sup>Molecular Biology Institute and <sup>4</sup>Brain Research Institute, University of California, Los Angeles, CA, 90024 and <sup>5</sup> Department of Neuroscience, University of California, San Diego, La Jolla, CA, 92093.

Huntington's disease (HD) causes a severe neuronal degeneration in striatum, which is accompanied by decreases in the striatal content of several neurotransmitters, including GABA. Several animal models mimic the pathophysiology and some of the biochemical alterations of HD, as well as inducing motor and learning deficits in the lesioned animals. Transplantation of fetal tissue in rodent models of HD has shown that the e survives, integrates into the host brain and induces recovery of some of the motor and learning deficits produced by the lesion. With a view to developing new therapeutic approaches to HD and other neurological disorders with deficits in GABA production, we have established cell lines that synthesize and secrete GABA. To obtain such cell lines we have infected rat primary fibroblasts with GAD65 cDNA in a retroviral vector. The engineered fibroblasts, but not the uninfected fibroblasts, express GAD65 mRNA, the GAD polypeptide and GAD enzymatic activity. Furthermore, we have shown, in vitro, that the infected fibroblasts secrete GABA into the surrounding medium (and that GABA overflow increases 6 fold in response to K+-induced depolarization). employing kainic acid lesioned rats to assess the effect of grafting GABA producing fibroblasts into the lesioned striatum. LISE OF RECONSTITUTED SENDAL VIRAL ENVELOPES TO DELIVER A NPY-CONTAINING ADENO-ASSOCIATED VIRUS VECTOR TO NEUROBLASTOMA AND GLIAL CELLS IN CULTURE. C.M. de Fiebre\*, D. Notabartolo, P. Wu and E.M. Meyer. Dept. of Pharmacology and Therapeutics, Univ. of Florida College of Medicine, Gainesville, FL 32610.

A reconstituted viral envelope system has been used as a vehicle to deliver foreign DNA to cells. These so-called virosomes are reconstituted proteoliposomes derived from the Sendai virus without intrinsic genetic material. Intact viruses are solubilized in Triton X-100. Foreign DNA is added and encapsulated by removing the detergent with SM-2 Biobeads in the presence of exogenous phosphatidylcholine. Previous studies in our laboratory have displayed that virosomes are capable of infusing exogenous substances into neocortical-derived synaptosomes as well as primary neuronal and glial cultures. In the present study, we used this system to encapsulate an adenoassociated virus vector, pJDT95, into which we subcloned the gene for NPY (cDNA). These virosomes were then used to deliver the vector to a neuroblastoma cell line, SH-SY5Y, and to glial cells in culture. Preliminary results suggest that the vector increased message for NPY; however, NPY levels were not increased. SH-SY5Y cells were killed by the vector, but not by the virosomes, potentially because of deleterious effects of transiently increased levels of NPY or because of anti-oncogenic effects of the pJDT95. Glial cells may not have displayed increased levels of NPY due to lack of post-translational processing capabilities

IMMORTALIZED PANCREATIC B-CELL LINES AS GABA-IMMORTALIZED PANCREATIC B-CELL LINES AS GABA-RELEASING NEURAL IMPLANTS T. K. Swoboda\*, A. P. Signore, B. Zielinski, J. Tseng, T. Kiezeloff, P. A. Tresco, P. Acbischer, Section of Artificial Organs, Biomaterials, and Cellular Technology, Brown University, Providence, R.I. 02912

A neural graft releasing yaminobutyric acid (GABA) may be useful in the treatment of a variety of CNS disorders including Huntington's A neural graft releasing γ-aminobutyric acid (GABA) may be useful in the treatment of a variety of CNS disorders including Huntington's disease, Parkinson's disease, and epilepsy. Pancreatic β-cells have been shown to express glutamic acid decarboxylase (GAD). This suggested that immortalized β-cells may release GABA, and therefore avoid the problem of loss of gene expression encountered with the use of genetically engineered cell lines. HPLC analysis of two such cell lines, the NIT-1 (mouse derived) and the RIN-1046.38 (rat derived) revealed that both release GABA. Under static incubation conditions, NIT-1 cells released 11.7±0.26, and RIN cells 21.3±0.80 fg GABA/cell/min. The potential of these cell lines as neural implants is being assessed with encapsulation technology, which circumvents the possibility of tumor formation and host graft rejection. NIT-1 and RIN cells suspended in a hydrogel were loaded into acrylic copolymer capsules. Capsules maintained in vitro for up to 4 weeks showed GABA release in the range of 60 - 160 pg/capsule/minute for both types of cell lines. Histologic analysis revealed viable NIT-1 and RIN cells. Three male Sprague-Dawley rats received intracerebral NIT-1 containing capsules to assess short term viability of the encapsulated cell line in vivo. Viable cells were present upon histological examination 4 weeks post implantation. The data indicates that encapsulated cell lines derived from the pancreatic β-cells may be useful as a GABA-delivery system within the CNS. useful as a GABA-delivery system within the CNS.

## 331.6

Improved killing of glioma cells in culture and in vivo using retrovirus vector with herpes simplex virus thymidine kinase gene and wild type retrovirus. Y Takamiya MP Short\*, F Moolten, C Fleet, XO Breakefield, RL Martuza. Neuroscience Ctr, MGH, Charlestown, MA 02129; Neurosci Prog, Harvard Med Sch, Boston, MA 02115, and Dept of Neurosurg, Georgetown U, Washing, DC 20008.

Previously we demonstrated that the efficiency of retrovirus-mediated delivery of

genes sensitizing tumor cells to nucleoside analogues could be increased by adding helper wild type virus (MoMLV). In the present study, packaging cells (psi 2-STK) releasing a replicative-defective retroviral vector encoding the herpes simplex thymidine kinase (HSV-TK) gene under the transcriptional control of the SV40 promoter-enhancer element were infected with MoMLV. These infected packaging cells (psi2-STKWT) release both wild type retrovirus and the retrovirus vector containing the HSV-TK gene. In culture, psi2-STKWT cells were several thousandfold more sensitive to the toxic effects of the nucleoside analogue, ganciclovir (GCV), than were control cells of the psi2 packaging line. This sensitivity surpassed previous results obtained with a retroviral rather than SV40 promoter. Psi2-STKWT and psi2-STK cells did not differ significantly in GCV sensitivity, suggesting that in this system wild type retrovirus exerted no independent debilitating effect on cell growth. When psi2-STKWT cells were cocultured with glioma cells (C6BU1pBAG cells), the glioma cells (although not carrying the HSV-TK gene themselves) were rendered 1000-fold more sensitive to GCV treatment than glioma cells co-cultured with control psi2 cells in similar ratio. Regression of tumors in response to GCV therapy was also noted in nude mice inoculated subcutaneously with a combination of psi2-STKWT cells and C6BU1pBAG cells. These findings suggest that the efficiency of retrovirusmediated transfer of GCV sensitivity is increased by placing the HSV-TK gene under the transcriptional control of the SV40 promoter-enhancer, and that cells ing potent vectors can exert lethal effects in vitro and in vivo on tumor cells in their vicinity in conjunction with a drug that is otherwise innocuous

LONG-TERM SURVIVAL AND MATURATION OF NEURONS DERIVED FROM THE HUMAN CELL LINE N-TERA 2 AFTER TRANSPLANTATION INTO NUDE MOUSE BRAIN S.R.Kleppner\*, J.O.Troianowski, V.M.-Y.Lee Inst. of Neurological Sciences and Dept. of Path. and Lab. Med., Univ. of PA, Philadelphia, PA 19104

We have previously shown that the N-Tera 2 (NT2) cell line, derived from a human teratocarcinoma, can give rise to pure cultures of fetal cholinergic neurons after treatment with retinoic acid. Having described the *in vitro* phenotype of these neurons, we were interested in phenotypic modifications of these neurons in a CNS environment. When implanted into adult athymic mice these neurons are viable for at least 6 months and show no signs of tumorogenesis. Using a panel of human specific antibodies, we have characterized the phenotype of these cells over the course of 6 months. Before implantation, cells were immunopositive for N-CAM, MAP2, Tau, vimentin, NF-M, NF-L and exhibited low levels of NF-H. Within three weeks after implantation, the grafts exhibited process outgrowth, within three weeks arter implantation, the grarts exhibited process outgrowth, the extent of which may depend on the exact location of the graft. After 6 months  $in\ vivo$ , all markers remained the same except for NF-H which increased expression dramatically by 6 months post-implant. While the continued presence of vimentin indicates that these cells partially maintain a fetal phenotype  $in\ vivo$ , the appearance of NF-H may be a sign that they are beginning to mature. Additionally, preliminary results show that NT2-neurons transfected with a  $\beta$ -gal expression plasmid continue to express  $\beta$ -gal at low levels 6 months after transplantation suggesting that the NT2 neurons retained the expression of foreign genes after stable transfection into the undifferentiated NT2 cells. Thus, NT2 neurons exhibit long-term survival in a CNS environment and stable expression of a transfected gene, making them an ideal system for further studies utilizing gene therapy.

### 331.9

ADRENAL CHROMAFFIN CELLS AND TRANSGENIC NGF-PRODUCING ASTROCYTE CO-GRAFTS PARTIALLY RESTORE FUNCTION IN THE UNILATERAL 6-OHDA RAT MODEL OF PARKINSON'S DISEASE. L.A. Cunningham\*, M.P. Short 1, X.O. Breakefield 1, M.C. Bohn. Dept. of Neurobiology and Anatomy, University of Rochester Medical School, Rochester, NY 14642 and <sup>1</sup>Molecular Neurogenetics Unit, MGH, Harvard Medical School,

Boston, MA 02114.

Our previous studies demonstrated that astrocytes genetically modified to constitutively express a mouse B-NGF transgene support the survival and neuronal transdifferentiation of intrastriatal adrenal chromaffin cell grafts at two weeks (Brain Res. 56:1192-202). The aims of the present study were to determine whether these effects would be maintained for longer post-grafting periods and whether the grafts would reduce apomorphine-induced turning behavior in the unilaterally 6-OHDA-tesioned rat. Suspensions of postnatal day 12 adrenal chromaffin cells and transgenic astrocytes (AC + AsN.8) were mixed 1:1 (160,000 total cells) and grafted into the dopamine-denervated striatum of the adult Fischer 344 rat (n=7). Chromaffin cells grafted alone (AC, n=4) or with normal astrocytes (AC + As, n=4) served as controls. When co-grafted with the transgenic astrocytes, the survival of the adrenal chromaffin cells was enhanced 5-12 fold over controls as assessed by tyrosine hydroxylase immunoreactivity 10 weeks post-grafting (1168  $\pm$  143 vs. 221  $\pm$  128 and 99  $\pm$  5 TH-IR cells; AC + AsN.8 post-grafting (1168 ± 143 vs. 221 ± 128 and 99 ± 5 TH-IR cells; AC + AsN.8 vs. AC, and AC + As grafts, respectively, p<0.01). Furthermore, 36% of the TH-IR cells in the transgenic co-grafts displayed a phenotype characteristic of differentiated sympathetic neurons, i.e., large soma (30-40 μm in diameter), TH-IR neuronal processes and extensive process elongation. The effects of the transgenic astrocytes on chromaffin cell survival and morphology were paralleled by a 40% reduction in apomorphine-induced rotation, suggesting a partial restoration of striatal function. The results of this study demonstrate that genetically engineered astrocytes are an effective vehicle for delivering β-NGF trophic support. Supported by NS08906 and the PEW Charitable Trust

## 331.11

INTRACEREBRAL TRANSPLANTATION OF GENETICALLY ENGINEERED MUSCLE CELLS REDUCES EXPERIMENTAL PARKINSONISM IN RATS. S.S. Jiao\*, P. Williams and J.A. Wolff. Department of

Pediatrics & Medical Genetics, Waisman Center, University of Wisconsin, Madison, WI 53706.

The intracerebral transplantation of genetically modified cells has been proposed for the treatment of several genetic and acquired neurologic disorders. Our previous work has shown that primary cultured muscle cell allografts survive in the rat brain longterm in a healthy and differentiated state and might be a useful relating and differentiated state and might be a useful replatform" for transgene expression in the brain. The present work indicates that primary cultured muscle cells lipofected with pCMVTH gene expressed tyrosine hydroxylase (TH). In rats with unilateral 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal dopamine pathway, grafts of pCMVTH-transfected muscle cells transplanted into the caudate nucleus or in the cells transplanted into the caudate nucleus or in the lateral ventricle reduced apomorphine-induced rotational behavior for at least two months. TH gene expression was localized to the muscle-brain grafts. These results explore the ability of genetically engineered primary muscle cells to serve as a feasible approach to gene therapy for the rat model of Parkinson's disease. The use of plasmids avoids the potential deleterious effects of retroviral vectors and the unstable expression of retrovirally transduced genes. unstable expression of retrovirally transduced genes.

RECOVERY IN THE RAT 6-HYDROXYDOPAMINE MODEL OF PARKINSON'S DISEASE BY DIRECT INTRASTRIATAL INJECTION OF HSV-1 VECTORS WHICH EXPRESS THE HUMAN TYROSINE HYDROXYLASE GENE. M.J. During\*, A.I. Geller, A.Y. Deutch, K.L. O'Malley. Sect. Neurosurg. & Neuroend., Yale Univ. Sch. Med., New Haven, CT; Div. End., Children's Hospital, Boston, MA; Dept. Psych., Yale Univ. Sch. Med.; Dept. Neurobiol. & Anatomy, Washington Univ. Sch. Med., St. Louis, MO.

We have developed Herpes Simplex Virus (HSV-1) vectors that stably express a gene in cultured neurons, and in vivo, following stereotactic injection into the adult rat brain. A HSV-1 vector that stably expresses human tyrosine hydroxylase (pHSVth) in cultured striatal cells directs regulated release of L-dopa and dopamine from these cells.

The efficacy of intrastriatal injection of pHSVth on recovery in the 6hydroxydopamine rodent model of PD was assessed using apomorphineinduced asymmetrical rotation. Groups of lesioned rats received intrastriatal stereotactic injection with pHSVth or pHSVlac (expresses  $E.\ Coli\,\beta$ -galactosidase), or saline. Rats which received pHSVth had an 80+10% reduction in apomorphine-induced contralateral rotational behavior, whereas both control groups maintained baseline rates of rotation. Furthermore, the reduction in rotational behavior persisted for the entire 6 month duration of followup. *In vivo* expression of TH in striatal neurons and glia surrounding the injection site and biochemical recovery of striatal dopamine neurotransmission are currently being investigated using immunohistochemistry and microdialysis.

### 331.10

CHROMAFFIN CELLS COGRAFTED WITH NGF-PRODUCING FIBROBLASTS EXHIBIT NEURONAL FEATURES G.R. Chalmers 1\*, K. Niijima2, P.H. Patterson2, D.A. Peterson1, L.J. Fisher 1 and F.H. Gage 1. Dept. of Neurosciences, UCSD, La Jolla, CA, 92093 and <sup>2</sup>Biology Division, California Institute of Technology, Pasadena,

Adrenal chromaffin cells (ACC) can differentiate in vitro into sympathetic neurons under the influence of nerve growth factor (NGF). Such a phenotypic change, and whether transformed neonatal ACC are functional in a rat model of catecholamine function, was examined. Adult rats were a rat model of catecholamine function, was examined. Adult rats were unilaterally lesioned with 6-hydroxydopamine injections into the substantia nigra and assessed with apomorphine (APO) and amphetamine (AMP). Rats then received an injection of either: 1) ACC+NGF-producing fibroblasts, 2) ACC+control fibroblasts, 3) NGF-producing fibroblasts, or 4) control fibroblasts into the denervated striatum, and were behaviorally tested for 8 wks. At 2 months grafts were processed histochemically for neurofilament, MAP2, NGF receptor, SCG10 (indicators of a neuronal phenotype), chromogranin A (CGA, indicator of ACC phenotype) and tyrosine hydroxylase (TH) immunoreactivity (IR). ACC+NGF grafts showed extensive TH, NGF receptor and neurofilament IR throughout the graft, and MAP2 and SCG10 expression in ACC bodies. CGA expression was negative. ACC+control fibroblast grafts showed TH-IR limited to ACC bodies conly, and very limited IR to other neuronal markers. The NGF-producing fibroblast grafts showed positive IR for some neuronal markers, producing fibroblast grafts showed positive IR for some neuronal markers, reflecting a slight ingrowth of host fibers. No clear differences between the groups were observed in APO or AMP induced rotational behavior. These behavioral observations are being evaluated further.

TEMPERATURE-SENSITIVE SUBSTANTIA NIGRA NEURAL CELLS FOR CNS TRANSPLANATION: IN VITRO ANALYSIS AND GRAFTING INTO PARKINSONIAN RATS AND MONKEYS. LH.

GRAFTING INTO PARKINSONIAN RATS AND MONKEYS. LH. Kordower\*, S.B. Schueler, C.H. Markan¹, W. Melega¹, R. Anton¹, and D. Bredesen¹. Dept. Neurological Sci. Rush Presbyterian Med. Ctr., Chicago Illinois 60612 and ¹ U.C.L.A., Los Angeles CA, 90024. Temperature-sensitive immortalized tyrosine hydroxylase (TH) positive rat nigral neural cells (Durand et. al., Soc. Neurosci. Abstr., 16: 40, 1990) were infected with recombinant retroviruses effecting the expression of increased levels of TH. These cells proliferate at the permissive temperature of 33°C but are terminally differentiated at the restrictive temperature of 38°C. The parental line produced low levels of TH mRNA, TH protein, and <5 ng dopamine/mg protein as assessed by northem blot analysis, immunohistochemistry, and HPLC respectively. In contrast, a retrovirus-infected line produced higher levels of TH mRNA and protein, as well as 2200 ng dopamine/mg protein.

Instrastriatal transplants of the parental cell line (at 38°C) only reduced

and protein, as well as 2200 ng dopamine/mg protein.

Instrastriatal transplants of the parental cell line (at 38° C) only reduced apomorphine-induced rotation by 30% in unilateral nigrostriatal lesioned rats. In contrast, the retrovirus-infected cell line reduced apomorphine-induced rotations by 65%. Cells survived implantation as determined by prelabeling grafted neurons with Hoechst dye. No tumor formation occurred. However in vivo, these cells appeared to have down regulated TH production. Numerous temperature sensitive cell survived grafting for 1 month in immunosuppressed MPTP treated monkeys as identified by both Hoechst labeling and TH-immunohistochemistry. Glial fibrillary acidic protein-immunohistochemistry revealed only a limited host astrocytic response to the implant. These data provide further evidence that conditionally immortalized cells of neural CNS origin are potentially valuable as genetically engineered neural transplants.

# TRANSPLANTS OF THE SYMPATHOADRENAL (MAH-B2) CELL LINE SURVIVE AND DIFFERENTIATE WITHIN THE ADULT PERIPHERAL NERVOUS SYSTEM.

L.C. Doering\*, S.J. Birren\* and D.J. Anderson\*. Division of Anatomy, McMaster University, Hamilton, Ontario, CANADA L8N 3Z5 and \*Division of Biology, California Institute of Technology, Pasadena, CA 91125, U.S.A.

A current focus of transplantation research centers on the delivery of specific products by transplants of genetically modified cells. The sympathoadrenal cell line (MAH-B2) has been established by the immortalization of embryonic rat adrenal cells with a recombinant murine retrovirus containing the v-myc oncogene.

We examined the survival of MAH-B2 cells after transplantation into the brain and the peripheral nervous system (PNS). Cells were grown in vitro at high density for 3-5 days, collected and then injected as suspensions into the striatum or the sciatic nerves of adult Wistar rats. Quantitative and qualitative aspects of the transplants were assessed by immunocytochemistry.

No significant survival of the cells was seen in the striatum. In contrast, the peripheral nerves contained  $3.0-5.0 \times 10^3$  MAH-B2 cells/graft. After 2-3 weeks post-grafting, the small, rounded cells differentiated into large sympathetic-like neurons aligned parallel to the Schwann cell columns Grafted MAH-B2 cells expressed MAP2, neurofilament subtypes and catecholamine enzymes (DBH, TH). There was no evidence of uncontrolled growth of the cells within the nerves (5 months longest time point).

These experiments indicate that the MAH-B2 cells survive well and differentiate when grafted into the PNS. Combined peripheral nerve/MAH-B2 cell transplants will be studied in animals with striatal dopamine depletion. (Supported by The Parkinson Foundation of Canada)

### 331.15

SURVIVAL OF NEURONAL CELL LINE IMPLANTS IN THE CNS OF HISTOINCOMPATIBLE RAT HOSTS. L.S. Shihabuddin\*, L.A. White, S.M. Onifer, S.R. Whittemore and V.R. Holets. The Miami Project, Univ. of Miami School of Medicine, Miami, FL 33136.

Our previous studies demonstrated that the temperature-sensitive neuronal cell line RN33B was able to survive and differentiate with varied morphologies depending on the site of integration. In the present study, we addressed the issue of immunological rejection of RN33B transplants into the CNS, as in vitro studies had suggested that neuronal differentiation of RN33B cells made them less susceptible to cytotoxic T cell lysis (White et al., adjacent poster). RN33B cells were derived from Sprague-Dawley rats and expressed the RT1.A<sup>ch</sup> class I MHC epitopes. Allogeneic transplants of ß-galactosidase labeled RN33B cells were unitaterally made into the hippocampus and cerebral cortex of histoincompatible Lewis rats (RT1.A<sup>c</sup>). Two weeks later, 4 transplanted Lewis rats were challanged intraperitoneally with RN33B cells pretreated with \(\gamma\)IFN, which upregulated class I MHC expression. The animals were allowed to survive 3 weeks. In parallel, 4 control Lewis rats also received identical transplants and were sacrificed after 5 weeks. The appearance of the transplanted RN33B cells in the two groups was compared by immunocytochemical and morphological criteria. RN33B cells were not detected in the challanged hosts. In contrast, cells in the unchallanged hosts survived in both sites and differentiated with multiple neuritic processes. Our results suggest that while allogeneic RN33B cell transplants can be induced to be immunologically rejected, neuronal cell line transplants may prove to be useful in replacing damaged endogenous CNS neurons. The survival of chronic RN33B cell transplants is presently under investigation.

transplants is presently under investigation.

## 331.17

INTERMITTENT IMMUNOSUPPRESSION ENHANCES SURVIVAL OF INTRACEREBRAL TRANSPLANTS OF THE A7 IMMORTALIZED CELLS. G. S. Okoye', W. J. Freed' and H. M. Geller. Neurosurgical Research Laboratory, UMDNJ-Robert Wood Johnson Medical School, and The Graduate School, Rutgers University, Piscataway, NJ 08854 and 'NIMH Neurosciences Center at St. Elizabeth, Washington, DC 20032.

We have previously shown that A7 immortalized glial cells survive as an intracerebral implant and promote neurite outgrowth, at least for a short period of time. In this study, we evaluated 1) the ability of intermittent short-term immunosuppression to prolong the survival of A7 cells and 2) the host brain reaction to the implant. We implanted 10<sup>5</sup> A7 cells as previously described in male rats randomized to either control conditions or immunosuppressed using cyclosporine (12.5 mg/kg daily starting 1 day before transplantation for 7 days, followed by intermittent daily dose of 12.5 mg/kg). After a period of from 1 week to 12 weeks, animals were sacrificed and the number and location of surviving A7 cells were evaluated using antibodies to SV40 large The dosing of the 12 weeks rats stopped 7 weeks posttransplantation. The reaction of the host brain was evaluated using antibodies recognizing neuronal and glial-specific proteins, as well as tenascin and lymphocyte markers. Preliminiary results indicated significant increase of the survival of A7 cells in the immunosuppressed rat brain as compared to the control. Some immunoreactivity to tenascin, CD-4 and CD-8 lymphocyte markers were evident in the host brain. These preliminary results suggest that short-term intermittent immunosuppression may prolong survival of A7 cells in the rats brain. In addition, there is some host brain reaction in both control and immunosuppressed rats. Supported by NIH P01 NS 21469.

DIFFERENTIATION OF AN IMMORTALIZED NEURONAL CELL LINE RENDERS THEM LESS SUSCEPTIBLE TO CYTOTOXIC T CELL LYSIS *IN VITRO*. L.A. White \*1, R.W. Keane<sup>2</sup>, & S.R. Whittemore <sup>1,2</sup>, The Miami Project¹ and Depts. of Neurological Surgery¹ and Physiology & Biophysics², Univ. Miami School of Medicine, Miami, FL 33136

The expression of class I antigens of the major histocompatibility complex (MHC) allows cells to be recognized and killed by cytotoxic T lymphocytes (CTL) in cases of allogeneic graft rejection. Recent evidence has suggested that CNS neurons are resistant to CTL-mediated lysis (Keane et al., Transplantation, in press), and we tested whether a CNS-derived neuronal cell line showed similar properties. The temperature-sensitive, neuronal cell line RN33B, derived from E12 Sprague Dawley medullary raphe, expresses the RT1.4c<sup>th</sup> class I, but not class II, MHC antigens in the undifferentiated state. Neuronally differentiated RN33B cells do not express class I MHC antigens, although treatment with interferency -{IFN-γ}⟩ can induce class I, but not class II, MHC expression. To determine whether class I MHC expression is a requirement for RN33B cell killing, we performed standard in vitro cytotoxicity assays using <sup>51</sup>Crelease as an index of target cell lysis. Our results showed that undifferentiated RN33B cells were killed by alloantigen-specific CTLs, whereas differentiated RN33B cells were markedly less susceptible to CTL-mediated lysis, even after induction of class I MHC expression. These studies suggest that resistance of CNS neurons to CTL-mediated cell killing depends on the degree of neuronal differentiation rather than the level of class I MHC expression. Whether RN33B cells are refractory to lysis after transplantation into allogeneic CNS is examined in the adjacent poster (Shihabuddin et al.). Supported by The Miami Project and NS26887.

ION CHANNEL CURRENTS IN CULTURED HCN-1A NEURONS FROM HUMAN CORTEX. Y. Song\*, J.M. Simard, K. Werrbach-Perez, H.M. Eisenberg, R. Perez-Polo, K.N. Westlund, C. Hulsebosch. University of Texas Medical Branch, Galveston, TX 77550.

A neuronal cell line (HCN-1A) was recently established from human cortical tissue obtained from a megalencephalic child (Ronnett et al, Science 248:603-605, 1990). Immunocytochemical evidence indicating a neuronal origin was presented, but expression of ion channels was not demonstrated. For the present study, HCN-1A cells were cultured in DMEM with 15% fetal calf serum and induced to differentiate with nerve growth factor 10 ng/ml, forskolin 1 mM, and dibutyryl-cAMP 1 mM. Cells or membrane patches were voltage clamped using conventional patch clamp methods. Using appropriate recording solutions, we identified and characterized TTX-sensitive Na<sup>+</sup> currents, two types of Ca<sup>2+</sup> channel currents, including L-type and possibly N-type currents, and three types of K<sup>+</sup> currents, including a voltage dependent outward rectifier, a TEA-sensitive 146 pS Ca<sup>2+</sup> -activated K<sup>+</sup> channel, and a 23 pS outward current channel. These data provide additional evidence for a neuronal phenotype, and demonstrate functional potential that will be important in transplant experiments.

THE EFFECT OF GLUTAMATE RECEPTOR ANTAGONISTS AND AN UPTAKE BLOCKER ON GLYCOGEN CONTENT AND CELL VOLUME IN CULTURED

ASTROCYTES. R.S. Dombro, A.S. Bender, A. Padron, D.G. Hutson and M.D. Norenberg. VAMC & Depts. of Surg. & Pathol. Univ. Miami School of Medicine, Miami, FL 33101. Changes in astrocyte glycogen levels often accompany alterations in cell volume. Glutamate (GLU) causes both an increase in astrocyte glycogen content and cell volume. To investigate the mechanism of the GLU-stimulated glycogen investigate the mechanism of the GLU-stimulated glycogen increase and its relation to changes in cell volume, the effect of various GLU receptor blockers and the GLU uptake inhibitor, trans-4-carboxy-L-proline (t-PDC) were tested. GLU (1 mM) increased glycogen content by 54% and cell volume by 27% after 90 min of treatment. The following GLU receptor blockers were tested: 50  $\mu$ M DNQX, 50  $\mu$ M NBQX, 0.5 mM APH and 0.5 mM MK-801. None of these blockers had any effect on glycogen content or volume except for MK-801 which reduced glycogen by 34% and volume by 27%. Since NMDA receptors are not present on astrocytes, the effect of MK-801 must not be that of a GLU receptor antagonist. The uptake inhibitor, t-PDC, increased glycogen content by 70% and cell volume by 47%. This "paradoxical" action may have been due to its acting as a GLU analog rather than an uptake inhibitor. Thus, GLU-induced changes in astrocyte glycogen content are associated with parallel changes in cell volume. However, these effects do not appear to be receptor-mediated. (Supported by VA Medical Research Service and NIH grant AM 38153).

### 332.3

ETHANOL-INDUCED RELEASE OF ASPARTATE AND TAURINE IN PRIMARY ASTROCYTE CULTURES

H.K. Kimelberg\*, M. Cheema, H. Tong, E. O'Connor and S.K.

Goderie, Division of Neurosurgery, Albany Medical College, Albany,
NY 12208, and Rensselaer Polytechnic Institute, Troy NY 12180

Exposure of primary astrocyte cultures to isoosmotic ethanol from 10 to 100 mM leads to release of the preloaded amino-acids [3H] taurine and [3H] D-aspartate, whereas hyperosmotic ethanol causes no release. results in cell swelling (i.e. it is hypotonic) while hyperosmotic ethanol causes no change in volume (i.e. it is isosomotic). The release is inhibited by an anion channel blocker, L-644,711, shown to inhibit release of amino-acids due to hypoosmotic media- or potassium-induced swelling. The release is not dependent upon extracellular calcium and shows a decline in response to successive exposures to ethanol, i.e. apparent "desensitization". Thus, the swelling-induced ethanol, i.e. apparent desensitization. Thus, the swelling-induced release of amino-acids by ethanol corresponds in its properties to swelling-induced release in astrocytes due to hypotonic or high K<sup>+</sup> media. Interestingly, if one combines an exposure to hyperosmotic ethanol, which normally has no effect, with high K<sup>+</sup> medium, the high K<sup>+</sup> medium-induced release of [<sup>3</sup>H] D-aspartate is potentiated. Release due to isoosmotic ethanol or the potentiation of the high K<sup>+</sup> response by isoosmotic or hyperosmotic ethanol may contribute to the evolving pathology in the CNS during acute or chronic exposure to ethanol or in conjunction with traumatic and/or ischemic brain injury. Supported by NS 23750 and 30303.

## 332.5

CHARACTERISTICS OF TAURINE UPTAKE IN HYPEROSMOTICALLY TREATED CEREBRAL ASTROCYTE CULTURES. J.W. Beetsch\* and J.E. Olson. Department of Emergency Medicine, Wright State University School of Medicine, Dayton, OH 45401

H-Taurine uptake was characterized in astrocytes from rat cerebral cortex grown in normal and hyperosmotic culture conditions to investigate mechanisms of cell volume regulation and adaptation to states of altered osmolality. With high concentrations of taurine (lmM), uptake is linear for both conditions for at least 30 min. This uptake rate was not affected by exposure to hyperosmotic conditions. The mean ± SEM apparent binding constant for carrier-mediated transport, K<sub>m</sub>, was not altered by hyperosmotic conditions (14.1 ± 3.2 µM in isoosmotic media, 13.9 ± 5.6 µM in hyperosmotic media). The maximal velocity of uptake, V<sub>max</sub>, (mean ± SEM) of taurine was significantly (p<0.05) larger in isoosmotically treated astrocytes (1.13 ± 0.10 mg·min/nmol) compared with that of hyperosmotically treated astrocytes (0.62 ± 0.10 mg·min/nmol). The diffusional transport rate was significantly larger in cells grown in hyperosmotic conditions (0.71 ± 0.12 µL/mg·min) compared with cells grown in isoosmotic conditions (0.20 ± 0.12 µL/mg·min). Thus, accumulation of taurine by cultured cerebral astrocytes exposed to hyperosmotic conditions is not due to an increased uptake rate. Other mechanisms, such as decreased taurine release or increased synthetic enzyme activity, may lead to the accumulation of taurine in cerebral astrocytes in vitro and, perhaps in situ. Supported by NS 23218.

ASTROCYTE MODULATION OF CEREBRAL VESSEL FUNCTION VIA EICOSANOIDS AND NITROSYL FACTORS. S. Murphy\*, S. Kardos, S.A. Moore, K.I. Orgren and F.M. Faraci. Depts.

S.A. Moore, K.I. Orgren and F.M. Faraci. Depts. Pharmacology, Pathology and Internal Medicine, Univ. of Iowa College of Medicine, Iowa City, IA 52242.

Astrocytes release eicosanoids and also nitrosyl factors. To reveal whether these factors influence vascular function, astrocyte-conditioned medium was superfused onto cerebral artery segments and microvesselderived endothelial and smooth muscle cells in culture. Astrocytes induced relaxation in preconstricted basilar arteries, dependent upon the number of cells added but not on prostanoid synthesis. Relaxation was inhibited by arginine analogs and depended upon intact endothelium, suggesting the latter released a nitrosyl factor. Addition of agents (quisqualate, bradykinin) that evoke release of an astrocyte nitrosyl product to denuded vessels in the presence of astrocytes caused marked relaxation (20%), which was reversed by arginine analogs.

In studies with cerebral microvessel cells, addition of

In studies with cerebral microvessel cells, addition of the thromboxane analog U46619 caused dose-dependent release of the vasodilator prostacyclin. In addition, rapid transfer of conditioned medium from ATP-stimulated rapid transfer of conditioned medium from ATP-stimulated astrocytes caused similar increases in prostacyclin release from ATP-insensitive endothelial/smooth muscle cells. These results suggest that evoked release of astrocyte eicosanoid and nitrosyl factors influence adjacent vascular cells, indicating the potential role of astrocytes in modulating cerebral vessel function. Supported by NS 24621.

### 332.4

EFFECTS OF EXTRACELLULAR ATP AND GROWTH FACTORS ON DNA SYNTHESIS IN CULTURED ASTROCYTES. JT Neary', Q Zhu, SR Whittemore<sup>1</sup> and MD Norenberg. Lab Neuropathol, VA Med Ctr, Dept Pathol & The Miami Project<sup>1</sup>, Univ Miami Sch Med, Miami, FL 33101.

Astrocyte proliferation is one of the characteristics of reactive gliosis which occurs following CNS injury. Growth factors such as bFGF and EGF stimulate astrocyte proliferation, and bFGF levels increase following CNS injury. Recently it has been reported that ATP, which is released extracellularly following tissue injury, also increases DNA synthesis in astrocytes. We have now studied the effects of extracellular ATP in combination with growth factors on astrocytic DNA synthesis. Agents tested included bFGF (50 ng/ml), EGF (10 ng/ml), PDGF (2.5 ng/ml), and NGF (100 ng/ml). Cultures were treated with media containing 0.5% horse serum for 2 days, ATP (50-1000 µM) and/or growth factors were then added for 18 hr followed by an additional incubation in 3H-thymidine Under these conditions, 3H-thymidine incorporation was increased 30-60% by ATP and 4-8 fold by bFGF, EGF, and PDGF; NGF was slightly inhibitory (75% of control). When ATP was added in the presence of bFGF, 3H-thymidine incorporation was markedly increased in a synergistic manner (20-fold stimulation) in mature astrocytes (28 div). Smaller effects were observed in immature cells (15 div). Synergism was not observed with the other growth factors. These findings indicate that ATP markedly enhances bFGF-stimulated DNA synthesis in astrocytes and suggest that ATP may be an important determinant of the astrocytic response following CNS injury. (Supported by Dept. of Veterans Affairs.)

## 332.6

GLIAL RESPONSE TO GLUTAMATE AND GABA IN THE ISOLATED INTACT MOUSE OPTIC NERVE. Arthur M. Butt\* and M.G.Tutton. Dept. Physiology, UMDS, St. Thomas's Hospital, London SE1 7EH, U.K.

Experiments were carried out on isolated intact optic nerves from 23-59 day old mice. Glial cells were impaled with microelectrodes back-filled with 2% horseradish peroxidase in 0.5M KCl. Membrane potentials ( $E_{\rm m}$ ) were measured and the response to high [K<sup>+</sup>], lmM glutamate, or ImM GABA was recorded, and cells were then dye-injected for subsequent identification as astrocytes or oligodendrocytes. Astrocytes have a significantly (p<0.001) higher  $E_m$  (-69 + 1 mV, n=193) than oligodendrocytes (-64  $\pm$  1 mV, n=34). Both cell types depolarize in high [K<sup>+</sup>] in a Nernst-like manner. Both astrocytes and oligodendrocytes respond to glutamate and GABA in one of four ways: 1) respond to both glutamate and GABA; 2) respond to glutamate but not GABA; 3) respond to GABA but not glutamate; and 4) respond to neither glutamate or GABA. The response, where it occurs, is a 2-5 mV depolarization which is reversible, and ongoing experiments indicate both the glutamate and GABA responses are Na<sup>+</sup>-dependent. We are currently investigating the basis of the variation between responses in astrocytes and oligodendrocytes.

This work is supported by the Wellcome Trust (AMB) and the Smith and Nephew Foundation (MGT).

INVOLVEMENT OF ARACHIDONIC ACID IN THE STIMULATION OF 2-DEOXY-D-[1-3H] GLUCOSE UPTAKE EVOKED BY NORADRENALINE IN ASTROCYTE CULTURES N. Yu¹, J.-L. Martin¹, N. Stella¹², L. Pellerin⁵¹ and P.J. Magistretti¹ Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland¹ and INSERM U114, Collège de France, Paris, France².

Noradrenaline (NA) and VIP have been shown to promote the hydrolysis of glycogen in primary cultures of mouse cerebral cortical astrocytes (Sorg and Magistretti, 1991). In view of this action on energy metabolism we have examined the effect of NA and VIP on 2-deoxy-D-[1-3H] glucose (2-DG) uptake. Basal 2-DG uptake by cultured astrocytes corresponds to  $3.5\pm0.3$  nmol/mg prot/min of glucose. NA stimulates in a time- and concentration-dependent manner 2-DG uptake. This effect is inhibited by 90 % in the presence of 10  $\mu$ M cytochalasin B, a specific glucose transporter inhibitor. The EC30 of NA is  $0.5~\mu$ M with a maximal effect resulting in a 2-fold increase over basal level at 10  $\mu$ M. A time lag of  $\approx 5$  min occurs between NA application and stimulation of 2-DG uptake. This contrasts with the rapid glycogenolytic action of NA which is half-maximal within 5 min and with the NA-evoked increase in glucose-6-phosphate intracellular level which raises from  $2.2\pm0.3$  to  $3.5\pm0.3$  nmol/mg prot within 2 min. In contrast, despite its glycogenolytic action, VIP does not influence 2-DG uptake. Application of arachidonic acid (AA) also stimulates 2-DG uptake in a cytochalasin B-sensitive manner, with an EC50 of  $\approx 40~\mu$ M. These observations correlate well with the fact that NA but not VIP stimulates  $^3$ H-AA release in the same preparation. These observations suggest that the release of AA may mediate the stimulation of 2-DG uptake evoked by NA in cultured astrocytes.

Sorg and Magistretti, Br. Res. 563 227-233, 1991.

### 332.9

PHARMACOLOGICAL PROPERTIES OF THE GABA, RECEPTOR OF ACUTELY ISOLATED HIPPOCAMPAL ASTROCYTES S. Duffy<sup>1</sup>, D.D. Fraser<sup>1</sup>, D. Hoppe<sup>2</sup>, H. Kettenmann<sup>2</sup>, and B.A. MacVicar<sup>1</sup>, Neuroscience Research Group, U. of Calgary, AB, Canada and <sup>2</sup>Dept. Neurobiol, U. Heidelberg, Heidelberg, Germany.

GABA-evoked responses were studied in astrocytes acutely isolated from rat hippocampus using either patch clamping or fluorometric measurements of  $[{\rm Ca}^{2+}]_i$ . GABA ( $100\,\mu{\rm M}$ ) evoked inward currents in virtually all cells held at -80 mV to -100 mV (n=50, range of 50-300 pA). The mean  $E_{\rm rev}$  was -38 mV, corresponding to the  $E_{\rm Cl}$  indicating that GABA opened CI'-selective channels. The threshold [GABA] was  $\mu{\rm M}$ . Currents were maximal between  $100\,\mu{\rm M}$  - 1 mM and desensitized rapidly at these concentrations. The CI' current was also activated by the GABAA agonist muscimol but not by the GABAB agonist baclofen (both  $100\,\mu{\rm M}$ , n=5). The GABA-evoked currents were blocked by the GABAA antagonist bicuculline, and by the CI channel blocker picrotoxin, but not by the GABAB antagonist 2-OH saclofen (all  $100\,\mu{\rm M}$ , n=5). GABA-evoked current was potentiated by the barbiturate pentobarbital ( $100\,\mu{\rm M}$ , n=4), by diazepam ( $20\,\mu{\rm M}$ , n=3) and by the inverse agonist DMCM ( $20\,\mu{\rm M}$ , n=6/8). GABA would be expected to depolarize astrocytes because  $E_{\rm Cl}$  is positive to  $E_{\rm m}$ . To determine whether these depolarizations were sufficient to open voltage-dependent Ca channels, astrocytes were loaded with the  ${\rm Ca}^{2+}$ -sensitive dye indo-1. In 30 % of the cells, GABA (1 mM) evoked a transient ( ${\rm Ca}^{2+}$ 1, increase which was blocked by picrotoxin ( $100\,\mu{\rm M}$ , n=2) and by the Ca channel blocker verapamil ( $100\,\mu{\rm M}$ , n=4). Verapamil had no effect on the GABA-evoked current (n=3), indicating that abolition of the [ ${\rm Ca}^{2+}$ 1]; signal was due to block of voltage-gated Ca channels. These data indicate that astrocytes express GABAA ( ${\rm Ca}^{2+}$ 1, dependent processes.

## 332.11

HIPPOCAMPAL DEAFFERENTATION INCREASES <sup>3</sup>H-THYMIDINE INCORPORATION BY ASTROCYTES *IN VITRO*. J.R. Day\*, 1. Rozovsky and C.E. Finch. Andrus Gerontology Center, University of Southern California, Los Angeles. CA 90089.

Ünilateral lesioning of the rat entorhinal cortex (ECL) induces astrocytic changes and reactive synaptogenesis in the adult hippocampus. Astrocyte reactivity, assayed by increased glial fibrillary acidic protein ensues rapidly after ECL. Reports indicate that astrocyte reactivity induced *in vivo* may persist *in vitro* (Lindsay et al., 1982). This study determined if astrocytes cultured at various times after ECL reflected changes paralleling to those *in vivo*. Astrocytes from cortex and hippocampus were cultured separately for 4 days, transfered to serum free medium (24 h), and labelled with 10 μCi <sup>3</sup>H-T/ml (24 h). The same number of viable cells was initially plated in all groups, yet at 4 and 14 days after lesion, the ipsilateral hippocampus and cortex contained more adherent cells than the non-lesioned side. The proportion of <sup>3</sup>H-T labelled cells from ipsilateral hippocampus was the same at both of these times (80%). The proportion of labelled astrocytes from the unlesioned hippocampus and both cortical hemispheres decreased from 80% (44) to 65% (14d) *in vitro*. This equivalent incorporation by astrocytes cultured 4 and 14 days after lesion from the deafferented hippocampus may reflect the extended reactivity displayed by these cells *in vivo* in response to the ongoing synaptic reorganization induced by the lesion. Thus, hippocampal deafferentation induces an astrocytic response which persists up to 14d *in vitro*. These results suggest that gene expression is a target of this signal as shown by the enhanced mitogenic response *in vitro*. These data support the hypothesis that ongoing neurodegenerative processes can significantly alter astrocyte gene expression for extended periods of time. (Supported by: J.D. & C.T. MacArthur Program in Successful Aging; NIA 07909)

VIP AND NORADRENALINE EXERT A LONG-TERM CONTROL ON GLYCOGEN LEVELS IN ASTROCYTES: BLOCKADE BY PROTEIN SYNTHESIS INHIBITION. O. Sorg. M. Stolz, S. Beggah and P.I. Magistretti\*. Institut de Physiologie. Université de Lausanne. Switzerland.

Institut de Physiologie, Université de Lausanne, Świtzerland. VIP and noradrenaline (NA) have been previously shown to promote glycogenolysis in primary cultures of mouse cerebral cortical astrocytes<sup>1</sup>. We report now, in the same cultures, a second, temporally-delayed, action of VIP or NA: thus following glycogenolysis, an induction of glycogen resynthesis is observed, resulting, within 9 hours, in glycogen levels that are 6 to 10 times higher than those measured before the application of either neurotransmitter. VIP pulses as short as one minute are sufficient to double, 9 hours, later glycogen levels. The induction of glycogen resynthesis triggered by VIP or NA is dependent on protein synthesis, since both cycloheximide and actinomycin D abolish it entirely. The ability to elicit glycogenolysis is not sufficient per se to trigger the induction of glycogen resynthesis: thus two glycogenolytic agents such as methoxamine and phorbol 12,13-dibutyrate, both acting via protein kinase C activation, are unable to induce glycogen resynthesis. This observation, taken together with the fact that dibutyryl-cAMP application also results in enhanced glycogen resynthesis, strongly suggests that the long-term effect of VIP or NA is mediated by the cAMP second-messenger pathway.

Adenosine is also glycogenolytic<sup>1</sup>; however it only marginally induces glycogen resynthesis. We therefore further characterized the glycogenolytic action of adenosine: 2-chloroadenosine promotes glycogen breakdown with an EC50 of 3 µM. In addition, ATP and its non-hydrolysable analog ATP-γ-S also promote glycogenolysis, both with EC50s in the low µM range, thus indicating a new functional role of ATP receptors in astrocytes.

STEROIDOGENIC ACTIVITY OF RAT CEREBELLAR ASTROCYTES. R.J. Gasperini. C.R. Anderson\*. T.G. Watson.

Dept. of Biological Sciences, Deakin University, Geelong, Vic. 3217, Australia Primary cultures of astrocytes from neonatal (0-3 day old) rat cerebella have been used to investigate the presence and cellular localization of various steroidogenic enzymes. Monolayer cultures have been established with a simple technique utilizing a rapid trypsinization and trituration of excised rat cerebella. The cells obtained were cultured in Minimal Essential Medium (MEM) supplemented with 2 mM L-glutamine, penicillin/streptomycin and 5-10% fetal calf serum (FCS). After 2-3 weeks growth in 5%CO2/95%air (or when confluency was reached) the cultures were shown to be significantly free (>95% astrocytes) of contaminating cell types (such as neurons and oligodendrocytes) as determined by glial fibrillary acidic protein (GFAP) and galactocerebroside-c (GAL-c) immunoreactivity and general microhistological criteria for astrocytes.

Incubation of these cultures in serum-free medium for 24 - 48hr. with the radiolabelled steroids [14C]-Progesterone, [14C]-Androstendione, [14C]-Testosterone and [3H]-Pregnenolone have yielded significant amounts of products which, upon purification and identification by TLC and recrystalization to specific activity, suggest an astrocytic localization of the enzymes 17B-hydroxysteroid dehydrogenase isomerase (17B-HSD), 36-hydroxysteroid dehydrogenase isomerase (17B-HSD), 208-hydroxysteroid oxidoreductase (208-HOR), with specific activities significantly higher than those found in whole brain homogenates. The results indicate that primary monolayer cultures of astrocytes provide a well-defined tissue source for the demonstration of a possible *de novo* biosynthesis of steroid entities in the neonatal rat brain.

NEUROGLIAL RESPONSES TO THE DOPAMINERGIC NEUROTOXIN MPTP IN THE MOUSE STRIATUM. J.W. Francis\*, J. Yon Visqer, G.J. Markelonis, and T.H. Oh. Dept. Anatomy, Univ. Maryland Sch. Med., Baltimore, MD 21201.

Treatment of C57/BL6 mice with MPTP results in the

degeneration of nigrostriatal dopaminergic neurons followed by a reactive gliosis in the striatum. examined both astroglial and microglial/macrophage responses to dopaminergic denervation of the striatum by MPTP. Following treatment, GFAP immunoreactivity increased, reached a peak at two days and persisted for at least six weeks in striatal astrocytes. Vimentin was also markedly increased in astrocytes 48 hr after treatment. There was no appreciable difference in immunoreactivity to laminin between normal and MPTPtreated striata. GFAP protein levels increased only 100% and 190% above normal levels 24 and 48 hr after MPTP treatment, respectively. By contrast, GFAP mRNA levels were increased 4-fold and 15-fold above the control 24 and 48 hr after treatment, respectively. Immunocytochemical studies failed to detect either Mac-1positive or IL-18-positive microglia or macrophages in normal or MPTP-treated striatum. Both Western and Northern blot analyses failed to show measurable IL-18 protein or IL-18 mRNA in normal or MPTP-treated striata Our results suggest that a factor(s) other than IL-18 may initiate reactive astrogliosis in this neurotoxic model of glial scarring (Supported by NIH grant NS 15013).

INVOLVEMENT OF PROTEIN PHOSPHATASE IN ASTROCYTE VOLUME REGULATION. A.S. Bender\* and M.D. Norenberg. Lab Neuropath Univ Miami Sch Med & Vet Admin Med Ctr Miami, FL 33101.

During exposure to hypoosmotic stress, astrocytes regulate their volume by activating the KCl cotransporter, inducing the efflux of K' and Cl' with obliged water resulting in regulatory volume decrease (RVD). The activation of the KCl cotransporter depends on a phosphorylation-dephosphorylation cycle, mediated by kinases and phosphatases. During hypoosmotic stress there is a reduction in <sup>32</sup>P incorporation in 24 and 21 kDa proteins, and during RVD <sup>32</sup>P incorporation in these two proteins, and during NVD - Incorporation in these two proteins returns to normal levels (Neary et al., 1990; Soc. Neurosci. Abstr. 17, 1147). Okadaic acid (OA), a highly specific inhibitor of protein phosphatase 1 (PP1) and 2A (PP2A), was used to examine the role of phosphatases in activating the KCl cotransporter and in volume regulation. Following hypoosmotic stress, OA (100 nM) inhibited  $K^{\star}$  release, increased the amount of  $K^{\star}$  accumulation and release, increased the amount of  $K^{\star}$  accumulation and inhibited RVD. Since these events were not inhibited at 1 nM (when PP2A is completely inhibited) and only partialy at 100 nM, it suggests that PP1 (which is completely inhibited at 1  $\mu$ M) is inhibited by OA and may be involved in the activation of KCl cotransporter. Our results indicate that activation of the KCl cotransporter during hypoosmotic stress is associated with a net dephosphorylation which may be responsible for RVD. (Supported by USPHS grants NS-30291 and AM-38153 and the Department of Veterans Affairs).

### 332.15

HETEROGENEITY IN BRAIN ASTROCYTES AND CULTURED ASTROCYTES REVEALED BY MONOCLONAL ANTIBODIES. Elisabeth Welter. Christine J. Skordeles and Dennis M.D. Landis\*. Departments of Neurology and Neurosciences, Case Western Reserve University, Cleveland, OH

We have generated monoclonal antibodies which bind to epitopes present in astrocytes by using a plasmalemmal fraction from cultured rat astrocytes as an immunogen. Many of these antibodies bind to subpopulations in situ or in vitro

The mAb 4C6 is an IgM which binds to the surface of rare flat cells in secondary cultures of astrocytes; most of these cells do not have GFAP immunoreactivity. In low density cultures, 4C6 may stain a few of a cluster of cells, all of which are GFAP+; this pattern would suggest that clonally related cells are heterogeneous in this aspect of their phenotype. Similar flat cells are stained in cultures enriched for oligodendroglia, but 4C6 does not co-localize with galacto-cerebroside immunoreactivity. The mAb does stain microglia from P2 rat brain and endothelial cells derived from adult brain or aorta.

The mAb 6E9 binds to an intracellular epitope whose distribution resembles that of GFAP. The mAb stains most astrocytes in cerebral cortex, but in the cerebellum it stains only the astrocytes in the granular layer, and not Bergmann glia or astrocytes in the white matter. The mAb 5E6 binds in a complementary pattern in the cerebellum; it stains an intracellular epitope which resembles GFAP in Bergmann processes and in astrocytes in the white matter, but not in the astrocytes of the granular layer.

## 332.17

IN VITRO NUCLEOCYTOPLASMIC LOCALIZATION OF J1-31 ANTIGEN. M.V. Singh, K. Price, R. Bhatnagar, and S.K. Malhotra\*, Department of Zoology, University of Alberta, Edmonton, Canada T6G 2E9

A monoclonal antibody, Mab J1-31, was shown to recognize a cytoplasmic, astrocyte specific antigen (J1-31 antigen) in sections of CNS tissue fixed in paraformaldehyde. This antigen is distinct from GFAP and vimentin and is a more intense marker than GFAP for proximal reactive astrocytes located in the immediate vicinity of a destructive CNS lesion (Predy et al., 1988, J. Neurosci. Res. 19, 397-404; Malhotra et al., 1992, Brain Res. Bull. in press). The reactive antigen was shown to be a 30 kD protein by immunoprecipitation of autopsy samples from a multiple sclerosis patient (Singh et al., 1986, Biosci. Rep. 6, 73-79). Further studies on cultured astrocytes from neonatal rat brain, glioma cell lines of rat and human origin, cultured human fibroblasts, and biopsies of primary human astrocytomas show that immunostaining with Mab J1-31 is localized in the nucleus as well as in the cytoplasm following methanol fixation. No nuclear staining is detected in sections of normal adult rat CNS or non-CNS tissues. Western blot analyses of C6 and 9L rat glioma cells and human fibroblasts reveal two protein bands at 64 kD and 77 kD in cell homogenates. Nuclei isolated from the glioma cells show the same two bands. Nuclear localization of J1-31 antigen appears to be correlated with cell growth under tissue culture conditions, neoplastic transformation or the stage of cell growth in vitro.

myo-INOSITOL LEVELS DURING CELL VOLUME REGULATION IN ASTROCYTES. R.E. Isaacks, A.S. Bender, J.H. Bruce, and M.D. Norenberg. VA Med. Center and Univ. Miami Sch. Med., Miami, FL 33125.

Our previous studies on myo-inositol (MI) uptake in

Our previous studies on myo-inositol (MI) uptake in astrocytes under varying media osmolalities suggest that MI may function importantly in volume regulation. The present studies consider the levels of MI in astrocytes exposed to hypo- and hypertonic conditions to determine whether MI may be serving as an osmolyte involving the preservation of astrocyte volume. Primary astrocyte cultures from neonatal rats were incubated in either hypotonic (180 mosm/kg  $\rm H_2O\rm)$ , isotonic (310 mosm/kg  $\rm H_2O\rm)$ , on hypertonic (440 mosm/kg  $\rm H_2O\rm)$ ), modified DMEM media containing 40  $\mu\rm MI$  MI levels were measured on extracts of astrocyte cultures by converting to its per(trimethylsilyl) derivative and analyzing by GLC using a glass column packed with 3% OV-17 on 80/100 Chromosorb W(HP) at 190°C column temperature with nitrogen carrier gas flow rate of 90 ml/min. In isotonic media, the level of MI was 30.5  $\pm$  4.9  $\mu\rm g/mg$  protein and that level was maintained for 48 hours. When astrocytes were exposed to hypotonic media, the levels of MI were undetectable within 6 hours and remained at that level for 48 hours. Astrocytes in hypertonic media had increased in MI level by 34% within 6 hours which continued to increase to 3-fold by 24 hours. Our results indicate that MI functions as an organic osmolyte in volume regulation of astrocytes.

### 332.16

MONOCLONAL ANTIBODIES WHICH BIND TO REACTIVE ASTROCYTES. Stephen D. Collins\*, Michael B. Bolesta, and Dennis M.D. Landis. Departments of Neurology and Neurosciences, Case Western Reserve University, Cleveland, OH 44106

We have generated monoclonal antibodies (mAb) which bind to epitopes whose expression is changed in the context of the astrocytic reaction to injury.

Millipore filters were inserted into the cerebral cortex of normal adult rats. Ten days later, the filters and adherent cells were removed and used as an immunogen in the generation of mAbs. An epitope bound by the mAb 13A11 is barely detectable in normal brain astrocytes and cultured astrocytes, but its expression is clearly increased after forebrain is injured by a stab wound or implantation of a filter. The mAb 01E4 binds to an intracellular epitope which is distributed very much like GFAP in astrocytes, but is also present in microglia and oligodendroglia; it too is increased after injury. A previously described mAb, 8C10, binds to the surface of cultured astrocytes and oligodendroglia, and the expression of its corresponding epitope is dramatically increased after injury.

Some of the astrocytic changes occurring during the reaction of the brain to injury may involve interactions with microglia. We have found that astrocytes in organotypic cultures of rat hippocampus acquire structural characteristics which resemble those of reactive astrocytes, and may be further modified after stab wounds in the slice. By obtaining slices of hippocampus at various postnatal ages, and by adding cultured microglia, we may be able to determine whether the presence of microglia alters astrocyte differentiation in the slices as it is reflected in mAb binding.

SYNAPSIN I mRNA IN THE RAT CNS BY IN SITU HYBRIDIZATION. R.H. Melloni, Jr.\*, L. M. Hemmendinger, J. E. Hamos, and L. J. DeGennaro. University of Massachusetts Medical Center, Worcester, MA 01655.

Synapsin I is the best characterized member of a family of neuron-

specific phosphoproteins thought to be involved in the regulation of specific phosphoproteins thought to be involved in the regulation of neurotransmitter release. Here, we present the first extensive in situ hybridization study detailing the regional and cellular distribution of synapsin I mRNA in the developing and adult rat central nervous system. Both the regional distribution and relative levels of synapsin I mRNA established by in situ hybridization were confirmed by RNA blot analysis. Our data demonstrates the widespread yet regionally variable expression of synapsin I mRNA throughout the developing and adult rat CNS. In the adult rat brain, the greatest abundance of synapsin I mRNA was found in the large pyramidal neurons of the CA3 and CA4 fields of the hippocampus, and in the mitral and internal granular cell layers of the olfactory bulb. Other areas abundant in synapsin I mRNA were the layer II neurons of the piriform cortex and layer II and V neurons of the entorhinal cortex, the granule cell neurons of the dentate gyrus, the pyramidal neurons of hippocampal fields CA1 of the dentate gyrus, the pyramidal neurons of hippocampal fields CA1 and CA2, and the cells of the parasubiculum. In general terms, the patterns of expression of synapsin I mRNAs paralleled those encoding other synaptic terminal-specific proteins, such as synaptophysin, VAMP-2, and SNAP-25. In addition, to determine specifically how synapsin I mRNA levels are related to levels of synapsin I protein, we examined the local distribution patterns of both synapsin I mRNA and protein in the adult rat hippocampus. These data revealed differential levels of synapsin I mRNA and protein within and between defined synaptic circuits of the rat hippocampus.

### 333.3

LOCALIZATION OF RNA AT SYNAPSES: IDENTIFICATION OF A SYNAPTOSOMAL GAP-43 RNA-BINDING PROTEIN. \*M.E. Chicurel, C. DeFranco, @D.M. Terrian, and H. Potter. Program in Neuroscience, Dept. Neurobiology, Harvard Medical School, Boston, MA; @Dept. Anatomy and Cell Biology, East Carolina School of Medicine, Greenville, NC 27858-4354.

One mechanism that may contribute to both the generation and maintenance of neuronal polarity, and which also provides a potential for synaptic plasticity, is the subcellular compartmentalization of mRNA together with factors involved in translation. This proposal of localized translation is supported by the observation that a specific RNA population is associated with the dendritic component of a vertebrate CNS synapse: the hippocampal mossy fiber (MF)-CA3 synapse. An abundant member of this population is GAP-43 mRNA. We have identified a protein found in a preparation of MF-CA3 synaptosomes that specifically binds the GAP-43 mRNA. The binding site was localized to the 3' untranslated region (UTR) by mobility-shift assay. A pyrimidine-rich tract in the GAP-43 3' UTR is apparently required for protein binding activity. Our preliminary data suggests that this protein may affect translation of GAP-43 mRNA. M.E.C. is a Howard Hughes fellow.

THE COMPLETE GENE ENCODING HUMAN B-50/GAP-43 P.C. de Groen, L.H. Schrama, H.B. Nielander, W.H. Gispen and P. Schotman. (SPON: European Neuroscience Association) Div. Mol. Neurobiol., Rudolf Magnus Inst., Lab. Physiol. Chem., Inst. Molec. Biol. & Med. Biotechnol., Univ. of Utrecht, Padualaan 8, 3584 CH Utrecht, The Netherlands

Previously, we reported the structure of the human B-50/GAP-43 gene contained in 3 exons - based on the reported human cDNA and on isolated genomic clones for exons 2 and 3, and PCR-derived genomic clones for exon 1 (Schrama et al. 1990, Soc. Neurosci. Abstr. 16:154.11; Nielander et al. 1991. idem 17:457.14).

We now have isolated the 5' region of the human B-50/GAP-43 gene. Using a PCR-clone as probe, we have screened a Lambda EMBL3 genomic library and have found 10 genomic clones. Thus far, one clone has been analyzed in detail. Restriction analysis showed that it consists of 3 kb sequence upstream of the open reading frame (ORF) and approximately 10 kb of intron 1. There was no overlap with previously isolated genomic clones containing 13 kb intron 1 and the complete exon 2. Comparison of human and rat sequence 5' of the ORF revealed homology of the untranslated region until approximately -1 kb; however, long GT (Z-DNA) and AG repeats (H-DNA) as seen in the rat gene were not present. Computer analysis of the human sequence for potential binding sites of vertebrate-encoded transcription factors (NAR 1992;1:3-26) did not reveal any neuron-specific DNA elements. Three TATA box binding protein sequence motifs were present, but none was close to main transcription initiation sites as determined by Northern blotting.

We conclude from these results, that the overall gene structure of human B-50/GAP-43 is similar to that of the rat gene.

### 333.4

ANALYSIS OF B-50/GAP-43 TRANSCRIPTION STARTS BY NORTHERN BLOTTING AND GENETIC VARIATION IN H-DNA LENGTH OF THE RAT B-50 (GAP-43) GENE. L.H. Schrama\*, M.G.A. Rensen-de Leeuw, W. Korver and B.J.L. Eggen. Rudolf Magnus Inst., Lab. Physiol. Chem., Inst. Mol. Blol. & Med. Biotechnol., Univ. of Utrecht, Padualaan 8, 3584 CH Utrecht, NL.

The neural-specific phosphoprotein B-50 (GAP-43) gene is encoded by a single copy gene. The gene includes 3 exons (1,2). In order to gain more insight in the regulatory elements of the B-50 promoter, we have been determining the B-50 regulatory elements of the 5-30 promoter, we have been determining in 6-30 promoters transcription starts. Determination of these by conventional techniques such as primer extension, S1 nuclease mapping and RNase protection proved to be very difficult, probably due to the high degree of secondary structure (1-3). Two other techniques were more successfull; primer extension combined with PCR (PE-PCR) and Northern blotting. With PE-PCR the longest transcripts in 8 day old brain poly(A)\* mRNA are found to extend to -465 upstream of the ORF. Similar data were obtained by others (2). In order to determine the number of B-50 mRNAs with a long 5\* UTR, Northern to the to determine the indirect of 2-30 intrivials with a long 5 UTN, Northern blotting was used. Only a minor portion of the B-50 mRNAs have a long 5' UTR, the majority has a short 5' UTR.

Comparison of the primary structure of the B-50 gene upstream of the ORF with

Comparison of the primary structure of the B-50 gene upstream of the ORF with previously published sequences (1,2) showed that the length of H-DNA varied. The H-DNA containing region of the B-50 gene was amplified by PCR on isolated Wistar DNA or commercial Sprague-Dawley DNA (Clontech). The resulting PCR products were subcloned in the TA vector and sequenced with the T7 sequencing method (Pharmacia) and an anti-sense primer very close to the H-DNA. The length of the H-DNA varied between (AG)<sub>35</sub> and (AG)<sub>46</sub> in the Wistar DNA and between (AG)<sub>36</sub> and (AG)<sub>47</sub> in Sprague-Dawley, whereas analysis of exon 1 genomic clones revealed (AG)<sub>25</sub> (1), (AG)<sub>35</sub> (2) and (AG)<sub>46</sub> (3). The influence of the H-DNA length on the B-50 promoter activity in various stages of EC cell differentiation is currently investigated (Eggen et al., this meeting).

## 333.6

EXPRESSION CLONING OF NOVEL BRAIN-SPECIFIC cDNAs WITH M6 MONCLONAL ANTIBODY. Y. Yan. C. Lagenaur, and V. Narayanan\*, Departments of Neurobiology, Anatomy, and Cell Science, and Pediatrics, University of Pittsburgh, Pittsburgh, PA

M6 is a monoclonal antibody obtained by immunizing a rat with a partially purified membrane fraction of a mouse brain homogenate. The corresponding antigen(s) is a 35 kDa glycoprotein distributed througout the CNS, found primarily on the surface of neuronal cell bodies and their non-myelinated processes, and the choroid plexus and proximal renal tubules. Addition of M6 antibody or its Fab fragments to cultured cerebellar neurons interferes with neurite outgrowth (Lagenaur, et al, 1992). We report here the cloning of mouse brain cDNAs with an M6 antibody probe.

A λgt11 expression library representing adult mouse brain was screened with an M6 antibody recognizing denatured M6 antigen. Two positive clones, 321 and 511 (containing 130 bp and 100 bp inserts respectively), were sequenced, and used as probes for Northern blots. 321 and 511 hybridize to an approx. 4 kb mRNA in brain and kidney, not found in liver or heart. When the library was re-screened with 321, a larger cDNA, 3211, containing a 710 bp insert, was obtained. 3211 contains a segment highly homologous to a transmembrane domain of proteolipid protein (PLP) exon 3.

CLONING OF A CDNA ENCODING RAT BRAIN GABA TRANSAMINASE. L.K. Medina-Kauwe\* 1, N.J.K. Tillakaratne 2, J.-Y. Wu<sup>4</sup>, & A.J. Tobin 1, 2, 3 Molecular Biology Institute, 2 Department of Biology, 3 Brain Research Institute, University of California Los Angeles, Los Angeles, CA, 90024, 4 Department of Physiology and Cell Biology, University of Kansas, Lawrence, KS, 66045

GABA transaminase (GABA-T) is the catabolic enzyme of the inhibitory neurotransmitter, GABA. We have isolated several cDNA clones encoding rat brain GABA-T by two independent cloning methods. A  $\lambda ZAP$  rat hippocampal cDNA expression library was screened using an anti-mouse GABA-T antibody (Saito et al., Brain Research 65,287,1974) and a PCR-derived bovine GABA-T cDNA probe (Kwon et al., J Biol Chem 267,7215, 1992). Two of the cDNAs isolated by immunological screening with the anti-GABA-T antibody show high DNA and amino acid sequence identity to porcine heart citrate synthase (Evans et al, Biochemistry 27,4680,1988). However, most of the cDNAs isolated by both methods show a high DNA sequence identity to that reported by Kwon et al. for a bovine GABA-T cDNA. The derived amino acid sequence predicts a putative leader peptide similar to the signal sequences of several proteins targetted to mitochondria. Our cDNAs hybridize strongly to a 6.4 kb RNA, and weakly to a 2.1 kb RNA. We are now in the process of determining whether the protein produced in a bacterial expression system from our cDNAs have GABA-T enzyme activity

## 333.9

MOLECULAR CLONING AND ANALYSIS OF TWO CEREBELLIN-RELATED GENES CBL-1 AND CBL-2 THAT DIFFERENTIALLY EXPRESSED IN THE RODENT NERVOUS SYSTEM. B. Kavety. J. Hempstead and J.I. Morgan\*. Department of Neuroscience, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

To elucidate the molecular mechanisms that govern cell-specific gene expression in the developing nervous system, we have cloned a series of genes whose expression is restricted to cerebellum. One such gene termed cbl-1 encodes a protein, precerebellin, that contains the sequence of cerebellin, a hexadecapeptide previously identified to be highly enriched in cerebellum. The expression of cbl-1 is greatly reduced in certain cerebellar mutant mice that were previously shown reduced in certain cerebellar mutant mice that were previously shown to contain reduced levels of cerebellin peptide. Analysis of cbl-1 gene structure reveals the presence of two introns. Furthermore, we have detected a novel type of splicing in the 3' untranslated region of the RNA. Southern analysis suggested the presence of other genes related to cbl-1. A cDNA, termed cbl-2, has been cloned using a PCR strategy from whole brain mRNA. Although this cDNA encodes a highly related polypeptide, that includes a cerebellin-like motif, it appears to be more ubiquitously expressed in the CNS than cbl-1. We are now examining the regulatory sequences of the two genes to determine the element(s) that could account for their differential expression using transgenic mouse technology. expression using transgenic mouse technology.

## 333.11

NUCLEOTIDE SEQUENCE OF RAT CALRETININ cDNA. K.I. STRAUSS and D.M. JACOBOWITZ', Lab. of Clin. Sci., NIMH, Bethesda, MD 20892. Calretinin (CR) is a 29 kDa, neuron specific calcium binding protein (CaBP). Previous studies have shown a unique localization of CR throughout the CNS in mammals, birds, reptiles, amphibia, and fish. In order to explore the role of CR in the brain and its regulation at the molecular level, we have cloned and analyzed the rat cDNA coding for CR. An immunoreactive clone was isolated from a rat brain cDNA expression library in lambda gt11. The insert was subcloned into the Eco RI site of the pGEM-4Z transcription vector for further analysis. The identity of the 1.45 kb insert was confirmed by comparison with human CR. The rat cDNA sequence comprised a 54 bp 5' untranslated region, an 816 bp open reading frame (ORF) with start and stop codons, and a 579 bp 3' untranslated region. A polyadenylation signal and 13 adenylate residues were found near the 3' end. The nucleotide and amino acid sequences in the proposed coding region were remarkably homologous to human CR (94.3% and 99.6%, respectively), and chick CR (79% and 87% respectively). An 83% homology was found between human and rat (but not chick) sequences within the 36 bp upstream of the initiation codon, with no other homology in the 3' and 5' untranslated regions. The ORF has 271 codons coding for a putative protein of 31.4 kDa. Only one amino acid differed between rat and human CR. This was a conservative conversion from Ile-235 in human to Met-235 in rat (and chick) CR. Further sequence analysis revealed that, among human, rat, and chick CR coding regions, there was no single position with a different nucleotide in all three species. At the 297 positions where two of the species had identical nucleotides but the third differed, the chick was different 76% of the time, the rat 19% of the time, and the human 5% of the time, supporting the accepted evolutionary distance between birds, lower mammals, and primates. The abundance of CR in

CLONING OF TWO RELATED ORPHAN RECEPTORS WHICH MAY BE INVOLVED IN DEVELOPMENT. A.J. MacLennan\*, D.C. Lado, Browe, B.R. Davies, and G.P. Shaw. Dept. of Neuroso Univ. of Florida, Gainesville, FL 32610. We have used medium stringency library screening Dept. of Neuroscience, 32610.

techniques and RACE PCR methods to isolate two rat cDNAs (H218 and rat-edg) that encode putative G-protein coupled receptors (pH218 and prat-edg) which, based on their similarity are likely to be responsive to the same unidentified endogenous ligand(s). Rat-edg is the rat homolog of "edg-1", a gene which has been implicated in endothelial cell differentiation (Hla and Maciag, 1990:JBC, endothelial Cell differentiation (Hia and Maciag, 1990:M) Vol. 265, p. 9308). Our Northern analyses indicate that H218 and rat—edg mRNNs are expressed in brain, several peripheral organs, and PC12, C6, and NIH 3T3 cells. All these tissues except PC12 cells contain a 3.2 kb rat—edg transcript. A 4.9 kb rat-edg transcript was detected only in brain and PC12 cells. In brain, rat-edg mRNA was detected in all regions examined and is most abundant during later stages of postnatal development whereas H218 mRNA is most abundant during embryonic brain development. H218 mRNA is also rapidly increased in RJK88 hamster ribroblasts by the tumor promoter, PMA. In addition, the presumed cytoplasmic C-terminal domain of pH218 contains a sequence similar to motif I of the SH2 domain present in phospholipase C type II. Finally, based on overall homology, pH218 may be distantly related to TRK.

CHARACTERIZATION OF cDNAs ISOLATED FROM AN IMMORTALIZED MOTOR NEURON HYBRID CELL LINE BY SUBTRACTIVE SCREENING. S.H. Pasternak,\* N.R. Cashman, K.E.M. Hastings. Dept of Neurology and Neurosurgery, McGill University, Montreal PQ H3A 2B4

We have developed N18TG2 neuroblastoma X dissociated mouse spinal cord (NSC) hybrid cell lines for the study of the molecular biology of the motor neuron. One of these hybrid cell lines, NSC34-4-6, expresses many motor neuron-like characteristics not found in the parental neuroblastoma, including the ability to extend processes and make stable contact with myotubes in culture, and the expression of choline acetyltransferase, neurofilaments and an S-laminin receptor (J. Neurosci., 1991). A cDNA library of this NSC34 cell line was examined by differential and subtractive screening in order to isolate genes expressed in the hybrid cells but not in the N18 neuroblastoma parent (Neurosci. Abs. '89). Two cDNAs were isolated which correspond to known neural genes: GAP-43 (important in axonal growth cone extension) and chromogranin B (a component of neurosecretory vessicles). Three additional clones were isolated whose sequences are not present in GenBank (release 71). One of these sequences identifies a transcript of 2900 bases on a northern blot which is several fold more abundant in mouse spinal cord than brain or liver, but also expressed at high levels in other tissues (kidney, spleen and lung). A second novel sequence is detectable by PCR at a higher level in spinal cord than brain or liver, but is also present in other mouse tissues. The final cDNA is detectable by PCR primarily in brain and spinal cord. While this expression data suggests that these cloned cDNAs are not motor neuron specific, they may still be expressed in motor neurons. We are currently isolating full length cDNAs of these clones and mapping their cellular expression by in situ hybridization.

## 333.12

CLONING OF NOVEL CYSTEINE PROTEASES FROM RAT BRAIN USING DEGENERATE OLIGONUCLEOTIDES TO CONSERVED SEQUENCES. Suzana Petanceska and Lakshmi Devi Department of Pharmacology, New York University Medical Center, NY 10016.

Cysteine proteases are involved in many diverse cellular processes

ranging from processing of precursor proteins to intracellular degradation. Since cysteine proteases play a vital role in normal cellular protein metabolism, it is understandable that cysteine proteases have been implicated in a number of disease states including cancer, arthritis, protein metabolism, it is understandable that cysteine proteases have been implicated in a number of disease states including cancer, arthritis, and Alzheimer's disease. In an effort to identify novel cysteine proteases, polymerase chain reaction and primers directed against the catalytic sites of previously cloned cysteine proteases were used. From rat brain mRNA, a 600 basepair band was amplified; cloning and partial sequence analysis of this band resulted in the identification of cathepsins B and L, and five novel sequences. The novel cDNAs contained a number of residues conserved in lysosomal cysteine proteases, including the active site residue His<sup>139</sup> (papain numbering). In addition, the amino acid homology between the novel sequences and either cathepsins B, L, or H ranged from 63% for PCR27 to 32% for PCR31. Northern blot analysis relvealed that the mRNA for these novel putative cysteine proteases is differentially expressed in brain, lung, liver, kidney, spleen, ileum, and heart. One of the brain-specific putative cysteine proteases is expressed at such low levels that it could be detected only by PCR amplification of the cDNA generated from the brain mRNA. The tissue-specific expression implies highly specific functions for the five novel proteins. This strategy of cloning proteases using PCR amplification of the conserved regions will be useful in the identification of the proteases involved in growth, development and disease states; this was previously limited by the abundance of the mRNA and/or of the tissues.

MOLECULAR CLONING AND ANALYSIS OF βHLH-ENCODING cDNA CLONES EXPRESSED IN EMBRYONIC RAT BRAIN. D.I. Lugo\* R. Molinar-Rode, A. Lievano. F. Franco del Amo, and J.I. Morgan. Depts. of Neurosciences and Developmental Biology, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

One of the goals of developmental neurobiology is to investigate the molecular mechanisms that direct the ontogeny of the nervous system. A strategy for this study is to search for developmental control genes expressed in the early nervous system. An important class of such molecules includes proteins with common DNA-binding and dimerization domains, the basic helix-loop-helix (bHLH) family. Some members of this family are MyoD, involved in myogenic determination and products of the achaete-scute complex of Drosophila which are involved in neural determination. In order to try to identify additional members of this class of molecules that might be implicated in mammalian neurodevelopment we have constructed an embryonic day 10 rat brain library and have begun screening with a 254bp probe spanning the bHLH domain of the recently identified mammalian achaete-scute homologue, MASH-1. This probe was generated by synthesizing specific oligonucleotides and amplifying the bHLH region of MASH-1 from NGF-treated PC12 total RNA by reverse transcriptase coupled to the polymerase chain reaction. Various clones have been isolated using low stringency conditions and preliminary characterization has begun. in-situ hybridization to rat embryonic sections, gel shift assays as well as transfection studies will provide insights as to their potential role during neurodevelopment.

ISOLATION OF cDNAS ENCODING NOVEL MEMBERS OF THE THYROID HORMONE/RETINOIC ACID RECEPTOR SUPERFAMILY FROM RAT HIPPOCAMPUS. Sandra Peña de Ortiz\* and Gordon A. Jamieson Jr. Division of Toxicology, Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati Ohio 45267

Steroid hormones, thyroxines, and retinoids regulate gene expression in the hippocampus by activating members of the steroid/thyroid hormone receptor superfamily. Members of this gene superfamily function as nuclear receptors that regulate transcription in a ligand-dependent fashion. We hypothesized that additional ligand molecules exist, which function in the hippocampus by regulating still unidentified nuclear receptors. Hence, we initiated studies to isolate novel members of this gene superfamily from rat hippocampus. To achieve this goal we designed degenerate oligonucleotide primers targeted to the highly conserved zinc finger region of these receptors for use in the Polymerase Chain Reaction (PCR). Rat hippocampal cDNA was prepared and subjected to PCR using the above mentioned primers. We amplified and subsequently cloned the zinc finger regions of four members of the steroid/thyroid hormone receptor superfamily, including the rat glucocorticoid and thyroid hormone receptors. Two of our clones, hippocampal zinc fingers (HZF) 2 and 3, encode novel zinc finger motifs of putative members of the thyroid hormone/retinoic acid receptor superfamily. These novel cDNA clones are 58% to 76% homologous to known nuclear receptors. Analysis of the deduced amino acid sequence for both these clones revealed differences in residues that are conserved among all other known members of the superfamily. Current efforts are focused on using northern blot analysis to determine the tissue specificity of HZF2 and HZF3 expression, in situ hybridization to define the distribution of transcripts for these molecules in the brain, and 3'-anchored PCR to isolate the ligand binding region of these receptors so that ligand identification studies can be initiated. Supported by ONR NO0014-90-J-1898 and a NIMH Minority Fellowship.

IDENTIFICATION OF IMMEDIATE-EARLY GENES ENCODING NON-NUCLEAR SIGNALING MOLECULES IN THE MOUSE CENTRAL NERVOUS SYSTEM. B. S. Hilbush\* R. Molinar-Rode. M. D. Hayward, and L. I. Morgan. Dept. of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

Roche Research Center, Nutley, NJ 07110.

Polypeptide growth factors, neurotransmitters, and other ligands elicit a rapid and transient induction of several cellular immediate-early (cIE) genes whose products are thought to mediate long-term phenotypic changes and altered neuronal behavior in target neurons. The class of cIE genes is defined by the property of superinduction in the presence of protein synthesis inhibitors. In general, the cIE class encodes nuclear proteins such as the transcription factors c-fos and c-jun. Since the response to environmental signals may necessitate rapid changes in other components of cellular signaling machinery, the repertoire of inducible genes may not be limited to nuclear proteins. Thus, we have investigated whether the immediate-early response in the nervous system includes inducible genes involved in signal transduction processes. As an initial screen, we utilized reverse transcription coupled to the polymerase chain reaction (RT-PCR) to detect brain transcripts superinduced during cycloheximide treatment. Total RNA was prepared from brains of adult mice treated with or without cycloheximide for 4 hr and 1-2 ug of RNA was used for RT-PCR with PCR primer pairs designed to amplify genes encoding a broad spectrum of signaling molecules. PCR products were identified which were either significantly increased or newly present in response to cycloheximide. The identified products were used as cDNA probes for Northern blot analysis to confirm superinduction of specific mRNA by seizure-inducing agents or cycloheximide. Using these approaches, we have identified inducible genes among the superfamilies encoding ligand-gated ion channels and G proteins and synapse-associated proteins. These results suggest that components of signaling processes may constitute part of the immediate-early response in neurons.

CLONING AND EXPRESSION OF A RAT GLYCINE TRANSPORTER.

B. Borowsky\* and B.J. Hoffman. Laboratory of Cell
Biology, NIMH, Bethesda, MD 20892.

We have isolated a cDNA clone for a novel Na<sup>+</sup>-

We have isolated a cDNA clone for a novel Na<sup>+</sup>-dependent transporter by screening a rat basophilic leukemia cell (RBL) cDNA library with a degenerate oligonucleotide corresponding to a region conserved between the GABA and NE transporters. Transient expression of this cDNA in CVl cells confers saturable, Na<sup>+</sup>-dependent uptake of glycine (Km- 50-70 uM). This glycine transporter shows significant sequence similarity to other members of the Na<sup>+</sup>-dependent transporter family, i.e. GABA, NE, DA, 5HT and betaine. In situ hybridization histochemistry demonstrates the presence of this glycine transporter mRNA in both CNS and peripheral tissues. Glycine is an inhibitory neurotransmitter found predominantly in the lower brainstem and spinal cord. The presence of this suggests that glycine may have important functional roles outside the CNS. Pharmacologic characterization and anatomic distribution of the glycine transporter will be discussed.

### 333.16

REGULATION OF C-FOS EXPRESSION BY VIP IN PRIMARY CULTURES OF CEREBRAL CORTICAL ASTROCYTES AND NEURONS. <u>1.-L. Martin\*<sup>1</sup>, S. de Rham¹, C. Rossier¹, T. Bardoscia¹, N. Stella¹, <sup>2</sup> and P.l. Magistrett¹ I. Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland¹ and INSERM U114, Collège de France, Paris, France².

The expression of c-fos was examined in primary cultures of astrocytes</u>

The expression of c-fos was examined in primary cultures of astrocytes and neurons by Northern blot analysis. Cultures were prepared from mouse cerebral cortex; neonates (1-2 days) and 16-17 days embryos were used for astrocytes and neurons respectively. In astrocytes, VIP induced c-fos expression in a concentration-dependent manner, with a significant effect already observed at 0.1 nM; maximal induction occurred at 1 µM. The stimulation of c-fos expression was time-dependent, being detectable at 30 min and maximal between 1 to 3 hours. C-fos mRNA levels returned to control values within 9 hours. Similar effects were observed when VIP was applied as a 10-minute pulse. In contrast the expression of other immediate-early genes such as c-myc, c-jun, c-src, c-Ha-ras and c-mos was not affected by VIP. In view of the induction by VIP of a transcription factor such as c-fos, we have engaged, using a subtractive hybridization approach, in the isolation of cDNA clones whose expression might be enhanced following VIP exposure. To this end we have prepared control and VIP-stimulated astrocyte cDNA libraries with the following characteristics: primary plaque number of ~ 2 x 10<sup>6</sup> (~ 1% nonrecombinants) and average insert size > 2 kb. The expression of c-fos was also examined in primary neuronal cultures. In this cell type also, VIP 1 µM increased the amount of c-fos transcripts. In addition, glutamate agonists acting at ionotropic, e.g. AMPA and NMDA, or metabotropic receptors, e.g. trans-ACPD, stimulate c-fos expression. However GABA and the cholinergic agonist carbachol were without effect. Supported by FNRS grants 31-32338.91 to JLM and 31-26427.89 to PJM.

## 333.18

NOVEL ras/rap-RELATED GENE EXPRESSED IN BRAIN AND REGULAT-ED BY SYNAPTIC ACTIVITY. <u>+K. Yamagata and P.F. Worley\*</u>. Department of Neuroscience and +Howard Hughes Medical Institute, Johns Hopkins University Sch. of Med., Baltimore, MD 21205.

We are examining the genomic response of neurons to synaptic activity as a means to understand the molecular basis of plasticity. Differential screening of cDNA libraries has been used to identify a previously uncharacterized gene (rasp) that is expressed at high levels in normal adult cortex of the rat and is rapidly inducible in the hippocampus by electroconvulsive seizures. The rasp gene is also inducible in PC12 cells by growth factors (NGF, FGF, EGF) and is expressed in several peripheral tissues. Full length Rasp cDNA (1.1 Kb) encodes a 183 aa protein with 43.3% and 37.7% aa identity with yeast H-Ras 1 and human Rap 2, respectively. Regions of homology include four putative GTP-binding regions and the Ras effector region. A full length bacterial GST-Rasp fusion protein binds GTP. Additionally, Gln 64 of Rasp is homologous to Gln 61 of Ras, a residue that is important for Ras activity and is absent in Rap family members. Our studies identify a novel Ras-like GTP-binding protein that may play a role in the cellular response to neuronal activity.

TRANSCRIPTIONAL REGULATION OF THE HUMAN NPY GENE DURING DIFFERENTIATION OF SH-SY5Y NEUROBLASTOMA CELLS G. Andersson\*, S. Påhlman°, V. Parrow°, I Johansson° and U. Hammerling‡.
\*Dept of Medical Genetics, Uppsala Univ, Box 589, S-751 23 Uppsala, Sweden. Dept of Pathology, Uppsala Univ. ‡ Medical Products Agency,

Dept of Pharmacology, Uppsala.

We have examined the transcriptional regulation of the human SH-SY5) neuropeptide Y (NPY) gene during differentiation of human SH-SYSY neuroblastoma cells. Cells were differentiated with the phorbolester 12-O-tetradecanoylphorbol-13-acetate (TPA), in the presence of fetal calf serum and NPY mRNA expression profiles were determined. A sustained strong induction of NPY mRNA expression was detected. The mRNA levels of c-jun and c-fos, that belong to the AP-1 family of transcription factors, were also examined. Both c-jun and c-fos mRNAs were induced with a synchronous and biphasic pattern. An early transient (30-120 min) was followed by a later (>8 hrs) increase in mRNA expression. The induced NPY mRNÁ expression coincided with the second peak of c-<u>iun</u> and c-<u>fos</u> expression. Nuclear protein extracts were prepared from uninduced and induced SH-SY5Y cells and tested for the ability to bind to an AP-1 DNA element, present in the NPY promoter. Induced AP-1 binding activity was detected following TPA treatment. In contrast, no effects of Sp1 mRNA expression or Sp1 DNA binding activity were detected. Thus it seems clear, that although several Sp1 sites are present in the NPY promoter, the induction of NPY expression in SH-SY5Y cells by TPA does not involve changes in Sp1 activities. Rather, changes in AP-1 activities appear to be important for the induction of NPY expression in this system. In order to functionally correlate these in vitro data, we are performing transient transfections with reporter constructs carrying the NPY promoter AP-1 site.

PROTEIN KINASE C AS A MEDIATOR OF EXCITATION-ACETYLCHOLINE RECEPTOR GENE INACTIVATION COUPLING IN CHICK SKELETAL MUSCLE C. F. Huang, J. Tong, and J. Schmidt\* Dept. of Biochemistry and Cell Biology, State University of New York at Stony Brook, Stony Brook, NY 11794.

The signaling pathway connecting membrane depolarization and gene activity in skeletal muscle remains largely unknown. We have investigated short-term effects of plasma membrane electrical activity on acetylcholine receptor (AChR) subunit genes. Using transcription elongation (run-on) analysis, we have found that electrical stimulation of denervated chick skeletal muscle in vivo rapidly and selectively inactivates AChR subunit genes.

We have also studied the possible involvement of protein kinase C (PKC) in this response and have made the following observations: (1) Electrical stimulation of skeletal muscle rapidly activates PKC within the nuclear compartment; nuclear enzyme activity which is barely detectable in unstimulated muscle rises by 2 orders of magnitude upon stimulation. (2) Phorbol 12-myristate 13-acetate (PMA), an activator of PKC, blocks AChR subunit gene transcription, in the absence of electrical activity, within minutes after intramuscular application. (3) The activity-triggered gene inactivation is blocked by the protein kinase inhibitor staurosporine or by depletion of PKC resulting from chronic pretreatment of muscle with PMA.

We conclude that PKC is an integral component of the pathway coupling membrane excitation and AChR gene control.

TETANUS AND BOTULINUM A NEUROTOXINS: DIFFERENT EFFECTS ON CA++-STIMULATED EXOCYTOSIS. T. Binscheck and H. Bigalke,

(SPON: European Neuroscience Association).

Medical School of Hannover, Institute of Toxicology, 3000 Hannover 61, Germany.

Tetanus and botulinum A neurotoxins inhibit exocytosis in bovine chromaffin cells by interfering with a process occuring at a late stage in the cascade leading to the fusion of vesicles with the plasma membrane. The intrinsic activity of both toxins can be attributed to their light chain which must be reduced to become toxic. We have investigated the time dependent intracellular activation of the toxins and their interaction with Ca++-dependent processes. The application of the lock-in method allows exocytosis to be monitored on-line by recording the changes in the membrane capacitance which result from the fusion of vesicles with the plasma membrane Since chromaffin cells lack specific binding sites for both toxins, electroporation was necessary in order to enable the toxins to enter the cells. Two hours after incorporation of BoNtx (6.6nM) stimulation with 1µM Ca++ failed to increase the membrane capacitance whereas, in the presence of 100 µM Ca++, an increase could still be observed. After 24 hr, however, exocytosis was blocked independently of the Ca++-concentration used. Thus, it is only at early stages, that the target of BoNtx can be modulated by intracellular calcium. In the case of Tetx only the light chain (6.6nM) could block exocytosis within the first two hours, when cells were stimulated with 1µM Ca++. The protoxin (6.6nM), on the other hand, could not inhibit exocytosis before 24 hr. This indicates that Tetx must be activated inside the cell by a time consuming process. This work was supported by the German Research Council.

SYNCHRONIZATION OF QUANTAL INHIBITORY DENDRITIC RESPONSES. H. Korn\*, N. Ankri and D.S. Faber\*. Institut Pasteur, Paris and \*SUNYAB, Buffalo, NY.

Intracellular recordings from the Mauthner (-M) cell's lateral dendrite 300µm distal to the soma were obtained in vivo with KCl microelectrodes. As in the soma were obtained in who will Kellinteletectious the some spontaneous depolarizing IPSPs (suppressed by strychnine) dominated synaptic noise, but, in contrast, autocorrelations showed periods of regular oscillations in the range of 40 to 60 Hz. In TTX (1μM) bathed preparations, an automatic detection and analysis program revealed two prominent classes of miniatures, with the mean size of the largest being 2 to 4 times that of the first (or minimum quantal unit, mqu), the kinetics of both matching those of quanta recorded in the soma (J. Neurophysiol. 1990, 63,198-222). The mqus occur randomly, whereas the larger components (second class) produce the 40-60 Hz rhythm. Low Ca<sup>++</sup> high Mg<sup>++</sup> solutions gave the same initial results and a progressive decrease in the relative number of events comprising the second class. The latter appeared to be composite, i.e. made of synchronized multiples of mqu; desynchronization was manifest by the presence of inflections on their rising phases, incremental units having the same kinetics as in control. Consequently, the first peak of the amplitude distribution appeared in isolation at the end of the recording session. Impulse-independent large events could arise at synapses with extended receptor matrices and/or from multiquantal release at terminal boutons having several closely-spaced active zones. Both hypotheses are consistent with ultrastructural evidence (C. Sur et al., this volume). However the gradual fragmentation of the largest components in conditions of decreased release probability supports the second interpretation.

### 334.2

A NOVEL INSIGHT INTO THE MECHANISM OF ACTION OF BOTULINUM TOXIN IN A CHOLINERGIC NEURONAL CELL CULTURE MODEL. P. Ray\*, J.D. Berman, B.G. Schuster and J.K. Lovelace. Division of Experimental Therapeutics, Walter Reed Army Institute of Research, Washington DC 20067.

Botulinum neurotoxin type A (BoTx) acts by inhibiting the stimulus-induced acetylcholine (ACh) release at peripheral neuromuscular junctions. However, the detailed mechanism of this effect remains elusive. We studied this mechanism using the cholinergic neuronal pheochromocytoma PC12 cell line. Cultured monolayer PC12 cells were differentiated by treatment with 50 ng/ml nerve growth factor for 4 to 5 days to enhance cellular ACh synthesis and release properties. Stimulation of these cells with high K\* (80 mM) in the perfusion medium caused a marked increase (4-5X) in [<sup>3</sup>H]ACh release in a Ca<sup>2+</sup>-dependent manner. K\*-stimulated [<sup>3</sup>H]ACh release was totally inhibited by pretreatment of cells with a low concentration (< 10 nM) of BoTx for 2 hr. High K<sup>+</sup> also stimulated the release of arachidonic acid ([<sup>3</sup>H]AA) from the cell membrane, which was inhibited by BoTx (< 10 nM). The toxin concentration-dependence and time course of this stimulated release of [3H]ACh and [3H]AA suggest a possible regulatory role of AA in the stimulus-induced ACh release process and its inhibition by BoTx.

## 334.4

AP VELOCITY FROM HH AXON EQUATIONS

J.L. Winslow(1,2), M.P. Charlton(2)\*. (1)Biomedical Engineering, (2)Physiology Dept. U. Toronto, Toronto, Ont. M5S 1A4.

Synchrony of APs at particular positions in neural networks is important for network responses, including synaptic plasticity phenomenae. Since the HH equations are nonlinear, various analyses to calculate velocity of APs in the literature remain as

approximations. To calculate velocity of an AP,  $V_{AP}$ , the HH equations were solved numerically for different parameter values. For a 100  $\mu$ m straight axon, divided into 101 compartments with constant diameter,  $V_{AP}$  was calculated. For each i-th compartment, at location  $X_i$ , the time,  $T_i$ , of maximum AP voltage was calculated.

location  $X_i$ , the time,  $T_i$ , of maximum AP voltage was calculated. The slope of  $X_i$  verus  $T_i$  is  $V_{AP}$ . Velocity versus the space constant,  $\lambda = |R_m r/2\rho|^{1/2}$  is a straight line, for membrane resistivty,  $R_m$ , fiber radius, r, and axoplasmic resistivity,  $\rho$ , thus  $V_{AP} \mu m/msec = K \lambda cm$  For example, crustacean constants give  $K = 433 sec^{-1}$ . This may be viewed as: Length of the leading bow wave of conductive depolarization determines AP velocity. This agrees with experimental literature that  $V_{AP}$  is proportional to  $e^{1/2}$ 

This method demonstrates that as an AP propagates over an axon presynaptic varicosity,  $V_{AP}$  is decreased to broaden the AP in time. This implies that Ca channels are open longer, hence more neurotransmitter is released.

#### 334 5

RETROGRADE DETERMINATION OF PRESYNAPTIC PLASTICITY: QUANTAL ANALYSIS AT A CENTRAL SYNAPSE. G.W. Davis\* and R.K. Murphey. Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01002.

A quantal analysis applied to the sensory synapses of the cricket cercal system supports a presynaptic mechanism for facilitation. EPSPs recorded from the large ventro-medial dendrite of the MGI, at or near the sight of synaptic input, provide enough resolution to discriminate failures from unitary responses. Twin pulses (at 100Hz instantaneous frequency) were delivered to the sensory neuron (SN) to evoke facilitation. The first and second EPSPs were then grouped separately for analysis. The mean quantal content (m), calculated by the failure method, increases in the second EPSP while the quantal size (q) remains constant (N=4)

We have investigated how presynaptic plasticity such as facilitation is determined developmentally by examining a single SN that contacts two target interneurons, MGI and 10-3. Our results show that the terminals of a single, identified SN can express facilitation on MGI, and simultaneously express homo-synaptic depression on 10-3. In addition, when numerous identified SNs are examined, all those contacting MGI facilitate while all those contacting 10-3 depress, regardless of the age or amplitude of the synaptic connection. Based on the data indicating that facilitation is pre-synaptic, we hypothesize that the ability of a SN to facilitate is determined locally, at the synapse, by an interaction with the post-synaptic cell. Supported by NSF grant #BNS 90-96180.

### 334.7

THE EFFECTS OF ADENOSINE, BACLOFEN, AND Cd<sup>2+</sup> ON MINIATURE EPSCs AND IPSCs IN THE HIPPOCAMPUS REVEAL NOVEL MECHANISM OF PRESYNAPTIC ACTION Scott M. Thompson\*, Massimo Scanziani, Marco Capogna, and Beat H. Gähwiler Brain Research Institute, Univ. of Zurich, 8029 Zurich Switzerland

Presynaptic inhibition of neurotransmitter release in the CNS is Presynaptic inhibition of neurotransmitter release in the CNS is often thought to be mediated by inhibition of voltage-dependent Ca<sup>2+</sup> channels in the axon terminal. We have compared the effects of the Ca<sup>2+</sup> channel antagonist Cd<sup>2+</sup> and several transmitters that inhibit evoked synaptic transmission with regard to their effects on spontaneous miniature EPSCs and IPSCs (in TTX) using whole-cell voltage-clamp to record from CA3 neurons in hippocampal slice cultures. Cd<sup>2+</sup> (20-100 uM) blocked evoked EPSCs and IPSCs. Baclofen (10 uM) and adenosine (50 uM) blocked evoked EPSCs Bactoten (10 tM) and adenosine (50 tM) blocked evoked EPSCs and also decreased the frequency of miniature EPSCs, without affecting the distribution of their amplitudes. Bactofen blocked evoked IPSCs, but did not affect miniature IPSC amplitude or frequency. Cd<sup>2+</sup> had no effect on either the frequency or amplitude of miniature EPSCs or IPSCs. These results demonstrate that bactofen and adenosine do not decrease glutamate release from presynaptic endings by inhibiting axon terminal Ca<sup>2+</sup> channels, but presynaptic endings by inhibiting axon terminal Ca<sup>2+</sup> channels, but rather by inhibiting the release process itself. The observation that baclofen reduces the frequency of miniature EPSCs but not IPSCs, and our previous finding that Ba<sup>2+</sup> blocks the effect of baclofen on IPSPs but not EPSPs (Thompson & Gähwiler, J. Physiol. v451, 1992), allow us to conclude that GABA<sub>B</sub> receptors exert distinct actions at excitatory and inhibitory synapses.

## 334.9

PRESYNAPTIC INHIBITION OF EPSPs BY
NOREPINEPHRINE IN AREA CA3 OF
HIPPOCAMPAL SLICE CULTURES
Massimo Scanziani\*. Beat H. Gähwiler and Scott M. Thompson.
Brain Research Institute, Univ. of Zurich, 8029 Zurich Switzerland
Norepinephrine (NE) reduces the frequency of spontaneous
epileptiform burst discharges in the disinhibited hippocampus. We
investigated the effects of NE on pharmacologically isolated nonNMDA receptor mediated EPSPs which were evoked in CA3
pyramidal cells by mossy fiber or recurrent collateral stimulation in
hippocampal slice cultures (Thompson & Gähwiler, J. Physiol. 451,
1992). These EPSPs depended linearly on membrane potential and
followed stimulation frequencies up to 10Hz without changing
their amplitude or latency, and are therefore likely to represent
monosynaptic non-NMDA receptor-mediated responses. NE
(5uM) strongly reduced the amplitude of EPSPs without affecting
the amplitude of currents induced by application of AMPA,
suggesting that NE decreases presynaptic glutamate release. This
action was unaffected by the beta receptor antagonist timolol but
was blocked by the alpha receptor antagonist phentolamine. action was unaffected by the beta receptor antagonist timolol but was blocked by the alpha receptor antagonist phentolamine. Treatment of cultures with pertussis toxin or phorbol esters abolished the effects of NE, while application of the protein kinase inhibitor staurosporin enhanced the effect of NE. Despite the presumed presynaptic action, NE did not affect the frequency or the amplitude distribution of miniature EPSCs recorded in the presence of TTX with the whole-cell patch-clamp technique. Presynaptic inhibition of the EPSP probably underlies the anticonvulsive action of NE in the hippocampus.

SHORT-TERM MODULATION OF MONOSYNAPTIC TRANSMISSION IN

SHORT-TERM MODULATION OF MONOSYNAPTIC TRANSMISSION IN HIPPOCAMPAL CULTURES. S. Mennerick', D.B. Clifford, and C.F. Zorumski. Depts. of Psychiatry and Neurology, and Program in Neuroscience, Washington Univ. Med. School, St. Louis, MO 63110.

Many chemical synapses display a facilitated response to the second of a pair of short interval stimuli. However, in cultures of postnatal rat hippocampus studied with whole cell recording techniques, the majority of excitatory (glutamatergic) and inhibitory (GABAergic) monosynaptic responses display a marked paired pulse depression (PPD). characterize PPD at excitatory synapses.

Stimuli delivered at intervals between 10 msec and 5 sec elicit a PPD that Stimuli delivered at intervals between 10 msec and 5 sec elicit a PPD that is insensitive to inhibitors of glutamate receptor desensitization and to inhibitors of glutamate uptake. PPD is also not affected by incubation of cells in 50-250 ng/ml pertussis toxin for 12-72 hr. This treatment abolished presynaptic inhibitory effects of  $1\mu M$  2-chloroadenosine (2-CA) and of 10  $\mu M$  baclofen. This result combined with the finding that PPD occurs in autaptic responses of single excitatory cells on microisland cultures makes a role for modulatory transmitters unlikely.

modulatory transmitters uninetry.

Treatments that decrease the probability of transmitter release also decrease PPD. Therefore, a low extracellular Ca\*\*:Mg\*\* ratio, baclofen, and 2-CA reduce the first response to a stimulus pair proportionally more than the second response. In some cases decreasing the probability of release can transform PPD into paired pulse facilitation. This result is consistent with a model of transmission in which in which terminals activated during the first of a pair of stimuli become refractory to a second pulse, but terminals not activated by the first stimulus are 'primed' for a response to a second stimulus. Mechanisms of PPD consistent with this model are feedback by glutamate onto presynaptic receptors and rapid depletion of releasable transmitter stores

# EFFECTS OF PERTUSSIS TOXIN, PHORBOL ESTER, AND BARIUM ON OPIOID PEPTIDE ACTION IN HIPPOCAMPAL SLICE CULTURES.

IN HIPPOCAMPAL SLICE CULTURES.

Marco Capogna, Beat H. Gähwiler\* and Scott M. Thompson.

Brain Research Institute, Univ. of Zurich, 8029 Zurich Switzerland
Opioid peptides indirectly excite hippocampal pyramidal cells by
decreasing GABA release from interneurons. We have investigated
the mechanisms underlying this disinhibition in the rat
hippocampus in vitro. In the presence of CNQX and D-APV (20µM
each), stimulation close to intracellularly recorded CA3 cells
elicited monosynaptic GABA, receptor-mediated IPSPs. Under
these conditions, application of the µ receptor-preferring
enkephalin analogue FK 33-824 (3nM-1µM) produced a dosedependent, reversible, and naloxone-sensitive decrease in IPSP
amplitude. Incubation of cultures with pertussis toxin prevented
the reduction of IPSPs by FK 33-824. Stimulation of protein kinase
C with phorbol ester strongly diminished the presynaptic effect of
FK 33-824. Application of staurosporin slightly enhanced the
reduction of IPSPs by FK 33-824 and prevented the effect of
phorbol ester on FK 33-824 responses. In contrast, the K\* channel
blocker barium (1mM) did not affect the depression of IPSPs phorbol ester on FK 33-824 responses. In contrast, the K<sup>+</sup> channel blocker barium (1mM) did not affect the depression of IPSPs induced by FK 33-824. These results demonstrate that µ receptor-mediated presynaptic inhibition of IPSPs, like that mediated by GABA<sub>B</sub> receptors (Thompson & Gähwiler, J. Physiol. v451, 1992), is caused by pertussis toxin-sensitive G proteins which can be inactivated by stimulation of protein kinase C. Unlike GABA<sub>B</sub> actions, however, the effects of µ receptors do not result from an increase in a barium-sensitive K<sup>+</sup> conductance.

## 334.10

OPPOSITE EFFECTS OF CHOLINOCEPTOR ACTIVATION ON SPONTANEOUS AND EVOKED IPSCs IN HIPPOCAMPAL CAI PYRAMIDAL CELLS J.C. Behrends and G. ten Bruggencate, Department of Physiology, Univ. of Munich, Germany. Spon.: EBBS Among the reported cholinergic actions in the hippocampus is a suppression evoked inhibitory postsynaptic potentials (IPSPs). This apparent disinhibition by cholinergic drugs contrasts with a simultaneous increase of the frequency of spontaneous IPSPs.

This problem was assessed by recording bicuculline-sensitive spontaneous and stimulus-evoked inhibitory postsynaptic currents (s- and eIPSCs, respectively) in CA1 pyramidal cells (PCs) of guinea pig hippocampal slices. Superfusion of carbachol (1-10  $\mu$ M) or eserine (10  $\mu$ M) resulted in a sustained increase in the frequency and amplitudes of sIPSCs, while eIPSCs evoked from the str. radiatum were suppressed. Both effects were antagonized by atropine (1  $\mu$ M). The facilitatory action on sIPSCs was unaffected by incubation with CNQX and APV (20  $\mu$ M), while recording in the presence of 0.6 µM TTX yielded no evidence for an action on miniature sIPSCs, suggesting that carbachol as well as released acetylcholine directly excite GABAergic interneurones. IPSCs elicited in the presence of CNQX and APV by stimulation of str. pyramidale were also reduced by carbachol and eserine.

These data suggest that GABAergic interneurones can be excited by cholinoceptor activation in the in vitro hippocampus, resulting in increased tonic inhibition of PCs. The depression of eIPSCs might be explained by interference of tonic discharge with evoked release. The nature of this interaction is currently being investigated.

ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS REDUCES EPSCs and IPSCs IN NEONATE RAT SYMPATHETIC PREGANGLIONIC NEURONS. S. Y. Wu\* and N. J. Dun. Department of Anatomy, Medical College of Ohio, Toledo, OH 43699

Whole cell-patch clamp recordings were made from sympathetic preganglionic neurons (SPNs) in transverse spinal cord slices of 10-16 day old rats. Glutamate (L-Glu, 10-300  $\mu$ M), quisqualate (QA, 0.1-3 µM), kainate (KA, 0.3-10 µM), ibotenate (10-25  $\mu$ M), L-AP4 (25-100  $\mu$ M) and the metabotropic receptor agonist trans-ACPD (100-300 µM) attenuated mono-synaptic excitatory (EPSCs) and inhibitory (IPSCs) postsynaptic currents elicited by stimulation of lateral funiculus without causing a significant change of holding current; the reversal potential and decay time constant of EPSCs or IPSCs were also not altered. At higher concentrations, these agonists, except L-AP4, induced an inward current in some SPNs. While reducing the EPSCs, the inward current induced by exogenous L-Glu was not changed by L-AP4 and trans-ACPD. The metabotropic receptor antagonist L-AP3 increased the EPSC amplitude by 20-30%. It is concluded that metabotropic L-Glu receptors are present on excitatory and inhibitory nerve fibers presynaptic to SPNs, and that they may be tonically activated by endogenously released L-Glu or a related excitatory amino acid. EFFECTS OF GABAB RECEPTOR ACTIVATION ON SPONTANEOUS SYNAPTIC ACTIVITY OF RAT HIPPOCAMPAL NEURONS IN CULTURE K.D. Phelan $^{1*}$ , K.S. Wilcox $^{2}$ , and M.A. Dichter $^{1,3}$ , Departments of Neurology $^{1}$  and Physiology<sup>2</sup>, University of Pennsylvania School of Medicine and Graduate Hospital<sup>3</sup>, Philadelphia, PA 19104.

Activation of GABA<sub>B</sub> receptors inhibits synaptic transmission and decreases neuronal excitability at pre- and postsynaptic sites, presumably by decreasing g<sub>Ca</sub> and increasing g<sub>C</sub>, respectively. We took advantage of the absence of postsynaptic GABA<sub>B</sub> receptors in our cultures to compare the effects of presynaptic GABA<sub>B</sub> receptor activation on spontaneous excitatory (IPSC) and inhibitory (IPSC) currents generated within small neuronal networks using standard whole-cell voltage-clamp

Baclofen (BAC, 2-200 μM), a selective GABAB agonist, blocked spontaneous IPSCs and non-NMDA receptor mediated EPSCs at concentrations that failed to completely block NMDA receptor mediated EPSCs (NMDA-EPSCs). Sustained application of BAC initially reduced the amplitude, duration and frequency of NMDA-EPSCs but was followed by a partial recovery. BAC did not alter responses to exogenous application of NMDA. The proposed GABAB receptor antagonists, phaclofen (100-300 μM) and 2-OH-saclofen (100 μM) did not consistently block the effects of BAC on NMDA-EPSCs and also acted as partial agonists. The competitive NMDA receptor antagonist, DL-APV (10-30 μM), produced a similar decrease followed by partial recovery of NMDA-EPSCs suggesting that postsynaptic NMDA receptor resensitization during synaptic depression may account for part of the recovery phenomenon. Preliminary paired cell recordings reveal a similar recovery following BAC inhibition of evoked EPSCs raising the possibility of "desensitization" of presynaptic GABAB receptors in culture. of presynaptic GABAB receptors in culture.

of presynaptic GADAB receptors in culture.

These results may have important implications regarding the clinical use of baclofen to dampen overexcitation mediated by NMDA receptors. Supported by the American Epilepsy Society/Milken Family Medical Foundation (KDP) and USPHS grants NS 24927 and NS 24260 (MAD).

INTRACELLULAR MECHANISMS OF FACILITATORY AND INTERACEDULAR MECHANISMS OF FACILITATORY AND INHIBITORY EFFECTS OF L-DOPA ON THE CHOLINERGIC TRANSMISSION IN THE GUINEA-PIG MEISSNER PLEXUS.

K. HIRAI & Y. KATAYAMA\*. Dept. Autonom. Physiol., Tokyo Med. & Dent. Univ., Tokyo 101, Japan.

Neurotransmitter-like or neuromodulatory of L-DOPA were investigated.

actions of L-DOPA were investigated with intra-cellular recording from guinea-pig Meissner cellular recording from guinea-pig Meissner neurones. L-DOPA at 30 nM augmented fast EPSPs, Meissner affected cholinergic depolarizations not elicited by puff application of acetylcholine (ACh). The augmenting effect of L-DOPA on the fast EPSPs was counteracted by L-DOPA methylester. The fast EPSPs were depressed by 10  $\mu M$  L-DDPA, but transiently augmented after rinsing the drug. L-DOPA methylester did not affect the inhibitory action on the fast EPSPs, but antagonized the potentiation following the inhibition. The AChdepolarization was inhibited by 10 µM L-DOPA. Intracellular free calcium concentration ([Ca<sup>2</sup>]:) Intracellular free calcium concentration ([Ca\*]<sub>1</sub>) was measured with fura-2-microspectrofluorimetry. A transient increase in the [Ca\*]<sub>1</sub>, evoked by action potential ( $\Delta$ [Ca\*]<sub>AP</sub>) was facilitated by 30 nM L-DOPA, but decreased by the drug at 10  $\mu$ M. It is concluded that L-DOPA at low concentration enhances the  $\Delta$ [Ca\*]<sub>AP</sub>, increasing the transmitter-release, but at high dose diminishes the  $\Delta$ [Ca\*]<sub>AP</sub>, inhibiting the neurotransmission.

PHORBOL ESTERS ENHANCE MONOSYNAPTIC IPSCs IN RAT HIPPOCAMPAL PYRAMIDAL CELLS. T.A, Pitler & B.E. Alger, Dept. of Physiol., Univ. of MD Sch. Med., Baltimore, MD 21201.

Activators of protein kinase C (PKC), such as phorbol esters (PEs), enhance excitatory synaptic transmission, but their effects on inhibitory transmission are less clear. Using whole-cell voltage-clamp recording techniques in the rat hippocampal slice preparation we examined the effects of PEs on evoked GABAergic IPSCs. All cells were recorded in the presence of glutamate antagonists CNQX and APV to isolate GABAergic responses. We found that 3  $\mu$ M phorbol 12,13-diacetate (PDA) significantly enhanced GABA<sub>A</sub>-mediated synaptic events. 4-α-PDA, an inactive analog which does not activate PKC, had no effect on IPSCs. PDA did not affect iontophoretically applied GABA responses, suggesting that the increase in IPSCs amplitude by PDA was due to a presynaptic action.

PEs also block both pre- and post-synaptic GABA<sub>B</sub>-mediated effects. Since activation of presynaptic GABA<sub>B</sub> receptors inhibits transmitter release, it was possible that the enhanced GABA transmission caused by PDA was due to block of the autoinhibitory GABA<sub>B</sub> receptor. We found, however, that paired pulse depression of IPSCs, which is believed to result from presynaptic GABA<sub>B</sub> receptor activation, was not blocked by PDA. Our work suggests either that synaptically released GABA doesn't activate presynaptic GABA<sub>B</sub> receptors or that GABA<sub>B</sub> receptors on presynaptic inhibitory terminals are not affected by PEs, unlike GABA<sub>B</sub> receptors previously studied. Furthermore, the increase in GABA release by PDA is not caused by PE-induced depression of the autoinhibitory GABA<sub>B</sub> receptor.

EFFECTS OF REPETITIVE STIMULATION ON SYNAPTIC TRANSMISSION IN THE CHICK CILIARY GANGLION.

R.E. Poage and J.E. Zengel\*, Depts. of Neurosci. and Neurosurg.,
U. of Fla. Coll. of Med. and VA Med. Ctr., Gainesville FL 32610.

Four components of stimulation-dependent increases in transmitter release have been observed at peripheral synapses: 2 components of facilitation, augmentation, and potentiation. In this study we investigated whether similar processes are present in the chick ciliary ganglion.

Embryonic (stage 48) chick ciliary ganglia were recorded from using extracellular nerve trunk recording. The preparation was perfused with a low Ca<sup>++</sup> and/or high Mg<sup>++</sup> oxygenated saline oxygenated saline solution to reduce quantal content (20-23°C).

The preganglionic nerve trunk was stimulated with 1-1000 impulses (20-50 Hz) to condition the nerve terminals. Testing impulses applied after the conditioning trains established that ganglionic transmission was enhanced during tetanic stimulation and returned to control levels following the tetanus with four apparent time constants of decay (~60 ms,~420 ms,~30 s, and ~150 s). These time constants are similar to those reported for other preparations.

Thus, the components of stimulus-dependent increases in release described in other preparations appear to be present in the chick ciliary ganglion. Because of the large size of the calical nerve endings of the ciliary ganglion, it should be possible in the future to record electrical events in the nerve terminal under conditions of increased release. The results of these studies should contribute to a better understanding of the mechanisms underlying stimulation-dependent changes in release.

## 334.16

EFFECTS OF SECONDARY MESSENGER ON NERVE TERMINALS OF MOUSE SKELETAL MUSCLE. M.C.Tsai\*, M.L.Chen, W.H. Hiseh and S.Z.Fan. Department of Pharmacology, College of Medicine, National Taiwan University, No.1., Sec.1., Jen-Ai Road, Taipei, Taiwan, R.O.C. 100

The effects of secondary messenger on the motor nerve

activity were studied on mouse triangularis sterni nerve - muscle preparations. The perineural waveforms were recorded with extracellular electrodes placed in the perineural sheaths of motor nerves. Both forskolin, perineural sheaths of motor nerves. Both forskolin, a known activator of adenylate cyclase, and 4-alpha-phorbol-12,13-didecanoate (PD-De), a protein kinase C stimulator, decreased the slow calcium current in the motor nerve terminal. Neither forskolin nor PD-De decreased (a) the sodium current, (b) the fast and slow potassium currents, (c) the calcium activated potassium current and (d) the fast calcium current of the nerve terminal. It is corpluded that forskolin and PD-De act on the clow concluded that forskolin and PD-De act on the slow calcium current of the nerve terminal. The secondary messenger may play a functional role on the transmitter releasing process. DIFFERENTIAL EFFECTS ON MEMBRANE POLARIZATION BY THE κ<sub>1</sub>-OPIOID RECEPTOR AGONIST U-50,488 IN PRESYNAPTIC CALYX NERVE TERMINALS OF THE CHICK CILIARY GANGLION. G.H. Fletcher\* and V.A. Chiappinelli, Dept. of Pharm. and Physiol. Sci., St. Louis Univ. Sch. of Med., St. Louis, MO 63104. This study examined the electrophysiological effects of x-opioids, since

previous work in this laboratory has shown that opioid peptides acting at mu and delta receptors are active on presynaptic calyx nerve terminals of chick ciliary ganglion. The actions of the  $\kappa_1$ -opioid receptor agonist U-50,488 on calyciform nerve terminals were investigated in vitro by intracellular recording. Bath application of U-50,488 (30-300 µM) elicited dose-dependent membrane hyperpolarization (2-12 mV) with an increase in input resistance (Rim). However, at the highest concentration examined (1 mM), there was first a membrane hyperpolarization followed by a slow depolarization (2-10 mV), that was associated with a further rise in  $R_{in}$  . The hyperpolarizing response elicited by 300  $\mu M$  U-50,488 was completely blocked by 3 mM Cs $^+$ , a known blocker of a cationic inward rectifier in this terminal region (Fletcher and Chiappinelli, <u>Brain Res.</u> 575:103-112, 1992). This resulted in the unmasking of a depolarizing action of U-50,488 at this lower concentration, which was subsequently inhibited by the K<sup>+</sup> channel blocker Ba<sup>2+</sup> (1 mM). These dual effects of U-50.488 were antagonized by the  $\kappa_1$ -opioid receptor antagonist nor-binaltorphimine (10-30  $\mu$ M), indicating that the drug-induced effects are likely to represent specific actions linked to the activation of opioid receptors. Supported by NIH grant EY06564 to V.A.C.

USE-DEPENDENT ACTIONS OF NICOTINIC BLOCKERS IN USE-DEPENDENT ACTIONS OF NICOTINIC BLOCKERS IN
BULLFROG SYMPATHETIC GANGLIA: ARE THEY
PRESYNAPTIC? W Shen\* and JP Horn Department of Physiology,
University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.
We have examined the blockade of fast cholinergic EPSPs in

bullfrog sympathetic ganglia. Surprisingly, different nicotinic receptor

antagonists all produced use-dependent block during repetitive stimulation at low frequencies that are physiologically realistic.

Compound nicotinic EPSPs and resultant action potentials (APs) in sympathetic B neurons were recorded extracellularly from rami of lumbar ganglia. In the absence of drugs, postsynaptic responses followed repetitive stimulation without decrement for hundreds of impulses at frequencies as high as 20 Hz. At doses that partially antagonize nicotinic transmission, structurally unrelated drugs (eg. 30 µM d-tubocurarine, 30 µM mecamylamine, 30 µM nicotine, 0.1-0.3 µM neuronal bungarotoxin, and 2 analogs of lophotoxin) all produced a similar use-dependent block of compound fast EPSPs and APs. This block occured at frequencies as low as 0.5-1 Hz. It was progressive block occured at frequencies as low as 0.5-1 Hz. It was progressive during the first 7-9 responses in a train and thereafter persisted at a plateau ranging between 20-80% of the first response. The rate of decrement was faster during 10 Hz stimulation. Postsynaptic response amplitude recovered when the preparation was allowed to rest for 10 seconds. It seems unlikely that all the drugs used are open channel blockers. Instead we propose that use-dependent block reflects presynaptic nicotinic receptors which may normally act to facilitate Ach release in sympathetic ganglia. Preliminary intracellular recordings indicate that the properties of use-dependent block are similar at the single cell level. Supported by NIH grants NS21065 and NS01427.

ENKEPHALINS PRODUCE DIFFERENT EFFECTS IN CELL BODIES AND NERVE TERMINALS OF CHICK EDINGER-WESTPHAL NEURONS. V.A. Chiappinelli\*, K.M. Wolf, C. Feng and L.L. McMahon. Dept. Pharm. Phys. Sci., Saint Louis Univ. Sch. Med., St. Louis MO 63104

Within a single neuron, receptors may be located near the cell soma or some distance away in the axon terminals. Since the roles of these two classes of receptors are distinct, we asked whether the effect of activation of receptors differs depending on their location within a neuron. Neurons located in the lateral division of the avian Edinger-Westphal nucleus (EWL) were used to test this point. These cells innervate ciliary ganglion neurons via large, calyciform nerve endings, many of which contain the peptides leucine-enkephalin (LENK) and substance P (SP; Reiner et al., Vis. Neurosci. 6:451, 1991). Presynaptic receptors for LENK and SP are also found on these terminals (Dryer and Chiappinelli, Brain Res. 336:190, 1985). Intracellular current clamp recordings from EWL somas were obtained in brain slices using methods described in Sorenson and Chiappinelli (Neuron 5:307, 1990), while EWL nerve terminals were impaled in intact ciliary ganglia in vitro. Pressure ejection of LENK depolarized and decreased input resistance in 81% (17/21) of EWL nerve terminals, due in part to activation of a sodium current. In sharp contrast, similar exposure to LENK hyperpolarized 88% (15/17) of EWL somas by up to 25 mV. This was associated with a decrease in input resistance, indicating that LENK activated a potassium channel in EWL cell bodies as it does in certain other central neurons (North et al., PNAS 84:5487, 1987). We conclude that LENK-sensitive receptors on EWL somas activate different ion channels than LENK-sensitive receptors on EWL terminals in the ciliary ganglia. Supported by NIH EY06564 to V.A.C.

POTASSIUM CHANNELS: PHARMACOLOGY AND EFFECTS OF TRANSMITTERS

## 335.1

BLOCKADE BY PEPTIDIC TOXINS OF MK1 POTASSIUM CURRENTS IN CHO CELLS. D.G. Owen, B. Robertson\*, A. Hall<sup>®</sup>, & J.A. Scott, Wyeth Research (UK), Huntercombe Lane Sth., Berks. SL6 0PH, UK and <sup>®</sup>Dept. Biochemistry,

Imperial College, Imperial College Rd, South Kensington, London SW7 2AY, UK.

Toxin I and other dendrotoxin (Dtx) homologues are potent blockers of voltageactivated K+ currents in cultured rat sensory neurones (Owen et al, 1990) and α-Dtx and δ-Dtx, in particular, block different components of K+ current which may reflect and 6-Dtx, in particular, block different components of K current which may reflect distinct K+ channel subtypes (Hall et al, 1991). In the present study we have examined the properties of a number of Dtx homologues versus a single voltage-

examined the properties of a number of Dtx homologues versus a single voltage-activated K\* channel type identified in mouse brain, MK1 (Tempel et al., 1988). MK1 was expressed stably in chinese hamster ovary (CHO) cells and sub-cultured according to standard tissue culture methods. Whole-cell electrophysiological recordings were made 0-3 days following replating of cells, using an AxoPatch-1D or AxoClamp-2A voltage-clamp amplifier, patch electrodes (2-8Mohm) and standard filling and bathing solutions. Cells were held at between -60mV and -100mV and outward currents which were elicited with depolarizing voltage steps activated within 3ms and decayed only slightly (≤ 10%) during a 500ms period. The threshold for activation was ca -40mV. No corresponding voltage-activated K+ currents were observed in cells transfected with control vector (lacking MK1-sequence).  $\alpha$ -Dtx (10nM),  $\delta$ -Dtx (10nM) and Toxin I (100nM), inhibited 52%, 85% and 90%, respectively, of the total outward current recorded at +60mV. Mast cell degranulating peptide (MCDP) also blocked a proportion of the current (23% at 1µM). Whereas block by α-Dtx and δ-Dtx was more pronounced at depolarized potentials, Toxin I showed little voltage-dependence. Interestingly, the maximal degree of block of MK1 by 8-Dtx, in particular, was much higher than that observed for the native K<sup>+</sup> currents in DRG cells (ca 30%).

THE SEIZURE-INDUCING ANESTHETIC ENFLURANE REDUCES TRANSIENT OUTWARD CURRENT IN CULTURED RAT HIPPOCAMPAL NEURONS M.V. Jones Dept. Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637

The volatile anesthetic enflurane (ENF) is known to induce seizure-like activity in the cortical EEG<sup>1</sup>, and synchronous spike firing in hippocampal pyramidal neurons The mechanism of this effect is unknown, however many convulsant agents, such as 4-aminopyridine, are able to reduce transient outward currents (TOC), and induce repetitive firing. <sup>3</sup> I have studied the action of ENF and halothane (HAL) on neuronal TOC. Hippocampal neurons from day 20 embryonic rats were dissociated and grown in culture. Whole-cell recordings were made at 25°C using an intracellular solution based on K gluconate, and perfused with saline containing 50mM TEA, 5 solution based on K gluconaice, and pertused with satine containing 50mm 1EA, 5 mM CsCl, and 0.2 µM TTX. Depolarizing commands from hyperpolarized potentials (-120 to -40 mV) evoked TOCs, defined as the current remaining after all currents not steady state inactivated at -40 mV were subtracted. TOCs show half-activation near -20 mV, half-inactivation near -80 mV, and decay as a sum of exponentials. The bathing medium was sampled repeatedly during each experiment for anesthetic measurement by gas chromatography. <sup>4</sup> ENF (0.1 - 1.2 mM) produced up to a 40% reversible depression of TOC amplitude, and increased the overall rate of inactivation in all ten neurons studied. Higher concentrations of ENF produced larger effects. When the current in the presence of ENF is subtracted from the control current, the difference current is itself a TOC which decays as a single exponential function ( $\tau = 34 \pm 3$  ms (S.E.M.)). HAL (n=4) also modulated TOCs, but to a lesser degree. ENF appears to produce about twice the effect of HAL, at concentrations that are equieffective at producing clinical anesthesia. This effect may contribute to the ability of ENF to induce seizure activity, and may explain why HAL does not share this property. Supported by training grant 5-T32-GM-07151 and by RO1-GM45129 to N.L. Harrison. 1) Prog. Drug Res. 26: 225, 2) Br. J. Anaesth. 62: 301, 3) Neurosci. Lett. 64: 299, 4) J. Physiol. 449: 279.

#### 335 3

DENDROTOXIN AND MAST CELL DEGRANULATING PEPTIDE: POTASSIUM CHANNEL TOXINS INDUCE NEURONAL DAMAGE IN THE RAT IN VIVO. C. Mourre<sup>1</sup>, M. Lazdunski<sup>2</sup>, H.E. King\*1 Dept. Psychol., Washington and Lee Univ., Lexington, VA 24450, and <sup>2</sup>CNRS-IPMC, Sophia-Antipolis, F-06650 Valbonne, France.

Dendrotoxin (DTX, 200 pmol) and mast cell degranulating peptide (MCD, 200 pmol) were injected unilaterally into the ventricles. Patterns of cell loss and neuronal degeneration were studied after 48 h survival times using cresyl violet and Fink-Heimer silver staining procedures.

Following injections of DTX, all rats were observed to display similar seizures but neuronal damage was found in only 30% of the subjects. The pattern of damage was bilateral and included argyrophilic cells and degeneration in numerous structures especially hippocampus (CA1 and CA3 cell fields), septum, amygdala, thalamus, hypothalamus and entorhinal cortex. In several subjects additional damage was noted in neocortex, cerebellum and the colliculi.

The behavioral pattern of seizures following injections of MCD differed from that found with DTX and the neuronal damage was more limited but included hippocampus (CA1 and CA3 cell fields), ventral subiculum, septum, amygdala, and nucleus accumbens.

Although the amounts of DTX and MCD injected were near the lethal dose, the potassium blockers induced different patterns of seizure activity and neuronal damage.

## 335.5

Block by capsaicin of potassium currents in pituitary melanotrophs. S.J. Kehl . Dept. of Physiology, U.B.C., Vancouver, B.C., V6T 1Z3.

Capsaicin blocks K currents in dorsal root ganglion neurones and vertebrate axons. I report here that capsaicin also affects both the fast  $(I_K(f))$  and the slow  $(I_K(s))$  voltage-gated K currents of rat melanotrophs. Whole-cell currents were recorded at room temperature by using conventional patch clamp techniques. In acutely dissociated cells 50 µM external capsaicin decreased the amplitude and increased the rate of decay of Ir(f) and Ir(s). The onset of the block was fast and in most cells was completely reversible. In cultured melanotrophs expressing only  $I_K(s)$  capsaicin had identical effects. In addition to being concentration dependent, the actions of capsaicin were voltage-dependent. For example, compared to the current evoked at 20 mV the steady-state current at -10 mV was reduced to a smaller extent and "inactivation" was less evident. The relaxation rate of current tails in 50 µM capsaicin was well-fitted by the sum of two exponentials, one being faster the other slower than the single exponential fitted to control responses. The activation rate of I<sub>K</sub>(s) was not altered. The simplest interpretation of these data is that capsaicin acts as an open channel blocker.

MICROMOLAR ZINC MODULATES K+ CHANNEL GATING NIL.Harrison\*, H.K.Radke, G.Talukder, J.M.H.ffrench-Mullen¹, M.M.Tamkun² and D.M.Lovinger². Anesthesia, The University of Chicago, ¹Pharmacology, ICI Pharmaceuticals and  $^2$ Molecular Physiology and Biophysics, Vanderbilt University,  $Zn^{2+}$  ions are present in many regions of the brain, and are released from the mossy fibers into the CA3 region of the hippocampus on stimulation. We have studied the effects of  $Zn^{2+}$  on a variety of  $K^+$  currents. Transient outward currents (TOC) were recorded in cultured (e20) rat hippocampal neurons and acutely isolated guinea pig CA1 neurons. The K+ channels RK1, HK1 and HK2 (rKv1.1, hKv1.4 and hKv1.5), cloned from rat and human tissue and present in brain, were studied in mouse L cells stably transfected with the appropriate cDNA. Whole-cell recordings were made from single neurons at 20°C, using intracellular solutions based on 145mM K gluconate and continuous extracellular perfusion with HEPES-buffered saline conta K<sup>+</sup>, 0.2mM Ca<sup>2+</sup>, 20mM TEA, 5mM Cs<sup>+</sup> and 500nM TTX. Depolarizing commands from -120mV elicited transient outward currents (TOCs) in both types of neuron. Recordings from L cells were performed without ion channel blockers. Zn2 solutions were applied by bath, or from a rapid perfusion system. All effects of Zn2+ were reversible. In cultured (e20) rat hippocampal neurons and guinea pig isolated hippocampal neurons, Zn<sup>2+</sup> (2-200µM) shifted the activation and inactivation curves for the TOC to the right by a maximum of 30-50mV; this concentration-dependent modulation of gating behavior was modeled using a single binding site model, giving a  $K_D$  for  $Zn^{2+}$  of approximately 15 $\mu$ M.  $Zn^{2+}$  did not alter the reversal potential for tail currents of the TOC (-88mV), but did slow activation of the current. Similar effects were observed in L cells expressing the HK1 channel, a rapidly inactivating K<sup>+</sup> channel. In L cells expressing the non-inactivating delayed rectifier-type channels RK1 and HK2, a similar modulation of gating was observed, with activation slowed and the activation curve shifted to the right, consistent with a KD for  $Zn^{2+}$  of approximately 20µM. We conclude that some of the physiological effects of  $Zn^{2+}$  may result from modulation of  $K^+$  channel gating.

A-CHANNEL BLOCK BY \( \alpha\)-DENDROTOXIN IS REVERSED BY A BLOCKER OF DELAYED RECTIFIER K CHANNELS. R.S. Rogowski, B.K. Krueger & M.P. Blaustein, Physiol. Dept., U. of Maryland Med. Sch., Baltimore, MD 21201.

Toxins Ts<sub>k2</sub> and Ts<sub>k4</sub>, from the scorpion, Tityus serrulatus, selectively block delayed rectifier K (DRK) channels in synaptosomes (IC<sub>50</sub>'s = 60 and 7 nM, respectively; Mol. Pharmacol. 40:932, 1991). In contrast, adendrotoxin (a-DaTX) selectively blocks A-type K channels, but not DRK channels (loc. cit. 34:152, 1988). We studied interactions between the Tityus toxins and α-DaTX in binding and \*Rb efflux experiments. Ts<sub>kt</sub> displaced <sup>12</sup>I-\(\alpha\)-DaTX from synaptic membranes, SM (IC<sub>20</sub> = 1 nM), but 600 nM Ts<sub>kt</sub> did not affect <sup>12</sup>I-\(\alpha\)-DaTX binding. Scatchard analysis showed that maximum binding of 128 I - a-DaTX, 2.8 pmol/mg SM protein, was reduced to 1.9 and 1.6 pmol/mg protein by, respectively, 2 and 4 nM  $Ts_{M}$ . The apparent affinity of  $^{12}I$ - $\alpha$ -DaTX for its receptor ( $K_{D} = 0.8$ nM) was decreased by 2 and 4 nM Ts<sub>ke</sub>: K<sub>D</sub> increased to 1.4 and 2.5 nM, respectively. These data suggest an un-competitive, allosteric interaction between Ts<sub>K</sub> and α-DaTX at the <sup>12</sup>I-α-DaTX receptor. Ts<sub>K</sub> and Ts<sub>K</sub> both selectively blocked the non-inactivating (DRK channel) component of K-stimulated \*Rb efflux from synaptosomes; their effects were not additive.  $\alpha$ -DaTX (IC<sub>20</sub> = 90 nM) inhibited only the rapidly-inactivating additive.  $\alpha$ -Data (10.5 = 50 third numbered only the representations) (A-channel) component of \*Rb efflux. The effects of Ts<sub>E2</sub> and  $\alpha$ -DatX on the \*Rb efflux were additive, as expected for two toxins that block different K channels. In the presence of 600 nM a-DaTX and 80 nM Ts<sub>ke</sub>, however, only the DRK channel component was blocked. Thus, Ts<sub>κ</sub> relieves the block of A-channels by α-DaTX.

### 335.6

BEFECT OF 4-AMINOPYRIDINE ON BOVINE CHROMAFFIN CELL MEMBRANES. L. Kaoural<sup>-</sup>, I. Bekavac<sup>-</sup>, J.M. Tirfaro<sup>1</sup> and M.I. Glavinovic<sup>-</sup>, Departments of Anesthesia<sup>-</sup>, Anesthesia Research and Physiology<sup>-</sup> McGill University, Montreal, P.Q., Canada H3G 176 and Department of Pharmacology<sup>3</sup>, University of Ottawa, Ottawa, Ont., Canada K1H 8M5.

Ever since the early findings in squid axon (Yeh et al. Biophys. J. 16, 77-81, 1976) it has been well established that 4-aminopyridine (4-AP) blocks potassium currents. 4-AP is now known to block fast inactivating (I<sub>4</sub>) potassium current. Such actions of 4-AP usually occur at concentrations that are comparatively high (0.1-1mM). 4-AP is also known to augment quantal release at squid synapse (Llinas et al., Biophys. J., 16, 83-86, 1976) and at neuromuscular junction (Lundh & Thesleff, J. Pharmacol., 42, 411-12, 1977) but at micromolar concentrations. If as speculated augmentation of release occurs because of blockade of potassium conductance this raises the question of whether otherwise the same channels have different 4-AP sensitivity at secretory cells or whether these are altogether different potassium channels.

Experiments were done on excised inside out membrane patches.

channels.

Experiments were done on excised inside out membrane patches from bovine chromaffin cells. The microelectrodes were filled with Locke solution. The internal solution nominally had 0.1 - 0.3 µM free calcium. Experiments were performed at room temperature (20-23°C). 4-AP at low concentrations (10-100 µM) reduced outward current by blocking a small conductance channel which judging by I-V curve was permeable mainly to potassium. Outward current was further reduced due to the shift in the current baseline that appears to be essentially voltage independent and whose variance increased. The baseline changes could be due to activation of transport mechanism (or a pump) and/or due to the effect on probably several very small channels.

A NEW INTERPRETATION OF THE MECHANISM OF BLOCKADE OF THE DELAYED RECTIFIER POTASSIUM ION CHANNEL IN NERVE AXON MEMBRANE BY INTRACELLULAR TETRAETHYLAMMONIUM IONS. J.R. Clay\* Lab of Biophysics, NIH, Bethesda, MD 20892.

K+ channels in nerve are blocked in a voltage-dependent manner when TEA+ is applied intracellularly. The original TEA+ results from squid axons appeared to suggest that the channel gates had to open before blockade could occur. A re-examination of this issue in souid axons has revealed that the effect of TEA+ is consistent with an alternative interpretation in which TEA+ can bind to its blocking site within the channel equally well when the channel gates are either closed or open. Blockade by other ions does appear to depend upon the state of the gating mechanism. For example, the channel must be open for blockade to occur by either butyltriethylammonium (C4) or pentyltriethylammonium (C5), but not with propyltriethylammonium (C3) or TEA+ (C2). The electrical distance of blockade for all of these ions is ~0.3 from the inner membrane surface. These observations suggest that the "head" of the Cn ion cannot reach the blocking site with n > 3 unless the gates are open thereby allowing the "tail" of the molecule to enter the permeation pathway. In contrast, TEA+ and C3 can reach the blocking site independent of gating, because these ions do not have a "tail" sufficiently long to interfere with gating

DIVALENT CATIONS SELECTIVELY ALTER THE VOLTAGE DEPENDENCE OF INACTIVATION OF A-CURRENTS IN CHICK AUTONOMIC NEURONS. Mary E. Wisgirda\* and Stuart E. Dryer. Program in Neuroscience, Department of Biological Science, Florida State University, Tallahassee, FL

A-currents were studied in acutely dissociated chick autonomic neurons. Parasympathetic neurons from the ciliary ganglion were obtained from E10-E14 embryos, and neurons from the lumbar sympathetic chain were obtained from E16-E19 embryos Standard whole-cell patch clamp recording methods were used. Switching from salines containing 4 mM Mg<sup>2+</sup> to salines containing 4 mM Ca<sup>2+</sup> caused a large positive shift in the steady-state inactivation curve, but had no effect upon the voltage dependence or kinetics of activation, deactivation, the rate at which channels became inactivated or the rate at which channels recovered from inactivation. This effect saturated with increasing concentrations of Ca2+. Other group IIA divalent cations were less effective than Ca<sup>2+</sup>, in the order Ca<sup>2+</sup>>Ba<sup>2+</sup>>Mg<sup>2+</sup>=Sr<sup>2+</sup>. Application of 4mM Mg<sup>2+</sup> partially antagonized the effects of 4mM Ca<sup>2+</sup>. The results suggest the existence of a specific divalent cation binding site accessible from the external face of the membrane that selectively affects inactivation This work was supported by NIH Grant NS-27013.

CHARACTERIZATION OF K+ CHANNELS ACTIVATED BY CROMAKALIM IN INSIDE-OUT PATCHES FROM CULTURED RAT HIPPOCAMPAL NEURONS. D.M. Politi\* Rogawski. Neuronal Excitability Section, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

We have previously reported that cromakalim activates a glyburide-sensitive K+ channel in cell-attached recordings from cultured embryonic rat hippocampal neurons (single channel conductance, 16-34 pS). In the present study, we investigated the pharmacological properties of cromakalim-activated single channel currents in inside-out excised patches. In these recordings, the cromakalim-activated K+ channels had a unitary conductance between 23 and 50 pS in physiological solution and a maximal conductance of 60-70 pS in symmetrical  $K^+$ . The channels showed a moderate degree of outward rectification. In several patches these channels were inhibited by application of 3 mM ATP-K2 to the cytoplasmic side of the membrane. These data, and the observation that cromakalim and energy depleting conditions activate the same glyburide-sensitive channels, indicate that the K+ channels opened by cromakalim in hippocampal neurons are likely to be of the ATP-sensitive type.

DRK1 K+ CHANNEL TRANSCRIPTS AND POLYPEPTIDES ARE EXPRESSED IN PC12 CELLS AND ARE REGULATED BY NGF. N. Sharma, A. K. Kleinklaus, N. V. Marrion, G. D'Arcangelo, S. Halegoua, and J. S. Trimmer\*, Departments of Pharmacology, Neurobiology & Behavior, and Biochemistry & Cell Biology, SUNY, Stony Brook, NY 11794.

Changes in neuronal membrane excitability occur with development and plasticity due to differences in the levels of activity of specific ion channels. We have shown that, in rat brain, the delayed rectifier K+ channel isoform drk1 (K<sub>v</sub>2.1) is restricted to neurons, and that levels of drk1 polypeptide expression in brain exhibit distinct temporal and spatial patterns. Thus differential expression of drk1 may be involved in determining excitability changes in neurons. We have investigated the expression of drk1 in the rat pheochromocytoma cell line PC12, which expression of art in the rat precent on the PC12, which has been used as a model system to study changes in neuronal phenotype upon neuronal growth factor treatment. PC12 cells express endogenous drk1 polypeptide at levels similar to those found in adult rat brain neurons. In response to 24 hours of NGF treatment, levels of drk1 polypeptide increase 4-5-fold. This increase is maintained up to 144 hours of NGF treatment. An increase in drk1 mRNA levels is also seen upon NGF treatment. Immunofluorescent localization of the drk1 polypeptide in these cells reveals plasma membrane-associated staining of the cell bodies in both untreated and NGF-treated PC12 cells. Intense staining is observed in the growth cones of NGF-differentiated PC12 cells. Thus drk1 is expressed at high levels in the plasma membrane of both untreated and NGF-treated PC12 cells and may be a component of the delayed rectifier-like K+ currents found in these cells.

GLIBENCLAMIDE-SENSITIVE HYPERPOLARIZARIZATION BY CROMAKALIM, MINICKED BY METABOLIC INHIBITION, IS ABSENT IN ONE OF TWO SUBSTRAINS OF N1E-115 CELLS.

IN ONE OF TWO SUBSTRAINS OF NIE-115 CELLS.

E.J. Hunnicutt,Jr.\*, J.N.Davis and J.C.Chisholm.

Miles Inst. Preclin. Pharmacol., West Haven, CT 06516.

A specific subset of K-channels (K<sub>ATD</sub>) defined pharmacologically by sulfonylurea inhibitors such as glibenclamide (GLB), and by K-channel agonists including cromakalim (CRK), is known to be present in mammalian neurons. We now report the presence of GLB-inhibitable, CRK-induced hyperpolarization in only one of two substrains of the clonal neuroblastoma line, N1E-115. In original N1E-115 cells depolarized in the continued presence of 55 mM K<sup>+</sup>, CRK produced a dose-dependent and complete repolarization, with similar potency to that seen in hippocampal neurons (ED $_{50}$ =300 µM). Furthermore, with single cell measurements using a fluorescent membrane potential dye, only this strain, responding to CRK and GLB, also responded to acute metabolic inhibition by oligomycin and 2-deoxy-D-glucose application. The repolarization produced by oligo/2DG in depolarized cells was rapid (within 10 min) and complete. Finally, the most potent block of maximal CRK response was achieved with GLB only when applied before the agonist, suggesting the possibility of a state-dependence to GLB block. In con-CRK and metabolic challenge in a substrain of NIE-115 (MIPP-NIE) cells strongly supports the KATP channel as mediator of this CRK action in original NIE-115 cells.

### 335.12

MODULATION BY ADENOSINE OF THE CROMAKALIM-INDUCED CURRENT IN GUINEA PIG VENTRICULAR MYOCYTES. John R. McCullough\* and Mary L. Conder. Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton NJ 08543-4000.

Although adenosine (ADEN) alone has relatively few electrophysiological

actions in mammalian ventricle, it has recently been reported to activate actions in mammalian Ventricle, it has recently been reported to activate ventricular ATP-sensitive K+ channels (KATP). The potassium channel opener (KCO), cromakalim (CROM), is also known to open KATP in cardiac cells. The effects of ADEN on the CROM-induced current in cardiac cells are not known. We used whole-cell patch clamping techniques to study the interaction of ADEN and CROM in ventricular myocytes isolated from adult guinea pigs (350g). Steady state whole-cell K+ currents were elicited by slow voltage ramps (6-10 mV/sec from -130 to +50 mV) from a holding potential of guilled pigs (530g). Steady state wine-teril in Contents were enabled by 300 young and steady state wines (8-10 mV) from a holding potential of -80 mV and drug effects were quantified by comparing the outward K+current at +20 mV (IK). ADEN alone (50 μM) had no significant effect on IK: 0.48±0.07 nA in control vs 0.46±0.13 nA in ADEN (n=13). In 9 cells, a threshold concentration of CROM (30 μM) caused a small, but significant increase in IK (0.42±0.05 nA, control vs 1.08±0.27 nA, CROM [p<0.05]) and addition of 50 μM ADEN further increased IK (1.76±0.46 nA, p<0.03). Similar effects were seen with the addition of 10 μM ADEN to 30 μM CROM. The possible G-protein involvement in ADEN enhancement of CROM effects was studied by using intracellular GTP-γS and A-protomer of pertussis toxin (PT). GTP-γS (100 μM) enhanced the IK effects of 30 μM CROM (1.3±0.18 nA control vs 3.3±0.85 nA, CROM, p<0.05), while PT (0.2 μg/ml) inhibited ADEN enhancement of CROM. These results suggest that in cardiac ventricular cells ADEN may modulate the actions of CROM on IK through a G-protein mediated mechanism. Since ADEN is released in myocardial ischemia, ADEN may enhance the ability of low concentrations of KCO to open KATP.

## 335.14

M CHANNEL MODULATION BY MUSCARINE IS AFFECTED BY INTRACELLULAR FREE Ca2+ AND A LIPOXYGENASE INHIBITOR S.P.Yu\* and P.R.Adams Howard Hughes Med. Inst., Department of Neurobiol. & Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

Muscarinic modulation of the M-current  $(I_{\rm ab})$  features a suppression followed by a transient overrecovery upon removal of agonist. We reported (Biophys J. 59:78a, 1991) that  $[Ca^{2*}]_i$  modulates  $I_M$  in bullfrog sympathetic ganglion neurons. Increasing  $[Ca^{2*}]_i$  from zero to 80 nM by intracellular perfusion doubled the size of  $I_M$ . The arachidonic acid (AA) pathway is involved in the  $Ca^{2*}$  modulation of  $I_M$  (Soc Neurosc Abs. 17(1):67, 1991). We studied the possible relations between [Ca<sup>2+</sup>], and muscarine

responses, and the role of the AA pathway in overrecovery.

The experiments were performed in dissociated bullfrog ganglion B cells using whole cell recording and intracellular perfusion. Ringer contained 0.5 mM EGTA, 2.0 mM Mm<sup>2+</sup> and no added Ca<sup>2+</sup>. To keep the concentration of free BAPTA constant, internal solutions of zero and 80 nM Ca<sup>2+</sup> were prepared with 11.4 mM and 20 mM

Muscarine (1  $\mu$ M) inhibited most of  $I_M$  (69 $\pm$ 9% blockade, n=6) at 80 nM [Ca<sup>2+</sup>], while it displayed much less effect (29 $\pm$ 12% blockade, n=8) at zero [Ca<sup>2+</sup>]. At zero [Ca2+], little overrecovery occurred. At 80 nM [Ca2+], IM transiently increased by 38% (n=21) when muscarine was removed. Overrecovery diminished with repeated application of muscarine. In intracellular perfusion experiments performed on a single application of muscarine. In intracellular perfusion experiments performed on a single cell starting with zero  $[Ca^{2n}]$ , larger overrecovery was observed from a second application of muscarine after raising  $[Ca^{2n}]$ , to 80 nM (n=11). The lipoxygenase inhibitor, NDGA (1  $\mu$ M), blocked overrecovery (1.06 $\pm$ 0.4 fold increase, n=4) with little effect on suppression of  $I_M$ . Indomethacin (10  $\mu$ M), a cyclooxygenase inhibitor, neither affected overrecovery (1.47 $\pm$ 0.07 fold increase, n=3) nor  $I_M$  suppression. The data suggest that a minimum level of  $[Ca^{2n}]$ , is required for optimal suppression  $I_M$  by the procession of  $I_M$  is required for optimal suppression.

of  $I_{\rm M}$  by muscarine and for overrecovery. The lipoxygenase pathway may be involved in the transient enhancement of  $I_{\rm M}$ .

METABOTROPIC GLUTAMATE RECEPTOR ACTIVATION INHIBITS POTASSIUM CONDUCTANCES IN NEURONS OF THE BASOLATERAL AMYGDALA. M.D. Womble\*, K. Rusin and H.C. Moises. Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

The activation of muscarinic cholinergic receptors or metabotropic glutamate receptors on hippocampal pyramidal neurons produces membrane depolarization and a loss of the slow afterhyperpolarization (AHP). We have previously shown in neurons of the basolateral amygdala (BLA) that muscarinic agonists have a similar effect, partially due to the inhibition of the M-current  $(I_{\rm M})$  and the slowly-decaying AHP current  $(I_{\rm AHP})$ . Therefore, we examined  $I_{\rm M}$  and  $I_{\rm AHP}$  in BLA pyramidal neurons of rat ventral forebrain slices for possible modulation by trans-ACPD, a metabotropic glutamate receptor agonist. Bath application of ACPD (20-100  $\mu{\rm M})$  de-polarized the cell, decreased spike frequency accommodation and reduced the slow AHP. The M-current was identified in single-electrode voltage-clamp as a slow inward current relaxation during a 1 s voltage step to -55 mV from a holding potential of -40 mV. Application of ACPD reduced  $I_{\rm M}$  amplitude to 33  $\pm$  7.5% of control ( $\pm$  S.E.M.; n=12). The decay of  $I_{\rm AHP}$  was examined following a 900 ms step depolarization from a holding potential of -60 mV. The amplitude of this current was reduced to 43.6  $\pm$  12.2% of control (n=12) following ACPD application. The inhibitory effect of ACPD on  $I_{\rm M}$  and  $I_{\rm AHP}$  was reversed by washing and was not prevented by APV (50  $\mu{\rm M})$ , CNQX (20  $\mu{\rm M})$  or atropine (2  $\mu{\rm M})$ . Since the metabotropic glutamate receptor subtype has been shown to be linked to stimulation of phosphoinositide (PI) hydrolysis, these findings suggest that the inhibition of  $I_{\rm M}$  and  $I_{\rm AHP}$  in BLA pyramidal neurones may be mediated by an increased rate of PI turrover. MUSCARINIC MODULATION OF VOLTAGE-GATED POTASSIUM CURRENTS IN ACUTELY-DISSOCIATED RAT NEOCORTICAL NEURONS. R.C., Foehring. Department of Anatomy and Neurobiology, University of Tennessee, Memphis, Memphis, TN 38103-4901.

Acetylcholine, acting at neocortical muscarinic receptors, has been implicated as important in learning, memory and several other forms of plasticity. Deficits in these processes accompanies the loss of cholinergic neurons in disease states such as Alzheimer's disease, but little is known regarding the biophysical mechanisms of action of muscarinic agonists on neocortical neurons.

This study examined the modulation of voltage-gated K+ currents by muscarinic agonists in acutely-dissociated neurons from rat sensorimotor or visual cortex and human temporal neocortex. There are three components to the voltage-gated K+ currents in these cells: non-inactivating ( $I_K$ ), rapidly inactivating ( $I_A$ ) and slowly-inactivating. Muscarine (50nM-100  $\mu$ M; n=22 cells) or Carbachol (500 -1 mM; n=17) reduced, in a dose-dependent manner, the amplitude of the slowly-inactivating current observed during a 200 ms test pulse to -10 mV. This reduction resulted from a 3-10 mV hyperpolarizing shift in the steady-state inactivation curves. Activation voltage-dependence was unaltered. In 17 of 22 cells, muscarine also increased the current amplitude during the early part of the test command. This was due to an increase in the contribution of  $I_A$ . All of these effects were readily reversible. Supported by NINDS grant NS27180 and EPICARE, Memphis, TN.

T6G 2H7

PROSTAGLANDIN  $E_2$  MODULATES  $I_{\kappa}$  IN SUBCULTURED RAT TAIL ARTERY VASCULAR SMOOTH MUSCLE CELLS <u>J. Ren\*, E. Karpinski and C.G. Benishin.</u> Dept. of Physiology, University of Alberta, Edmonton , Alberta, Canada

Arachidonic acid has been shown to modulate potassium (K) channels in vascular smooth muscle cells (VSMC). The role of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), a metabolite of arachidonic acid, in the modulation of K channels has not been demonstrated. In this study, vascular smooth muscle cells were isolated by collegenase-elastase dissociation using the tail artery of 12-14 week male Wistar-Kyoto (WKY) rats. The cells were cultured in DMEM with antibiotics and supplemented with 10% fetal bovine serum. Subcultured cells (passages 8-12) were used for these studies. The whole-cell version of the patch clamp technique was used to measure potassium channel currents in these cells. Recordings were made using low intracellular Ca2+ (high pipette EGTA) solution to minimize the activation of the Ca2+-activated K channels. From a holding potential of -80 mv, test pulses to more positive potentials generated a voltage-dependent, delayed rectifier K current  $(I_K)$ . The current was activated at -40 to -30 mv and showed almost no inactivation. This current was inhibited by approximately 50% (test potential +30 mv) with 10 mM TEA. PGE<sub>2</sub> (1-100 μM) suppressed the outward K current. This suppression was concentration dependent. The kinetics of the current remained the same before and after PGE2 and there was no shift in the activation voltage. This result suggests that PGE2 modulates K channels (Ik) in subcultured rat tail artery vascular smooth muscle cells.

TWO MUSCARINE SENSITIVE POTASSIUM CURRENTS DIFFERENTIALLY INHIBITED BY BARIUM AND CESIUM. I.S. Coggan\*. D.L. Kreulen. Dept. of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ

Muscarine evoked currents were studied under voltage clamp conditions in guinea pig celiac ganglion neurons in primary culture. Muscarine was applied for a short duration (1.5 sec) and responses were analyzed by time course, amplitude and voltage dependency. Cells were also tested for the presence of M-current, identified by its kinetics, voltage dependency and sensitivity to muscarinic agonists. No correlation was found between the magnitude of M-current and the amplitude of the response to muscarine.

Inward current responses to muscarine were produced by the inhibition of two potassium currents: the M-current and a voltage-independent K+ current. In most cells, the net response to muscarine was due to inhibition of both currents. Cesium and barium were used to test whether these two currents could be separated by differential sensitivity to potassium channel blockers. The cations were added to the bath medium as the chloride salts, each at 2.0 mM.

M-current was blocked to a greater degree by both barium and cesium (93% and 56%, respectively) than was the net response to muscarine (60% and 18%, respectively). In cells with no M-current, cesium had no effect on response muscarine. These data indicate that M-current and the muscarine sensitive leak current may be mediated by different channels. HL-27781, Lilly Research Labs.

SUBSTANCE-P MODULATES SEPARATE SET OF POTASSIUM CURRENTS IN BULLFROG PRIMARY AFFERENT NEURONS. T. TOkimasa M. Ishimatsu & T. Akasu. Dept. Physiol., Kurume Univ. Sch. Med., 67 Ashi-machi, Kurume 830, Japan.

A slowly inactivating delayed rectifier potassium current  $(I_K)$  and a noninactivating M-type potassium current  $(I_M)$  were recorded from dissociated bullfrog dorsal root ganglion cells as described previously (Tokimasa et al. J. Physiol., 435: 585-604, 1991). The pipette solution contained ATP (5 mM). Substance-P (SP, 100 nM) was added to the superfusate for 1-2 min every 25 min. SP facilitated by up to 70 % the  $I_K$  activation at the onset of step commands from -120 mV to potentials less negative than -60 mV. However, this was associated with a marked reduction in the amplitude for the 'non-zero' steady-state  $I_K$  (facilitation of inactivation), an action being responsible for a membrane depolarization in unclamped cells. These actions of SP quickly desensitized by about 80 % in about 2 min. Control  $I_K$  was regained within 5 min when the bath application of SP was discontinued. Substitution with ATP- $\gamma$ -S in place of 5 mM-ATP in the pipette solution rendered the SP actions on  $I_K$  irreversible. GTP- $\gamma$ -S (30-100  $\mu$ Min the presence of ATP) gave essentially the same results as with ATP- $\gamma$ -S. The actions of SP on  $I_K$  were attenuated to less than 30 % by pre-incubating the cells with pertussis toxin (PTX, 500 ng ml<sup>-1</sup>) for 24 h at 22 °C. These observations suggest that the receptor occupancy by SP results in the activation of a class of GTP-binding proteins leading to the facilitation of both the activation and inactivation of  $I_K$  and that desensitization of the SP-induced responses may require a hydrolyzable form of ATP inside the cells.  $I_M$  was also inhibited by SP to less than 30 %. In terms of desensitization and its sensitivity to ATP- $\gamma$ -S and GTP- $\gamma$ -S, the actions of SP on  $I_M$  were quite similar to that for  $I_K$ . However, pre-incubation of the cells with PTX (500 ng ml<sup>-1</sup>, 24 h, 22 °C) did not significantly attenuate the SP-induced inhibition of  $I_M$  implying that another class of GTP-binding proteins is involved for  $I_M$ .

## 335.20

FURTHER STUDIES OF THE BLOCKING ACTION OF TRH ON A PERSISTENT K<sup>+</sup> CURRENT OF RAT MOTONEURONES. N. Fisher and A. Nistri 2 1 Queen Mary and Westfield College, London El 4NS, U.K. and 2 Lab. Biophysics, SISSA, Via Beirut 4, 34014 Trieste, Italy.

In spinal motoneurones a K<sup>+</sup> current active at rest ( $I_{K(T)}$ ) is depressed by TRH in a voltage-sensitive fashion, thus producing an inward (depolarizing) current associated with a fall in cell conductance. Using single electrode voltage clamp the properties of this effect of TRH were investigated on neonatal rat motoneurones in vitro held at resting membrane potential (around -75 mV) and bathed in tetrodotoxin-containing medium. In the presence of TRH (1  $\mu$ M) hyperpolarizing test pulses elicited Cs<sup>+</sup>-insensitive inward currents displaying time-dependent outward relaxations which were enhanced or depressed by depolarizing or hyperpolarizing prepulses, respectively. The steadystate inward current induced by TRH was attenuated by high concentrations (1.5 mM) of Ba<sup>2+</sup>, an effect seemingly independent of Ca<sup>2+</sup> channel activity as it was maintained after application of Cd<sup>+</sup> (0.2-0.5 mM). Carbachol (50  $\mu$ M) produced an inward current and a cell conductance decrease but did not prevent the effects of TRH as it also produced a Ba<sup>2+</sup>-sensitive inward current (with a conductance fall), although its potency was several fold smaller than that of TRH. Two pharmacologically inactive analogues of TRH, its deamidated form and histidylprolinediketopiperazine were found to be ineffective. These data support a selective and potent action of TRH in modulating  $I_{K(T)}$  of spinal motoneurones. Supported by Takeda-Cyanamid.

AN ANTI-G<sub>aq</sub> ANTIBODY BLOCKS THE PLC-DEPENDENT BRADYKININ RESPONSE IN NG108-15 CELLS. F. Belardetti \*, S. Gutowski and P. Sternweis Dept. Pharmacology, Univ. TX Southwestern Med. Ctr. Dallas, Dallas, TX 75235.

Specific transmitter receptors, through activation of a pertussis toxin (PTX)-insensitive G protein, stimulate PIP, breakdown and generation of IP3 and DAG in central neurons. By triggering Ca++ release in the cytoplasm and activating PKC, respectively, these two messengers regulate a variety of effector molecules, including ion channels. We have examined the role of a recently discovered PTX-insensitive G protein, G<sub>a</sub> (Science, 251, 804), in coupling the bradykinin (BK) receptor to this cascade by using the NG108-15 neuroblastoma x glioma cell line and an antibody raised against the common C-terminal peptide of Gaa and its homolog,  $G_{a11}$  (JBC 266, 20519). Differentiated cells were voltage-clamped at -40 mV using large patch pipettes (<1 M  $\Omega$ ) filled with internal medium (IM, mM): 120 KCl, 20 HEPES, 0.1 MgCl<sub>2</sub>, 2 ATP and 0.1 GTP. Under these conditions, external application of BK (10 μM) transiently activated a Ca<sup>++</sup>-dependent outward K<sup>+</sup> current. When IM plus the antibody (9:1) was perfused inside the pipette for 20-30 min using a fine tubing placed near its mouth, the BK response averaged 246 ± 256 pA (n=6, mean ±SD). If instead preimmune IgG was perfused in cells of approximately similar size, the response to BK was 550 ± 493 pA (n=6). These data indicate that G<sub>a</sub> and/or its homologs mediate the modulatory action of a neurotransmitter on a K+ channel.

PROPERTIES OF THREE DISTINCT VOLTAGE-ACTIVATED K\* CURRENTS OF MURINE HIPPOCAMPAL NEURONS. X.Y. Li, J.J. Choi\*, and J.J. McArdle. Departments of Pharmacology & Toxicology and Anesthesiology, New Jersey Medical School (UMDNJ), Newark, NJ 07103-2714.

(UMDNJ), Newark, NJ 07103-2714.

Using the whole cell configuration of the patch voltage-clamp technique, two transient K<sup>+</sup> currents were distinguished from the delayed rectifier current (IK) of hippocampal neurons enzymatically isolated from adult mice. The time constant of inactivation was 55 ± 16 ms and 560 ± 150 ms for IAf and IAs, respectively. While 4-aminopyridine (4-AP, 5 mM) depressed the peak amplitude of IAf by 50%, neither TEA (10 mM) nor the chemical phosphatase 2,3-butanedione monoxime (BDM, 10 mM) altered this parameter. In contrast, the amplitude of IAs was reduced to 50% and 60% of control, respectively, by TEA and BDM. A pre-conditioning hyperpolarizing voltage step to -120 mV from a holding potential of -50 mV enhanced the amplitude of IAs. The magnitude of this enhancement was directly proportional to the duration of the prepulse and suppressed by both TEA and BDM, but not by 4-AP. Similar voltage-clamp protocols only slightly enhanced or even decreased IAf. Likewise, non-inactivating IK, which accounted for 10-30% of the total whole cell K<sup>+</sup> current, was unaffected by varying membrane potential from -120 to -50 mV. While TEA inhibited IK, both 4-AP and BDM were without effect. The sensitivity of these K<sup>+</sup> currents to the external Ca<sup>+2</sup> concentration was IAs> IAf=IK. These data suggest that three pharmacologically distinct K<sup>+</sup> channels contribute to the whole cell current of adult hippocampal neurons. NIAAA grant AA08025 supported this work.

## ION CHANNEL MODULATION II

### 336.1

DIRECT MEASUREMENT OF CYTOPLASMIC Ca BUFFERING IN SNAIL NEURONS SUGGESTS CO-LOCALIZATION OF Ca AND CAN CHANNELS. L.D. Partridge\*, T.H. Müller, D. Swandulla. Max Planck Institute for Biophysical Chemistry, Göttingen, Germany & Dept. of Physiology, University of New Mexico, Albuquerque, NM 87131.

Calcium ions play an important role in coupling electrical activity in neurons to the activation of Ca-activated channels such as the CAN channel. The number Ca ions available to activate CAN channels depends on the diffusion of Ca from open Ca channels and on the cytoplasmic Ca buffering capacity. We measured the Ca binding capacity of snail neurons so that we could estimate Ca availability for CAN channel activation.

The large burster neuron of  $Helix\ pomatia$  was voltage clamped with a two-electrode voltage clamp and  $I_{\rm Ca}$  was measured in response to depolarizing voltage clamp pulses. Fura-2 was iontophoresed into the cell and simultaneous fluorescent images were obtained. 380/360 ratio measurements were used to determine  $[{\rm Cal}_i]$ , while  $[{\rm fura-2l}_i]$ , was determined from the 360 signal. The fraction of incoming Ca bound to fura-2 was calculated along with the fura-2 buffering capacity of the cell at various times during the iontophoresis. A double reciprocal plot was used to determine the endogenous buffering capacity of the cytoplasm, which was found to be approximately 500. Thus only about one in 500 Ca ions entering the burster neuron are free to activate Ca-activated channels. Comparing model calculations of CAN current activation with experimentally observed CAN currents suggests that the actual distance between Ca and CAN channels is significantly less than is expected from a uniform distribution of both channel types. Hence Ca and CAN channels are likely to be co-localized.

## 336.3

OPIOID PEPTIDE MODULATION OF CALCIUM-ACTIVATED POTASSIUM CURRENT IN ADRENAL CHROMAFFIN CELLS. W.A. Twitchell\* and S. G. Rane. Department of Biological Sciences, Purdue University, West Lafayette, IN 47907.

W. A. Twitchell\* and S. G. Rane. Department of Biological Sciences, Purdue University, West Lafayette, IN 47907.

Adrenal chromaffin cells have opioid peptide receptors, they co-secrete opioids and catecholamines, and there is a peptide component to their preganglionic input. We are investigating opioid peptide effects on chromaffin cell potassium (K) and calcium (Ca) currents in order to assess the physiologic role of these peptides in the adrenal gland, and to develop a cellular model for opioid receptor action on neuronal cells. Adult bovine chromaffin cells were isolated by standard techniques and cultured on collagen-coated substrate at a starting purity of >90%. To isolate Ca-activated K currents in whole-cell (WC) and outside-out patch (OP) configurations the pipette solution had 150 mM K and 1 µM free Ca, and the bath had cadmium to block voltage-gated Na current. Cells (or patches) were held at 0 mV to inactivate voltage-gated Na current and a delayed-rectifier type K current. Voltage ramps to 100 mV evoked WC currents or large-conductance, single channel currents (OP) with the voltage-dependence characteristic of maxi-K type Ca-activated K channels. The general opioid receptor agonist Leu-enkephalin (10 µM) increased WC Ca-activated K current throughout the voltage ramp by 95±9% (n=19 cells). The µ receptor agonist DAGO (10 nM) also increased Ca-activated K current (82±18%, n=4) while the x receptor agonist DYNA 1-13 (30 nM) was ineffective (n=5). Activity of large-conductance (100 pS) K channels in OPs was potentiated by bath applied Leu-enk (5/5 patches) or DAGO (3/3 patches), suggestive of tight coupling between receptor and channel. To insure that opioid potentiation of WC activated K current was not an indirect consequence of up-modulation of Ca current, we tested Leu-enk on WC Ba currents (10 mM Ba in the bath, 150 mM Cs, 2 mM BaPTA in the pipette). Leu-enk (10 µM) inhibited Ba currents by 18±2% (n=4 cells), an effect which would be expected to suppress rather than potentiate Cacitivated K curre

PATCH CLAMP STUDY OF Ca-ACTIVATED NONSELECTIVE CATION CHANNELS IN CHICK EMBRYO DORSAL ROOT GANGLION CELLS. S. Razani-Boroujerdi\*, L.D. Partridge. Dept. of Physiology, Univ. of New Mexico, Albuquerque, NM 87131

Calcium-activated nonselective cation (CAN) channels have been studied in a number of cell types. In neurons, these channels are frequently associated with bursting and secretory activity. We have used inside-out membrane patches to study Ca activation of CAN channels in isolated sensory neurons of 10 to 14 day old chick embryos. The CAN channel in these neurons has a unit conductance of about 30 pS, is slightly voltage sensitive, and is rapidly activated by cytoplasmic free Ca<sup>++</sup>. Calcium activation of this channel was studied by perfusing the cytoplasmic surface of inside-out patches with buffered Ca $^{++}$  solutions. Free [Ca $^{++}$ ] between  $10^{-11}$  and  $10^3$  M was prepared from Ca++/EGTA or Ca++/HEDTA solutions calculated for the ionic strength, pH, and temperature. Free Ca++ was determined using fura-2 and fluorescent microscopy. The K<sub>D</sub> for Ca<sup>++</sup> activation of the CAN channel was between 0.1 and 1.0 µM and the Hill coefficient was not significantly different from one.

## 336.4

# DIFFERENTIAL MODULATION OF TTX-SENSITIVE AND TTX-INSENSITIVE $N_8^+$ CURRENTS BY PROTEIN KINASE C IN SPINAL CORD ASTROCYTES

C.L. Thio\* and H. Sontheimer. Dept. of Neurology, Yale Univ. School. of Medicine, New Haven, CT 06510.

Cultures of rat spinal cord astrocytes contain two astrocyte types which are distinguishable by their morphology as stellate, process bearing, or flat, "pancake," cells. Both astrocyte types are capable of expressing high densities of voltage-activated Na<sup>+</sup> channels (~8/µm<sup>2</sup>). Stellate astrocytes, like most cultured neurons, express exclusively TTX sensitive currents (Kd~5nM), whereas pancake cells express TTX insensitive sodium currents (Kd~1000nM). We have found that these currents also differ in their response to activation of protein kinase C (PKC) by phorbol 12-myristate 13-acetate (PMA). TTX sensitive sodium currents, expressed in stellate astrocytes, showed a marked (up to 55%) decrease in peak current in response to a 5-10 minute exposure to 1 µM PMA. In contrast, TTX insensitive sodium currents, expressed in pancake cells, increased up to 30% upon exposure to 1µM PMA. Both PMA effects could be blocked by pretreatment with the PKC inhibitor H7 suggesting that the effect is mediated by activation of PKC. Analysis of current kinetics  $(\tau_m, \tau_h)$ suggests that the observed changes are due to alterations in inactivation  $(\tau_h)$ , while in both types of responses, activation  $(\tau_{m)}$ , steady-state inactivation (ho) curves and the current voltage relationship remain unchanged in PMA.

ACTIVITY OF CYCLIC-AMP DEPENDENT SODIUM CHANNELS IN Pleurobranchaea californica PEDAL GANGLION IS ELEVATED WITH INTERNAL CALCIUM. L.C. Sudlow & R. Gillette. Dept. of Physiology and Biophysics, U. of Ill., Urbana Il 61801.

Cyclic-AMP-activated sodium currents  $(I_{(Na,eAMP)})$  underly neuromodulator induced bursting in the neurons of P. californica (Green & Gillette, 1983, Nature 306:784; 1988, J.Neurophys. 59:248). Using inside-out patches from serotonergic pedal neurons of P. californica (Sudlow & Gillette, 1991, Soc. Nsci. Abs 17:1390) we have characterized the interactions of cAMP and Ca+ I<sub>(Na,cAMP)</sub> at the single channel level. cAMP (1 mM) activated an inward current of  $-2.08 \pm 0.19$  pA (mean  $\pm$  sem, n=8) with a 22 pS conductance. As the saline contained no ATP, phosphorylation does not appear to be required for activity. The channels exhibited a percent open time (Po) of 2.84 ± 0.45% and a mean open time (MOT) of 2.46 ± 0.46 msec. The I-V relationship demonstrated a decrease in current at hyperpolarizing potentials and an increase at depolarizing potentials. When Ca<sup>++</sup>; and cAMP were applied Po increased in a [Ca++] dependent manner but there was no change in the amplitude of the openings. Po (13.9%) and MOT (3.57 msec) were maximal in 200 nM Ca<sup>++</sup>; with cAMP. Ca<sup>++</sup>; entering during bursting augments the activation of I<sub>(Na,cAMP)</sub> by cAMP. From the I-V curve, depolarization causes an elevation in I<sub>(Na,CAMP)</sub>. This positive feedback contributes to the excitation during bursting. This research was supported by NIH RO1 NS26838 to RG.

Comparison of the Action of two Protein Kinase C Activators on Dihydropyridinesensitive Ca<sup>2+</sup> Channels in Neonatal Rat Ventricular Myocytes Q. Y. Liu, E. Karpinski, C. G. Benishin\* & P. K. T. Pang Dept. of Physiology, University of Alberta, Edmonton, Canada T6G 2H7

It has been reported that  $Ca^{2+}$  channels can be modulated by protein kinase C (PKC) which phosphorylates  $Ca^{2+}$  channel proteins. Two PKC activators,  $4\beta$ phorbol 12-myristate 13-acetate (PMA) and 1-oleoyl-2-acetyl-rac-glycerol (OAG), were used to investigate the effect of PKC activators on Ca2+ channel currents in neonatal rat ventricular cells. The whole cell version of the patch clamp technique was used. From a holding potential of -40 mV, test pulses to more positive potentials generate L type Ca<sup>2+</sup> channel currents (20 mM Ba<sup>2+</sup> was used as the charger carrier). The current was activated at -20 mV and the peak current occurred at +10 mV. PMA (200 nM) or OAG (60  $\mu$ M) significantly increased the L type  $Ca^{2+}$  channel current in cardiac myocytes. However, the effect of PMA on the L type current reached its peak at 3-5 min after addition of the drug to the bath and then gradually decreased. Fifteen min after the addition of PMA, the current decreased below the control level. When OAG was used, the current reached its peak at 5-10 min and then was maintained at this level for 15 min. The results obtained show that the two PKC activators increase Ca2+ channel currents uniquely with respect to time. An explanation of these results which are consistent with other reports is that PMA down-regulates PKC whereas OAG persistently activates PKC. In addition, the Ca<sup>2+</sup> channels modulated by PMA or OAG were sensitive to nifedipine. Nifedipine (10 µM) completely blocked the L type Ca2+ channel current which included both the enhanced current induced by OAG or PMA and the current generated by depolarization, indicating that PKC-activated channels were also DHPnels. In summary, the results from these experiments suggest that PMA and OAG, PKC activators, activate DHP-sensitive L type Ca2+ current in neonatal rat ventricular cells in unique temporal patterns

SHORT-TERM INCREASES IN TRANSIENT CA CURRENTS IN RAT THALAMIC CELLS FOLLOWING CORTICAL INJURY.

J. M. Chung\*, J. R. Huguenard, and D. A. Prince. Dept. of Neurology, Stanford Univ. Med. Ctr., Stanford, CA 94305

Changes in voltage-dependent ionic conductances in cerebral neurons following cortical injury have not been extensively investigated. Such alterations might have a role in mediating neuropathologic processes such as retrograde degeneration. Unliateral ablations of somatosensory cortex were employed to produce axotomy and deafferentation of thalamic relay neurons (RNs). We isolated neurons from ventrobasal complexes both lpsi- and contralateral to the lesion and recorded Ca currents using whole-cell voltage-clamp. One day after cortical ablation, transient currents (I7), but not L-type currents, increased significantly in RNs ipsi- (I<sub>T</sub> = -293 pA, n=10) but not contralateral  $(I_T = -174 \text{ pA}, n=10)$  to the site of cortical lesion. Three days post lesion, I<sub>T</sub> amplitudes were -103 pA (n=6) for ipsi- and -233 pA (n=6) for contralateral RNs. The early increases in I, were not accompanied by changes in either kinetics or voltage dependence of activation and inactivation. These findings suggest that cortical lesions can alter I, through changes in the number of available channels or the channel unit conductance. We speculate that this selective early increase in I, may have a role in the development of thalamic injury following cortical lesions. (Supported by NIH grants NS06477 and a Pimley postdoctoral fellowship to JMC.)

#### 336.6

ROLE FOR PROTEIN KINASE C IN MUSCARINIC MODULATION OF SINGLE CALCIUM CHANNEL CURRENTS IN INSULIN-SECRETING HIT-T15 CELLS. J.A. Love\*, N.W. Richards, C. Owyang, and D.C. Dawson. Depts. of Internal Medicine and Physiology, Univ. of Michigan Med. Center, Ann Arbor, MI 48109

Muscarinic agonists potentiate glucose-stimulated insulin secretion and protein kinase C (PKC) appears to play an important role in this effect. We have demonstrated (Neurosci. Abst. 17:62, 1991) that muscarinic agonists increase the activity of single, L-type, voltage-dependent Ca<sup>++</sup> channels, independent of changes in membrane potential, in cell-attached patches from HIT-T15 cells. We used phorbol esters and DAG analogs to test the role of PKC in channel activation. Acute exposure (5-40 min) to the phorbol ester PMA (200 nM) increased fractional open-time (.048 vs. 120) in 5/5 cells while the inactive compound 4 α-phorbol had no effect (.064 vs. 075) in 3/3 cells. Similarly, the DAG analog DC<sub>10</sub> (5 μg/ml) significantly increased fractional open-time (.040 vs. 086) in 5/7 cells. Exposure to bethanechol (100 μM) resulted in an significantly increased fractional open-time (.030 vs. 101) in 6/6 cells. However, in cells chronically exposed to PMA (200 nM; 20-32 hrs) to deplete PKC activity, bethanechol caused a small increase in fractional open-time (.061 vs. 076) in only 3/7 cells. Conversely, in 4/5 cells chronically exposed to the inactive compound 4α-phorbol (200 nM; 20-32 hrs), bethanechol caused increases in fractional open-time (.038 vs. 120) comparable to those seen in untreated cells. These results suggest that PKC plays an important role in mediating muscarinic stimulation of Ca<sup>++</sup> channel activity in HIT-T15 cells. Supported by the NIH.

CYCLIC GMP REGULATES CALCIUM CHANNELS IN NEURONS OF RABBIT VESICAL PARASYMPATHETIC GANGLIA. T. Akasu' 1. T. Nishimura 4 B. J. Krier 2. 1Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, Japan & 2Dept. Physiol. Mich. State Univ. East Lansing, MI 48824, USA.

The effects of dibutyryl guanosine 3',5'-cyclic monophosphate (db-cGMP) were studied, in vitro, on calcium channels of neurons in rabbit vesical parasympathetic ganglia (VPG), using intracellular and single-electrode voltage-clamp recordings. Db-cGMP (100 μM) produced a biphasic response, initial depolarization associated with a decrease in membrane input resistance followed by hyperpolarization with increased input resistance. Db-cGMP increased the amplitude and duration of spontaneous hyperpolarization. Under voltage-clamp recording, db-cGMP (0.01-1 mM) caused a concentration dependent, transient inward current followed by a long-lasting outward current. Membrane conductance was increased and decreased during the inward and outward currents, respectively. The inward current produced by db-cGMP was depressed in nominally Ca<sup>2+</sup>-free solution, by Co<sup>2+</sup> (1 mM) and nicardipine (10 μM) but not by δ-conotoxin (2 μM). The mean reversal potentials of the inward current was +42 mV and -20 mV in the presence and absence of Ca<sup>2+</sup> in the external solution, respectively. The inward current was not altered by lowering [Na<sup>+</sup>]<sub>0</sub>, raising [K<sup>+</sup>]<sub>0</sub> or by [Cs<sup>+</sup>]<sub>1</sub>. Ca<sup>2+</sup>-insensitive component of the inward current was increased by lowering [Cl<sup>-</sup>]<sub>0</sub> and blocked by a stillbene derivative, STTS. Voltage-dependent high-threshold (δ-conotoxin sensitive) Ca<sup>2+</sup> currents were depressed during the db-cGMP-induced inward current and facilitated during the outward current. IBMX potentiated the effects of db-cGMP on Ca<sup>2+</sup> channels. CGMP (1 mM) was less potent than db-cGMP (1 mM) in causing both inward and outward currents or modulation of Ca<sup>2+</sup> currents. GTP, GDP, GMP, guanosine, 8-bromo-cAMP and forskolin had no effect on the membrane currents. It is concluded that intracellular cGMP not only activates resting Ca<sup>2+</sup> and Cl<sup>-</sup> channels but also modulates voltage-dependent Ca<sup>2+</sup> channels in VPG neurons.

EFFECTS OF ADENOSINE ON VOLTAGE-DEPENDENT CALCIUM CURRENTS IN MOUSE SPINAL NEURONS. M. Mynlieff\* and K.G. Beam. Dept. of Physiology, Colorado State University, Fort Collins, CO 80523

Adenosine has been shown to reduce evoked release of acetylcholine from the mammalian neuromuscular junction, an effect mediated by A1 receptors and abolished by pertussis toxin treatment. We have previously shown that adenosine (40  $\mu$ M) decreased the transient high-voltage activated (HVA) calcium current (28.9  $\pm$  3.7%, n = 9), the sustained HVA calcium current (23.2  $\pm$  2.7%, n = 9) and T-current (25.0  $\pm$  10.4%, n = 7) in identified mouse motoneurons. Adenosine did not inhibit dihydropyridine potentiated tail current indicating that the inhibition of the sustained HVA current is not due to an inhibition of L type channels. Currently we are using whole-cell voltage clamp recording from large (>15  $\mu m$  in diameter) embryonic mouse spinal neurons to study the pharmacology of the adenosine effect. The A1 agonist, N6-cyclohexyladenosine (CHA) inhibited the transient HVA current (Kd ~ 50 nM, maximal effect = 38.1% inhibition). The non-selective agonist, 5'-N-ethylcarboxamide adenosine (NECA) inhibited the transient HVA current (Kd ~ 31 nM, max. eff. 47.8%) and the sustained HVA current (Kd ~ 43 nM, max. eff. = 34.6%). In contrast to CHA, NECA also showed variable inhibition of the T-current. The A1 antagonist 8-cyclopentyltheophylline (CPT, 100nM) blocked the effect of 250 nM NECA on the HVA currents but not the effect on Tcurrent. These data suggest that the inhibition of HVA current is mediated by A1 receptors and the inhibition of T-current may be mediated by A2 receptors. Since the inhibition of neuromuscular transmission has been shown to be mediated by the A1 receptor, it is likely that this effect is produced by a reduction in the non-L type HVA calcium current. Suppo by NIH grant NS-26416 to KGB and NIH fellowship NS-08769 to MM.

#### 336 11

COMPARISON BETWEEN THE EFFECTS ON CA CURRENT OF AN ADENOSINE ANALOGUE AND THE GENERAL ANAESTHETIC PROPOFOL IN CHICK-EMBRYO SENSORY NEURONS. M.Ottolia, V.Maqnelli, M.Nobile, C.Usai Ist. Cibernetica e Biofisica, CNR, 16146 Genova, Italy, and Ist. Fisiologia Umana, Univ. di Ferrara, 44100 Ferrara, Italy. (Spon: E.N.A.). Adenosine and its analogue are known to interact with some general anaesthetics. We studied Ca current in dorsal root ganglion (DRG) neurons from 10+12 day old chick embryos, treated with the adenosine analogue R-PIA (10 μM) and the general anaesthetic Propofol (300 μM). R-PIA reduced by 50% low-voltage activated (LVA) calcium current in a reversible manner. R-PIA also affected the ω-conotoxin sensitive component of the high-voltage activated (HVA) Ca+current (70% reduction). In cells where the HVA current was almost completely insensitive to this toxin, R-PIA was also ineffective. Both Propofol and R-PIA blocked part of the HVA current, but, when applied together, the resulting current block was the linear sum of the separate reductions. Reciprocal potentiation was not observed. In neurones where Propofol blocked completely the calcium current R-PIA did not produce effects. These results suggest that Propofol interacts mainly with type L channels, while R-PIA acts on type N Ca channels.

## 336.13

THE GENERAL ANAESTHETIC PROPOFOL AFFECTS Ca<sup>++</sup> CURRENT IN CHICK EMBRYO SENSORY NEURONS. R. Olcese, E. Maestrone , M. Nobile, C. Usai\*. Ist. di Cibernetica e Biofisica, CNR, 16146 Genova, Italy, and Ospedale Civile di Sondrio, 23100 Sondrio, Italy. The effects of the general anaesthetic Propofol on calcium current were studied, in dorsal root ganglion neurons from 10÷12 day old chick embryos. Propofol (300  $\mu\text{M}$ ) reversibly reduced both low-voltage activated Ca current (LVA) by 80% and high-voltage activated Ca current (HVA) by 20÷70%. Moreover the anaesthetic modified HVA current inactivation kinetics: with Propofol in the external solution the inactivation time constant  $\tau_{\rm h}$  was approximately the 50% of the control (Propofol:  $\tau_{\rm h} \approx 55$  ms; control:  $\tau_{\rm h} \approx 120$  ms). To discriminate between HVA current components we used  $\omega$ -conotoxin (5  $\mu$ M) that selectively blocks N type Ca channels. We found that the effects of propofol were stronger on  $\omega$ -conotoxin insensitive currents. This result suggests that propofol interacts preferentially with  $\omega$ -conotoxin insensitive "L" type Ca channels. In cell attached patches, Propofol added to the external solution had no effects on channel activity, indicating that the block is mediated by a tight drug-channel interaction.

## 336.15

GTP ANALOGUES MAINTAIN GABAA RECEPTOR FUNCTION IN DORSAL ROOT GANGLION CELLS. D. J. Bradshaw\* and M. A. Simmons Dept. of Pharmacology, Marshall University, Huntington, WV 25755-9310.

Preliminary data from our lab has agreed with previous reports that the hydrolysis of ATP might be necessary for the GABAA receptor to maintain function with repeated agonist exposure. The objective of this study was to evaluate a possible role for GTP on GABAA receptor function. Individual bullfrog dorsal root ganglion (DRG) cells were voltage clamped at -70 mV using whole cell recording. GABA (100 μM) was applied extracellularly via the recording electrode. The GABA-activated inward current was recorded in the presence of tetrodotoxin and cesium. Results are given as the mean percentage of current remaining at 10 and 25 minutes, respectively, postimpalement. When the recording electrode contained no ATP or GTP the response to GABA exhibited run-down to 79% at 10 minutes and 4% at 25 minutes. Inclusion of GTP-γ-S or GMP-PNP (5 mM) protected against this run-down. With GTP-γ-S the responses remaining were 118% and 78% at 10 and 25 minutes, respectively. With GMP-PNP the responses that remained were 108% and 70%. Intracellular application of ATP (1.5 mM) gave similar results. Inclusion of UDP (10 mM) with ATP, to inhibit transphosphorylation, revealed 2 types of neurons. Cells with large initial responses to GABA (mean of -2.86 nA) gave stable responses of 108% and 102%. Cells that had smaller initial currents (-0.16 nA) ran down to 49% and 23%. Our results show that GTP may regulate the function of the GABAA receptor by a mechanism that is distinct from the regulation by ATP.

#### 336.12

INHIBITORY AND EXCITATORY EFFECTS OF ADENOSINE ON CA1 NEURONES IN RAT HIPPOCAMPUS IN VITRO. H. Li²& J.L. Henry Depts of Physiol. & Psychiat., McGill Univ. Montreal, Quebec Adenosine participates in synaptic and metabolic functions in the CNS. Inhibitory actions are brought about by a presynaptic inhibition of transmitter release and through a postsynaptic increase in a K<sup>+</sup> conductance. Recently, we have found in in vivo experiments that a postsynaptic inhibitory effect is blocked by the K<sub>ATP</sub> channel blocker, glibenclamide (Synapse, in press). Experiments were done to explore this possibility in vitro. Results from 64 cells in the CA1 hippocampal region indicated that adenosine and adenosine 5'-monophosphate(AMP) added to the perfusion fluid at 100 μM evoked a hyperpolarization (range 3-15 mV) associated with a 30% reduction in input resistance (range 5-50%; n=32), and blocked EPSPs and IPSPs evoked by stimulation of the stratum radiatum and alveus, respectively. In addition to this well-known hyperpolarization, adenosine and AMP also produced a delayed depolarization associated with an increase in spontaneous spikes in 50% of the cells (n=32); recovery occurred over 30 min. For comparison, baclofen was tested as it is also thought to be coupled to a K<sup>+</sup> channel; 100 μM induced a hyperpolarization similar to that induced by the purines but the delayed depolarization was not observed. When only 1 μM of adenosine or AMP was given no measurable effect occurred on resting membrane potential or input resistance but there was a delayed increase in spontaneous action potentials, suggesting a dose-dependent separation of the inhibitory and excitatory effects. Glibenclamide prevented purine-induced hyperpolarization but did not block the inhibition of PSPs or the delayed depolarization. Our results indicate that the modulation of synaptic transmission in the hippocampus by adenosine involves inhibitory effects mediated via at least 2 or 3 mechanisms, as well as excitatory effects. (Support: Canadian MRC)

NOVEL MODULATION OF VOLTAGE-DEPENDENT SODIUM CHANNELS BY G-PROTEINS IN SENSORY NEURONS, R.Y.K. Pun\* and R. C. Gesteland. Dept. of Physiol. & Biophy., and Dept. of Anat. & Cell Biol.. Univ. of Cincinnati. OH 45267.

Anat. & Cell Biol., Univ. of Cincinnati, OH 45267. There is considerable evidence that voltage-dependent ion channels in excitable membranes are modulated by G-proteins and phosphorylation. We report here a novel action in which the availability of Na<sup>+</sup> channels in frog olfactory neurons (ORNs) is enhanced by GTP and GTP- $\gamma$ -S. The steady-state inactivation of Natcurrents (I<sub>Na</sub>) was shifted ~20 mV towards positive membrane potentials by both GTP and GTP- $\gamma$ -S, whereas the activation was not significantly shifted. Our results indicate that activation of G-proteins, and/or phosphorylation of the Na<sup>+</sup> channels in frog ORNs can lower the threshold for spike generation by increasing the availability of Na<sup>+</sup> channels. This is in contrast to the findings in the heart where G-proteins reduce Na<sup>+</sup> channels availability. Experiments were performed on freshly isolated ORNs using the whole-cell voltage clamp technique. The effects of the nucleotides (100  $\mu$ M) were evaluated by inclusion in the pipet-solution. With pipet solution alone, the V<sub>1/2</sub> for I<sub>Na</sub> inactivation was ~80.2 ± 3.8 mV (n=8; mean ± s.e.m). GTP- $\gamma$ -S and GTP both shifted the V<sub>1/2</sub> to more positive potentials (GTP- $\gamma$ -S, ~61.5 ± 3 mV, n=9; GTP, ~61.7 ± 3.1 mV, n=10; t-test, p<0.01 in both cases). The V<sub>1/2</sub> for I<sub>7/2</sub> sactivation was not shifted significantly (control, ~46.8 ± 2.9 mV, GTP- $\gamma$ -S, 41.1 ± 2.4; n=6). Interestingly, the negative shift in I<sub>Na</sub> inactivation with time was also delayed and reduced when GTP or GTP- $\gamma$ -S was present in the pipet. (Supported by NIH Grants DC 00352 and DC 00347)

## 336.16

PERTUSSIS TOXIN SENSITIVE G-PROTEIN(S) MEDIATE MULTIPLE ACTIONS OF FRRFAMIDE IN AN IDENTIFIED HELISOMA NEURON. E.H. Bahls\* and P.G. Haydon. Department of Zoology and Genetics, Iowa State University, Ames, 1A, 50011.

FMRFamide produces a presynaptic inhibition of transmitter release in neuron B5 of Helisoma trivolvis through multiple pathways. These include a reduction in a voltage sensitive calcium current, a reduction in the responsiveness of secretory machinery to changes in internal calcium and an increase in a potassium current. It has previously been demonstrated that the actions of FMRFamide on calcium current and secretory machinery are mediated through a pertussis toxin (PTX) sensitive G-protein(s). To test for the involvement of a similar G-protein in mediating activation of the potassium current, we injected the A protomer of PTX into acutely isolated B5 somata. PTX injection reduced the magnitude of the FMRF-amide-activated potassium current at 0 mV from  $1.68 \pm 0.66$  nA (n=4, heatinactivated PTX) to  $0.06 \pm 0.24$  nA (n=4) suggesting that a PTX-sensitive G-protein is also involved in mediating the action of FMRFamide on the potassium current.

Arachidonic acid metabolites have been shown to be required for the activation of the potassium current. FMRFamide's activation of potassium current is reduced to  $10\pm7\%$  of control by the phospholipase A2 inhibitor BPB. However, in the presence of  $10\mu$ M BPB, FMRFamide's reduction of calcium current remained at  $87\pm28\%$  (n=7) of control, suggesting that arachidonic acid is not involved in the modulation of calcium current. However, the time constant of the effect of FMRFamide on calcium current is  $1.82\pm0.56$  sec suggesting that other, as yet undetermined second messengers are involved in the reduction of calcium current by FMRFamide.

5.HT ACTIVATES MILLTIPLE SURSTATES OF INWARDLY RECTIFYING K+ CHANNELS IN RAT DORSAL RAPHE NEURONS. N.J.Penington, J.S.Kelly and A.P.Fox Univ.Chicago, Chicago IL, 60637; Univ. Edinburgh U.K.

Single inwardly rectifying K+ channel currents were recorded from acutely isolated adult serotonergic dorsal raphe (DR) neurons using the cell-attached patch (C/A) and outside-out (O/O) configuration. Four equally spaced conductance levels were observed in both modes of recording, with conductance levels averaging 11, 21, 30, and 40 pS but a range of larger conductance levels (50-120 pS) were also seen less frequently. The single channel I-V relation was linear in the range -20 mV to -100mV. The different conductance levels showed direct transitions between each other and apparent direct closures from the higher conductance state. This suggested that they resulted from substates of a single channel rather than several different channels. When the neurotransmitter 5-Hydroxytryptamine (5-HT) was added to the bath, during recording in the C/A configuration, the channels in the patch showed no change in their probability of opening indicating a lack of an easily diffusible second messenger. The single K<sup>+</sup> channel activity however was increased by an average of 670% by the addition of 5-HT to the bath when recording channel activity in the O/O configuration. In high [K+] some single channel activity was always present even in the absence of any ligand. All K<sup>+</sup> channel subconductance levels increased in activity, but in 15 cells the level that increased most was the 30 followed by the 40 pS conductance level. These findings lend further support to the interpretation that the conductance levels may be substates of one another, and that the 30 and 40 pS levels are favored in the presence of 5-HT. If the different conductance levels represented separate channels, the effect of 5-HT would not be expected to be observed on so many conductance levels.

### 336.19

NEUROTRANSMITTER MODULATION OF CALCIUM CURRENTS RECORDED IN RAT SUBSTANTIA NIGRA ZONA COMPACTA NEURONS *IN VITRO*. M.S. Washbum\* and L.T. Meltzer Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI. 48105.

Modulation of calcium currents (I<sub>Ca</sub>s)by various neurotransmitter agents was investigated using whole-cell recordings from substantia nigra zona comapcta (SNZC) dopaminergic neurons in vitro. Such cells were identified electrophysiologically in current-clamp recordings by their broad action potentials, regular pacemaker firing and current-ctamp recordings by their oroxal action potentials, regular paceronaer tiring airong anomalous rectification. We earlier presented evidence for the existence of  $I_{Cas}$  which appeared to represent the T, N and L classes of  $I_{Cas}$  (Soc. Neurosci. Abstr, 1991). In the present study, GABA (10-30  $\mu$ M) reversibly reduced the inward currents evoked by stepping from a holding potential of -80 or -40 mV to a comand potential of 0 mV. These effects appeared to be mediated via activation of GABAB receptors since they occurred in the presence of the GABAA antagonist bicuculline methiodide (30  $\mu M),$  were mimicked by the GABAB agonist baclofen (3-30  $\mu M)$  and were reversed by the GABAB antagonist 2-hydroxysaclofen (100-200  $\mu M).$  Baclofen (10 μM) reduced the high-threshold currents evoked from -40 or -80 mV by approximately 20% and did not affect the voltage-dependence of activation of the currents, although the activation of the currents evoked from -40 mV was slowed in some cells. The the activation of the currents evoked from -40 mV was slowed in some cells. The transient low-threshold calcium current evoked by stepping from -95 mV to between -60 and -35 mV was not reduced by GABA or baclofen. These results provide additional physiological significance for the GABAergic innervation of the SNZC from the striatum and substantia nigra pars reticulata. Furthermore, the results suggest that GABA, in addition to hyperpolarizing SNZC neurons, may modulate the activity of these cells by changing their calcium permeability. A number of other agents were tested for their ability to modulate  $I_{\rm CaS}$  in SNZC cells. The D2 dopamine agonist quinpirole, serotonin, noradrenaline, the metabotropic glutamate receptor agonist trans-ACPD and the cholinergic agonists oxotremorine-M and carbachol (each at a concentration of 10-30  $\mu$ M) had no consistent effect on either the high- or low-threshold  $I_{\rm CaS}$  recorded in SNZC dopaminergic neurons.

INOSITOL TRISPHOSPHATE-MEDIATED CURRENTS IN XENOPUS OOCYTES REFLECT SPATIAL AND TEMPORAL DERIVATIVES OF INTRACELLULAR CALCIUM I. Parker

DERIVATIVES OF INTRACELLULAR CALCIUM I. Parker and Y. Yao. Lab. Cellular and Molecular Neurobiology, Dept. Psychobiology, University of California, Irvine, CA 92717.

Inositol 1,4,5-trisphosphate (InsP3) functions as a second messenger in Xenopus oocytes to liberate Ca<sup>2+</sup> from intracellular stores, and thereby activate a Ca<sup>2+</sup>-dependent membrane CI-conductance. However, signals recorded by fluorescent indicators reveal that elevations of intracellular free Ca<sup>2+</sup> are more prolonged than the corresponding membrane current responses. To resolve this discrepancy, we have imaged intracellular free Ca (using fluo-3) while simultaneously recording membrane currents evoked by agonist application and photorelease of InsP3 from a caged precursor. The results show that the time course of the current corresponds well with the temporal and spatial derivatives of intracellular free Ca<sup>2+</sup> (ie. the rate of rise of Ca<sup>2+</sup> concentration with time and across the oocyte surface). The basis of this effect remains to be determined, but probably does not involve inactivation or desensitization of the Cl<sup>-</sup> channels, since little depression is seen with paired photorelease of Ca<sup>2+</sup> from caged Ca<sup>2+</sup>. Whatever the mechanism, the Cl<sup>-</sup> conductance appears to act as a high-pass filter, so that spikes or oscillations of Ca<sup>2+</sup> are transduced as electrical signals, while steady signals are blocked. This property is consistent with the action Particles. are blocked. This property is consistent with the notion (Berridge et al., Phil. Trans. R. Soc. Lond. B320, 325, 1988) that information transmitted by the InsP<sub>3</sub>/Ca<sup>2+</sup> pathway may be encoded digitally as the frequency of Ca<sup>2+</sup> spiking.

5-HT3 CHANNEL ACTIVATION BY SEROTONIN IS ANTAGONIZED BY COCAINE IN NEURONS FROM RAT NODOSE GANGLION. P. Fan. S. Visentin and F.F. Weight\*. Lab. Molecular & Cellular Neurobiology, National Institute on Alcohol Abuse & Alcoholism, Rockville, MD 20852

Behavioral effects related to cocaine administration have been reported to be altered by 5-HT3 antagonists (Pharmac. Ther. 47: 181-202, 1990). We studied the effect of cocaine on serotonin activation of 5-HT3 channels in neurons freshly dissociated from rat nodose ganglia using the whole-cell patch-clamp technique. Serotonin activated a fast inward current with a concentration-response curve from 0.1 to 100 μΜ (EC<sub>50</sub>=4.55 μΜ; Hill coefficient=1.33). Cocaine produced a concentration-dependent reduction of peak serotonin-activa concentration-dependent reduction of peak serotonin-activated current amplitude (IC $_{50}$ =0.99  $\mu$ M, Hill coefficient =1.15 with 1  $\mu$ M serotonin). Increasing concentrations of serotonin produced a parallel shift to the right of the cocaine concentration-response curve (IC $_{50}$ =4.9  $\mu$ M, Hill coefficient=1.26 with 10  $\mu$ M serotonin). Schild plots revealed an average pA $_{2}$ =5.4 and K $_{B}$ =3.8  $\mu$ M. The results are consistent with competitive antagonism of serotonin activation of neuronal 5-HT3 channels by cocaine. This effect is in a concentration range that occurs in plasma during cocaine abuse.

FMRF-AMIDE MODULATES MULTIPLE IONIC CONDUCTANCES IN THE LEECH RETZIUS CELL. C.L. Sahlev\*1, I.A. Strong<sup>1</sup>, and A. Kleinhaus<sup>2</sup>. <sup>1</sup>Dept. of Biological Sciences, Purdue University, W. Lafayette, IN 47907 and <sup>2</sup>Dept. of Cell Biology and Anatomy, New York Medical College, Valhalla, NY

The Retzius cell (R) is a serotonergic, multifunction neuron which is crucial for the control and integration of vital behaviors. We have previously reported that the endogenous transmitters serotonin (5-HT) and FMRF-NH2 (FMRF) modulate the excitability of the R cell in opposite directions (Acosta et al., J. Exp. Biol., 1989; Kleinhaus & Sahley, Soc Neurosci Abs., 1989). 5-HT inhibits the R cell and decreases the action potential (AP). FMRF transiently depolarized the R cell, broadened its AP and transformed its firing pattern from a "beating" to a "bursting" rhythm. We now present voltage-clamp evidence that FMRF's effects on the R cell can be explained by the modulation of multiple ionic conductances. In the negative potential region (-110 to -30 mV) FMRF transiently induced a voltage independent inward current, (Ins), a nonspecific or divalent cation current. This current is unaffected by altering Na<sub>0</sub>, K<sub>0</sub> (.3 to 30 mM) and Clo (20 to 140 mM) and ClJ and can be observed in solutions with formal  $Ca^{+2}$  or  $Ba^{+2}$  (1 to 8 mM). This current may underlie the FMRF-induced depolarization. In addition, FMRF also increased the amplitude of voltage activated Ca<sup>+2</sup> currents and decreased the amplitude of IA without altering their voltage dependencies. We suggest that these effects account for FMRFs effect on AP duration and increased firing rate. (Whitehall CS, AK; R01 MH 44789 CS)

INTERACTIONS OF DITHIOLS WITH REDUCED OR ARSENYLATED NICOTINIC RECEPTORS AND RECEPTOR PEPTIDES. R.H. Loring, Y.M. Dou, W. Lane, C. Rossant, and E. Hawrot‡. Dept. of Pharmaceutical Scien Northeastern Univ., Boston, MA 02115 & ‡Dept. of Molecular & Biochemical Pharmacology, Brown Univ., Providence, RI 02912.

We have shown that reduced Toppedo nicotinic receptors arsenylated with p-

aminophenylarsinoxide (APA) 1) cannot be reoxidized with dithiobisnitrobenzoate (DTNB), 2) do not bind  $^{125}$ l- $\alpha$ -bungarotoxin (BGT), and 3) are protected against irreversible bromoacetylcholine (BAC) alkylation (Loring, et al., Mol. Brain Res., in press). Effects 1 & 2 are reversed by the antiarsenical dithiol, dimercaptoesulfonate (DMPS). Curiously, DMPS by itself protects reduced receptors against irreversible alkylation by BAC, suggesting that DMPS oxidizes reduced nicotinic receptors. We therefore investigated whether similar dithiols either oxidize or remove APA from various subtypes of reduced or arsenylated nicotinic receptors. In solution, APA forms stable complexes with DMPS, dimercaptosuccinate (DMSA), dimercaptopropanol (BAL), and a reduced peptide of Torpedo receptor ( $\alpha$ 182-197), but does not react with with dithiothreitol (DTT) or mercaptoethanesulfonate (MESA). APA (10 µM) plus 300 µM DTT readily arsenylates immunoimmobilized Torpedo receptors. BAL and DMPS both re-APA from arsenylated Torpedo receptors and protect reduced receptors against alkylation by BAC, while DMSA and MESA do not. Preliminary studies suggest aukylation by BAC, while DMSA and MESA do not. Preliminary studies suggest that DMPS removes APA from an arsenylated Torpedo peptice (α181-198), and that BAL and DMPS reverse the effects of arsenylation on <sup>120</sup>1-BGT binding sites in chick retina, and on <sup>3</sup>H-cytisine binding sites immunoprecipitated from chick brain using mAb299. Thus, APA may be used with DTT to trap a variety of reduced nicotinic receptor subtypes in an arsenylated state, and BAL or DMPS may be used to reverse the effects of APA and to reoxidize the receptors.

A DISULPHIDE BOND IS INVOLVED IN THE AGONIST BINDING SITE OF NICOTINIC ACETYLCHOLINE RECEPTORS IN THE INSECT NERVOUS SYSTEM. D.Bai, C.A Leech and D.B.Sattelle\*. AFRC Laboratory of Molecular Signalling, Department of Zoology, Downing Street, Cambridge, CB2 3EJ, UK.

Insect nicotinic acetylcholine receptors can be functionally expressed in *Xenopus* oocytes following injection of mRNA encoding an  $\alpha$ -subunit alone. These studies indicate that the agonist binding site is located on the a-subunit and sequencing of these subunits has shown the presence of conserved cysteine residues which could form an extracellular disulphide bond. Compounds which reduce disulphide bonds, such as dithiothreitol, inhibit the nicotine-induced depolarization of cockroach motoneurone Df by 55%. This effect can be prevented by high concentrations of agonist suggesting that occupancy of the ligand binding site masks the disulphide bond against reduction. Here we show that the nicotine-induced depolarization in cells with reduced receptors can be restored to control values by treatment with dithionitrobenzoate, which reoxidizes the disulphide bond. These reversible effects on the agonist-induced depolarization suggests an important role of disulphide bonds in the extracellular ligand binding site of α-subunits from insect nervous system nicotinic acetylcholine receptors.

NICOTINIC BINDING IN RAT BRAIN MEMBRANES ENHANCED BY CLASSICAL NEUROLEPTICS A.J. Dwork\* and D. Liu, Neuropathology, Columbia U. and N. Y. State Psychiatric Inst. New York, NY 10032

Various phenothiazines behave as noncompetitive antagonists of peripheral nicotinic acetylcholine receptors (NACHR). Antagonism of central NACHR by neuroleptic drugs could contribute to the effects of these drugs in vivo, and differences among drugs might account in part for different clinical profiles. As a first step in evaluating this possibility, we examined the effects of various neuroleptics on the specific binding of [PH](-)nicotine to rat brain membranes, assuming that noncompetitive antagonists would enhance desensitization and ence increase the affinity of NACHR for agonist. Binding was assayed by filtration, with nonspecific binding determined in the presence of 100 µM carbamylcholine. The assays were performed on ice, neuroleptics were shielded from light, and alcohol was removed from the radioligand before use. Under these conditions, specific binding of 1-2 nm [H](-)nicotine was enhanced 15-45% by either 100 μM thioridazine, 0.01-100 μM haloperidol, or  $100~\mu\text{M}\text{-}1~\text{mM}$  fluphenazine. Neither clozapine nor (-)sulpiride produced any enhancement at concentrations up to 1 mM, and (-)sulpiride inhibited binding in a dose-dependent manner with IC<sub>50</sub>=0.1-1.0 mM. Saturation studies demonstrated a decrease in Kd for (-)nicotine of  $\sim 15\%$  in the presence of 100  $\mu$ M thioridazine or fluphenazine, and of  $\sim 30\%$  in the presence of 100  $\mu$ M haloperidol, suggesting that these drugs do cause a conformational change in brain NACHR consistent with desensitization. Fluphenazine also produced an apparent increase in Bmax (~25%), which could perhaps be explained by exposure of previously sequestered receptors via an effect of the drug on

REDOX EFFECTS OF NEREISTOXIN ON NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) OF CHICK CILIARY GANGLION.

Y. Xie\*, L-H. Tangt, E. Aizenmant & R.H. Loring. Dept. of Pharmaceutical Sciences, Northeastern University, Boston, MA 02115 & ‡Dept. of Physiology, University of Pittsburgh, Pittsburgh, PA 15261
We have shown that nereistoxin (NTX, 4-N,N-dimethylamino-1,2-dithiolane)

blocks nicotinic function in chick retina by reducing nAChRs. Here we examine NTX effects on nAChRs in chick ciliary ganglia. Extracellular recordings reveal that NTX ( $IC_{50} \approx 10 \,\mu\text{M}$ ) inhibits nAChR-mediated synaptic transmission in a long-lasting manner that is not reversible upon washing. The oxidizing agent dithiobisnitrobenzoic acid (DTNB, 1 mM) completely reverses NTX's actions NTX-treated ganglia are irreversibly alkylated by bromoacetylcholine (BAC, 100  $\mu$ M, with 2  $\mu$ M neostigmine). We find similar results in preliminary studies using the whole-cell patch-clamp recording technique. 100  $\mu$ M NTX substantially blocks inward currents in ciliary ganglion cells induced by the nicotinic agonist DMPP ( $100 \mu M$ , 1 sec). DTNB ( $500 \mu M$ , 1 min) completely reverses NTX's inhibition. These studies suggest that NTX reduces nAChRs of chick ciliary ganglia and thus inhibits nicotinic function. In intact chick ciliary ganglia, 30 µM DMPP only weakly protects nAChRs against NTX reduction (23% of control) but substantially protects nAChRs against reduction by dithiothreitol (2 mM; 86% of control). We find that NTX is a potent and selective reducing agent for nAChRs and has no effect on NMDA receptors. We hypothesized that NTX might diffuse across the cell membrane to be reduced to dihydronereistoxin, which could reduce the disulfide bond near the agonist binding site of nAChRs. However, low pH (4-6) decreases NTX potency only 10-15 fold, whereas high pH (8-10) slightly enhance NTX inhibition (~2 fold). Thus, protonized NTX (NTX pK<sub>a</sub>=7.2) still blocks nAChRs. The precise mechanism of NTX's actions remains to be determined. (Supported by NS22472, DA04975, and the Smokeless Tobacco Research Council).

NEW ACETYLCHOLINE RECEPTOR LIGANDS FROM CONUS VENOMS.

NEW ACETYLCHOLINE RECEPTOR LIGANDS FROM CONUS VENOMS. L. J. Cruz\*. C. Hopkins, J. Torres, J. Dykert. C. Miller, D. Yoshikami, B. M. Olivera, and J. Rivier. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112, Marine Science Inst. U. P. Diliman, Philippines, and Clayton Foundation Laboratories for Peptide Biology, Salk Institute, La Jolla, CA 92037. The venoms of fish-hunting Conus species have provided a number of ligands for ion channels and receptors. Among these are 6 homologous  $\alpha$ -conotoxins (13 - 15 amino acids long with 2 disulfide bonds) which inhibit nicotinic acetylcholine receptors and compete with the binding of  $\alpha$ -bungarotoxin. Recently 3 new conotoxins paralytic to fish and acting on nAChR have been isolated, sequenced and synthesized. Two of these are structurally very different from the known  $\alpha$ nAChR have been isolated, sequenced and synthesized. Two of these are structurally very different from the known  $\alpha$ -conotoxins; one represents a novel class of nAChR ligands. The 23-amino acid peptide from C. purpurascens (conotoxin PIII) reversibly decreases the peak of the endplate current and accelerates the decay of the epc. The ability of conotoxin PIII to affect the kinetics of the epc distinguishes it from most other AChR antagonists and suggests a use-dependent block of the AChR. The other peptide from C. purpurascens ( $\alpha$ A-conotoxin PI) has 25 amino acid residues and 3 disulfide bonds, and blocks postsynantic responses to introportically applied conotoxin PI) has 25 amino acid residues and 3 disulfide bonds, and blocks postsynaptic responses to iontophoretically applied carbamylcholine and competes with the binding of  $\alpha$ -bungarotoxin. Thus, it behaves as an  $\alpha$ -type toxin although its structure is very different from that of known  $\alpha$ -conotoxins. AChR ligands from Conus species with different feeding preferences are currently being characterized.

# 337.6

DEFINITION OF A NOVEL AGONIST BINDING SITE ON NICOTINIC ACETYLCHOLINE RECEPTORS (nAChrs). T. Tano<sup>1,2\*</sup>, E.F. R. Pereira<sup>1,2</sup> A. Maelicke<sup>3</sup> and E.X. Albuquerque<sup>1,2</sup> Pept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD, USA, 21201; <sup>2</sup>Lab. Mol. Pharmacol. II, IBCCF, RJ, Brazil, 21944; <sup>3</sup>Inst. Physiol. Chem., Johannes-Gutenberg Univ. of

Med. Sch., Duesbergweg, D-6500 Mainz, Germany.

Recent studies have demonstrated that physostigmine (Phy) activates nAChRs from several sources (Mol. Pharmacol., 28:527, 1985; Eur. J. Biochem., 200:671, 1991; Soc. Neurosci. Abs., 17:233.15, 1991). However, the agonist action of Phy observed in Torpedo vesicles, cell-attached patches obtained from single fibers of frog interosseal muscle and outside-out patches excised from cultured fetal rat hippocampal neurons were not blocked by competitive nicotinic antagonists. On the on the hand, benzoquinonium (BZQ), a competitive and non-competitive antagonist at nAChRs, blocked the agonist action of Phy in all these preparations. Here, using outside-out patches obtained from fetal rat hippocampal neurons grown in culture for To 3-25 days, we showed that BZQ ( $1 \mu M$ ) also activated single channel currents in the presence of APV (50  $\mu M$ ), atropine (1  $\mu M$ ) and TTX (0.3  $\mu M$ ), which resembled those evoked by Phy and had conductances of about 28 and 42 pS. Furthermore, photolabeling studies carried out in *Torpedo* membranes revealed that the binding site of Phy on the nAChR was located just a few positions in front of the disulfide-bridged loop, Cys-128-Cys-142. Most of the labeling appeared on the Lys-125. This residue (and its nearest neighbors) is conserved in most nAChR  $\alpha$ -polypeptides, This residue (and its nearest neighbors) is conserved in most  $\Lambda$ ChR  $\alpha$ -polypeptides, but is absent in non- $\alpha$  polypeptides (TiBS, 12:199, 1988; TiPS, 11:485, 1990). Clearly, the area around and including Lys-125 is within the N-terminal hydrophilic domain of the  $\alpha$ -subunit, a region well suited for the binding of extracellular ligands. The Phy site thus appears to be located adjacent to, but separate from the ACh binding site on the extracellular side of the nAChR. These results raised the question whether there is an endogenous agonist for this binding site, and if so, what the physiological relevance of such a finding would be. Support: U.S. Army Med. Res. & Devel. Comm. DAMD 17-88-C-8119 & USPHS NS25296. CNPq Fellow (EFRP).

AGONIST SENSITIVITY OF THE NICOTINIC ACETYLCHOLINE RECEPTORS (nAChR) OF FETAL RAT HIPPOCAMPAL NEURONS IN CULTURE. M. Alkondon\* and E.X. Albuquerque. Dept. Pharmacol. Exp. Ther., Univ. Maryland, Sch. Medicine, Baltimore, MD 21201.

In the present study, we used the whole cell patch clamp technique to characterize further the subtype/s of nAChR present on cultured fetal rat hippocampal neurons. Several nicotinic agonists such as (+)Anatoxin-a (AnTX) (1-50  $\mu$ M), cytisine (10-300  $\mu$ M), DMPP (10-600  $\mu$ M), (-)nicotine (10-300  $\mu$ M), acetylcholine (ACh) (10-600  $\mu$ M) and carbachol (10-1200 μM) evoked whole cell currents, whose peak amplitude increased in a concentration-dependent manner. Among these agonists, AnTX showed the highest potency while carbachol showed the least. Increasing the concentration of each of the agonists shortened the rise time and also accelerated the decay phase of the whole cell currents which followed the peak during a brief agonist pulse of 1-2 sec. Hill plot analysis gave slope value of more than one, indicating the possible involvement of two agonist binding sites. The EC50 values determined from these plots showed some variation among different neurons (2-3 fold). Also, the measured peak amplitude of the whole cell currents activated by higher concentrations of the agonists was surprisingly larger than that predicted from the double reciprocal plot using lower range of agonist concentrations. These results suggest that there may be more than one subtype of nAChR on the fetal rat hippocampal neurons grown in culture. Support: U.S. Army Med. Res. & Devel. Comm. Contr. DAMD-17-88-C-8119 and USPHS NS25296.

## 337.9

CHRONIC NMDA RECEPTOR ACTIVATION DOWN-REGULATES NEURONAL NICOTINIC RECEPTOR IN CULTURED CEREBELLAR GRANULE CELLS. M. Didier, S.A. Berman AND S. Bursztajn\*, Mailman Res. Ctr, McLean Hosp/ Harvard Med. Sch. Belmont, MA 02178.

Nicotinic acetylcholine receptors (nAchRs), as other calcium permeable channel-receptors, may play a crucial role during neuronal development. We have characterize nAchRs in developing cerebellar granule cells in primary culture which require high concentration of K+ or NMDA to survive and differentiate. L-[3H] nicotine binding experiments revealed the presence of a single class of saturable and specific binding sites, having a high affinity for or incotine (2 nM). The nicotinic binding site expression followed a transient developmental pattern with a peak during the synaptogenesis period in high K+culture condition (Bmax in order of 200 fmole/ mg protein). Nicotine-dependent 45Ca2+ uptake was d-tubocurarine-sensitive and shared a similar developmental pattern (i.e. a maximum around 10-14 days in culture). In contrast, chronic application of NMDA decreased by 50 % the total number of nicotine binding sites with no change in the affinity for nicotine and correlated with a reduction in nicotine-activated 45Ca2 + uptake. Sensitivity to NMDA receptor antagonists as well as to removal of glutamate by pyruvate transaminase treatment suggest a glutamatertgic component in the nicotinestimulated 45Ca2+ influx. Preliminary results using monoclonal antibodies, revealed the presence of alpha4 and beta2 subunits in most of neurons. Nonneuronal cells did not express nAchRs as shown by [3H]nicotine binding and immunocytochemistry. The time-dependent specific nAchRs expression and the potential association between nAchRs and the NMDA receptor activation suggest that nAchRs may regulate the glutamatergic activity during synaptogenesis. Moreover, the NMDA receptor could modulate the nAchRs expression in the developing central nervous system. Further experiments, using molecular probes, are in progress to determine the nAchR subtypes expressed and the potential change in their expression by chronic NMDA treatment.

## 337.11

CARDIOVASCULAR RESPONSES TO NICOTINE IN THE PARAVENTRICULAR NUCLEUS OF THE RAT. A.A. Houdi\*, R.T. Dowell, M. Welch and J.N. Diana Tobacco and Health Research Institute and College of Pharmacy and Dept. of Physiology, University of Kentucky, Lexington, KY 40546.

Although the central effects of nicotine in mediating sympathoadrenal and cardiovascular responses are well documented, the precise mechanisms and the brain sites involved in mediating these central effects of nicotine remain undefined. The paraventricular nucleus (PVN) has been suggested as site of integration for autonomic and endocrine cardiovascular responses. In this study, we investigated the role of the PVN in nicotine -induced alteration in mean blood pressure (MAP), heart rate (HR) and peripheral vascular resistance in conscious, freely moving rats. Bilateral administration of nicotine (4.5ug/0.1ul/site) into the PVN produced dose dependent rapid, and marked increase in MAP (+28 mmHg) and a mild decrease in HR (-13 bpm). Nicotine into the PVN also produced a significant parallel increase in mesentric vascular resistance (+100% of control) but had no appreciable effect on either iliac or renal vascular resistances. On the other hand, intracerebroventricular (icv) administration of nicotine (19ug/rat) produced a lesser increase in MAP and a more pronounced bradycardia when compared to PVN administration. Also, icv administered nicotine, increased both mesentric and iliac vascular resistances (+60% and +40% of control, respectively). Intra-arterial (i.a.) administration of nicotine (0.1mg/kg) produced a lesser increase in MAP and a marked decrease in HR compared to either icv or PVN administration. Nicotine, administered i.a., also increased mesentric and renal váscular resistances (+60% and +50% of control respectively) and an initial decrease followed by an increase in iliac vascular resistance. This effect of nicotine was dose dependent. Saline treatments of rats had no significant effects on cardiovascular parameters. These data suggest that PVN nicotinic receptors play a major role in central sympathoadrenal activation by nicotine, while i.a. and icv administration of nicotine activates both sympathetic and parasympathetic nervous system components.

RECEPTORS D.J. Anderson\*, J.L. Raszkiewicz, and S.P. Amerić, Neuroscience, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL 60064. Regionally selective loss of neuronal nicotinic receptors (nAChRs) labeled by [3H](-)nicotine ([3H]NIC) has been correlated with age- and disease- associated dementias. Recently nicotine has been shown to improve performance of learning and memory tasks in aged rodents, monkeys and humans. This study sought to determine: 1) whether similar age and regionally selective losses could be detected with the new nicotinic ligand, [3H]cytisine ([3H]CYT); and 2) whether the relative affinities of 8 reference compounds were altered by age or region. Washed membranes were prepared from the frontoparietal cortex (CX), striatum (STR), hippocampus (HPC), and brain stem (BS) of male Sprague-Dawley rats which were 3-4 months or 27 months of age. Brain areas were pooled from groups of three animals. Maximal binding was determined with 4 nM [ $^3$ H]CYT and 6 nM [ $^3$ H]NIC using 10  $\mu$ M (-)NIC to determine nonspecific binding. K, values for reference compounds were determined from concentration-inhibition curves using 1.2 nM [<sup>3</sup>H]CYT. Aged animals showed a similar reduction of receptor density in all brain areas investigated. The decreases in [3H]CYT and [3H]NIC binding were 24% and 29% in STR, 23% and 25% in CX, 21% and 20% in HPC, and 26% and 24% in BS respectively. The rank order potencies of reference compounds against [3H]CYT were: Cyt> anatoxin-A> (-)NIC> lobeline = MCC> DMPP> (+)NIC> DHβE. No differences in rank order or affinity were seen between the young and aged animals for each of the brain regions, although regional differences in affinity do exist. The age-related loss of nAChRs independent of a change in the affinity of ligands for the receptor supports the concept that the therapeutic potential of nicotinic

AGE RELATED CHANGES IN RAT BRAIN NEURONAL NICOTINIC

agents will be maintained with age.

MODULATORY ROLE OF NICOTINE ON NMDA-INDUCED INCREASES IN CGMP LEVELS IN RAT CEREBELLAR SLICES. Pamala Adams, Hong Cheng, Kathy Kohlhaas, Stephen P. Arneric and James P. Sullivan\*. Neuroscience, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL, 60064-3500

Accumulating evidence suggests that pharmacological similarities exist between nicotinic receptors and the glutamate receptor specific for N-methyl-D-Aspartate (NMDA). The nicotinic agonists (-) nicotine and lobeline partially inhibit NMDA-induced responses in cultures rat cortical neurons and displace [3H] MK-801 binding in washed membranes ( Aizenman et. al., Brain Res. 551: 355, 1991). The present study investigates the effect of nicotine on NMDA-induced increases in cGMP levels in rat cerebellar granule slices.

Slices (0.4 mm) were prepared from 8-10-day-old Sprague-Dawley rat cerebella and incubated at 37° for 60 min. in Krebs-Henseleit buffer. The slices were subsequently exposed to NMDA for 3 min. and cGMP levels determined by radioimmunoassay as described previously (Steiner et. al., J. Biol. Chem. 247: 1106, 1972). Addition of NMDA (100 μM) caused cGMP levels in the slices to rise Addition of Minda (100  $\mu$ m) caused color levels in the sites to lise from < 1 to about 110 pmol/mg protein (n=5; p<0.05). Preincubation of the slices with nicotine (100  $\mu$ M) for 5 min. completely inhibited this response (n=4; p<0.05). The inhibition was half-maximal at about 1  $\mu$ M. No changes in cGMP levels were observed when nicotine (100-1000  $\mu$ M) was administered on its own. These results suggest a role for nicotine in modulating the increases in cGMP levels elicited by activation of NMDA receptors.

Current evidence suggests that the cerebral
microvasculature is directly influenced by
cholinergic nerve input and certain cholinergic
agents. In this study we measured nicotinic
cholinergic receptors associated with the brain
microvasculature using [H]acetylcholine (ACh) and
[H]nicotine as ligands in cerebral microvessels
(CMV) isolated from postmortem human and pig [H]nicotine as ligands in cerebral microvessels (CMV) isolated from postmortem human and pig brains. Specific binding sites for ACh (displaced by carbachol and in presence of 1 nM atropine) were higher in CMV (71 ±17 and 22 ±7 fmol/mg protein for human and pig, respectively) compared to cerebral cortex (27 ±4 and 16 ±2; n=3-6; at about Kd conc.) irrespective of species. Similar results were obtained with [H]nicotine binding. In contrast, [H]pirenzipine and [H]QNB binding, indices for muscarinic receptors, wre low (about 10-20% of cortex) in CMV compared to the cerebral cortex in both species. These results and other studies on the localization of receptor mRNAs suggest that CMV contain nicotinic receptors which may be involved in the modulation of the cerebral may be involved in the modulation of the cerebral microcirculation by cholinergic neurons.

MUSCARINIC AGONIST OXOTREMORINE-M EVOKES NICOTINIC RESPONSE IN CELIAC GANGLION NEURONS. <u>S.R. Knoper. J.S. Coggan. H. Xian. D.L. Kreulen and R. Gruener\*</u>. Depts. of Pharmacol., Physiol. and Internal Med., Univ. of AZ, Tucson, AZ.

Oxotremorine-M (Oxo-M, RBI, Inc.) is commonly used as a selective muscarinic agonist (Birdsall et. al., 1978). In guinea pig celiac ganglion neurons in primary culture Oxo-M elicits fast inward current transients, in addition to slow muscarinic transients, under whole cell voltage clamp which were similar to nicotinic responses evoked by acetylcholine (ACh) and 1,1-dimethyl-4-phenyl-piperazinium iodide (DMPP). The potency for Oxo-M (EC<sub>50</sub> = 300  $\mu$ M) was less than that for ACh (EC<sub>50</sub> = 50  $\mu$ M). The reversal potentials of Oxo-M and ACh responses were near 0 mV. Neither response showed rectification. Reduction in [Na+]o shifted the reversal potential toward hyperpolarized potentials. The nicotinic receptor antagonist dtubocurarine (dTC, 30 µM) blocked the inward current response to Oxo-M. In contrast the muscarinic antagonist atropine (1.2 µM) did not attenuate the response. Another selective muscarinic agonist, oxotremorine (sesquifumarate salt), did not produce any nicotinic response, HL-27781, Lilly Research Labs.

### EXCITATORY AMINO ACIDS: ANATOMY AND PHYSIOLOGY II

## 338.1

METABOTROPIC EXCITATORY AMINO ACID RECEPTOR ACTIVATION TRIGGERS RESPONSIVENESS OF PURKINJE CELLS TO THE TROPHIC ACTION OF NGF H. Mount.\* C.F., Dreyfus, & I.B. Black, Dept. Neuroscience & Cell Biology, Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ 08854.

Johnson Medical School, UMDNJ, Piscataway, NJ 08854.

We have previously reported that trophic factors and neurotransmitters in concert regulate survival of cultured rat cerebellar Purkinje cells (Cohencory et al. J. Neurosci. 11, 462, 1991). In particular, excitatory amino acid (EAA) transmitters and nerve growth factor (NGF) increased survival, whereas neither alone was effective. In the present studies, we sought to identify molecular mechanisms through which EAAs participate in the trophic interaction.

trophic interaction.

Initially, we characterized the potential role of ionotropic EAA receptors by employing the antagonists MK-801, D-APV and DNQX. Each increased cell number, suggesting that endogenous ionotropic activity decreased survival. To determine whether metabotropic EAA receptor stimulation modulates survival, the metabotropic agonist ACPD [15,3R]-1-aminocyclopentane-1,3-dicarboxylic acid, 1 µM) was tested. ACPD alone had no effect on survival. However, simultaneous exposure to ACPD and NGF increased Purkinje number. Moreover, this increase in survival was blocked by the selective metabotropic antagonist, L-AP3 (L(+)-2-amino-3-phosphono-propionic acid, 1 µM). Use of L-AP3, in the absence of added agonist, reduced cell number, suggesting that endogenous metabotropic stimulation is normally necessary for survival. In sum, these studies reveal a novel mechanism whereby an excitatory neurotransmitter shapes neural development by simultaneous neurotoxic and neurotrophic actions that are

respectively mediated by ionotropic and metabotropic receptors.

Glutamate receptor channels on embryonic Drosophila myotubes: Ion permeation
H. Chang, S. Ciani & Y. Kidokoro\*
Jerry Lewis Center, UCLA School of Medicine, L.A.,
CA 90024, \*Present address: Gunma University
School of Medicine, 39-22 Showa-machi 3-chome,
Maebashi 371, Japan

The ion permeation mechanism of the glutamate receptor channel in embryonic Drosophila myotubes was studied using the patch clamp technique in the inside-out configuration. The channel was found cation-selective. When the Na' concentration was 140mM on both sides of the patch membrane the current-voltage relation was straight between -100 and +100mV and the single channel conductance was 159pS. When the Na' concentration was reduced symmetrically the I-V curve remained straight but the slope declined. The conductance-activity relation for Na' was described by a hyperbolic curve. The maximal conductance was 196pS and the half-saturating activity was 40mM. In the bi-ionic condition the reversal potential was measured and K', Rb', Cs' and NH<sub>4</sub>' were found to have similar permeabilities as Na' but Li' had a smaller permeability. Divalent cations, Ca' and Mg<sup>2+</sup>, permeated the channel but reduced the single channel conductance. A model based on the Eyring rate theory with two binding sites was used to fit these data.

### 338.2

NMDA EXPOSURE REDUCES INTRACELLULAR pH JN CULTURED HIPPOCAMPAL NEURONS. <u>K.M. Raley-Susmant, R. R. Kopitott, and R. M. Sapolskytt.</u> † Dept. of Biology, Vassar College, Poughkeepsie NY 12601; †† Dept. of Biological Sciences, Stanford University, Stanford CA 94305.

Previous work has demonstrated transient changes in pH associated with exposure to GABA and glutamate . Further, changes in extracellular pH have profound effects on NMDA receptor-mediated currents (Traynelis and Cull-Candy, Nature 345:347. 1990). Thus, pH changes appear to play an important modulatory role in neuronal function. In this study, we analyzed the changes in intracellular pH (pHi) in cultured hippocampal neurons in response to bath application of NMDA, under constant extracellular pH conditions . Briefly, cultured hippocampal neurons, days 10-12 in culture, were loaded with the pH indicator dye, BCECF. Intracellular pH was determined as the change in the ratio of emission at 499 and 439 nm. Cells were superfused with Ringer's solution (pH 7.4), buffered with HCO<sub>3</sub>/CO<sub>2</sub>. Following measurement of basal intracellular pH for 1-2 min, cells were exposed to Ringer's containing different concentrations of NMDA (10, 100, 500, 1000 μM) for 1 min. Solutions were switched back to normal Ringer The average basal pH<sub>i</sub> of the neurons tested was 7.195  $\pm$  0.045 (n= 42 neurons). Superfusion with 500  $\mu$ M NMDA produced an acidification of intracellular pH (average  $\Delta$ pH<sub>i</sub> -0.164  $\pm$  0.019 pH units). In most cases, the acidification was transient. The acidification occurred over a wide range of NMDA concentrations, and occurred in the presence and the absence of HCO3. Intriguingly, the effect of NMDA on intracellular pH exhibited a refractory period of several minutes. These results suggest that NMDA exposure can have a substantial effect on intracellular pH, which could have profound effects on cellular metabolism and neuronal function.

1S,3R-ACPD POTENTIATES AMPA- AND SUPPRESSES MUSCIMOL-CURRENTS IN THE NUCLEUS OF THE TRACTUS SOLITARIUS (NTS). Steven R. Glaum & Richard J. Miller. Dept. Pharm. Phys. Sci. The University of Chicago, 947 E. 58th, Chicago, IL 60637. The NTS is the principle central nucleus for the coordination of cardiovascular, respiratory and visceral autonomic reflexes. We recently

The NTS is the principle central nucleus for the coordination of cardiovascular, respiratory and visceral autonomic reflexes. We recently reported that the metabotropic glutamate (GLU) receptor agonist 1S,3R-ACPD inhibited EPSCs and IPSCs evoked from the region of the tractus solitarius (TS) and also produced a direct postsynaptic excitatory effect mediated by the reduction of a K' current (Glaum & Miller, JNS, in press). The latter effect, mimicked by high frequency stimulation of the TS, was occluded in the presence of 1S,3R-ACPD, suggesting endogenous GLU can activate ACPD receptors. We have now examined the effects of 1S,3R-ACPD (2-100µM) on postsynaptic currents evoked by pressure-ejection of the GLU agonist AMPA (I<sub>ADPA</sub>) and the GABA-A agonist muscimol (I<sub>ADPA</sub>) onto neurons located in the dorsomedial subdivision of the NTS adjacent to the area postrema in transverse brainstem slices. We also compared the effects of 1S 3R-ACPD and high frequency TS stimulation on I...

to the area postrema in transverse brainstem slices. We also compared the effects of 1S,3R-ACPD and high frequency TS stimulation on I<sub>MOSC</sub>.

Whole-cell patch recordings of visually-identified cells were made with K-gluconate electrodes in the presence of TTX (0.5μM) and either DNQX (10μM)D-APS (50μM) or bicuculline (10μM). 1S,3R-ACPD reversibly reduced the amplitude of I<sub>MOSC</sub> by 10-80% (n=17). The effect did not desensitize with repeat exposure to 1S,3R-ACPD and was not affected when cells were dialyzed with GTP-¥-S (40μM, n=4). In the absence of TTX, SOHz stimulation of the TS also suppressed I<sub>MOSC</sub> an effect occluded by 1S,3R-ACPD (100μM). In contrast, I<sub>MOSC</sub> was potentiated in the presence of 1S,3R-ACPD by 113-428% (n=19) in a reversible, non-desensitizing, GTP-¥-S-insensitive (n=3) manner. These effects are discussed in reference to the role of GLU and GABA at baroreceptor afferent synapses. Supported by DA-02575, DA-02121 & MH40165.

ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS DECREASES SYNAPTIC INHIBITION IN HIPPOCAMPUS BY REDUCING EXCITATION OF INHIBITORY INTERNEURONS. Manisha A. Desai\* and P. Jeffrey Conn. Dept. of Pharmacology, Emory University School of Medicine, Atlanta, GA 30322

We have previously shown that the selective metabotropic glutamate receptor agonist trans-1-amino-1,3-cyclopentanedicarboxylic acid (t-ACPD) decreases synaptic inhibition in hippocampal area CA1. We now report a series of experiments aimed at determining the mechanism of t-ACPD-induced disinhibition. Our data support the hypothesis that t-ACPD decreases inhibitory postsynaptic potentials (IPSPs) by decreasing synaptic excitation of inhibitory interneurons. This is based largely on the finding that the active isomer of t-ACPD, 1S,3R-ACPD does not decrease monosynaptic IPSPs elicited by stimulation of inhibitory interneurons in the presence of glutamate receptor antagonists nor does it decrease spontaneous IPSPs recorded in pyramidal cells. We also found that 1S,3R-ACPD reduces both feedforward and recurrent inhibition. Furthermore, 1S.3R-ACPD decreases both the fast (GABAa) and slow (GABAb) components of The GABAa component of the IPSP is mediated by interneurons at the stratum oriens/alveus border and basket cells. In contrast, GABAb IPSPs are mediated by interneurons in the stratum lacunosum/moleculare. Thus, 1S,3R-ACPD is likely to reduce synaptic excitation of both of these groups of interneurons.

DEVELOPMENTAL CHANGE OF NMDA RECEPTOR-MEDIATED EXCITATORY POSTSYNAPTIC CURRENTS IN RAT VISUAL CORTICAL NEURONS. G. Carmignoto\* and S. Vicini FGIN, Georgetown Univ., Wash. DC Following the hypothesis that in the visual cortex NMDA receptors partecipate in

experience-dependent modifications of synaptic strength, we investigated whether a change of the functional properties of NMDA receptors involved in synaptic transmission is one of the cause for the age-dependent decline of visual cortical plasticity. NMDA receptor function was studied in coronal slices prepared from Whole-cell patch-clamp recordings were used to study rats of various age. spontaneous and evoked post-synaptic currents (EPSCs). Pure NMDA-mediated EPSCs were recorded from layer IV neurons in response to stimuli applied to either the white matter or various intracortical locations in the presence of 10 µM NBQX and 10 µM bicuculline methiodide. These EPSCs recorded at a holding potential 50 mV positive to the reversal potential (4 ± 2 mV, mean ± SD, n=20) were best described by a two component exponential decay with a fast (30-70 msec) and a slow (200-300 msec) time constant. The relative contribution to the EPSC amplitude of the slow component changes dramatically with age, decreasing from 100 % (n=14) at day 9 to less than 20% (n=11) at day 35. The time course of spontaneous NMDA receptor mediated EPSCs matched that of evoked currents. This decrease was significantly delayed in dark reared rats and it was completetely prevented in animals whose neuronal cortical activity was totally blocked by daily intracortical TTX injections (0.5 mM in 2 µl citrate buffer). These results indicate that the age-dependent decline of visual cortical plasticity is associated with a change in synaptic NMDA receptor function. Current experiments are exploring in outside-out patches excised from layer IV visual cortical neurons of developing rats the intrinsic kinetic properties of NMDA receptor-channels which may underlie this change. Supported by NIH grant PO1 NS 28130.

## 338.9

CORTICOSTEROID ACTIONS ON SYNAPTIC TRANSMISSION IN THE RAT CA1 HIPPOCAMPAL AREA. M. Joëls and E.R. de Kloet\*. Exp. Zoology, Univ. Amsterdam and \*Leiden Univ., The Netherlands.

The rat adrenal hormone corticosterone enters the brain and binds to mineralocorticoid (MRs) and glucocorticoid receptors (GRs). We studied the effect of MR- and GR-occupation on intracellularly recorded EPSPs, f(ast) IPSPs and l(ate) IPSPs evoked in hippocampal CA1 neurons of adrenalectomized (ADX) rats by stimulation of the Schaffer collaterals. We used maximal stimulus intensity, which evoked a large EPSP at the Erev for the fIPSP but was just subthreshold for an action potential, and an intensity that evoked a half-maximal EPSP. Recording was performed at Erev for the fIPSP (ca. 73mV) and 7mV depolarised from this level (suprathreshold for induction of action potentials). We compared synaptic responses before, during steroid application (20 min.) and up to one hour after steroid treatment. In another set of experiments we compared synaptic responses before steroid application with responses in other neurons obtained 1-4hrs after steroid treatment. In control recordings from ADX rats resting membrane potential, resistance, accomodation and afterhyperpolarization (AHP), EPSP- and fIPSP-amplitude did not change over 80 min.; however, the number of action potential evoked by maximal synaptic stimulation at Erev+7mV decreased. Occupation of MR prevented this decrease. GR-activation reduced both the number of action potentials and the EPSP-amplitude. Regardless of the steroid-treatment IIPSPs diminished in time. The steroid-actions on synaptic transmission do not seem to be long-lasting since 1-4 hrs after application EPSP-, fIPSP- and IIPSP-amplitudes were no longer different from the controls. By contrast, GR-mediated increases of the AHPamplitude (confirming previous findings) predominantly occur after such a long delay. We conclude that corticosteroids have a short-term effect on synaptic transmission in the CA1 area such that MR-occupation maintains the excitability while GR-activation decreases EPSP-amplitude and excitability.

PROTECTION FROM NMDA-INDUCED DELAYED INJURY IN THE HIPPOCAMPAL SLICE WITH BRIEF POST-NMDA MAGNESIUM.
R.A.Wallis\* and K.L.Panizzon. Neuronal Injury Laboratory, Dept. of Neurology, UCLA Sch. of Med., Los Angeles, CA 90024.

Delayed neuronal injury induced by NMDA receptor activation appears to exacerbate neuronal damage seen with ischemia and trauma. investigated the role of delayed opening of the NMDA receptor associated channel in this injury, using the hippocampal slice as an in vitro model of delayed injury. With this preparation, exposure to  $10~\mu$ M NMDA for a mean of  $5.3~\pm~0.6$  mins., produced rapid loss of the orthodromic CA1 population spike (PS). This potential returned with perfusion of standard artificial CSF. However, the orthodromic CA1 PS could be elicited thereafter for only a mean 12.4  $\pm$  1.6 hrs., compared to paired, unmedicated slices, in which a PS could be evoked for a mean of 22.6  $\pm$ 4.0 hrs. With final loss of the orthodromic CA1 PS, the antidromic CA1 PS was lost as well, suggesting that delayed PS loss was due to neuronal cell injury, rather than effects of synaptic depression. High magnesium treatment, given after NMDA exposure, protected against NMDA-induced delayed PS loss. With perfusion of artificial CSF containing 10 mM magnesium for 35 mins. after NMDA exposure, the orthodromic CA1 PS could be evoked for 20.3  $\pm$  2.1 hrs. In paired slices receiving NMDA exposure only, this potential could be evoked for only 13.8  $\pm$  1.0 hrs. These data suggest that brief NMDA exposure induces a persistent open state of the NMDA receptor associated channel, which may be an important component in the evolution of NMDA-induced delayed neuronal injury. They additionally indicate that blockade of these channels after NMDA receptor activation can protect against the later development of delayed injury.

## 338.8

GLUTAMATE-ACTIVATED **CURRENTS** WITH SLOWER DESENSITIZATION RATES IN OUTSIDE-OUT PATCHES FROM SPINY VS. ASPINY HIPPOCAMPAL HILAR NEURONS C.T. Livsey\* and S. Vicini FGIN and Dept. of Pharmacology, Georgetown Univ., Washington.,

The desensitization rate of non-NMDA glutamate receptors was investigated in outside-out membrane patches obtained from morphologically-identified spiny "mossy cells" (SMCs) and aspiny hilar interneurons (AHIs) in young rat pocampal slices. The fast (less than 0.2 msec on rate) application of a 1 mM pulse of L-glutamate for 100 msec in the presence of TTX (1  $\mu M)$  and MK801 (10  $\mu M$ ) onto patches produced large (30-1000 pA mean amplitude) glutamate-activated currents (GACs) that decayed exponentially despite the continued presence of agonist. These desensitization rates differed markedly between patches obtained from the two cell types,  $8.0 \pm 1.9$  ms (mean  $\pm$  SD) in 15 SMCs compared to 2.2 ± 0.41 ms in 8 AHIs. Spontaneous excitatory postsynaptic current (sEPSC) decay time constants in the same neurons averaged  $8.2 \pm 2.8$  ms and  $2.7 \pm 0.71$  ms, respectively. Current to voltage relationships of the GACs did not differ between SMCs and AHIs, with comparable reversal potentials and no evidence of outward rectification. An increase of the L-glutamate concentration to 5 mM increased GAC amplitudes but did not affect desensitization rates. Brief (< 2 ms) pulses of 1 mM glutamate produced rapidly decaying (2.3  $\pm$  0.3 ms, n=7) GACs that were indistinguishable between the two neuronal classes. The difference in desensitization rates between SMCs and AHIs might demonstrate a functional correlate to the substantial heterogeneity in the molecular structure of glutamate receptor subunits. Supported by NIH grant PO1 NS 28130.

VOLTAGE DEPENDENCE OF SPONTANEOUS EXCITATORY CURRENTS DURING POSTNATAL DEVELOPMENT. E.C. Burgard\* and J.J

DURING POSTNATAL DEVELOPMENT. E.C. Burgarde and J.J.
Hablitz. Neurobiology Research Center, University of
Alabama at Birmingham, Birmingham, AL. 35294.

Spontaneous and evoked EPSCs were recorded in
neocortical slices from 3-12 day old rat pups using
whole cell patch clamp techniques. Spontaneous EPSCs in
layer II-III neurons were rare on postnatal day 3 and gradually increased in frequency over the next 9 days. In normal extracellular saline, the 10-90% rise time, area, and decay time constant of spontaneous EPSCs increased with depolarization and decreased upon hyperpolarization from RMP (-65 mV). EPSC amplitude decreased with depolarization hyperpolarization. The NMDA re and increased with The NMDA receptor antagonist APV  $(10\mu\text{M})$  decreased these parameters only at depolarized membrane potentials. Removal of extracellular magnesium reversibly increased these parameters in an APVsensitive manner. Evoked EPSCs, at negative holding potentials, were much larger and longer than spontaneous EPSCs. Evoked EPSCs displayed a biphasic decay time constant characterized by a late APV-sensitive component that was not observed in spontaneous EPSCs. All EPSCs were blocked by CNQX (5µM).

These results indicate that NMDA receptors are

spontaneously activated and display musensitivity early in postnatal development. magnesium sensitivity early in postnatal development. In contribution of NMDA receptors to evoked EPSCs appears to be much greater than to spontaneous EPSCs. (NS22373)

GLUTAMATE-INDUCED INHIBITION OF PAIRED PULSE FACILITATION OF MONOSYNAPTIC EXCITATORY POSTSYNAPTIC POTENTIALS AND CURRENTS IN SPINAL MOTONEURONS. F. Nakamura, M. Kuno\*, H. Gotani and S. Matsuura. Dept. of Physiol., Osaka City Univ. Med. Sch.,

NUNCETNAPTIC EXCITATION? POSTSYMAPTIC PUTENTIALS AND CURRENTS IN SPINAL MOTONEURONS. F. Nakamura, M. Kuno\*, H. Gotani and S. Matsuura. Dept. of Physiol., Osaka City Univ. Med. Sch., Abeno-ku, Osaka 545, Japan.

Excitatory amino acids are distributed throughout the central nervous system and might modulate neuronal activity via both pre- and postsynaptic mechanisms. We examined glutamate-induced changes in the paired pulse facilitation of monosynaptic excitatory postsynaptic potentials evoked by stimulation of the lateral column fibers (LC-RPSPs) on lumbar motoneurons in the frog spinal cord. The spinal cord was isolated under anesthesia with pentobarbitone and arterially perfused with oxygenated Ringer. Glutamate (1 mM) depolarized cells with either increase or decrease in RPSP amplitude. In most cells tested, the paired pulse facilitation was reduced by glutamate when the EPSP amplitude either increased or decreased. The glutamate-induced facilitation was seen in both the presence and absence of Mg²\* and was not affected by the concomitant application of glutamate and antagonists for non-NMDA and NMDA receptors, 6-cyano-7-nitro-quinoxalinediones (CNQX) and 2-amino-5-phosphonovalerate (APV). Glutamate reduced the facilitation of excitatory postsynaptic currents (RPSCs) recorded at a constant mombrane. phosphonovalined (APV). Glutamate reduced the facilitation of excitatory postsynaptic currents (EPSCs) recorded at a constant membrane potential under voltage clamp, independently of changes in the EPSC amplitude and the input conductance. These results suggest that glutamate modulates release of excitatory transmitters via mechanisms insensitive to Mg<sup>2+</sup>, CNQX and APV.

ACTIVATION OF NMDA RECEPTORS BY GLUTAMATE & ASPARTATE B. Edmonds\* & D. Colquhoun. UCL, Gower St., London, WC1E6BT, UK

We have investigated the dependence of the decay of NMDA receptor currents on the apparent affinity of the agonist used to activate the receptor. Concentration jumps of 0.1 s receptor currents on the apparent affinity of the agonist used to activate the receptor. Concentration jumps of 0.1 s duration (exchange time < 0.2 ms) were made with 3 µM glycine (GLY) plus either aspartate (ASP, 0.1 mM) or the higher apparent affinity agonist glutamate (GLU, 0.02 mM) on outsideout patches from hippocampal granule cells. Relaxations after agonist removal were fitted with either 1 or 2 exponentials. For ASP the time constant  $(\tau)$  of the fast component was 41±6 ms (n=5) whereas GLU gave a  $\tau$  of 74±9 ms (n=8). Unlike ASP, GLU currents usually required 2 exponentials for good fits. These data support the idea that slow relaxations with GLU are partly

data support the idea that slow relaxations with GLU are partly due to the high apparent affinity of GLU for the receptor. The single channel basis for different relaxation rates was investigated using 0.1  $\mu$ M GLY and either GLU (0.03  $\mu$ M) or ASP (0.15  $\mu$ M). Open- and closed-time distributions were fitted with 2 and 5 components, respectively. For GLU (n=3) the mean with 2 and 5 components, respectively. For GLU (n=3) the mean  $\tau_s$  (ms)  $(and relative areas <math>(\pi)$ ) for gaps were:  $\tau_1=.06\pm.00$   $(41\pm.12)$ ;  $\tau_2=.76\pm.12$   $(21\pm2.3)$ ;  $\tau_3=13.1\pm.25$   $(9.1\pm.99)$ ;  $\tau_4=367\pm47$   $(5.2\pm.98)$ ;  $\tau_5=4996\pm2135$   $(24\pm1.9)$ . Gaps for ASP (n=4):  $\tau_1=.06\pm.01$   $(40\pm2.7)$ ;  $\tau_2=.62\pm.08$   $(20\pm2.0)$ ;  $\tau_3=6.9\pm3.4$   $(4.7\pm1.5)$ ;  $\tau_4=127\pm19$   $(3.7\pm.7)$ ;  $\tau_5=4896\pm1579$   $(32\pm3.0)$ . Open times for GLU:  $\tau_1=.34\pm.02$   $(34\pm3.5)$ ;  $\tau_2=3.2\pm.27$   $(67\pm3.5)$ . Open times for ASP:  $\tau_1=.36\pm.05$   $(36\pm6.0)$ ;  $\tau_2=2.5\pm.23$   $(64\pm6.0)$ . Gap components 3 and were shorter and had smaller relative areas for ASP than for GLU, which may contribute to the faster relaxations with ASP.

### 338.12

VASOPRESSIN MODULATES GLUTAMATE ACTION IN THE MEDIAL SEPTUM AND DIAGONAL BAND OF BROCA OF THE RAT.

Frank J.C.M. van Eerdenburg\* and Quentin J. Pittman.

Neuroscience Research Group, University of Calgary, Calgary, T2N 4N1, Canada.

Vasopressin (AVP) injected in the ventral septal area reduces fever caused by bacterial endotoxin or prostaglandin E. AVP can also initiate motor disturbances and convulsive activity in this area. Intracellular recordings were carried out with K-Acetate/biocytin filled electrodes in coronal brain slices of the diagonal band of Broca (DBB) and medial septum (MS) of the rat. AVP (1 \( \alpha \)) reduced or blocked the depolarizing effect of glutamate in 22 out of 55 neurons studied. This effect of AVP appeared to be (time)dose dependent and in some cells voltage dependent (the modulatory effect of AVP disappeared when the cell was hyperpolarized by injecting (-)current). The effect could be blocked by a V1 receptor antagonist. In most of the cells in which the depolarization by glutamate was modulated by AVP, AVP itself had no visible effect on the cell's electrophysiological characteristics. In 17 out of 69 cells studied AVP (1 \( M \)) depolarized the cell. An effect also present when a V2 agonist, dDAVP (1 \( M \)), was used and was most prominent the first and second time AVP was applied, after which the effect diminished and disappeared. Since the DBB and MS are of importance for cortical input, this study indicates that AVP may modulate cortical functions. cortical functions.

# PEPTIDES: ANATOMICAL LOCALIZATION-HUMAN AND PRIMATE

## 339.1

CALCITONIN GENE-RELATED PEPTIDE IMMUNO-REACTIVITY IN VISCERAL SENSORY PATHWAYS IN THE HUMAN BRAIN. S. de Lacalle\* and C. B. Saper.
Departments of Pharmacological and Physiological Sciences and
Neurology, University of Chicago, USA.

It has been proposed that calcitonin gene-related peptide (CGRP)

may serve as a neuromodulator in visceral sensory pathway particularly in the parabrachial projections to the thalamus, amygdala and cortex in the rat (Yasui et al., J Comp Neurol 290:487,1989; 308:293,1991). We have examined the distribution of CGRP-like immunoreactive (CGRP-ir) innervation of several areas of the human brain involved in the transmission of visceral sensory information. Two populations of CGRP-ir cells were present: one in the parabrachial complex (PB), including the homologues of the external medial and external lateral subnuclei; and the second in the posterior intralaminar external lateral subnuclet; and the second in the posterior intralaminar thalamic complex, including the subparafascicular, lateral subparafascicular, posterior intralaminar, and peripeduncular nuclei. In addition, scattered CGRP-ir cells were found in the periventricular hypothalamus. CGRP-ir terminals were found in projection areas of the external medial PB, including the ventroposterior parvicellular nucleus of the thalamus, the principal visceral sensory relay nucleus and the insular cortex; in external lateral PB targets, including the central nucleus of the amygdala and the bed nucleus of the stria terminalis; and in the terminal field of the posterior intralaminar thalamic complex, including the amygdaloatriatal transition region and the insular cortex. These CGRP-ir pathways are nearly identical to those that have been defined in the rat, suggesting that CGRP may code chemically for ascending visceral sensory pathways in the human brain as well.

## 339.2

LOCALIZATION OF CALCITONIN GENE-RELATED PEPTIDE (CGRP) IMMUNOREACTIVITY FOLLOWING HUMAN SPINAL CORD INJURY. R. Melinek\* and V.R. Holets The Miami Project and Depts of Neurological Surgery and Cell Biology and Anatomy, University of Miami, Miami, Fl 33136

Changes that occur in CGRP immunoreactivity following injury to the human spinal cord were examined in spinal cords from 3 female patients (aged 37-69 years) at 1, 8 and 13 years after injury. Two of the patients had cervical injuries (C5 and C7) and one had a high thoracic injury (T2). CGRP immunoreactivity above (C1-C3) and below (lumbar in two cases, thoracic in the third) the level of injury was compared to age- and sex-matched normal human spinal cord. Fifty to 100 µm vibratome sections were cut and processed for immunostaining using the avidin-biotin immunoperoxidase method. Whereas motoneurons above the lesion were CGRPimmunoreactive, below the lesion they were not. By contrast, both above and below the lesion, primary afferent fibers in the dorsal horn (lamina I-IV) and in lamina X showed intense CGRP-like immunoreactivity. The results corroborate those of animal studies, and suggest that CGRP levels in motoneurons may be regulated, in part, by supraspinal afferent input. (Supported by The Miami Project to Cure Paralysis, The Daniel Heumann Fund for Spinal Cord Injury, and the American Heart Association, Florida Affiliate)

ATRIAL NATRIURETIC PEPTIDE-LIKE IMMUNOREACTIVITY (ANP-LIR) IN THE HUMAN BRAIN. I.C. McKenzie, N.E.I. Berman, L.Y. Compton, W.-L. Liu and R.M.Klein\*, Dept. of Anatomy, Howard Univ. Col. Med., Washington, DC 20059 and Dept. of Anatomy and Cell Biology, Univ. Kansas Med. Ctr., Kansas City, KS 66160.

Atrial natriuretic peptide is a potent vasorelaxant which has been identified in Types I & II astrocytes and neurons in the canine brain and has been implicated in control of brain fluid and electrolyte homeostasis (McKenzie, 1992). To determine whether a similar nomeostasis (McKenzie, 1992). To determine whetner a similar system might exist in human brain, we stained sections of striate cortex, cerebellum and hypothalamus from 3 hr postmortem human brain using antibodies against proANP (Thibault) and ANP IV (Inagami). The proANP antibody stained fibrous astrocytes (type II) in white matter of striate cortex and protoplasmic astrocytes in Layer I and infragranular cortical layers. The type II astroglia possessed long thin processes which often appeared beaded. Many of these processes closely approached cerebral blood vessels. The ANP IV antibody, which is directed against the C-terminus of the peptide, stained both types I and II astroglia in cerebral cortex as well as modified type I types I and II astroglia in cerebral cortex as well as modified type I astroglia forming part of the glia limitans. This antibody also stained type I astrocytes in the hypothalamus and scattered Bergmann glia of the cerebellum, as well as isolated pyramidal neurons in the striate cortex. These results suggest that ANP may play a role in control of cerebral blood flow or maintenance of the blood-brain barrier in human brain. The difference in the population of cells stained by the two antibodies implies a difference in processing of ANP among the cell types. Supported by AHA-Kansas, MH38399 and HL45241.

PEPTIDERGIC INNERVATION OF THE HUMAN SUPRA-TEMPORAL PLANE. P. LaRussa\*, R.E. Powers, G. Zhang and X. Tang. Department of Psychiatry and UAB Brain Resource Program, University of Alabama at Birmingham, Birmingham, Alabama 35294.

The distribution of peptidergic neurons and fibers was examined in supratemporal planes (STP) from six normal human subjects including superior temporal gyrus, Heschl's gyrus and the planum

temporale.

Multiple levels of acrolien fixed right and left STP were sequentially sectioned and immunostained in the coronal, sagittal and axial plane using antisera to somatostatin (SS) substance P (SP), neuropeptide Y (NPY) and neurotensin (NT). Representative sections from each region were mapped using standard cytoarchitectonics definitions. A variable plexus of NPY fibers was seen in most regions of the STP however few fibers were stained with antisera to NT. A variable number of SS immunostained neurons were present throughout the STP and few neurons were stained with antisera to NT. A modest number of NPY immunostained neurons were present in the cortex of STG in HG and PT however many medium and small sized NPY neurons were present in the subcortical white matter. continuous lamina of SP immunostained neurons resembling double tufted cells was present in layer 3 of posterior STG, HG and rostral portions of the PT and a smaller number were present in layers 5 and 6. Few SP immunoreactive neurons were present in the white matter. These data support substance P and neuropeptide Y as important transmitters in human auditory cortex.

## 339.7

THE DISTRIBUTION OF CHOLECYSTOKININ AND NEUROTENSIN IN THE NUCLEUS ACCUMBENS OF MACAQUE MONKEY. K. Ikemoto\*, M. Narita, T. Maeda, M. Hayashi, and K. Satoh. Dept. of Psychiatry and Anatomy, Shiga University of Medical Science, Otsu 520-21, Primate Research Center, Kyoto University, Japan.

Using avidin-biotin peroxidase immunohistochemical technique the distribution of cholecystokinin (CCK) and neurotensin was investigated in the nucleus accumbens of macaca fuscata. monkeys were deeply anesthesized and perfused with mixed aldehydes. In the rostral portion of the nucleus accumbens, neurotensin containing-cell bodies were triangular or fusiform in shape, and they were observed in its lateral part. mid-level of the nucleus, a similar type of neurotensin-containing cell bodies was observed in the mid-lateral part, and at the caudal level of the nucleus, immunoreactive cells, fusiform in shape, were found in its medial part. Neurotensin-containing fibers were densely distributed in the medial half of the nucleus. CCK-containing fibers were observed in the medialdorsal part of the nucleus accumbens. The distribution of these two neuropeptides was apparently different, suggesting that they might have different roles in the nucleus accumbens.

PEPTIDERGIC NEURONS IN HUMAN HIPPOCAMPUS. R.E. Powers\* and W.S. Young, III. UAB Brain Resource Program, University of Alabama at Birmingham, Birmingham, Alabama 35294 and NIMH, Bethesda, MD 20892.

The distribution of peptidergic neurons in human hippocampus

was mapped using hybridization histochemistry in sequential sections was mapped using hybridization histochemistry in sequential sections of fresh frozen hippocampus from six normal human subjects. Hybridization histochemistry was performed with <sup>35</sup>S-labeled oligodeoxynucleotide probes for somatostatin (SS), substance P (SP), leucine enkephalin (LEU), dynorphin (DYN), neuropeptide Y (NPY), and cholecystokinin (CCK). Neuronal labeling was mapped at 3 levels, rostral at the pes hippocampus, mid-hippocampus at the level of the relacious of the corner sallesum.

the splenium of the corpus callosum.

Large numbers of granule cells expressed DYN. Many neurons in the polymorphic layer of the dentate gyrus contained SS, NPY, SP, CCK and DYN transcripts. Pyramidal neurons were infrequently labeled with any probe. Bipolar and basket shaped neurons in the stratum oriens were labeled with SS, SP, NPY, CCK and DYN probes. The distribution of labeled neurons for all peptides were relativally acceptant throughout the restrogardal extent of the relatively constant throughout the rostrocaudal extent of the hippocampus. SS, NPY, LEU and SP probes labeled similar populations of neurons in the dentate and CA4.

This study demonstrates and extensive network of peptidergic neurons in human hippocampus that is similar in all levels. These studies are in general agreement with mapping using immunocytochemistry and the distribution is similar to that seen in rodents and non-human primates.

## 339.6

LOCALIZATION OF CORTICOTROPIN-RELEASING FACTOR, GALANIN AND NEUROPEPTIDE Y IN THE HUMAN LOCUS COERULEUS.

M.C. Austin\*, J.A. Weikel, P.M. Rice, J.J. Mann and V. Arango, Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Studies report that the locus coeruleus (LC) of the rat receives a substantial corticotropin-releasing factor (CRF) innervation, and that CRF has an excitatory influence on LC neurons. CRF-immunoreactive (IR) fibers are also found in the LC of non-human primates, but there is no documentation of a CRF input to the human LC. The significance of demonstrating such an input lies in the fact that CRF is hypersecreted and norepinephrine neurotransmission is altered in depressed patients. Immunocytochemical studies report that galanin and neuropeptide Y (NPY) are found in LC neurons of the rat and human. Using immunocytochemistry or in situ hybridization, we sought to determine whether the human LC receives a CRF input and to examine gene expression for galanin and NPY in the human LC. Postmortem human brain tissue was obtained at autopsy, the brainstem dissected and either frozen or immersed in formalin. All cases had negative toxicological screens and no known neurologic or psychiatric disorders. Coronal sections of the LC were processed for in situ hybridization or immunocytochemistry. Dense CRF-IR fibers were found predominantly in the dorsal LC and the medial and lateral aspects of the central gray of the pons. The density of CRF fibers was less in the ventral LC. CRF-IR fibers contained numerous large varicosities and appeared to envelop some LC perikarya. Galanin and NPY mRNA were localized to a minority of LC neurons. Both galanin and NPY mRNA were found in pigmented as well as non-pigmented cells study confirms the presence of CRF-IR terminals in the human LC providing an anatomical basis for CRF modulation of LC activity and that galanin and NPY are co-transmitters in the human LC. The localization of these neuropeptides in the human noradrenergic LC suggests a role for these peptides in the pathophysiology of depression. (Supported by MH40210, MH46745)

## 339.8

SUBSTANCE P/NEUROKININ A (SP/NKA) mRNA EXPRESSION IN THE PRIMATE ENTERIC NERVOUS SYSTEM (ENS). K. Anderson\* and C. Sternini. CURE, Department of Medicine, Brain Research Institute, UCLA and VAWC at Wadsworth, Los Angeles, CA 90073.

The mRNAs encoding for the tachykinin peptides, SP, NKA and neurokinin B (NKB) are generated by separate genes, the preprotachykinin (PPT) I, encoding for SP and NKA, and the PPT II, encoding for NKB, which are differentially expressed in the central nervous system. We investigated the expression of tachykinin-encoding mRNAs in the ENS of primates by means of in situ hybridization histochemistry with 35S-labeled RNA probes complementary to SP/NKA or NKB mRNA. Fixed sections or whole mounts of different regions of the gastrointestinal tract of the Macaca and Cebus monkeys were gastrointestinal tract of the *Macaca* and *Cebus* monkeys were used. SP/NKA-encoding mRNA is expressed in numerous ganglion cells of the myenteric and submucous plexuses with the following density: stomach, duodenum, and ileum > colon >> following density: stomach, duodenum, and fleum > colon >> jejunum. By contrast, specific signal could not be detected with the NKB antisense RNA probe. Hybridization signal was not observed in tissue hybridized with sense RNA probes. We can conclude that: 1) the PPT I gene, encoding for SP, NKA and the posttranslational products, neuropeptide K and 7, is transcribed in enteric neurons of primates, and 2) the NKB-encoding PPT II gene is either not transcribed or transcribed at very low levels in

Supported by NIH grants DK38752 & 40469. We thank Dr. J.E. Krause for the PPT cDNAs.

High levels of enkephalin mRNA are found in the striatum and limbic-associated regions of the monkey telencephalon. W.X.Lu\* and S.N. Haber. Dept. of Neurobiology and Anatomy, Univ. of Rochester, Rochester, N.Y. 14642
Using a free floating method for in situ hybridization (Brain Res, in press), we studied the distribution of mRNA for preproenkephalin

(ENK) in the monkey forebrain. The free-floating sections, stored in ryoprotectant solution, were rinsed in PBS, and directly hybridised at 37°C for 20 hours in a tube with ENK oligonucleotide probe labeled with 35°S-dATP and terminal deoxynucleotidyl transferase(10 x 106 cpm/ml). After post-hybridization wash in 0.5 x SSC at 60 °C, the sections were mounted and processed for autoradiography. The results from the autoradiograms reveal high levels of specific hybridization to mRNA for ENK in the monkey striatum with low background levels. The distribution of specific label is patchy, with clusters of silver grains separated by areas containing less label. Within a given small area, densely labeled individual cells are found among cells with little or no specific labeling. At the macroscopic level, within a general region of the striatum, there are patches of specific hybridization intermingled with areas containing low background, less-specific hybridization, forming a mosaic-like pattern. Adjacent sections stained for ENK immunohistochemistry and processed for in situ hybridization show a high correlation between patches of dense immunoreactivity and high specific ENK mRNA hybridization. Specific hybridization to mRNA of from the autoradiograms reveal high levels of specific hybridization to right correlation between patches of defise limitation detactivity and might specific ENK mRNA hybridization. Specific hybridization to mRNA of ENK is evident throughout the cortical mantal, concentrated in layers 2 and 3. High levels are found in the orbitofrontal cortex, agranular insular cortex, entorhinal cortex, the dentate gyrus, and parts of the amygdala. Supported by NIMH MH 45573 7 NIH NS22511

## 339.11

INCIDENCE OF NEUROHYPOPHYSEAL HORMONES IN NEUROENDOCRINE AND NON-NEUROENDOCRINE LUNG TUMORS A.S. Friedmann\*, V. A. Memoli, and W.G. North, Depts of Physiology and Pathology, Dartmouth Medical School, Lebanon, NH 03756 USA

Previous studies performed in this laboratory have shown that the majority of patients diagnosed with small cell lung carcinoma have elevated plasma levels of vasopressin (VP), oxytocin (OT), and their associated human neurophysins (VP-HNP, OT-HNP), while levels of these substances in patients diagnosed with non-neuroendocrine lung tumors are almost all normal. To further investigate the expression of neurohypophyseal peptides by lung tumors, the incidence of VP-HNP in 44 neuroendocrine tumors was determined immunohistochemically using rabbit polyclonal antibodies specific for this neurophysin. Twenty-two non-neuroendocrine tumors were also examined for the presence of VP, VP-HNP, OT, and OT-HNP using mouse monoclonal and rabbit polyclonal antibodies specific for these substances. Widespread VP-HNP immunoreactivity was demonstrated in 38 of the 44 neuroendocrine tumors. In the 22 non-neuroendocrine tumors, positive staining for VP-HNP was limited to one squamous cell tumor and one adenocarcinoma. Very intense staining was also seen in healthy bronchial glands adjacent to the neurophysin-containing adenocarcinoma. Immunoreactivity for VP, OT, and OT-HNP could not be detected in any of the nonneuroendocrine tumors. These data indicate that the high incidence of neurohypophyseal peptide production in lung carcinomas is specific to neuroendocrine tumors and could be of value in tumor diagnosis.

IDENTIFICATION OF TWO GANGLIONATED PLEXUSES IN THE HUMAN GALLBLADDER (GB). R. De Giorgio J. Parodi, T. Zittel, R. Kleinman, F.C. Brunicardi, V.L.W. Go, J.M. Becker and C. Sternini. CURE, Depts. of Medicine and Surgery, BRI, UCLA & VAMC-Wadsworth, Los Angeles, CA 90073; and Dept. of Surgery, Harvard Medical School, Brigham & Women's Hospital, Boston, MA 02115.

The neurochemical organization of the human GB innervation is still undefined. We studied the tissue targets and the chemical coding of neurons of human GBs obtained from cholecystectomized patients and donors. Tissue sections were processed for immunohistochemistry with calcitonin gene-related peptide (CGRP), neuropeptide Y (NPY), tachykinin (TK), and vasoactive intestinal polypeptide (VIP) antibodies. Two major ganglionated plexuses were identified by peptide immunoreactivities (IRs): the plexuses were identified by peptide immunoreactivities (IRs): the innermost, in the lamina propria; the outermost, in the fibromuscular layer. In both plexuses, VIP-IR was detected in almost all neurons. NPY- and TK-IRs were found in numerous ganglion cells (NPY->TK). Many VIP-IR neurons co-expressed NPY-, and some TK-IR, suggesting that VIP-, NPY- and TK-IRs colocalized in a subpopulation of neurons. CGRP-IR was restricted to axons which often contained TK-IR. The densities of IR nerves distributed to the musers and fibromysular layer was: distributed to the mucosa and fibromuscular layer was: VIP≥NPY>TK>>CGRP. In conclusion: 1) the human GB has vive Nri > 1x > CORP. In conclusion: 1) the numan OB has two ganglionated plexuses and is supplied by a dense peptidergic neural network; 2) distinct populations of neurons can be identified by their phenotypical expression.

Supported by NIH grant DK 38752 (CS); SKB Fellowship (RDG).

# ONTOGENY OF SEROTONIN RECEPTORS

## 340.1

SEROTONIN HYPERSENSITIVITY IN ADULT RAT NEOSTRIATUM AFTER NEONATAL 6-OHDA TREATMENT: AN IONTOPHORETIC

SEROTONIN HYPERSENSITIVITY IN ADULT RAT NEOSTRIATUM AFTER NEONATAL 6-OHDA TREATMENT: AN IONTOPHORETIC STUDY. M. El Mansari. A. Ferron\* and L. Descarries. Centre de recherche en sciences neurologiques (Département de physiologie), Université de Montréal, Montréal, Québec, CANADA H3C 3J7.

Destruction of nigro-striatal dopamine neurons by cerebroventricular administration of 6-OHDA in newborn rat (3-day-old) results in a serotonin (5-HT) hyperinnervation of the rostral neostriatum in the adult, accompanied by an increased number of 5-HT1B and 5-HT2 receptors (Radja et al., this volume). To determine the functional consequences of these changes, the effects of iontophoretically applied 5-HT and two 5-HT agonists, mCPP (5-HT1B exclusive) and DOI (5-HT2 selective), were examined in the rostral neostriatum of neonatally lesioned rats anesthetized with urethane. Neuronal responsiveness was quantitatively assessed by means of the IT50 index, which measures the amount of drug required to obtain a 50% depression of firing rate. In controls, the firing rate of most spontaneously active units was reduced by all three agents, with comparable mean IT50 values for 5-HT (1800 nC), mCPP (1780 nC) and DOI (1470 nC). Three months after the lesion, the sensitivity to 5-HT and its two agonists was significantly increased compared to control (5-HT, 915 nC; mCPP, 960 nC; DOI, 900 nC; p < 0.001; t test). These results indicate that the 5-HT hyperinnervation and up-regulation of 5-HT receptors is also associated with an hypersensitivity to this transmitter. Thus, even though microdialysis experiments in this model have shown that the basal levels of extracellular 5-HT remain similar to control because of increased reuptake (Jackson D. and Abercrombie E.D., J. Neurochem. 58:890, 1992), this same concentration of 5-HT recoul have greater functional effects. (Supported by a H.H. Jasper Fellowship and MRC grant MT-3544).

## 340.2

SEROTONIN 5-HT1 AND 5-HT2 RECEPTORS IN ADULT RAT BRAIN AFTER NEONATAL 6-OHDA TREATMENT: AN AUTORADIOGRA-PHIC STUDY. F. Radja\*, T.A. Reader, K. M. Dewar and L. Descarries. Centre de recherche en sciences neurologiques (Départements de physiologie, psychiatrie et pathologie), Université de Montréal, Mouréal, Qué., CANADA. Neonatal destruction of nigro-striatal dopamine (DA) neurons by cerebroventricular injection of 6-OHDA results in a serotonin (5-HT) hyperinnervation of the rostral neostriatum (NS) in adult rat. Quantitative ligand binding autoradiography was used to evaluate the density of 5-HT1 and 5-HT17 receptors in the forerbarin and midbrain, 3 or 6 months after the lesion. 5-HT1A, 5-HT1B, 5-HT1annAB and 5-HT2 sites were labeled with [3H]8-OH-DPAT, [125][cyanopindolol, [3H]5-HT and [125]]DOI, respectively. Three months after the lesion, the density of 5-HT1B and 5-HT1nonAB receptors was increased by almost 40% throughout the NS, and by 50% in the globus pallidus. Binding to 5-HT1B receptors was considerably increased (60%), though this was restricted to the rostral NS only. In contrast, 5-HT1A binding sites, measured after 6 months, were unchanged in all regions studied. These data indicate that the 5-HT hyperinnervation of the rostral NS following neonatal nigro-striatal DA lesion is accompanied by an up-regulation of 5-HT1B and 5-HT1nonAB receptors throughout the NS and in some of its territories of projection (SN and globus pallidus), which suggests an effect of the DA denervation. In SN, the elevation of these receptors is consistent with their predominant axon terminal localization on afferent fibers. The even AFTER NEONATAL 6-OHDA TREATMENT: AN AUTORADIOGRAtheir predominant axon terminal localization on afferent fibers. The even greater elevation of 5-HTZ receptors in the rostral NS remains to be explained; its distribution suggests a causal link with the 5-HT hyperinnervation. (Supported by the FRSQ, and MRC grants MT-6967 and MT-3544).

EXPRESSION OF SEROTONIN 5-HT<sub>1C</sub> and 5-HT<sub>2</sub> RECEPTORS IN THE DEVELOPING RAT CENTRAL NERVOUS SYSTEM. R. P. Hellendall\*, U. Schambra. J. P. Liu. and J. M. Lauder. Dept. of Cell. Biol. and Anat., Univ. of N. Carolina, Chapel Hill, NC 27599.

Previous work has provided evidence for serotonin (5-HT) as a differentiation signal in the developing CNS. To analyze the putative sites of action of 5-HT during neurogenesis, we have studied the expression of mRNAs for two 5-HT receptors (5-HT1<sub>C</sub>, 5-HT2) by evaluating *in situ* hybridization in the prenatal rat brain. At E14, signal for 5-HT1<sub>C</sub> was found in the choroid plexus and in marginal/intermediate (m/i) zones of the midbrain, brainstem, and spinal cord including catecholaminergic and 5-HT cell groups. By E18-21 many forebrain regions displayed label, including the hippocampus (CA1), in addition to more intense signal in midbrain, brainstem, and spinal cord. Expression in the choroid plexus appeared to peak between E16-E18 although considerable hybridization signal remained at E21. 5-HT2 transcripts were first apparent at E14 in the ventricular and m'i zones of the midbrain and in the intermediate zones of a number of other areas extending through the rostral-caudal axis of the brain. As with 5-HT1<sub>C</sub> mRNA, signal increased over rostral and brainstem areas at late gestational ages with significant labeling appearing in the olfactory bulb, cerebellum, cortical plate and subplate, dentate gyrus, noradrenergic and 5-HT raphe brainstem nuclei. These observations are consistent with previous studies in the adult. In addition, both the 5-HT1<sub>C</sub> and 5-HT2 receptor transcripts were also present over the meninges at E16 which has not been previously reported and may represent a transient expression of these receptors. The pattern of expression in the embryonic rat brain indicates receptors for 5-HT are often present along pathways and at target sites for 5-HT axons prior to synaptogenesis. This observation, in conjunction with our work indicating 5-HT can act as a differentiation signal for target neurons, suggests prenatal 5-HT receptors are positioned to mediate this effect.

## 340.5

PLASTICITY AND ONTOGENY OF [H]PAROXETINE BINDING SITES. M.R. Pranzatelli\* and J.M. Martens. Departments of Neurology, Pediatrics, Pharmacology, The George Washington University, Washington, DC 20010.

5,7-Dihydroxytryptamine (5,7-DHT) injected i.p. in neonatal rats increases 5-HT in brainstem while depleting it in cortex, hippocampus, and spinal cord. To study the mechanism of regional differences, we measured the 5-HT transporter site using [H]paroxetine. Regional differences in  $B_{\text{MAX}}$  of vehicle-injected rats were significant: brainstem, diencephalon > striatum, cortex, spinal cord > hippocampus, cerebellum. Regional ontogeny also differed: at day 7, B<sub>MAX</sub> was 39% of adult levels in cortex compared to 63% in brainstem. Thirty days after 100 mg/kg 5,7-DHT i.p.,  $\hat{B}_{MAX}$  was increased in brainstem (+67%) and diencephalon (+136%), but decreased in cortex (-59%), hippocampus (-94%), spinal cord (-99%), striatum (-41%), and cerebellum (-37%). K<sub>D</sub> was unaltered. Changes in B<sub>MAX</sub> correlated with the 5-HT concentration we reported previously using HPLC. The threshold dose for B<sub>MAX</sub> effects was 50 mg/kg and 200 mg/kg was lethal. Binding site changes were apparent one week after 5,7-DHT lesions, but increases in diencephalon and brainstem were not maximal until 3 weeks, whereas percent decrease in cortical sites did not change over time. Lesion effects on [H]paroxetine site ontogeny were region-dependent: cortical sites increased with age but spinal sites did not. The regional, dose, and time effects of neonatal 5,7-DHT lesions made by i.p. injection on [\*H]paroxetine binding sites are evidence for brainstem 5-HT hyperinnervation (sprouting) as a cause of increased 5-HT concentrations.

## 340.7

LOCALIZATION OF 5-HT<sub>la</sub> RECEPTORS ON ASTROCLIAL CELLS OF ADULT RAT BRAIN P.M. Whitaker-Azmitia\*, C. Clarke, and E. Azmitia Dept. of Psychiatry, State University of New York, Stony Brook, New York 11794-8101

Astroglial cells in primary culture have 5-HT $_{1a}$  receptors which are linked to the release of the neuronal growth factor, S-100B. Since S-100B, and 5-HT $_{1a}$  receptors have been implicated in both Down's Syndrome and Alzheimer's Disease, it is important to know if 5-HT $_{1a}$  receptors do in fact still occur in astrocytes in the mature brain where they could continue to regulate S-100B. However, to date, the presence of this receptor on astroglial cells of an intact adult animal has not been shown. In the current study, we have used double-immunolabelling to show the presence of 5-HT $_{1a}$  receptors on astroglial cells in adult rat brain. Astroglial cells were stained using a monoclonal anti-GFAP (1/400) and a peroxidase-conjugated secondary anti-body (visualized with DAB). 5-HT $_{1a}$  receptors were stained with an anti-5-HT $_{1a}$  (1/5,000) and an alkaline-phosphatase substrate III).

Frequency of double-labelled cells was highest in the hippocampus and almost completely absent from the striatum.  $5-\mathrm{HT}_{1a}$  labelling was apparent in the somal cyto-plasm (but not the nucleus) and along the processes especially the distal ends. Within brain regions,  $5-\mathrm{HT}_{1a}$  staining was unevenly distributed with some heavily labelled astrocytes immediately adjacent to unlabelled astrocytes.

PRENATAL COCAINE EXPOSURE ALTERS HIPPOCAMPAL SEROTONIN, 5-HT<sub>1A</sub> RECEPTOR, AND S-100 $\beta$  IMMUNOREACTIVITY IN THE NEONATAL RAT.

H.M. Akbari\*<sup>1</sup>, P.M. Whitaker-Azmitia<sup>2</sup>, and E.C. Azmitia<sup>1</sup>.

Department of Biology, New York University, NY, NY 10003

Department of Psychiatry, SUNY-Stony Brook, Stony Brook,NY 11794

We have previously found that cocaine delays the maturation of the serotonin (s-HT) innervation of the hippocampus. Recent work in our laboratory has shown that serotonin modulates the release of S-100β, a cortical and serotonergic trophic factor, by activating 5HT<sub>1</sub>, receptors. In this study, we immunocytochemically examined the hippocampal distribution of 5-HT fibers, 5-HT<sub>1</sub>, receptors, and S-100β in neonatal rats prenatally exposed to cocaine. Timed pregnant dams were injected subcutaneously with either cocaine (40 mg/kg/3 cc) or saline from gestational day 13 to parturition. Pups representing a minimum of three dams were randomly selected on postnatal day 7 and processed for immunocytochemistry. In cocaine-treated animals, 5-HT immunoreactive fibers were decreased as previously described (Akbari et al., 1992), while increased 5-HT<sub>1</sub>, immunoreactivity was seen in the hilus of the dentate gyrus and in the stratum lacunosum-moleculare of the CA fields of the hippocampus. As predicted, S-100β immunoreactivity was lowest in regions of highest 5-HT fiber depletion. These results support the hypothesis that 5-HT functions as a developmental signal by interacting with the 5-HT<sub>1</sub>, receptor and increasing S-100β levels. Our findings demonstrate that the delayed maturation of the 5-HT innervation of the hippocampus results in decreased levels of the trophic molecule S-100β, which could cause a retardation of dendritic and

## 340.6

EVIDENCE FOR CRITICAL PERIODS OF 5-HT<sub>la</sub> RECEPTOR INFLUENCE ON BRAIN DEVELOPMENT X. Zhang\*, E.C. Azmitia, P.M. Whitaker-Azmitia Dept. of Psychiatry, State University of New York, Stony Brook, New York 11794-8101

axonal arborizations of hippocampal neurons. This may represent a molecular mechanism for the neurobehavioral abnormalities associated with prenatal

cocaine abuse. Supported by NIDA contract 271-90-7403.

 $5 \mathrm{HT_{1a}}$  receptors play an important role in regulating brain development. The current study examined the effects of 1 mg/kg 8-OH-DPAT given at various postnatal ages on subsequent development of rats. Treatment times were PD 3-10, PD 10-17 and PD 15-22.

Animals treated PD 3-10 gained weight more rapidly than controls and maintained a higher weight until PD 17 (28.8g vs. 33.4 pc.05). Incisor eruption and eye-opening took place one day earlier in 8-0H-DPAT animals. Conversely, animals treated PD 10-17 showed eye-opening one day later and gained weight more slowly. These animals were still significantly lighter at PD 40 (139.8 g vs. 114.6 p.<.01). Animals treated from PD 15-22 were also significantly lighter at PD 40 (132.3 g vs. 113.8 p<.04).

At PD 25, animals treated from PD 3-10 were significantly more anxious than controls, based on time spent in the dark (61.6% vs. 85.6 p<.01), but no other treatment time produced an effect. At PD 24, animals treated from 10-17 (but no other time) showed greater rates of spontaneous alternation (40.7% vs. 70.9 % p<.001). None of the treatment groups showed changes in open field activity, catalepsy or olfaction.

## 340.8

Functional role of the 2nd extracellular loop of the 5-HT<sub>1A</sub> receptor using an antipeptide antibody in primary neuronal culture. <u>Efrain C. Azmitia<sup>®</sup> Xiao Ping Hou<sup>1</sup>. XI Gu<sup>1</sup> and Patricla-Whitaker-Azmitia Department of Biology; New York University, NY,NY 10002 and SUNY at Stony Brook, NY 11794</u>

The  $^5$ -HT $_{1A}$  receptor has been cloned and shown to be a seven transmembrane spanning molecule. An antipeptide antibody was raised against a specific segment of the  $^2$ -Pd extracellular loop of the receptor (Azmitia et al, 1992). The antibody and the peptide itself were tested in a serum-free midbrain raphe tissue culture system to determine if the neuronotrophic actions of the 5-HT $_{1A}$  receptor mediated by activation of  $^5$ -100ß could be altered. Application of ipsapirone, a  $^5$ -HT $_{1A}$  agoinst, and  $^5$ -100ß were able to stimulate the uptake development of serotonergic neurons. Spiroxatrine, a non-selective  $^5$ -HT $_{1A}$  antagonist, and antibodies against  $^5$ -100ß, inhibited the  $^5$ -HT  $_{1A}$  paths the 2nd external loop, but not against GFAP or the  $^5$ -HT $_{1A}$  ard cytoplasmic loop, was inhibitory at a dilution of  $^1$ /25,000. Purification of the antibody immunoglobulin by protein A Sepharose column separation showed significant inhibition of the  $^5$ -HT  $_{1A}$  by the purified and crude antibody could be reversed by addition of excess  $^5$ -HT $_{1A}$  agonist. The results suggest that the 2nd cytoplasmic loop may be active in regulating the expression of  $^5$ -HT $_{1A}$

# SEROTONERGIC FIBERS ARE NOT DEVELOPED IN THE HIPPOCAMPUS AND NEOCORTEX IN THE S-100B RETARDED MUTANT MOUSE (POLYDACTYLY NAGOYA). S.Ueda', X.F.Gu and E.C.Azmitia. Dept. of Biology, New York University, NY, NY 10003.

The homozygote (Pdn/Pdn) of this mutant mouse shows several brain abnormalities, and a significant decrease of S-100B (Naruse et al. Dev. Brain Res.51(2)1990). In order to clarify the effects of the retarded production of S-100β on the development of monoaminergic neuron system, immunocytochemical studies of TH, 5-HT, S-100β and GFAP, and HPLC study for 5-HT and 5-HIAA of Pdn/Pdn mouse were examined, the results were compared with those of wild type (+/+) mouse. In both animals, S-100β positive cells and serotonergic fibers were widely distributed throughout the brains. However, hippocampus and caudo-dorsal cortex of Pdn/Pdn mouse were markedly reduced in S-100β positive cells and serotonergic fibers. Abnormal distribution of GFAP positive fibers was also

observed in the neocortex and hippocampus of the Pdn/Pdn brain. No difference were seen in the TH fibers distribution. In the HPLC study, the content of 5-HT and 5-HIAA of hippocampus and cortex of Pdn/Pdn mouse was lower than that of +/+ mouse. These results suggest that S-100β is a scrotonergic growth factor, and this mutant mouse is a useful model to study neuro-glial neurotrophic interactions

DEVELOPMENT OF BRAINSTEM AND HYPOTHALAMIC SEROTONIN IMMUNOREACTIVE SYSTEMS IN THE HAMSTER. G.I. Botchkina and L.P. Morin\*, Dept. Psychiatry, SUNY, Stony Brook, NY 11794.

The appearance of serotonin immunoreactive (5-HT-IR) cells and fibers in the brainstem and basal forebrain has been studied from embryonic day 8 to postnatal day 21. On **E8**, a relatively small bilateral group of very densely IR neurons is present in the most ventral part of the rhombencephalon just caudal to the mesencephalic flexure (MF). A few 5-HT-IR ascending and descending fibers of the raphe nuclei are also seen near the cells. E11-E12: A dramatic increase in 5-HT-IR neurons occurs between the MF and pontine flexure, where cells are located in both ventral and dorsal parts. E11: a dense bundle of 5-HT-IR axons ascends laterally over the curvature of the MF. E13: the bundle reaches the posterior hypothalamus and bifurcates with one group ascending rostrally through the dorsal preoptic area. The second group ascends through the ventro-lateral hypothalamus. The hypothalamic area adjacent to the suprachiasmatic nucleus (SCN) and optic chiasm has significant 5-HT-IR. The bilateral group of 5-HT-IR neurons in the ventral medulla is large by E13, and a much smaller set is also found more dorsally. From E13 to E15, terminal arborization is occurring and aggregations of 5-HT-IR neurons becomes looser, but changes in the distri-bution of 5-HT-IR cells and fibers within the brain stem and hypothalamus appear to be minimal.

Neurogenesis in the hamster SCN occurs between E10-E13 (Davis et al., Brain Res. 1990, 519, 192-199) and the major ascending 5-HT pathway is adjacent to the SCN as early as E13. Nevertheless, no 5-HT-IR is seen within the SCN prenatally. The 5-HT-IR fibers appear in the SCN by **postnatal day 3-5**, largely occupying the periphery of the nucleus, and achieve the adult pattern by postnatal day 10. Supported by NS22168.

<sup>3</sup> Dept. of Psychiatry, SUNY-Stony Brook, Stony Brook, NY 11794

Three previously described antipeptide antibodies directed against different regions of the rat 5-HT<sub> $\Lambda$ </sub> receptor (the N-terminus loop, the 2nd extracellular loop, and the 3rd cytoplasmic loop [Azmitia et al., 1992]) were used to immunocytochemically characterize the distribution of the 5-HT<sub>1A</sub> receptor in the spinal cord of adult monkey (Macaca f.) and its developmental expression in rat spinal cord. Commercial antibodies against 5-HT and S-100ß were used on adjacent sections to compare the 5-HT fiber and S-100ß cellular distribution to that of the 5-HT, receptor. 5-HT, immunoreactive (IR) cells (neurons and astrocytes) and processes were observed to be heavily labelled in the superficial lamina of the dorsal horn, in the region of the central grey, and in the ventral horn of the spinal cord. In adults, we found 5-HT<sub>1A</sub>-IR and S-100-IR in ventral horn motor neurons, but not in the neonatal rat. 5-HT<sub>1A</sub>-IR cells were also seen in the Descending Motor Root of V and in the Supraspinal nucleus of the lower medulla. In all regions, 5-HT<sub>1A</sub> stained cells are localized to the same areas where dense 5-HT fiber innervation and intense S-100ß cellular labelling was observed. Our results using 5-HT<sub>1A</sub> receptor antibodies correlate with previous autoradiographic studies, and suggest co-localization with S-100B. This supports the notion that 5-HT may play a role, through the 5-HT<sub>1A</sub> receptor in regulating S-100B, a protein shown to have neuronotrophic properties on motor and serotonergic neurons

THE INFLUENCE OF INSULIN ON MODULATION OF ION CURRENTS

IN THE BAG CELL NEURONS OF APLYSIA.

E.A. Jonas, R.J. Knox, D.H. Solomon, J.H. Schwartz\*, and L.K. Kaczmarek, Dept of Pharmacology, Yale University School of Medicine.

Receptors, such as the insulin receptor, which stimulate tyrosine kinase activity, play an important role in cell growth. There have been few studies, however, on the actions of such pathways on the excitability of neurons. An insulin receptor is expressed in the bag cell neurons of Aphysia (see Solomon et. al., Neurosci. abst., 1992). These cells control a sequence of reproductive behaviors in this animal. We have now investigated the effects of insulin on the regulation of ionic conductances in the bag cell neurons. By using a single electrode voltage clamp technique, we have demonstrated that a twenty four hour treatment with 5µM insulin induces a two fold increase in the voltage-dependent calcium current in the bag cell neurons as compared to untreated controls. In addition, insulin also causes an acute increase (over the course of twenty minutes to an hour) in action potential amplitude and a decrease in action potential duration. These acute effects were seen in 65% of cells from animals examined during the summer months, when the animals are most likely to reproduce. The acute changes are associated with an increase in both the voltage-dependent calcium current and an increase in the delayed rectifier potassium current. Our studies suggest that insulin may play a role in the regulation of both short and long term changes in excitability in the bag cell neurons.

A TYROSINE KINASE RECEPTOR FOR APLYSIA INSULIN-LIKE PEPTIDE(S) MODULATES EXCITABILITY IN APLYSIA BAG CELL NEURONS. D.H. Solomon\*,

E.A. Jonas, R.J. Knox, A.M. Elste, L.K. Kaczmarek and J.H. Schwartz, Center for Neurobiology & Behavior, Columbia University, New York, NY 10032. While well characterized receptor-coupled second messenger pathways produce ongoing modulation of neuronal activity, tyrosine kinases are typically implicated in critical choices of survival or differentiation of developing neurons. But how receptor tyrosine kinases modulate synaptic transmission is not yet understood. In the marine molluse, Aplysia, we have characterized a tyrosine kinase receptor for a putative molluscan insulin, which is a possible invertebrate neurotransmitter. Using a *vertebrate* insulin-binding domain antibody, we found an  $M_{\rm f}$  130,000 protein that is predominately localized to bag cell neurons and which is similar in size to the Drosophila insulin receptor a subunit. We cloned the cDNA encoding this protein from a bag cell neuron library by a degenerate PCR strategy. Sequencing revealed a cDNA with an overall inferred amino acid sequence identity of 42% to the human insulin receptor and 93% sequence identity to the *Drosophila* receptor kinase domain. The tetrabasic α/β subunit cleavage site is conserved as are three of the four tyrosine autophosphorylation sites. Immunoprecipitation with an insulin receptor-tyrosine kinase domain monoclonal antibody and kinase assays demonstrate that, in bag cell neurons, high nanomolar concentrations of vertebrate insulin stimulate insulin specific tyrosine autophosphorylation. Immunocytochemistry shows that the abundance of the bag cell receptor is regulated during Aplysia reproductive development: in sexually immature animals we find strong immunoreactivity in the cell bodies whereas in large mature animals very little receptor is seen. In addition, insulin applied to bag cell neurons in culture results in an increase in evoked action-potential amplitude, suggesting that the peptide also produces a tyrosine kinase-mediated change in the excitability of these cells. In addition to their role in growth and metabolism, endogenous Aplysia insulin-like peptides may function to modulate synaptic transmission controlling reproductive behaviors through tyrosine protein phosphorylation.

LONG-TERM MEMORY IN *APLYSIA*: MOLECULAR SIGNALS FOR THE UBIQUITIN-MEDIATED PROTEOLYSIS OF REGULATORY SUBUNITS OF THE cAMP-DEPENDENT PROTEIN KINASE. <u>A.N. Hegde\*</u> <u>D. Chain and J.H. Schwatz</u>, Cent. for Neurobiol. & Behav., Columbia Univ., NY, NY 10032

Behavioral sensitization of defensive reflexes and the underlying presynaptic facilitation of sensory-to-motor neuron synapses lasts for several min (short-term) or days (long-term). Short-term facilitation has been explained by cAMP-dependent modulation of ion channel function. Long-term (LT) facilitation requires additional molecular processes including new protein synthesis. A key molecular event is persistent activation of the cAMP-dependent protein kinase (PKA). Greenberg et al (Nature 329: 65, 1987) showed that regulatory (R) subunits are lost 24 h after LT training; this could account for the persistent activation of PKA at basal levels of cAMP that occurs in LT facilitation (Sweatt & Kandel, Nature 339: 51, 1989). Despite dependence on new protein synthesis, loss of R results from proteolysis rather than diminished synthesis (Bergold et al, PNAS 87: 3788, 1990; Neuron 8: 387,1992). Loss of R is tissue-specific: in muscle, R is not downregulated at high levels of intracellular cAMP. Earlier we established that neuronal and embryonic R subunits are degraded by ubiquitin-mediated proteolysis and postulated that factors targeting R for degradation, which are limiting in naive neurons, are among the new proteins synthesized. To test this hypothesis we compared degradation of R subunits from neurons and muscle. We find that muscle R (M1) can readily be degraded in vitro through the ubiquitin pathway. Evidence from molecular cloning indicates that M1 is encoded by the same gene as N4, a major neuronal isoform and a homolog of vertebrate R1. In addition, vertebrate R1 and R11 can be degraded by the same mechanism. We also find that free ubiquitin is present at very low concentrations in muscle. The signals for loss of Rs may be a feature of tissues that exhibit plasticity rather than tissue-specific structural specialization of R subunits. Ubiquitin itself and components of the ubiquitin proteolytic pathway might be among the new proteins made in sensory neurons during LT sensitization.

### 341.5

THE ROLE OF PHOSPHOLIPASE A<sub>2</sub>-ACTIVATING PROTEINS IN NEURONAL SIGNAL TRANSDUCTION. <u>R. Diaz-Arrastia\*</u>, <u>A.M. Elste</u>, <u>and J.H. Schwartz</u>, Dept. of Neurology and Center for Neurobiol. & Behav., Columbia Univ., New York, NY 10032

Lipoxygenase metabolites of arachidonic acid (AA) are second messengers in *Aplysia* neurons (Piomelli et al, *Nature* 328:38, 1987). Evidence has been presented that these metabolites are produced from AA released by receptor-mediated activation of a phospholipase-A<sub>2</sub> (PLA<sub>2</sub>). Calignano et al (*Mol Brain Res* 9:347, 1991) described a M<sub>r</sub> 30,000 protein that stimulates PLA2 in the nervous system of A protein with similar activity, phospholipase A2-Aplysia. activating protein (PLAP), has been cloned from murine smooth muscle (Clark et al, PNAS 88:5418, 1991). We used molecular probes from smooth muscle PLAP to demonstrate that a similar (but not identical) protein is present in vertebrate brain. Northern blots reveal that PLAP cDNA mRNAfrom vertebrate brain. to immunoblotting we find that anti-PLAP antibodies recognize a  $M_f$  45,000 protein that is abundant in brain, and subcellular fractionation reveals that the PLAP antigen is enriched in synaptosomal and microsomal fractions. Immunocytochemistry indicates that the PLAP antigen is present in many (but not all) neurons throughout the vertebrate brain. We are currently studying how the production of second messengers through the AA pathway is regulated by PLA2 and the role of PLAP in this process.

ACETYLCHOLINE AND PROCTOLIN DO NOT STIMULATE CAMP PRODUCTION IN THE LOBSTER CARDIAC GANGLION, YET THEIR PHYSIOLOGICAL ACTIONS ARE MIMICKED BY CYCLIC NUCLEOTIDES. H. Hashemzadeh-Garqari, D. G. Winder, and J. Freschi Neurology

Department and Neuroscience Program, Ernory University, Atlanta, GA 30322. The neuromodulators acetylcholine (ACh) and proctolin cause a slow depolarization by activating a voltage-dependent Na\* current in motoneurons of the lobster cardiac ganglion (Freschi & Livengood, J. Neurophysiol. 62: 984, 1989; Freschi, Neurosci. Lett. 106: 188, 1989). To characterize the biochemical second messengers that couple the receptors to the ion channels, we conducted electrophysiological and biochemical experiments. When applied by superfusion, phosphodiesterase inhibitors, lipid-soluble analogues of cAMP and cGMP, and the adenylate cyclase stimulator forskolin mimicked ACh and proctolin by producing a voltage-dependent Na\* current in voltage-clamped motoneurons. However, by biochemical assay we found that neither methacholine nor proctolin caused an increase of cAMP production above baseline control. In these same experiments, serotonin, which had previously been shown to stimulate cAMP production in the cardiac ganglion (Lemos & Berlind, J. Exp. Biol. 90: 307, 1981), increased cAMP production an average of 800% above control. Furthermore, serotonin did not evoke an inward Na\* current. Various nonspecific inhibitors of protein kinase did not block the effects of the neuromodulators. In conclusion, our present results suggest that the activation of a voltage-dependent Na\* conductance by ACh and proctolin does not occur through a cAMP-dependent mechanism. It remains possible that other cyclic nucleotides, such as cGMP, serve as second messengers for messenger may interact with the ion channel without activating protein kinase.

#### 341.4

THE CA<sup>2</sup>·-ACTIVATED PROTEIN KINASE C (PKC), APL I, IS PERSISTENTLY STIMULATED DURING LONG TERM SENSITIZATION IN APLYSIA. W. S. Sossin\* R. Diaz-Arrastia. T. Sacktor, and J. H. Schwartz. Center for Neurobiology & Behavior, Columbia University, New York, NY 10032.

Apl I, a Ca2+-activated PKC, and Apl II, a Ca2+-independent PKC, are present in the nervous system of the marine mollusk Aplysia (Kruger et al, J. Neurosci. 11:2303-2313, 1991). 5-HT, a transmitter that causes presynaptic facilitation in Aplysia, stimulates only a Ca2+-activated form (Sossin & Schwartz, J. Neurosci. 12:1160-1168, 1992 ). But surprisingly, translocation of Apl I is not detected under these conditions. To investigate the possibility that other isoforms of PKC are translocated after application of 5-HT, we separated PKCs on hydroxyapatite and examined the resulting fractions for kinase activity, reaction with antibodies to PKCs, and autophosphorylation. The results indicate that Apl I and Apl II are the only two major isoforms of PKC in the Aplysia nervous system. Thus, the activation caused by 5-HT must be due to stimulation of Apl I, perhaps by increasing the specific activity of an already membrane-associated form. Long-term sensitization training also only stimulates a Ca<sup>2+</sup> activated isoform, presumably Apl I, and this stimulation is present 2 h after the last sensitizing stimuli. A Ca2+-independent PKC activity though, presumably Apl II, is stimulated during the transition between short- and long-term memory, suggesting that it too has a role in the induction of long-term sensitization. The presence of only two isoforms makes Aplysia advantageous for understanding the specific roles of Ca2+-activated and Ca2+-independent PKCs in the physiological control of neuronal function.

#### 341.6

G PROTEIN α-SUBUNITS EXHIBIT A NEURON-SPECIFIC LOCALIZATION IN THE CENTRAL NERVOUS SYSTEM OF THE POND SNAIL LYMNAEA STAGNALIS. H van Heerikhuizen\*, W. Weidemann, J.C. Knol. E.R. van Kesteren, R.J. Plania and E. Vreugdenhil, Department of Biochemistry and Molecular Biology, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands.

The Netherlands. G protein mediated signal transduction pathways play an important role in neuronal communication. Aiming at the elucidation of such pathways we have chosen the central nervous system (CNS) of the pond snail Lymnaea stagnalis as a model. This CNS contains a relatively small number of neurons (~ 15,000) many of which can easily be identified, are of giant size (up to 0.4 mm) and have been extensively and multidisciplinary studied. We have cloned cDNAs encoding G protein-coupled receptors, G protein α-subunits

We have cloned cDNAs encoding G protein-coupled receptors, G protein  $\alpha$ -subunits and G protein effector molecules. Here we report on the cloning of four subtypes of G protein  $\alpha$ -subunits,  $G\alpha_0$ ,  $G\alpha_1$ ,  $G\alpha_2$  and  $G\alpha_0$ . Using immunocytochemistry and molecular biological techniques we have studied the neuron-specific expression of  $G\alpha_0$ ,  $G\alpha_1$  and  $G\alpha_2$ . Surprisingly expression is mainly found in axon tracts rather than in cell bodies, suggesting that signal transduction mediated by these G protein  $\alpha$ -subunits is primarily taking place at the axonal level. A number of well-characterized, identified cell groups have been found to (co-)express specific G protein  $\alpha$ -subunits. E.g.,  $G\alpha_0$ ,  $G\alpha_1$  and  $G\alpha_2$  are expressed in a subset of the growth-controlling light green cells, whereas  $G\alpha_1$  and  $G\alpha_2$  are expressed in the caudodorsal cells which are involved in egg-laying and egg-laying behaviour.

 $\alpha$ -subunits is primarily taking place at the axonal level. A number of well-characterized, identified cell groups have been found to (co-)express specific G protein  $\alpha$ -subunits. E.g.,  $G_{\alpha}$ ,  $G_{\alpha}$ , and  $G_{\alpha}$  are expressed in a subset of the growth-controlling light green cells, whereas  $G_{\alpha}$ , and  $G_{\alpha}$  are expressed in the caudodorsal cells which are involved in egg-laying and egg-laying behaviour. Benefitting from the large size of these neurons, we are currently performing microinjections with plasmids expressing G protein  $\alpha$ -subunits, or synthetic oligonucleotides antisense to G protein  $\alpha$ -subunit cDNAs. This way we can either up or down regulate a specific G protein  $\alpha$ -subunit subtype and study the effect of such a perturbation on ligand-stimulated signal transduction in these neurons.

## 341.8

IP<sub>3</sub>-ACTIVATED ION CHANNELS IN THE PLASMA MEMBRANE OF OLFACTORY RECEPTOR NEURONS. <u>D.A. Fadoo\*Pand B.W. Ache.</u> Whitney Lab. Depts. of Zool. & Neuroscience, Univ. of Florida, St. Augustine, FL 32086. An antibody directed to the 19 C-terminal residues of a cDNA clone of

An antibody directed to the 19 C-terminal residues of a cDNA clone of a mammalian cerebellar IP₃ receptor (kindly supplied by Dr. P. DeCamili) immunolabelled the outer dendrites of lobster olfactory receptor neurons (ORNs) *in situ*. The IP₃ receptor antibody (αIP₃-R), which recognized a band > 200 kDa in membrane preparations of mouse brain, also recognized a band of similar m.w. in membrane preparations of the outer dendrites of lobster ORNs and 36h cultured lobster ORNs. A second band ≈127 kDa was also labelled in the dendrites. Excitatory odors evoke a transient inward current in voltage-clamped cultured ORNs. Introducing αIP₃-R into cultured ORNs through the patch pipette selectively increased odor-evoked inward current an average of 427±48% (n=5). Odors applied to cultured ORNs evoked channel activity in 5 of 19 cell-attached patches. IP₃ applied to the inside face of cell-free patches of membrane activated two types of channels in 55 of 68 patches (73.7±5.7 pS (n=12) and 30.0±1.6 pS (n=16)). Both channels had mean open times best fit by a double exponential; t₁=0.45±0.07 msec and t₂=5.47±1.6 msec. The Pr₀pen was both pH, IP₃ and calcium concentration dependent, and for the larger channel, was independent of voltage between -90 mV and 60 mV. Neither channel inactivated under continuous stimulation and both were completely and reversibly blocked by 10 μm ruthenium red or 2.5 μm heparin. In one cell it was possible to calibrate an inside-out patch of membrane to IP₃ and then "cram" it into a second cell. Applying an excitatory odor to the bath subsequently activated a channel with properties identical to the one in the control calibration. Collectively, the data suggest that IP₃ directly activates at least one type of ion channel in the plasma membrane of lobster ORNs, which is the effector of the excitatory transduction cascade in these cells. Supported by ONR N0014-90-J-1566 & NRSA 1-F31-MH10124-01A1.

EFFECTS OF EXTRACELLULAR ATP ON NEURONAL Ca2+ HOMEOSTASIS. M.L. Koenig\*C.A. Fincke, and M.A. DeCoster. Div. Neuropsych., Walter Reed Army Inst. Research, Washington, DC 20307-5100.

Although there are numerous reports in the literature indicating that extracellular ATP can influence Ca<sup>2+</sup> homeostasis in different cell types (review: Biochim Biophys Acta 1134, 31-45; 1992), relatively little has been published on potential effects in primary neurons or neuronal cell lines. Since substantial quantities of ATP can be co-released from nerve terminals along with classical neurotransmitters, and because ATP may even be the primary neurotransmitter in some neurons, we have investigated the possibility that micromolar concentrations of ATP can alter intracellular Ca<sup>2+</sup> ([Ca]) dynamics in cultures of rat forebrain neurons and NG108-15 neuroblastoma-glioma hybrid cells.

Neurons taken from the forebrains of fetal rat pups (embryonic day 15) and

differentiated NG108-15 cells were plated onto glass coverslip chamber slides and loaded with the  $Ca^{2+}$ -sensitive dye indo-1 (2  $\mu$ M; 60 min; 37°C). [Ca], was measured confocally in single, identified cells (typical field =  $120 \mu m^2$ ;5-10 cells) using an ACAS 570 interactive laser cytometer (Meridian; Okemos, MI).

Fetal neurons were generally not responsive to ATP at concentrations up to 200 μM. In a representative experiment, 100 μM ATP induced an immediate, but small and transient increase in [Ca], in only 3 of 10 neurons. In contrast, differentiated NG108-15 cells were very sensitive to treatment with extracellular ATP showing a rapid (2-3s) rise in [Ca], when exposed to 10 μM ATP followed by a prolonged (60-100s) return to the pre-peak baseline. [Ca], increased in all cells by 6-7 fold in the presence of extracellular Ca²+ ([Ca], b), but by only 4-6 fold in it's absence. The data suggest that purinergic receptors are more common and abundant on NG108-15 cells than they are on fetal neurons and that at least part of the the ATP-induced increase in [Ca], in NG108-15 cells is due to an influx of [Ca].

### 341.11

MEASUREMENT OF SEROTONIN STIMULATED CALCIUM RELEASE USING BIOLUMINESCENT AEQUORIN EXPRESSED IN HUMAN CELLS. Y. Sheu\*, L Kricka, D. Pritchett, Children's Seashore House; Depts. of Ped. and Pharm., Path. Lab. Med., HUP., U. of Penn.; Phila., PA 19104

Aequorin, a bioluminescent protein from the jellyfish, consists of apoaequorin, coelenterazine, and bound oxygen. It emits light upon binding calcium. We investigated whether aequorin expressed in mammalian cells is an appropriate indicator of calcium release in response to neurotransmitters. The 5-HT2 receptors, a member of G protein coupled receptor family, stimulate phosphoinositide hydrolysis upon interacting with agonists and release intracellular calcium. The coding region of aequorin cDNA, prepared from mRNA of Aequorea victoria, was amplified by PCR and cloned into the eukaryotic expression vector pRK7. Serotonin 5-HT2 receptor cDNA was cloned expression vector pRAY. Serotomin 3-H12 receptor cDNA was cloned into a similar vector. Two days after human embryonic kidney 293 cells were co-transfected with aequorin cDNA and 5-HT2 receptor cDNA, aequorin was reconstituted by incubating with coelenterazine in the reaction solution. These cells luminesced upon serotonin treatment. The response was saturable and dose dependent, and it was inhibited by serotonin antagonists. Human 293 cells stably expressing aequorin seem to suffer no harmful effects due to long term expression of aequorin. This method proves to be a convenient and reliable way to access intracellular calcium concentration change in mammalian cells. This technique thus broadens the range of experiments in which calcium can be measured.

## 341.13

THAPSIGARGIN-INDUCED CA2+ INFLUX IS INDEPENDENT

OF DEPLETION OF THE IP<sub>3</sub>-SENSITIVE CA<sup>2+</sup> STORE IN NG108-15 CELLS. T.M. Lo\* and S.A. Thayer. Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN55455.

Bradykinin (BK)-induced intracellular Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>i</sub>) transients were studied in single NG108-15 cells with indo-1-based microfluorimetry. 1 min exposure to BK (30 nM) completely depleted the Inositol 1,4,5-triphosphate (IP<sub>3</sub>)-sensitive store which required extracellular Ca2+ to refill. Depletion of the store with BK did not activate  $Ca^{2+}$ ,  $Ba^{2+}$  or  $Mn^{2+}$  influx, suggesting that capacitative  $Ca^{2+}$  entry is not present in these cells. However,  $Ca^{2+}$  influx could be elicited by either prolonged exposure to BK, or treatment with the microsomal Ca<sup>2+</sup>-ATPase inhibitor, thapsigargin (TG). BK-induced Ca<sup>2+</sup> influx was sustained as long as the agonist was present. TG (10 nM) mobilized  $Ca^{2+}$  over the course of 3-5 min, completely depleting the IP3-sensitive  $Ca^{2+}$  store. In contrast, removing extracellular  $Ca^{2+}$ for 10 min only partially depleted the store, suggesting that Ca2+ leaks from the store at a relatively slow rate. Thus, TG releases Ca<sup>2+</sup> from the store in addition to preventing uptake. TG also elicited a sustained and irreversible Ca2+ or Ba2+ influx, in contrast to depletion of the store with BK. These data suggest that depletion of the IP<sub>3</sub>-sensitive Ca<sup>2+</sup> store and induction of Ca<sup>2+</sup> influx by TG are mediated by different mechanisms. We question the validity of using TG-induced Ca<sup>2+</sup> influx as a measure of capacitative Ca<sup>2+</sup> entry.

OBSERVATION OF NEURONAL INTRACELLULAR CALCIUM OSCILLATIONS USING A REAL-TIME LASER SCANNING CONFOCAL MICROSCOPE. M.A. DECOSTER', B.J. DAVIS, M.L. KOENIG AND F.C. TORTELLA. Dept. Med.

Neurosci., Walter Reed Army Inst. Res., Washington, D.C. 20307-5100. The 10\*-fold concentration difference between extracellular ([Ca]<sub>o</sub>) and intracellular ([Ca]) calcium requires that neurons be able to buffer changes in [Ca], or face a disruption of normal physiology and potentially, cell death. Using a real-time laser scanning confocal microscope (Insight System, Meridian Instruments, Inc.), we have monitored intracellular calcium [Ca], oscillations in primary rat cortical neurons loaded with the fluorescent calcium dye Fluo-3. Using ionomycin to maximize and EGTA to minimize [Ca], we calculated basal concentrations of neuronal free calcium to average 125 nM. Basal [Ca], oscillations were only observed in neurons that had been in culture for greater than a week, suggesting that older cultures may be more sensitive to excitatory stimuli. Often, the [Ca], oscillations observed were synchronized between multiple neurons simultaneously analyzed in a given field. A sustained increase in [Ca], was established in mature neurons (>7 days) when treated with toxic concentrations of glutamate (> 40  $\mu$ M). In contrast, younger neurons (<7 days) were less sensitive to glutamate. When mature neurons were monitored in calcium-free medium, basal [Ca], oscillations were absent or appeared less robust than oscillations observed for cells in calcium-containing medium. Addition of calcium-containing medium to neurons in calcium-free medium elicited an immediate increase in neuronal [Ca], but this higher [Ca], was eventually buffered by the neurons. In conclusion, monitoring the [Ca], dynamics of young and mature neuronal cultures using a real-time laser scanning confocal microscope provides information about the relative ability of these neurons to buffer endogenous and exogenous changes in calcium.

## 341.12

REGULATION OF CYTOSOLIC FREE CALCIUM IN FURA-2 LOADED DOG

TRACHEAL SMOOTH MUSCLE CELLS. C.M.Yang and W.M.Hu.\*. Depart. of Pharmacol. Chang Gung Medical College, Taiwan, R.O.C.

In order to analyze the factors regulating agonist-stimulated Ca<sup>+2</sup> mobilization, cytosolic free [Ca<sup>+2</sup>] ([Ca<sup>+2</sup>]<sub>i</sub>) ulated  $\operatorname{Ca}^{+2}$  mobilization, cytosolic free  $[\operatorname{Ca}^{+2}]_1([\operatorname{Ca}^{+2}]_1)$  was measured directly in fura-2 loaded canine tracheal smooth muscle cells (TSMCs). Stimulation of muscarinic receptors (mMChRs) by carbachol produced a dose-dependent rise in  $[\operatorname{Ca}^{+2}]_1$ . In the presence of external  $\operatorname{Ca}^{+2}$ , the initial transient  $[\operatorname{Ca}^{+2}]_1$  rapidly occurred and followed by a sustained elevation. The sustained elevation was dependent on the external  $\operatorname{Ca}^{+2}$ , Removal of  $\operatorname{Ca}^{+2}$  by the addition of EGTA caused a rapid decline in  $[\operatorname{Ca}^{+2}]_1$  to baseline. In the absence of external  $\operatorname{Ca}^{+2}$ , only an initial  $[\operatorname{Ca}^{+2}]_1$  was seen which then ddeclined to baseline; the sustained elevation could be evoked by addition of 1.8 nM  $\operatorname{Ca}^{+2}$  in the continued presence of carbachol. mAChR occupation by carbachol was required to maintain the elevated level of  $[\operatorname{Ca}^{+2}]_1$ ; addition of muscarinic anatgonist atropine, caused  $[\operatorname{Ca}^{+2}]_1$  to decline to base line. The  $\operatorname{Ca}^{+2}$ -channel blockers, diltiazem and verapamil, decreased both the initial and sustained elevation of the Ca<sup>+2</sup>-channel blockers, diffinated and veraponiting decreased both the initial and sustained elevation of  $[Ca^{+2}]_1$  in response to carbachol. These results demonstrate that the initial detectable increase in  $[Ca^{+2}]_1$  stimulated by carbachol is due to the release of  $Ca^{+2}$  from the internal stores, whereas the contribution of external  $Ca^{+2}$  occurs later and at least partially involves a diltiazem- and verapamil- sensitive process. (supported by NSC81-0412-B182-4 and CMRP-340).

## 341.14

MITOCHONDRIA BUFFER PHYSIOLOGICAL CALCIUM LOADS IN RAT DRG NEURONS. LL. Werth\* and S.A. Thayer. Department of Pharmacology, University of Minnesota Medical School, Minneapolis, MN 55455. Intracellular calcium concentration ([Ca2+]i) was measured in single rat dorsal root ganglion (DRG) neurons grown in primary culture. Superfusion with 50 mM K+ increased [Ca<sup>2+</sup>] $_i$  from 97 ± 12 to 1199 ± 108 nM. Recovery to basal [Ca<sup>2+</sup>] $_i$ consisted of three distinct phases; a rapid initial phase followed by a plateau (528 ± consisted of three usafute phases. When stimulated in the presence of the mitochondrial uncoupler CCCP (I µM) the plateau (25a slow phase) studied in the presence of CCCP, was not affected by removal of extracellular Na\*, indicating that Na/Ca exchange is not responsible for this phase. During the plateau phase, intracellular pH (Ph<sub>i</sub>) decreased from 7.13 to 6.97. This decrease in pH<sub>1</sub> was dependent on extracellular  $Ca^{2+}$ , suggesting that during the plateau  $Ca^{2+}$  was cycled by the mitochondria.  $Ca^{2+}$  cycling effectively uncoupled electron transport from ATP synthesis and resulted in a H<sup>+</sup> accumulation in the cytoplasm. Ten action potentials (10 Hz), elicited by electrical field stimulation, increased  $[Ca^{2+}]_i$  to 412 ± 26 nM. Recovery to basal  $[Ca^{2+}]_i$  was described well by a single exponential corresponding to the slow, Na+ independent phase (tau=7-17 seconds). A plateau in the recovery became apparent as the train was lengthened to 25-30 action potentials. Return to basal  $[Ca^2+]_i$  consisted of a rapid initial phase (tau  $\leq$  2 seconds), a plateau and a slow phase (tau=8-50 seconds). µM CCCP eliminated the plateau and the recovery was fit well by a single exponential. The time constant of recovery from small [Ca<sup>2+</sup>]; loads was unchanged exponential. The time constant of recovery from small [Ca<sup>2+</sup>]<sub>1</sub> loads was unchanged by CCCP. We conclude that large Ca<sup>2+</sup> loads are initially buffered by fast mitochondrial sequestration, Ca<sup>2+</sup> is then cycled by mitochondria until a slow, Na<sup>+</sup> independent process, presumably a Ca<sup>2+</sup> ATPase, removes the Ca<sup>2+</sup> from the cytoplasm. Mitochondria do not contribute to buffering of small [Ca<sup>2+</sup>]<sub>1</sub> transients. A train of 25-30 action potentials introduces a Ca<sup>2+</sup> load of sufficient magnitude to recruit mitochondrial Ca<sup>2+</sup> buffering.

INHIBITION OF GUANYLATE CYCLASE BY METHYLENE BLUE INCREASES [Ca2+]i IN MOUSE CORTICAL ASTROCYTES. J.A. Edwards\* and H.S. White. Anticonvulsant Drug Development Program, Department of Pharmacology & Toxicology, University of Utah, Salt Lake City, UT 84108.

The role of astrocytes in the etiology of seizure disorders has only recently

begun to be investigated. Type I mouse cortical astrocytes are known to both synthesize and release nitric oxide (Murphy et al., 1990), a molecular messenger which increases intracellular cGMP through activation of soluble guanylate cyclase (GC). De Sarro, et al. (1991) have shown that nitric oxide plays a role in excitatory amino acid (EAA)-induced seizure activity since N-monomethyl-Larginine (an inhibitor of nitric oxide synthesis) and methylene blue (MB, an inhibitor of GC) were both shown to block EAA-induced seizures in rats. Since seizure activity is partially calcium dependent, we examined the effects of MB on the intracellular calcium concentration in type I mouse cortical astrocytes using the fluorescent probe indo-1. The results obtained to date demonstrate that MB increases the intracellular calcium concentration in a biphasic manner. Inhibition of GC by perfusion of 300 nM, 1 µM, and 3 µM MB for 10 min. increased [Ca2+]i by 26, 132, and 66%, respectively. In contrast, increasing [cGMP]i (50  $\mu$ M 8-bromo-cGMP, 10 min.) decreased [Ca2+]i by 13%. Perfusion with a combination of 8-bromo-cGMP (50 µM) and MB (1 µM) attenuated the increase in [Ca2+]i induced by MB alone. These data suggest that cGMP may be involved in the regulation of [Ca2+]i in mouse cortical astrocytes. Future studies will examine further the effects of nitric oxide, guanylate cyclase, and cGMP on [Ca2+]i in mouse conical astrocytes and the role of these second messengers in the initiation and propagation of seizure acitivity. (Supported by NIH grants 2-RO1-NS22200 and GM07579).

## 341.17

PHARMACOLOGICAL CHARACTERIZATION OF IP<sub>3</sub>-DEPENDENT CA $^{L^+}$ . REGULATED CA $^{L^+}$  RELEASE. <u>E.A. Finch 1,3 J.L. Hill 3 and S.M. Goldin 2,3 1</u> Program in Neuroscience and  $^2$ Biol. Chem. Dept., Harvard Med. Sch., Boston, MA; <sup>3</sup>Cambridge NeuroScience, Inc., Cambridge, MA.

"Cambridge NeuroScience, Inc., Cambridge, MA.

We have previously reported that extravesicular Ca<sup>2+</sup> acts as a coagonist with IP<sub>3</sub> to rapidly potentiate and more slowly inactivate IP<sub>3</sub>-induced <sup>45</sup>Ca<sup>2+</sup> release (Finch et al., Science 252:443, 1991) and that ATP further potentiates this Ca<sup>2+</sup> regulated IP<sub>3</sub>-dependent Ca<sup>2+</sup> release. These findings suggest functional homology with the structurally homologous ryanodine receptor of sarcoplasmic reticulum. The  $IP_3$ -dependent  $Ca^{2+}$ -regulated  $Ca^{2+}$  release activity was highly enriched in vesicles derived from cerebellum which also expressed high levels of IP<sub>3</sub> receptor, as derived from cerebellum which also expressed high levels of  $\rm IP_3$  receptor, as demonstrated by use of  $\rm IP_3$  receptor antibodies. We have examined the effects of various pharmacological agents known to act on components of  $\rm Ca^{2+}$  stores on the subsecond kinetics of both  $\rm IP_3$ -induced and  $\rm Ca^{2+}$  induced  $\rm Ca^{2+}$  release. The microsomal vesicle preparation used for these studies contained both  $\rm IP_3$ -sensitive and ryanodine-sensitive  $\rm Ca^{2+}$  stores. Thapsigargin (2  $\mu$ M), which inhibits microsomal  $\rm Ca^{2+}$  ATPase, inhibited up to 80% of ATP-dependent  $\rm Ca^{2+}$ 

inhibits microsomal Ca -AlPase, inhibited up to ovo or AlPasepearent Ca uptake. Vesicles preincubated with submaximal concentrations of thapsigargin prior to  $Ca^{2+}$  loading exhibited diminished  $P_3$  and  $Ca^{2+}$ -induced  $Ca^{2+}$  release. The regulation of the remaining  $P_3$ -mediated  $Ca^{2+}$  release by  $Ca^{2+}$  and the kinetics of  $Ca^{2+}$  release were unaffected by the diminished  $Ca^{2+}$  content of the vesicles.

Exposure of microsomal vesicles to ryanodine (10µM), caffeine (10µM), or ruthenium red (10µM) prior to and during Ca<sup>2+</sup> loading did not alter the Ca<sup>2+</sup> release pattern elicited by subsequent superfusion with IP3. However, simultaneous exposure of vesicles to IP<sub>3</sub> and either caffeine or ruthenium red inhibited IP<sub>3</sub>-mediated Ca<sup>2+</sup> release. These results further support the hypothesis of functional homology between IP3 and ryanodine receptors and demonstrate that pharmacological agents such as caffeine and ruthenium red which were thought to be selective for  ${\rm Ca}^{2+}$  induced  ${\rm Ca}^{2+}$  release inhibit  ${\rm IP}_3$ -induced  ${\rm Ca}^{2+}$  release as well.

IMMUNOREACTIVITY FOR CALCIUM-BINDING PROTEINS IN THE CHICK EDINGER WESTPHAL NUCLEUS. J.T. Fujii\* and Z. Lucaj. Dept. of Anatomy and Cell Biology. Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Antibodies against parvalbumin and calbindin were used to screen Edinger Westphal nuclei of newly hatched chicks to determine whether immunoreactivity for either protein is preferentially associated with a particular subpopulation of Edinger Westphal neurons. Primary antibodies were obtained from Dr. M. Celio or Sigma and were visualized using biotin-avidin HRP. In some experiments, sections were also stained for neuron specific enolase

Light to moderate immunoreactivity for parvalbumin was observed in scattered neurons throughout the Edinger Westphal nucleus. The most heavily stained neurons were often found localized in the lateral and central parts of the nucleus. Consistently in some sections of each brainstem, the most heavily stained neurons were clustered along the lateral edge of the nucleus. The medial parts of the nucleus, particularly at the more rostral levels, had fewer and more lightly stained positive neurons. This pattern of parvalbumin immunoreactivity corresponds to the distribution of rapidly firing neurons in the Edinger Westphal nucleus and is in agreement with previous work which associates parvalbumin with neurons firing at high frequency.

Despite the presence of robust staining in our positive controls, no immunoreactivity for calbindin was observed in the Edinger Westphal nucleus.

This work was funded by NSF BNS-8719391.

EFFECTS OF CAFFEINE ON [Ca<sup>2+</sup>]<sub>in</sub> SIGNALS AND SECRETION IN PORCINE ADRENAL CHROMAFFIN CELLS. Y. Xu and E.J. Forsberg. Dept. of Physiology, Univ. Wisconsin, Madison, WI 53706. A possible involvement of Ca<sup>2+</sup>-induced Ca<sup>2+</sup> release (CICR) in muscarinic agonist-induced, extracellular Ca<sup>2+</sup>-

(CICR) in muscarinic agonist-induced, extracellular Ca\*-independent, secretion in porcine adrenal chromaffin cells was examined. Caffeine produced rapid increases in [Ca²-]<sub>in</sub> in a ryanodine-sensitive manner. In addition, caffeine pretreatment eliminated methacholine- (a selective muscarinic agonist) and thapsigargin- (thapsigargin depletes Ins(1,4,5)P<sub>3</sub>-sensitive Ca²- pools) induced increases in [Ca²+]<sub>in</sub> as well as methacholine-induced secretion when Ca²--free solutions were used. However, other results suggest that CICR does not play a major role in methacholine-induced increases in [Ca²+]<sub>in</sub> but rather indicate that Ins(1,4,5)P<sub>3</sub> and caffeine activate Ca²+ pools, if they exist, can rapidly equilibrate. Caffeine was also observed to block nicotinic responses but not K\*-induced responses, suggesting that caffeine blocks nicotinic receptor-channels. We also observed that induced responses, suggesting that caffeine blocks nicotinic receptor-channels. We also observed that caffeine consistently decreased [Ca<sup>2+</sup>]<sub>in</sub> when [Ca<sup>2+</sup>]<sub>in</sub> had been raised by either methacholine, nicotine or K<sup>\*</sup>- an effect which may have been due to the inhibition of either adenosine receptors or cyclic nucleotide phosphodiesterases since aminophylline, 3-isobutyl-1-methylxanthine and since aminophylline, 3-isobutyl-1-methylxanthine and caffeine, all of which share these inhibitory activities, were all found to reduce elevated [Ca<sup>2\*</sup>]<sub>in</sub>.

PURIFICATION AND CALCIUM-BINDING ACTIVITY OF CALRETININ EXPRESSED IN E. COLI

J.H. Rogers, W-T. Cheung and D.E. Richards (SPON: Brain Research Association). Physiological Lab., University of Cambridge, Cambridge CB2 3EG, England.

Calretinin is a neuronal cytosolic calcium-binding protein of the EF-hand family, with 60% homology to calbindin-D28k. The chick calretinin cDNA sequence was reconstructed in a M13 vector and then transferred into an expression plasmid, so that the calretinin gene was under a T7 promoter and inducible by IPTG. This was expressed in E. coli and produced by IPTG. immunoreactive calretinin, which in two-dimensional electro-phoresis had the same size (29 kDa) and pl (4.8-5.0) as chick retinal calretinin. The bacterially expressed calretinin was purified with successive ammonium sulfate precipitation, DEAE chromatography, hydroxyapatite chromatography, G-75 chromatography, and Mono-Q chromatography. About 1.0-1.5 mg of pure calretinin was obtained per litre of bacterial culture, representing 0.5-1.5% of the initial protein. Calcium-binding activity of purified calretinin was measured by equilibrium dialysis in Ca.EGTA mixtures with 45Ca, in 100 mM NaCl, 20 mM PIPES pH 7.0. It displayed a  $K_d$  of 0.3  $\mu$ M.

GLUCOSE - 6 - PHOSPHATE **MODULATES** REGIONALLY ENDOPLASMIC RETICULUM CALCIUM POOLS IN RAT BRAIN. Verma\*, D.J. Hirsch and S.H. Snyder. Johns Hopkins University Sch. of Med., Dept. of Neurosci, Baltimore, MD 21205.

Glucose-6-phosphate (G6P) is a major intermediary metabolite with several important functions. Recently energy dependent <sup>45</sup>Ca<sup>2+</sup> uptake has been shown to be enhanced by mM amounts of G6P in microsomal preparations from these Using phosphate or oxalate supported, Mg-ATP tissues. Using phosphate or oxalate supported, Mg-AIV dependent \*SCa2\* uptake into rat brain microsomes and fresh frozen sections, G6P was found to dose-dependently reduce net \*SCa2\* accumulation. 15% of the rat brain Ca2\* pools are affected by G6P at maximally effective doses of 5-10 mM. Sensitivity to G6P is specific as other sugar analogs including glucose-1-phosphate, glucose-1,6-diphosphate, galactose-phosphate, glucose-6-sulfate and 2-deoxy glucose-6-phosphate were without effect. Effects of G6P were 6-phosphate were without effect. Effects of G6P were reversed by heparin and were additive with effects of inostiol 1,4,5-trisphosphate and caffeine. Regional analyses using microsomal preparations or fresh analyses using microsomal preparations or fresh frozen sections evaluated by autoradiography revealed selective enrichment of G6P sensitive  $Ca^{2*}$  pools in the brain stem, spinal cord, deep cerebellar nuclei, white matter and hippocampus. These patterns do not resemble any previously localized  $Ca^{2*}$  pools and suggest a new role for G6P in CNS physiology. Relationship of the G6P sensitive  $Ca^{2*}$  pool to

EFFECTS OF BENZODIAZEPINE LIGANDS ON FREEZING BEHAVIOR AND REGIONAL EEG ACTIVITY IN RHESUS MONKEYS. S.E. Shelton, R.J. Kekstas, R.J. Davidson, and N.H. Kalin. Departments of Psychiatry and Psychology, Univ. of Wisconsin, Madison, WI 53792.

Many species "freeze" as an adaptive response to threatening situations. The equivalent of freezing behavior in humans may be the extreme behavioral inhibition exhibited by pathologically shy children. In addition, an animal's duration of freezing is believed to reflect its degree of fearfulness

We previously established that presenting the profile of a face to rhesus monkeys elicits freezing behavior. To examine the brain regions that mediate freezing, we implanted electrodes on the left and right frontal parietal cortical surfaces of two young rhesus monkeys. The monkeys w posed to a human facial profile and EEG was monitored by radiotelemetry. Because we have found that benzodiazepines modulate freezing and affect frontal EEG asymmetry, we also examined the effects of benzodiazepine ligands on regional EEG. One subject exhibited selective freezing behavior in response to the challenge; the other did not. The animal that froze also had the more pronounced EEG changes, characterized by relative activation of the right frontal cortex. This is consistent with the right frontal activation seen in humans and monkeys in relation to negative affective states. We compared the effects of diazepam and β-carboline on EEG asymmetry and found that the latter produced greater relative right-sided activation than the former in both frontal and parietal cortical regions. The effects of diazepam are consistent with our earlier study measuring EEG with scalp electrodes in manually restrained monkeys. The data suggest that the therapeutic actions of benzodiazepines may be due to the modulation of the balance of activation between select regions of the two cerebral hemispheres.

### 342.3

MASKING OF THE CHLORDIAZEPOXIDE DISCRIMINATIVE STIMULUS BY BUSPIRONE AND CAFFEINE. J.M. Peirce\*, D.V. Gauvin, & F.A. Holloway. Univ. of Okla. Hlth. Sci. Cntr., Dept. Psychiat. & Behav. Sci., Okla. City, OK USA 73190-3000.

Twelve rats were trained in a drug discrimination (DD) task after injections of either chlordiazepoxide (CDP; 5 mg/kg, i.p.) or saline (SAL) in a two-lever food-motivated operant task

We compared the interaction between CDP and: 1) flumazenil, 2) BUSPIRONE (BUSP) and 3) CAFFEINE (CAF). Co-administration of CAF shifted the CDP DD function to the right. These results are similar to those previously reported by Ator & Griffiths (Eur J Pharm, 237, 393-403, 1986) with both baboon and rat

Because of the disruptive effects of CDP-BUSP combinations, interaction tests had to be conducted with 3 mg/kg CDP, a dose which, by itself, engendered >90% CDP-appropriate responding. Like CAF, BUSP attenuated the DD properties of 3CDP, and shifted the DD function to the right.

The shifts in the CDP DD functions by both CAF and BUSP were paralleled by a downward shift in the rate functions. These drug interactions are contrasted by those produced by CDPflumazenil tests. The data are similar to previous reports of "perceptual masking" of drug stimuli (Gauvin & Young, Drug Dev. Res., 16, 151-162, 1989).

## 342.5

DIFFERENTIAL EFFECTS OF CARBAMAZEPINE AND PK11195 ON CONFLICT BEHAVIOR IN THE RAT. T.J. Hill\*, and R.L. Commissaris. Dept. Pharmaceut. Sci., Wayne State Univ., Detroit, MI 48202.

The present study examined the effects of the antiseizure agent carbamazepine (CBZ) and the peripheral benzodiazepine antagonist PK11195 on behavior in the conditioned suppression of drinking (CSD) conflict task. In daily 10-min sessions, water-restricted female rats drank from a tube which was occasionally electrified  $(0.25-0.5~\mathrm{mA}~\mathrm{shocks}~\mathrm{signaled}~\mathrm{by}~\mathrm{a}~\mathrm{tone})$ . Acute challenges with CBZ or PK11195 were conducted at weekly intervals using a cross-over design. When examined following 10, 20 or 60-min pretreatment (preTx) intervals, CBZ exerted modest and dose-related anti-conflict effects at doses from 5-20 mg/kg; higher doses significantly suppressed both punished and unpunished responding (water intake). In contrast, whether tested using a 10, 20 or 60-min pre-Tx, PK11195 failed to increase punished responding at doses of 5-40 mg/kg. In addition, combination studies revealed that there was no evidence for additivity between 10 mg/kg CBZ and 10 mg/kg PK11195. The present findings are not consistent with the hypothesis that CBZ exerts its anticonflict effects via antagonist actions at peripheral BZ receptors. The mechanism underlying the anti-conflict actions of CBZ remains undetermined. (Supported in part by USPHS MH47181).

MASKING OF THE CHLORDIAZEPOXIDE (CDP) CUE BY CAFFEINE (CAF) IN A THREE-CHOICE CDP-SAL-CAF DRUG DISCRIMINATION TASK. F.A. Holloway\*, K.L. Goulden, & D.V. Gauvin. Univ. Oklahoma Hlth. Sci. Cntr., Dept of Psychiatry & Behavioral Sciences, Oklahoma City, OK USA 73190.

We have reported the blockade of the cuing properties of CDP (5 mg/kg) by CAF in rats trained in a two-choice drug discrimination (DD) task (see Peirce, Gauvin, & Holloway, this meeting). To further explore the nature of this interaction, we trained 12 rats in a three-choice DD task using 3 mg/kg CDP, SAL, and 50 mg/kg CAF as training stimuli.

Both CDP and CAF produced dose- and drug-dependent increases in responding on the injection-appropriate lever. Interaction tests were conducted with CAF and CDP. We have previously shown that high CAF doses produced pentylenetetrazole (PTZ)-appropriate responding in rats trained in a 3-choice CDP-SAL-PTZ DD task (Gauvin & Holloway, Beh. Pharmac., 2, 417-428, 1991) suggesting that these CAF doses were anxiogenic. We predicted that anxiogenic doses of CAF would block the DD (i.e. anxiolytic) properties of CDP. High doses of CAF in combination with CDP engendered saline- or default-appropriate responding. These results suggest that the interoceptive stimuli produced by both training stimuli may lie in overlapping orthogonal dimen-

STUDIES ON THE DEVELOPMENT OF BEHAVIORAL TOLERANCE TO MIDAZOLAM IN RATS. J.S. Fu and N.W. Pedigo, Jr.\*, Departments of Pharmacology and Anesthesiology, Univ. of Kentucky Medical Center, Lexington, KY 40536.

The pharmacological tolerance to benzodiazepines has been extensively investigated, but few studies have assessed the tolerance to ultra-short acting benzodiazepines. Development of behavioral tolerance to midazolam (MDZ) was assessed in Fischer 344 rats trained to respond for food presentation under a fixed-ratio 30 schedule (FR30). The dose-response curve for rate-suppressing actions of MDZ (0.1-3.2 mg/kg) was established in experimentally naive rats, with an ED<sub>50</sub> of 0.53  $\pm$  0.04 mg/kg. At the highest dose (3.2 mg/kg, sc), MDZ almost completely inhibited response rate. These rats were divided into two groups (n=6 each) to study the chronic effects of MDZ on scheduled behavior: group I animals were administered MDZ (3.2 mg/kg/day) 5 min before the FR30 while subjects in group II were administrated MDZ sely after the session. Following six weeks chronic immediately after the session. treatment, the rate-suppressing effects of a challenge dose of MDZ (3.2 mg/kg) were significantly impaired in group I animals compared to naive rats (26% vs 90% reduction from baseline, respectively, p<.05). In group II, the same dose of MDZ produced moderate tolerance, with a 50% decrease in baseline response rate on the FR30 schedule. Based on these studies, we conclude that chronic MDZ induced both pharmacological and behavioral tolerance.

## 342.6

NON-SEDATIVE DOSE LORAZEPAM DISSOCIATES THE
NEUROCHEMICAL AND BEHA VIORAL CORRELATES OF FEAR
CONDITIONING IN THE RAT. A.M. Rasmusson\*, L.E. Goldstein, B.S.
Bunney, and R.H. Roth. Child Study Center and Depts of Pharmacology and
Psychiatry, Yale University School of Medicine, New Haven, CT 06510.

We have recently rigorously characterized a model of fear conditioning in
the rat. The studies are carried out during the rat's dark (active) phase. On Day
1, the rat is placed in a novel environment for 30 minutes (habituation phase)
and then randomly presented ten tones (CS) paired with ten 0.4 mA footshocks
(US) over 30 minutes (conditioning phase). On Day 2, the rat is reexposed to
the environment and presented ten tones over 30 minutes (extinction phase).
The animals are then sacrificed and their brains dissected for tissue analysis of
dopamine (DA), serotonin (5HT), and metabolite levels by HPLC-ED. Trunk
blood is collected for serum corticosterone measurement. Animal behaviors are
remotely coded during the habituation, conditioning, and extinction periods for blood is collected for serum corticosterone measurement. Animal behaviors are remotely coded during the habituation, conditioning, and extinction periods for locomotion, grooming, freezing and ultrasonic vocalizations. Previous studies using this model have shown that increases in plasma serum corticosterone, DA and 5HT turnover in the prefrontal cortex (PFC), ultrasonic vocalizations, and freezing behavior are under strong CS control; the latter four components of the conditioned fear response (CFR) are also highly correlated. A non-sedative dose of lorazepam (0.5 mg/kg, IP), given 20 minutes prior to testing, completely blocks increases in PFC DA & 5HT turnover, but does not affect the neurohumoral and behavioral components of the CFR. Ondansetron (1.0 mg/kg IP) had no discernable effect on any of the components of the CFR. mg/kg IP) had no discernable effect on any of the components of the CFR. R016-6028, a partial benzodiazepine agonist, is currently under study. Supported in part by USPHS grants MH14092 and MH25842, and Tourette's Society of America.

EFFECTS OF ORAL LORAZEPAM AND ALPRAZOLAM ON FR RESPONDING IN RATS. M.J. Kallman\*, H.B. Ayvasik, and S. Allen. Depts. of Psychology and Pharmacology, University of Mississippi, University, MS

The oral effects of two benzodiazepines, lorazepam (LZ) and alprazolam (AP), were compared on fixed ratio (FR)-30 responding. Twenty, male S-D rats were trained to respond on an FR-30 schedule for a sweetened milk reinforcer. Once responding stabilized a dose response and time course were determined for each drug (N=10 rats/drug) when the drug was given by oral gavage. A dose of 3.0 mg/kg LZ produced a significant reduction in lever responses and a reduction in lever contact time. The peak effect for a 3.0 mg/kg dose of LZ time. The peak effect for a 3.0 mg/kg dose of LZ was observed at 180 min. after gavage. Onset of activity for AP was more rapid than observed for LZ since the timepoint of peak effect was at 15 min. following gavage. AP produced significant increases in rate of responding at low doses and decreases in rate and increases in duration of responses at higher doses (10-15 mg/kg). Both benzodiazepines alter FR responding when given orally but the less potent LZ has a more rapid onset of effect. This research was supported by DA-05253.

### 342.9

EFFECTS OF POST-TRAINING ADMINISTRATION OF THE M2 ANTAGONIST METHOCTRAMINE ON SPATIAL MEMORY. M.J. Stillman, B. Shukitt-Hale, R.M. Kong, A. Levy, and H.R. Lieberman. Military Performance and Neuroscience Division, United States Army Research Institute of Environmental Medicine, Natick, MA 01760-5007, 'GEO-CENTERS, INC., Newton Centre, MA 02159, and 2IIBR, Ness Ziona, ISRAEL.

Muscarinic autoreceptors in the hippocampus appear to be of the M2 receptor subtype, since both in vitro and in vivo investigations have shown increased acetylcholine (ACh) release following administration of  $M_2$  antagonists. Therefore,  $M_2$  antagonists could improve memory and performance by potentiating cholinergic function. One  $M_2$  antagonist, AF-DX 116, appears to improve spatial memory. The purpose of this study was to examine the effect of post-training administration of the M2 antagonist methoctramine on a spatial memory task. Seven male Fischer rats were trained to criteria on an eight-arm radial maze task, using a within-subjects design. On test days, rats were removed from the maze after their first four choices and then injected with methoctramine (0.15, 0.30, or 0.60 mg/kg, s.c.) or vehicle in a randomized order. Retention was then tested after a four-hour delay. Methoctramine had no effect on: percent correct in the next four choices; the number of trials needed to obtain the remaining four pellets; or the latency to obtain the remaining

## 342.11

TARGET SITES FOR THE STEROID ANESTHETIC 3α-5α-PREGNANOLONE ARE PRESENT IN MIDBRAIN-HINDBRAIN OF MICE. J.G. Thalhammer\*, C. Bukusoglu, W.M. Mok and N.R. Krieger. Anesthesia Res. Lab. Harvard Med. School and Brigham & Women's Hospital, Boston, MA 02115.

The steroid  $3\alpha$ -hydroxy- $5\alpha$ -pregnan-20-one  $(3\alpha)$ , a metabolite of progesterone, mediates the loss of the righting response (LRR) in mice by its actions at a receptor target site in brain (J. Neurochem. 57,1296, 1991). To localize this receptor by pharmacological methods, we removed all brain structures that are not required for the righting behavior. Midbrain decerebrate mice with brainstem and cerebellum intact are fully able to right themselves (Klin. Wochenschrift 9,404, 1923). Here we report that  $3\alpha$  is still able to induce LRR in decerebrate mice.

Male albino mice (CD-1, 20 g) were anesthetized and the forebrain wa removed by gentle suction with the guidance of a dissection microscope. After mice were completely recovered,  $3\alpha$  was injected (i.v.) in a cremaphor (20%) saline (80%) vehicle and LRR was monitored. For a group of 10 decerebrate mice (which were fully able to right themselves), a dose of 1.5 mg/kg 3α resulted in LRR within 40 sec for 100% of the mice. This result is essentially comparable to that previously observed with intact mice although LRR is achieved more rapidly. The same dose administered to intact mice resulted in LRR within 9 min for 80% of those tested (n = 5).

This is the first evidence that functional target sites for  $3\alpha$  and the neuroanatomical circuits that mediate steroid responsive LRR are present in the midbrain-hindbrain. The behavior did not reveal any involvement of the spinal cord although a possible involvement cannot be fully ruled out. Other related or dentical receptors may also be present in the forebrain but are not essential to the behavior studied. (Supported by NIH grant GM 42672)

MITOCHONDRIAL BENZODIAZEPINE RECEPTORS AND RAPID TOLERANCE TO THE SEDATIVE EFFECTS OF BENZODIAZEPINES IN RATS. C. Ambrosio, R. Reggio and M. Massotti\*. Lab. of Pharmacology, Istituto Superiore di Sanità, 00161, Roma, Italy.

In studying tolerance to benzodiazepines (BZ), it is important to take into account that along with sedation these drugs also induce signs of weak behavioural stimulation. These can be clearly observed in electroencephalographic (EEG) studies. In the EEG pattern, the sedative effects of BZ is associated with high voltage, low frequency waves (synchronization), and the stimula-

tory effect is associated with > 14Hz, low voltage waves ( $\beta$ -like activity). The i.v. administration once a day for 5 days of diazepam (10 mg/kg) flunitrazepam (2.5 mg/kg), clonazepam (2.5 mg/kg), zolpidem (3 mg/kg), alpidem (10 mg/kg) and Cl 218,872 (10 mg mg/kg) suggests that these drugs can be classified into three distinct groups on the basis of their ability to change both the EEG pattern with respect to the 1st day of injection and the density of mitochondrial BZ binding sites in rat brain cortex: a) with diazepam and flunitrazepam, changes in the EEG periods of synchronization (decrease) and  $\beta$ -like activity (increase) are associated with changes in the Bmax values of 3H-PK 11195 (increase) and 3H-Ro 5-4864 (decrease); b) with alpidem, a reduction in the periods of EEG synchronization, without changes in  $\beta$ -like activity, is associated with a reduction in both 3H-PK 11195 and 3H-Ro 5-4864 Bmax values; c) with zolpidem, clonazepam and Cl 218,872 no change in the EEG or binding parameters are observed.

These data suggest that mitochondrial BZ site can play a role in the central adaptive changes underlying tolerance to the BZ.

EFFECTS OF REPEATED ADMINISTRATION OF HORSE SERUM EFFECTS OF REPEATED ADMINISTRATION OF HORSE SERUM BUTTAYRLCHOLINESTERASE ON BEHAVIOR, BLOOD-ENZYME LEVELS AND ANTIBODY PRODUCTION IN RATS. R.F. Genovese". X-C.M. Lu. M.K. Gentry. R. Larrison and B.P. Doctor. Divisions of Neuropsychiatry and Biochemistry, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Administration of butyrylcholinesterase (BChE) improves

outcome from subsequent exposure to organophosphorus (OP) agents. We examined the effects of repeated administration of purified horse serum BChE. Rats (n=10) were trained to leverpress for food under a variable interval 18 s (VII8) schedule of reinforcement. The schedule produced relatively fast and constant response rates throughout daily 30-min sessions. BChE (500 U) was injected IP prior to the start of 5 sessions over a 15-day period. Blood was sampled before the first injection, and on the day following each injection. Blood BChE activity increased following injections 1-3 but returned to near control levels following injections 4-5. Moreover, production of IgG and IgM serum antibodies correlated with the reduction in blood BChE activity. Response rates under the VI18 schedule were unaffected throughout the period. Thus, purified horse serum BChE may be advantageous for extended prophylactic OP therapy since behavioral performance was not disrupted. efficacy from repeated administration, however, may be limited, since 1) increases in blood-enzyme levels were not maintained, and 2) immunoreactive effects from repeated administration are

## 342.12

THE POTENT, RAPID AND BEHAVIOR-SPECIFIC ACTIONS OF ANDROGENS. D. Domek, I. Niekrasz, A. Garnica and T. Seale\*. Dept. Pediatrics, U. Oklahoma HITh. SCI. CLT., Oklahoma City, OK 73104
Abuse of testosterone derivatives and the finding that non-anabolic steroids have behavioral and neurochemical effects underscore the need for study of the acute and chronic behavioral actions of androgens. We have identified anxiolytic-like effects in mice after the acute administration of testosterone (T) and dihydrotestosterone (DHT) as measured in a novel murine assay (Toubas et al. 1990 Pharmacol. Biochem. Behav. 35:121) sensitive to benzodiazepine and serotonin anxiolytics. Behavior was assessed in male 10 week BALB/CBK mice (n=10/dose) 30 min. after IP injection of T and DHT. Large, dose dependent reductions in aversive behavior were observed without changes in locomotor activity. The estimated ED50 values for T and DHT were 0.032 and 0.06 mg/kg respectively (110 and 210 nmoles/kg). Mouse T production is about 0.16 mg/kg/d (560 nmoles). Effects of T and DHT were compared to those of estradiol (E) and dexamethasone (DEX). Both E and DEX elicited similar behavioral changes but were much less potent. ED50 values for E and DEX respectively were 0.3 and 0.25 mg/kg (1100 and 637 nmole/kg). Classic androgen mediated events require changes in gene expression taking hours to days. The rapid, paradigm-specific behavioral changes we found upon androgen administration and the high potency of these androgens compared to the non-androgenic steroids suggest the presence of androgen binding sites in the brain that modulate non-sexual behaviors.

EFFECTS OF THE CCK ANTAGONISTS CI-988 AND MK-329 ON THE DISCRIMINATIVE-STIMULUS EFFECTS OF COCAINE. <u>B.W. Massey\*</u>, <u>K.E. Vanover, and W.L. Woolverton</u>. The Drug Abuse Research Center, The

K.E. Vanover, and W.L. Woolverton. The Drug Abuse Research Center, The University of Chicago, Chicago IL 60637.
Cholecystokinin (CCK) and dopamine (DA) have been shown to be colocalized in neurons in the mesolimbic DA pathway and there is evidence that CCK modulates DA neurotransmission. Antagonists for both CCK A and CCK B receptors have been developed and produce opposite effects on DA neurotransmission. Since blockade of DA reuptake into mesolimbic DA neurons is involved in at least some of the behavioral effects of cocaine, compounds that act on CCK receptors may alter those behavioral effects of cocaine. Rats (N=7) act on CCK receptors may alter those behavioral effects of cocaine. Rats (N=7) and rhesus monkeys were trained in a two-lever drug discrimination paradigm to discriminate cocaine (rats: 8.0 mg/kg, i.p.; monkeys: 0.2 or 0.4 mg/kg, i.m.; 10 min pre-session) from saline rats (rats: 1.0 ml/kg, i.p.; monkeys: 0.1 ml/kg, i.m.; 10 min pre-session). Lever pressing was maintained by food (all rats, two monkeys) or shock avoidance (one monkey). In rats, the CCK B antagonist CI-988 (1.0-32 mg/kg), the CCK A antagonist MK-329 (0.5-2.0 mg/kg) or their vehicles were administered i.p., 30 min prior to cumulative cocaine dose-response functions. In monkeys, CI-988 was administered i.m., 30, 60 or 120 min presserion in combination with the training does of cocaine. Is both receive the session in combination with the training dose of cocaine. In both species, the percentage of responses emitted on the drug lever (% DL) varied between approximately 100% following the training dose of cocaine and 0% following saline. Intermediate doses of cocaine occasioned intermediate % DL. C1-988 had no effect on either % DL or rate of lever pressing in either rats or monkeys.

Although there was a tendency for the cocaine dose-response function to shift to the right in combination with MK-329 in rats, this trend did not achieve statistical significance. Higher MK-329 doses are now being tested. These results suggest that blockade of CCK receptors does not alter the DS effects of cocaine (Supported by NIDA grants DA-00250, DA-05951 and DA-00161).

UNIQUE BEHAVIORAL PROFILES OF CCK ANTAGONISTS IN RATS. J.G. Wettstein\*1, A. Grouhel1, B. Earley2 and J.L. Junien.1 1Institut de Recherche Jouveinal, 94265 Fresnes, France and <sup>2</sup>University College,

The non-peptide, benzodiazepine-derived CCK-A and CCK-B receptor antagonists devazepide and L-365260, respectively, were studied alone and with other drugs in conditioned and unconditioned behavioral procedures in rats. The individual effects of the CCK antagonists were usually determined over a range of doses covering 2 - 4 log units (e.g., 0.01 - 10.0 mg/kg). Devazepide and L-365260 had little or no effect under the following three operant schedules: VI/FR conflict, FI-2 (food presentation) and FR-10 (food presentation). Neither drug markedly altered the behavioral effects of amphetamine nor the  $\beta$ -carboline FG 7142 under the VI/FR schedule; L-365260 did not alter the ratedecreasing effects of the dopamine agonists [-]apomorphine and quinpirole under the FI schedule; and both CCK antagonists potentiated the ratedecreasing effects of the dopamine antagonists SKF-83566 and raclopride under the FR schedule. In a conditioned avoidance procedure, however, L-365260 did not alter behavior itself and apparently did not influence the actions of SKF-83566 and raclopride. The CCK antagonists had limited effects on general behavioral activity as measured by locomotor and open field testing. Lastly, although devazepide and L-365260 had some antianxiety-like effects in the elevated plus maze procedure, these actions were neither particularly consistent nor dose-related. Together, the results show that two prototype CCK antagonists from this chemical series possess profiles of action that do not resemble those of known drugs with which one can make direct comparisons.

# RECEPTOR MODULATION, UP AND DOWN REGULATION II

## 343.1

FUNCTIONAL SUBSENSITIVITY OF  $\alpha_2$ -ADRENERGIC HETERORECEPTORS OR 5-HT1C RECEPTORS MEDIATING CLONIDINE-INDUCED GROWTH HORMONE RELEASE FOLLOWING CHRONIC GLUCOCORTICOID AND 5-HT UPTAKE INHIBITING ANTIDEPRESSANT TREATMENTS. Charanjit S. Aulakh, James L. Hill, S. N. Pradhan\*, and Dennis L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD

We have recently demonstrated that clonidine stimulates growth hormone secretion by activation of a2-adrenergic heteroreceptors present on 5-HT nerve terminals which in turn, enhance 5-HT activity via stimulation of post synaptic 5-HT<sub>1C</sub> receptors to promote growth hormone releasing factor (Aulakh et al., in press). In the present study, we investigated the effects of chronic treatment with hydrocortisone (25 mg/kg/day), fluoxetine (2.5 mg/kg/day), clomipramine (5-mg/kg/day), imipramine (5-mg/kg/day), clorgyline (1 mg/kg/day), m-chlorophenylpiperazine (m-CPP, 2.5 mg/kg/day), 1-(2,5-dimethoxy-4iodophenyl)-2-aminopropane (DOI, 2.5 mg/kg/day) and 8-OHDPAT (0.25 mg/kg/day) on clonidine-induced increases in growth hormone levels in male Wistar rats.

Chronic treatment with clorgyline, m-CPP, DOI and 8-OHDPAT did not have any significant effect but chronic treatment with hydrocortisone, fluoxetine, clomipramine and imipramine significantly attenuated clonidine-induced increases in growth hormone levels These findings suggest development of functional subsensitivity of either  $\alpha_2$ -heteroreceptors or 5-HT<sub>1C</sub> receptors or both following chronic treatment with 5-HT uptake inhibitors and glucocorticoids.

# 343.3

DOWN-REGULATION OF OPIOID RECEPTOR BINDING IN NEURO-

DOWN-REGULATION OF OPIOID RECEPTOR BINDING IN NEURO-BLASTOMA CELLS BY DELTORPHIN C AND DERMORPHIN. L.M.J. Attila\*, L.H. Lazarus, and S. Salvadori\*. LMIN/NIEHS, RTP, NC 27709 and 'Univ. of Ferrara, I-4400 Ferrara, Italy.

There is clear evidence that δ opioid receptors are down-regulated in NG108-15 neuroblastoma glioma cells by long-term opioid agonist treatment. The effects of agonists on μ opioid receptors in clonal cell lines is not yet clarified: this may be due to lack of specific opioid agonists in these experiments. In this study we used frog skin heptapeptides, deltorphin C (DEL-C) and dermorphin (DM), to induce down-regulation of opioid δ and μ receptors, respectively. Receptor binding was assessed with [\*HJDPDPE (δ) and [\*HJDAGO (μ). NG108-15, SK-N-SH or SH-SY5Y cells were treated for 24 h with nM concentrations of DEL-C or DM, washed and the cells allowed to recover in fresh media for 0 to 5 days. Cells were treated with pertussis toxin (PTX; 0.1-100 ng/ml) or cholera toxin A (CTX-A; 10 ng/ml) for 24 h either before or after the opioid peptide treatment. Down-regulation of δ binding was found both after DEL-C and DM treatment, the latter being 100-fold less potent. PTX dose-dependently down-regulation of δ binding to 80%, and was additive with DEL-C. Recovery of down-regulation of δ binding to several days when induced by PTX but only 1-2 days when induced by DEL-C or DM. Down-regulation of μ binding but did not change the effects of DEL-C or DM. Down-regulation of μ binding was also found after Del-C or DM treatment. The recovery of μ binding after washout of the opioid agonist was, however, much slower than δ binding. PTX pretreatment similarly caused an additive down-regulation of μ binding. Trx pretreatment similarly caused an additive down-regulation of μ binding or, when given after the opioid-induced down-regulation of μ binding. In conclusion, δ receptor turnover seems to be faster and more readily modified by agonist treatment than μ receptors and differs in its response to CTX-A.

## 343.2

MOLECULAR MECHANISMS OF CHRONIC MORPHINE UPREGULATION OF THE cAMP SYSTEM IN THE LOCUS COERULEUS. K.L. Widnell, C.M. Bergson, J.A. Clark and E.J. Nestler'. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale School of Medicine, New Haven, CT 06508. We have previously shown that chronic opiate administration increases levels of Gi/Go ADP-ribosylation and of adenylate cyclase

and cAMP-dependent protein kinase (PKA) activities in the rat locus coeruleus (LC) (see *J. Neurosci.* 12:2439, 1992). This upregulation of the cAMP system has been shown to mediate aspects of opiate tolerance, dependence and withdrawal exhibited by these neurons (Eur. J. Pharmacol., 211:47,1992). study, we addressed the mechanisms underlying the previous changes in ADP ribosylation and enzyme activities. We found that chronic morphine increases levels of immunoreactivity in the LC of Goα, Giα1, Giα2, PKA catalytic subunit and PKA regulatory subunit II (RII), but has no effect on Gsa, Gß, or RI. Northern blot analysis is underway to assess whether these protein changes are associated with alterations in mRNA levels. We previously showed an upregulation of tyrosine hydroxylase (TH) protein and mRNA levels. in the LC after chronic morphine treatment (*J. Neurosci.*, 10:2649, 1990). We are currently studying morphine regulation of TH transcription in the LC using a transgenic mouse line (kindly provided by D. Chikaraishi at Tufts). The transgene contains 4.8 kb of upstream DNA from the rat TH gene positioned 5' to the bacterial chloramphenicol acetyltransferase (CAT) reporter gene. This transgenic mouse could provide a model system for studies of the molecular mechanisms of opiate action.

## 343.4

DIFFERENTIAL REGULATION OF \$1-ADRENERGIC RECEPTOR (\$1AR) MRNA AND LIGAND BINDING BY ANTIDEPRESSANTS AND NOREPINEPHRINE (NE) DEPLETION. M. O. Butler', K. Hosoda and R.S. Duman. Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

The density of B1AR binding sites is decreased by chronic antidepressant treatments while levels of \$1AR binding are increased by administration of agents which deplete NE. The present study was carried out to examine the influence of these treatments on expression of β1AR mRNA measured by RNase protection assay. Chronic ECS treatment (10-14d) decreased levels of both \$1AR mRNA and ligand binding in frontal cortex. BIAR ligand binding was also decreased by imipramine (IMI) treatment (3-28d) but expression of \$1AR mRNA was regulated in a biphasic manner; IMI treatment for 7-14d increased while treatment for 17-28d decreased \$1AR mRNA levels. In contrast, NE depletion had an effect on \$1AR mRNA opposite to that of IMI; 7d after 6-hydroxydopamine (6-OHDA) treatment levels of β1AR mRNA were decreased but 14 d after neurotoxin treatment levels of β1AR mRNA returned to control. Taken together, the results demonstrate differential regulation of \$1AR mRNA by antidepressant and 6-OHDA treatments and a complex relationship between β1AR mRNA expression and synaptic levels of NE. These results will be discussed with regard to the mechanisms that regulate \$1AR mRNA expression, which have been elucidated in C6 glioma cells (see Hosoda et al. this volume).

"LOCUS COERULEUS-LIKE" CELL LINE: A MODEL SYSTEM FOR STUDIES OF OPIATE AND ANTIDEPRESSANT DRUG ACTION.  ${
m R.S.}$ Duman R.Z. Terwilliger, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

In recent years, we have been studying the molecular mechanisms underlying the actions of a number of psychotropic drugs and stress in the locus coeruleus (LC) in vivo. In an effort to establish an in vitro model system for further characterization of the in vivo findings, we have carried out preliminary studies on an "LC-like" cell line derived from a brainstem tumor of a transgenic mouse in which the transgene consisted of a 773 bp fragment of the tyrosine hydroxylase (TH) promotor fused to the SV-40 T antigen (Suri, Fung, and Chikaraishi, Soc Neurosci Abs 17, 528, 1991). The cell line expresses TH and synthesizes norepinephrine but not epinephrine; it also expresses neurofilaments and neuron-specific enolase but not glial fibrillary acidic protein. Membranes prepared from the cells display high levels of CRF- and VIP-stimulation of adenylate cyclase, and of  $\alpha_2$ adrenergic, opiate, and NPY-inhibition of the enzyme, receptor responses expected in LC. Treatment of the cells with CRF, forskolin, or cyclic AMP analogues causes the cells to extend neuritic processes within 2 hr. In addition, CRF or forskolin treatments down regulate CRF- but not VIP-stimulated adenylate cyclase. Treatment of the cells with morphine for 5 days increases levels of cyclic AMP-dependent protein kinase and TH as seen in the LC in vivo. These studies support the use of this cell line to investigate the molecular regulation of LC neuronal function by opiate, CRF, and antidepressant treatments.

#### 343.7

DIFFERENTIAL REGULATION OF B-ADRENERGIC RECEPTORS (6-ARs) AND 6-AR mRNAS BY DESIPRAMINE AND CARBAMAZEPINE IN CULTURED C6 GLIOMA CELLS G.Chen. C.Hough, H.Manji\*, D-M.Chuang, and W.Z.Potter. Exp Ther Branch and Biol.Psych. Branch, NIMH, Bethesda, MD 20892

Chronic treatment with the tricyclic antidepressant desipramine (DMI) causes downregulation and desensitization of B-adrenergi receptor <u>in vivo</u> (animals) and <u>in vitro</u> (cultured cells). We recently found that DMI treatmant (10 μM for 6 days) induced β-AR downregulation and desensitization in C6 glioma cells was accompanied by a significant decrease in the steady-state level of  $\beta$ -AR mRNAs, which was time (10  $\mu$ M for 0-7 day) and dose (0-25  $\mu$ M for 6 days) dependent . Carbamazepine (CARB), an anticonvulsant, has a similar structure to DMI, but in contrast to anticonvulsant, has a similar structure to DMI, but in contrast to DMI, CARB is a clinical effective antimanic agent. Exposure of C6 glioma cells to CARB resulted in a time (50  $\mu$ M for 6 days) and dose (0-100  $\mu$ M for 6 days) dependent increase in the number of  $\beta$ -AR. CARB exposure also signicantly altered the steady-state level of  $\beta$ -AR mRNAs. The mechanism(s) by which these two tricyclic agents differentially regulate the levels of  $\beta$ -AR mRNAs is currently under investigation

## 343.9

LONG-TERM EFFECTS OF PIRENZEPINE ON REPRESENTATIONAL MEMORY AND MUSCARINIC RECEPTORS. W.S. Messer. Jr.\* and M. Bohnett. Department of Medicinal & Biological Chemistry, College of Pharmacy, Univ. of Toledo, Toledo, OH 43606.

Previous studies have documented a role for  $M_1$  muscarinic receptors in representational memory function.

muscarinic receptors in representational memory function. Intrahippocampal injections of pirenzepine initially result in memory impairments, while repeated treatments are less effective and lead to increases in muscarinic receptor binding. The long-term behavioral and neurochemical effects of pirenzepine were examined following intrahippocampal injections. Autoradiographic methods were utilized to localize muscarinic receptors. In behavioral studies, intrahippocampal injections of pirenzepine (70  $\mu g$  per hippocampus) initially impaired memory function (71  $\pm$  1.7 %). By the third session, performances were significantly above chance levels (83  $\pm$  0.0 %). In autoradiographic studies, the binding of 2.0  $\mu$  nm [ $^3 H$ ]-(R)-QNB to rat brain sections provided an estimate of maximal levels of muscarinic receptor binding. ( $^3 H$ ]-(R)-QNB binding increased in several brain areas after four days (15 - 53 %) and two weeks (11 - 56 %) of treatment relative to control animals. The time-course of behavioral and biochemical effects

The time-course of behavioral animals.

The time-course of behavioral and biochemical effects suggest that long-term pirenzepine injections increase the number of muscarinic receptors, which is associated with improved performance on the representational memory task. Supported by NS 25765 and NS 01493.

β1-ADRENERGIC RECEPTOR (β1AR) DOWN REGULATION IN C6 GLIOMA CELLS: EVIDENCE FOR INHIBITION OF BIAR GENE TRANSCRIPTION BY A TRANSIENT REPRESSOR, K. Hosoda\*, G. Feussner\*, P.H. Fishman\*, and R.S. Duman. Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508 and \*National Institutes of Neurological Disorders and Stroke, NIH, Bethesda, MD 20892.

To elucidate the molecular mechanisms underlying regulation of β1AR expression in brain and other tissues, we are studying β1AR in C6 glioma as a model cell system. Exposure of cells to isoproterenol (ISO) or forskolin for 1hr increased levels of \$1AR mRNA by approximately 70% while longer treatment (2-7 hr) resulted in a time dependent 50% decrease in levels of \$1AR mRNA. Levels of \$AR ligand binding were decreased by ISO and forskolin treatments (1-7 hr). The half-life of \$1AR mRNA, determined in the presence of actinomycin D, was 104 min and was not significantly influenced by either ISO or forskolin treatments, indicating no change in mRNA However, ISO treatment (2 hr) did decrease by 40% the rate of \$1AR transcription, measured by in vivo labeling of nascent mRNA with thiouridine. Addition of exotoxin A, a protein synthesis inhibitor, blocked the down regulation of \$1AR mRNA; in fact, in the presence of exotoxin A, ISO or forskolin treatment (2-7 hr) increased levels of  $\beta1AR$  mRNA by up to 400%. The results demonstrate that down regulation of  $\beta1AR$  mRNA occurs via decreased transcription rate and suggest that this decrease may be dependent on the synthesis of a transient repressor protein.

#### 343.8

DESIPRAMINE DESENSITIZES BETA-ADRENERGIC SIGNAL TRANSDUCTION WITH IMPAIRED RECOVERY IN OLD AND

TRANSDUCTION WITH IMPAIRED RECOVERY IN OLD AND SUPERSENSITIVITY IN MATURE RATS. G. Rajakumar\*, M.M. Koller, K. Horvath and P.J. Scarpace, GRECC, VA Medical Center, and University of Florida, Gainesville, Florida 32608

We assessed β-adrenergic receptors (βAR) in the cerebral cortex and βAR and isoproterenol dose resopnse stimulation of adenylate cyclase activity (AC) in the parotid gland (P) in control, 28 d desipramine (DMI) (10 mg/kg) and following a 2 d and 14 d washout (WO) period in 6-, 12- and 24-month old female F344 rats. βAR density decreased in cortex (73 ± 5 fmol/mg, 6 mo; 63 ± 2, 12 mo; 52 ± 3.24 mo; n.e. 0.001) but was unchanged with age in P. (54 ± 5.55). this y decrease in cortex (73  $\pm$ 3 moring, 6 mo, 33  $\pm$ 2, 12 mo, 25  $\pm$ 3, 24 mo; p < 0.001) but was unchanged with age in P (54  $\pm$ 5, 55  $\pm$ 2, 49  $\pm$ 4). DMI down regulated  $\beta$ AR in cortex (45  $\pm$ 3, p < 0.005) and P (32  $\pm$ 1, p < 0.001). In cortex, there was full recovery by 2 d WO in 6 mo (79  $\pm$ 3), upregulation at 14 d WO in 12 mo (100  $\pm$ 7), and there was no recovery in 24 mo (39  $\pm$  2, p < 0.05). In P there was full recovery by 2 d at all ages with an upregulation in 12 mo (82  $\pm$  9, p < 0.002). In P maximum isoproterenol (32  $\mu$ M)-stimulated AC  $\pm\,9,\,p<0.002).$  In P maximum isoproterenoi (32  $\mu M$ )-stimulated AC was unchanged with age but decreased with DMI treatment (57  $\pm\,5.8$  pmol cAMP/min/mg, control; 22  $\pm\,5$ , DMI, p < 0.001). There was full recovery by 2 d in 6 mo (51  $\pm\,6$ ) and by 14 d WO in 24 mo (54  $\pm\,10)$ ). In 12 mo there was a supersensitivity of AC (93  $\pm\,15$ ) that corresponded to the receptor upregulation. These data indicate that DMI desensitizes BARs in peripheral tissue similar to the well known effects on brain tissue. There is an unexplained upregulation of BAR and supersensitivity of AC in the 12 mo rats after 14 d WO and impaired recovery of AC in the 24 mo. Supported by the Dept. of Vet. Affairs, PHS grant DE 08845 and Univ. Zurich, Switzerland.

## 343.10

REGIONAL CHANGES IN RAT CENTRAL NICOTINIC ACETYLCHOLINE RECEPTORS FOLLOWING NOSE-ONLY EXPOSURE TO MAINSTREAM CIGARETTE SMOKE. S.L. Yates\*1, K.G. Fernandes2, E.N. Fluhler2, P.M. Lippiello<sup>2</sup>. Duke University Medical Center, Integrated Toxicology Program, NC 27710 and 2RJR-NABISCO, Pharmacology Winston-Salem, NC 27102.

Smokers are reported to have a higher density of nicotinic acetylcholine receptors (nAChR) than non-smokers. Whether this increased receptor density is a response to smoking or a result of genetic variability is not known. While chronic nicotine infusion of rats and mice results in the up regulation of central nAChR, changes in receptor density in response to nicotine exposure via cigarette smoke have not previously been studied in animals. Furthermore, a causal relationship between cigarette smoking and changes in nAChR density in humans has not been established. In this study male Sprague-Dawley rats were nose-only exposed 1-hr/day, 5-days/week, for 13-weeks to mainstream cigarette smoke, which consisted of the following (Mean±SD): 0.64±0.03 mg/L wet total particulate material, 773±53 ppm CO, and 37±2 μg/L nicotine. 3H-Nicotine binding was measured in various brain regions of smoke-exposed and sham-exposed animals. In smoke exposed animals there was a trend for nAChR up regulation (approximately 25%) in the cortex and striatum, while there was no apparent change in receptor density in the midbrain, hippocampus, and cerebellum. Smoke exposure did not alter the affinity of the receptor for nicotine in these brain regions. These results suggest that smoke exposure can alter nAChR density in rats, and may be relevant to understanding the basis of receptor up regulation in human smokers.

DIFFERENTIAL EFFECTS OF OLFACTORY BULBECTOMY ON GABA RECEPTORS IN THE RAT BRAIN. T. Dennis\*. V. Beauchemin and N. Lavoie, Neurobiological Psychiatry Unit, Department of Psychiatry, McGill University, Montréal, Quebéc, Canada, H3A 1A1.

Officery bulbectomy (OBX) is generally recognized as a useful model for the study of the neurobiology of depression and the mechanisms of action of antidepressant treatments. Following OBX, rats display antidepressant-reversible behavioral and biochemical changes. Although GABA<sub>8</sub> binding densities are decreased in frontal cortex 14 days after OBX (*Lloyd & Pichat, Br.J.Pharmacol. 87:36P, 1985*), the time-course of these changes have not been determined. The present study investigated the effects of OBX on GABA<sub>8</sub>, GABA<sub>8</sub> and benzodiazepine (BZD) binding parameters 7, 14, 21 and 28 days after bilateral OBX.

Male Sprague-Dawley rats were anesthetized and mounted in a stereotaxic frame. The olfactory bulbs were exposed, sectioned and aspirated. Animals were housed in groups of 4 until sacrifice. Cerebral membranes were incubated with [³H]GABA, in the presence of baclofen or isoguvacine, and [³H]flunitrazepam to define GABA<sub>A</sub>, GABA<sub>B</sub> and BZD receptors, respectively. GABA<sub>A</sub> and BZD receptor densities in frontal cortex were increased 7, 14, 21 and 28 days after OBX. In hippocampus, GABA<sub>A</sub> receptor densities increased after 7 days but decreased thereafter. No change in BZD Bmax values were observed in hippocampus, while, in hypothalamus, a transient increase was observed 7 days post-lesion. GABA<sub>B</sub> receptor densities were unaftered in hippocampus and hypothalamus up to 28 days following OBX, but were decreased from 14 days onward in frontal cortex. Increased GAB<sub>B</sub> binding densities in cerebellum were accompanied by decreases in affinity.

These changes in GABA<sub>A</sub> and GABA<sub>B</sub> binding parameters are likely to result in alterations of GABAergic neurotransmission, which might underlie the behavioral deficits elicited by OBX. Supported by MRCC and FRSQ.

EXPOSURE TO WAR IS ASSOCIATED WITH DECREASED PLATELET BENZODIAZEPINE RECEPTORS IN HUMANS. M. Gavish\* N. Laor, L. Karp, E. Dagan, A. Reiss and R. Weizman. Dept. of Pharmacol., Rappaport Fac. of Med., Technion, Haifa, Israel.

Mitochondrial benzodiazepine receptors (MBR) play a major role in steroidogenesis and are sensitive to stress and hormonal changes. Stress affects MBR bidirectionally, i.e., acute stress up-regulates MBR, while repeated stress down-regulates these receptors. To further explore the possible link between stress and MBR, we determined the pharmacodynamic characteristics of platelet MBR in 11 Israeli civilians 1 day prior to the Gulf war, during the war (30 days after initiation of the missile attacks), and 4 weeks after cessation of the war. Hamilton anxiety rating scale (HAM-A) and Beck depression inventory (BDI) scores were significantly higher before and during the war when compared to the postwar scores. The density of platelet MBR before the war was significantly reduced (-22%, p<0.05) when compared to postwar values. Values during the war did not differ significantly from the postwar values. The decrease in HAM-A scores (postwar values minus prewar values) correlated significantly with the increase in MBR density (r = -0.62, p<0.05). A significant correlation was also obtained when comparing the changes between post- and during-war levels [postwar values minus during-war values (r = -0.70, p<0.05)]. No such correlation was demonstrated with BDI. It is concluded that sustained stress of war is associated with reduction in MBR density.

ALTERATIONS IN HIPPOCAMPAL GLUTAMATERGIC BINDING SITES FOLLOWING LESIONS OF THE RAT MEDIAL SEPTUM. F.M. Inglis. J.A.D.M. Tonnaer† & J. McCulloch (SPON: Brain Research Association) Wellcome Surgical Institute, University of Glasgow, U.K. and †Organon Laboratories Ltd, Oss, Netherlands

Using quantitative in vitro autoradiography, we investigated the glutamatergic response to cholinergic deafferentation of the hippocampus.

Lesions of the medial septum were produced in rats by intracerebral injection of ibotenate at stereotaxically defined coordinates. Three weeks post-lesion, binding to glutamate receptor subtypes in the hippocampal and septal regions was imaged with [3H]-kainate, [3H]-AMPA and NMDA-displaceable [3H]-glutamate. Muscarinic binding sites were measured using [3H]-QNB.

Following septal lesions, [3H]-QNB binding was reduced significantly in the subiculum, and in the medial and lateral septum compared to sham-operated controls. In other hippocampal regions, [3H]-QNB binding was unaltered. Following septal lesions, [3H]-AMPA binding to AMPA receptors was significantly reduced in the stratum pyramidale of CA1-3, in the CA1 stratum radiatum, and in the CA2 stratum launosum moleculare. [3H]-AMPA binding was also reduced in the deep layers of the medial entorhinal area, the superficial layers of the lateral entorhinal area and in the medial septum. No significant alterations were measured in the dentate gyrus. In contrast to reductions in [3H]-AMPA binding, [3H]-kainate and NMDA-displaceable [3H]-glutamate binding to kainate and NMDA receptors remained unaltered in the hippocampal and septal regions following medial septal lesions. These results demonstrate that in addition to cholinergic modifications, glutamatergic receptor subtypes are altered differentially following cholinergic denervation of the hippocampus.

BLOCKADE OF KINASE AND PHOSPHATASE ACTIVITY PREVENTS CORTICAL AMINO ACID RECEPTOR REGULATION, B.A. Pasqualotto\*, R.A. Lanius, and C. Shaw. Departments of Ophthalmology, Neuroscience, and Physiology, University of British Columbia, Vancouver, Canada. Using an in vitro adult rat cortical slice preparation we have examined the effects of increases in cell electrical activity or agonist stimulation in relation to the action of phosphorylating and dephosphorylating enzymes on an AMPA receptor population using the antagonist I3HI-CNQX, Increases in electrical activity induced by the administration of veratridine and glutamate (V+G) result in a decrease in the number of AMPA receptors in adult cortex; conversely, the inhibitory GABAA receptor population is increased by this treatment. Both receptor populations decrease following treatment with their respective agonists, quisqualate and muscimol (Shaw & Lanius, Soc Neurosci. Abstr. 1992). Increases in both AMPA and GABAA receptors were seen following treatment with alkaline phosphatase. Decreases were observed following protein kinase administration (Lanius & Shaw, Soc. Neurosi. Abstr. 1992). For AMPA receptors the down-regulation induced by V+G, agonist, or kinase could be blocked by protein kinase inhibitor. Upregulation induced by alkaline phosphatase could be blocked by phosphatase inhibitors such as sodium vanadate or phenylarsine oxide. These results suggest that the down-regulation of AMPA receptors by increases in cell electrical activity and by agonist are dependant on the activity of phophorylating enzymes while the up-regulation of these receptors is dependant on the activity of dephosphorylating enzymes.

## 343.14

CROSS-TOLERANCE OF LORAZEPAM AND ALPRAZOLAM: PRESERVATION OF SPECIFIC REGIONAL EFFECTS ON BENZODIAZEPINE BINDING. L.G. Miller\*, J.J. Byrnes. D.J. Greenblatt. R.I. Shader. Dept. of Pharmacology and Experimental Therapeutics and Neuroscience Program, Tufts Univ. School of Medicine, Boston, MA 02111.

Clinical and behavioral data support cross-tolerance among some benzodiazepines, but evidence is limited concerning the most commonly used benzodiazepine alprazolam. We administered alprazolam (ALP) and lorazepam (LRZ), 2 mg/kg/d, to mice for 1-14 days using subcutaneous osmotic pumps. Some mice were treated with ALP for 7 d followed by LRZ for 7 d, or vice-versa. Pentylenetetrazole-induced seizure threshhold was determined, and benzodiazepine binding was evalued in 5 brain regions at 1 and 14 d. Mice became tolerant to both ALP and LRZ after 7 d. Discontinuation of either drug after 7 d led to a decrease in threshhold at 11 d. Substitution of LRZ for ALP or vice-versa maintained tolerance in both cases. Tolerance was similar in ALP 7d/LRZ 7 d or the reverse combination and either ALP or LRZ for 14 d. Benzodiazepine receptor binding in cortex was reduced at 14 d compared to 1 d in cortex and hippocampus after lorazepam, but only in cortex after alprazolam. Substitution of LRZ for ALP produced results similar to 14 d of LRZ, and vice-versa. These results indicate complete behavioral crosstolerance between lorazepam and alprazolam. Benzodiazepine receptor downregulation occurs in cortex and hippocampus with lorazepam, but ont ocrtex alone with alprazolam.

SEIZURE-INDUCED CHANGES IN GluR2 AND GluR3 mRNA EXPRESSION SUGGEST DISTINCT REGULATORY MECHANISMS. §\$ Gold\*, §G. Lynch, and †C. Gall. § Dept. of Psychobiology and †Dept. of Anatomy & Neurobiology, Univ. of California, Irvine CA 92717.

Psychobiology and Tubert. of Anatomy & Neurobiology, Univ. of California, Irvine CA 92717.

We recently demonstrated that limbic seizures decrease the expression of mRNA encoding the GluR1 subtype of non-NMDA glutamate receptor (Gall et al., 1990); 30 hrs after the placement of a seizure-producing lesion, GluR1 mRNA was reduced by 80% and 48% in the dentate gyrus granule cells and superficial neocortex, respectively. We now report seizure-induced changes in mRNA levels for the GluR2 and GluR3 receptor subtypes. A 10 hr episode of recurrent limbic seizures was induced by electrolytic lesion of the dentate gyrus hilus and mRNA levels were evaluated by in situ hybridization using 35S-labeled cRNA probes. In animals killed 30 hours post-lesion, hybridization to GluR2 mRNA was decreased by 45% in stratum granulosum and by 70% in superficial neocortex (layers II/III). At this time point, GluR3 mRNA was also decreased in superficial neocortex (54%) and piriform cortex (63%) but, in contrast to the other subtypes, GluR3 mRNA was increased to 133% of control levels in stratum granulosum. These opposing changes at the mRNA level for GluR2 and GluR3 in stratum granulos unggest the possibility that receptor properties change in the granule cells following seizures. Hollman et al. (1991) have demonstrated differences in calcium permeability dependent upon the proportionate expression of the GluR1, GluR2, and GluR3 mRNA described here may alter Ca<sup>++</sup>-mediated post-synaptic processes in the dentate gyrus. Supported by a FAW from NSF and NS26748 to C.G.

MODIFICATION OF THE ω6 POLYUNSATURATED FATTY-ACID COMPOSITION OF RAT ASTROCYTES IN PRIMARY CULTURE: EFFECTS ON BASAL AND RECEPTOR-MEDIATED CAMP FORMATION AND UPTAKE OF ADEMOSINE AND GLUTAMARE M.G. Murphy and Z. Byczko. Dept. of Physiology & Biophysics, Dalhousie University, Halifax, Nova Scotia Canada B3H 4H7

Receptor and transport functions were examined in primary cultures of rat astrocytes whose membrane polyunsaturated-fatty-acid (PUFA) profiles were dramatically modified by 3-weeks' exposure to delipidated serum ± linoleic acid. Enrichment in ω6 PUFA (20.4, 22:4, 22:5) did not alter basal levels of cAMP, or cAMP formation stimulated by forskolin, histamine, isoproterenol, NECA or 5-HT. However, dopamine (DA, 10<sup>-6</sup> M)-stimulated cAMP synthesis was significantly lower in PUFA-enriched than in PUFA-deficient cells (620 ± 30 and 410 ± 20 pmol/mg protein, respectively). The cells did not contain inhibitory DA receptors. [³H]glutamate uptake into the astrocytes was not affected by ω6 PUFA enrichment, however, that of [³H]adenosine was reduced relative to control values. These findings indicate that ω6 PUFA affect membrane processes in a very selective manner, and suggest that they may play a role in directing events that occur during early development. CHARACTERIZATION OF TRANSACTIVATION PROPERTIES AND FUNCTIONAL DOMAINS OF THE MINERALOCORTICOID RECEPTOR. R. Rupprecht, J. L. Arriza, D. Spengler, J. M. H. M. Reul, R. M. Evans, F. Holsboer\* and K. Damm. Max-Planck-Institute of Psychiatry, Clinical Institute, Dept. of Neuroendocrinology, Munich, Germany and Gene Expression Lab., The Salk Institute, La Jolla, CA 92037.

The human mineralocorticoid (hMR) and glucocorticoid receptor (hGR) mediate biological responses to adrenal corticosteroids and synthetic ligands. In transient transfection studies employing a human neuroblastoma cell line, a mouse mammary tumour virus luciferase fusion gene was used to monitor the trans-activation properties of both receptors. The hMR was more sensitive for cortisol than the hGR. However, the hMR stimulation of this promoter was only 2-4% of the maximum level obtained with the hGR. To examine the molecular basis of this differential response, a series of hMR/hGR hybrid receptors were created and their properties determined. These experiments demonstrated that the hMR amino terminus is lacking the strong trans-activation function present in the equivalent hGR domain. In addition various reporter constructs revealed that the amino termini of hGR and hMR differentially promote or inhibit synergistic transactivation functions of the DNA- and ligand binding domain of both receptors.

PRETREATMENT OF CORTICAL CULTURES WITH BDNF SIGNIFI-CANTLY REDUCED THE EFFECTS OF ACUTE BDNF ON THE STIMULATION OF PHOSPHATIDYLINOSITOL HYDROLYSIS. D.R. Kaplan\*, H.R. Widmer, F. Hefti, F. Ohsawa, T. Denton\* and B. Knüsel. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089 and 'NCI-Cancer Research and Developmental Center, Frederik, MD 21701.

The hydrolysis of phosphatidyl 4,5-bisphosphate (PI) produces two potent intracellular second messenger molecules. Recently we reported that the neurotrophin, brain-derived neurotrophic factor (BDNF), stimulates Pl-hydrolysis in primary cultures of fetal brain neurons within 15 min. We also observed that BDNF rapidly stimulates the phosphorylation of phospholipase- $C\gamma1$  (PLC) by activating *trk*-type protein kinase receptors. The action of BDNF seems to be neuron specific since the relative effect of BDNF on PI hydrolysis in cortical cultures treated with cytosine arabinoside (which resulted in glial cell-free cultures) was significantly increased compared to untreated cultures. Moreover, we reported earlier that no stimulation was observed in preparations of non-neuronal cultures. We now present evidence that long-term pretreatment with BDNF for 4 days essentially abolishes the PI response to acute stimulation with the same factor (104%, compared to 132% without pretreatment). The stimulation due to addition of bFGF was not affected (119% and 122%). These results suggest specific downregulation of a BDNF responsive PI mechanism. Pretreatment resulted in slightly increased protein (+7%) and lipid levels (+4%). No effect was observed on the number of GFAP positive cells and on GFAP protein level. We conclude from our data that signal transduction of BDNF in rat brain cultures involves PI hydrolysis specific for this factor. Other results show that PLC is stimulated by activation of *trk*-type receptor proteins.

## 343.20

IMMUNOCYTOCHEMICAL DETECTION OF NEURONAL ESTROGEN RECEPTORS AFTER TIMED ESTROGEN ADMINISTRATION AND WITH DIFFERENT ANTI-RECEPTOR ANTIBODIES. A. A. Gerall\* and L. Givon. Dept. of Psychology, Tulane Univ., New Orleans, LA 70118.

Endogenous or exogenous estrogen reduces estrogen receptor (ER) immunoreactivity (ir) when detected with the anti-ER monoclonal antibody H222spg. This lessening of ER-ir could be due to estrogen's changing the receptor's conformation so that H222's binding site is obscured or to its forming an estrogen-ER complex that down-regulates ER expression. Estrogen could alter complex that down-regulates ER expression. Estrogen could alter its receptor's conformation within 10 min after administration, but over an hour is required for it to instigate down-regulation. Ovariectomized Swiss-Webster mice were injected i.m. with 4 µg estradiol-178(E<sub>2</sub>) or oil at either 10 min, 1, 4, 12, 24, or 48 hr before perfusion. Brain sections were processed immunocytochemically with H222spt (Courtesy of Abbott Labs.). No ER-ir was obtained in the 10 min and 1 hr E<sub>2</sub>-mice. ER-ir began to appear in the 4 hr E<sub>2</sub>-mice and increased gradually to oil-control levels by 48 hr. Secondly, ER-ir obtained with H222, whose epitope is in the ER's steroid binding domain, was compared with that detected with the anti-ER polyclonal antibody, ER-715 (National Hormone and Pituitary Program and NIDDK), whose epitope is in the ER's hinge region. Alternate serial brain sections from ovariectomized mice injected with oil or E<sub>2</sub> 10 min or 1 hr before perfusion were processed with H222 of ER-715. Both antibodies yielded similar distribution and density of neuronal ER-ir in oil-mice and no ER-ir

distribution and density of neuronal ER-ir in oil-mice and no ER-ir in the 10 min and 1 hr E<sub>2</sub>-mice. Neither conformational nor downregulation processes alone account for the obtained results.

# HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: OTHER

CHRONIC FREE TESTOSTERONE (T) IN FEMALE AND FEMINIZED MALE RATS DURING 15-30 DAYS OF AGE: MASCULINIZATION OF POSITIVE FEEDBACK REGULATION OF FSH AND LH. S.D. GALE\*, AND G.J. BLOCH, Dep't of Psychology, Brigham Young U., Provo,UT,84602. T implants during postnatal days 15-30 can permanently defeminize endocrine and behavioral function in female rats, as well as defeminize and masculinize reproductive function in neonatally gonadectomized (NeoGxd) males (Gale et tally gonadectomized (NeoGxd) males (Gale et al., Neurosci. 90,91). To determine whether this chronic T-treatment affects positive feedback regulation of LH and FSH, female and NeoGxd (feminized) male rats were given estradiol benzoate at 75 days of age, followed by 2mg of progesterone 48 hours later. Radioimmunoassay progesterone 48 nours later. Radiolmmunoassay indicated significantly reduced plasma LH and FSH levels in T-implanted female rats when compared to controls (blank implants). Similar ly, plasma LH levels were reduced in T-implant-Similared, neonatally gonadectomized males. These results indicate that in addition to previously reported permanent effects on behavior and estrus cycles, chronic T during 15-30 days of age, a period well beyond the classical critical period of 6-10 days, also masculinizes the hypothalamic-pituitary regulation of gonadotropins. NIH HD-27334.

## 344.2

SEX STEROIDS AND GALANIN-IMMUNOREACTIVE (GAL-I) CELLS IN THE MEDIAL PREOPTIC AREA (MPOA): CELL

CELLS IN THE MEDIAL PREOPTIC AREA (MPOA): CELL SIZE AND MALE-SPECIFIC PLEXUS. C.B. Eckersell, R. Mills, and G.J. Bloch\*. Dep't of Psychology, Brigham Young Univ., Provo, UT, 84602.

GAL-I cells are localized within sexually dimorphic components of the MPOA, are dependent on gonadal steroids, and a high percentage accumulate estrogen (Eckersell, Neurosci, 91; Bloch, Brain Press). We measured the size of CAL-I Res, in press). We measured the size of GAL-I cells in the central medial preoptic nucleus (MPNc) in gonadectomized (Gxd) males & females; Gxd, testosterone males (T males); Gxd, estrogen males & females (E males, E females) and intact males. Diameters were largest in the intact and T males, smaller in E males & E females, and smallest in Gxd rats. In addition, a highly dense area of GAL-I cell bodies with interdigitating processes was defined as the MPOA "GAL-I plexus." Plexus volume was greatest in E, "GAL-I plexus." Plexus volume was greatest in E, T and intact males, smaller in the Gxd male, but was vanishingly small within the Gxd or E female. The density of cells and processes within the plexus was greatest in the T, E and intact male, less in the Gxd male and least in the Gxd female; total cell number was distributed similarly. These results suggest a male-specific These results suggest a male-specific larly. role of gonadal steroid-sensitive GAL cells within the MPN. NIH HD-27334

SEX DIFFERENCE IN THE EFFECT OF MATING ON C-FOS IMMUNOREACTIVITY IN LHRH NEURONS OF THE FERRET. G.M. Lambert\*, B.S. Rubin and M.J. Baum. Dept. of Biology, Boston University, Boston, MA 02215 and Dept. of Anatomy, Tufts University, Boston, MA 02111.

Several studies suggest that LHRH output from basal hypothalamic neurons and the consequent pituitary secretion of LH rises in female, but not in male ferrets after mating. At the rostral, medial, and caudal levels of the preoptic-hypothalamic continuum a significantly higher percentage of LHRHimmunoreactive (IR) neurons was co-labelled with nuclear FOS-IR in mated than in unpaired females. No such effect occurred in males, suggesting that the sex dimorphism in mating-induced LH secretion reflects a selective activation of LHRH neurons in the female ferret forebrain. Significantly more FOS-IR neurons (not co-labelled with LHRH) were detected in the bed nucleus of the stria terminalis (BNST), the medial preoptic area (mPOA) and the medial amygdala (MA) of mated versus unpaired females. By contrast, mating significantly augmented FOS-IR only in the MA of male ferrets. The heightened responsiveness of LHRH neurons to mating in females may depend on sensory inputs from a limbic circuit which includes the MA, BNST, and mPOA. AN ANALYSIS OF TEMPORAL CHANGES IN TYROSINE HYDROXYLASE (TH) mRNA LEVELS IN A1 AND LOCUS COERULEUS (LC) NEURONS IN PROESTROUS, DIESTROUS AND ANDROGEN-STERILIZED RATS (ASR). J-J.Liaw, J-R.He and C.A.Barraclough. Sch. Med., Univ. Maryland, Baltimore, MD 21201.

TH is the rate limiting enzyme for the synthesis of norepinephrine (NE) and we showed that increases in TH mRNA levels in A1 and LC neurons can serve as an index of increased activity within these cells. These noradrenergic neurons innervate the hypothalamus and NE secretion increases concomitant with preovulatory LH surges in proestrous but not diestrous and ASR which do not have LH surges. ASR received 1.25 mg of testosterone propionate at 5 days of age and both cyclic and sterile rats were used for study at ~100 days of age. Rats were sacrificed at various hours throughout the day and the brains were frozen-sectioned and processed for in situ hybridization histochemistry using a synthetic 48 base mer specific to TH mRNA. Levels of TH mRNA were measured by quantitative image analysis methods. Plasma LH in proestrous rats began to rise about 1500 h, and peaked between 16-1700 h. In similar proestrous rats, A1 TH mRNA levels increased significantly between 1645-1715 h and were still elevated between 20-2030 h compared to 0930-1030 h. No changes in A1 message levels occurred at any hour in diestrous or ASR.
TH mRNA in LC did not change in any of the groups of animals studied.

These observations suggest that the increased secretion of hypothalamic NE during proestrous afternoon is due, in part, to increased activity within A1 neurons not solely to modulation of NE release by local inhibitory neurons within the hypothalamus. Supported by NIH Grant HD-02138.

## 344.7

DOPAMINERGIC BLOCKADE REVEALS A SEXUALLY-DIVERSE ROLE FOR OXYTOCIN (OXY) IN THE REGULATION OF PULSATILE PROLACTIN (PRL)

DOPAMINERGIC BLOCKADE REVEALS A SEXUALLY-DIVERSE ROLE FOR OXYTOCIN (OXY) IN THE REGULATION OF PULSATILE PROLACTIN (PRL) SECRETION. F. J. López and J. Bartolomé\*. Reprod. Neuro-endocr. Section, LMIN. N.I.E.H.S. RTP, NC 27709.

Pulsatile PRL secretion is primarily controlled, at the hypothalamic level, by a dopaminergic inhibitory tone. As previously shown by our group, the effects of some hypothalamic peptides with PRL releasing activity are masked by this prevailing inhibitory tone. In the present studies, the role of OXY on pulsatile PRL secretion is evaluated in females during the afternoon of estrus and male rats. Animals were assigned to one of four groups: control, oxytocin antagonist (OXYa), domperidone (DOM) and DOM + OXYa. They were bled at 3 min intervals for 3 hours and PRL levels evaluated for pulsatility using the algorithm Detect. In male rats, OXYa did not modify any pulsatility parameter under basal condi-tions; however, under a complete dopaminergic blockade the antagonists increased quantitative parameters were not affected by OXYa, although DOM treatment significantly increased pulse frequency. In female rats, however, OXY appears to exhibit a stimulatory role on pulsatile PRL secretion were reduced by OXYa administration. This effect was also apparent under a complete dopaminergic blockade. As in the case of male rats, qualitative parameters were not affected by OXY, nevertheless, DOM induced a marked elevation in pulse frequency. This data indicate a differential role of OXY in the regulation of pulsatile PRL secretion in male and female rats during estrus. Whereas in male rats OXY appears to play an inhibitory role which is evident after a complete dopaminergic blockade, in female rats endogenous OXY stimulates pulsatile PRL secretion.

IMMUNOCYTOCHEMICAL COLOCALIZATION OF DOPAMINE BETAHYDROXYLASE AND LUTEINIZING HORMONE RELEASING HORMONE
NEURONAL ELEMENTS BY ELECTRON MICROSCOPY IN THE ROSTRAL.
FOREBRAIN OF THE FEMALE CS7EL/6J MOUSE. M.M.M.iller's and L.
Zhu. Departments of Obstetrics and Gynecology, Experimental
Medicine and Anatomy, McGill University, Montreal, Quebec.
Dopamine beta-hydroxylase (DBH), a marker for the
noradrenergic (NA) system, is synthesised in a
subpopulation of midbrain neurons projecting to preoptic
area (POA) where luteinizing hormone releasing hormone
(LHRH) perikarya are located. Both NA and LHRH are important to reproductive function. The present ultrastructural
study was designed to determine the frequency with which
NA neuronal elements interact with LHRH structures.
Sections from four normally cycling proestrous female
C57BL/6J mice (5 mo old) were evaluated using polyclonal
antibodies and 3,3',5,5'-tetramethylbenzidine to identify
LHRH, and 3 3' diaminobenzidine to identify DBH neuronal
elements. Neuronal elements from randomly selected
ultrathin tissue sections were counted according to
category and corrected for surface area analysed. Categories included neurons, dendrites, axons, and terminals.
When frequency of immunolabeling of each type of immunolabeled neuronal element was assessed, DBH was found in
5.0±0.42% of terminals and 0.06±0.01% of axons. A small
population of POA perikarya contained LHRH (0.89±0.19%);
1.19±0.11% of all recipient dendrites were LHRH immunopositive. Among double labeled structures only one DBH terminals.
These data suggest that direct NA interactions with LHRH
neurons may form an important component in the neural
network which modulates gonadotropin secretion. Supported
by NIH RO1 AG7795 (MMM).

### 344.6

TYROSINE HYDROXYLASE (TH) mRNA IN LOCUS COERULEUS OF DJUNGARIAN HAMSTERS IS REDUCED UNDER LONG DAY VS. SHORT DAY CONDITIONS. T.Porkka-Heiskanen\*, J.H.Urban, M.H.Vitaterna, F.W.Turek, J.E.Levine. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Previous work has demonstrated that in hamsters kept under short day (SD) norepinephrine turnover is decreased in median eminence but increased in anterior hypothalamic area, while dopamine turnover is decreased in both these areas. In the mediobasal hypothalamus, more complex, time dependent changes in cathecholamine turnover was observed (Steger et al, Biol Reprod 44,76-82,1991). In the present study we assessed the biosynthetic capacity of cathecholaminergic neurons under short day and long day (LD) conditions. Ten male Djungarian hamsters were moved to SD at the age of 3 weeks. 4 weeks later, after gonadal regression, 5 hamsters were moved to LD and 5 animals stayed under SD; both groups were sacrificed 3 weeks later. TH mRNA levels were measured using in situ hybridization. Sections through the brainstem were labelled using an oligonucleotide probe for TH. Computer analysis of the hybridization intensity revealed increases in tyrosine hydroxylase mRNA in hamsters kept under short day (80.8 ± 5.8 in SD vs. 69.4 ± 3.6 in LD, mean and std.dev. respectively, p<0.01). This result suggests that biosynthesis of tyrosine hydroxylase is increased in SD. We are continuing studies to determine possible changes in time-and region dependent patterns in cathecholamine synthesis in different cathecholaminergic nuclei in hamsters kept under different photoperiodic conditions.

## 344.8

SEASONAL REGULATION OF PROLACTIN SECRETION MAY INVOLVE MULTIPLE CONTROL MECHANISMS. <u>L.L. Badura\*, A. Lee, S. A. Zinn, and J.D. Salamone</u>. Depts. Physiology & Neurobiology, Animal Science, and Psychology, University of Connecticut, Storrs, CT 06269.

In many mammals, exposure to short or long photoperiods decreases or increases PRL secretion, respectively. Knife cuts, that disrupt the neural photoperiodic pathway, do not prevent the effects of short-days on PRL release and induce a decline in PRL in animals exposed to long days. In this study, DA turnover (DOPAC/DA) was measured in the region of TIDA cell bodies (ARC) and terminals (ME), and in the caudate region (CAUD), in animals exposed to long or short days, and that received knife cuts or sham surgery. In addition, a subset of these animals was infused with PRL for two days before sacrifice to determine the response of TIDA neurons to the positive feedback effects of PRL. DA and DOPAC levels for the tissues were determined via HPLC.

No differences in DA turnover across groups were detected for the CAUD. In the ARC, knife cuts, which lowered PRL levels, and PRL infusion resulted in the lowest levels of turnover; differences between PRL levels for short- and long-day animals were not mirrored by a similar effect upon turnover. In the ME, PRL levels were correlated with turnover for short day-housed animals. There were no differences between long-day sham and knife cut animals, indicating that the cuts did not disrupt DA activity in the ME, and suggesting the existence of a second regulatory system which may be photoperiod-sensitive. In addition, infusion of PRL increased DA turnover in the ME, but not ARC, of both knife cut and sham groups. PRL and photoperiod feedback effects differ for the cell body and terminal regions; thus the modulation of the TIDA system may involve multiple mechanisms.

ULTRASTRUCTURAL CHANGES IN RAT HYPOTHALAMIC ARCUATE NUCLEUS FOLLOWING DIAMINOCHLOROTRIAZINE FEEDING. M. K. Tennant', W. G. Jerome', J. C. Eldridge' and D. K. Sundberg\*¹. Depts of Physiology and Pharmacology', and Pathology', Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1083.

Administration of triazine herbicides to female rats was recently shown to increase the proportion of estrus days during estrous cycles, leading to an increase in circulating estradiol (Eldridge et al., Biol Reprod 44 (Suppl 1):133, 1991). Since estradiol has been shown to increase hypothalamic da (Brawer et al., Endocrinology, 1978 and Schipper et al., Biol Reprod, 1981), the possibility exists that triazine compounds could also induce hypothalamic damage due to their effects on estrous cycles. To test this hypothesis electron microscopy was used to assess hypothalamic gliosis, namely astrocyte and microglia granular content in the arcuate nucleus in animals chronically fed triazine. 20 week-old female Sprague-Dawley rats were fed 1000ppm Diaminochlorotriazine (DACT), the principal triazine metabolite in rats. DACT treatment resulted in a 4% increase in the granular content of astrocytes by 32 weeks of age (12 weeks of treatment) and a significant 36% increase by 48 weeks of age (28 weeks of treatment) compared to age matched vehicle fed controls. In addition, the total number of microglia was 41% higher after 12 weeks of treatment and 17% higher after 28 weeks of treatment. Despite the increase in microglia number, granular content did not appear affected by treatment when assessed as number of microglia with five or more inclusion granules. Our results suggest that DACT treatment is able to induce hypothalamic damage in female rats, as seen by degeneration in the arcuate nucleus. Since DACT alone has no intrinsic estrogenic activity, the treatment-associated pathology was likely caused by increased estrogen secretion resulting from a greater number of days in estrus.

#### 344.10

CASTRATION AND PROLACTIN BOTH INCREASE THE TURNOVER RATE OF DOPAMINE IN THE MEDIAN EMINENCE OF THE MALE RAT. M. Selmanoff, S.-K. Park, D.A. Strouse and J.-R. He\*, Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559.

Central catecholaminergic neurons projecting to specific hypothalamic structures are involved in stimulating and inhibiting the LHRH-containing neurosecretory neurons. We investigated the effects of orchidectomy and hyperprolactinemia on the tuberoinfundibular dopaminergic (TIDA) neurons 0, 2 and 6 days postcastration and in 2 day castrates receiving physiological testosterone (T) replacement. Adult male rats were administered purified ovine prolactin (oPRL), or its diluent, polyvinylpyrrolidone (PVP), every 12h (2,400µg/sc injection) for 0, 2 or 6 days, beginning at time 0. Dopamine (DA) turnover was estimated by the  $\alpha$ -methyl-p-tyrosine method. In control rats, median eminence DA turnover increased at 2 days, and then further, at 6 days postcastration. Testosterone replacement reversed this increase in 2 day rats. Exposure to oPRL increased DA turnover compared with PVP controls at both 2 and 6 days. Autoregulatory feedback suppression of oPRL on endogenous rat PRL secretion was observed at both 2 (7.1 ± 1.4 vs 2.9  $\pm$  0.1 ng/ml rPRL-RP-3) and 6 (7.7  $\pm$  0.8 vs 3.3  $\pm$  0.2) days postcastration. These findings demonstrate, for the first time, that autofeedback regulation of rPRL secretion persists through at least 6 days of oPRL exposure, and is temporally associated with markedly increased turnover in the TIDA neurons. The TIDA neurons respond predictably to sex steroid manipulation but apparently are not involved in the postcastration LH rise as direct inhibitory afferents to LHRH neurons. Increase of Tryptophan Hydroxylase Enzyme by Dexamethasone in Adrenalectomized Rat Midbrain Using Western Blots and Immunocytochemistry with Antipeptide Antibodies. Baolang Liao \*\*and Efrain C. Azmitia. Dept. of Biology, New York University, Washington Square East, New York, N.Y. 10003 We and others have previously demonstrated that adrenal steroids can regulate

We and others have previously demonstrated that adrenal steroids can regulate the activity of tryptophan hydroxylase activity after stress. This increase in activity has been proposed to consist of de novo protein synthesis because it was blocked by protein synthesis inhibitors and shown not to be due to an allosteric increase produced by phosphorylation of the enzyme. Recently, we have succeeded in raising antibodies against two unique amino acid sequences of the tryptophan hydroxylase molecule which show no homology to the other aromatic hydroxylase enzymes. The peptide domains selected were near the N-terminus (aa 66-91) and the C-terminus (aa 412-443). A single principle band was seen (approximate M.WT. 49,000) in Western analysis with WH-412 and WH-66 for the midbrain raphe area. In Western analysis from tissue obtained from adrenalectomized (adx) rats treated with dexamethasone (dex) or vehicle, an increase after dex was seen in the WH-412 labeled band after 12-96 hr. of exposure, but not after only 4 hours. The percentage change seen by densitometry measurement showed a 30-50% increase. The immunocytochemical staining with WH-66 at dilution upto 1/10,000 showed specific cellular staining in all the serotonergic raphe nuclei. Comparison of the WH-immunoreactive cells in the dorsal and median raphe nuclei showed a marked increase in staining after 48 hr. exposure to dexamethasone. These findings indicate that glucocorticoids secreted during stress increase the amount of tryptophan hydroxylase enzyme protein in the serotonergic neurons of the rat brain. This increase in protein amount can explain the long-term increases in serotonin synthesis after exposure to stress, and provides important insights into the role of translation of tryptophan hydroxylase enzyme protein in serotonergic cell body in neuroendocrine homeostasis. THYROID FUNCTION RUNS IN PHASE WITH REPRODUCTION AND PINEAL ACTIVITY IN THE FREE-LIVING INDIAN PARAKEET. T. N. Krishnaprasadan and Vibhakar C. Kotak\* Sardar Patel University, Vallabh Vidyanagar 388 120 Gujarat, India.

Seasonal changes in the ultrastructure of thyroid, and circulating levels of T3 & T4 were examined in relation to reproductive cycles and pineal function in the free-living, sub-ropical Indian Rose Ring Parakeet. These birds peak reproduction during January-March when pituitary LH, spermatogenic activity, and androgen tumover are highest and reproductive behaviors are fully expressed. Moderate synthetic changes in the thyroid and elevation in T4 during the prebreeding months of November and December is related to drop in ambient temperature. Elaboration of microvilli, colloid turnover, and increases in appearance of well defined Golgi, RER, mitochondria and T3 & T4 occurred during the breeding months of January to March that may augment greater androgen turnover, and possibly rules out any inhibitory influence of androgens over thyroid. This active thyroid profile also ran in phase with pro-reproductive pineal function. Significant (P<0.05) drop in T3 & T4 levels after March occurred during long-day length, post-breeding months of summer when thyroid synthetic and secretory activity was minimal. Low levels of thyroid hormones during the post-breeding phase may, via long loop, sensitize the hypothalamus to the negative feedback of androgen eventually to reduce pituitary LH output, and may also be responsible for low androgen clearance. In sum, pituitary, thyroid, pineal and testis endocrine functions run hand in hand in this winter breeding species.

NEUROPEPTIDE-Y(NPY), WHICH DECREASES THYROID BLOOD FLOW(TBF), IS NOT A PRIMARY MEDIATOR OF THE ACUTE TBF RESPONSE TO SYMPATHETIC NERVE STIMULATION. M. Dey. M. Michalkiewicz, L. Huffman and G.A. Hedge. Dept. of Physiology, West Virginia University Health Sciences Center North, Morgantown, WV 26506.

It has been suggested that TBF is regulated by both sympathetic and parasympathetic nerves. The purpose of our experiments was to study the role of NPY in the sympathetic neural control of TBF. Sympathetic nerve fibers to the thyroid contain both norepinephrine(NE) and NPY. Therefore, NE(15 nmol; iv bolus) and NPY(12 or 1.7 nmol/kg BW; iv infusion; 4 min) were administered to anesthetized male rats (250-300g) either alone or together, with or without an  $\alpha$  adrenergic receptor blocker (phentolamine; 10 mg/kg BW; iv bolus). Experiments were also performed in which the cervical sympathetic trunks(CST) were stimulated(30 Hz, 10 V; 0.5msec; 2 min) with or without phentolamine. TBF was monitored continuously by laser Doppler flowmetry. Results are expressed either as TBF or thyroid vascular conductance(TVC). NE or NPY at both doses decreased TVC relative to that in control, saline-infused, rats(p<0.05). No potentiation of the NE effect by NPY was observed when NE(iv bolus) was injected 2 min after a high or low dose of NPY. However, the effect of a second dose of NE, injected 15 min after the end of the low dose of NPY, was prolonged compared to the effect of a second dose of NE in saline-infused rats. Phentolamine blocked the effect of NE, but not that of NPY. Stimulation of the CST decreased TBF (p<0.01 vs. sham) and this effect was completely blocked by phentolamine. These results suggest that NPY does not take part in the mediation of the acute TBF response during sympathetic nerve stimulation. However, NPY may prevent adrenergic desensitization following prolonged sympathetic activity. This is suggested by the observation that the TBF effect of a second dose of NE is prolonged in rats pretreated with NPY(Supp. by NSF DCB-8904470).

EFFECT OF PHOTOPERIOD ON FAT CELL RECEPTORS AND ADENYLATE CYCLASE IN DJUNGARIAN HAMSTERS. J.G. Mercer, C.B. Lawrence and P.J. Morgan. The Rowett Research Institute, Bucksburn, Aberdeen, U.K. AB2 9SB.

The Djungarian hamster, Phodopus sungorus campbelli, presents a useful model for the study of the effect of photoperiod on food intake and body weight regulation. Adult male hamsters respond to short photoperiod (8:16 h light:dark) with dramatic reductions in body weight followed by decreased voluntary food intake; body weight reductions of 20% are typical following 8 weeks exposure. Reductions in the size of adipose tissue pads in excess of 50% contribute to these weight changes, although the net lipolysis exhibited by animals housed under short photoperiods is non-uniformly distributed among subcutaneous and abdominal fat pads. In other biological systems, such as the Zucker rat, such differences in adiposity are associated with modulated sympathetic tone, and at the level of the adipocyte by differences in receptor levels and in the activation of adenylate cyclase by stimulatory ligands (Strassheim et al., Biochem. J. 276:197, 1991). We have adopted a similar approach to the mechanisms underlying short-photoperiod induced fat mobilisation. β-adrenergic and A<sub>1</sub>-adenosine receptors have been characterised by binding incubations with 1251-iodocyanopindolol and 3H-PIA, respectively. The β-adrenergic and A<sub>1</sub>-adenosine receptor profiles of animals with well established photoperiod-induced weight loss did not differ significantly from those of long-day housed controls. The effect of photoperiod on the ability of lipolytic ligands to stimulate adipocyte adenylate cyclase is being investigated.

UNILATERAL BUT NOT BILATERAL OLFACTORY
BULBECTOMY INHIBITS BODY WEIGHT GAIN IN
GOLDEN HAMSTERS.

DR. Pieper\*, K.D. Johnson
The Color of Physiology,
Providence Hospital, Southfield, MI 48037.

The relation of the olfactory bulbs and photoperiod to the regulation of body weight was studied in male golden hamsters.

METHODS: The animals underwent sham operation (SH), bilateral olfactory bulbectomy (BX) or unilateral bulbectomy (UBX). They were left on long photoperiod (LD 14:10) for 5 weeks and were transferred to short photoperiod (LD 10:14) for 11 weeks.

**RESULTS:** The UBX hamsters gained less weight on long or short photoperiod than the SH group, while the BX hamsters gained at least as much weight as the SH group. Final body weights: SH 144  $\pm$  2.7; BX 151  $\pm$  4.0; UBX 104  $\pm$  4.8 (mean  $\pm$  SE); p < 0.001

**SUMMARY:** Thus we report the novel finding that unilateral, but not bilateral olfactory bulbectomy, reduces body weight gain in male golden hamsters.

## 345.7

BRAIN STEM AFFERENTS TO THE DIAGONAL BAND OF BROCA (DBB) IN THE RAT: RETROGRADE TRACING WITH RHODAMINE LATEX MICROSPHERES (RLM). V.V. Senatorov\*, R.M. Buijs and L.P. Renaud. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada, K1Y 4E9.

Previous electrophysiological studies in the rat have revealed that an abrupt rise in arterial pressure prompts a transient and selective cessation of activity in hypothalamic vasopressin (VP)-secreting magnocellular cells. That this response is attenuated after 6-hydroxydopamine lesions in the DBB suggests participation of ascending catecholaminergic afferents. Earlier studies using retrograde tracers that diffuse from the injection site have indeed indicated that DBB is likely to receive innervation from brainstem areas containing catecholaminergic cells. We now report that discrete DBB injections of a non-diffusible retrograde tracer RLM also label cells in brainstem areas containing catecholaminergic neurons. In pentobarbital anaesthetized Long-Evans rats, a picospritzer was used to inject RLM (0.03-0.20 µL) stereotaxically into the left horizontal limb of the DBB. After 7 days animals were reanaesthetized and sacrificed by transcardial perfusion with 3% paraformaldehyde. Brains were sectioned at 50 µm in the coronal plane by vibratome. In addition to other regions, retrogradely labeled neurons were found among the following catecholaminergic cell groups: nucleus tractus solitarius (NTS); rostral and caudal ventrolateral medulla (VLM); and the locus coeruleus (LC). In NTS and VLM, labeled cells were observed bilaterally; in LC labeled cells were generally ipsilateral to the injection site. The utilization of this tracer offers a more precise definition of DBB afferents. Moreover, confirmation that at least some of the labeled cells in these brainstem sites are noradrenergic in nature should provide an anatomical basis for the inference that specific noradrenergic neurons participate in a neural network that transmits information from peripheral baroreceptors to VP neurons. SECRETION OF THIOPHOSPHORYLATED AND SULFATED CHROMAFFIN VESICLE MATRIX PROTEINS. <u>I.C. Brooks\* and M.H. Brooks.</u> Marquette Univ. Sch. of Dent., Milwaukee, WI 53233.

Incubation of chromaffin cells with either [35S]thiophosphate or 35SO<sub>4</sub> resulted in radiolabelling of the same set of proteins; these were isolated along with chromaffin vesicles and were released upon vesicle lysis. We have now studied the ability of the cells to synthesize and release these proteins in an effort to understand their role in chromaffin vesicle function.

Thiophosphorylated or sulfated proteins were released upon nicotine stimulation of chromaffin cells, collected and identified by SDS-PAGE and fluorography. Radiolabel was removed from both thiophosphorylated and sulfated proteins by chondroitinase ABC treatment, suggesting that they are part of the proteoglycan component of chromaffin vesicle matrix proteins. The data also suggested that the cells might interchangeably use sulfate or thiophosphate in sulfation reactions. However, the two compounds appear to be independently inserted into matrix proteins. Pretreatment of chromaffin cells with DCNP (2,6-dichloro-4-nitrophenol), an inhibitor of protein sulfation by PAPS (3'-phosphoadenosine 5'-phosphosulfate), resulted in the apparent loss of label from normally labeled proteins. However, all of the label was present in a band that moved near the front in gels and was released upon stimulation of the cells. The data suggest that thiophosphate is incorporated into a small molecular weight component of a larger proteoglycan molecule and that sulfation may be necessary for attachment of the small component to the larger component. The Effect of Abdominal Sympathectomy on Bone Remodeling in Rats During Simulated Weightlessness. H.W. Burden, C. M. Manring, G. Price and D.M.Terrian\*. Dept. of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858

Adult female Sprague Dawley rats were subjected to lumbar sympathectomy (retroperitoneal approach) or sham surgery. One week later, sympathectomized and sham operated rats were fitted in a back harness and the animals suspended at an angle of 30° head-down tilt (day 0). The harness allowed full ambulation via the forelimbs while the hindlimbs were completely nonweight bearing. A control group of sham operated animals were allowed to ambulate normally (gravity control). On day 14, tibias were removed for histomorphometric analysis. Osteoclasts in the proximal tibial metaphysis were visualized with a tartrate-resistant acid phosphatase procedure and the area and perimeter of metaphyseal trabeculae were determined using a point counting method with a Merz grid. The area of metaphyseal trabeculae was significantly reduced in suspended sham-operated animals (18.7  $\mp$  1.2  $\mu$ 2 gravity control, p<0.05). Hindlimb suspension also significantly (p<0.05) reduced the trabecular perimeter length. Sympathectomy significantly reversed the effect of simulated weightlessness on the area (24.7  $\mp$  12 $\mu$ 2,p<0.05), but not perimeter length, of the trabeculae. Lastly, sympathectomy significantly (p<0.05) increased the number of osteoclasts along the perimeter of tracebulae of suspended rats. These data indicate that the sympathetic innervation to bone actively participates in the bone remodeling that occurs in this model of simulated weightlessness. Supported by NASA Grant No. NAGW-2927.

ELECTROTONIC COUPLING BETWEEN NEUROSECRETORY CELLS IN THE CRAYFISH EYE-STALK. Alvarado-Alvarez, R., García, U\*. and Aréchiga, H. Dept. Fisiología, Biofísica y Neurociencias, CINVESTAV-IPN, Apdo. Postal 14-740, 07000 México, D.F.

07000 México, D.F. Electrotonic coupling is a common feature in neurosecretory systems. It has been described among rat magnocellular neurons and bag cells of Aplysia. In the X organ-sinus gland system, of crustaceans dye-coupling and gap-junctions have been described, but no electrophysiological evidences of electrical coupling have so far been documented (Aréchiga et al. 1985). The purpose of this work is to study such coupling by using both dye injection and electrophysiological recordings. By using conventional intracellular recordings (tip resistance 30-60 Mg) pairs of neurons from the most superficial layer of X organ (about 30 neurons) were simultaneously impaled. We estimated that only 30% of them were coupled. When pairs of coupled neurons were found, Lucifer yellow was injected only in one neuron with a low tip resistance micropipette (about 2 Mg), in all the cases more than one neuron was stained. Mean values of input resistance from coupled and uncoupled neurons were 24 + 16 Mg(n=46) and 58 + 18 Mg(n=53) respectively. Voltage changes induced by hyperpolarizing current injection in the cell body. Action potentials evoked by depolarizing current injection showed peak time latencies about 300 µs, the coupling was non-rectifying. Three cases were found with indirectly electrical coupling, it means uncoupled neurons but synchronized presumably by a third, not recorded cell. From dye injection experiments we not only found pairs of stained neurons, but also groups of three or more neurons. Dye injections suggest that the site of coupling could be more or less 100 µm away from the some.

MORPHOLOGICAL AND BIOCHEMICAL ALTERATIONS OF THE CEREBRAL CORTEX AND BRAIN STEM IN ADULTS ATMYMIC MICE. G.G. Ortiz., I.E. Velázquez-Brizuela, C. Beas-Zárate, M. Cervantes. I. de la Ross A.\* Y.A. Feria-Velasco. Lab. Exp. Neuropath., Centro Inv. Biomed. Occte. I.M.S.S., Lab. Neurochem. Univ. de Guadalajara., Guadalajara, JAL., Universidad Autónoma de Guadalajara and Unidad Biomed. Centro Médico Siglo XXI., I.M.S.S. México D.F.

The athymic mouse is a mutant with thymus hypoplasia and for this reason serious deficiencies in its cellular immune system are present. It also presents alterations in its neuroendocrine system due to a decrease in its hormones (LH, FSH, T3, T4, etc). In this report a morphological (light miscroscopy) and biochemical (DNA, RNA, and protein quantification) study of the cerebral cortex, cereballum and berian stem of adult athymic mice (60 and 90 postnatal days) was performed. The sensory-motor of the cerebral cortex showed a packaging in layers V-VI with loss of its boundaries. The cerebellum did not show structural alterations (under this systems of analysis), and the brain stem displayed degeneration in the superior and inferior olivary nuclei and in a trajectory of neurons that cross the medial vestibular and intercalated nuclei and localized between the hypoglossal nucleus and dorsal motor nucleus of the vagus. At 60 postnatal days low levels of RNA and proteins were found, and at 90 postnatal days DNA, RNA, and proteins were found to be significantly less in all studied areas.

Conclusion: The athymic mouse presents degeneration and cellular death as a result of a secondary effect of low levels of trophic hormones that it normally displays during its development,

RUTA CHALEPENSIS ACTION ON INTESTINAL SMOOTH MUSCLE OF FEMALE GUINEA PIG. X. García\*, L. Cartas-Heredia and E. Gijón. Department of Physiology, Sch. of Med. UNAM. Ap. P. 70-250 México D. F. 04510 MEXICO.

70-250, Mexico D.F., 04510. MEXICO.

Previous studies have shown different responses between male and female guinea pigs to the autocholinergic action of rue alcoholic extracts(1). Rue action is studied in isometric recordings of intestinal segments in vitro of female guinea pig, during different phases of estral cycle determined by vaginal smear. Tissues showed different sensitivity to the same dose of acetylcholine or histamine (0.lig/ml) depending of the estral cycle phase. Rue causes biphasic responses, where relaxation of the smooth muscle predominates when the tissue comes from an animal in estro, while during other cycle phases there is a contraction-relaxation response. Rue blocks contraction responses induced by acetylcholine or histamine in dose dependent form. This effect reverts after washing the preparation. These results suggest that the anticholinergic or antihistaminergic effect is not modified during the estral cycle, while that rue direct action on tonus and basal activity of smooth muscle is modified by hormonal levels.

ALCOHOLIC EXTRACT OF RUTA CHALEPENSIS' ACTION ON SPONTANE-OUS MIOMETRIAL ACTIVITY OF FEMALE GUINEA PIG. E. Gijón\*, L. Cartas-Heredia and X. García. Department of Physiology, Sch. of Med., UNAM, A.P. 70250, 04510 México, D.F. MEXICO Rue is an european plant that has been used in tradi-

tional medicine from infusions or alcoholic extracts for the treatment of menstrual disorders, histeria, parasitic infections, muscular pain, and as an abortive. Alcoholic extract of <u>Ruta Chalepensis</u>' action is studied on isometric mechanical activity from uterine segments of female guinea pig on different stages of the estral cycle, determined by vaginal smear. Uterine sensibility to acetylcholine or his tamine 0.1 µg/ml was tested before and after adding rue alcoholic extract to the bath. First, it was observed that basal sensibility to acetylcholine or histamine is modified during the estral cycle, being higher during proestro. Secondly, rue increases tonus and spontaneous vity in all phases of estral cycle, showing higher effects during estro. Third, rue inhibits in dose dependent form acetylcholine or histamine contraction. The increase in basal activity and inhibitory effect of rue, revert after washing the preparations. These results suggest that rue exerts an effect on sarcolema and an increase of intracellular calcium.

### 346.1

ANGIOTENSIN II DEPOLARIZES NEURONS IN THE SUBFORNICAL ORGAN OF RAT IN VITRO. K. Inenaga, T. Nagatomo, H. Kannan and H. Yamashita\* Dept. of Physiol., Univ. Occupational & Environmental Health, Sch. Med., Kitakyushu 807, Japan.

Angiotensin II (AII) excites the subfornical organ (SFO) neurons. To clarify excitatory mechanisms of AII on the SFO neurons, intracellular recordings were made in SFO neurons of rat brain slice preparations. The slices were made from adult male Wistar rats after decapitation. Bath application of AII at  $1\mu M$  depolarized the neurons with increase of firing rate in normal and TTX-containing media. The non-pentidergic AII-receptor antagonist Losartan potassium at 100 nM suppressed the depolarizing effects. The AII responses might be induced in two ways. First the depolarization was accompanied with increase of membrane resistance, and the amplitude of the depolarization decreased with increase of resting membrane potentials, suggesting blockade of potassium channels by AII. Second the response was accompanied with apparent decrease of membrane resistance and the amplitude of the depolarization was increased with increase of the resting membrane potentials, suggesting that different channels other than potassium channels are involved in the latter response. These suggest that AII directly depolarized neurons in the SFO through some channels containing potassium channels.

# 346.3

ACTIVATION OF cFOS IN PVN OXYTOCIN NEURONS EXPOSED TO COCAINE AND DOPAMINE. L.J. Sim<sup>2</sup> and M. Morris. Dept. of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, N.C. 27157.

A hypothalamic tissue culture system has been developed to evaluate the effects of cocaine and related agents on specific neurons of the paraventricular nucleus (PVN). Dissociated PVN cultures from neonatal rats were treated with KCI(50 mM), cocaine or dopamine (10 $\mu$ m) for one hour. Cultures were fixed one hour after treatment and stained immunocytochemically for cfos using a nickel enhanced chromogen to produce a purple reaction product. Cultures were then stained for oxytocin (OT) or tyrosine hydroxylase (TH) using DAB to produce a brown chromogen. In control cultures, 26% of OT and 33% of TH cells were also cfos-ir. These values were considered baseline levels of activation. Depolarization with KCI Cocaine and dopamine increased activation of both OT and TH cells. treatment increased activation of OT neurons, but had no effect on TH cells. Increases of 46.2% and 97.4% were noted with cocaine and dopamine. These studies demonstrate that dopamine and cocaine respectively. specifically activate OT neurons and may provide a neuronal mechanism for the neuroendocrine/cardiovascular effects of cocaine. (Supported by PMA)

RELAXIN EXCITES SUBFORNICAL ORGAN NEURONES ANTIDROMICALLY IDENTIFIED AS PROJECTING TO THE SUPRAOPTIC NUCLEUS BUT NOT THOSE PROJECTING TO THE MEDIAL SEPTUM. B.C. Wilson and A.J.S. Summerlee\* Dept. of Biomedical Sciences, University of Guelph, Guelph, Ontario, Canada, N1G-2W1.

Previous work has indicated that relaxin (RXN) acts at the subformical organ (SFO) to affect the release of oxytocin (OT) and vasopressin (VP). In addition, RXN has been shown to bind to the SFO. Therefore, experiments were done to determine if exogenous RXN affected the extracellular electrical activity of two populations of SFO neurones.

Extracellular electrical recordings were made from SFO neurones antidromically identified from either the medial septum (MS)(n=6) or the right supraoptic nucleus (rSON)(n=7) in urethane-anaesthetized female rats (n=20). Control recordings were taken from neurones located in parietal association cerebral cortex (n=7). Five minutes after stable recording, rats were treated with saline (SAL; 0.1 ml i.v.) as a vehicle control and then five minutes later with VP (5.5 mU in 0.1 ml SAL i.v.) to control for nonspecific cardiovascular effects of RXN-induced VP release. Fifteen minutes later, rats were treated with RXN (5µg in 0.1 ml SAL i.v.) after which a further 10 minutes of recording was completed. Firing frequency (Hz) was calculated for each neurone in five time bins (bin length= 1min) in the pretreatment period and after each successive treatment. Mean frequencies in each time bin were calculated for each group of neurones and compared using ANOVA and Student's "t test.

RXN i.v. significantly (P<0.05) elevated mean firing frequency of SFO neurones antidromically identified as projecting to the rSON 3 minutes post-treatment. However, RXN had no effect on the extracellular electrical activity of MS-projecting neurones or cortical control neurones. This suggests that RXN is affecting release of OT and VP through a monosynaptic pathway linking the SFO and the magnocellular nuclei. Supported by NSERC Canada.

MORPHINE WITHDRAWAL EXCITATION INDUCES c-fos GENE EXPRESSION IN RAT MAGNOCELLULAR OXYTOCIN NEURONES.

J.A. Russell\*, M. Hamamura, L. Johnstone, G. Munro (SPON: Brain Research Association), Department of Physiology, University Medical School, Edinburgh, U.K.

Department of Physiology, Jichi Medical School, Japan. Acute morphine inhibits oxytocin (OXT) neurones, but dependence develops during i.c.v. morphine infusion for 5 days (Bicknell et al J.Physiol. 396 319-347; 1988). In anaesthetized dependent rats naloxone (5mg/kg) increases OXT neurone firing-rate 3.5-fold, but has no effect in controls; consequently naloxone increases OXT secretion in dependent rats 10-fold more than in controls. Vasopressin neurones are unaffected. To determine whether withdrawal induces c-fos expression in dependent oxytocin neurones, cryostat sections through hypothalamus from anaesthetized dependent rats were hybridized with a 35-labelled oligonucleotide c-fos mRNA probe and exposed on film for quantitative autoradiography (Hamamura et al, J.Physiol. 444, 51-63; 1991). c-fos mRNA signal in the SON and PVN was detected only after naloxone (+40 min). In conscious dependent rats, 90 min after naloxone, posterior pituitary oxytocin (but not vasopressin) was depleted by 17% and plasma oxytocin doubled; Fos protein, detected by immunocytochemistry on cryostat sections, was strongly expressed in the SON and PVN. The data suggest rapid c-fos gene activation in magnocellular oxytocin neurones hyperexcited during naloxone-provoked morphine withdrawal.

Supported by the MRC, AFRC, British Council.

CENTRAL SEROTONIN INDUCES VASOPRESSINAND OXYTOCIN SECRETION AND A SPECIFIC PATTERN OF C-FOS EXPRESSION IN RAT BRAIN. J.A. Saydoff <sup>1,2</sup>F. Leanza <sup>1</sup>, M. Carnes <sup>3</sup>, and M.S. Brownfield <sup>1,2</sup>. Dept. Comparative Bioscience <sup>1</sup>, Sch. Vet. Med., Neuroscience Training Program <sup>2</sup>, Univ. Wisconsin, Madison, WI 53706, and Dept. of Geriatrics <sup>3</sup>, Veterans Administration Hospital, Madison, WI 53705.

The aim of this study was to map potential brain pathways whereby central serotonin (5-HT) stimulates the secretion of vasopressin (VP) and oxytocin (OT). A chronic indwelling i.e.v. cannula followed by chronic arterial and venous femoral lines were surgically placed in rats. Freely moving, conscious rats had blood samples taken at -15, 5, and 15 min. and were perfuse fixed with 4% parafomaldehyde in PBS at 90 min. At time -5 min., rats were given i.e.v. vehicle or the 5-HT1C/2 antagonist LY53857 (10 ug). At time 0 min., rats were given i.e.v. vehicle, 10 ug 5-HT, or 200 ng angiotensin II (AII). 5-HT and AII induced large increases in VP and OT plasma levels. The increases in VP and OT induced by 5-HT were attenuated by LY53857.

Immunocytochemistry for c-Fos was performed on forebrain areas of the rat brains. 5-HT increased c-Fos expression relative to the vehicle control group in OVLT, nucleus medianus, lateral septum, periventricular area, supraoptic nucleus, and paraventricular nucleus (PVN). LY53857 attenuated 5-HT induced c-Fos expression primarily in the lateral septum, nucleus medianus, OVLT, and PVN. All induced an overlapping, but distinct pattern of c-Fos expression.

These findings are consistent with central 5-HT1C/2 receptors contributing to serotonergic stimulation of VP and OT secretion and the pathway for this effect may involve the lateral septum, nucleus medianus, OVLT, and/or PVN.

PHARMACOLOGICAL DIFFERENTIATION OF SEROTONERGIC (5HT) STIMULATION OF OXYTOCIN AND VASOPRESSIN SECRETION IN THE CONSCIOUS RAT. M.S. Brownfield 1.2. J. Armstrong 1. P. Rittenhouse 3. O. Li 3. and L.D. Van de Kar 3. Dept. Comp. Biosci. 1, Neurosci. Training Prog. 2, Univ. of Wisc., Madison, WI 53706 and Dept. Pharmacol., Loyola Univ., Maywood IL 60153. Serotonin (5-HT) and an assortment of drugs that activate the brain serotinergic system including releasers, uptake inhibitors and agonists stimulate oxytocin (OT)

Serotonin (5-HT) and an assortment of drugs that activate the brain serotinergic system including releasers, uptake inhibitors and agonists stimulate oxytocin (OT) and vasopressin (VP) secretion. Our results show that serotonergic control of oxytocin (Saydoff et al., J. Pharm. Exp. Ther. 257:95, 1991) and vasopressin (Brownfield et al., Neuroendocrinology 257:277, 1988) is mediated mostly by 5-HTIC/5-HTI2 receptor mechanisms. This general conclusion is agreed on by work from other laboratories but some details are still controversial, particularly with regard to receptor mechanisms. In this abstract we present evidence which confirms this general finding but reveals that serotonergic regulation of these two hormones can be differentiated pharmacologically.

can be differentiated pharmacologically.

Stimulated OT and VP secretory responses are similar to the releaser/uptake inhibitor fenfluramine. However, OT secretion is more sensitive to 5HT agonists MK212 and mCPP than is VP. The 5HT releaser PCA has a weak stimulatory effect on OT and VP secretion but following blockade of alpha-1 receptors by prazocin PCA significantly stimulates the secretion of both hormones. RU24969, considered a 5HT1a,b agonist stimulates OT but not VP when given alone, but pretreatment with the 5HT2/1C antagonists: LY53857 inhibits the OT response but not VP; ritanserin stimulates both OT and VP; spiperone inhibits OT and elevates VP. The 5HT2/1C agonist DOI stimulates OT but not VP when given alone and pretreatment with ritanserin inhibits the OT response. Pretreatment with 5HT1A agonist ipsapirone before DOI significantly elevates OT and VP secretion over DOI treatment alone. These studies suggest that different pathways, each containing serotonergic elements, act on OT and VP cells. (Supported by NIH 45812)

MORPHOLOGICAL CHARACTERIZATION OF SYNAPTIC INPUTS TO THE SUPRAOPTIC NUCLEUS (SON) FROM MEDIAN PREOPTIC NUCLEUS AND ADJACENT REGIONS' IN THE RAT. W.E. Armstroff, H. Wong & M. Tian. Dept. of Anat. Neurobiol., Univ. Tenn., Memphis, Memphis, TN 38163.

Light microscopic studies suggest the presence of direct projections to the SON from the median preoptic nucleus (MPN) and from nearby periventricular regions, areas known to be important for osmotic regulation. In the present investigation we examined anterogradely labeled varicosities in the SON with the electron microscope to determine the presence and nature of synaptic contacts after placement of the anterograde tracers phaseolus vulgaris leucoagglutinin or biotinylated-dextran in or near the MPN.

The densest labeling in the SON arose from injections involving the MPN, but substantial labeling was present from injections near the lamina terminals and from dorsal, anterior periventricular regions. However, only limited inputs were found with injections in the more caudal periventricular strata despite revealing a massive input to the bed nucleus of the stria terminalis and to much of the caudal hypothalamus (excepting ventromedial nucleus). Regardless of the density of labeling or injection placement, synaptic contacts in the SON were largely axodendritic and symmetrical, with terminal diameters on the order of 1 x 0.5 µm. Occasionally axo-somatic, and more rarely, axo-axonic synapses were observed, as were asymmetric contacts.

Symmetrical contacts are thought to mediate inhibitory postsynaptic actions, although exceptions are encountered. These results provide evidence for monosynaptic, putatively inhibitory connections from the MPN and rostral periventricular regions to the SON in the rat. The homogenous appearance of these contacts and the preference for dendrites as postsynaptic targets from both regions suggest a similarity in function regarding the control of SON neurons. Supported by NIH #NS23941(WEA).

THE LAMINA TERMINALIS IS A SOURCE OF THE GABAergic INNEVATION OF THE MAGNOCELLULAR NEUROSECRETORY SYSTEM. B.L. Roland\* and P.E. Sawchenko, The Salk Institute, La Jolla, CA 92037

GABA is an important inhibitory neurotransmitter in the neuroendocrine system. We recently used retrograde tracing and immunohistochemical methods to identify a number of local, intrahypothalamic, sources of glutamic acid decarboxylase-immunoreactive (GAD-ir) projections to the paraventricular nucleus (PVH). Complementary anterograde transport studies indicated that these local sources project principally to the parvocellular division of the PVH, with only meager contributions to the magnocellular parts of the PVH or to the supraoptic nucleus (SO). Three new lines of evidence raise the possibility that cell groups lining the lamina terminalis comprise an important source of the GABAergic innervation of magnocellular neurons. First, hybridization histochemical localization with cRNA probes revealed extensive expression of genes encoding both isoforms of GAD (i.e., GAD65 and GAD67) in the subfornical organ (SFO), the median preoptic nucleus (MePO) and the vascular organ of the lamina terminalis (OVLT). Second, combined localization of GAD mRNAs with retrograde tracer following injections into the PVH revealed retrogradely labeled cells with above-background GAD mRNA signal in the SFO, MePO and the OVLT. Third, discrete unilateral knife cuts in the coronal plane, just caudal the OVLT and extending 2 mm laterally from the midline and 2 mm dorsally from the base of the brain, reduced GAD-ir in the magnocellular division of the PVH and in the SO on the ipsilateral side. These results are consistent with those of electrophysiological studies demonstrating inhibitory components (some bicuculine-sensitive) of the response of identified magnocellular neurons to electrical stimulation of cell groups associated with the lamina terminalis.

#### 346.8

ANGIOTENSIN-INDUCED SALT APPETITE IN RATS: AN INHIBITORY ROLE FOR CENTRAL OXYTOCIN. R.E. Blackburn\*, A.D. Demko, G.E. Hoffman, E.M. Stricker, and J.G. Verbalis. University of Pittsburgh, Pittsburgh, PA 15261.

In several models of salt appetite in rats, NaCl intake can be inhibited by treatments associated with pituitary oxytocin (OT) secretion. We investigated the potential involvement of OT in the NaCl intake stimulated by angiotensin II (All), a treatment similarly associated with OT secretion. Male rats with indwelling intracerebroventricular (icv) cannulae were maintained on pelleted chow, water, and 2% NaCl solution. On experimental days all food and fluids were removed 1 h prior to treatment. Rats were given icv injections of either 150 mM NaCl (NS,  $5\,\mu$ l) or an OT receptor antagonist (OVT,  $10\,\mu$ g/rat in  $5\,\mu$ l); 30 min later rats were given either All (S ng/rat in  $5\,\mu$ l) or NS icv. Intakes of water and saline were monitored every 15 min for the next hour. Cumulative fluid intakes (ml) are below (\* p < 0.01 compared to NS + All):

15 min H<sub>2</sub>O 2% NaCl Group NS + All (n=17) OVT + All (n=17) 12.8 ± 1.9 2.3 ± 0.5 7.3 ± 1.0\* 17.8 ± 1.9 5.4 ± 0.7 16.9 ± 2.4 12.4 ± 1.4\*  $8.0 \pm 2.0$ 1.2 ± 0.5\* OVT + NS (n=11) 0.5 ± 0.2\* 2.3 ± 0.6\* NS + NS (n=11)  $0.6\pm0.4^{\star}$ 0.5 ± 0.2\*  $1.7 \pm 0.8$ \*  $0.9 \pm 0.4$ \*

Central OT-receptor antagonism potentiated the volume of 2% saline ingested by 2-3 fold following icv All but did not interfere with the dipsogenic actions of All; OVT alone did not increase saline intake. Immunocytochemical studies demonstrated that icv All at this dose caused pronounced c-Fos expression in both magnocellular and parvocellular hypothalamic OT neurons. Our results confirm that central All activates OT neurons, and suggest that some of these central OT projections may mediate an inhibitory component of the salt appetite induced by central All, as well as other treatments, in the rat.

## 346.10

PATCH-CLAMP ANALYSIS OF SPONTANEOUS SYNAPTIC CURRENTS IN RAT SUPRAOPTIC NEURONS J.-P Wuarin\* and F.E. Dudek Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024 and Dept. of Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523.

Excitatory and inhibitory amino acids have been shown to mediate electrically evoked synaptic responses in neurons recorded in hypothalamic supraoptic and paraventricular nuclei. Using whole-cell patch-clamp recordings, we tested the hypothesis that amino acid transmitters mediate all spontaneous excitatory and inhibitory postsynaptic currents (EPSCs and IPSCs) in supraoptic magnocellular neuroendocrine cells. A total of 27 cells were recorded. Resting membrane potential was -63±2.5 mV (mean± SE, n=21) and input resistance was  $726\pm50$  M $\Omega$  (n=25). Numerous spontaneous EPSCs and IPSCs were observed in all cells. With tetrodotoxin (0.5  $\mu$ g/ml, n=3) in the perfusion solution, EPSCs and IPSCs were still clearly distinguished from background noise, indicating that miniature spontaneous synaptic currents were detected. In bicuculline (10  $\mu$ M), no IPSCs were seen (n=10). No IPSCs or EPSCs were detected in bicuculline (10 µM) and 6-cyano-2,3-dihydroxy-7-nitroquinoxaline (CNQX) (10 µM, n=6). The decay phase of averaged spontaneous currents could be well fitted by single exponentials with time constants ranging from 5.5 to 6.6 ms for IPSCs (3 cells) and from 1.3 to 3.0 ms for EPSCs (4 cells). These results suggest that in supraoptic magnocellular neurons, glutamate or related excitatory amino acids mediate all the spontaneous EPSCs by acting primarily on non-NMDA receptors at resting membrane potential, and that activation of GABAA receptors mediates all spontaneous IPSCs.

PERSISTENT SUPRAOPTIC (SON) & SUPRACHIASMATIC (SCN) DYNORPHIN-A ABNORMALITIES IN ADULT ACTIVITY-BASED ANOREXIC (ABA) RATS EXPOSED TO NEONATAL MORPHINE. P.F. Aravich, R.A. Howell, S.N. Downing, T.S. Rieg, L.E. Doerries. Dept. Anat./Neurobiol., Eastern Virginia Med. Sch., Norfolk, VA 23501; Christopher Newport Univ., Newport News, VA 23606; V.A. Med. Ctr., Hampton, VA 23667.

Opioid abnormalities have been linked to anorexia nervosa (AN) and may

or may not be produced by neonatal morphine exposure. Because of interest in the relationship between exercise and AN, we have been exploring ABA in the rat and have reported dynorphin A abnormalities. This experiment determined if neonatal morphine exposure causes persistent changes in hypothalamic dynorphin A content in ABA rats and if these alterations affect susceptibility to the syndrome. Female Sprague-Dawley pups were injected on postnatal days 1-8 with morphine sulfate (0, 0.5 or 5.0 mg/kg, sc). They were weaned on day 23 and maintained on Purina chow until day 53, at which time they were subjected to ABA (1.5 h/day food; 22.5 h/day running wheel All rats were sacrificed following a weight loss of 25%. The SON and SCN were analyzed for dynorphin A (per mg protein) via RIA. It was found that neonatal morphine exposure had no reliable effect on 24-hr openfield activity just prior to ABA, body weight prior to ABA, susceptibility to ABA (i.e., number of days to weight-loss criterion) or food intake during ABA. It did, however, reliably decrease average wheel turns per day and had a differential effect on regional hypothalamic dynorphin A content, elevating it in the SON and decreasing it in the SCN. This investigation demonstrates that neonatal morphine exposure reduces ABA-induced running and has longterm, differential consequences on hypothalamic dynorphin systems. The effects of neonatal morphine in normal weight rats and on circadian and neural lobe function in ABA rats remain to be determined.

## 346.13

CHARACTERIZATION OF PROJECTIONS TO THE NEURO-HYPOPHYSIS BY TRANSNEURONAL PASSAGE OF PSEUDO-RABIES VIRUS. R.C. McLear, B.J. Oldfield, L.W. Enquist, D.E. Pleasure\* and R.R. Miselis. Dept. of Animal Biology, School of Veterinary Medicine, University. of Pennsylvania, Phila., Pa 19104

There are conflicting opinions as to the primary source of afferents to the magnocellular (Mg) neurons of the neurohypohyseal system for osmotic control of vasopressin secretion. One view has nearby neurons as the source of osmotic input. Another view proposes more distant neurons in the structures of the lamina terminalis as the primary source of osmotic information for the modulation of vasopressin secretion. We have used the transneuronal passage of Bartha (Ba-an attenuated strain of pseudorabies virus) to locate second order neurons innervating the Mg neurons of the neurohypophysis. At short survival times (≤ 16 hours) Ba labels only the Mg neurons of the paraventricular, supraoptic and accessory nuclei. At longer survival times (20-28 hours) Ba passed transneuronally into second order neurons which were confined to the subfornical organ, median preoptic nucleus, organum vasculosum of the lamina terminalis, the caudal ventrolateral medulla and vagal complex. In these time periods there was very little labeling of neurons nearby the magnocellular nuclei suggesting a primacy of input from the above more distant nuclei in the modulation of Mg function. Osmoreceptors may lie among these neurons. Supported by NIH GM 27739.

## 346.15

THE EFFECTS OF HISTAMINERGIC INPUTS ON SUPRAOPTIC NUCLEUS NEURONS IN RAT HYPOTHALAMIC SLICES. Q.Z. Yang\* and G.I. Hatton, University of California Riverside, Riverside, CA 92521.

Earlier extracellular studies by others and intracellular studies in our laboratory showed that histamine (HA) has excitatory effects on phasically firing neurons in the supraoptic nucleus (SON). Our dual intracellular recordings revealed that HAergic cells of the tuberomammillary nucleus (TM) are directly presynaptic to phasically firing vasopressin (VP) cells and their activation elicited EPSPs and action potentials.

In the present study, we investigated the effects of electrical stimulation of the TM in horizontally cut hypothalamic slices, with particular interest in responses of continuously firing, putative oxytocin (OX) neurons. Extracellular electrical stimulation of the TM evoked short latency (3-4 ms) fast IPSPs in most putative and all immunocytochemically identified OX neurons. These responses could be blocked by H<sub>2</sub>-, but not H<sub>1</sub>- antagonists. IPSPs could also be blocked by picrotoxin, but not by 10  $\mu$ M bicuculline. Taken together with the earlier studies, these data suggest that HAergic input serves to differentially modulate OX and VP release via monosynaptic contacts with SON neurons. Support by NS16942.

NEW EVIDENCE FOR CIRCUITS LINKING THE RETINA TO THE SUPRAOPTIC NUCLEUS IN RATS. J. D. Levine\* and R. R. Miselis. Dept of Animal Biology, University of Pennsylvania, Philadelphia, PA 19104.

Previous studies have shown that the lateral component of the retinohypothalamic tract terminates dorsal to the caudal SON, as well as, sparsely throughout the SON. In this study, we ask whether pseudorabies virus (PRV), a transynaptic neuroanatomical tracer, will label cells in these areas. The Wild type (Wt; 4X108 or 6X108 pfu/ml) and Bartha (Ba; 5X108 or 9X108 pfu/ml) strains were employed to identify retinorecipient neurons located within the SON and peri-SON terminal field in the female albino rat. Following bilateral sympathectomy to eliminate the confounding sympathetic innervation of the eye, each rat received a uniocular injection of 20 µl CT-HRP and 2-3 µl Wt or Ba. A double labeling protocol was adopted to display both the CT-HRP reaction product and infected neurons in the same section. The Wt infected a small group of cells within the SON and within the CT-HRP labeled peri-SON terminal field. In contrast, Ba infected only an occasional cell in this region. These findings demonstrate that retinal ganglion cells may innervate the SON directly. This provides an anatomic basis for photic influence on magnocellular function. Currently, we are examining the possibility that cells in the peri-SON terminal field might be interneurons that provide retinal ganglion cells indirect access to magnocellular neurons.

EFFECT OF ANGIOTENSIN II ON SUPRAOPTIC NEURONS OF THE ADULT RATS WITH SLICE PATCH CLAMP METHOD. T. Nagatomo, K. Inenaga, Y. Ueta, F. Izumi\* and H. Yamashita. Depts. of Physiology and Pharmacology\*, Univ. of Occup. and Environ. Health, School of Medicine, Kitakyushu 807, Japan.

We have already reported in vitro experiment that angiotensinII (AII) increases the firing rate of rat supraoptic neurosecretory cells. (Okuya et al 1987). To elucidate the mechanism of the action, we used patchclamp techniques in the thin slice preparations and recorded from the microscopically identified supraoptic neurons of the adult Wistar male rats. Effects of AII on isolated potassium currents of the supraoptic neurons were investigated. To separate IA and IK, Na+ free and Co2+ (2mM) containing perfusion medium were used to block Na+ and Ca2+ related currents. IA was isolated by substracting currents either at two holding potentials (-80mV and -50mV), or before and after application of 4-AP (5mM). In some experiments, TEA (5mM) was also added to the perfusion medium to suppress Ik components. Bolus injection of AII ( $10^{-5}M$ ,  $100\mu l$ ) and bath application of AII ( $10^{-7}M$ ) suppressed IA amplitude in responsive neurons with decrease of 32% and 29%, respectively. On the other hand, Ik was suppressed only slightly. These results indicate that AII excites neurosecretory cells partly through suppression of IA.

## 346.16

UP-AND DOWN-REGULATION OF κ-OPIOID MODULATION OF OXYTOCIN SECRETION IN THE NEUROHYPOPHYSIS THROUGH PREGNANCY. R.J. Bicknell\*<sup>1</sup>, A.J. Douglas<sup>2</sup>, S. Dye<sup>1</sup> and G. Leng<sup>1</sup>. <sup>1</sup>AFRC Institute of Animal Physiology and Genetics Research, Babraham, Cambridge CB2 4AT and <sup>2</sup> Dept. of Physiology, University Medical School, Edinburgh EH8 9AG, UK

During pregnancy in the rat an endogenous opioid inhibition over oxytocin (OXT) neurones is activated which may allow accumulation of neurohypophysial stores, prevent premature OXT secretion and, during parturition, regulate the spacing of deliveries. One site of opioid action is autoregulatory, involving κ-receptors in the neurohypophysis and mediated via opioids co-secreted with OXT. We have gauged the magnitude of autoregulatory restraint during pregnancy. We compared the rise in plasma OXT concentration produced by i.v. cholecystokinin (CCK;  $20\mu g/kg)$  before (CCK1) and after (CCK2) injection of the  $\kappa$ -antagonist norbinaltorphinine (norBNI;  $20\mu g/kg$ ) in conscious rats. In non-pregnant rats the ratio CCK2/CCK1 was 2.00±0.13 indicating a doubling of CCK-induced OXT output in the presence of norBNI. In mid-pregnancy (days 8-14) the ratio CCK2/CCK1 was significantly higher at 2.56±0.20 (P<0.05) and in late pregnancy (days 15-21) was significantly lower at 1.67±0.08 (P<0.05 vs non-pregnant). In vitro, the opioid antagonist naloxone (10.5M) potentiated electrically evoked OXT secretion by 265%. This potentiation was significantly less in neurohypophyses from 16 and 21 day pregnant rats (30% and 25% reduction respectively). Prodynorphin mRNA levels in the supraoptic nuclei were unchanged in late pregnancy as was neurohypophysial content of dynorphin A 1-8: content of met -enkephalin was however significantly reduced on day 21 (P<0.01). Our data suggest that an upregulation of autoinhibitory opioid mechanisms restraining OXT secretion occurs in early or mid-pregnancy, followed by downregulation of this mechanism. Altered synthesis/secretion of proenkephalin rather than prodynorphin peptides may be involved. Since overall opioid tone over OXT neurones is enhanced in late pregnancy, activation of central opioid systems is indicated at this time.

FUNCTIONAL ROLE OF APAMIN SENSITIVE K+ CURRENT STEADY STATE FIRING OF RAT SUPRAOPTIC NEUROENDOCRINE CELLS. K. Kirkpatrick' and C.W. Bourque. Montreal General Hospital and McGill University, Montreal, Canada.

Magnocellular neuroendocrine cells (MNCs) express an apamin sensitive gK(Ca) that is responsible for the afterhyperpolarization (AHP) that follows evoked trains of action potentials. Voltage and current clamp experiments on 29 supraoptic MNCs impaled in superfused hypothalamic explants examined the properties and function of the current underlying the AHP (IAHP). Hybrid clamp analysis revealed  $I_{AHP}$  to have a linear I-V relation with an  $E_{rev}$  near -98 mV (n=4) which shifted by 56 mV/log[K\*]<sub>o</sub>. While an apamin sensitive AHP did not follow single impulses (100 nM;n=14) IAHP could be activated with trains of as few as 3 action potentials suggesting that in tonically firing MNCs, AHP channels may be active in the steady state. Application of a voltage clamp following a period of spontaneous firing revealed a decaying outward current reversing near -98 mV, that was absent in the presence of apamin (n=11). Bath application of 100 nM apamin to tonically firing cells caused a dramatic increase in firing rate (n=5) but had no effect on silent cells (n=3). This study suggests that in addition to it's recognized roles in spike frequency adaptation and post burst inhibition, IAHP is tonically activated to limit the rate of MNC spiking activity. Modulation of IAHP therefore presents a means to regulate neurohypophysial hormone release

### REGULATION OF AUTONOMIC FUNCTION: OTHER

## 347.1

SYMPATHETIC-EVOKED MYDRIASIS IS ANTAGONIZED BY HISTAMINE H<sub>3</sub> RECEPTOR ACTIVATION IN ANESTHETIZED CATS. M.C. Koss\*1, G. Figueiras<sup>2</sup> and J.A. Hey<sup>3</sup>. University of Oklahoma College of Medicine<sup>1</sup>, Oklahoma City, OK, University Autonoma de Guadalajara<sup>2</sup>, Guadalajara, Mexico and Schering-Plough Research Institute<sup>3</sup>, Bloomfield, NJ.

Frequency-dependent pupillary dilations were evoked by electrical stimulation of the preganglionic cervical sympathetic nerve (sympatho-excitation) or the hypothalamus (parasympathoinhibition) in sympathectomized cats. Systemic administration of the selective  $H_3$  receptor agonist R- $\alpha$ -methylhistamine ( $R\alpha MeHA$ ) produced a dose-dependent depression of mydriasis due to sympathetic activation but had no effect on responses elicited by parasympathetic withdrawal. RaMeHA was much more effective in depressing sympathetic responses obtained at lower frequencies when compared to higher frequencies of stimulation. This inhibitory effect of RαMeHA was antagonized by the H<sub>3</sub> blocker thioperamide (3 mg/kg i.v.) but not by combined pretreatment with H<sub>1</sub> and H<sub>2</sub> blockers, chlorpheniramine (300 µg/kg i.v.) and cimetidine (5 mg/kg i.v.). RaMeHA was without effect on pupillary responses elicited by i.v. (-)-epinephrine (1-30  $\mu$ g/kg). These results demonstrate that histamine H<sub>3</sub> receptors modulate sympathetic activation of the iris at a site proximal to the iris dilator muscle. A likely mechanism would be prejunctional inhibition of NE release although a ganglionic action cannot be excluded. Supported by EY09344.

EFFECT OF ANTIBODIES AGAINST ACETYLCHOLINESTERASE ON EXPRESSION OF PEPTIDES AND CATECHOLAMINE SYNTHESIZING ENZYMES IN THE RAT ADRENAL GLAND.

EXPRESSION OF PEPTIDES AND CATECHOLAMINE SYNTHESIZING ENZYMES IN THE RAT ADRENAL GLAND.

A. Dagerlind 1.\* T. Hökfelt 1 and S. Brimijoin 2. 1 Dept. of Histology and Neurobiology, Karolinska Institute, P.O. Box 60400, S-104 01 Stockholm, Sweden and 2 Dept. of Pharmacology, Mayo Clinic, Rochester MN 55905.

In the rat, systemic administration of monoclonal antibodies (1.5mg, i.v.) against acetylcholinesterase (AChE) caused autonomic dysfunctions such as pilocrection (30 min after the injection) and ptosis (1b). Four days after the antibody administration a total disappearance of AChE immunoreactive fibers was seen in the adrenal medulla. However, a small number of AChE immunoreactive chromaffin cells and intramedullary ganglion cells, also seen in the control adrenal medulla, remained positive. In addition, the antibody injection affected levels of several peptides present both in fibers and chromaffin cells in the adrenal gland. The number of cells expressing calcitonin gene-related peptide (CGRP), galanin (GAL) and enkephalin (ENK) was dramatically increased compared to the very few cells observed expressing these three peptides in the normal gland. The sparse networks of CGRP and GAL positive fibers were however unchanged. In contrast, the dense network of ENK fibers present in the normal adrenals totally disappeared after the antibody injection. Substance P (SP) and somatostatin (SOM) positive cells, not present in the normal gland, appeared after AChE antibody administration, although to a much lower degree as compared to CGRP, GAL and ENK cells. No certain differences between normal and reaated animals could be observed with regard to neuropeptide Y (NPY) or either of the catecholamine (CA) synthesizing enzymes tyrosine hydroxylase (DBH) and phenylethanolamine N-methyltransferase (PNMT) immunoreactive chromaffin cells. The data presented here suggest a decentralization of the adrenal gland due to a detruction of preganglionic fibers and terminals by the anti-AChE antibody.

### 347.2

DIABETIC BB/W RATS HAVE IMPAIRED ADRENOMEDULLARY CATECHOLAMINE SECRETION. R.A. Wilke, P.I. Lelkest and C.J. Hillard\*. Dept. of Pharmacology, Medical College of Wisconsin Milwaukee, WI 53226 and †Dept. of Medicine, University of Wisconsin, Milwaukee, WI 53201.

After years of having their disease, many insulin-dependent diabetics lose the capacity to secrete catecholamines (CA) from their adrenal medullae. The mechanism for this pathological change is unknown. In order to gain some insight into the nature of this abnormality, we have isolated rat adrenal glands, perfused them in a retrograde fashion, and fluorometrically measured the CA content of the perfusate as an index of adrenal medullary secretion. With this preparation, we have demonstrated that secretion of CA in response to transmural electrical stimulation of splanchnic nerve terminals (600 cycles at 80 V) is severely attenuated in glands from female BB/Wistar rats with diabetes of 4 month duration (65% reduction when compared to their agematched, nondiabetic controls). Furthermore, we have found that (in the presence of 500  $\mu$ M mecamylamine) CA secretion in response to direct stimulation of the medulla with 20 mM potassium is reduced 40% in adrenal glands from the diabetic rats, evidence that the adrenal medulla itself is hypofunctional. Finally, using HPLC, we compared the content of both epinephrine and norepinephrine in adrenal medullae from these rats. There were no significant differences between diabetics and controls, indicating that the above secretory defect is not due to a difference in the amount of stored catecholamines available for release. Mechanistic studies such as these continue to enhance our understanding of the etiology of long-term diabetic complications hypoglycemia unawareness and autonomic neuropathy.

# 347.4

ENDOGENOUS ADENOSINE RESTRAINS CATECHOLAMINE FROM ADRENAL MEDULLA RATS.

SECRETION FROM ADRENAL MEDULLA IN RATS. C.J. Tseng\*, W.Y. Ho, C.J. Kuan and C.S. Tung. Depts. of Pharmacology and Physiology, National Defense Medical Center, Taipei, Taiwan, R.O.C.

The purpose of this study was to test the hypothesis that endogenous adenosine restrains norepinephrine and epinephrine release from adrenal medulla. We examined the effects of an adenosine receptor antagonist, 1,3-dipropyl-8-psulfophenylxanthine (DPSPX), on the epinephrine and norepinephrine release. Plasma catecholamine was measured by HPLC with E.C. detection. In conscious, unrestrained rats, DPSPX significantly increased plasma catecholamine in control rats and rats treated with hydralazine. The effect of increased plasma catecnolamine in control rats and rats treated with hydralazine. The effect of DPSPX on plasma catecholamine was significantly greater in rats treated with hydralazine compared with control rats. This effect was attenuated in rats pretreated with converting enzyme inhibitor, captopril. Epinephrine was significantly reduced in rats received acute adrenectomy. These results demonstrated that under basal physiological physiological demonstrated that under basal conditions, endogenous adenosine tonically inhibits catecholamine secretion from adrenal medulla, which is achieved partially by inhibitory effect of adenosine on renin-angiotensin system, and this effect is augmented whenever the sympathetic system is stimulated.

MAP-2 AND GAP-43 IMMUNOREACTIVITY IN THE INTACT AND DECENTRALIZED PELVIC PLEXUS OF RATS N.M. Minorsky\* and W.G. Dail Anatomy Dept., Univ. New Mexico, Sch of Med., Albuquerque, NM 87131 Neurons in the pelvic plexus reacquire innervation after chronic interruption of preganglionic input. One explanation for the emergent innervation is that intrinsic synapses form between ganglion neurons. The present study uses immunocytochemical labelling for cytoskeletal proteins to examine whether dendrites or axons contribute to the newly formed synapses. Specifically this study examines the incidence with which Map-2-IR (dendritic) and Gap-43-IR (axonal) fibers appose penile neurons in the intact and chronically decentralized pelvic plexus of rats. Results indicate that in both the intact and decentralized ganglia, Map-2-IR fibers are scarce and appose fewer than 15% of the penile neurons. By comparison, Gap-43-IR fibers enclose 57% of the penile neurons in the intact ganglia. This value, which drops to 27% after acute nerve lesion, increases to 48% in the chronically decentralized animal. The paucity of Map-2-IR fibers, and the apparent restitution of Gap-43-IR plexuses following chronic nerve lesion, suggest that decentralized neurons are reinnervated by axons.

REPLICATION, ASSEMBLY & INTERCELLULAR TRANS-PORT OF PSEUDORABIES VIRUS IN RAT CNS. B.H. Lee. <sup>1</sup>, R.B. Lynn<sup>2</sup>, L.W. Enquist. <sup>3</sup>, J.B. Grinspañ<sup>4</sup>, R.R. Miselis<sup>4</sup>, & J.P. Card<sup>3</sup>. <sup>1</sup>Geongsang Natl. Univ., Korea, <sup>2</sup>Thomas Jefferson University, Philadelphia, PA, <sup>3</sup>DuPont Merck Pharmaceutical Co., Wilmington, DE, and <sup>4</sup>University of Pennsylvania, Philadelphia, PA.

Pseudorabies virus has been used extensively to map multisynaptic circuits of neurons in the central nervous system. The utility of this method is based upon the assumption that transneuronal passage of virus occurs preferentially at synapses and that neurons are not infected by release of virus into the extracellular space. Although numerous projection specific patterns of neuronal transport have been offered in support of this conclusion, clear documentation of the pathways of viral replication, assembly, intracellular transport and egress from infected neurons have not been established. In the present study, we have used electron microscopy to characterize these processes in neurons of the dorsal motor vagal nucleus which were infected by injecting virulent or attenuated strains of PRV into the ventral wall of the stomach. Systematic examination of infected neurons in serial micrographs demonstrated a highly organized pathway of viral replication and transport which utilized existing cellular machinery and biased transport of virions to sites of afferent synaptic input. Among the most important aspects of this process was the application of a Golgi-derived envelope to newly replicated viral capsids. This bilaminar membrane appeared to be instrumental in intracellular transport and permitted fusion events that allowed virions to pass between neurons at sites of synaptic contact. Virions were distributed throughout the full extent of the dendritic arbor, but release only occurred at sites of afferent synaptic contact.

THE ROLE OF GLIA AND MACROPHAGES IN TRANSNEURONAL PASSAGE OF PSEUDORABIES VIRUS. <u>I.P.</u> Card<sup>1</sup>\*<u>L. Rinaman</u><sup>2</sup>, & <u>L.W. Enquist</u> <sup>1</sup>. <sup>1</sup>DuPont Merck Pharmaceutical Co., Wilmington, DE and <sup>2</sup>Medical College of Pennsylvania, Philadelphia, PA.

Pseudorabies virus (PRV) is a neurotropic swine alpha herpesvirus that has been used extensively to map multisynaptic circuits in the CNS. The most convincing evidence for specific transport of virus through synaptically linked populations of neurons has been achieved with attenuated strains of virus. However, all strains produce pathological changes in neurons after prolonged replication that could compromise the circuit-specific transport of virus. We previously demonstrated that infection of neurons with virulent and attenuated strains of PRV produces a predictable temporal response of glia and macrophages that appears to isolate and restrict spread of virus from chronically infected neurons. In the present study, we have extended that analysis to the ultrastructural level. Inoculation of the stomach wall with virulent and attenuated strains of PRV led to infection of neurons in the dorsal motor nucleus of the vagus (DMV). However, the basic structure of the DMV, and the neuropil in particular, were remarkably free of pathology, even in specimens from animals chronically infected with the most virulent strain of PRV. Infected neurons were invested with and effectively isolated by processes of reactive astroglia and polymorphonuclear macrophages. Some of these cells ultimately became infected by virus, but exhibited a defect in envelopment that prevented release of infectious virus. These findings are consistent with the conclusion that the non-neuronal response to viral infection of neurons contributes to specific transport of virus through multisynaptic circuits of neurons.

## RESPIRATORY REGULATION: CHEMORECEPTION

# 348.1

ACTIVITY OF RESPIRATORY NEURONS DURING HYPOXIA IN CHEMO-DENERVATED CATS. J.E. Melton, S.J. England, M. Douse, J. <u>Duffin and J.A. Neubauer\*</u>. UMDNJ-R. W. Johnson Med. Sch., New Brunswick, NJ 08903 and Univ. of Toronto, Toronto, ONT M5S1A8.

In anesthetized, chemodenervated cats, phrenic nerve activity decreases during hypoxia culminating in apnea at an arterial 0, saturation of 50%. To determine if decreased respiratory activity is due to inhibition of premotor inspiratory neurons by Bötzinger bulbospinal expiratory neurons, extracellular activity was recorded from expiratory neurons in the Bötzinger complex and bulbospinal inspiratory neurons in the dorsal (DRG) and ventral (VRG) respiratory groups during acute hypoxia. All neurons progressively decreased firing rates during hypoxia. Expiratory neurons became silent prior to, and inspiratory neurons with or immediately following, loss of phrenic nerve activity. During recoxygenation, phasic firing was evident in 35% of inspiratory and expiratory neurons before, with onset of the remainder coincident with, return of phrenic nerve activity. Firing rates increased during reoxygenation, returning to prehypoxic levels within 2 min. These data suggest: 1) Hypoxia inhibits/disfacilitates Bötzinger expiratory and DRG/VRG inspiratory neurons in the chemodenervated animal; 2) Bötzinger expiratory neurons in the chemodenervated animal; 2) Bötzinger expiratory neurons are not the source of hypoxic inhibition of these inspiratory neurons; 3) Phasic activity of subpopulations of respiratory neurons precedes the onset of integrated motor output. Supported by HL16022 and MRC Canada.

SYNERGY BETWEEN THE AMOUNT OF TYROSINE HYDROXYLASE IN RAT NUCLEUS TRACTUS SOLITARIUS AND VENTILATORY ACCLIMATIZATION TO CHRONIC HYPOXIA.

<sup>1</sup> M. Denavit-Saubié\* 3P. Schmitt. F. Pujol and 2 J.M. Péquignot. Institut A. Fessard - CNRS, 91198 Gif-sur-Yvette (France) 2 URA 1195 - CNRS, Fac. de Médecine Grange-Blanche, 69008 Lyon (France) and 3 UMR105 - CNRS, Fac. de Médecine A. Carrel, 69008 Lyon (France).

Long term hypoxia causes a gradual rise in ventilation which is transmitted by peripheral chemosensory pathways to the caudal part of the nucleus tractus solitarius (NTS). Since this area is rich in catecholamines, the aim of this work was to study their evolution during ventilatory acclimatization by measuring Norepinephrine (NE) turnover and the quantity of tyrosine hydroxylase (TH) in the caudal and rostral parts of the NTS. Two groups of rats Sprague-Dawley were kept either in normoxia (21%O2) or in hypoxia (10%O2/90%N2) during 3, 7, 14 and 22 days. TH protein, NE turnover, tidal volume and respiratory frequency were measured. Ventilation increased progressively during the first week of hypoxia and then stabilized. In the caudal part of the NTS, there was a concurrent increase in both NE turnover and TH content which reached maximal levels after 14 days, while the rostral part of the NTS was unaltered. There is a strong relationship between the biochemical and the physiological responses to long term hypoxia and the distinction between caudal and rostral part of the NTS reflects the target of chemosensory inputs.

DEOXYGLUCOSE UPTAKE AND OXYGEN PARTIAL PRESSURE IN THE ISOLATED PERFUSED BRAINSTEM OF ADULT GUINEA PIG. T. Schäfer<sup>+</sup>, M.P. Morin-Surun, M. Denavit-Saubié and R. Naquet<sup>\*</sup>. Institut Alfred Fessard, C.N.R.S., F-91198 Gif-sur-Yvette Cedex, France. <sup>+</sup>Dept. of Applied

Physiology, Ruhr-University, W-4630 Bochum, FRG.

Physiology, Ruhr-University, W-4630 Bochum, FRG.
Recently we have demonstrated that in the adult brainstem preparation, perfused through the basilar artery, a functional respiratory network is preserved (Morin-Surun et al., 1992, Exp. Brain Res., in press). Electrophysiological studies showed that the ventral respiratory group (VRG) is functioning in this preparation. To detect the metabolic conditions and oxygen supply within this region we measured deoxyglucose uptake and oxygen partial pressures in the tissue. Deoxyglucose, given as a single bolus into the basilar artery, follows the same pathway as glucose, but remains trapped as follows the same pathway as glucose, but remains trapped as deoxyglucose 6-phosphate and is not metabolized any further. The autoradiographic mapping of 2-[14C] deoxyglucose in the adult guinea autotatographic mapping of 2-1° CJ deoxygiucose in the addit guinea pig brainstems indicates glucose utilization in the whole cross sections of the entire brainstem. Tissue oxygen partial pressures were measured in steps of  $100 \mu m$  using an  $O_2$ -sensitive microelectrode (Diamond, tip 25  $\mu m$ ), calibrated in two Krebs solutions saturated with air and nitrogen, respectively, at the same temperature as the perfusion solution (Krebs, 95%  $O_2$ , 5%  $CO_2$ , 25°C, no oxygen carrier). Mean pO<sub>2</sub> (n=5) was  $476\pm105$  mmHg on the ventral surface superficial to the VRG, 350 $\pm43$  mmHg at 200  $\mu$ m below the surface,  $141\pm29$  mmHg at 1200  $\mu$ m,  $33\pm16$  mmHg at 2200  $\mu$ m and  $114\pm26$  mmHg at 3200  $\mu$ m. We conclude that both, glucose utilization and oxygen supply are preserved in the isolated perfused brainstem.

## 348.5

MODULATION OF THE RESPIRATORY RESPONSES TO HYPOXIA AND HYPERCAPNIA BY SYNAPTIC INPUT ONTO CAUDAL HYPOTHALAMIC NEURONS. E.M. Hom and T.G. Waldrop'. Dept. of Physiology & Biophysics, Neuroscience Program and College of Medicine, Univ. of Illinois, Urbana, IL 61820.

Prior results from this laboratory have demonstrated that the respiratory response to hypercapnia is accentuated by microinjection of GABA antagonists or GABA synthesis inhibitors into the caudal hypothalamus of both cats and rats. However, no evidence was found for involvement of hypothalamic GABA in the respiratory response to hypoxia. The purpose of the present study was to determine if mechanisms of synaptic input other than GABAergic onto caudal hypothalamic neurons affects the respiratory responses to hypoxia. The respiratory (diaphragmatic EMG) responses to hypoxia (10% O<sub>2</sub>) and hypercapnia (5% CO<sub>2</sub>) were recorded in anesthetized rats before and after bilateral microinjection of CoCl<sub>2</sub> (100 mM) into the caudal hypothalamus in order to block synaptic transmission. Both hypoxia and hypercapnia elicited increases in tidal diaphragmatic activity and respiratory frequency prior to the microinjections. The respiratory response to hypercapnia was increased (+27.3%) after CoCl<sub>2</sub> microinjections; this finding is consistent with prior results obtained with blockade of GABAergic input. In contrast, the respiratory response to hypoxia was diminished (-38.3%) after the CoCl<sub>2</sub> microinjections. The results of this study support our after the COCl<sub>2</sub> microinjections. The results of this study support our prior findings that neurons in the caudal hypothalamus modulate the respiratory response to hypercapnia. In addition, our findings suggest that an excitatory input onto hypothalamic neurons modulates the respiratory responses to hypoxia. (Supported by NIH 38726 and AHA).

TRANSIENT AND SUSTAINED PATTERNS OF OPTICAL ACTIVITY IN THE CAT VENTRAL MEDULLARY SURFACE TO CO2 STIMULATION. X-W. Dong\*, D. Gozal, D.M. Rector, & R.M. Harper. Brain Res. Inst. and Dept. of Anatomy & Cell Biology, UCLA Sch. of Med.; Div. Neonatol. & Ped. Pulmonology, Children's Hospital, USC Sch. of Med., Los Angeles, CA.

Neuronal activity patterns in chemoresponsive fields of the ventral medullary surface (VM) were examined by measuring reflected light changes during hypercapnic ventilatory challenges. The VM was exposed through a ventral surgical approach in ten adult cats under sodium pentobarbital anaesthesia. A 3.2 mm diameter optical probe and charge coupled device camera were placed on the VM surface, and tissue was illuminated by 700 nm light. Images were digitized at 2-3 sec intervals before, during, and for 30 min after hypercapnic challenges with 3, 5, and 10 % CO2 in O2. Each image was subtracted from baseline, and reflectance changes in both overall and regional areas were assessed. Derivatives of these measures were then plotted sequentially. After an initial delay of approximately 30 sec from onset of CO2 administration, marked transient changes in reflectance occurred, with subsequent baseline shifts during the stimulus. Upon return to room air, transient optical responses in both overall and regional activity were again observed. The direction and extent of the response depended on both the area of the VM surface and the CO2 concentration of the gas, respectively. Chemoresponsive neurons in the VM apparently respond with both transient and sustained changes in activity; the transient responses are reminiscent of on" and "off" discharges observed in other sensory systems.

WHOLE CELL PATCH RECORDINGS OF VENTROLATERAL MEDULLARY NEURONS THAT ARE STIMULATED BY HYPOXIA. P.C. Nolan and T.G. Waldrop. Dept. of Physiology & Biophysics, Neuroscience Program and College of Medicine, Univ. of Illinois, Urbana, IL 61801.

Recent studies suggest that neurons in the ventrolateral medulla (VLM) are involved in the mediation of cardiorespiratory responses to hypoxia. Prior results from this laboratory obtained with extracellular insporta. From this tabolatory ordinated with extractional recordings have shown that a high proportion of VLM neurons increase their discharge frequency during hypoxia in vivo and in vitro. The present study employed whole cell current clamp recordings in a brain slice preparation to determine intracellular responses of VLM hypoxia-sensitive neurons. Neuronal morphology was examined by including lucifer yellow neurons. Neuronal morphology was examined by including lucifer yellow in some of the recording pipettes. Brain slices (300-500  $\mu$ m) from male Sprague-Dawley rats were placed in an interface chamber and perfused with nutrient media equilibrated with 95% O<sub>3</sub>/5% CO<sub>2</sub>. VLM neurons had a resting  $V_{\rm M}$  of -54.6±2.2 mV and a peak input resistance of 275.7±21.0 MΩ. A severe hypoxic stimulus (5% CO<sub>3</sub>/95% N<sub>3</sub>) elicited a depolarization (6.7 mV±1.7) that persisted for the duration of the stimulus (30-90 sec). A similar response (4.6±0.8 mV) was produced by a more moderate level of hypoxia (10% O<sub>3</sub>/5% CO<sub>3</sub>/85% N<sub>3</sub>). Neurons studied were distributed from the caudal aspect of the facial nucleus to the rostral portion of the lateral reticular nucleus and ventral to the nucleus ambiguus. The hypoxia-sensitive neurons were multipolar with several projections from the cell body. These neurons were multipolar with several projections from the cell body. These findings indicate that the excitation of VLM neurons by hypoxia is associated with a depolarization. Thus, activation of neurons in this medullary area may contribute to cardiorespiratory responses to hypoxia (Supported by NIH 38726 and AHA-IL Affiliate).

### 348.6

OPTICAL ACTIVITY OF THE VENTRAL MEDULLARY SURFACE IN THE KITTEN DURING HYPOXIC STIMULATION. D. Gozal, X-W. Dong, D.M. Rector, J. Zhang\* and R.M. Harper. Div. Neonatol. & Ped. Pulmonology, Children's Hospital, USC Sch. of Med.; Brain Res. Inst. and Dept. of Anatomy & Cell Biology, UCLA Sch. of Med., Los Angeles, CA.

The functional topography of cells within the ventral medullary

surface (VM) was assessed in developing kittens during mild hypoxic exposure by optical imaging procedures. The VM was exposed through a ventral surgical approach in five kittens, 10-20 days of age, under sodium pentobarbital anaesthesia. An imaging device, consisting of a 3.2 mm diameter optical probe with 25  $\mu$ fiber resolution and charge coupled device camera, was placed on the VM surface, and tissue was illuminated by 700 nm light. Images were digitized at 2-3 sec intervals before, during, and for 30 min after hypoxic challenges with  $12\% O_2$  in  $N_2$ . Images within each epoch were averaged and subtracted from baseline. The statistical significance for each pixel change was determined by analysis of variance (α=.05). Most kittens became apneic after an initial increase in ventilatory activity. Overall neuronal activity increased immediately after hypoxic exposure, and persisted unless apnea developed. Cessation of breathing resulted in a marked decline of activity. During mild hypoxia, neuronal activity in the VM surface of the kitten parallels ventilatory patterns. (Supported by HD22506 & NIDR DE 07212)

ELECTROPHYSIOLOGIC EFFECTS OF CHANGES IN PCO<sub>2</sub> ON RAT MEDULLARY NEURONS IN VITRO. G.B. Richerson\*. Department of Neurology, Yale University and VAMC, West Haven, CT. 06516

The central chemoreceptors for respiration have been localized to the medulla, but have not yet been identified. To characterize possible cellular mechanisms underlying respiratory chemoreception, modulation of neuronal excitability by changes in PCO2 was compared in respiratory related and other regions of the rat medulla using whole cell patch clamp recordings in brain slices. Rats (10-21 days) were anesthetized, and slices (100 um) were prepared with a vibratome. Slices were maintained in a perfusion chamber on a fixed stage upright microscope. Low power visualization permitted neuroanatomical localization using histologic landmarks, and visualization at 400X with Nomarski optics allowed recordings from anatomically identified neurons

To prevent dialysis of pH buffers, calcium, and other intracellular constituents which could lead to a change in the normal response to CO2, the amphotericin perforated patch technique was used. Electrodes were filled with a solution containing KMethanesulfonate 135 mM, KCl 30 mM, HEPES 5 mM, EGTA 1 mM, and amphotericin B 1 mg/ml. After stabilization of acce resistance, whole cell recordings of membrane potential were possible for 1-2 hours. PCO<sub>2</sub> was systematically changed from 5% to 7% and 9%, and the resulting changes in resting potential, firing rate, synaptic activity, and response to depolarizing current were measured. There was a diversity of responses to changes in PCO<sub>2</sub>, with transient and prolonged, inhibitory and excitatory effects which varied by cell type and location, presumably reflecting differences in function. These differences are likely to contribute to control of respiratory output in vivo. Supported by Dept. of Veterans Affairs, and NIH.

CU, RECEPTION IN THE SNAIL, H. ASPERSA. J.S. Erlichman, J.C. Leiter, and F.V. McCann, Dartmouth Medical School, Department of Physiology, Lebanon, NH 03756.

Gas exchange in the terrestrial gastropod, H. aspersa, is accomplished through a vascularized diffusion lung referred to as the markle. aspersa, is accomplished through a vascularized diffusion lung referred to as the mantle. The opening of the mantle cavity to the external environment is controlled by an occlusible breathing pore called the pneumostome. In these experiments we show that exposure of small regions of the visceral ganglia to low concentrations of CO, (4-6% CO<sub>2</sub>) result in large increases in the diameter of the pneumostome, similar to that observed in the intact animal exposed to hypercapnia. Thomas (J. Physiol. 354:3-22, 1984) has shown that the recovery of intracellular pH (pHi) to acidification is dramatically reduced when Cl conductance is altered. To determine if inhibiting the acidification is dramatically reduced when Cl-conductance is altered. To determine if inhibiting the rate of pHi recovery alters the rate or magnitude of the pneumostome opening, we perfused the snail brain with 4.5-6% CO, equilibrated saline solutions (pH 7.2) with and without the Cl-channel blocker DIDS (10 uM). We found that the pneumostomes opened more quickly (11/13) and to a greater extent (10/13) when the brains were perfused with high CO,/DIDS solutions compared to high CO, solutions alone. Similar results were obtained in Cl-substituted solutions. We conclude that H. aspersa may be a useful model for examining chemoreception as it pertains to the control of breathing, and that the ventilatory effects of hypercapnia may be mediated by a) pHi, b) the rate of pHi recovery. ## 348.11

CARDIORESPIRATORY EFFECTS OF KAINIC ACID ON BRAINSTEM CHEMOSENSITIVE ZONES R.M. Douglas, D.G. Bernard, Y. Pan, S.G. Burgest, R. Millis, J.A. Holloway, C.O. Trouth\*

Dept. of Physiol. & Biophysics, Howard University Coll. of Med. Washington, D.C. 20059

Physiological investigations have indicated that neurons located on the ventral medullary surface (VMS) subserve central respiratory chemosensitivity and vasomotor control. This study purports an attempt to identify the respiratory component involved. In spontaneously breathing rats, medullary neuronal activity (MNA) in the caudal chemosensitive zone on the VMS was studied in response to inspired CO2 and topically applied acetylcholine (ACh) before and after topical application of kainic acid (KA), an excitotoxic amino acid analogue of glutamate, to the VMS. Inspired CO<sub>2</sub> and ACh increased MNA and diaphragmatic activity (DA). KA, which purportedly destroys neuronal cell bodies but not fibers of passage, caused a marked increase in MNA and DA. This was followed by a gradual (over 30 min) decline in MNA and DA with eventual loss of activity and respiratory arrest. Within 10-15 min of artificial respiration, MNA and DA recovered, however, with reduced sensitivity to inspired CO2. It was not possible to maintain MNA and DA for more than 5-6 minutes after weaning the animal from the respirator. These results suggest that (1) KA compromises the ability of the superficial neurons to maintain the central drive to respiration, (2) KA appears to deplete the neuronal metabolic stores of superficial CO2 sensitive neuronal elements, and (3) the cardiovascular component of the VMS seems unimpaired by the topical application of KA.

CHOLINERGIC MECHANISMS INVOLVED IN BRAINSTEM RESPIRATORY CO<sub>2</sub>-CHEMOSENSORY CONTROL. D.G. Bernard, L.M. Sexcius, R.M. Millis, C.O. Trouth. Dept. of Physiol. & Biophysics, Coll. of Med., Howard Univ., Washington, D.C. 20059.

The effect of cholinergic mechanisms on extracellular CO<sub>2</sub>-sensitive neuronal activity recorded at the caudal brainstem respiratory chemosensitive area on the ventral medullary surface (cVMS) was investigated in chloralose-urethane anesthetized adult and newborn cats. Endogenous cholinergic activity was identified by measuring the cholinolytic effects produced by the topical application of atropine sulfate (ATR) to the cVMS during peak neuronal responses to inspired CO<sub>2</sub> (hypercapnic breathing). The responsiveness of newborns (1-6 days) to inspired CO2 was markedly reduced compared to adult cats. cVMS CO2-sensitive neurons were excited by topically applied acetylcholine and physostigmine. ATR reversed the CO2 induced excitation of neuronal activity to near control values whereas hexamethonium was less effective. Application of prazosin and propranolol in mock cerebrospinal fluid pH 7.4 produced no significant change in either neuronal or respiratory activity. These results suggest 1) age differences in cVMS neuronal response to inspired CO2, 2) ATR blocks the CO2 induced excitation of these neurons suggesting muscarinic receptor involvement and 3) the cVMS contains CO<sub>2</sub>sensitive cells which are excited by ACh and Phy. SUPPORT: NIH-NIGMS Grant #: S06GM08016

MECHANISMS OF CO2-INDUCED DEPOLARIZATION IN SNAIL Lymmaea Stagnalis GIANT NEURONS. F. Hayashi, C. Jiang, R. Takeda' & G. G. Haddad. Section of Respiratory Medicine, Dept. Pediatrics, Yale School of Medicine, New Haven, CT 06510.

To test the hypothesis that CO2 has a direct effect on neuronal membrane properties, intracellular recordings were performed in snail (Lymnaea) neurons and the ionic mechanisms for the CO2-induced changes were studied. Visceral and right parietal ganglia were dissected and maintained in-vitro in room air and room temperature. Membrane potential (Vm), input resistance (Rm) and intra-/extracellular pH (pH<sub>1</sub>, pH<sub>2</sub>) were measured in giant neurons (VD<sub>1-3</sub>, RPD<sub>1-2</sub>) in these ganglia. These cells had a baseline Vm of -61±6 mV (n-43, meant5D), and an Rm of 32±8 MO (n-7). Superfusion of these cells with a gas mixture containing 15% CO2 produced a depolarization of 14±6 mV (n-17) and an increase in Rm of 79%. Both pH<sub>1</sub> and pH<sub>2</sub> were reduced during CO2 exposure by 0.6 (n-17) and 0.8 (n-5) pH units respectively, and perfusing cells with acidified solution (the same pH<sub>2</sub> as during CO2 exposure) mimicked the effect of CO2 on Vm and Rm. K\* channel blocker, Cs\* (10 mM), markedly (60%) reduced the CO2-D from 17.0±5.0 mV to 7.0±1.0 mV (n-4, P<0.01), but 4-AP and apamin did not produce any change in CO2-D. Blockade of Ca\*\* channels with a Ca\*\*-free medium plus Co\*\* (5 mM) or Mg\*\* (6 mM) also significantly decreased (40%) the CO2-D (n-4, P<0.05). Na\* and C1\* channels were probably not involved, since TTX (10 µM), Na\*-free or C1-free media did not have any effect. We conclude that 1) CO2 induces a dose-dependent depolarization in snail giant neurons; 2) the CO2-D seems to be mediated by intra- or extracellular acidification; and 3) inactivation of K\* channels and/or activation of Ca\*\*-dependent mechanisms seem to underlie the CO2-D.

### 348.12

AGE DIFFERENCES IN CHOLINERGIC AND CATECHOLAMINERGIC NEURONS IN RAT BRAINSTEM RESPIRATORY CHEMOSENSITIVE ZONES. Y. Pan\*. R. M. Douglas and C. O. Trouth, Dept. of Physiol. & Biophysics, Coll. of Med., Howard Univ., Washington, D.C. 20059

Central respiratory chemosensitivity has been ascribed to cholinergic neurons on the ventral medullary surface (VMS) which are sensitive to changes in the H+ ion concentration of the cerebrospinal fluid and to increased inspired carbon dioxide. We examined the chemosensitive areas of newborn and adult rats by immunocytochemical techniques for the presence and distribution of cholinergic and catecholaminergic neurons. Alternating cryostat sections from the rat medulla were studied using primary antibodies against choline acetyltransferase (ChAT) and tyrosine hydroxylase (TH). In the adult rat, multipolar ChAT positive neurons were found in the caudal chemosensitive area and in the nucleus reticularis lateralis. Bipolar TH positive neurons with fibers running parallel to the VMS were identified. The newborn rat, by contrast, was almost devoid of ChAT neurons in the caudal VMS. Lightly positive ChAT neurons began to appear about the 4th day. In the newborn, TH positive neurons have the same distribution as in the adult. Thus in the rat, the newborn period (1-4 days) is characterized by (1) paucity of cholinergic neurons and (2) reduced sensitivity to inspired carbon dioxide. These results suggest that age related differences in the responsiveness to physiological stimuli might be referable to the integrity or development of cholinergic neurons. LOCUS COERULEUS (LC) NEURONS EXPRESS C-FOS IMMUNOREACTIVITY UPON STIMULATION OF CENTRAL CHEMOSENSORY SYSTEM. M.A. Haxhiu\*, B. Erokwu, N.R. Prabhakar, N.S. Cherniack, and K.P. Strohl. CWRU, Cleveland, Ohio. Neurophysiologic and pharmacologic studies showed that the central CO<sub>2</sub> sensitive structures are located in a relatively discrete region of the ventral medulla. Recently, we found in cats and confirmed in rats that chemosensory neurons can be identified by using c-fos expression in response to hypercapnia. Hence, it is now possible to study the location of activated cells by hypercapnia in other brainstem regions involved in autonomic and respiratory control. In these studies we utilized c-fos protein expression to investigate the effect of CO<sub>2</sub> on LC neurons, and to determine pathways which might mediate hypercapnic response. Experiments were performed on awake, and on anesthetized, paralyzed and artificially ventilated rats and cats. Awake animals were exposed for 1 hour to room air (6 rats and 1 cat), or to 15% CO<sub>2</sub> in room air (8 rats and 2 cats). Frozen sections of brainstem (50 µm) were immunostained for c-fos protein using avidin-biotinylated peroxidase complex (ABC). In both species, hypercapnia induced c-fos expression in LC neurons, a response which was not altered by deafferentation of in LC neurons, a response which was not altered by deafferentation of peripheral chemoreceptors (3 rats). A similar effect was found in α-chloralose anesthetized cats artificially ventilated with hypercapnic gas mixture. Local application of 2% lidocaine on ventral surface of medulla (VMS) attenuated but did not abolish LC c-fos expression (n=2). Activation of cell bodies by topical application of NMDA (10 (m=2). Activation of cent nounes by topical application of NMDA (10 monol) on VMS, induced strong c-fos expression in LC neurons (m=4). We conclude that LC show early gene responses to hypercapnia, and structures located on ventral surface of medulla may play a significant role in this response. WIDESPREAD SITES OF BRAINSTEM VENTILATORY CHEMORECEPTORS. <u>E.L. Coates, A. Li, and E.E. Nattie\*</u>

Dartmouth Medical School, Department of Physiology,

Dartmouth Medical School, Department of Physiology, Lebanon, NH 03756

We have used a novel method to study the location of central chemoreceptors (J. Physiol. 441:433-451,1991). Microinjections (1 nl) of acetazolamide (AZ, 10°M), an inhibitor of carbonic anhydrase, were made in a number of locations throughout the brainstem of chloralose-urethan-anaesthetized, vagotomized, carotid denervated, paralysed, servo-ventilated rats and cats. We found that phrenic nerve activity was stimulated with AZ injections located beneath the ventrolateral medulla, in the region of the nucleus tractus solitarii, and in the region of the locus coeruleus. The rationale of our approach was to produce a local region of acidosis around the site of AZ injection. This is attributed to delayed CO, AZ injection. This is attributed to delayed CO<sub>2</sub> hydration and/or delayed formation of carbonic acid from metabolically produced H+. To determine the size of the region of the AZ induced tissue acidosis we of the region of the AZ induced tissue acidosis we measured the pH of the brain tissue with H+ selective electrodes (tip dia = 20um) placed at distances of 0 - 700um from the AZ injection pipette. We found that pH changes could not be detected at distances greater than 400um. These results indicate that the tissue acidosis produced by AZ injections is limited. In addition, the number and location of sites where AZ injections stimulated phrenic nerve activity indicates a widespread distribution of respiratory chemoreceptors. (Supported by HL 28066 and HL 07449).

DISTRIBUTED BRAIN STEM RESPIRATORY NEURAL NETWORKS AND PHRENIC NERVE DISCHARGE: CORRELATIONS DURING CAROTID CHEMORECEPTOR STIMULATION. K. F. Morris\* A. Arata. R. Shannon and B. G. Lindsey. Physiol. & Biophysics, Univ. South Florida Med. Ctr., Tampa, Fl. 33612. Stimulation of carotid body chemoreceptors (CStim) results in three changes in phrenic nerve activity: a large increase, a decaying afterdischarge (Eldridge et al. Resp. Phys. 40:49) and long term enhancement (Millhorn et al. Resp. Phys. 41:87). We studied the involvement of brainstem respiratory related neural networks in these responses. Spike trains of neurons were recorded simultaneously (max.=20, mean=12.7) in the ipsilateral n. tractus solitarius (NTS), rostral (region of retrofacial n.) and caudal ventral respiratory group (VRG), the contralateral VRG, and medullary raphe n. (RN) of 10, anesthetized, vagotomized, artificially ventilated cats. Phrenic nerve efferent activity was recorded. CStim was by injection of 200 ul of CO saturated saline solution via the external carotid artery. We analyzed 275 spike trains with respiratory cycle-triggered and peristimulus-time histograms (PSTHs), and spike triggered average histograms of unrectified and full wave rectified phrenic multumit activity (PSTAs). Cross-correlograms (CCS) of 1,829 pairs were analyzed. We detected, in PSTHs of spike trains from all five medullary regions, long-time scale (sec.) firing rate changes correlated with phrenic responses to CStim. Short-time scale (ms) correlations included; positive lag peaks in CCs with chemoresponsive, respiratory modulated VRG trigger neurons and RN targets; central peaks and troughs in PSTAs with chemoresponsive respiratory modulated triggers in NTS and VRG. The data provide evidence for a subset of routes by which CStim evoked changes in central inspiratory drive are communicated to midline neurons implicated in cardiorespiratory integration (Lindsey et al. these proceedings) and to phrenic motor neurons. MECHANICS OF THE PACINIAN CORPUSCLE: STATIC AND DYNAMIC MEASUREMENTS. B.Pietras\* and S.J. Bolanowski. Institute for Sensory Research, Syracuse University, Syr., NY 13244

The input-output (IO) function relating the magnitude of the Pacinian corpuscle (PC) receptor-potential and stimulus amplitude is highly nonlinear showing saturation, hysteresis, and an asymmetric, full-wave rectification. These functions were obtained by monitoring the displacement of the stimulator and not the PC itself. Thus it is possible displacement of the stimulator and not the PC itself. Thus it is possible that the nonlinearities are introduced by inadequate stimulus definition and/or the mechanics of the accessory capsule interposed between the stimulus and the neural element. A series of experiments were conducted using video microscopy on cat mesenteric PCs to determine: 1) reactive forces as measured under static displacement conditions with stimulus probe and PC size as parameters; 2) whether and how the perimeter and internal portions (lamellae) of the PC's accessory capsule follow dynamic displacement stimuli in the steady-state (sinusoidal, 1-600 Hz, stimulus probe size, 125-500 µm dia.) and 3) the resultant reactive forces produced by such dynamic stimulation. It was found that for the static conditions by such dynamic stimulation. It was found that for the static conditions the reactive forces are nonlinear, showing a quadratic relationship between force and displacement. Increases in probe size increase the reactive force, but they are not correlated with PC size. For the dynamic case, the capsule and internal lamellae closely follow the stimulus albeit with attenuated and internal lamellae closely follow the stimulus albeit with attenuated amplitude from the perimeter of the capsule to the neurite. Additionally, the dynamic reactive forces are nonlinearly related to stimulus displacements displaying prominent hysteresis. Thus the hysteresis in the IO function may be explained if the pertinent stimulus dimension is force-related, although none of the observed mechanical properties can explain saturation or the asymmetric, full-wave rectification. These latter two are likely a result of the neural transduction mechanisms. two are likely a result of the neural transduction mechanisms.

INTENSITY AND FREQUENCY CHARACTERISTICS OF FIBERS INNERVATING THE CAT HINDPAW. K. Grobaski. C.M. Checkosky\* and S.J. Bolanowski. Institute for Sensory Research and Dept. of Bioengineering, Syracuse Univ., Syracuse, NY 13244.

There have been conflicting reports in the literature regarding whether the neural innervation of the tactile pad of the cat's hindpaw is a suitable model for human glabrous skin. For example, it has been argued that the cat possesses only three physiologically defined fiber types, Pacinian corpuscle (PC), rapidly adapting (RA), and slowly adapting (SA) fibers, the SA category not divisible into SAI and SAII subgroups as is found for the SA category not divisible into SAI and SAII subgroups as is found for humans. To help clarify the issue, frequency (FC) and intensity characteristics (IC) of single units (n > 116) in the medial plantar nerve were obtained in response to bursts of sinusoidal vibrations. Additionally, adaptational properties and receptive-field (RF) organization were ascertained using punctate (von Frey) stimuli. The results that were ascertained using punctate (von Frey) stimuli. The results that were obtained could be grouped readily into four categories, the categories reminescent of those found for fibers innervating human glabrous skin: a) PC fibers (22.2%) having very large RFs, fast adaptation, high sensitivity, U-shaped FCs in the 40-400 Hz range, phase-locking, and ICs showing plateaus at multiples of the stimulus frequency; b) RA fibers (22.2%) having small RFs, fast adaptation, moderate sensitivity, U-shaped FCs in the 10-150 Hz range, phase locking, and ICs showing plateaus at multiples of the stimulus frequency; c) SA I fibers (20.0%) having small RF slow adaptation moderate sensitivity positive sloping having small RF, slow adaptation, moderate sensitivity, positive sloping FCs in the 10-150 Hz range, phase locking, and ICs also showing plateaus and d) SA II fibers (35.6%) having large RFs, slow adaptation, low sensitivity, negative sloping FCs in the 20-300 Hz range, little phase locking, ICs without plateaus and characteristic, low-rate, spontaneous activity. Supported by NIH grants DC00380 and DC00098.

QUANTITATIVE ANALYSES OF THE CYTOPLASMIC EXTENSIONS AND MITOCHONDRIAL LOCATION WITHIN PACINIAN CORPUSCLES (PC). <u>I.E. Landcastle. D. Sulitka. N.B. Slepecky. S.C. Chamberlain\* and S.J. Bolanowski, Institute for Sensory Research and Dept. of Bioengineering, Syracuse Univ., Syr., NY 13244. It is speculated that the sites of mechanotransduction within PCs are the cytoplasmic extensions (E) emanating along the major axis of the neurite which is elliptical in cross section. For example, we have proposed the existence of two groups of E responding in phase opposition.</u>

existence of two groups of E responding in phase opposition. Furthermore, because transduction is an active process the presence of Furthermore, because transduction is an active process the presence of mitochondria (M) at these sites is required. To explore the possibility that there are two groups of E and to assess the organization of M, analyses were performed on 22 PCs. Regarding the E (n=137), four parameters were measured: height (H) of projection from the neurite (mean, 1.68 µm, s.d., 1.30 µm); length (L) parallel to the neurite (mean, 0.52 µm; s.d., 0.29 µm); width at their base (BW; mean, 1.49 µm; s.d., 1.20 µm) and widest width (WW; mean, 0.97 µm; s.d. 0.61 µm). The distributions relating the number of E to either H, BW or WW are unimodal but skewed to lower values and for L is bimodal (0.32 µm and 0.64 µm) suggesting a basis for the two E idea. The relationships among the various E dimensions are: BW = -0.93 + 4.69L; WW = 0.06 + 1.53L; H = 0.18 x 100.934 W; H = 0.217 x 101.4L, ; H = -0.46 + 3.06BW - 1.7BW<sup>2</sup> + 0.37BW<sup>3</sup>. Analysis of the M shows that they are grouped close to the neural membrane. The relation between number of M and polar-coordinate degree values is bimodal with the M number greatest along the major degree values is bimodal with the M number greatest along the major elliptical axis consistent with the location of the E, although they are also present, but to a much smaller degree, around the entire perimeter of the neurite. Supported by NIH grant DC00380.

MODALITY-BASED CLASSIFICATION OF THE RAT CUTANEOUS RECEPTORS BY MULTIVARIATE ANALYSIS. J.W. Leem', W.D. Willis and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77555.

A series of natural stimuli that elicit characteristic responses for

well-known types of cutaneous receptors in the rat has been defined in our laboratory. The aim of this study is to classify cutaneous

receptors into functionally meaningful groups on the basis of response similarity using multivariate statistical procedures.

A total of 188 cutaneous afferent units was identified as belonging to one of 9 receptor types in the foot skin of 62 anesthetized rats. Responses of units to 11 predefined stimuli were

examined using several multivariate statistical analyses.

More than 90% of total sample subjected to discriminant (93.1%) or cluster analysis (90.4%) of their responses to 11 stimuli were correctly categorized into their own receptor types. The test for the similarities among 11 stimuli using factor and cluster analyses revealed that 6 of them were distinct stimuli. Cluster analysis of responses of the same sample to those 6 stimuli yielded 6 groups, each of which contained members believed to contribute

or groups, each of which contained members believed to contribute to a particular sensation.

The results indicate that cutaneous receptors can be divided into modality-specific groups according to the similarities of their responses to 6 stimuli by several multivariate analyses. (Supported by NIH grants NS21266, NS11255 and NS09743 and a grant from Bristol-Myers Squibb Co.)

DEVELOPMENT OF A SILICON MICROPROBE FOR CONTROLLED MECHANICAL STIMULATION OF SENSORY NERVE TERMINALS B. J. Kane, G. Kovacs, C. Storment, and D. L. Tanelian\*. Departments of Electrical Engineering and Anesthesia, AEL 132, Stanford University, Stanford, CA 94305.

One of the factors limiting our understanding of mechanical transduction is the lack of means with which to apply precisely controlled mechanical stimuli to individual nerve terminals. The development of a device capable of this has been impeded by the small scale required in both the delivered force and the application area Such a probe must be small enough to activate single mechanosensitive nerve endings under visual guidance and measure the delivered force. In order to solve this problem silicon integrated circuit technology was used to produce miniature mechanical probes with passive force sensing circuitry on board. These probes are comprised of a cantilever silicon beam with a strain sensing piezoresistive element at the base to measure the strain as the beam deflects. Resistive bridge circuitry allows for temperature compensation of the probes. The probe fabrication process begins with a selective diffusion of boron into a silicon wafer to define the gross shape of the probe. This doped region is etched selectively in the final processing step to remove the probes from the bulk silicon wafer. Following the doping, an insulating silicon dioxide layer is grown over the boron doped regions and the thin-film piezoresistive material is then deposited and etched selectively to define the shapes of the strain sensing elements. Thin-film gold interconnects are then fabricated and the entire wafer is coated with a layer of insulating silicon nitride through which electrical contacts are etched. When etched free of the substrate the probes exhibit a proportional relationship between force applied at the tip and voltage output. These probes will eventually be mounted on an electromagnetic actuator to provide closed-loop feedback control of force and force application rate. Potential exists for these probes to be used in the study of mechanoelectric transduction in sensory nerves and other mechanosensory cells. Supported by the Stanford OTL Research Incentive Fund and NIH grant R01 NS28646-01A.

TACTILE DISCRIMINATION AND IDENTIFICATION OF THE SHAPES AND ORIENTATIONS OF ELLIPSOIDAL OBJECTS R.H. LaMotte, M.A. Srlnivasan' and A. Klusch-Petersen, Dept. of Anesthesiology, Yale University School of Medicine, New Haven, CT 06510 and Research Laboratory of Electronics, MIT, Cambridge, MA 02139.

Laboratory of Electronics, MIT, Cambridge, MA 02139.

The shape of an object is physically defined by the principal curvatures and their orientations at each point on its surface. The magnitude and/or rate of change in the curvature of the skin brought in contact with the object is then represented in the discharge rates of certain cutaneous mechanoreceptors (Srinivasan and LaMotte, Wenner-Gren Intl. Symp. Series, Vol.57, Ch.5, 1991). As part of ongoing studies of the neural coding of tactually perceived shape, we measured the capacities of humans (1) to detect deviations from sphericity of ellipsoidal objects applied to the fingerpad and (2) to discriminate or identify differences in the orientation of the major axes of ellipsoids or a cylindrical bar, relative to the axis of the finger and/or the direction of stroking the object over the skin. Each object had a radius of 5 mm along one axis, and for the ellipsoids, radius along the orthogonal axis ranged from 4.75 to 1 mm. A servo-controlled stimulator with 4 degrees of freedom rotated the object to a desired orientation in the horizontal plane and then vertically indented the stationary fingerpad to a maintained force of 40 then vertically indented the stationary fingerpad to a maintained force of 40 gwt. Either the contact center was fixed, or the object was stroked along a linear or circular trajectory over the skin.

The subjects detected deviations in sphericity on the order of 1mm in radius and, for the cylinder, discriminated differences in orientation of 5-10 and identified about 6 categories of orientation in 30° steps. Discrimination and identification of orientations deteriorated as the deviations from sphericity reduced. Results were interpreted in relation to the known sensitivities of rapidly and slowly adapting mechanoreceptive nerve fibers to changes in curvature of the skin brought about by contact with objects of different shapes. DISCRIMINATION OF PERIODIC TEXTURE PATTERNS ON THE HUMAN HAND. C.E. Kops and E.P. Gardner\* Dept. of Physiology and Biophysics, NYU Medical Center, New York, NY 10016

In order to evaluate a new theory of texture perception based upon the correlation of firing among individual afferents in the median nerve, we measured the ability of 15 human subjects to discriminate periodic dot patterns scanned across the tactile array of an OPTACON stimulator. Patterns differed in spatial period (4, 6 and 8 mm) and phase (0-135°), and were alternated twice in a two-alternative forcedchoice protocol. Subjects were asked to indicate whether a given pair of patterns felt the same or different, using a computer keyboard to signal responses. Accuracy of performance in the discrimination task appears directly related to differences in the correlation matrix computed from afferent firing patterns recorded in monkeys. Subjects were unable to discriminate patterns of 4 mm spatial period which were unable to discriminate patterns of 4 mm spatial period which differed in phase, except for vertical patterns in which alternate columns on the tactile array were silent. Discrimination of phase at wider spatial periods improved as the dot spacing increased, with the most accurate performance occuring at 8 mm spacing. Patterns whose relative phase angle differed by < 45° were more poorly differentiated than those of greater angular disparity. Stimuli of the same phase but different spatial frequencies were less accurately discriminated than patterns differing in both phase and spatial frequency, except at the narrowest spacing where none of the patterns could be differentiated. These data support our hypothesis that the neural mechanisms underlying texture perception may involve unique combinations of simultaneously activated afferents. (Supported by NIH Research Grant NS11862 from NINDS).

FINITE ELEMENT MODELLING OF MECHANORECEPTIVE TERMINAL DEFORMATION IN GLABROUS SKIN. Z.Gao and J.R.Phillips\* University Laboratory of Physiology, Parks Road, Oxford. OX1 3PT. U.K.

We have used the Finite Element (FE) method to investigate

which stress/strain components in the skin are transduced b the different classes of mechanoreceptive terminals when the glabrous skin is stimulated. The FE skin model takes into account the surface ridges, the interdigitation of the dermalepidermal border and the different mechanical properties of the epidermis, dermis and subcutaneous tissues. The behaviour of the model is examined under a variety of conditions and material properties (e.g. laterally moving and stationary stimuli; homogeneous elastic and viscoelastic media and layers of dissimilar materials). When the epidermis and dermis are modelled as one homogeneous material the predictions of the FE model corresponded to those of a simple continuum model. However, when the epidermal material is made much stiffer than that of the dermis (as is the case for real skin), the horizontal strain at locations where Meissner's corpuscles are found is much greater than that predicted by the homogeneous model under the same loading conditions. This observation provides quantitative support to the idea that the dermal/epidermal interdigitations act to amplify the distortion of mechanoreceptive terminals when the skin is stimulated. ## 349.8

REPRESENTATION OF TEXTURE PATTERNS ON THE SKIN BY POPULATIONS OF CUTANEOUS AFFERENTS. E.P. Gardner and D. Gardner\* Depts. of Physiology and Biophysics, NYU Medical Center, and Cornell University Medical College, New York, NY

Spatial event graphs (SEGs) have been reconstructed from peripheral nerve responses to regular two-dimensional dot patterns scanned across the hand using an OPTACON stimulator. Textures of were evaluated. While each texture evokes a stereotyped SEG, the SEGs of individual afferents show varying degrees of overlap depending upon the relative positions of their receptive field centers. The firing patterns of a pair of cutaneous afferents are perfectly correlated when the spatial period and phase of the dot pattern precisely match the distance vector. Correlation of firing is reduced at Neuron B for one pattern, and correlated only 60% of the time for another pattern, while correlations with Neuron C may measure 25% and 75% respectively. A correlation matrix relating the firing of a reference afferent, located near the center of the tactile array, with all other pairs of stimulated afferents was computed for each of the patterns, allowing us to relate synchrony of firing to stimulation parameters. We propose that the neural mechanisms underlying texture perception may involve unique combinations of simultaneously activated afferents. Textures could be represented by the correlation of firing of specific groups of cutaneous afferents as reflected in the total spike output of central neurons, rather than by isomorphic representation of the timing of stimulation of unique skin locations. (Supported by NIH Research Grant NS11862 from NINDS)

SEROTONIN BIPHASICALLY ACTIVATES AND THEN INHIBITS TYPE I AFFERENT UNITS SERVING TOUCH DOMES IN VITRO. L. He, P.R. Burgess, R.P. Tuckett\* and K.B. English. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, Utah, 84108

A skin/nerve preparation was utilized for in vitro study of the effects of serotonin (5HT) and its antagonists on single type I unit afferent discharge. Type I afferents terminate upon Merkel cells in the basal epidermis, and in rats both Merkel cells and type I nerves are immunopositive for serotonin.

Back skin (4 cm²) from adult rats (n=15) was excised along with its

accompanying dorsal cutaneous nerve and artery, and pinned epidermal side up to a silgar-coated perfusion chamber. The afferent nerve and artery were threaded through a hole into an adjacent oil-filled chamber for nerve recording and drug administration. Branches of rat dorsal cutaneous nerves are small enabling discharge of single type I units to be monitored with whole nerve recording. Type I responses (n=17) were studied during controlled mechanical stimulation (indentation and retraction velocity = 8.3 µm/sec; plateau amplitude = 150 µm, 42 sec duration) of touch domes before, during and after 5HT (5, 50, 500  $\mu$ M dissolved in perfusion fluid plus 0.1% hydralazine). Unit responses (n=17) to 5HT were also compared to controls (n=14) receiving drip infusion of perfusion fluid plus 0.1% hydralazine.

Mechanically evoked activity of seventy percent of the units tested was enhanced and subsequently inhibited upon repeated stimulation following 5HT. However, a majority (84%) of control units showed decreased responsiveness with repeated stimulation. In addition, ketanserin, a 5HT, antagonist, inhibited mechanically initiated activity in 67% of the tested units (n=10) which subsequently recovered to pre-treatment responsiveness. These results suggest 5HT may be a neuromodulator or transmitter in the Merkel cell/neurite complex. Supported by NIH grant 07938.

SENSORY EFFECTS OF ELECTRICAL STIMULATION DURING PARTIAL NERVE BLOCK BY LOCAL ANESTHETICS IN HUMANS. F.A. Popitz-Bergez\* S.A. Raymond, J.G. Thalhammer. Anesthesia Research Laboratory, Brigham & Women's Hospital, Harvard Medical School, Boston, MA 02115

Brigham & Women's Hospital, Harvard Medical School, Boston, MA 02115
When single cutaneous afferent axons in the rat are exposed to local anesthetics
(LA) at concentrations which slow but do not block impulse conduction, electrical
stimulation (ES) can produce conduction block. We are now studying the possible
sensory correlate of this effect in human volunteers by applying ES (50-100 Hz just
above sensory threshold for perception) during recovery from LA block of the
superficial radial nerve via skin electrodes distal to the block.
Four volunteers, 20-48 yrs, were injected with 1.5 cc of 1% lidocaine at the wrist
and a 2x2 cm skin area in the distribution of the blocked nerve was delineated on
the injected and control hands for sensory testing. The subjects were asked to
report the sensations evoked by repeated stimuli: touch (end of a smooth cotton
swab), cold (steel rod at 0°C for 10 s), pinprick (25G spinal stylet), noxious heat
(steel rod at 50°C for 10 s). Directional sensitivity and the capability to perceive
the spatial extent of an area bounded by strokes on the skin were tested by outlining
the square on the skin and "drawing" 2 cm long lines within the square using the
swab.

Several observations were reported by all subjects in 6 trials: Several observations were reported by all subjects in 6 trials: During block resolution: 1. When touch could be detected reliably on both hands, subjects could not identify the direction of stroking on the blocked side. This effect was accentuated by ES. 2. Cold sensation waxed (to even painful levels) and waned during some of the 10 s tests. It was abolished within a 1-2 s by ES, but recovered slowly over -1 min after ES was switched off. 3. Cold was usually the last modality to become detectable during recovery, and its block always outlasted the block of pain. Without LA: ES alone reduced aftersensations evoked by cold and pinprick, and diminished the "brightness" of sensations, but did not prevent correct recognition of modality. We hypothesize 1) that the disruption of impulse discharge patterns by LA does not confuse modality recognition by subjects but does reduce sensory discrimination and 2) that ES potentiates LA blockade of sensation.

A GATE THAT SWINGS IN THE OPPOSITE DIRECTION: INHIBITION OF TOUCH BY PAIN. A.V. Apkarian\*, R.A. Stea, S. Bolanowski. Dept. Neurosurgery, SUNY Health Science Center, Syracuse, NY 13210 and Institute for Sensory Research, Syracuse University, Syracuse, NY 13244. Regional blood flow studies show decreased neuronal activity in the somatosensory cortex during nociception in humans (Stea et al. Neurosci Abst 17:293 1991). This implies an alteration of touch perception during pain. The hypothesis, that touch thresholds are elevated during coincident pain, was tested in 10 volunteers in psychophysical studies which employed a tonic thermal stimulus and a vibrotactile stimulus to the right thenar eminence. Thresholds and absolute magnitude estimates of pain, was tested in 10 volunteers in psychophysical studies which employed a tonic thermal stimulus and a vibrotactile stimulus to the right thenar eminence. Thresholds and absolute magnitude estimates of suprathreshold vibrotactile stimuli were assessed with the skin temperature at 31 °C (control), at the pain threshold and above pain threshold (42-47 °C). Vibrotactile thresholds were determined using ascending, descending and two alternative forced choice techniques. Vibrotactile magnitude estimates were done with an open scale. Three frequencies were tested: 1, 10, 100 Hz, these frequencies chosen since changes in skin surface temperature alone do not produce changes in threshold. Changes in auditory threshold (1 kHz) were also measured. Mild to moderate pain resulted in increased vibrotactile thresholds in all but one subject. The mean change was 9-90 that 100 Hz, 8.2db at 10 Hz and 8.3db at 1 Hz. The changes occurred regardless of the method of threshold determination. Magnitude estimate curves during pain increased in slope, and showed recruitment. The threshold change was abrupt and first detected at temperatures just below the subjects' pain threshold. Auditory thresholds were unchanged during painful stimulation of the hand. The touch threshold changes are not attributed to attentional changes since they occurred just below pain threshold (where nociceptors become active) and were not observed in audition. The 2.5 fold increase in touch threshold during pain, indicates the existence of a gate which inhibits touch, perhaps to sharpen the perception of pain. Supported. by NIH Grant DC0098 to SJB.

TACTILE AFFERENT FUNCTION AFTER HUMAN CERVICAL SPINAL CORD INJURY. C. K. Thomas\* and G. Westling. The Miami Project to Cure Paralysis, Univ. of Miami Sch. of Med., Miami, FL 33136.

The function of tactile afferent units innervating the glabrous skin of the hand was examined in 11 individuals who had impaired or absent touch perception due to chronic (>1 year post injury) cervical (C3-C6) spinal cord injury. Such information is fundamental if the intent is to use signals from these natural sensors to control the electrical stimulation of paralyzed muscles1. Activity of single tactile fibers in the median nerve was recorded using microneurography<sup>2</sup>. Measurements were made of: 1) how the afferent response adapted (fast or slow; FA or SA) to maintained indentation; 2) the force required to activate the receptor mechanically (mechanical threshold); 3) the size of the receptive field using the von Frey hair which provided 4 or 5 times the threshold force [type I (FAI, SAI) and type II (FAII, SAII) units have small and large fields respectively]; 4) the conduction delay when the receptor was stimulated mechanically, then electrically. The proportion of FAI, FAII, SAI and SAII units sampled (33%, 24%, 32% 11%; n=66) and single afferent electrical conduction velocity were similar to control data<sup>3,4</sup>. There was also a significant delay in the afferent response when the receptive field was stimulated mechanically, as expected from control data<sup>5</sup>. However, mechanical FAII units compared to control data<sup>6,7</sup>. Thus, tactile afferent signals may be useful to regulate force in paralyzed muscles during manipulation provided the information from different receptor types can be extracted and processed selectively

# PAIN PATHWAYS: SUPRASPINAL

ORGANISATION OF ASCENDING AXONS ORIGINATING FROM THE RAT SPINAL CORD STUDIED WITH THE PHA-L METHOD. R. Dallelt, P. Raboissont, J. F. Bernard, D. Le Bars and L. Villanueva. (SPON: European Neuroscience Association\*)

INSERM, U-161, 2, rue d' Alésia, Paris, and †Faculté de Chirurgie Dentaire, 63000, Clermont-Ferrand, (France).

The location of ascending axons originating from different laminae of the cervical spinal cord was examined by using the anterogradely transported lectin Phaseolus Vulgaris Leucoagglutinin (PHA-L) coupled with immunohistochemistry

Male Sprague-Dawley rats were anesthetised with chloral hydrate and PHA-L (5%) was electrophoretically injected into different laminae of the cervical spinal enlargement. Two weeks later, the rats were perfused transcardially, the spinal cord was removed and cut in serial sections which were reacted with PHA-L antibody and ABC complex. Ascending axons were observed in transverse sections from C1 level and were compared with those observed following large PHA-L injections in the lumbar cord enlargement.

The majority of ascending axons originating from all laminae of the cervical spinal enlargement were located ipsilaterally whereas those axons originating from the lumbar cord presented a widespread distribution, with a relevant contralateral component. This study confirms previous observations showing marked differences in the organisation of cervical as compared to lumbar spinal ascending somatosensory pathways. Supported by DRET.

## 350.2

SPINAL AFFERENT PROJECTIONS TO THE SUBNUCLEUS RETICULARIS DORSALIS (SRD) OF THE RAT MEDULLA STUDIED WITH THE PHA-L METHOD. P. Raboissont, A. Mallart\*, R. Dallelt, J. F. Bernard, D. Le Bars and L. Villanueva INSERM, U-161, 2, rue d' Alésia, Paris, and †Faculté de Chirurgie Dentaire, 63000, Clermont-Ferrand, (France).

SRD is a caudal area within the brainstem that processes specifically cutaneous and visceral nociceptive information from the whole body. Their neurones are exclusively activated by Aδ- and Cfibre inputs and encode cutaneous and visceral stimuli within the noxious range. We examined the spinal projections to the SRD following injections of Phaseolus Vulgaris Leucoagglutinin (PHA-L).

Male Sprague-Dawley rats were anesthetised with chloral hydrate and PHA-L (5%) was electrophoretically injected into different laminae of the cervical spinal cord enlargement. Two weeks later, the rats were perfused transcardially, the brain and spinal cord were removed and cut in serial sections which were reacted with PHA-L antibody and ABC complex.

Dense labelled terminals were found in the ipsilateral SRD and covered its rostrocaudal extent. The highest density of labelling was observed following injections in the deeper layers of the spinal cord. These data confirm that part of the spinal efferents to the SRD originate from the ipsilateral cervical cord. Together with our previous electrophysiological and anatomical data, this study suggests that the SRD provides a link in spino-reticulo-spinal loops implicated in the processing of pain. Supported by DRET.

ORGANIZATION OF THE PARABRACHIAL EFFERENT PROJECTIONS TO THE AMYGDALA: A PHA-L STUDY IN THE RAT. J.F. Bernard\*, M. Aldén and J.M. Besson. INSERM U 161, 2 rue d'Alésia, F-75014 PARIS, FRANCE.

Microinjections of *Phaseolus Vulgaris* leucoagglutinin (PHA-L) restricted (n=43) or adjacent (n=20) to subnuclei of the pontine parabrachial area (pPB) and revealed by immunohistochemistry permitted to demonstrate that the pPB projections onto the amygdaloid central nucleus (Ce) were topically organized:

1) The pPB region including the medial (pPBm), the waist area (pPBwa) and a part of the ventral lateral (pPBvl) subnuclei projects primarily to the medial subdivision of the Ce (CeM). Projections were also found in the basolateral posterior (BLP), basomedial posterior (BMP) and anterior cortical (ACo) nuclei of the amygdala.

2) The pPB region including the remaining portion of the pPBvl, the rostral portion of the central lateral subnucleus (pPBcl) and the outer-rostral portion of the external lateral subnucleus (pPBel) projects primarily to the lateral subdivision of the Ce (CeL).

3) The pPB region including the dorsolateral subnucleus (pPBdl), the caudal and the inner-rostral portion of the pPBel and the external medial (pPBem) subnuclei projects primarily to the lateral capsular subdivision of the Ce (CeLC).

It was suggested that the pPB - CeM pathway is implicated in gustative processes; the pPB - CeL pathway is implicated in visceral and chemosensitive processes; the pPB - CeLC pathway is implicated in respiratory, cardiovascular and nociceptives processes.

## 350.5

"DEEP" AND "SUPERFICIAL" NOCICEPTIVE STIMULATION EVOKE DIFFERENT BEHAVIORS AND INCREASE FOS-LIKE IMMUNOREACTIVITY IN DISTINCT REGIONS OF SPINAL CORD AND MIDBRAIN PERIAQUEDUCTAL GRAY K.A. Keay A. Depaulis<sup>†</sup> and R. Bandler\*. Dept. of Anatomy, University of Sydney, NSW, Australia. 2006. & †LNBC. Centre de Neurochimie. 67084 Strasbourg. France.

Australia, 2006. & ¹LNBC, Centre de Neurochimie, 67084 Strasbourg, France. We have reported that, the <u>lateral</u> region of the caudal third of the midbrain periaqueductal grey (PAG) which mediates flight and hypertension, receives inputs from lamina I and the lateral cervical nucleus [LCN] of the upper cervical spinal cord [UCC]; whereas the <u>ventrolateral</u> PAG region which mediates <u>hypotension</u> and immobility is targeted by cells in laminae VII & VIII. In the UCC, cells of lamina VII av III. The terieve a significant afferent input from the deep neck muscles, whereas cells of lamina I and the LCN receive a large input from cutaneous nociceptors. Thus we investigated the hypothesis that nociceptive activation of the deep neck muscles might activate the spinoventrolateral PAG projection. We used the technique of immunohistochemical detection of Eos protein as a marker of neuronal activation following, in the lightly anesthetised rat, either: i) bilateral injection of 5% formalin into the deep neck muscles; iii) bilateral subcutaneous injection of 5% formalin into the neck; or iii) radiant heat of the neck. The data showed that deep neck muscle injections significantly increased (up to 3x's) the numbers of Eos\_like immunoreactive cells in: i) the ventrolateral PAG and ii) laminae VII & VIII of the UCC. In contrast, the "superficial" noxious stimuli increased the numbers of Fos\_labelled cells in: i) the lateral & to a lesser extent the ventrolateral PAG and iii) in laminae I & the LCN of the UCC. Further experiments with freely moving rats demonstrated that "deep" noxious stimulation of the neck evoked aperonand immobility seemingly identical to that evoked by excitatory amino acid [EAA] stimulation of the ventrolateral PAG, whereas "superficial" noxious stimulation of the neck evoked defensive behaviours similar to those evoked by EAA stimulation of the caudal PAG, which in turn mediate quite distinct ventrolateral and lateral regions of the caudal PAG, which in turn mediate quite distinct ventrolateral and later

ENRICHMENT OF GLUTAMATE-LIKE IMMUNOREACTIVITY IN SPINOTHALAMIC TRACT TERMINALS IN THE NUCLEUS SUBMEDIUS OF THE CAT. A.-C. Ericson\*. A. Blomqvist, A.D. Craig, O.P. Ottersen and J. Broman. Dept of Cell Biology, Univ. of Linköping, Sweden, Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ, U.S.A., and Dept of Anatomy, Univ. of Oslo. Norway.

Oslo, Norway.

Previous light and electron microscopic studies have demonstrated that the nucleus submedius (Sm) is a specific lamina I spinothalamic tract (STT) termination site in the medial thalamus. The identity of the neurotransmitter(s) in the STT terminals in Sm is unknown. In this study the presence of glutamate-like immunoreactivity in the STT terminals was investigated with an electronmicroscopic immunogold-labeling technique. The STT terminals were identified by anterograde transport of WGA-HRP and subsequent tetramethyl benzidine histochemistry. The density of gold particles over STT terminals was compared with that over peroxidase-negative terminals of the same type as STT terminals (RL terminals), terminals of presumed cortical origin (RS terminals), presynaptic dendrites (PSDs), large neuronal cell bodies, and randomly selected areas in Sm. The density of gold particles over STT terminals, RL terminals and RS terminals was significantly higher than that over PSDs, cell bodies and tissue average. These observations indicate that glutamate may serve as a neurotransmitter for nociceptive and thermoreceptive information between STT terminals and Sm neurons.

EXPRESSION OF FOS-LIKE IMMUNOREACTIVITY AND PREPROENKEPHALIN mRNA IN THE RAT PARABRACHIAL NUCLEUS AFTER NOCICEPTIVE MECHANICAL STIMULATION OF THE SKIN. Q. Hermanson, H. Ericson, D. Larhammar and A. Blomqvist. Dept of Cell Biology, Univ. of Linköping, Dept of Neuropharmacol., Astra Research Centre, Södertälje, and Dept of Medical Genetics, Univ. of Uppsala, Sweden.

Previous anatomical studies have demonstrated that the parabrachial nucleus (PBN) is a major target for ascending fibers from the superficial lamina (lamina I) of the spinal and medullary dorsal horns. PBN neurons are the source of several peptidergic projections to the rostral brain stem and forebrain. In this study the expression of c-FOS-immunoreactivity and preproenkephalin A-mRNA (ppENK) was examined in PBN neurons after cutaneous nociceptive stimulation. Male Sprague-Dawley rats were pinched in the nape of the neck or the base of the tail. Another group of rats served as controls. Frozen sections were incubated with an antibody against FOS-protein or hybridized with a 35S-labeled cRNA probe to ppENK. Neurons expressing moderate to heavy ppENK-labeling were most abundant in the internal lateral, the central lateral and part of the external lateral parabrachial subnuclei. Cutaneous nociceptive stimulation resulted in FOS-like immunoreactivity in neurons within the terminal field of the spino-parabrachial projection. Quantitative data from the *in situ* hybridization, obtained by analysis of the optical density on X-ray films, suggested that the expression of ppENK in PBN neurons is influenced by nociceptive stimulation.

NOXIOUS HEAT-EVOKED FOS-LIKE IMMUNOREACTIVITY IN THE RAT MEDULIA. S.L. Jones\* and R.W. Blair. Departments of Pharmacology and Physiology, University of Oklahoma, Oklahoma City, Oklahoma 73190.

The medulla receives nociceptive information from the

The medulia receives nociceptive information from the spinal cord via multiple ascending pathways. In the present study, the expression of fos-like immunoreactivity was used to determine which populations of neurons in the medulia are activated by noxious heating of the hindpaw. Rats were anesthetized with pentobarbital, and the left hindpaw was immersed in 55-60°C water for 10sec for 30 consecutive trials at 2min intervals. Following a 2hr survival time, the rats were perfused, and the medulia was processed for fos-like immunoreactivity. Compared to control animals (n=5), animals exposed to noxious heat (n=5), demonstrated significantly greater numbers of fospositive neurons in the lateral reticular nucleus and in the surrounding reticular formation on the side contralateral to the noxious stimulus, but not on the ipsilateral side. No differences in the numbers of fospositive neurons in animals exposed to noxious heat compared to controls were noted in the: solitary nuclei, dorsal motor nucleus of the vagus, caudal raphe nuclei, spinal trigeminal nuclei and inferior olivary nuclei. Thus, noxious heat-evoked changes in fos-like immunoreactivity can be identified in medullary regions associated with pain, cardiovascular and motor function. (S.L.J. is supported by the Presbyterian Health Fdn. and OCAST and R.W.B. is supported by HL29618).

SPINOTHALAMIC TRACT TERMINALS IN THE CAT'S NUCLEUS SUBMEDIUS ARE PRESYNAPTIC TO GABA-IMMUNOREACTIVE LOCAL CIRCUIT NEURONS. A. Blomqvist\*. A.-C. Ericson. J. Broman, and A.D. Craig. Dept of Cell Biology, Univ. of Linköping, Sweden, and Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ, U.S.A.

This study examines the synaptic relationships in the nucleus

This study examines the synaptic relationships in the nucleu submedius (Sm) between spinothalamic tract terminals and GABA-immunoreactive profiles. Spinothalamic tract terminals were labeled with anterograde transport of WGA-HRP and subsequent tetramethylbenzidine histochemistry. GABA-immunoreactive profiles were identified in the electron microscope with an immunogold-labeling technique. GABA-like immunoreactivity was present in small neurons, presynaptic dendrites (PSDs), and F-type terminals. The spinothalamic tract terminals in nucleus submedius were presynaptic to GABA-negative dendrites that presumably originate from thalamocortical relay cells and to GABA-immunoreactive PSDs. The PSDs in turn were presynaptic to relay cell dendrites. In addition, the GABA-immunoreactive PSDs were in synaptic contact with other GABA-immunoreactive reminals of presumed cortical origin. When reconstructed in serial sections triadic arrangements typical for thalamic sensory relay nuclei were found between spinothalamic tract terminals, PSDs and relay cell dendrites. These results indicate that processing of spinothalamic tract input to Sm involves inhibitory circuits through GABAergic interneurons.

ORGANIZATION OF SPINOHYPOTHALAMIC TRACT AXONS IN THE Pain Physiology Lab., Dept. of Neurol., Mass. General Hosp. and Dept. of Neurobiol. Harvard Med. Sch., Boston, MA 02114.

Recently, Burstein, Giesler, and colleagues described direct nociceptive projections from the spinal cord to the hypothalamus. These studies indicated that spinohypothalamic tract (SHT) axons could reach the hypothalamus by a lateral route (through the lateral diencephalon) or by a medial route (by crossing the midline within the hypothalamus through the supraoptic decussation). In order to define more clearly the anatomical organization of the SHT, we quantitatively examined the effects of selective lesions of either the lateral or medial SHT projection on the distribution of retrogradely labelled neurons in the spinal cord.

Restricted electrolytic lesions were made in the area of either the medial projection, the lateral projection, or both; control animals received a lesion dorsal to the diencephalon. The retrograde tracer Fluoro-Gold (FG) was then injected unilaterally into the hypothalamus. Our findings indicate that of the 2722 SHT neurons counted in the spinal cord about 57% project to the hypothalamus through the lateral projection only, 27% project through the medial projection only, and 10% project through both pathways. Approximately 6% were not eliminated by lesions of both pathways, and thus may reach the hypothalamus through other routes. Neurons that project through the lateral route were present mainly contralateral (73%) to the injection site. Neurons that project through the medial route were found mostly ipsilateral (62%) to the injection site. The presence of ipsilaterally located cells following the medial lesion, and contralaterally located neurons following the lateral lesion suggest that about 25% of SHT neurons ascend in the ipsilateral spinal cord.

These findings indicate the existence of 2 major diencephalic pathways in which spinal cord neurons project to the hypothalamus. This information may be useful for future ablation studies attempting to examine the role of the SHT in pain.

## 350.11

PAIN EVOKED BY MICROSTIMULATION IN THE THALAMUS OF CHRONIC PAIN PATIENTS. J.O. Dostrovsky\*, K.D. Davis, F.E.B. Wells and R.R. Tasker, Dept of Physiology and Division of Neurosurgery, University of Toronto, Toronto, Ontario, Canada M5S 1A8

The role of the human thalamic ventrobasal complex (VB, or ventrocaudal nucleus) in nociception is puzzling since reports of nociceptive neuronal respo and stimulation-evoked pain are rare in the non-pain patient. In this study we investigated the incidence of painful sensations evoked by thalamic microstimulation in patients with chronic pain due to deafferentation or central lesions.

Data were obtained during stereotactic procedures for implantation of chronic deep brain stimulating electrodes. Tungsten microelectrodes were used to record neuronal responses and to deliver stimuli. Localization of VB was determined according to stereotactic coordinates and neuronal responses to innocuc somatic stimuli. At selected sites within VB, microstimulation (1s trains, 300Hz, 0.1-0.2ms pulses, <100µA) was performed and the patient was requested to describe the quality of the sensation and its peripheral location (projected field).

Microstimulation commonly evoked paraesthesia-type sensations. However, the majority of pain patients also reported painful sensations at stimulation sites in (and below) VB in more than half of the trajectories. These painful sensations were often described as 'sharp', 'shocking', 'burning' or 'unpleasant'. All patients were capable of differentiating paraesthesia from pain. There was often a mismatch between the location of the projected painful sensation and the receptive fields of the tactile neurons recorded at the same site. The incidence of the projected/receptive field mismatch and painful evoked sensations was unusually high when compared to patients with 'normal' pain sensibility. These results provide further support for previous hypotheses suggesting that alterations in the processing of nociceptive information in thalamocortical pathways occur in chronic pain conditions (supported by MRC of Canada)

# 350.13

COMPLICATIONS FOLLOWING CO-INJECTION OF WHEAT GERM AGGLUTININ-HRP (WGA-HRP) AND CHOLERAGENOID-HRP (B-HRP) INTO THE SCIATIC NERVE OF THE RAT. H. Liu. I.J. Llewellyn-Smith# and A.I. Basbaum\*, Depts. of Anatomy, Physiology and Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA and \*Center for Neuroscience, Flinders University, Bedford Park, South Australia.

Peripheral nerve injection of WGA-HRP or B-HRP respectively results in

Peripheral nerve injection of WGA-HRP or B-HRP respectively results in transganglionic labelling of small and large diameter primary afferent terminations in the spinal cord (Robertson and Grant, '85; LaMotte et al, '91). In this study, we report that after combined injections of the tracers into the sciatic nerve of the rat, there is an almost complete loss of transganglionic labelling in the spinal cord. In some rats one of the tracers (either 1.5µ1 5% WGA-HRP or 1.5µ1 1% B-HRP in 0.1 phosphate buffer and 5% DMSO) was injected into the sciatic on one side and a

on prospirate of the tracers into the opposite sciatic. After 48-72 hours the rats were perfused with 0.5% para and 2.5% glut and frozen sections of lumbar dorsal root ganglia (DRG) and cord were reacted with a TMB-tungstate procedure. Injections of WGA-HRP or B-HRP alone produced the expected pattern of labelling in DRG and spinal cord. After co-injection of the tracers we only detected a few small diameter DRG cells and some terminal labelling in laminae I and II; this was much less than with WGA-HRP alone. Only limited retrograde labelling of motoneuron somata was detected. In other rats either WGA-HRP or B-HRP was injected and 24 hours later the other tracer was injected, about 5mm proximal to the first. The rats were perfused at least 48 hours after injection of the second tracer. The labelling pattern in the DRG

and cord was characteristic of the first tracer injected, both in location and density.

Since the mutual inhibitory interactions were observed at the level of the DRG as well as the cord, we cannot determine whether the problem lies in transport or in uptake of the tracers. The fact that reduced labelling was observed even when the injections were separated temporally and spatially suggests that the underlying mechanism is more complicated than mere creation of a WGA-HRP/B-HRP complex that cannot be taken up and transported. Supported by: PHS grants DA/NIDA, NS21445, NS14627.

CHARACTERIZATION OF RESPONSES OF NEURONS IN THE VPL TO NOXIOUS COLORECTAL DISTENSION (CRD) IN THE RAT. R.M. Danzebrink\* and G.F. Gebhart. The Department of Pharmacology, The University of Iowa, Iowa City, Iowa, 52242, USA. Iowa City, Iowa, 52242, USA.

One hundred twenty four neurons in the ventral posterolateral nucleus (VPL) of the thalamus were characterized for their responses to noxious CRD (80 mmHg, 20s) and to non-noxious and noxious cutaneous stimulation in pentobarbital anesthetized rats using standard extracellular recording techniques. Thirty three/124 neurons responded exclusively to non-noxious (brush, 122) and (or noxious (princh) cutaneous stimulation. Ninety two three/124 neurons responded exclusively to non-noxious (brush, tap) and/or noxious (pinch) cutaneous stimulation. Ninety two of the total 124 neurons studied responded to noxious CRD and 82 of these neurons received convergent cutaneous input. Neurons were either excited (n=70) or inhibited (n=22) by noxious CRD and were distributed throughout the VPL. Thirty eight/82 neurons responded reproducibly and reliably to noxious CRD for 20-64 minutes. Eight/10 of these neurons tested responded in an intensity-dependent manner, suggesting that VPL neurons can encode the intensity of CRD. Thirty five of 55 neurons which responded to CRD also responded to distension of the esophagus, a presumed noxious stimulus (Meller and Gebhart, 1991), and these neurons were distributed throughout the VPL. These data suggest that neurons in the VPL receive convergent visceral and convergent cutaneous inputs and that they may be involved in sensory discriminative aspects of visceral nociception.

### 350.12

AFFERENTS CONNECTIONS OF THE AMYGDALOID COMPLEX (AC) OF THE RAT. COMPARISON OF TWO RETROGRADE TRACERS, FLUOROGOLD (FG) AND PSEUDORABIES VIRUS (PRV). L. Jasmin\*, H. Liang, K. Tarczy-Hornoch, J.P. Card\* and A.I. Basbaum. Depts of Anatomy, Physiology and Neurosurgery, UCSF, CA and \*Dupont-Merck, Wilmington, DE. We are studying the cells of origin of the nociceptive inputs to the AC of the rat with the transneuronal tracer, PRV. Distinguishing directly- from indirectly-labelled

with the transneuronal tracer, PRV. Distinguishing directly-from indirectly-labelled PRV-positive cell groups, however, requires a careful comparison with labelling produced by a sensitive tracer that is not transneuronally transported. To this end, we made stereotaxic injections of FG or PRV into the AC. Retrogradely-labelled FG and PRV cells were identified immunocytochemically with the ABC method. We confirmed the previously reported afferents to the AC with FG, including those few from the spinal cord. We also found retrogradely-labelled cells in locations that, to our knowledge, have not been described, including the thalamus: centrolateral, intermediodorsal, paracentral, posterior intralaminar, precommissural; hypothalamus:

dorsomedial, tuberomammillary, dorsal hypothalamic area, supraoptic tract area, tuber cinereum; pons: raphe pontis; medulla: reticularis gigantocellularis, subnucleus reticularis dorsalis, lateral reticular and the A1 region.

Presumed transneuronally-labeled cells (PRV only) were not found in the thalamus.

In the hypothalamus, far more PRV- than FG-labelled cells were recorded in the regions listed above. The same was true for the parabrachial complex of the pons. These results suggest that transneuronal labelling to local circuit neurons had occurred. PRV-only labelled cells were also recorded in hypothalamus: magnocellular, suprachiasmatic, subincertal, paraventricular; pons: subcoeruleus and some areas of the reticular formation; medulla; A5 region, area postrema, dorsal paragigantocellularis, gigantocellularis pars alpha, paratrigeminal, trigeminal pars caudalis, supragenual; spinal cord: laminae I and II. These data indicate that PRV reveals a remarkably diverse source of connections with the AC. Because of the great sensitivity of PRV, due to its replication in neurons, the possibility that some of the presumed transneuronally-labelled cells were directly-labelled must be considered. Supported by the MRC (Canada) and NS14627 and NS21445.

## 350.14

PET ANALYSIS OF BRAIN STRUCTURES DIFFERENTIALLY ACTIVATED BY NOXIOUS THERMAL STIMULI.

K.L. Casey

And K.A. Frey. 1.3. Depts. of Neurology 1, Physiology 2, and Division of Nuclear Medicine 3, University of Michigan and Neurology Research

Laboratories, VAMC, Ann Arbor, Mi. 48105

We identified regional increases in cerebral blood flow(CBF) that are differentially produced by noxious thermal stimulation of the skin. Nine healthy subjects (20 to 39 yrs) gave magnitude estimations of 5 sec thermal pulses applied with a contact thermode to the left forearm (resting temperature 31.8 +/-1.0 $^{\circ}$ C.). Stimuli of  $40^{\circ}$ C were rated as warm (2.1 +/-1.0 s.d.) and stimuli of  $50^{\circ}$ C as painful (8.9+/-0.9 s.d.) on a 0-10 scale with 7.0 as pain threshold. These stimuli were applied repetitively to 6 sites while positron emission tomographic (PET) scans were performed after the intravenous bolus injection of H<sub>2</sub> <sup>1.5</sup>O (66mCi). Three scans of each subject were acquired during 40°C and 3 during 50°C stimulation. Subtraction images were made and oriented with a stereotaxic atlas to reveal the brain structures differentially activated by 50°C stimuli. Guided by a priori hypotheses, the following structures were sampled at points of maximum difference over 6 ml volumes of interest and showed significant percentage increases in CBF (p=0.01(\*\*) or p=0.05(\*) by one-tailed t-test): Contralateral thalamus,3.0%; contralateral (but not ipsilateral) S2-insular cortex,2.9%; ipsilateral thalamus,2.3%; anterior cingulate gyrus,2.1%; pontomesencephalic junction,1.9%; and contralateral (but not ipsilateral) S1 cortex,1.6%. The cerebellar vermis showed a 3.1% increase, but was not included in the a priori hypotheses. These results memphasize the role of subcortical and limbic structures in pain. (Supported by Dept. of V.A. and a Bristol-Myers Squibb award).

THERMORECEPTIVE NEURONS AND BEHAVIORAL OUTCOME OF INJURY IN AREA 7B CORTEX OF MONKEYS. W.K.Dong\*, V.J.Roberts, T.Hayashi, B.M.Fusco, and E.H.Chudler. Departments of Anesthesiology and Psychology and Multidisciplinary Pain Center, University of Washington School of Medicine, Seattle, WA 98105

Two subgroups of thermoreceptive neurons have been identified in area 7b cortex (inferior parietal lobule) of monkeys during performance of an appetitive tolerance-escape task. Monkeys were allowed to initiate and terminate thermal stimulation of the face and were reinforced for completing trials that sometimes required tolerance of noxious temperatures (>44°-45° C). Reward was delivered after responding to an audiovisual cue. Subgroup 1: Low threshold, "warm" neurons had positively accelerating, non-linear stimulus-response functions when skin temperatures were increased from 32°C up to 43°-44°C. The S-R curves were steepest for final plateau temperatures between 38° and 44°C. Subgroup 2: High threshold, nociceptive-specific neurons crudely graded temperatures from 44°-48°C and encoded the entire duration of plateau temperatures without discharge adaptation. Pain tolerance thresholds were within the temperature range (46°-48°C) that elicited maximal discharge frequencies. Chronic focal compression of area 7 eliminated behavioral escape to all noxious temperatures including 51°-52°C. Ability to detect variable offset of thermal shifts in lieu of audiovisual cues for reinforcement indicates that thermosensitivity remained intact. Pain asymbolia has also been reported in man after posterior parietal cortex injury. Supported by NIH grants NS29459 and NS07217.

#### 350.16

RESPONSES OF VENTROLATERAL ORBITAL CORTEX NEURONS TO NOXIOUS VISCERAL STIMULATION IN THE RAT. <u>K.A. Follett\* and B. Dirks</u>. Division of Neurosurgery, University of Iowa Hospitals, Iowa City, IA 52242.

Cortical mechanisms of visceral nociception have not been wellstudied. This study was undertaken to determine if neurons in ventrolateral orbital cortex (VLO) respond to a physiologic noxious visceral stimulus (colorectal distension, CRD).

In pentobarbital-anesthetized rats, spontaneously active single neurons were isolated in VLO using standard microelectrode recording techniques. Their responses to graded balloon distension of the colon (40-80 mm Hg) were recorded. Cutaneous receptive fields were studied in these same neurons.

Twenty-nine neurons were isolated. Twenty-one responded to CRD. Nineteen of the 21 (90 %) were inhibited by CRD and 2 (10 %) were excited. Thresholds were as low as 40 mm Hg. Large, bilateral cutaneous receptive fields were identified in 14 of the 21 neurons (67%).

We have demonstrated that VLO neurons respond to a physiologic noxious visceral stimulus in a rat model. The nearly uniform (inhibitory) responses and wide cutaneous receptive fields are distinct from the variable CRD responses and discrete, contralateral cutaneous receptive fields of neurons we have studied previously in primary somatosensory cortex.

### PAIN MODULATION: SUPRASPINAL

## 351.1

SUPRASPINAL MORPHINE ANALGESIA: SYNERGY BETWEEN MESENCEPHALIC, PONTINE AND MEDULLARY SITES IN RATS. G.C. Rossi\*, G.W.Pasternak, J.M.Kiefel and R.J.Bodnar. Dept. of Psychology, Queens Col., CUNY, Flushing, NY 11367 and Dept. of Neurology, Memorial Sloan-Kettering Cancer Center, NY, NY 10021.

Spinal and supraspinal opiate systems display multiplicative analgesic interactions following ventricular and intrathecal morphine (JPET 215: 633-642, 1980). Since morphine analgesia can be elicited from the periaqueductal gray (PAG), locus coeruleus (LC) region, nucleus raphe magnus (NRM) and nucleus reticularis gigantocellularis (NRGC), the present study evaluated whether morphine analgesia elicited from pairs of these sites displays synergy on the tail-flick test in rats. A morphine doseresponse function was determined over 2 h for each site alone (ED<sub>50</sub>: PAG: 1.9ug, LC region: 4.3 ug, NRM/NRGC: 2.5 ug). Morphine was simultaneously administered into either the PAG and NRM/NRGC or the LC region and NRM/NRGC such that the sites alternately received either a fixed (1 ug) or variable (0.2-1) dose. Isobolographic analyses revealed that simultaneous morphine administration shifted the dose-response curve to the left (2-5 fold) for PAG-NRM/NRGC placements, and produced lesser, but significant leftward shifts for LC region-NRM/NRGC placements. In keeping with mu mediation of morphine analgesia from these placements (Brain Res. 447: 25-43, 1988), naloxonazine eliminated analgesic synergy between PAG and NRM/NRGC placements.

## 351.3

SERGYONIN RECEPTOR SUBTYPE ANTAGONISTS AND 2-DEOXY-D-GLUCOSE ANALGESIA: TEST-SPECIFIC EFFECTS IN RATS. M.C. Fisher and R.J. Bodnar\*. Dept. of Psychology, Queens Col., CUNY, Flushing, NY 11367.

Multiple serotonin receptor subtypes modulate opiate and opioid-mediated analgesia (e.g., Neurosci. Lett. 95: 313-317, 1988; Brain Res. 500: 231-240, 1989; JPET 256: 983-992, 1991). Since 2-deoxy-D-glucose (2DG) analgesia is mediated by endogenous opioids, the present study examined whether 5HT (methysergide: 5-10 mg/kg, ip), 5HT (ritanserin: 2.5 mg/kg, sc) or 5HT<sub>3</sub> (IGS 205930: 0.25-5 mg/kg, sc) antagonists altered 2DG analgesia on the tail-flick and jump tests over a 2 h time course in rats. Serotonergic antagonists exerted test-specific effects without altering nociceptive thresholds. On the tail-flick test, 2DG (450 mg/kg) analgesia was significantly reduced by IGS 205930 (40-47%), but not by methysergide (15-28%) or ritanserin (6%). In contrast, 2DG analgesia on the jump test was significantly potentiated across the time course by ritanserin (67-92%), methysergide (21-64%) and IGS 205930 (26-45%). Thus, whereas the 5HT<sub>3</sub> antagonist IGS 205930 selectively reduces 2DG analgesia on a spinally-mediated (tail-flick) nociceptive measure, the above serotonergic antagonists, but particularly ritanserin', potentiate 2DG analgesia on a supraspinal (jump) nociceptive test. (Supported by PSC/CUNY 662225).

## 351.2

SEROTONERGIC AND OPIOID ANTAGONISTS IN THE VENTRAL MED-ULLA INHIBIT MESENCEPHALIC MORPHINE ANALGESIA IN RATS. J.M. Kiefel\*, M.L. Cooper and R.J. Bodnar. Dept. of Psychology, Queens Col., CUNY, Flushing, NY 11367. Morphine analgesia elicited from the periaqueductal

Morphine analgesia elicited from the periaqueductal gray (PAG) is significantly inhibited by methysergide administered into the nucleus raphe magnus (NRM) and rucleus reticularis gigantocellularis (NRGC), indicating serotonergic mediation (Physiol. Behav. 51: 201-205, 1992). Given the existence of multiple serotonin receptor subtypes and an enkephalinergic PAG-NRM/NRGC pathway, the present study evaluated whether the 5HT3 antagonist, ICS 205930 (0.25-5 ug), the 5HT2 antagonist, ritanserin (0.25-2.5 ug) and the opioid antagonist, naltrexone (10 ug) in the NRM/NRGC altered PAG morphine (2.5 ug) analgesia. PAG morphine analgesia was significantly inhibited by NRM/NRGC injections of: ICS205930 on the tail-flick (91%) and jump (70%) tests, ritanserin on the tail-flick (94%) and jump (70%) tests. Thus 5HT2 and 5HT3 receptor subtypes participate in the serotonergic mediation of mesencephalic morphine analgesia in the ventral medulla, and an enkephalinergic pathway is also involved in this supraspinal analgesic system. (Supported by PSC/CUNY 662225).

# 351.4

AGING,GENDER AND GONADECTOMY EFFECTS UPON MORPHINE ANALGESIA IN RATS. A.K. Islam\* and R.J. Bodnar. Dept. of Psychology, Queens Col., CUNY, Flushing, NY 11367.

Morphine analgesia is sensitive to gender and aging differences in that analgesic magnitude is greater in male than in female rats, and is smaller in older (14-24 mo.) than in younger (4-9 mo.) female rats. The present study examined the roles of aging, gender and gonadectomy in morphine analgesia on the tail-flick test. Rats were anesthetized and received sham surgery or gonadectomy at 3 months of age, and tested in separate groups (n=8-10) at either 6,12,18, or 24 mo. of age. Analgesia was assessed at weekly intervals across a dose range (1-10 mg/kg, ip) and a 2 h time course. Whereas intact males and females displayed similar morphine dose-response curves at 6 mo. of age, morphine analgesia was significantly greater in older intact males. Aging increased analgesic sensitivity to morphine in intact males, and decreased sensitivity in intact females. Moreover, castration decreased and ovariectomy increased analgesic sensitivity to morphine relative to same-sex controls across all age groups. These data indicate that aging and gender variables interact with each other to alter the efficacy of morphine analgesia in rats, and that adult gonadectomy appears to modulate each gender's analgesic response across the aging process.

OPIATE REGULATION OF AMINO ACID RELEASE FROM THE NUCLEUS RAPHE MAGNUS (NRM) OF THE RAT. Liang Liu, Paul Green\* and Allan I. Basbaum. Depts. of Anatomy, Physiology and Keck Center for Integrative Neuroscience, University California San Francisco, CA 94143

A glutamatergic synapse in the NRM has been implicated in descending antinociceptive mechanisms. In this study, we used in vivo microdialysis to study basal and evoked release of glutamate, aspartate, taurine and glycine in response to microinjection of morphine into the NRM. Male Sprague-Dawley rats were stereotaxically implanted with a concentric microdialysis probe (150µm i.d.) with an attached side catheter (Frothingham and Basbaum, J. Neurosci, Meth. 1992). Recovery of amino acids began at least one day after surgical implantation. The probe was perfused with a Ringer's solution at 2.0 µl/min. Samples were collected at 15 minute intervals. Four samples were collected to determine basal concentrations. Then morphine (5.0µg/0.5µl saline) was microinjected through the side catheter over a 2.0 min period. A tail pinch test was used to assess analgesia. Samples were analyzed with pre-column OPA derivatization and fluorescence detection, within 24 hours.

Basal concentrations of the amino acids were: glutamate--22.7pm/30µl;

samples were analyzed with pre-column OPA derivatization and fluorescence detection, within 24 hours.

Basal concentrations of the amino acids were: glutamate--22.7pm/30µl; aspartate--0.5pm/30µl; taurine--16.3pm/30µl; glycine--3.4pm/30µl. Microinjection of morphine significantly increased the extracellular concentration of glutamate (40-300%). The increase was only detected in the two samples following the morphine injection. There was no change in the levels of the other amino acids. Injection of morphine vehicle produced no detectable change. In two animals in which the morphine microinjection did not produce analgesia, we did not detect an increase in glutamate levels.

It has been proposed that the analgesia produced by microinjection of opiates involves lifting of a tonic inhibitory (GABAergic) control of the spinally-projecting NRM neurons. The present results suggest that local injection of opiates may also "activate" these projection neurons, via the release of glutamate from the terminals of PAG neurons that arborize within the NRM. Our continuing studies are evaluating the receptors through which the morphine effect is generated and the Ca²+dependency of this release. Supported by PHS grants DE/DA08973, NS21445 and NS14627.

CHOLINERGIC NEURONS IN THE PEDUNCULOPONTINE TEGMENTUM MODULATE NOCICEPTION BY ACTING AT NICOTINIC AND MUSCARINIC RECEPTORS IN THE VENTROMEDIAL MEDULLA L.F. Fitzgerald\* and H.K. Proudfit. Dept. of Pharmacology, Univ. of Illinois at Chicago. Chicago, IL 60680.

Electrical or chemical stimulation of the cholinergic pedunculopontine tegmental nucleus (PPTg) produces antinociception in rats. Experiments were designed to establish that this antinociception is mediated by cholinergic receptors in the ventromedial medulla (VMM). Injection of atropine, pirenzepine or mecamylamine into the VMM blocked the antinociception produced by PPTg stimulation, methoctramine had no effect. In a separate series of experiments, injection of nicotine, methacholine or physostigmine into the VMM produced antinociception. Atropine antagonized the antinociception produced by nicotine, and mecamylamine antagonized the antinociception produced by methacholine. Finally, antinociception produced by physostigmine was antagonized by mecamylamine and atropine. These experiments indicate that PPTg stimulation produces antinociception by releasing acetylcholine which acts at nicotinic and muscarinic receptors in the VMM. Supported by National Institute on Drug Abuse USPHS Grant DA03980.

## 351.9

ACTIVATION OF OFF-CELLS IS A COMMON ELEMENT IN THE ANTINOCICEPTION PRODUCED BY DIRECT LOCAL APPLICATION OF BOTH OPIOIDS AND GABA, RECEPTOR ANTAGONISTS IN THE RAT ROSTRAL VENTROMEDIAL MEDULLA (RVM). M.M. Heinricher' and V. Tortorici. Dept. Neurol., Univ. Calif., San Francisco, CA 94143 and Instituto Venezolano de Investigaciones Científicas, Caracas, Venezuela. Blockade of GABA transmission in the RVM of lightly anesthetized rats produces inhibition of the tall flick reflex (TF), an effect consistent with the suggestion that opioids activate pain inhibiting neurons by inhibition of a GABA interneuron. The aim of the present study was to identify the neurons mediating the antinociceptive action of GABA antagonists by recording the activity of TF-related RVM neurons before and after local infusion of bicuculline methiodide (BIC) in doses sufficient to inhibit the TF (12.5-80 ng in 100 nl).

(12.5-80 ng in 100 nl).

Cells of one class, "off-cells" are identified by a TF-related pause in firing, and are thought to have a net antinociceptive effect. Following BIC, these and are thought to have a net antinociceptive effect. Following BIC, these neurons showed a prolonged period of continuous activity, with a smooth increase to a peak followed by a more gradual decline. The time course of this active period paralleled that of TF inhibition. "On-cells" are identified by a TF-related burst of activity. These cells did not become continuously active following BIC infusion. At low doses, on-cells displayed a decrease in firing in those cases in which the TF was inhibited.

These results demonstrate that the activity of off-cells is highly constrained by GABA, suggesting that disinhibition of these neurons results in antinociception. Coupled with observations indicating that opioids acting in RVM activate off-cells indirectly, these data demonstrate that disinhibition of off-cells is central to the antinociceptive actions of both opioids and GABA antagonists in RVM.

Supported by PHS grant DA05608.

ARE THE ANTINOCICEPTIVE EFFECTS OF THE KAPPA SELECTIVE AGONIST CI-977 SUPRASPINALLY MEDIATED? K.R. Gogas\*. J.D. Levine and A.I. Basbaum. Depts. of Anatomy, Physiology and Medicine and Keck Center for Integrative Neuroscience, University of California San Francisco, CA, USA. We previously reported that supraspinal administration of the mu opioid receptor agonist, DAMGO, produces a dose-related, naloxone-reversible inhibitior of noxious stimulus-evoked pain behaviors and spinal cord fos-like immunoreactivity (FLI) in the rat, by activating descending inhibitory pathways. To examine the contribution of descending inhibitory pathways to kappa-receptor mediated analgesia, we have studied the effect of icv administration of the selective kappa agonist, CI-977, on pain behaviors and on spinal cord FLI evoked by unilateral formalin injection into the hindpaw of rats. We also tested the effects of lesions of the dorsolateral funiculi (DLF) of the spinal cord on CI-977-mediated antinociception.

unilateral formalin injection into the hindpaw of rats. We also tested the effects of fesions of the dorsolateral funiculi (DLF) of the spinal cord on CI-977-mediated antinociception.

Cannulae were implanted into the third ventricle of male Sprague-Dawley rats (200-225g; Bantin-Kingman) one week prior to testing. In some cases, animals received either sham or bilateral lesions of the DLF at the T3 level, immediately prior to cannula implantation. On the day of testing, CI-977 was administered into the third ventricle (icv) 10 min prior to injection of 5% formalin into the dorsal surface of the hindpaw. CI-977 produced a dose-related (0.06-2.0 µg) antinociception; the effect of the highest dose was reversed by either icv naloxone (10 µg) or icv nor-binaltorphimine (10 nmol). A lower dose of naloxone (1.0 µg), which reverses icv DAMGO-mediated antinociception, was ineffective against CI-977. In contrast to our findings with morphine and DAMGO, the antinociception produced by icv CI-977. This lack of a dose-related inhibition of spinal cord fos-immunoreactivity. Furthermore, lesions of the DLF had no effect on the antinociception produced by icv CI-977. This lack of a dose-related inhibition of spinal cord FLI by behaviorally analgesic doses of icv CI-977, taken together with the DLF lesion data, suggests that supraspinal kappa opioid receptors can produce analgesia withour activating descending inhibitory controls. Supported by the Pharmaceutical Manufacturer's Assoc. and NIH grants NS14627, NS21445 and DE/NIDA 08973.

### 351.8

AF64A ATTENUATES NICOTINE-INDUCED ANTINOCICEPTION IN THE PPTG AND NRM. M.K. Nihei\* and E.T. Iwamoto. Graduate Center for Toxicology and Department of Pharmacology, University of Kentucky Coll.of Med., Lexington, KY 40536.

The effects of ethylcholine aziridinium ion (AF64A) pretreatment of the pedunculopontine tegmental nucleus (PPTg) or the nucleus raphe magnus (NRM) on nicotinic antinociception were examined in adult, male Sprague-Dawley rats. Nicotinic antinociception was induced by either nicotine administered s.c. or N-methyl carbamylcholine (NMC) microinjected into the PPTg or NRM. Seven days after the implantation of guide cannulas aimed at the PPTg or NRM, AF64A (0.06, 0.125, 0.25, 0.5 nmol), or phosphate buffer, was injected in a 0.06µl volume. One week later, 40 nmol of NMC in 0.5µl of buffer was injected into the same site. This dose of NMC induced maximal antinociception 5 to 15 minutes after its injection into the PPTg or NRM as assessed by the hot-plate and tail-flick tests. NMC-induced antinociception was inhibited by the 0.125, 0.25 and 0.5 nmol doses of AF64A adminstered in the NRM, and by the 0.5 and 1 nmol doses of AF64A administered in the PPTg. In separate experiments, 0.375 mg/kg s.c. of nicotine produced maximal antinociception 5 to 10 minutes after injection, in both the hot-plate and tail-flick tests. These responses were absent in animals pretreated I week earlier with 0.5, 0.25 and 0.125, but not 0.06 nmol of AF64A in the NRM. These data suggest that the antinociceptive effects of centrally administered NMC depend on the integrity of cholinergic neurons in the regions of the NRM or the PPTg. Furthermore, SC nicotine-induced antinociception depends on intact NRM cholinergic neurons. (Supported in part by NS28847 and the KTRB.)

INTRATHECAL BICUCULLINE ATTENUATES ANTINOCICEPTION PRODUCED BY MICROINJECTION OF GLUTAMATE INTO THE NUCLEUS RAPHE MAGNUS IN THE RAT. M.K. McGowan\* and D.L. Hammond. Department of Anesthesia and Critical Care, University of Chicago, Chicago, IL 60637.

In this experiment, we examined whether spinal GABA receptors mediate the antinociception produced by chemical stimulation of neurons in the nucleus raphe magnus (NRM). Rats were prepared under general anesthesia with an intrathecal (IT) catheter and a chronic guide cannula aimed at the NRM. One week postoperatively, baseline nociceptive sensitivity was determined using the tail flick test. Rats were then injected IT with either 0.3  $\mu g$  bicuculline methiodide (a selective GABA<sub>A</sub> antagonist) or with vehicle (0.9% saline). Three minutes later, 30 nmol L-glutamate was microinjected into the NRM and tail flick latency (TFL) was redetermined at fixed intervals thereafter. Microinjection of glutamate significantly increased TFL in vehiclepretreated rats compared to baseline TFL 1, 2, 5, and 15 minutes following glutamate administration (p < 0.01). However, TFL in bicuculline-pretreated rats was not significantly greater than their baseline TFL (p > 0.05) at any time after glutamate administration. These results suggest that GABA in the spinal cord may mediate descending inhibition from the raphe via an action at GABA, receptors. Supported by PHS Grant DA 07004.

MODULATION BY ANGIOTENSIN III OF ARTERIAL PRESSURE-RELATED AND PAIN-RELATED NEURONAL RESPONSIVENESS IN THE NUCLEUS RETICULARIS GIGANTOCELLULARIS OF RATS. S.H.H. Chan\* and H.-F. Tsai. Inst. of Pharmacology, Natl. Yang-Ming Med. Coll., Taipei, Taiwan, R.O.C.

We combined extracellular single-neuron recording and microiontophoresis to evaluate the modulation by angiotensin III (AIII) of arterial pressure (AP)— and pain (P)—related neuronal responsiveness in the nucleus reticularis gigantocellularis (NRGC). Spontaneously active NRGC neurons in adult, male Sprague-Dawley rats anesthetized with pentobarbital were evaluated for their responsiveness to pain (tail clamp) and transient hypertension elicited by phenylephrine (5 µg/kg, i.v.). The responses of NRGC neurons to hypertension and tail clamp, when delivered individually, were suppressed by microiontophoretically-applied AIII. These actions were antagonized by AIII receptor antagonist Ile<sup>7</sup>-AIII. In NRGC neurons that manifested both AP— and P-relatedness, the responsiveness to tail clamp was reduced upon a simultaneous elevation in systemic arterial pressure. Interestly, this preferential response pattern was reversed to one that favored nociception in the presence of AIII. These results reveal that neuropeptides such as AIII may differentially modulate neuronal responsiveness according to the prevailing physiologic status of the animal.

INVOLVEMENT OF AN ANTIANALGESIC EFFECT OF NEUROTENSIN IN THE NRM IN THE RESPONSE TO MORPHINE ADMINISTRATION IN THE PAG. M.O. Urban\* and D.J. Smith. Depts. Anesth. & Pharmacol., WVU-HSC, Morgantown, WV 26506

The neuropeptide neurotensin has been implicated in pain modulation in the CNS and has been localized in the descending projections from the periaqueductal gray (PAG) to the nucleus raphe magnus (NRM) (Beitz. J. Neurosci. 2: 892, 82). These studies were designed to determine if these neurotensin projections participate in pain modulation from opioids administered into the PAG. The experiments were conducted by utilizing intracerebral microinjections in awake male Sprague-Dawley rats and measuring the noxious heat induced tail-flick response (TFL). Microinjection of neurotensin into the NRM produces a biphasic effect as both antinociceptive (increased TFL) and hyperreflexive (decreased TFL) responses are observed. The hyperreflexive (antianalgesic) response is most prominent at lower doses of neurotensin (0.3 and 1 nmol) being exhibited by 86% and 50% of the animals, respectively. It was most evident at 10 min following injection and disappeared within 30 min. The antinociceptive effect of neurotensin is observed only at the higher doses (3-30 nmol). Morphine (6 nmol) injected into the PAG produces an antinociceptive effect that is enhanced by administration of the neurotensin antagonist [D-Trp11]neurotensin (3 pmol) or anti-neurotensin antiserum in the NRM. In contrast, 8-endorphin (10 nmol) injected into the PAG produces an antinociceptive response that is unaffected by these substances in the NRM. The data demonstrate that PAG-NRM neurotensin neurons are responsible for an antianalgesic component of morphine's action. In contrast, this pathway is apparently not involved in the antinociceptive effect of β-endorphin. This is consistent with the notion that separate descending pain inhibitory neuronal pathways are responsible for the action of these opioids from the PAG (Tseng and Tang, J. Pharmacol. Exp. Ther. 252: 546, 90). Supported by NIH 2 T32-GM07039 and the Anesthesiology Dept.

Fentanyi causes morphine - like increases in PAG histamine release when coupled with tail pinch.

K.E. Barke\* and L.B. Hough Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208.

Recent studies in our laboratory employing the techniques of antinociceptive measures, intracerebral injections and intracerebral microdialysis support the hypothesis that a portion of morphine's supraspinal antinociceptive effect is due to histamine (HA) release in the periaqueductal grey (PAG). Presently, the actions of fentanyl, a highly selective  $\,\mu$  agonist, were simultaneously studied on PAG HA release (with in vivo microdialysis) and on antinociceptive responses in the same animal. In animals repeatedly tested for antinociception (tail pinch method), fentanyl (0.3 mg/kg s.c.), significantly increased both extracellular HA levels (0.5 - 3.0 hr) and tail pinch latencies (0.5 - 2.5 hr). In contrast, the same dose of fentanyl had no effect on HA release in animals that were not tested for antinociception. Similarly, saline injections with or without tail pinch measurements had no significant effect on HA release, suggesting that tail pinch alone was not sufficient to cause HA release. Although previous results show that antinociceptive doses of opiates like morphine induce PAG HA release, the present results suggest that PAG HA release may not be obligatory for  $\mu$  opiate antinociception. Even though simultaneous measurements of transmitter release and nociceptive responses would appear to be a powerful approach to study analgesic mechanisms, the present results also show that such behavioral testing can influence in vivo neurochemical events, perhaps by induction of stress responses (Supported by DA-03816, and DA-05460).

Examining a possible GABAergic link between ON and OFF cells in the rostral ventromedial medulla. S. McGaraughty\*, S. Reinis, J. Tsoukatos, & M. Lemon. Department of Biopsychology, University of Waterloo, Waterloo, Ontario CANADA N2L 3G1.

Biopsychology, University of Waterloo, Waterloo, Ontario CANADA N2L 3G1.

Two classes of cells in the rostral ventromedial medulla (RVM), ON and OFF, are important in the descending modulation of noxious input. It has been previously hypothesized that these two types of cells communicate locally by GABAergic interneurons (Heinricher, Morgan, & Fields, 1991; McGaraughty, Reinis, & Tsoukatos 1991). Systemic morphine (10 mg/kg) followed by systemic naioxone (3 mg/kg), 30 min later, was given to rats anaesthetized with either pentobarbital (a GABA agonist) or with ketamine (a non-competitive NMDA receptor antagonist) and xylazine. In the ketamine paradigm picrotoxin (1 mg/kg), a GABA antagonist, was given 30 min after the injection of naloxone. Under both anaesthetic paradigms the animals were kept in a deep state of anaesthesia. The spiking activity of the ON and OFF cells was recorded. The ON cells were typically inhibited by morphine under both anaesthetics. However, the OFF cells demonstrated an excitatory response only under ketamine anaesthesia suggesting a possible GABAergic inhibition of OFF cells in the pentobarbital paradigm. The excitation of ON cells may increase the local release of GABA inhibiting OFF cell transmission.

#### 351.14

INTRA-VTA INJECTIONS OF THE SUBSTANCE P ANALOGUE, DI ME C-7, CAUSES ANALGESIA IN THE FORMALIN TEST FOR CHRONIC PAIN. N. Altier\* and J. Stewart. Center for Studies in Behavioral Neurobiology, Dept. Psychology, Concordia University, Montréal, Canada, H3G 1M8

Experiments were designed to investigate the analgesic effects of substance P (SP) injected into the ventral tegmental area (VTA). Rats were tested in the formalin test for tonic pain following an injection of 0.05 ml of 2.5% formalin into one hind paw immediately after bilateral intra-VTA infusions of 3.0 μg/0.5 μl/side of the synthetic SP analogue, DiMeC-7, or saline using a within subjects design. Pain responses were recorded for 72 min. Two weeks later, the same rats were assessed in spinal reflex tail-flick test for pain. Tail-flick latencies were recorded following immersion of the tail in 55°C hot water at 10 min intervals for one hour immediately following intra-VTA infusions of DiMeC-7 or the vehicle. In the formalin test, DiMeC-7 reduced pain responses during the first 30 min. In the tail-flick test, DiMeC-7-treated rats were, if anything, hyperalgesic compared to saline-treated rats. In a second experiment, the same formalin test procedure was used except that rats received intra-VTA infusions 25 min following a formalin injection. DiMeC-7 attenuated pain responses for at least 30 min. These results parallel those of Morgan and Franklin (1990) who showed that intra-VTA injections of morphine produced analgesia in the formalin, but not the tail-flick test, and reinforce the idea that different neural systems mediate tonic and phasic pain. The fact that SP release in the VTA has been implicated in the activation of dopamine neurons in stress (Bannon et al, 1983) suggests that SP might mediate a form of stress-induced analgesia.

## 351.16

Histamine antinocloeption in the periaqueductal grey. K.K. Thobum, L.B. Hough, J.W. Nalwalk, S.A. Mischler and M. Aschner\*, Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, NY

Since histamine (HA) has been previously implicated as a mediator of antinociception (ANC), its effects on hot plate (52°) antinociceptive responses were presently studied in detail after intracerebral injection. When administered into the rat ventrolateral periaqueductal grey (PAG), HA (0.03 - 0.3 µg/0.5 µl) induced significant ANC. The largest response (21% of maximum possible effect after 0.3 µg) occurred 5 and 10 min after HA injection. Larger doses of HA (10 - 100 µg) had biphasic effects on ANC. However, preliminary histological results suggest that these doses of HA induce tissue damage. Mapping studies showed that HA (1 µg, 5 min) induced significant ANC when given into the PAG, but not when administered into the median raphe, mesencephalic reticular formation or the dorsal PAG. HA ANC (0.3 µg, PAG) was significantly antagonized by co-administration of the opiate antagonist naloxone (1 ng), the H₂ antagonist tiotidine (1 ng) and the H₁ antagonist temelastine (20 pg). These results suggest that: 1) HA induces ANC in the PAG in non-toxic doses, 2) the response is anatomically specific, and 3) both HA receptors and opiate receptors may play a role in HA ANC. Since intracerebral tiotidine (1 ng/PAG) attenuates systemic morphine ANC (Hough et al., Brain Res. 1992, in press), inhibition of HA ANC by this treatment (shown presently) further supports the hypothesis that endogenous HA is a mediator of morphine analgesia (Supported by DA-03816).

INFLUENCES OF MORPHINE AND NALOXONE ON THE FUNCTION OF NOCICEPTIVE NETWORKS IN THE VENTRAL (POSTERIOLATERAL AND MEDIAL) THALAMUS OF THE RAT. J. Tsoukatos\*, S. Reinis, and S. McGaraughty. Dep. of Psychology, University of Waterloo, Waterloo, Ont., Canada, N2I 3G1.

We have previously identified three types of neuronal responses to noxious tail heating in the VPL and VM thalamus of ketamine-xylazine anaesthetised rats, i.e activation, inhibition, and no response. We have analyzed our results using a novel method developed in our laboratory (Reinis, Weiss, Mcgaraughty, and Tsoukatos, 1991). We have reported that morphine appeared to mimic the effects of heat, and that the effect was reversed by naloxone.

We have tried to replicate the above results studying the effects of noxious stimulation, when the network was under the influence of morphine or naloxone. Morphine (10 mg/kg) decreased the firing rate of the heat inhibited cells (the most common response) and increased the firing rate of the heat activated cells. These effects were reversed by naloxone (2 mg/kg).

The effects of morphine appeared shortly after the injection (2-4 minutes). The reversing action of naloxone was delayed by 10-20 minutes following the injection.

INTRAVENOUS MORPHINE INCREASES CSF NOREPINE-PHRINE IN SHEEP. C. Tong,\* J.C. Eisenach, Department of Anesthesia, Wake Forest University Medical Center, Winston-Salem, NC 27157-1009

Opioids alleviate pain by multiple mechanisms, including activation of bulbospinal inhibitory pathways, some of which are noradrenergic. To test this hypothesis in conscious animals, 6 adult sheep were prepared, after ACUC approval, with intravenous, arterial, and thoracic spinal catheters. On separate days, beginning at least 3 days after surgery, animals received iv morphine (0.5 or 1 mg/kg) followed by sampling of CSF at intervals for 1 hr for norepinephrine analysis by HPLC. Morphine caused an increase in CSF norepinephrine from 150±33 pg/ml at baseline to 300±190 pg/ml after 0.5 mg/kg and 530±200 pg/ml after 1.0 mg/kg (P <0.001). These results in a conscious, non-rodent species support previous investigations, primarily in anesthetized rats, demonstrating systemic or brainstem opioid induced spinal inhibition which is noradrenergic in nature and inhibited by spinally administered  $\alpha$ -adrenergic antagonists. Previous studies in sheep suggest opioid induced norepinephrine release is likely acting on  $\alpha_2$ -adrenoceptors, based on antinociceptive trials and radioligand binding studies in this species. Supported in part by grant GM35523 from the National Institutes of Health.

ROD SYNAPSE GEOMETRY AFFECTS TRANSMITTER CONCENTRATION AT THE BIPOLAR CELL. R. Rao\*1.2, G. Buchsbaum² and P. Sterling¹. Depts. of Neuroscience¹ and Bioengineering² Univ. of Pennsylvania, Philadelphia, PA 19104.

The cat rod synapse contains a single active zone: a linear array of about 100 vesicle release sites arching over the invaginating tips of a pair of bipolar dendrites. A pair of invaginating horizontal cell spines creates an extracellular volume of 0.1 µm<sup>3</sup>. We calculated some functional consequences of this unique geometry.

Assuming an intravesicular glutamate concentration of 100 mM, a 32 nm synaptic vesicle contains ~1000 glutamate molecules. If these are evenly distributed within the extracellular volume, the glutamate concentration is about 20  $\mu$ M. At this concentration 90% of the receptors are bound (2 non-cooperative binding sites/receptor;  $K_d = 0.7 \, \mu$ M). Thus, in darkness, tonic release of one vesicle at a time could maintain a saturating glutamate concentration within the invagination. This implies a low probability of release at each of the 100 sites.

A simple diffusion model predicts that following the release of one vesicle, glutamate concentration would peak at the bipolar dendritic tip (presumed site of APB receptors) in less than 0.5 ms. The height of the peak depends strongly on the locus of the release site along the 1.8 µm arch. Sites at the base and peak of the arch lie respectively 220 and 500 nm from the bipolar tips and this leads to a 5-fold difference in peak concentrations. Were the active zone not arched, but straight, the ratio of distances between closest and farthest sites to the bipolar tip would be 4-fold and this would lead to a 16-fold difference in peak concentrations. Thus, the arched form of the active zone minimizes the difference in peak concentrations due to different loci of release. EY00828

### 352.2

MODULATION OF CA CHANNEL PROPERTIES BY EXTRACELLULAR pH IN ROD PHOTORECEPTORS. Farid Mahmud & Steven Barnes\*, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada, T2N 4N1.

L-type Ca channels of many species undergo changes in gating and permeation with changes of extracellular pH. Here we extend these observations to the Ca channels of rod photoreceptors where there may be important physiological ramifications of endogenous interstitial pH changes shown to accompany the normal response to light.

Barium currents were recorded with whole-cell patch-clamp techniques from mechanically isolated tiger salamander rods under conditions designed to eliminate current contributions from other ion channels (bath (in mM): 20 BaCl<sub>2</sub>, 10 TEABr, 5 CsCl, 65 NaCl, 2.5 KCl, 8 glucose and 10 HEPES; intracellular solution: 100 CsCl, 3.5 MgCl<sub>2</sub>, 1 EGTA, 10 HEPES, pH 7.2). Current-voltage relations (I-V's) measured at test pH were always bracketed by I-V's in pH 7.4 to control time-dependent dialysis-related effects. Peak inward currents nearly doubled over the pH range of 6.9 to 8.1. Part of this increase is accounted for by pH-induced shifts of the Ca channel activation curve midpoint, which amounted to a 10 mV negative shift between pH 6.9 to 8.2. Proton block underlies a significant reduction of the fully-activated Ca channel conductance.

We show that synaptic transmission from rods depends on the third power of the Ca influx function and that proton-induced Ca channel changes account for observations of pH-regulated synaptic transmission. Proton modulation of Ca channels may lead to other effects on cell function involving the activity of Cagated channels and Ca-regulated enzymes.

Supported by the Alberta Heritage Foundation and the MRC.

# 352.3

MODULATION OF SYNAPTIC TRANSFER BY EXTRACELLULAR pH AT THE PHOTORECEPTOR OUTPUT SYNAPSE. <u>Vaishali Merchant\* and Steven Barnes</u>, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada, T2N 4N1.

We show that interstitial pH strongly modulates the transfer properties of the glutamatergic photoreceptor output synapse via presynaptic actions.

Dark-adapted larval tiger salamander retinal slices were used where control of

Dark-adapted larval tiger salamander retinal slices were used where control of extracellular pH is possible and where retinal neurons can be identified by their position in the slice and by their morphology (using 1% Lucifer yellow). Lightelicited current changes in horizontal cells and bipolar cells were measured with the whole-cell patch-clamp technique. Postsynaptic current changes were eliminated when the retinal slice was bathed in media of pH 7 and enhanced five-fold when bath pH was increased from 7.6 to 8. Overall the current changes showed an exponential dependence on extracellular pH, exhibiting an e-fold increase per 0.23 pH unit between pH 7 and 8. Horizontal cell responses to glutamate (2 to 50 uM) were unchanged between pH 7.6 and 8.0, and the light response of cones was fairly constant between pH 7.6 and 8.0, so neither explains the strong enhancment of postsynaptic response.

We account for transmission modulation via the pH-sensitivity of presynaptic Ca

We account for transmission modulation via the pH-sensitivity of presynaptic Cachannels. The Ca channel activation curve slides along the voltage axis as pH changes. Postsynaptic response shifts are predicted by laterally shifting Attwell et al.'s synaptic transfer function for the photoreceptor-horizontal synapse by amounts determined by the shift of Ca channel activation.

Light-induced alkylinization of the photoreceptor environment would shift the Ca channel activation curve negative, increase Ca influx and increase transmitter release. This could reset the photoreceptor synaptic output range during prolonged light or dark exposure.

Supported by the Alberta Heritage Foundation and the MRC.

RHODOPSIN-LIKE GENE EXPRESSED IN "GREEN" CONES IN GOLDFISH RETINA. P. A. Raymond\*, L. K. Barthel, J. K. Knight, S. A. Sullivan, Anat. & Cell Biol. and Neurosci. , Univ. Michigan, Ann Arbor, MI 48109

We used a bovine rhodopsin probe to isolate and sequence a cDNA clone (3.1.4) coding for goldfish rhodopsin, and we obtained additional goldfish visual pigment clones from K. Nakanishi. All clones were from the same retinal cDNA library (D. Goldman). Two of Nakanishi's clones (7.4.2 and 7.3) are highly homologous to human rhodopsin (>70% amino acid identity) and to the chicken rhodopsin-like gene (Wang,  $et\ al.$ , Biochem.31:3310, 1992) thought to represent the chicken "green" pigment. In order to determine whether the goldfish rhodopsin-like gene is expressed in rods or cones, we made sense and antisense digoxygenin-labeled riboprobes for  $in\ situ$  hybridization with 3  $\mu m$  cryosections of light- and dark-adapted whole eyes and isolated retinas.

The principal member of goldfish double cones (DC) contains a long wavelength-sensitive pigment (red) and the accessory member a middle wavelength-sensitive (green) pigment; long single cones (LSC) are either red or green. Riboprobes generated from clone 3.1.4 hybridized to rod photoreceptors in two locations: the perinuclear region and the myoid process adjacent to the ellipsoid, which is displaced up to 30 µm from the nucleus. Riboprobes to clones 7.4.2 and 7.3 hybridized to the perinuclear region of the accessory member of DC pairs and some but not all LSC. In dark-adapted retinas, where cone myoids are elongated, signal was not associated with the displaced ellipsoid as it was in rods. Sense probes in all cases gave no signal. These results show that green cones in goldfish retina contain a rhodopsin-like pigment. EY04318.

### BLUE CONES CONTACT OFF-MIDGET BIPOLAR CELLS

L. Klug, N. Tiv, Y. Tsukamoto1, P. Sterling2 and S.J. Schein\*. Dept of Psychology, UCLA, Los Angeles, CA, <sup>1</sup>Hyogo Coll Med, Hyogo, Japan and <sup>2</sup>Dept of Anatomy, Univ of Pennsylvania, Philadelphia, PA

"Blue cone" bipolars resemble On-midget bipolars in the location of their terminals in the inner plexiform layer, but many are contacted by more than one (widely spaced) cone. To determine whether S cones contact Off-midget bipolars as well as "blue cone" On bipolars, we examined 80 contiguous cone pedicles and their bipolars using electron micrographs of serial sections from macaque foveal retina.

Three of the 80 pedicles did not contact an On-midget bipolar. These three were smaller and had more synaptic ribbons (22) than did neighboring pedicles (17 - 20). The three unusual pedicles were widely spaced and did contact the dendrites of "blue cone" bipolars, suggesting that we have identified three S cones and their associated "blue cone" bipolars.

Each S cone pedicle also contacted its own Off-midget bipolar. This finding is consistent with the observation that S cones make both invaginating and triad-associated flat contacts with bipolars (Kouyama & Marshak 1992). Our finding, that S cones contact Off-midget bipolars as well as "blue cone" On bipolars, raises the question of why so few blue-Off, yellow-On responses have been found in ganglion and dLGN cells (Malpeli & Schiller 1978, de Monasterio 1979).

PHOTORECEPTOR TOPOGRAPHY IN THE RETINAE OF ANUBIS BABOONS. O. Fischer 1. M. Kirby 2. V. Jennings 2 and J. Mielke 3. 1 Dept. of Psych., Univ. of Calif., Riverside, CA 92521; 2 Dept. of Peds., Loma Linda Univ., Loma Linda, CA 92350; 3 Sch. of Opt., Univ. of Calif., Berkeley 94720.

The number and distribution of rods and cones in the retinae of anubis baboons (Papio anubis) were compared with the distribution of ganglion cells in this cies. These values were then compared with retinal topography described in other primate species.

We have estimated the number and distribution of rods and cones in wholemounted retinae using Nomarski differential interference phase contrast (NDIC) optics in conjunction with video-enhanced microscopy. The total number of rods (mean = 74 million) and cones (mean = 4 million) was intermediate between that described for the smaller retinae of macaques (Packer et al. 1989 J.C.N. 288:165) and the larger retinae of humans (Curcio et al 1990 J.C.N. 292:497). As observed for the retinae of macaques the distribution of cones in P. anubis was flattened peripherally, but dominated by a sharp central increase which peaked at the fovea (mean=217,000/mm<sup>2</sup>) and rod distribution increases slowly to a peak (mean=204,000/mm<sup>2</sup>) forming an annular ring which surrounds the central retina at the approximate eccentricity of the optic disk (4 mm). Within this ring there is a region of higher density in superior retina similar to the "dorsal rod peak" described by Packer et al. 1989 (J.C.N. 288:165). However, unlike other primate species (Wikler & Rakic 1990 J. Neurosci. 10:3390) the isodensity contours for both rods and cones in P. anubis are horizontally elongated peripheral to the optic disk in the same retinal position as the visual streak in ganglion cell distribution previously described for this species (Fischer & Kirby, 1991, Brain Behav. Evol. 37:189). Further, this correlates with the prominent streak in the ganglion cell distribution in the retinae of P. anubis compared to the retinal ganglion cell distribution of other primate species (Fischer & Kirby 1991).

# 352.9

IMMUNOCYTOCHEMICAL IDENTIFICATION OF PHOTORECEPTOR POPULATIONS IN THE RETINAS OF NORMAL AND RED-LIGHT-REARED TREE SHREWS. H.M. Petry\*, J.T. Erichsen and Á. Szél. Departments of Psychology and Ophthalmology & Visual Science, Univ. of Louisville, KY 40292; Department of Neurobiology & Behavior, SUNY at Stony Brook, NY 11794; Lab I of Electron Microscopy, Semmelweis Univ. of Medicine, Budapest Hungary

Microspectrophotometry shows the tree shrew retina to contain shortwavelength-sensitive (SWS) cones, long-wavelength-sensitive (LWS) cones, and rods (Petry & Hárosi, 1990). We present immunocytochemical data on the presence and retinal distributions of these photoreceptor types based on their affinity for monoclonal antibodies OS-2, COS-1 and anti-rhodopsin, which have been shown to be specific, respectively, for SWS cones, mid/LWS cones, and rods in other mammals (Szél et al. 1988). Retinas were obtained from normal adult tree shrews (Tupaia belangeri) and from adult tree shrews reared from birth to 8 wks of age in deep red light (>600nm). Rearing tree shrews in red light, which deprives SWS cones of photic stimulation, produces long-term deficits in chromatic/achromatic discriminations (Petry & Kelly, 1991). One goal was to explore the possibility that the discrimination deficits resulted from a reduced population of SWS cones. Results in normal shrews showed clear imm chemical differentiation of the three photoreceptor types, each with retinal variation in density. Counts from flatmounted retinas showed a total cone density of 12,000/mm<sup>2</sup> - 30,000/mm<sup>2</sup>. SWS cones comprised 4% - 11% of cones and displayed the hexagonal packing typical of this cone type. Percentages of SWS cones in the retinas of red-light-reared shrews were within the range determined for normals and no difference in SWS packing was apparent. These results argue that SWS cone integrity is not dependent on photic stimulation during early post-natal life. Supported by NIH R29-EY07113 (HMP) and R01-EY04587 (JTE).

CONE PHOTORECEPTOR MOSAIC OF THE GREEN THE SUNFISH. D. A. Cameron and S. S. Easter, Jr. Dept. of Biology, Univ. of Michigan, Ann Arbor, MI 48109-1048.

Recent evidence has implicated the geometrical birefringence of the double cones of the green sunfish (Lepomis cyanellus) as the biophysical basis of this vertebrate's polarization basis of this vertebrate's polarization sensitivity. Because of the intimate link between the organization of the cone photoreceptor mosaic and the psychophysical details of polarization sensitivity, we have examined the structural features of the *L. cyanellus* cone mosaic: (1) the arrangement of the cones is constant across the arrangement of the cones is constant across the retina (except for two regions), with double cones being nearly orthogonal to each other and aligned roughly ± 45° to the nearest retinal margin tangent; (2) the ratio of double to single cones is everywhere the same; (3) cone density is highest in the temporal retina; (4) retinal growth is circularly symmetric; (5) the retina maintains a roughly constant density of cones during growth by intercalating peripheral rows of cones amongst more central rows. These results will be presented as they relate to polarization will be presented as they relate to polarization vision and visual resolution.

PHOTORECEPTOR SHEETS ISOLATED FROM THE NEONATAL RAT RETINA LACK SYNAPSES AND OTHER RETINAL CELLS.

T.L. Valentino 1, and M.S. Silverman\*. Sensory Neuroscience Lab, Central Institute for the Deaf, and <sup>1</sup>Dept. of Biology, St. Louis University, St. Louis, MO. 63110.

We have presented evidence suggesting that photoreceptors transplanted in an we have presented evidence suggesting that pinoteceptors an anipalated in an intact outer nuclear layer (ONL) sheet form synapses with host retina in which endogenous photoreceptors and their synaptic connections were almost entirely eliminated (Silverman et al. Exp. Neurol. 115:87, 1992). However, the possibility remained that these synapses formed between transplanted hotoreceptors and non-photoreceptor retinal cells that were inadvertently included

To evaluate this possibility we analyzed ONL photoreceptor sheets isolated by vibratome sectioning (Silverman and Hughes, IOVS 30:1684, 1989) for the presence of ribbon-type synapses and non-photoreceptor retinal cells. The isolated presence of ribbon-type synapses and non-photoreceptor reunal ceas. And Solution ONL appeared as a uniform, almost transparent sheet (nonuniform areas were excluded from use). Electron micrographs were constructed from the photoreceptor in the 9 day old retina. Ribbon-type sheet and a comparable area (superior retina) in the 8-day-old retina. Ribbon-type synapses were identified as an electron-dense presynaptic ribbon structure surrounded by a cluster of vesicles apposed to postsynaptic processes. Determination of cell type was based on morphological characteristics such as cell

size and nuclear chromatin pattern.

The normal 8-day-old Sprague-Dawley rat retina contained an average of 27.5 synapses/100µm of outer plexiform layer (OPL). All were found within the OPL. In contrast, we have seen no synapses nor any non-photoreceptor cells in the isolated photoreceptor sheets. Because no photoreceptor synapses nor contaminating non-photoreceptor cells were seen in the isolated ONL, the significant increase in ribbon-type synapses we reported following photoreceptor transplantation apparently were formed between the transplanted photoreceptors and host retinal neurons.

# 352.10

AN ULTRAVIOLET-SENSITIVE CONE IN THE GERBIL RETINA. G. H. Jacobs\* and J. F. Deegan II. Dept. of Psychology, University of California. Santa Barbara. CA 93106

Gerbils are unusual among rodents in that their retinas contain relatively large numbers of cones. Earlier, electrophysiological experiments established that Mongollan gerbils (Meriones unguiculatus) have a cone pigment with a peak of c. 493 nm. Under photopic test conditions the gerbil retina behaved univariantly ove the range of 440 to 620 nm leading us to conclude that the gerbil has only a single class of cone (Jacobs & Neitz, Experientia, 1989, 45, 317). Govardovskil et al. (Vision Research, 1992, 32, 19) employed the monoclonal antibody OS-2 to label a second class of cone in the gerbii retina. By analogy to results on other mammals, they suggest these receptors to be "blue cones" with a sensitivity peak of c. 430 nm. Electroretinogram flicker photometry and behavioral discrimination tests have been used to show that the conclusions from both of these studies were in error: the gerbli indeed has a second cone type, but it is not a "blue" cone. In the presence of intense, long-wavelength adaptation the second cone of the gerbil is revealed to have peak sensitivity in the ultraviolet (UV), at c. 360 nm. Adaptation experiments show the sensitivities of the two cone types can be independently manipulated, and the behavioral results demonstrate that gerblis can utilize signals from the UV cone to make visual discriminations. AGE-RELATED CHANGES IN LIPID PEROXIDATION IN ISOLATED ROD OUTER SEGMENTS OF RAT RETINA. Ohia, S.E., Bagchi, M. and Stohs, S.J. Dept. of Pharmaceutical Sciences, Creighton University, School of Pharmacy & Allied Health Professions, Omaha, NE 68178.

Lipid peroxidation has been implicated in retinal degenerations such as those induced by constant illumination and exposure to oxygen. The aim of the present study was to investigate the effect of age on membrane lipid peroxidation in photoreceptor cells of the rat retina. Rod outer segments were isolated from Long-Evans rats aged between 23-90 days old as described by (1). Lipid peroxidation was determined colorimetrically based on the formation of thiobarbituric acid reactive substances (TBARS) using malondialdehyde as the standard. Absorbance values were measured at 535 nM and an extinction coefficient of 1.56 x  $10^5~{\rm M}^{-1}~{\rm cm}^{-1}$  was used. The following values were obtained for TBARS content in isolated rod outer segments from animals at different ages:

TBARS Content (nmoles/mg protein) 4.28 ± 0.17 5.96 ± 0.21 8.66 ± 0.31

90 days  $8.66 \pm 0.31$  Values give are means  $\pm$  S.E.M. of 4-6 experiments.

Age 23 days 45 days

TBARS content in rod outer segments from 90 days old rats was about twofold higher than in those obtained from 23 days old animals. Our results demonstrate that lipid peroxidation in isolated rod outer segment increases with age in retina from Long Evans rats.

DIFFERENT FORMS OF GLUTAMIC ACID DECARBOXYLASE (GAD) IN CAT AND MONKEY HORIZONTAL CELLS. N. Vardi\*, A. Tabaeczadeh, D. Kaufman¹ and P. Sterling. Dept. Anat., Univ. of Pennsylvania, Philadelphia, PA 19104-6058. Dept Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA 90024-1759.

Evidence that mammalian horizontal cells are GABAergic has been equivocal. Both cat and monkey horizontal cells are immunoreactive for endogenous GABA but do not accumulate exogenous GABA. Cat horizontal cells label with a mRNA probe for GAD, but they do not react with a widely used antiserum to GAD (from Oertel et al.). Monkey horizontal cells show the opposite pattern: they are negative for the mRNA probe but some do react with the Oertel antiserum. Since GAD was recently shown to be of 2 forms, 65 kDa and 67 kDa, we considered whether the apparently conflicting results might arise from a mismatch between these probes and the forms of GAD present in horizontal cells of the two species. Accordingly, we stained sections of aldehyde-fixed cat and monkey retina with antibodies specific for GAD65 (Chang and Gottlieb, '88; J. Neurosci 8: 2123 ) and GAD67 (Kaufman et al., '91; J. Neurochem 56: 720). Cat horizontal cells (types A & B) were immunonegative for GAD65 but positive for GAD67. Somas stained, as did their processes in the outer plexiform layer, including the type B axon terminal that invaginates the rod spherule. Monkey horizontal cells (types H1 & H2) showed the opposite pattern: somas and processes were immunopositive for GAD65 but negative for GAD67. The immunoreactivity for GAD67 in cat and its absence in monkey fit the hybridization results which showed presence of GAD mRNA in cat and absence in monkey. Indeed, this mRNA prob was directed at GAD67. This reconciles previous inconsistencies in the chain of evidence identifying GAD in mammalian horizontal cells and strengthens the conclusion that these cells are GABAergic.

DOPAMINE REDUCES CHANNEL OPEN TIME IN ZEBRAFISH HORIZONTAL CELL ELECTRICAL SYNAPSES. D. G. McMahon. Dept. of Physiology and Biophysics. University of Kentucky. Lexington. KY 40536.

Physiology and Biophysics, University of Kentucky, Lexington, KY 40536.

My laboratory is interested in defining the molecular mechanisms of synaptic modulation in the teleost retina. The zebrafish (<u>Brachydanio rerio</u>) is an attractive preparation for combining biophysical and molecular approaches to the study of retinal function. I now report <u>in vitro</u> studies of zebrafish horizontal cell electrical coupling and its modulation by dopamine.

Horizontal cells were dissociated and maintained in cell culture by standard techniques. Electrical coupling between contacting cell pairs was assayed by dual whole-cell patch clamp recording. Junctional conductance averaged 1.7 nS (23 pairs). Application of 50 uM dopamine reduced coupling in 5 of 7 pairs to an average of 45% of control, while 100 uM dopamine reduced coupling in 5 of 6 pairs to 41% of control. Dopamine's action peaked after approximately minute and recovery took 2-5 minutes. Dopamine did not alter extrajunctional voltage-gated conductances. In poorly coupled pairs, junctional channel activity of 25-35 pS, 65-75 pS and 130-140 pS was observed. In 3 such pairs, application of dopamine reduced coupling by reducing the frequency of junctional channel openings. The duration of channel openings, as analyzed by exponential fits of dwell-time histograms, was reduced by dopamine. At the 65-75 pS conductance level the mean time constant was reduced from 22.1 msec to 16.6 msec (1038 and 302 events). The mean unitary conductance was unchanged (71 pS pre dopamine vs 73 pS post). Similar results were observed at the 25-33 pS level.

These results provide a primary description of horizontal cell electrical coupling in the zebrafish and indicate that dopamine modulates coupling in a manner similar to its previously described action in other teleosts (perch, bass, caffish). Supported by NIH EYO9256 and the UKMC Research Fund.

### 352.1

THE SPATIAL PROPERTIES OF LIGHT ADAPTATION IN CAT HORIZONTAL CELLS. M.J.M. Lankheet, A.W. Przybyszewski and W.A. van de Grind (SPON: European Neuroscience Association). Utrecht Biophysics Research Institute, Department of Comp. Physiology, Utrecht University, Padualaan 8, 3584 CH Utrecht, The Netherlands.

Light adaptation in cone driven cat retinal ganglion cells has been shown to be a localized process. The size of the adaptation pool for the center mechanism was found to be at least as small as the size of an X cell center (Cleland and Freeman, 1988). In order to investigate whether photopic light adaptation takes place in the cones or, alternatively in the bipolars, we have studied the spatial spread of light adaptation in cat horizontal (H-) cell responses. H-cell activity was recorded in the optically intact, in situ eye. The mean luminance levels were in the high mesopic and photopic range and H-cell responses were mainly cone driven.

It was found that, in the photopic range, light adaptation is not a strictly local process. Adaptation signals effectively spread into non-illuminated parts of the H-cell receptive field. The size of the adaptation pool was quantified by measuring the increment threshold as a function of the diameter of an adapting background spot. The integration area for adaptation signals was found to be comparable to the size of the receptive field for the response proper.

These findings suggest that the spread of adaptation occurs in H-cells rather than in the photoreceptors. The results will be discussed in the light of ganglion cell receptive field organization and light adaptation mechanisms for ganglion cell centre and surround mechanisms.

## 352.14

GLUTAMATE MODULATES A CALCIUM CURRENT IN CATFISH HORIZONTAL CELLS THROUGH CHANGES IN INTRACELLULAR pH (pH.). <u>D.B. Dixon\*, K-I Takahashi and D.R. Copenhagen.</u> Dept. Ophthalmology, UCSF San Francisco, CA 94143

Glutamate is thought to be released tonically from photoreceptor and bipolar cells. Light evoked excitation of all classes of neuron postsynaptic to the rods and cones is via activation of APB, AMPA, and NMDA type receptors. We report here that glutamate can have a modulatory role on voltage-dependent currents in horizontal cells.

We used the whole-cell patch-clamp technique to record from isolated retinal horizontal cells. We studied a high threshold, non-inactivating calcium current (ICa<sup>++</sup>) which is blocked by nifedipine and cadmium. This current activates at potentials above -30 mV and contributes to the resting potential in darkness.

potentials above -30 mV and contributes to the resting potential in darkness. Earlier studies demonstrated that  ${\rm ICa^{+}}^+$  is altered by pH<sub>1</sub> (Takahashi et al, 1992). Intracellular acidification induced by bath application of acctate, or increased CO<sub>2</sub> or washout of NH<sub>4</sub>Cl reduced  ${\rm ICa^{+}}^+$ . Here we report that bath applied glutamate (1-5  $\mu$ M) reversibly reduces the peak  ${\rm ICa^{+}}^+$  by  ${\rm 27.8} \pm 6.5\%$  (n=6). Horizontal cells loaded with the pH indicator dye BCECF-AM were acidified by glutamate. We tested the hypothesis that the glutamate-induced reduction in  ${\rm ICa^{++}}^+$  was mediated via pH. This was done by loading the cells with patch pipet solutions containing high concentrations of pH buffer (25 mM HEPES). Under these conditions, glutamate suppression of  ${\rm ICa^{++}}^+$  was reduced. Additionally, simultaneous measurements of pH<sub>1</sub> and  ${\rm ICa^{++}}^+$  in single cells indicate that glutamate-induced acidification and reduction of  ${\rm ICa^{++}}^+$  can be recorded concurrently.

We propose that glutamate may have dual roles in the retina. It is a conventional excitatory neurotransmitter and may also be a neuromodulator which can influence cell excitability and transmitter release through modulation of ICa<sup>++</sup>.

MEMBRANE CURRENTS OF XENOPUS RETINAL HORIZONTAL CELLS

A. Akopian and P. Witkovsky\* Dept. Ophthalmology, New
York University Medical Center, New York, N.Y. 10016

York University Medical Center, New York, N.Y. 10016
We studied membrane currents of horizontal cells using the whole cell version of the patch clamp. Horizontal cells were isolated and maintained in short term culture by standard methods. The cells resembled those isolated from salamander retina (Gilbertson et al. J. Neurophysiol. 66:2002, 1991) and were distinguished from other cell types we tested by the presence of a prominent, fast-activating inward rectifier. In normal Ringer solution, the current-voltage function was triphasic, with a region of negative slope conductance between ca. -30 and -10 mV. The following currents were distinguished by pharmacological treatment: an inward rectifier active below -70 mV, a fast inward Na current, a prominent A-current blocked by 4-AP and a delayed outward rectifier, blocked by TEA. In the presence of a cocktail of TTX, 4-AP and TEA, two calcium currents were identified. A sustained, L-type current, blocked by Cd, was activated near -20 mV and peaked at 0 mV. A Cd-resistant, transfent Ca current activated near -50 mV and peaked at -20 mV. Supported by EY 03570 to P.W.

THRESHOLD EFFECTS OF DOPAMINE IN THE XENOPUS RETINA. D. Krizaj\* and P. Witkovsky, Depts. Ophthal. and Physiol. & Biophys. NYU Med Ctr., New York, N.Y. 10016

The extracellular concentration of dopamine (DA) in the Xenopus retina ranges from 150-600 nM as a function of lighting conditions and time of day. DA levels were high in light near subjective dawn and low in darkness. We reported previously (1) that a threshold dose for the DAinduced alteration and rod/cone input to horizontal cells (HC) was 2 um. We now find that if ascorbate is added to the solution, DA effects are obtained reliably at 0.5 µm. We recorded simultaneously from rods and HCs in superfused eyecups. Rod responses were elicited with scotopically balanced red and green flashes to test for possible cone input to the rod, as reported for salamander rods (2), but none was found. Under scotopic conditions, red and green LED's were modulated sinusoidally in counterphase and adjusted in intensity to produce a null response for both rod and HC. Both cells followed flicker to 4-6 Hz. The gain of the synaptic transfer was \$10. Addition of 0.5 - 1.0 μM DA was without effect on the rod null but it evoked a large imbalance in the HC. Red stimuli now elicited a greatly increased HC response that followed to 15 Hz. The DA effect was blocked by cis-flupenthixol. These data indicate that DA levels in the physiological range influence transmission of rod and cone signals through the retinal network. 1) Witkovsky et al., J. Neurophysiol. 62:864,1989 2)Hare & Owen, J. Physiol. 445:741, 1992. Support EY 03570

SEROTONIN-LIKE IMMUNOREACTIVITY AS A MARKER TO IDENTIFY ISOLATED BIPOLAR CELLS FROM THE SKATE RETINA. R.L.Chappell', E.Schlemermeyer, C.V.Logan, F.Mouly and M.Artinian. Hunter College and Graduate Center of the City University of New York, New York, NY 10021.

The all-rod nature of the retina of the skate (Raja erinacea) makes it of special interest when considering the role bipolar cells play in rod pathways from the outer to the inner plexiform layer. Our earlier studies using immunocytochemical techniques demonstrated PKC-like immunoreactivity in one class of skate bipolar cell having a morphology typical of "rod" ON-bipolar cells in duplex retinas. By preloading the retina with serotonin in the presence of pargyline, we were also able to confirm the presence of bipolar cells showing serotonin-like immunoreactivity (SLI). The SLI bipolar cell morphology, however, was found to be characteristic of OFF-bipolar cells with terminals branching in layers 1 and 4 of the inner plexiform layer. Double labelling confirmed that these two classes of skate bipolar cell were

We have now applied techniques for SLI developed on the intact skate retina to the identification of its isolated bipolar cells in culture, thus providing a basis for identification of SLI bipolar cells with their electrophysiological and pharmacological properties when studied using whole-cell patch recording techniques following retinal dissociation. Successful labelling of a population of isolated skate bipolar cells for SLI was accomplished using both FITC immunofluorescence and the ABC method with diaminobenzidine as the chromophore. In each case, the isolated bipolar cells were pre-loaded for one hour in skate Ringer containing  $20\mu M$ serotonin and 1mM pargyline. (Supported by NIH Grant EY-00777.)

DOPAMINE AND CAMP ACTIVATORS RELEASE INTRACELLULAR CALCIUM AND MODULATE THE CALCIUM CURRENT IN ISOLATED CATFISH HORIZONTAL CELLS.

Zinebi, F. and Christensen, B.N.\* Dept. Physiol. & Biophy.,

Univ. of Tex. Med. Br., Galveston, TX 77550.

Dopamine has been implicated in the regulation of the voltage sensitive calcium channel in retinal ganglion cells (Liu & Lasater, ARVO, 1992). Its effect is thought to be due to cAMP activation of protein kinase A. We have measured the effects of dopamine, forskolin, 8-bromo-cAMP and other cAMP/PKA modulators on both the calcium current and calcium release from intracellular stores in isolated cone horizontal cells. Dopamine either increases, decreases or has no effect on the calcium current measured in voltage clamped cells. Forskolin, a cAMP activator, always decreases the calcium current and this decrease can be reversed in some cases by dopamine

Catfish horizontal cells have caffeine sensitive intracellular calcium stores. Dopamine, forskolin and 8bromo-cAMP increase intracellular calcium measured in fura-2 loaded cells. The release is immediate, reaches a maximum within several seconds and declines slowly. The amount of the calcium increase is concentration dependent. These results support the hypothesis that the rise in intracellular calcium can modulate directly the calcium channel activity by a calcium dependent process.

Supported by Grant NIH EY-01897.

## 352.20

QUANTAL EXCITATORY TRANSMISSION TO OFF-CENTER BIPOLAR CELLS IN THE SALAMANDER RETINA. B.R. Maple' and F.S. Werblin, Graduate Group in Neurobiology, University of California, Berkeley, 94720 Spontaneous excitatory miniature synaptic currents were studied in voltage clamped bipolar cells under conditions in which presynaptic calcium influx was suppressed (2 mM Cobalt, 0 mM Calcium superfusate). Bandpass filtered excitatory events were fit to a gaussian-filtered difference of exponentials, and

suppressed (2 mM Cobalt, 0 mM Calcium superfusate). Bandpass filtered excitatory events were fit to a gaussian-filtered difference of exponentials, and from this two time constants, an amplitude, and an integrated charge were obtained for each hypothetical unfiltered event. Plotted as a density in an amplitude vs. charge graph, the events tended to cluster at regular intervals along several different slopes. This suggested the existence of several kinetically distinct types of quanta, each of which corresponded to the synchronous discharge of some number of presynaptic vesicles. Events were also scattered in a manner consistent with a process in which release was not perfectly synchronous, but tended to occur in clusters.

A useful measure of event kinetics was the charge/amplitude ratio, which was related to event "duration". For each kinetically distinct class of event, the amplitude distribution was heavily skewed towards the fundamental subunit. The following fundamental subunits (in terms of "duration" and peak amplitude) were observed at -50 mV: 2.3 msec, 0.9 pA and 2.4 pA; 4.3 msec, 2.3 pA; 7.4 msec, 1.2 pA and 5.5 pA. All three classes of kinetics were observed in most cells (even when axotomized), but in greatly varying proportions. Cells with telodendria ramifying in the distal 1/4 of the inner plexiform layer were strongly dominated by the 2.3 msec events, while 'Off' cells with telodendria ramifying more centrally in the IPL were dominated by the 7.4 msec events. 20 uM CNQX greatly reduced the mean amplitudes for all charge/amplitude ratios. Most likely, these quantal events are inputs from photoreceptor and dendrodendritic bipolar cell synapses. Since the concentration of glutamate in synaptic vesicles is probably extremely large compared to the K  $_{10}$  for bipolar cell glutamate receptors, the apparently independent action of vesicles released synchronously at the same active zone suggests that uptake is extremely rapid, and that the kinetic differences observed reflect different glutamate recep

# 353.1

FREQUENCY-RELATED DIFFERENCES IN THE SPEED OF HUMAN AUDITORY PROCESSING. David L. Woods\*, Claude Alain, Oren Zaidel, and Diego Covarrubias, Dept of Neurology, Davis, VAMC, Martinez, CA, 94553.

Two experiments were performed comparing auditory evoked potentials (AEPs) elicited by loudness-matched 250 Hz and 4000 Hz tone pips. Randomized sequences of stimuli were presented at short interstimulus intervals (mean 40-200 ms). The EEG was digitized continuously from 31 electrodes at a high rate (833 Hz/channel) to permit the simultaneous analysis of wave V (mean peak latency 6.8 ms), Na (20.1 ms), Pa (29.8 ms), Nb (38.4 ms), Pl (51.1 ms) and Nl (101.1 ms) components. In comparison with peak latencies following the 4000 Hz tones, the peak latencies of all components were delayed by 12.0-23.1% following 250 Hz tones. Frequency-related differences increased with component latency, ranging from 0.9 ms for wave V, to 23.0 ms for the N1. Interpeak latency differences were also prolonged. The results indicate central delays in the processing of low frequency auditory signals. The behavioral significance of these delays was evaluated in a a third experiment comparing simple reaction times (RTs) to the same stimuli. RTs were delayed by 15 ms following the 250 Hz tones. The rapid processing of high signal frequencies may play a role in the localization of sounds in space. Supported by a grant from the NIDCD to DLW and by a FCAR postdoctoral fellowship to CA.

RESPONSES OF CELLS IN AN AUDITORY THALAMIC NUCLEUS OF THE BARN OWL TO SOUND LOCALIZATION CUES. L. Proctor and M. Konishi Division of Biology, Caltech, Pasadena, CA 91125.

In the Barn Owl, nucleus ovoidalis is a thalamic nucleus which receives

ascending input from a midbrain auditory nucleus and projects to the forebrain auditory area, Field L. Field L contains neurons which are highly sensitive to sound location, as does the external nucleus of the inferior colliculus (ICx) (Knudsen & Konishi, Science, 202:778-780, 1978). ICx space-specific units respond only to sounds with a particular combination of interaural time difference (ITD) and interaural level difference (ILD). To date, ICx has been found to project exclusively to the optic tectum. This study was undertaken to determine the role of nucleus ovoidalis in processing ITD and ILD information and relaying this information to the forebrain.

We have recorded extracellular single unit responses from cells in nucleus ovoidalis which were stimulated with digitally synthesized sound (tone or noise) presented dichotically. Frequency is mapped along the dorsal-ventral axis of the nucleus, with higher frequencies represented dorsally. Isolated units had best frequencies which ranged from 10 KHz down to 500 Hz. The majority of units had frequencies which ranged from 10 KHz down to 500 Hz. The majority of units had rather narrow frequency tuning (approx 1 KHz wide at half peak) although a few units were isolated with much broader frequency tuning (approx. 5 KHz wide at half peak). Units typically were inhibited below spontaneous activity levels at frequency side bands flanking the best frequency peak. The majority of units isolated thus far were tuned to both ITD and ILD. Of the units which were tuned to ITD, none exhibited side peak suppression to noise stimuli, indicating tha phase ambiguity is preserved in these cells. The majority of ILD tuned neurons which have been isolated were either excited by stimuli from the contralateral ear (EI), or inhibited by the contralateral ear and excited by the ipsilateral ear (IE), with neither population apparently overrepresented. A few units were isolated which were selective for ILD (bell shaped tuning curves). Additionally, a few cells have been isolated which responded selectively either to ITD or ILD but not both.

ODING ASSOCIATIVE AUDITORY INFORMATION BY SPECTRAL GRADIENT ENHANCEMENT. F. Ohl, C. Simonis, H. Scheich\*. Dept. of Zoology, Tech. Univ., 6100 Darmstadt, Germany.

Learning-induced physiological plasticity in the adult auditory cortex has previously been demonstrated by a variety of techniques. A basic finding in imaging studies is the enlargement of representational areas which might correspond to the enhanced firing probability of single neurons as revealed by unit recordings. In addition, using the 2-deoxyglucose method we demonstrated asymmetric shifts of activated areas in the primary auditory cortical field A1 of Mongolian Gerbiis towards lower frequencies during the aquisition phase of an associative learning task ("tone bursts predict foot shocks") (Scheich, H., Simonis, C., Soc. Neurosci. Abstr., 17, 1991, p. 450). This implies that beside activity changes at the frequency-specific location within a tonotopic map there must exist learning mechanisms that produce oriented shifts of the frequency representation.

exist learning mechanisms that produce oriented shifts of the frequency representation.

To gain further insight into the relevant dynamic mechanisms we recorded electrophysiologically from 74 neurons in A1 of awake gerbils. Presenting mild electrodermal stimuli (EDS) to the animals' tails alone or pairing them with tone bursts of different frequencies increased or decreased the spike rate of 63% of the neurons up to 90%. The effects were non-frequency-specific in that the changes were proportional to the unit's tuning before conditioning. If, however, the EDS were paired with only one of the frequencies presented (CS+) the change of spike rate in response to frequencies neighbouring the CS+ was more positive than to the CS+ itself. This causes the CS+-response to lie on a point on the tuning curve (and supposedly in the map) where the change of activity along the spatial frequency gradient became enhanced. Hence, the increase of this spectral gradient (contrast) could be the most consistent and relevant feature of the dynamic rearrangement. This interpretation is also in accordance with the occurence of the maximum increase of the CS+-response istself reported by other authors (Weinberger, NM. et al., Concepts in Neurosci, 1, 1990, p. 91), because there the CS+ would come to lie on a spot of maximum spectral gradient, too. SENSITIVITY OF NEURONS IN THE INFERIOR COLLICULUS OF THE UNANESTHETIZED RABBIT TO INTERAURAL TEMPORAL DISPARITIES OF THE ENVELOPES OF HIGH-FREQUENCY TONES. R. Batra\*, S. Kuwada, and T.S. Stanford, Dept. of Anatomy, Univ. of Conn. Health Center, Farmington,

Interaural temporal disparities (ITDs) have traditionally been considered a cue for the Interaural temporal dispartites (11Ds) have traditionally been considered a cue for the azimuthal localization of low-frequency tones, that is, tones which have a half-wavelength greater than the width of the head. It is now apparent that ITDs may also be a cue in locating a high-frequency sound, if the sound has a low-frequency envelope. Neurons in the auditory pathways are indeed sensitive to this cue. Here we report the properties of neurons in the inferior colliculus (IC) of the unanesthetized rabbit to ITDs of the envelopes of sinusoidally amplitude-modulated, high-frequency

(2.2 kHz) tones.

Neurons that were sensitive to ITDs fell into two groups: those that were maximally excited at the same ITD at modulation frequencies > 250 Hz (MSO-like neurons) and those that were maximally suppressed at the same ITD (LSO-like neurons). We restricted our analysis to modulation frequencies > 250 Hz because at lower frequencies many neurons were sensitive to large ITDs which were unlikely to be associated with sound localization.

associated with soulid recalization. Most neurons of both types had characteristic delays in the range which the rabbit is likely to encounter in the free field ( $\pm$  300  $\mu$ s). Most delay curves of MSO-like neurons had peaks within  $\pm$  300  $\mu$ s, while most delay curves of LSO-like neurons had troughs within this range.

The peaks of the delay curves of MSO-like neurons were narrower than the troughs of

the delay curves of LSO-like neurons, and nearly as narrow as the peaks of the delay curves of LSO-like neurons, and nearly as narrow as the peaks of the delay curves of neurons sensitive to ITDs of low-frequency pure tones.

Thus, the coding for ITDs of envelopes is nearly as precise as that for ITDs of low-frequency pure tones. The MSO-like neurons may encode the location of a complex high-frequency sound, while the LSO-like neurons may help to sharpen the receptive fields of MSO-like neurons.

RESPONSE OF NEURONS IN LATERAL SUPERIOR OLIVE AND MEDIAL NUCLEUS OF THE TRAPEZOID BODY TO REPETITIVE STIMULATION: A BRAIN SLICE STUDY OF TEMPORAL INTEGRATION IN THE SUPERIOR OLIVARY COMPLEX. S.H. Wu\*and J.B. Kelly. Laboratory of Sensory Neuroscience, Psychology Department, Carleton University, Ottawa, Canada K1S 5B6.

Temporal integration in the superior olivary complex was investigated by recording the response of neurons in a mouse brain slice to repeated electrical stimulation of the trapezoid body. A 400  $\mu m$  brain slice was taken through the brain stem and maintained in an oxygenated saline solution following the procedure of Wu and Kelly (1991). Stimulating electrodes were placed on the trapezoid body and both extracellular and intracellular responses were recorded from the lateral superior olive (LSO) and the medial nucleus of the trapezoid body (MNTB). In both (LSO) and the medial nucleus of the trapezoid body (MNTB). In both structures, a single current pulse of sufficient strength elicited a single action potential. Excitatory postsynaptic potentials were apparent in intracellular recordings. In the MNTB, the neurons were capable of following very high rates of stimulation without reduction of response probability. Almost every MNTB neuron was capable of following repetition rates of 500 Hz and most were capable of following 1000 Hz. In contrast, most LSO neurons were incapable of following high rates of stimulation. Only a few neurons were capable of following rates of 500 Hz. The difference between LSO and MNTB in following repeated current pulse stimulation supports the idea that MNTB neurons are specialized for preservation of temporal information, whereas LSO neurons are specialized for binaural integration

PHYSIOLOGICAL MECHANISMS FOR CATEGORICAL RESPONSES REFLECTING THE VOICE ONSET TIME BOUNDARY IN AUDITORY CORTEX. M. Steinschneider\*, C.E. Schroeder, J.C. Arezzo and H.G. Vaughan, Jr., Albert Einstein College of Medicine, Bronx, NY, 10461.

Temporal information processing is a key component of speech perception. Its importance is exemplified by the selective impairment for discriminating rapidly changing sounds in dysphasic children. We studied the temporal pattern of neural activity which encodes the voice onset time (VOT) speech parameter by examining laminar profiles of current source density and multiunit activity to the syllables /da/ and /ta/ in auditory cortex of awake monkeys. VOT, the time interval between stimulus onset and stimulus periodicity, was varied from 0 to 80 msec in 20 msec increments.

VOT is reflected by responses time-locked to stimulus onset and to the onset of stimulus periodicity. Phasic responses to the latter speech segment are present with VOTs of 40 msec or longer and diminished for shorter VOTs. These patterns correlate with the /da/-/ta/ perceptual boundary. Two different mechanisms are responsible for this response differentiation: (1) hyperpolarizing events suggestive of active inhibitory processes follow an initial excitatory response to stimulus onset and diminish the second excitatory response to /da/, and (2) prolonged depolarizing events following stimulus onset attenuate the second excitatory response to /da/.

We conclude that both excitatory and inhibitory auditory cortical mechanisms determine the categorical VOT perceptual boundary, and suggest that dysfunction of these temporal processing mechanisms may contribute to the speech perception deficits of dysphasic children. EFFECTS OF INFERIOR COLLICULUS LESIONS ON THE AUDITORY BRAINSTEM RESPONSE IN RATS. D.G. Campbell and J.R. Coleman\*, Univ. South Carolina, Columbia, SC 29208.

The auditory brainstem response (ABR) is used experimentally and clinically to monitor the integrity of peripheral and central auditory pathways. The role of the inferior colliculus (IC) as a contributor to averaged surface potentials was examined in the rat. Bilateral IC lesions were made in male Long-Evans rats (90 days of age) and responses compared to age-matched controls. Electrocoagulative lesions were made stereotaxically under Ketamine/Acepromazine (100:1 mg/kg) anaesthesia. The ABR generating stimuli were 85 dB peSPL noise bursts (1.5 ms duration, 11.1/sec) presented monaurally to both left and right ears. Surface potentials were recorded (20 ms window, 512 presentations) from subdermal electrodes under Ketamine/Acepromazine (60:1 mg/kg) anaesthesia. Control animals displayed five major wave components (Cooper et al., Hear. Res. 43:171-180, 1990) followed by a negative deflection around 6.5 ms. Significant differences in the amplitudes of the IV-V wave complex (p<.001) and the following negative deflection (p<.01) were detected. Histology confirmed that experimental subjects had bilateral lesions of the caudal IC. It was concluded that the IC contributes to both the IV-V wave complex and the negative deflection at 6.5 ms in the rat. Supported by NSF DBS-9200624 and the Deafness Research Foundation.

AUDITORY CORTICAL EVOKED POTENTIALS IN THE CAT: SENSITIVITY TO SMALL BINAURAL TIME DIFFERENCES. <u>I.B.</u> Kelly<sup>1</sup> and D.P. Phillips<sup>2</sup>. <sup>1</sup>Laboratory of Sensory Neuroscience, Dept. of Psychology, Carleton University, Ottawa, Ontario K1S 5B6 and <sup>2</sup>Departments of Psychology and Otolaryngology, Dalhousie University, Halifax, Nova Scotia B3H 4J1.

The effect of binaural stimulation on the amplitude of click-evoked cortical potentials was investigated in barbiturate-anesthetized cats. Recordings were made with silver ball electrodes placed on the cortical surface and time-locked responses were averaged on line to obtain measures of latency and peak-to-peak amplitude. Evoked response amplitude was found to vary as a function of the interaural time difference (ITD) between paired clicks delivered to the two ears. Generally, the response amplitude was greatest when the leading click was delivered to the ear contralateral to the recording site. However, there was considerable diversity among recordings in the shape of the binaural response curve and the magnitude of the change in response amplitude. For some recordings, the response was reduced as much as 30% as the ITD was shifted in favor of the ipsilateral ear. For others, the reduction was as little as 5%. The effect of ITD was reflected in the ratio of response amplitudes recorded from the two hemispheres. The of response amplitudes recorded from the two hemispheres. The dynamic range of ITDs over which response amplitude was found to vary was around 1000  $\mu s$  in the cat. Comparable ITD data from the albino rat revealed a larger depth of response modulation, typically more than 50% amplitude reduction, and a smaller dynamic range, approximately 500  $\mu s$ . These differences are presented in terms of neural mechanisms for binaural processing in the two species. Research was supported by NSERC grants to J.B.K. and D.P.P.

INTERICTAL CHANGES AND CENTRAL AUDITORY PROCESSING.

D M Daly\*. Box 210855, Dallas, TX 75211.
Focal seizures disrupt function of the cortical areas in which they occur. When balance of inhibitions declines/fails, patients with seizures involving auditory cortex have reported certain sets of synthesized stop-like sounds as nasals, 'bleats', and then undifferentiable buzzes<sup>1</sup>. We here report changes in central auditory processing during supervised withdrawal of medication.

A 22 year old man developed partial seizures characterized by translational vertigo, blurred vision, and difficulty comprehending (but not hearing) speech; head and eyes may deviate left and left upper extremity may elevate; he then briefly has difficulty finding words and may appear mute. Spells occurred when he was inactive or not alert. EEGs with sphenoidals revealed a sleep sensitive left mesial temporal spike focus and spike discharges over right frontal regions.

Auditory testing with concurrent EEG began 24 h after last medication (CBZ, VPA). Performance differed significantly (p<0.0001) from standards (16 healthy: 16 patients with CPS medically controlled at least 6 mo), and from patient's own controlled performance. Sounds the patient had previously classified as [be]-[de]-[ge] he reported now as 'bleats' or buzzes; on [ge]-[ye] the mid point of the boundary decreased 20 ms. These changes persisted over 100 min. From the EEG, spikes occurred infrequently after responses; on occasion bursts of spikes occurred in the interval between sets and stopped when testing resumed.

Results indicate that diminished inhibition, and even disinhibition can persist without overt electrical concomitants in EEG.

UNMASKING OF AUDITORY TARGETS AND ENHANCEMENT OF SELECTIVITY TO A SOUND LOCALIZATION CUE BY SIMULATED MOTION IN THE OWL'S INFERIOR COLLICULUS. TT Takahashi and CH Keller\*Inst. of Neuroscience, Univ. of Oregon, Eugene OR 97405.

We tested, at the neuronal level, whether motion facilitates the detection of acoustic targets, as it does visual targets. Auditory neurons in the central nucleus of the barn owl's inferior colliculus (ICC), due to their selectivity for interaural phase difference (ΔΦ), are tuned to the azimuth of sound-sources and form a topographic map of ΔΦ. While recording from single ICc neurons, we presented tones that simulated either moving or stationary sound sources with or without background noise. The neuron's ΔΦ-specific response, quantified by the vector strength (analagous to the standard deviation), served as a measure of the neuron's solity to detect the tone.

Results suggest that neurons of the ICc are capable of exploiting the motion of sound sources. Tones that mimicked a stationary source could be obscured by noise, as judged by a neuron's vector strength, but if the ΔΦ changed continuously thus mimicking motion, the neuron's ΔΦ-specific response re-emerged. The latter was not observed when the stimulus mimicked a stationary, amplitude-modulated tone-source, suggesting that a change of position was required rather than a simple time-varying stimulus. The cells also showed a higher selectivity for ΔΦ in the absence of noise if the target-tone simulated motion. These results suggest that the place-code for space in the ICc is of finer grain for moving sources.

These phenomena were demonstrated with tonal stimuli, thus they can be subserved by neuronal interactions within a single isofrequency layer of the ICc. Since modulations in ΔΦ, but not in amplitude, could produce these phenomena, it is likely that the mechanism itself involves interactions between cells that represent adjacent ΔΦ values. Quantitative Analysis of the Neurophonic Frequency-Following Potential in the Central Auditory Pathway of the Long-Evans Hooded Rat. D.S. Weiss\*and S. Reinis. Dept of Psychology, Univ of Waterloo, Waterloo, ONT, Canada, N2L 3G1.

The neurophonic potential (NP) was observed in the auditory pathway of the Long-Evans rat in the lateral lemniscus (LL), lateral superior olive (LSO), trapezoid body (TB), and inferior colliculus (IC). The NP was not observed in the medial geniculate body nor was it organized tonotopically in the IC. However, a rudimentary organization of NP frequency was observed along the rostrocaudal dimension. The rostral IC was characterized by low frequency NPs between 400 to 1900 Hz. The response at the central nucleus reached the upper limits of the sound system at 4500 Hz. More caudal aspects of the IC were characterized by NP frequencies between 600 to 2700 Hz. Bands of neurophonic activity in the IC were interspersed with regions of NP absence. The NP persisted following a small electrolytic lesion suggesting that volume conduction played a role in the local transmission of the NP. Lesioning the LSO or TB ipsilateral to the stimulus abolished the neurophonic from the contralateral IC. The mass activity of cells was evaluated using high resolution histograms and correlograms of interspike intervals. Raw wave-forms were passed through a narrow band digital filter to remove the neuro-phonic sinusoid. Histograms constructed from both filtered and unfiltered data were characterized by peaks at regular multiples of the stimulus period. Two consistent findings in the mass activity correlograms for the filtered data were (i) a significant dip near the origin of the graph, and (ii) the dip was followed by one or more significant peaks at multiples of the stimulus period. It is suggested that the NP was generated by a graduated fluctuation in the base line activity of an ensemble of fibers or cells phase-locked to the stimulus tone. These results are discussed in relation to the volley principle of hearing.

RATE REPRESENTATION OF SECOND FORMANT FREQUENCIES OF /E/-LIKE STEADY-STATE VOWELS IN CAT AUDITORY NERVE. R. A. Conley\* and S. E. Keilson Johns Hopkins Center for Hearing Sciences Baltimore, MD 21205

The encoding of steady-state vowels in the firing rate of auditory nerve fibers has been well studied (Sachs & Young, 1979; Sinex & Geisler, 1983; Miller & Sachs, 1983; Delgutte & Kiang, 1984; Delgutte, 1984; Deng & Geisler, 1987). These studies have shown that rate profiles from high spontaneous rate fibers encode formants of steady-state vowel stimuli at low to moderate sound pressure levels and that low and medium spontaneous rate fibers provide a good representation at high sound

In this study, coding of the second formant of the vowel  $/\epsilon$ / was studied in the auditory nerve using synthetic vowel stimuli. Alternate forms of  $/\epsilon$ / with second formant peaks located at 1400, 1700 and 2000 Hz were generated synthetically and used as stimuli. Responses of a population of auditory nerve fibers to these three stimuli were recorded at two sound levels, 50 and 70 dB SPL.

Plots of mean spike rate or normalized rate vs. fiber characteristic frequency (CF) show second formant peaks, even in the high spontaneous population at 70 dB. Such peaks decrease as sound level increases and as formant frequency is lowered. The formant peaks are clearly represented in plots of rate differences between two vowels. Such plots closely resemble the ratio of the magnitudes of the two vowel spectra. The results suggest that information concerning the position of vowel formant peaks is present in the spike rate of the auditory nerve. These data will be used to predict cats' performance in discriminating vowel second formant frequency. Supported by grants from NIDCD.

TOPOGRAPHIC REPRSENTATION OF MULTIPLE ACOUSTIC TARGETS BY A NEURAL NETWORK. MK Fleming, WJ Goodwin, and TT Takahashi\* Dept of Psych., Stanford Univ., Stanford, CA & Inst. of Neurosci., Univ. of Oregon, Eugene, OR.

The barn owl's inferior colliculus contains a visual-system-like map of space built from auditory units with spatial receptive-fields. Visual maps can easily represent more than one stimulus. In the auditory system, however, sound-waves from multiple sources will sum at the eardrums, and, if two or more sound sources broadcast common spectral components, the binaural cues for the shared components, such as interaural phase and intensity differences, assume values that are the vector averages of those frequencies from the individual sources. For an auditory space-map to represent multiple targets accurately, other cues are therefore required. We investigated whether the owl's auditory space-map could represent two acoustic targets, given that the two targets had some unshared spectral components. Using standard back-propagation algorithms we trained a two-layered network to parse simulated sound-sources into hotspots of neural activity along a one-dimensional space map. The input layer consisted of units, which, like the cells of the central inferior collicular nucleus (ICc), were selective for a frequency and an interaural phase difference (aΦ). Simulated sources at given spatial loci can be represented as a spectrum of ΔΦs by this input layer. The output layer, like the external inferior collicular nucleus (ICx), consisted of neurons that were selective for a particular aΦ spectrum. Following training, the network was capable of accurately representing the targets' number and locations on the one-dimensional space map, provided that the simulated sources broadcast some unshared frequencies were represented with differing amplitudes. Most interestingly, analysis of the connectional weights revealed a projection pattern between input and output layers that was strikingly similar to the known connecti

FREE FIELD RESPONSES OF CELLS TO STATIC AND MOVING SOUND STIMULI IN THE ANTERIOR ECTOSYLVIAN CORTEX (AEC) OF CATS. H. Jiang\*, P. Poirier, F. Lepore, M. Ptito, and J.-P. Guillemot. Groupe de Rech. en Neuropsy. Exp., Université de Montréal and Université du Québec, Montréal, Qué., Can. H3C 317.

The posterior part of the anterior ectosylvian cortex (AEC), surrounded by a number of auditory areas (AI, AII and AAF), has been shown to contain neurons which respond to different characteristics of auditory stimuli. In the present study, single unit activity was recorded along the banks of the posterior part of the anterior ectosylvian sulcus in anesthetized-curarized cats. The stimuli consisted of static bursts of broad band noise or simulated moving sounds emitted from a series of 16 loud-speakers each separated by approximately 10°. These speakers were located at the azimuth on a perimeter surrounding the animal's head in an anechoic room. Most of the units encountered responded to a static sound presented at each of the 16 positions (78° ipsilateral to 78' contralateral). They showed, however, mainly contralateral dominance. Various forms of responses were obtained, including on, off and poststimulus rebound responses. Some neurons showed long sustained discharges to a static or/and a moving sound. Those units showing discharges to a static or/and a moving sound. Those units showing directional selectivity responded more strongly to the onset of static sound stimuli presented in the appropriate hemifield. A feature analogous to velocity tuning was also observed in some of the motion sensitive units. The movement sensitivity and the long sustained post-stimulus cell discharges suggest that the AEC may be involved in the processes mediating stimulus induced action in animals.

NEURONAL RESPONSES TO FREQUENCY MODULATED SOUNDS IN THE ANTERIOR AUDITORY FIELD (AAF) OF THE CAT'S CORTEX. B. Tian\* and I.P. Rauschecker. Neuroethology Unit, NIMH, Poolesville, MD 20837, U.S.A. and

I.P. Rauschecker. Neuroethology Unit, NIMH, Poolesville, MD 20837, U.S.A. and Max-Planck-Institut für biologische Kybernetik, W.-7400 Tübingen, Germany. Frequency modulated (FM) sounds are important components of auditory communication signals in many different species, including birds, bats, and primates. In addition, FM sweeps are the auditory equivalent to moving bars or spots of light in the visual domain, which have proved so effective for the stimulation of visual cortical neurons. We have studied responses of neurons to frequency modulated sounds in the cat's anterior auditory field (AAF), which has been suggested on the basis of neurophysiological and anatomical data to be the first area in the ascending auditory cortical pathway begides A I/Roville ret at 1901.

neurophysiological and anatomical data to be the first area in the ascending auditory cortical pathway besides AI (Rouiller et al., 1991).

Neurons in AAF responded well to FM sweeps with rates ("speeds") between 4 and 600 Hz/ms. Almost half of the units (96/210–46%) responded best to the higher FM rates (high-pass neurons), only 4 % were low-pass units. Fourty-eight percent showed band-pass characteristics with a preference for a certain range of FM rates. The instantaneous frequency at the response peak generally matched the best frequency in the pure-tone tuning curve. However, one third of the neurons responded with multiple peaks when tested with FM sweeps, while most of them were broad-band tuned with a light was the tested with a light was the light was t single peak when tested with tone bursts. Two thirds of the neurons in AAF had a preference for one direction of the FM sweep over the other, when a 50%-criterion was

preterence for one direction of the FM sweep over the other, when a 50%-enterion was applied to the difference in both responses.

The anterior auditory field seems to specialize in the processing of fast-changing, transient sounds, since neurons in other cortical areas more often prefer slower rates of frequency and amplitude modulation (Mendelson & Cynader, 1985; Schreiner & Urbas, 1988). An analogy with the visual cortex of the cat and its parallel organization into areas with different velocity preferences (areas 17 and 18) is still speculative, but could be tested further with anatomical and physiological techniques. The involvement of AAF in the processing of transient sounds contained in speciesspecific or prey-specific vocalizations and in auditory spatial analysis has to be considered.

AUDITORY BRAINSTEM PROJECTIONS TO THE SUPERIOR COLLICULUS OF THE FERRET A.J. King\*, Z.D. Jiang and

D.R. Moore Lab. of Physiology, Parks Road, Oxford OX1 3PT, U.K.

The superior colliculus (SC) is not tonotopically organized, but, instead, contains a map of auditory space. We have identified the source of ascending projections to the SC in the ferret, a species in which the auditory representation has been extensively studied. The distribution of retrogradely labelled neurons in auditory brainstem nuclei was examined, following injections of either horseradish peroxidase or rhodamine- and green-latex microspheres into the deeper layers of the SC. The heaviest projections arose from the nucleus of the brachium and the external nucleus of the inferior colliculus (IC), although back-labelled neurons were also found in rostral regions of both the dorsal and ventral nuclei of the lateral lemniscus. While the input from the IC to the SC is predominantly ipsilateral, labelled neurones were found in all these auditory nuclei on both sides of the brainstem. Discrete injections of the tracers revealed a much larger projection to the caudal than the rostral region of the SC, although the distribution of labelled neurons was broadly similar in each case. However, few neurons were double-labelled following injections of both types of fluorescent microsphere into distinct regions of the SC.

These findings suggest that the generation of a map of auditory space in the SC may be based on a convergent input from several auditory nuclei in the brainstem.

CORTICAL RESPONSES TO CORRELATES OF AUDITORY MOTION: EFFECTS OF INTENSITY AND RATE OF INTENSITY CHANGE. J.M. Toronchuk and M.S. Cynader\*. Depts. of Ophthalmology & Psychology, University of British Columbia, Vancouver, British Columbia, Canada, V5Z 3N9.

We have previously demonstrated that neuronal response properties, such as phasic vs. tonic, onset vs. offset, monotonicity vs. non-monotonicity and E/E vs. E/I can act synergistically, suggesting underlying mechanisms for selectivity to binaural correlates of auditory motion. Using AM ramps presented to the two ears, we have further investigated subtle interactions of these response properties turther investigated subtle interactions of these response properties which enable certain cells to be selectively responsive to particular combinations of intensity changes in the two ears. By holding the rate and absolute level of intensity change in the contralateral ear constant and varying either the rate of intensity change or the absolute intensity of the AM ramp in the ipsilateral ear, we have found that response selectivity is influenced by the rate/intensity function of a cell's response to ipsilateral sound. Cells with non-monotonic interaction between the two ears may respond preferentially to specific rates of between the two ears may respond preferentially to specific rates of relative intensity change. Cells with both on and off responses may have different binaural interactions for the two components resulting in a further refinement of selectivity. Specific examples will be shown illustrating these effects. Thus, the response of a specific cortical cell to auditory motion is dependent on both absolute intensity difference and also relative rate of intensity change at the two ears. BINAURAL UNMASKING IN FERRETS. J.E. Hine, R.L. Martin and D.R. Moore'. University Laboratory Physiology, Parks Rd., Oxford OX1 3PT, U.K.

In humans it is well-known that the detectability of noise-masked low frequency tones in one ear can be enhanced by presenting the same masking noise to the other ear. We have developed a technique to show binaural unmasking in ferrets using three different free-field speaker configurations. Each task requires discrimination between a 500Hz tone-in-noise stimulus and a noise-alone stimulus. The tone-innoise is always presented from a speaker positioned 90° right of the ferret's head. The difference between the tasks lies in the presence and position of a second source of identical noise. If present, the second speaker is either placed 90° left or right of the animal's head.

Results have been obtained for four normal adult ferrets using positive conditioning procedures and a descending method of limits. The mean masked threshold for two speakers 90° right (64.5±1.8dB SPL) was significantly higher than both one speaker 90° right (57±0.7dB SPL, p<0.05) and two speakers placed 180° apart (54+2.2dB SPL, p<0.01). Thus, there is an improvement in detectability of the tone due to the angular separation of the second source of noise. Data from two of the same ferrets who underwent unilateral cochlear removal suggests that this improvement is due to binaural processing. We intend to use this paradigm to study the functional, binaural consequences of hearing loss.

### 353.18

RESPONSE LATENCY OF UNITS OF AUDITORY (A<sub>T</sub>) CORTEX AND THEIR ABILITY TO SUPPORT SHORT LATENCY AUDITORY CONDITIONED BEHAVIOR. E. Zotova, C.D. Woody, and E. Gruen. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA 90024.

Patterns of unit activity were recorded from A<sub>T</sub> during conditioned blinking produced by 70 db click CS (forward paired with glabella tap and hypothalamic electrical stimulation; 570-10ms ISI; see Hirano et al., Br. Res. 1987) but not by a backward paired hiss DS of comparable intensity.

Averages of activity from 136 units in 3 cats showed onset latencies of 8-12 ms of response to CS, but the magnitude of response in the first 16 ms after CS presentation did not change significantly after conditioning. Thus elicitation of short (20ms) latency blink CRs by this CS is not enhanced by transmissions through A<sub>T</sub>. Enhancement of the response to the CS in units of the motor cortex at latencies 8-12 ms after stimulus presentation must be sup-

latencies 8-12 ms after stimulus presentation must be supported by other pathways or changes.

Interestingly, the onset latency of spike discharge activity elicited by the same click CS at the level of the inferior colliculus was 12-16 ms, suggesting that some transmissions to A<sub>7</sub> by classical auditory pathways may be slower than previously thought. (Supported in part by The Deafness Research Foundation and The Univ. Calif. -St. Petersburg State University Exchange Program.)

A BINAURAL AFTEREFFECT THAT TRANSFERS FROM ONE EAR TO THE OTHER. Z. Shu\*, N. V. Swindale, C. A. Laszlo<sup>†</sup>, and M. S. Cynader, Departments of Ophthalmology and <sup>†</sup>Electrical Engineering, University of British Columbia, Vancouver, B.C., Canada V5Z 3N9.

Distortions of visual perception following prolonged exposure to an unvarying stimulus have been frequently observed. The most familiar of these is the motion aftereftect in which, after a few minutes of viewing objects moving in a single direction, a stationary object appears to move in the opposite direction. By using an auditory stimulus that has either a notch- or a peak-shaped spectrum with the position of the notch or peak varying with time peak-shaped spectrum with the position of the notch or peak varying with time over a certain frequency range, we demonstrated [Shu et al. (1991), Society for Neuroscience Abstracts 17:304] an auditory aftereffect analogous to the visual motion aftereffect. Particularly, we showed that after adapting to upward motion of a moving spectral peak, a stationary peak appeared to move downwards, and vice versa. By adapting to one ear and testing with the other ear we are now able to show that this aftereffect is binaural: After prolonged listening with one ear to a moving peak stimulus that repeatedly moves in one direction, a stationary peak heard by the other ear appears to move in the other direction.

In a two-alternative forced choice experiment the task of the listener was to judge the direction of motion of the peak in a test stimulus heard with one ear, after listening to an adapting stimulus with the other ear. Probit analysis was used to estimate the 50% response rate on the resulting psychometric funcused to estimate the sow response rate on the estiming psychorhetic unc-tion, giving a measure of the stimulus velocity which sounded stationary to the listener. Our findings suggest that the auditory system may have a previously unsuspected binaural sensitivity to the motion of peaks and troughs in the spectra of complex sound sources. Furthermore, the binaural nature of the observed aftereffect implicates that this sensitivity is due to neural processing in the central auditory system, after the site of binaural combination.

VOLTAGE-DEPENDENTSODIUM CURRENTS RECORDED FROM DISSOCIATED RAT TASTE CELLS. M.S. Herness. Lab. of Neurobiology & Behavior, Rockefeller University, New York, NY 10021.

A detailed description of voltage-dependent sodium currents, obtained with whole-cell patch-clamp techniques on cells dissociated from foliate and circumvallate papillae, is presented to better understand transductive mechanisms of taste receptor cells. Best estimates suggest that 50% of taste receptor cells possess these sodium currents which were similar in current-voltage, time to peak current, and h∞ relationships as well as tetrodotoxin-sensitivity. Currents activate around -50 mV, reach a maximal inward current of 250 - 700 pA at -10 mV, and have reversal potentials at approximately 60 to 80 mV (126 mM [Na\*]<sub>out</sub>). Maximal sodium conductance (3 to 12 nS) occurs at +10 mV. Instantaneous current-voltage relationships appear linear. Voltage-dependent inactivation becomes evident as low as -90 mV and is complete by -30 mV. About 20% inactivation would exist at a resting potential of -70 mV. Temporal dependence of inactivation appears long, often lasting seconds. These data help to delimit the expanse and puissance of membrane excitability available to taste receptor cells for gustatory stimuli response.

THE PERMEABILITY OF THE TASTE BUD AND LINGUAL EPITHELIUM TO HE PERMEABILITY OF THE LASTE BUD AND LINGUAL EPITHELIUM TO HORSERADISH PEROXIDASE AND LANTHANUM IONS IN GERBIL CIRCUMVALLATE PAPILLAE. K.S. Lu\* and M.H. Chen, Department of Anatomy, College of Medicine, National Taiwan University. Taipei, TAIWAN, ROC.

The permeability barrier of the lingual epithelium is still controversial and that of the taste bud remains an enigma. This paper reports a series of experiments in

which horseradish peroxidase (HRP) and lanthanum ions (La+3) were used as tracers to investigate the barrier properties of the lingual epithelium and taste buds. HRP was introduced (1) either topically on the dorsal surface or subepithelially into the connective tissue of circumvallate papillae and (2) intravascularly into the anterior jugular vein. La+3 was applied through intracardial perfusion. The subsequent fate of both tracers was followed with the electron microscopy.

In gerbil circumvallate papillae, the lingual epithelium on the dorsal surface of

the papilla is partially cornified and that on the trench wall is uncornified or slightly cornified. When introduced subepithelially, HRP was visible in the connective tissue and extended through basal lamina into (1) the intercellular space, but not beyond the apical intercellular junction of taste buds, (2) superficial layer of the trench wall epithelium, and (3) the granular layer of dorsal lingual epithelium. Intravenous injection of HRP revealed that HRP penetrated the fenestrated endothelium of connective tissue and extended into the taste bud and the lingual epithelium as in subepithelial studies. Topically applied HRP failed to cross the lingual epithelium and the apical intercellular junction of the taste pore. La<sup>+3</sup> deposited over the intercellular space of the taste bud and the lingual epithelium. The extent of La<sup>+3</sup> deposition was essentially similar to that of HRP administered subepithelially or intravenously.

essentiarly similar to that of HRP administered subeplinellally of intravenously.

These preliminary data suggest that a permeability barrier to HRP or La<sup>+3</sup> exists in the lingual epithelium of dorsal lingual surface as well as in the epithelium and taste buds on the trench wall of the circumvallate papillae. DIFFERENTIAL RESPONSE CHARACTERISTICS OF CHORDA TYMPANI SINGLE FIBERS TO SALT STIMULI IN 129/J AND C57BL/6J MICE. K. S. Gannon\* and R. J. Contreras. Program in Neuroscience, The Florida State University, Tallahassee, FL 32306-

129/J and C57BL/6J inbred mouse strains exhibit differential consumption of and preference for NaCl solutions. It has been well documented that 129/J mice have a significantly greater preference for 0.08M NaCl than C57BL/6J mice. In the rat, the chorda tympani for 0.08M NaCl than C57BL/6J mice. In the rat, the chorda tympani nerve, which innervates salt-sensitive taste receptors on the anterior tongue, is critical for the control of salt intake. Previously, we found that chorda tympani electrophysiological responses to NaCl were similar in the two inbred mouse strains. However, following treatment of the tongue with the sodium channel transport blocker, amiloride hydrochloride, strain differences appear which may underlie the behavioral difference in sodium consumption seen in 129/J and C57BL/6J mice. Amiloride inhibition of the chorda tympani response to NaCl was significantly greater in C57BL/6J mice than in the salt-preferring 129/J mice. Until now, only whole nerve recordings have been obtained from the chorda tympani in these two strains of mice. To obtain a comprehensive understanding of peripheral gustatory neural coding of salt stimuli, salt-sensitive fibers within the chorda tympani need to be identified and their individual responses measured. At present, our research is devoted to assessing the response characteristics of single chorda tympani units to NaCl, KCl, and NH4Cl in 129/J and C57BL/6J mice before and after amilioride treatment of the tongue. (Supported by NIH grant amiloride treatment of the tongue. (Supported by NIH grant HL38630).

EFFECTS OF ACID STIMULI ON ISOLATED HAMSTER TASTE CELLS. T.A. Gilbertson\*. S.D. Roper and S.C. Kinnamon. Dept. of Anatomy and Neurobiology, Colo. State Univ., Ft. Collins CO 80523 and Rocky Mtn. Taste and Smell Center, UCHSC, Denver, CO 80262.

and rocky Min. Taste and Shell Center, UCHSC, Deliver, CO 80262.

The transduction of acid (sour) stimuli has been suggested to involve a variety of mechanisms including block of apical K+ channels, gating of Ca<sup>2+</sup> channels and changes in intracellular pH. Using a non-invasive recording technique, we recently showed indirect evidence suggesting that protons can permeate amiloride-sensitive (AS) Na+ channels causing taste cell excitation (Gilbertson et al. Soc. Neurosci. Abs. 17: 1216). To provide direct evidence that protons can permeate the AS Na+ channels, we have recorded whole-cell currents in taste Abs. 17: 1610. To provide threct evidence that protons can permeate the AS Na+ channels, we have recorded whole-cell currents in taste cells isolated from hamster fungiform taste buds. In an extracellular solution containing 140 mM NaCl, approximately half of all cells exhibit amiloride-sensitive currents. To test for the presence of a direct proton current, cells were placed in an extracellular solution containing 0 mM Na+ and 20 mM TEA to eliminate Na+ and K-currents, respectively. In over two-thirds of cells tested, pressure application of citric acid (pH 4.5) directed toward the cells' apical membrane elicited an inward current apparently carried by protons (mean amplitude  $\pm$  S.E. = 13.8  $\pm$  3.6 pA). At all physiological potentials (-100 to +20 mV), this current was inward, consistent with it being a proton current (Erev = +150 mV @ pH 4.5). In most cells, amiloride (30  $\mu$ M) completely blocked the proton current suggesting that protons were permeating the AS Na+ channels. In taste cells showing no amiloride sensitivity, acid stimuli decreased a standing current. This was accompanied by a decrease in the cell membrane conductance. Amiloride had no effect upon this reduction in current. Thus, protons may affect a variety of apically localized ion channels in taste cells, all of which may contribute to the detection of acid stimuli.

DIFFERENCES IN MATERNAL NACL INTAKE ALTER THE TERMINAL FIELD ORGANIZATION OF TASTE AFFERENTS IN THE NUCLEUS OF THE SOLITARY TRACT OF ADULT RATS. Robert J. Contreras\* I. L. Vandevelde, and E. K. Basco. Florida State University, Department of Psychology, Tallahassee, FL 32306-1051. Using horseradish peroxidase (HRP) anterograde transport, King & Hill (J. Comp. Neurol. 303: 159-169, 1991) have recently shown that the distribution of chorda tympant afferents within the nucleus of the solitary tract (NST) was altered in adult rats exposed to a sodium-deficient diet from the third day of gestation to postnatal day 35. It is well established that the chorda tympani nerve, which innervates salt-sensitive taste receptors within the anterior tongue, is critical for the control of salt intake in the rat. Our prior research indicates that the amount of NaCl consumed by adult rats is linearly related to the level of dietary NaCl their mothers consumed during pregnancy and lactation. Differences in NaCl intake are more striking when the adult offspring are examined after sodium depletion. We hypothesize and lactation. Differences in NaCl intake are more striking when the adult offspring are examined after sodium depletion. We hypothesize that there is a sensitive period in development when maternal NaCl intake can influence the terminal field organization of salt taste neurons within the brain, critical in determining long-term levels of NaCl ingestion under conditions of sodium repletion and depletion. Adult female rats were fed diets containing either basal 0.15% or high 3% levels of NaCl from conception to postnatal day 30. The offspring were then fed mid 1% NaCl for at least 2 months before analysis. The central terminal field of taste afferents was assessed after anterograde transport of wheat germ HRP applied to the central analysis. The central terminal field of taste allerents was assessed after anterograde transport of wheat germ HRP applied to the central end of the chorda tympani of 10 rats. Our preliminary analysis of 6 cases (3 basal & 3 high NaCl) indicates that there is a re-distribution of afferent terminal labelling among the dorsal, intermediate, and ventral zones of the NST. (Supported by NIH grant HL38630).

AN IN VITRO ASSAY FOR IRRITANTS. ELECTROPHYSIOLOGICAL PROPERTIES AND CHEMICAL REACTIVITY OF TRIGEMINAL (GASSERIAN) NEURONS IN TISSUE CULTURE. <u>J.Eugenin\*</u>, <u>S. Roberts</u>, <u>S. Carlyle</u>, <u>K. Rapp</u>, <u>and</u> R.P. <u>Tuckett</u>. Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, UT 84108, U.S.A.

Enzymatically dissociated trigeminal ganglion (TG) neurons from neonatal Sprague Dawley rats were plated on collagen coated dishes and cultured in DMEM/KGM (20/80) supplemented with 2% HS, 2% FBS, 2.3 mM sodium blcarbonate, 4.4 mM Hepes and 0.1 (μg/ml) 7-S NGF at 37 °C, 100% humidity and 5% CO2 in air.

After 3-12 days, membrane properties were measured in 142 units (membrane potential, 44.5 ± 0.6 mV; input resistance 41.9 ± 2.3 Ma; input capacitance 77.0 ± 3.5 pF; time constant 3.1 ± 0.5 ms, mean ± SEM). Depolarizing electrical pulses (5 ms) evoked action potentials (APs) 74.8 ± 0.9 mV in amplitude and  $6.8 \pm 0.2$  ms in duration, followed by afterhyperpolarization of  $7.9 \pm 0.3$  mV and  $99.19 \pm 9.5$  ms in duration. Forty four percent of cells showed time-dependent rectification to inward current and 63% generated multiple (2-4) APs to suprathreshold depolarizing pulses (100 ms). Chemicals pressure injected into the surrounding environment produced depolarization (up to 40 mV), depolarization plus APs, or APs only. Over 50% of tested neurons responded to administration (30 s) of either 1 µM capsalcin or 90 pM bradykinin. About 15% and 50% responded to administration (250 ms) of 10 mM serotonin and 300 µM histamine, respectively. TG neurons also responded to irritant substances such as hydrazine (60 pM) and nonadecafluorodecanoic acid (1

These findings support the notion that TG neurons in culture form an heterogenous, chemosensitive population and suggest that cultured sensory neurons can be used as a model for studying cellular mechanisms of irritancy

A CALCIUM-DEPENDENT ANION CONDUCTANCE IN NECTURUS TASTE RECEPTOR CELLS. Randall S. Taylor & Stephen D. Roper\* Dept. of Anat. & Neurobiol., Colorado State University, Ft. Collins CO 80523 and The Rocky Mtn Taste & Smell Center, Deriver CO 80262.

It was first shown in 1983 that taste cells are excitable and thus possess voltage-dependent tonic conductances. Kinnamon and Roper (J. Gen. Physiol., **91**:351. 1988) demonstrated the presence of a Ca<sup>2+</sup>-dependent K+ conductance in *Necturus* taste receptor cells. McBride and Roper (J. Memb. Biol. 124:85. 1991) demonstrated that taste cells also possess TEA-insensitive, Ca<sup>2+</sup>-dependent currents that were affected by altering the chloride equilibrium potential. Although the data were indirect, they concluded that taste cells possess a Ca<sup>2+</sup>altered by attering the chloride equilibrium potential. Although the data were indirect, they concluded that taste cells possess a Ca<sup>2+</sup>-dependent Cl<sup>-</sup> conductance in addition to the other ionic conductances previously described. Here we report the results of whole-cell patch-clamp studies on this presumptive Ca<sup>2+</sup>-dependent Cl<sup>-</sup> current. Upon depolarization of taste cells in thin lingual slices or of isolated taste cells, we have recorded a Ca<sup>2+</sup>-dependent Cl<sup>-</sup> current in Necturus taste cells. That is, after replacing all permeant ions but Na<sup>+</sup>, Ca<sup>2+</sup> and Cl<sup>-</sup> and adding TTX to the bath (bath: 96 mM NaCl, 20 mM CaCl<sub>2</sub>, 10 mM HEPES; patch pipette: 140 mM NMDG-tartrate, 10 mM NaCl, 1 mM MgCl<sub>2</sub>, 0.1 mM EGTA (=10<sup>-8</sup> M Ca<sup>2+</sup>), 5 mM ATP, 0.5 mM GTP, 0.5 mM cAMP, 5 mM HEPES), we found a slowly activating outward currenting outward current that disappeared when Cl<sup>-</sup> was replaced with isethionate or other impermeant anions. The outward current was also eliminated when Ba<sup>2+</sup> was substituted for Ca<sup>2+</sup>, even in the presence of Cl<sup>-</sup>. The pharmacology of these chloride channels is the next step in understanding the role these channels may play in taste transduction. We speculate that Ca<sup>2+</sup>-dependent Cl<sup>-</sup> currents may be involved in distinguishing between the taste of salts that have different anion compositions. SELECTIVITY OF LINGUAL FIBERS TO CHEMICAL STIMULI ON RAT TONGUE. Y. Wang and S. A. Simon\*. Department of Neurobiology, Duke University, Durham, NC 27710.

The mechanisms by which chemical stimuli enter lingual epithelia and elicit responses from lingual fibers are largely unknown. To obtain such information, single unit extracellular recordings from 88 rat trigeminal ganglion cell bodies were measured in response to chemical stimuli flowed over rat tongue. Fiber types were identified by measurements of conduction velocity and responses to memeasurements of conduction velocity and responses to mechanical and thermal stimuli. Chemical stimuli included NaCl, KCl, NH4Cl, CaCl2, LaCl3, nicotine, hexanol, capsaicin and menthol. About 75% of C fibers, 25% of A $\delta$  fibers and 0% of A $\delta$  fibers responded to hyperosmotic (to 2.5 M) concentrations NaCl, KCl and NH4Cl. In contrast, no responses were elicited by CaCl2 (to 1.0 M) and LaCl3 (1.0 M). Thus, the irritating and/or painful sensations elicited by these salts arise only from C and A $\delta$  fibers.

The responses to these monovalent salts were reversibly inhibited by 3.5 mM LaCl3. These data suggest that La+++ blocks tight junctions in lingual epithelia, thus preventing salts from diffusing into the epithelia where they can interact with C and A $\delta$  fibers. Also consistent with this interpretation is that La+++ does not inhibit the responses menthol and hexanol which permeate the epithelia by partitioning into plasma and axonal membranes. Work  $\boldsymbol{w}$  supported by NIH DC0165 and from the Smokeless Tobacco Research Council.

IMP AS STIMULUS IN PARAMECIUM CHEMORECEPTION. J. L.

IMP AS STIMULUS IN PARAMECIUM CHEMORECEPTION. J. L. Van Houten\* and W. Q. Yang University of Vermont, Dept. of Zoology, Burlington, VT 05405-0086.

Paramecia are attracted or repelled by chemical stimuli. Generally attractants are fermentation or other bacterial products that function as food cues. Repellents seem to signify non-optimal pH or ionic strength. IMP is a stimulus for paramecia and, because it is an indication of bacterial action on food (used in the fish industry) it could serve as a food cue for paramecia. Instead, it seems to repel the cells. The behavioral responses to IMP in T-mazes are inhibited by GMP or AMP but not by cAMP or CMP. Interestingly, K-glutamate also inhibits, drawing a parallel with putative MSG taste.

FINE STRUCTURE OF TASTE BUDS ON THE LAMB EPIGLOTTIS. R.D. Sweazey, C.A. Edwards and B.M. Kapp. School of Dentistry, University of Michigan, Ann Arbor, MI 48109.

Previous investigations have described in detail the fine structure of taste buds located in the oral cavity and aryepiglottal folds. However, similar detailed information is currently lacking for taste buds located on the laryngeal surface of the epiglottis. Therefore, we examined the fine structure of taste buds on the lamb epiglottis using electron microscopy. Five lambs aged 30-45 days were perfused using a modified Karnovsky's fixative, the epiglottis removed and processed to epoxy using standard procedures. Thin sections of epiglottal taste buds were examined by T.E.M. Taste buds were located in small groups and ranged in size from 25-35 um. In addition to undifferentiated basal cells, three general groupings of cells similar to those previously observed in taste buds of the oral cavity could be distinguished. Type I cells were most numerous and contained typical apically located membrane-bounded dense vesicles, numerous free ribosomes and rough endoplasmic reticulum, spindle shaped nuclei with numerous small invaginations, and numerous slender microvilli projecting into the taste pore. Type II cells contained no apical membrane-bound vesicles, had less rough endoplasmic reticulum, spherical nuclei, and small numbers of blunt microvilli projecting into the pore. Type III cells had round to oblong nuclei that were frequently deeply invaginated, large numbers of vesicles ventral to the nucleus, and a peg like apical projection into the taste pore. In addition to these different cell groups, numerous small nerve processes were observed adjacent to all three cell types. In many of these nerve-cell boundaries synaptic-like thickenings of the membrane and clear and dense-cored vesicles could be identified. Our results suggest that the fine structures of taste buds located on the epiglottis is similar to those previously observed in taste buds of the oral cavity and aryepiglottal folds. Supported by N.I.H. Grant DC00735.

VOLTAGE CLAMP STUDIES OF THE AMILORIDE-INSENSITIVE NEURAL RESPONSE. Q.YE. G.L.Heck., D.L.Hill and J.A.DeSimone. Dept. of Physiology, VCU, Richmond, VA 23298. Dept. of Psychology, UVA, Charlottesville, VA 22903.

rhystology, Vol., Richmond, VA 22296. Dept.01 Fsychology, OVA, Charlottesville, VA 22903.

The chorda tympani (CT) response of many mammals to Na\* salts is anion dependent. This anion effect is mediated in part by anion-dependent field potentials set up across apical shunt pathways [1]. In these studies, we found another anion effect which was related to the amiloride-insensitive component (AIC) of the Na\* salt CT response [2]. The AIC is negligible for non-chloride salts and for NaCl at concentrations under about 50mM. Accordingly the neural responses to 25mM NaCl and sodium gluconate (NaGlu) were identical at any clamping voltage, with enhancement at negative voltages and suppression at positive voltages. At 90mV the suppressed response approached the AIC. At 0.2M, NaGlu and NaCl responses converged at -60mV, however, at more positive voltages NaCl responses exceeded those of NaGlu. At 90mV the NaCl response approached the AIC for NaCl. Furthermore, the AIC was independent of voltage at any NaCl concentration. The voltage-independence of AIC can be explained by an electroneutral penetration of NaCl across the shunt barrier giving NaCl access to basolateral channels or possibly to cells without an apical projection. The existence of Na\* channels on the basolateral side of the taste bud can be demonstrated immunohistochemically and supports shunt penetration as a second stimulation mechanism available to NaCl but supports shunt penetration as a second stimulation mechanism available to NaCl but not other Na\* salts. Studies of the voltage sensitivity of the CT in rats deprived of Na\* throughout development, which exhibit no amiloride sensitivity, may help us to understand the Na\* salt taste mechanism in depth. (Supported by NIH grant DC 00122)

CLONING THE PLASMA MEMBRANE CALCIUM PUMP GENE IN PARAMECIUM. N.L. Elwess\*, G. Mawe\*, and J.Van Houten\*. 
#Dept. of Zoology, \*Dept. of Anatomy and Neurobiology, University of Vermont, Burlington, VT, USA 05405

of Vermont, Burlington, VT, USA 05405

Paramecium can detect metabolites of bacteria, its food source. These attractants are thought to be detected through one of at least two chemosensory transduction pathways found in Paramecium, the one which seems to involve a plasma membrane calcium pump. Attractants hyperpolarize the plasma membrane and, for most attractants, this hyperpolarization appears to be dependent upon a pump current, such as from a calcium plasma membrane pump. Through the use of the polymerase chain reaction, we have identified sequences which seem to represent a family of ion translocation ATPase genes. This family of ion pump genes is not just restricted to the plasma membrane calcium pump that we believe is involved in chemoreception, but should include other calcium pumps, such as those found on the ER, mitochondria, and alveoli (a specialized calcium sequestering organelle of ciliates). Therefore, to ensure that the gene of interest is the plasma membrane calcium pump primers for PCR were designed to include the calmodulin binding domain which is unique to the plasma membrane calcium pump pamp other calcium pumps. PCR products of the appropriate size as judged from published mammalian plasma membrane pump sequences are being sequenced. Cloning the plasma membrane calcium pump gene should provide the necessary and sequence information to produce nucleotide probes and antibodies against peptides to more directly localize the pump and determine its role and function in the chemosensory transduction pathway.

DIRECT INPUT FROM PRIMARY SOMATOSENSORY CORTEX TO PYRAMIDAL TRACT CELLS IN THE RAT MOTOR CORTEX. T. Xiong\* and L.L. Porter. Dept. Anat. & Cell Biol., USUHS, Bethesda, MD 20814.

The connection between axons arising from primary somatosensory cortex (SI) and pyramidal tract (PT) cells of the motor cortex was investigated in adult rats. The anterograde tracer, Dextran Tetramethylrhodamine (DT) was injected into the electrophysiologically tracer, injected into the electrophysiologically identified forelimb representation of SI. Fast Blue (FB) was stereotaxically injected into the medullary corticospinal tract to identify PT cells. The dendritic arbors of the PT cells were visualized by intracellular injection of Lucifer Yellow into FB labeled PT cells of the motor cortex in lightly fixed tissue slices (150µm, cortex in lightly fixed tissue slices (150µm, sagittal plane) under fluorescence microscopy. The DT injection resulted in patch-like labeling in motor cortex. Most labeling was found in layers II-III with some in layers V-VI. Boutonlike swellings along DT labeled axons were often found apposed to both the apical and basal dendrites of PT cells, indicating synaptic connectivity. Our results suggest that PT cells receive direct input from SI. Thus the activity of the motor cortex output neurons may be influenced by this projection.

INPUT-OUTPUT ORGANIZATION OF THE RAT VIBRISSAE MOTOR CORTEX. E. Miyashita<sup>1</sup>, H. Asanuma<sup>1\*</sup> and A. Keller<sup>2</sup>. <sup>1</sup>The Rockefeller University, New York, NY 10021, <sup>2</sup>Dept. Anatomy, USUHS, Bethesda,

In order to study cortical control mechanisms of the rat vibrissae motor area, retrograde and anterograde tract tracing techniques were used to define the input-output organization of the rat were used to define the input-output organization of the rat vibrissae motor area. Wheat germ agglutinin conjugated horseradish peroxidase (Sigma type VI, 3% solution) or *Phaseolus vulgaris* leucoagglutinin (Vector Lab., 2.5% solution) were injected iontophoretically into physiologically defined rat vibrissae motor area. The rat vibrissae motor cortex was defined using intracortical microstimulation method (10 trains of 300 Hz, 250  $\mu$ sec pulses; etimular streagth  $\epsilon = 50 \mu \Delta l$ ) stimulus strength  $< 50 \mu A$ ).

The rat vibrissae motor area had reciprocal connections with the lateral agranular cortex (AGI) in the contralateral side and the ipsilateral somatosensory cortex (SCx). Labeling in the vibrissae region of the SCx consisted of several distinct patches. In the thalamus, it had dense reciprocal connections with the dorsolateral part of the ventral lateral nucleus and the ventrolateral part of the intralaminar nucleus and less dense reciprocal connections with the ventromedial nucleus. Labeled terminals were found mainly in the dorsolateral part of the striatum, the intermediate and deep layers of the superior colliculus, the lateral part of the central gray, the mesencephalic reticular formation, the parvocellular portion of the red nucleus, the pontine nucleus, and the pontine reticular formation. Especially in the pontine nucleus, the labeled terminals formed discrete dense patches. Supported by NIH grants NS 31078 and NS 10705.

# 355.5

PHYSIOLOGICAL HETEROGENEITY OF IDENTIFIED NON-PYRAMIDAL CELLS IN RAT FRONTAL CORTEX  $\underline{Y}$ . Kawaguchi\* and Y. Kubota. Lab. for Neural Systems, Frontier Research Program, RIKEN, Wako 351-01, Japan

Physiological and morphological properties of layer V non-pyramidal Physiological and morphological properties of layer V non-pyramidal cells were studied in slices of rat frontal cortex by whole cell, current-clamp recording and intracellular staining by biocytin. One class (fast-spiking (FS) cells) had input resistances lower than 400 M $\Omega$  and spikewidths at half amplitude shorter than 0.8 ms; the other (low-threshold spike (LTS) cells) had higher input resistances than 400 M $\Omega$  and spikewidths longer than 0.8 ms. Afterhyperpolarizations (AHPs) following action potentials consisted of a single component in FS cells, but two components with early and late peaks were observed in LTS cells. AHPs of FS cells had faster time-to-peak and larger amplitude than the early component of the AHPs of LTS cells. Low threshold spikes were observed in hyperpolarized potentials in LTS cells, not in FS cells. Spike trains elicited by depolarizing pulses in FS cells showed almost no spike-frequency adaptation, while those in LTS cells showed adaptation. A combination of stimulation-induced EPSPs with depolarization caused repetitive firing in FS cells which was abolished by NMDA receptor blockers. Repetitive firing was not observed in LTS cells under these conditions. Dendrites of FS cells were mostly smooth, but those of LTS cells possessed a modest but consistent population of spines. Axons of FS cells tended to run horizontally along layers and on this basis some resembled basket cells. Axons of LTS cells were more vertically oriented and extended in columnar fashion through layers I to VI. These suggest layer- and column-specific differentiation of neocortical intrinsic neurons with different firing modes.

CONNECTIONS OF VIBRISSAL REGIONS IN RAT SENSORY-MOTOR CORTEX. L.L. Porter\*, R. Izraeli. Dept. of Anat. & Cell Biol., USUHS, Bethesda, MD 20814.

Projections to the vibrissal region of motor cortex were studied in the rat as a step toward understanding information processing in the sensory-motor cortex. Intracortical microstimulation (ICMS) was delivered to the motor cortex of lightly anesthetized rats. Tungsten-in-glass microelectrodes were used to identify sites at which movement of a single vibrissa was elicited by low threshold current (5-20  $\mu$ A). The number of vibrissae which moved depended on the level of anesthesia. A WGA-HRP (2.5%) filled pipette (15 μm) was placed into the site of stimulation and a small amount of the tracer was delivered by iontophoresis. Series of alternate sections were cut in the coronal or tangential plane and processed for HRP or cytochrome oxidase. Retrogradely labeled cells were observed in the ipsilateral barrel field of SI. They were organized in a columnar array with cells in both supragranular and infragranular layers. Analysis of adjacent cytochrome oxidase stained sections revealed that labeled cells were aligned with barrel structures representing the vibrissae. They were not restricted to the barrel corresponding to the whisker which responded to ICMS in motor cortex, but spread to adjacent barrels. Labeled neurons were also found lateral to the barrel field, in the second somatosensory cortex. Here, label was diffuse but extensive and bilaminar. In addition, labeled cells were observed in the ipsilateral thalamus and in the contralateral vibrissal motor cortex. Future studies will be performed to determine the functional role of sensory cortex input on motor cortex activity. Supported by NIH Grant No. NS 27038.

## 355.4

MEASUREMENT OF LESION PARAMETERS FOR STUDIES OF MOTOR RECOVERY AFTER SENSORIMOTOR CORTEX INJURY IN THE RAT. L.B. Goldstein\* and R. Kamis. V.A & Duke Medical Centers, Durham, NC 27705

The ability of rats to traverse a narrow elevated beam has been used to quantitate recovery of hindlimb motor function after unilateral sensorimotor cortex injury. Lesion extent is an important variable to consider in studies of the effects of drugs on beam-walking recovery. consider in studies of the effects of drugs on beam-walking recovery. However, histologic evaluation precludes neurochemical measurements in brain tissue. The present study was carried out to determine how well the dimensions of cortex lesions measured at the surface of the brain correlate with beam-walking recovery in comparison with standard histology. After behavioral training, rats (n=20) underwent suction-ablation of the right sensorimotor cortex. Beam-walking was measured over the next 12 days. The maximum medial extent of the lesion (closest approximation of the lesion to the inter-hemispheric fissure) and lesion surface area were measured from digitized images of the dorsal surface of each brain. Maximum % cingulate cortex damage and lesion volume were each brain. Maximum % cingulate cortex damage and lesion volume were measured from serial coronal histologic sections. Both lesion maximum medial extent and maximum cingulate cortex damage (r=0.83 and 0.76, p=0.0001, respectively) but not lesion surface area or lesion volume (r=0.27, p=0.27 and r=0.43, p=0.06, respectively) were correlated with beam-walking recovery. Measurement of lesion surface maximum medial extent also was reliable (intra- and inter-observer reliability were r=0.82 and 0.82, p=0.0001, respectively). Lesion surface maximum medial extent provides a valid and reliable measure for studies of beam-

walking recovery after sensorimotor cortex suction-ablation injury. Supported by the N.I.H. (NS 01162) and the V.A.

FURTHER EVIDENCE THAT THE RETICULAR FORMATION IS THE MAJOR SOURCE OF MEP IN THE RAT. J.-H. Sohn\*, B.R. Park1, J.J. Kim<sup>2</sup>, K.S. Cho, J.H. Kim The Miami Project To Cure Paralysis, Dept. of Neurol. Surg., Univ. of Miami, Miami, FL 33136, <sup>1</sup> Dept. of Physiol., Won Kwang Univ., Iri, Korea <sup>2</sup> Dept. of Anat., Chosun Univ., Kwangjoo, Korea Motor evoked potentials (MEPs) produced by electrical stimulation of rat

sensorimotor cortex (SMC) have been shown to originate from the reticular formation (RF). However, the possibility that other brain structures might also be activated during SMC stimulation has not been completely ruled out. The object of this study was to investigate whether any component of the MEPs originates from activation of red nucleus (RN) and/or vestibular nucleus (VN). Evoked potentials (EPs) were monitored epidurally from 20 Sprague-Dawley female rats (250-300 g) at T10 and L3 spinal cord levels, using two pairs of teflon-coated wire electrodes with a 1 mm exposed tip. The right SMC was stimulated using a screw (0.5 mm in diameter) while RN, VN and RF were stimulated through microelectrodes placed stereotaxically in the target nuclei. A striking similarity was found in waveform and conduction velocity between MEPs and RF-EPs. Selective spinal cord lesions placed at T8 to disrupt either rubrospinal or vestibulospinal tracts did not affect the amplitudes and latencies of MEPs. However, lesion of the ventral cord dramatically reduced the amplitudes and conduction velocities of both MEPs and RF-EPs. Intracerebral injection of local anesthetics, which blocked RN-EP or VN-EP, did not alter either the amplitudes or latencies of the MEPs, indicating that RN and VN do not contribute to MEPs generated by cortical stimulation. The results indicate that the MEPs originate from the reticular formation and conduct along the ventral funiculus. PRESYNAPTIC ACTION OF 5-HYDROXYTRYPTAMINE IN RAT CORTICAL NEURONS. E. Tanaka, H. Hasuo\* and R. A. North

Vollum Institute, Oregon Health Sciences
University, Portland, OR 97201.

Intracellular recordings were made from layer
V neurons of the rat anterior cingulate cortex Electrical stimulation of the in vitro. Electrical stimulation of the subcortical white matter or layer V evoked synaptic potentials with four components; fast epsps blocked by CNQX, fast epsps blocked by APV, fast ipsps blocked by bicuculline (500 nM - 10 \mu M), a slow ipsps blocked by saclofen (100 \mu M). 5-HT(1 -300 \mu M) reduced the amplitude of the epsps; this was concentration-dependent with a 50% reduction at about 23  $\mu M$ . Both CNQX-sensitive and APV-sensitive components were equally inhibited by 5-HT; the GABA, and GABA, components were not affected. Depolarizations evoked by brief superfusion of glutamate were not affected by 5-HT. The presynaptic inhibition of epsps was blocked by cyanopindolol (100 nM), and was mimicked by TFMPP (100 - 300 nM). These results show that glutamate terminals express 5-HTI<sub>B</sub> receptors, activation of which presynaptically inhibits transmitter release.

NEURAL FIRING PATTERNS IN CULTURES OF RAT CEREBRAL CORTEX. T.S. Donta\* and J.A. London. Division of Neurological Sciences and Dept. of Biostructure and Function, University of Connecticut Health Center, Farmington, CT 06030.

We have been characterizing the suitability of slices of rat cerebral cortex maintained in vitro for multiple-site optical recordings using voltage-sensitive dyes and a photodiode array. The goal is to observe how the activities of neurons from different cortical layers are synchronized, and to then infer a role for this activity in cortical processing. Anatomical analysis has shown that normal cortical cell types exist in the cultures, and that cortical layering is maintained in vitro for two to three weeks. Reported here are some typical neural firing types found using extracellular glass electrodes. Recordings from cultures of somatosensory (SI) and agranular insular cortex (AI) were made. Spontaneous activity, and activity after bath application of Lglutamate has been recorded. Regularly spiking neurons with firing rates of 30-100 Hz were found, as well as bursting neurons. Neurons firing doublet spikes were also seen. Both regularly spiking neurons and bursting neurons were found in SI and AI, and regularly spiking neurons were recorded from more often after addition of L-glutamate. These types of activities are consistent with activities found in vivo. Combined with multi-site optical electrophysiology, the in vitro cortical model has considerable potential for studying cortical function. INVOLVEMENT OF D1 DOPAMINE RECEPTORS IN PREMOTOR AND MOTOR CORTICAL FUNCTIONS IN MONKEYS. T. Sawaguchi\*, I. Yamane, and K. Kubota. Dept. of Neurophysiol., Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, Japan.

To examine the roles of dopamine receptors in cortical motor functions, selective dopamine antagonists (SCH23390 for D1 and sulpiride for D2 receptors) were locally injected into premotor and motor cortices of two rhesus monkeys who performed a reaching task with their arms. The monkeys initiated the task by pressing a central lever. After receiving a visual go signal, they then released the lever and reached out to one of three target locations (left, upper, or right) that had been indicated 2-5 s before. Local injections of SCH23390 (10-50  $\mu$ g/3-5  $\mu$ l) into postarcuate areas of the premotor cortex (over 10 sites) increased reaction time (from the go signal to movement onset), decreased the frequency of task trials and created no clear change in reaching time (from movement onset to offset). SCH23390 injections into hand-arm areas of the motor cortex (over 7 sites) increased the reaching time without clear change in the reaction time or the frequency of task trials. By contrast, injections of sulpiride (50 µg) or SCH23388 (50 µg, an inactive analogue of SCH23390) into the effective sites by SCH23390 in either the premotor or motor cortex had no clear effects on task performance. These results suggest that the activation of D1 dopamine receptors is normally involved in the functions of the premotor and motor cortices; i.e., initiation of directional reaching movements for the premotor cortex and motor execution for the motor cortex.

NEUROTROPHIN INDUCTION IN THE ADULT RAT BRAIN FOLLOWING ADMINISTRATION OF THYROID HORMONE. J. B. Pan\*, D. Casuto, S. Watanabe, S. P. Arneric, and T. Giordano. Neuroscience Research,

Abbott Laboratories, Abbott Park, IL 60064.

Neurotrophins, in particular NGF, have been proposed as a potential therapy in the treatment of Alzheimer's disease; however, the size of these compounds preclude their passage across the blood brain barrier. Induction of the neurotrophins by small molecules may circumvent this problem. In this study rtPCR was used to measure the abundance of NGF, BDNF, and NT-3 RNA relative to that of cyclophilin RNA following peripheral administration of thyroid hormone (TH) to aged (20-22 month old) male Sprague-Dawley rats. NGF and NT-3 exhibited a statistically significant increase (+50%, p<0.05) in the hippocampus relative to cyclophilin following TH administration. These increases did not correlate with an increase in ChAT activity, an enzyme which had been shown to be enhanced by NGF and BDNF, in the hippocampus. In the cerebral cortex, TH administration increased levels of all neurotrophins (49%-NT-3; 30%-NGF; and 30%-BDNF), but these effects were not statistically significant, whereas ChAT activity did demonstrate a statistically significant increase (28%, p<0.01). The fact that BDNF statistically significant increase (28%, p<0.01). The fact that BDNF did not increase significantly in either region was supported by the absence of a thyroid responsive element in the upstream region of the BDNF gene. These results indicate that TH administration was capable of co-ordinately increasing the accumulation of NGF and NT-3 transcripts thus offering the potential of modulating multiple neurotrophin systems with a single small molecule.

IMMUNOHISTOCHEMICAL ANALYSIS OF THE ACETYLCHOLINE (ACh) INNERVATION OF NEOCORTICAL AREAS IN ADULT CAT.

(ACh) INNERVATION OF NEOCORTICAL AREAS IN ADULT CAT. C. Avendaño\* D. Umbriaco, L. Descarries and R. W. Dykes. Centre de recherche en sciences neurologiques (Départements de physiologie et de pathologie), Université de Montréal, Montréal, Québec, Canada H3C 317. The ACh innervation of the primary somatosensory, visual and auditory areas of adult cat cerebral cortex was studied using monoclonal antibodies against purified rat brain choline acetyltransferase (ChAT; Cozzari et al., Soc. Neurosci. Abstr. 15: 200, 1990). ChAT positive fibers were found in all layers of every area examined. Both laminar and areal differences were noticed. of every area examined. Both laminar and areal differences were noticed. Common features included a dense innervation of layer I, mostly from horizontally running fibers, a relatively sparse innervation of layers II, III, V and VI, and a denser innervation of layer IV. The latter, however, was heavily innervated in the somatosensory and auditory areas, but only slightly more than layer III in the visual area. Most ACh fibers appeared very thin and bore many varicosities of various sizes, both as en passant and terminal boutons. The small varicosities were the most numerous, but many fibers showed a combination of large and small varicosities. There were also a few thick and extractly impropose tries fibers with a coverage results to the size before in combination of large and small varicosities. There were also a few thick and strongly immunoreactive fibers with a course parallel to the pial surface in layers I and II, or ascending through the deeper layers. Moreover, sparsely distributed strands or clusters of unusually large varicosities were observed, mainly in infragranular layers and sometimes forming pericellular arrangements. The fibers bearing such varicosities were variable in thickness. Lastly, a few ChAT-immunoreactive nerve cell bodies were found in the somatosensory cortex. Most of these occupied layers I-III and had a small, oval or polygonal soma with 1-3 primary dendrites oriented in various directions. SPATIAL EXTENT AND BEHAVIORAL DEPENDENCE OF COHERENCE OF 25-35 HZ OSCILLATIONS IN PRIMATE SENSORIMOTOR CORTEX. V. N. Murthy, D.F. Chen and E. E. Fetz\*, Dept. of Physiol. & Biophys. and Regional Primate Research Ctr., Univ. of Washington, Seattle, WA 98195.

Local field potentials (LFPs) in sensorimotor cortex of awake monkeys intermittently exhibit coherent oscillations at 25-35 Hz; the strength and spatial extent of coherence were examined during different behaviors. Sliding-window cross-correlation functions were computed for pairs of LFPs recorded at separate sites. The amplitude of the correlation peak closest to the origin (correlation strength) increased during challenging sensorimotor tasks - e.g., picking raisins from a Klüver board (0.89±0.05), or retrieving food from unseen locations (0.92±0.04). With the monkey inactive, oscillatory episodes at the same sites occurred infrequently and showed lower correlation strengths (0.60±0.16). With greater separation of the recording sites, the oscillations were coherent less often and their correlation strength decreased. Natural stimulation of the contralateral arm or leg evoked oscillations in the lateral or medial part of motor cortex, respectively. Simultaneous stimulation of hand and leg increased LFP oscillations at both sites, but did not increase their coherence. To determine if coherence increased during behavior that involved coordinated activation of sites, LFPs were recorded simultaneously from left and right motor cortices when the monkey manipulated objects with one hand alone and with both hands. Oscillatory episodes increased in both hemispheres when the monkey used either hand alone or both hands together. The coherence of oscillations across hemispheres occurred just as often and was just as strong during single-handed movements (0.82±0.11) as during bimanual manipulations (0.76±0.10). Findings to date suggest that if coherent cortical oscillations are involved in sensorimotor associations, they would occur at a finer level of spatial or behavioral resolution than revealed by our recordings. [NS12542 & RR00166]

BRAIN STATE MATRIX COMPUTATIONAL APPROACHES TO NEOCORTICAL LIMBIC RHYTHMS, Creighton University, Omaha, NE 68178, C. C. Turbes. \*

The brain information processing between stimulus inputs and motor out puts is expressed behaviorally as correlates of such cognitive processes as attention, perception and memory. It is necessary to partition these processes into first order functions so that different brain systems which subserve these separable functions can be delineated and their relationships studied.

Most important in such studies is the development of measurements operations for those component brain functions, a brain states matrix.

The EEG and sensory and cognitive "40HZ" a frequency band of the gamma range (35 - 85 Hz) which centers on specific coherent frequencies with focused arousal. These measurement operations have been used to show the interaction of the neural substrate, neural mechanisms, behavioral correlates and chemical alterations of focused arousal and behavioral immobility states and (13 to 17 Hz) SMR rhythms

The coherent and resonant properties of these cell assemblies of the neocortex and the limbic system are demonstrated in these studies. Coherent oscillations are determined by using coherence, partial coherence, phase spectral and tau coherence spectral analyses of templates of synaptic connections.

# COHERENT OSCILLATIONS IN PRIMARY MOTOR AND SENSORY CORTICES DETECTED USING MEG AND MFT. F. Lado\*, U. Ribary, A. Ioannides, J. Volkman, M. Joliot, A. Mogilner, R. Llinás. Center for Neuromagnetism, Dept. of Physiology and Biophysics, NYU Medical Center, New York, NY 10016, USA.

It has recently become possible to compute the 3-D distribution of electrical brain activity from recordings of the scalp MEG (Ribary et al., 1991, PNAS, 88:11037-41). This method, Magnetic Field Tomography (MFT) was implemented in the analysis of a distinct oscillatory activity (15-30 Hz) observed during the execution of simple hand movements. The dynamics of the MEG field during this task could not be accounted for by a single stationary cortical source (Lado et al., Soc. Neurosci Abstr., 1991, 126.14). Rather, MFT analysis demonstrated two spatially separate superficial sources during oscillatory bursts. The anatomical origins of the signals were determined by superimposing the 3-D distribution of brain activity on 3-D MRI reconstructions. Oscillatory activity usually originated in the hand region of primary motor cortex. Frequently, however, activity was also observed in the hand region of primary somatosensory cortex. When present, activity in these two regions was synchronized, although a phase shift in the time course of activity in the two sources was also observed. Comparison of superficial with depth recordings indicated that activity in the primary motor cortex frequently alternated with deep activity at the same frequency. From these observations we conclude that synchronized oscillatory activity is present in anatomically distinct regions of the brain. We speculate that this activity serves to dynamically group an ensemble of neurons active in a behavior.

# SOME TECHNIQUES FOR PROCESSING MULTICHANNEL NEURONAL RECORDINGS. D.R. Humphrey\*, D.J. Reed.

K. Mewes and M. Burrow. Lab. of Neurophysiology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

We are engaged in a project in which simultaneous, multi-unit recordings will be obtained from 24 to 64 closely spaced sites in the precentral motor cortex of the awake, behaving monkey, and from 8 to 16 intramuscular EMG electrodes. Such a deluge of data requires new technologies for visually scanning patterns of neural and muscular discharge, for quantitative comparison of these patterns, for studying statistical variability in the patterns during apparently identical movements, and for detecting slow but consistent changes in them as

new motor skills are acquired.

For visual, on-line monitoring, we have developed software for displaying multichannel data in an **n** X **m** matrix, where the color of each matrix cell represents the mean or integrated level of activity over a finite (20-50 ms) time interval at a single recording site. By storing selected matrices, statistical comparisons can be made of activity patterns across brain and muscular domains during different movements, at different times during a given movement, and at different stages of skill acquisition. We are also developing pattern recognition hardware and software, based upon cluster analysis, which allow changing neuronal patterns to be tracked quantitatively as new skills are acquired, or to detect (from brain signals) the emergence of intended limb movements. Such data can potentially be used for control of neural prosthetic devices or functional neuromuscular stimulation in paralyzed patients. Video tapes illustrating the operation of these software systems will be

Supported by NIH Grant NS 28858 and Contract N01-NS-1-2308.

MOTOR CORTEX OSCILLATORY NEURAL ACTIVITY DURING VOLUNTARY MOVEMENT IN MACACA FASICULARIS. G. Gaái\*, J. N. Sanes,

and J. P. Donoghue. Dept. Neuroscience, Brown University, Providence, RI 02912
This experiment evaluated oscillatory local field potentials (LFPs) in primary motor cortex (MI) and area 6 during instructed delay movements. Microwires (70 µm) were implanted in the forelimb region of MI and area 6 and EMG wires were implanted in arm muscles. Sites were identified and classified according to movements evoked by intracortical electrical stimulation. Simultaneous recordings from up to 12 electrodes for LFPs (10-80 Hz filtered) and unit discharge were evaluated for task related activity across several days during wrist movements in a visually guided instructed delay (1.5-3.5 sec) task.

LFPs oscillating between 20-40 Hz could be recorded from most MI and area 6

sites. Oscillations could occur for several sec or only for 100-300 msec. The oscillations were most prevalent during the instructed delay and the beginning of the reaction period, but were typically suppressed during movement. Sites at which digit movements were recorded tended to have the greatest suppression effect, whereas the one wrist site in MI continued to ave the greatest suppression etc., whereas the movement. Cross correlograms often showed relatively high amounts of synchronous activity from the different sites during the instructed delay period. Synchronization appeared greatest for sites at which digit movements were evoked;

activity was desynchronized abruptly at these sites around movement onset.

Single units showed phasic, task related activity at movement onset. To date, we have not found neurons with activity in phase with LFP oscillations. Discriminated neurons also did not show significant evidence of oscillation in discharge rate.

These data indicate that synchronous activity occurs widely in motor cortex during instructed delays. LFPs in nearby and distant sites can be highly correlated, though we have yet to find evidence of synchrony between individual neurons and LFPs. Changes in correlation of LFPs at nearby and distant sites may suggest signals related to preparation for movement, with coherence diminishing during actual movement. NON-HOMOGENOUS DISTRIBUTION OF CALCIUM ELECTROGENESIS ALONG THE DENDRITES OF NEOCORTICAL PYRAMIDAL NEURONS. I. Reuveni. A. Friedman\* and M.J. Gutnick. Dept. Physiology, Faculty of

Health Sciences, Ben-Gurion University of the Negev, Beersheva, Israel.

Under conditions of 24 mM TEA and 1 μM TTX, intracellularly recorded pyramidal neurons generate prolonged Ca++ plateaus; these often (>50% of cells) show step-wise repolarization to one or more lower-amplitude plateau levels. Using NEURON (Hines, Int. J. Biomed. Computing, 24:55-68, 1989), the existence of several stable voltage levels was simulated by two different models:1) the presence of multiple, electrotonically separated sites of Ca++ spike electrogenesis in the dendritic tree, and 2) the presence in a single compartment of several different types of Ca++ channel, each with its own voltage dependence. In experiments, brief hyperpolarizing pulses during the large plateau terminated it without terminating the lower "step"; this could be simulated in both computer models. However, the observed effect of prolonged depolarizing or hyperpolarizing currents on the breakpoint from which each plateau level repolarized could only be simulated with the multicompartmental model. Thus, the more depolarized the breakpoint, and hence the more proximal the spike initiation zone, the less it was affected by the injected current. In experiments, the ratio of the breakpoint voltages for the different plateau levels was equal to the ratio of the highest repolarization velocities. This indicates that at the sites of Ca++ electrogenesis, breakpoint voltage and time course of repolarization was the same for the spatially disparate spikes. Because it could be shown that the breakpoint voltage was closely related to a specific region on the voltage activation curve of the Ca+current underlying the spike, the findings strongly suggest that the same ++ channel is involved both proximally and distally in the dendrites.

Supported by a grant from the DFG (SFB 194).

ENSEMBLE NEURON ACTIVITY IN MEDIAL FRONTAL CORTEX OF AN AWAKE BEHAVING ANIMAL: ADVANCES IN METHODOLOGY. JM Paris\*, SF Sawyer, A Kirillov and DJ Woodward, Dept. Phys. and Pharm., Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27157.

The purpose of this study was to develop a new technical approach for recording ensembles of single neuron activity in the medial frontal cortex in awake rats. The medial frontal cortex is a complex brain region proposed to play a role in the temporal organization of behavior as well as providing an anatomical substrate for the reinforcing properties of drugs of abuse. We have recently obtained initial results recording ensemble unit activity in the neostriatum of behaving rats. Two bundles of 8 microwires were stereotaxically implanted into the medial frontal cortex of male Long-Evans rats. Microwire localization was verified from X-rays and histology at the completion of the experiment. Neuronal activity, consisting of groups of isolated single units, was recorded during spontaneous activity and compared to that obtained while the animal was locomoting on a treadmill. In a preliminary study, nine clearly defined stable units in a single rat were monitored over a two-month period. Two units demonstrated alterations in activity during phasic treadmill walking. During the 30 sec treadmill ON periods, one unit decreased activity while the other increased firing. interesting finding for this latter unit was a characteristic endogenous 3 sec cycling of activity during the 30 sec treadmill ON periods. The activity of the remaining units was not related to treadmill-enslaved locomotion. These alterations in neuronal activity were not elicited by presentation of either a conditioned tone paired with the treadmill ON period or an unconditioned tone. These findings indicate that routine study of the activity of neuron ensembles across long-term behavioral states is now feasible. Supported by DA-05381 (JMP), DA-02338, MH-44337, AFOSR-90-0416 and Biological Humanics Foundation (DJW).

CORTICORETICULAR ACTIVITY DURING VOLUNTARY GAIT MODIFICATIONS IN THE CAT. B. Kably and T. Drew. Dept. Physiology, Université de Montréal, Canada, H3C 317

Single unit activity was recorded from the peri-cruciate cortex during a task in which cats modified their gait in order to step over obstacles attached to a moving treadmill. A cat was implanted for recording electromyographic activity from flexor and extensor muscles of each of the four limbs; a recording chamber was placed over the right pericruciate cortex, and microwire electrodes (50µm diameter) were implanted into the caudal medulla to identify pyramidal tract neurones (PTNs). In addition, arrays of microwire electrodes were implanted into both sides of the medullary reticular formation (MRF) to identify corticoreticular neurones (CRNs). In continuing experiments, 24 PTNs have been recorded during locomotion; 6 of these PTNs were identified as CRNs. All 6 neurones were identified from the left MRF (contralateral to the recording site), from regions in which stimulation (11 pulses, 0.2ms duration, 330Hz) evoked flexion of the left forelimb and extension of the right forelimb. Four (4/6) of the CRNS were identified from electrodes on at least two of the bundles (separated in the antero-posterior direction by 2mm). All 6 CRNs were phasically modulated during locomotion and 4/6 changed their pattern of discharge when the cat modified its gait in order to lift the left limb over the obstacles. It is possible that, during gait modifications, such neurones, via their projections to the MRF, may be involved not only in increasing the activity of flexor muscles in the left, contralateral, limb but also in augmenting the level of extensor muscle activity in the supporting, right limb. (Supported by the MRC, FRSQ and FCAR).

VOLTAGE-GATED CURRENTS CONTRIBUTE TO SPONTANEOUS MEMBRANE POTENTIAL SHIFTS IN NEOSTRIATAL PROJECTION NEURONS. C.J. Wilson\*, Department of Anatomy and Neurobiology, University of Tennessee, Memphis, TN

In unanesthetized animals, and in animals anesthetized using urethane, neostriatal spiny projection neurons in vivo undergo spontaneous membrane potential shifts, alternating between a very polarized state (-80 to -90 mV) and a subthreshold depolarized state (-45 to -55 mV) from which may arise action potentials. The transition to the depolarized state has been show to require afferent synaptic input, but the existence of a preferred membrane potential and the shape of the membrane potential transition may depend upon active membrane properties. To test this hypothesis, cells were loaded intracellularly with QX-314 (10-50 mM in the electrode) to block Na currents, or with Caesium (0.5 to 2 M in the electrode) to block K currents during in vivo intracellular recording in rats anesthetized with urethane.

For neurons not firing spontaneous action potentials (most cells), blockade of Na\* currents using QX-314 had no effect on the membrane potential or on the time spent at either membrane potential state. In contrast, blockade of K\* currents with Cs shifted the membrane potential in the depolarized state in the depolarizing direction, causing all cells to become spontaneously active. Additionally blocking action potentials with QX-314 caused the depolarized state to elicit large plateau potentials (-20 to -10 mV). When these were prevented by passage of constant hyperpolarizing current, spontaneous membrane potential variations were continuous, showing no preferred membrane potentials. These results indicate that while the spontaneous membrane potential shifts are timed by synaptic input, their shapes and amplitudes are determined by intrinsic properties of the spiny projection cells, and especially by potassium currents engaged at subthreshold membrane potentials.

A SLOWLY-INACTIVATING K+ CURRENT CONTRIBUTES TO RAMP POTENTIALS IN STRIATAL NEURONS. E.S. Nisenbaum\*, Z.C. Xu, and C.J. Wilson; Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee-Memphis, Memphis, TN 38163 Recent voltage-clamp studies using acutely dissociated cells have

Recent voltage-clamp studies using acutely dissociated cells have demonstrated that rat striatal neurons possess a slowly-inactivating Acurrent (I<sub>As</sub>) which can be distinguished from other K+ currents on the basis of voltage-dependence, kinetics, and sensitivity to 4-aminopyridine (4-AP). Using current injection protocols inspired by voltage-clamp studies designed to isolate I<sub>As</sub>, the present experiments have examined the voltage-dependence of activation and inactivation of I<sub>As</sub>-like responses in striatal neurons recorded from an *in vitro* corticostriatal slice preparation.

In response to near-threshold depolarizing current pulses, striatal neurons displayed a slow, ramp-like potential. Moreover, when spike discharge occurred, the time to first spike was delayed toward the end of the depolarization. Application of a low concentration (30 µM) of 4-AP, which selectively blocks I<sub>AB</sub>, reduced the slope of the ramp depolarization and decreased the latency to first spike discharge. When cells were hyperpolarized to -90 mV with a pre-pulse, the slope of the ramp potential was increased. In contrast, a depolarizing pre-pulse to -60 mV reduced the slope of the ramp depolarization. The time-course of recovery from inactivation showed that long (3-4 s) hyperpolarizing pre-pulses were required in order to remove inactivation of I<sub>AB</sub>-induced ramp potential. Together, these data indicate that a slowly inactivating K+ current is present in neurons within the slice, and that the voltage-dependence, kinetics, and pharmacology of this current are similar to the I<sub>AB</sub> current previously described in acutely dissociated cells. (Support: ONR: N00014-92-J-1113, NARSAD, Tourette's Syndrome Association).

DEVELOPMENTALLY REGULATED TRANSIENT CURRENTS IN RAT NEOSTRIATAL GRAFTS. Z.C. Xu\*, C.J. Wilson Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis. Memphis, TN 38163

Previous studies of embryonic and adult rat neostriatum have shown that some transient currents are expressed at different developmental stages. For example, the voltage-dependent, slowly-inactivating K<sup>+</sup> current appears only in striatal neurons of adult animals. In contrast, the low-threshold Ca<sup>++</sup> current is present only in embryonic striatal neurons. Using these two currents as indicators of maturity, the present study investigated the developmental status of rat neostriatal grafts.

A cell suspension of striatal primordia collected from 16 day gestation embryos was implanted into the kainic acid-lesioned neostriata of adult rats. Intracellular recording in viiro was performed two to six months after transplantation. A voltage-dependent, slowly-inactivating transient current, which caused a sag in the response to depolarizing current steps, was evident in graft neurons. This component of the response to injected current steps was sensitive to low concentrations of 4-AP (30  $\mu\text{M})$ . In addition, a low-threshold Cd-sensitive component was found in graft neurons. This component and a TTX sensitive component were responsible for the short duration depolarizing hump elicited by a depolarizing current pulse. These results indicate that two different developmentally regulated currents exist in graft neurons and suggest a heterogeneous maturation of ionic currents in neostriatal graft neurons. Supported by NS26473.

# 356.4

CONTRALATERALLY PROJECTING CORTICOSTRIATAL AXONS INNERVATE BOTH COMPARTMENTS OF THE STRIATUM. A.E. Kincaid\* and C.I. Wilson. Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN 38163.

Recently it has been shown that neurons located in different layers of the cortex project preferentially to different compartments of the striatum. Neurons located in the deeper cortical layers project to the calbindin-poor patches and neurons in the more superficial layers project to the calbindin-rich matrix. This suggests that corticostriatal neurons can be divided into at least two different classes based on which compartment they innervate. Since crossed corticostriatal neurons represent a single well-defined cell type, we tested the hypothesis that these neurons innervate one compartment preferentially.

We used a combination of biocytin tract tracing and calbindin immunohistochemistry to determine the pattern of axonal innervation of crossed corticostriatal neurons. Biocytin was visualized using nickel chloride-enhanced DAB, producing a black reaction product, and calbindin was visualized using DAB alone, producing a brown reaction product.

Axons were traced to the contralateral hemisphere where they entered the striatum from the dorsal or lateral subcortical white matter. Axons with apparent boutons en passant were located in both the patch and matrix compartments of the contralateral striatum, similar to the pattern in the ipsilateral striatum. These results suggest that a single cell type can project to both compartments of the striatum and demonstrate that both compartments of the striatum receive information from neurons located in the contralateral cortex. Supported by NS20743.

DOPAMINERGIC DEPLETION AFFECTS THE TIME CONSTANT OF MEMBRANE TRANSIENTS PRODUCED IN RAT STRIATAL NEURONS BY HYPERPOLARIZING CURRENT PULSES. M. J. Twery\*, L. A. Thompson and J. R. Walters. NINDS, NIH, Bethesda, MD 20892.

Deficits in brain dopamine alter striatal function and the response of

neurons in striatal output areas to dopaminergic stimulation. The present study investigated whether dopaminergic deficiency produced by either a unilateral lesion of dopamine cells or reserpine altered passive membrane characteristics exhibited by striatal neurons in tissue slices. Intracellular recordings from striatal neurons located ipsilateral (n=45) to a 6hydroxydopamine (6-OHDA)-induced lesion of midbrain dopamine cells (6-18 wk) revealed a decrease (p<0.05) in the mean time constant ( $\tau^*$ , the larger tau of a double exponential curve fit) of the membrane transient required the following produced by small hyperpolarizing current pulses compared to contralateral control neurons (n=37). The reduction in  $\tau^*$  was not accompanied by changes in either membrane potential or input resistance (R<sub>in</sub>). When striatal neurons were differentiated according to current-voltage relations, the mean neuronal capacitive parameter, \u03c4\*/Rin, was significantly lower among the ipslateral neurons exhibiting relatively linear relations compared to contralateral controls (p<0.05). The mean  $\tau^*/R_{in}$  of neurons exhibiting a strong pattern of inward rectification associated with depolarization did not appear to be affected by denervation. Ongoing studies in reserpinized rats (1 mg/kg/day, 6 days), suggest that reductions in  $\tau^*$ , but not  $\tau^*/R_{In}$  occur as a result of acute dopamine depletion (n=12). The results suggest that intrinsic membrane properties in striatal neurons with relatively linear currentvoltage relations may be under the influence of factors closely associated with the function of nigrostriatal nerve terminals.

TONIC EXCITATORY INFLUENCE ON CAUDATE (CD) AND GLOBUS

TONIC EXCITATORY INFLUENCE ON CAUDATE (CD) AND GLOBUS PALLIDUS (GP) NEURONS IS MEDIATED BY AMPA BUT NOT NMDA RECEPTORS. L.A. Thompson\*, R. P. Soltis, J. R. Walters, and M. D. Kelland. ETB, NINDS, NIH, Bethesda, MD, 20892, USA.

Manipulations of excitatory amino acid (EAA) transmission with selective receptor antagonists have been suggested as having therapeutic potential for disorders of the basal ganglia such as Parkinson's disease. In order to evaluate the tonic influence of EAA systems on spontaneous neuronal activity in the basal ganglia, we have examined the effects of systemic administration of the AMPA receptor antagonist NBQX and the NMDA antagonist dizocilpine (MKreceptor antagonist NBQX and the NMDA antagonist dizoclipine (MK-801) on spontaneously active CD Type I, GP Type II (+/- waveform), substantia nigra pars reticulata (SNpr), and entopeduncular nucleus (ENT) neurons. Extracellular single unit recordings were carried out in locally-anesthetized, paralyzed rats. NBQX (cumulative dosing, 1.0 - 33.3 mg/kg i.v.) had a significant dose-related inhibitory effect on the firing of CD (n=6) and GP (n=5) neurons. At the highest dose, firing rate was decreased to 22 ± 7% and 9 ± 4% of the basal rate in the CD and GP, respectively. NBQX had no effect on the activity of SNpr neurons (n=5). Snowed either excitatory or neurons (n=5). Some ENT neurons (n=5) showed either excitatory or neurons (n=5). Some ENI neurons (n=5) showed eitner excitatory or inhibitory responses to NBQX that were not related to dose in the range tested. In contrast, MK-801 (0.003 - 3.3 mg/kg i.v.) had no significant effect on spontaneously active neurons in the CD (n=6), GP (n=6), or SNpr (n=7), but inhibited ENT neurons (n=4) in a dose-dependent manner. These results suggest that AMPA receptor activation plays a role in the tonic activity of CD Type I and GP Type II neurons, while NMDA receptor activation may have a relatively greater influence on

# 356.9

COMPARATIVE TIME-COURSE OF HALOPERIDOL-INDUCED CATALEPSY AND ALTERATION IN ENKEPHALIN (ENK) mRNA LEVELS IN RAT STRIATUM J.M. Delfs\*, C. R.Smith, B. S.Neal and M-F Chesselet, Inst. of Neurol. Sci., and Depts of Psychiatry and of Pharmacol. U. of Penn. Phila, PA 19104 ENK-containing striato-pallidal neurons are thought to be critical for the control of movement by the basal ganglia. The cataleptogenic drug haloperidol (HAL) increases levels of ENK mRNA in the striatum. The goal of this study was to determine whether a direct relationship exists between HAL-induced catalepsy and striatal ENK mRNA levels. Adult rats received daily <u>sc</u> injections of vehicle (Tween 80) or HAL (1 mg/kg). All rats were tested for catalepsy 2 and 4 hrs after the injection every 3-4 days. HAL-treated rats consistently exhibited marked catalepsy after 3-21, but not 28 days of treatment. Rats were sacrificed 24 hrs after the last drug injection and sections from the striatum processed for in situ hybridization histochemistry with a 35S-RNA probe for ENK mRNA (S. Sabol, NIMH). ENK mRNA was increased in the striatum and nucleus accumbens of rats sacrificed after 7, 14, 21 and 28, but not 3, days of treatment with HAL. There was no correlation between the magnitude and time course of ENK mRNA changes and the catalepsy score of individual rats. The data indicate that, with this regimen, sustained changes in striatal ENK mRNA precede and outlast HAL-induced catalepsy. Supp. by PHS grants MH44894, GM34781 and MH17168.

A ROLE FOR EXCITATORY AMINO ACID (EAA) RECEPTORS IN MEDIATING THE BASAL ACTIVITY OF RAT GLOBUS PALLIDUS (GP) NEURONS AND THEIR ACTIVATION BY THE SUBTHALAMIC NUCLEUS (STN). R.P. Soltis\*, J.R. Walters and M.D. Kelland. ETB, NINDS, NIH, Bethesda, MD 20892, USA.

EAA receptors play an important role in modulating basal ganglia function. The STN, as a source of putative glutamatergic projections within the basal ganglia, has received particular attention in this regard. To examine the effects of local EAA receptor blockade on GP neuronal activity under basal conditions and following activation of the STN input, drugs were infused directly into the GP and/or the STN while recording extracellular single-unit activity of Type II (+/- waveform) GP neurons in anesthetized rats. Local infusion of NMDA (30-300 pmol/200 nl) or AMPA (0.01-1.0 pmol) elicited increases in the firing rate of GP neurons in a dose-dependent fashion. In contrast, the NMDA antagonist dizocilpine (MK 801; 0.01-0.1 nmol) produced no discernable effect on basal firing rate; local infusion of the AMPA receptor antagonist NBQX (0.1-1.0 nmol) reduced the firing rate up to 50% of baseline. These data agree with our observations that systemic administration of NBQX inhibits the firing rate of GP neurons whereas dizocilpine produces no significant effect on the firing rate of these cells (Thompson et al., Neurosci. Abs., 1992). Infusion of the GABA-A receptor antagonist bicuculline methiodide (10 pmol/100 nl) into the STN elicited increases in the firing rate of GP neurons that were reversed by infusion of the non-selective EAA antagonist kynurenic acid (30 nmol) into the GP. Thus, EAA receptors mediate, at least in part, the basal activity of GP neurons as well as the increase in neuronal activity resulting from activation of a presumed glutamatergic input from the STN.

## 356.8

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL EVIDENCE FOR TWO DISTINCT CELL TYPES IN THE RAT GLOBUS PALLIDUS WITH DIFFERENT RESPONSES TO SYSTEMIC APOMORPHINE. M.D. Kelland\*, R.P. Soltis and J.R. Walters. ETB, NINDS, NIH, Bethesda, MD 20892, USA.

Extracellular single-unit recording techniques were used to examine the rat globus pallidus (GP). In both locally-anesthetized, paralyzed rats and ketamine-anesthetized rats we observed two distinct extracellular waveforms, which we have labelled Type I (-/+) and Type II (+/-). There were no significant differences in the mean firing rate, firing pattern or number of cells/track between these cell types, but there was a significant trend towards higher numbers of fast-firing Type II cells. Surprisingly, Type I GP neurons were inhibited by systemic apomorphine. This is in contrast to the well-established excitation of Type II GP cells by apomorphine. Pretreatment with a subthreshold tachyphylactic dose of apomorphine reduced the responsiveness of both cell types to a subsequent high dose of apomorphine; pretreatment with dizocilpine (MK 801) changed the pattern of response to apomorphine only with regard to Type II GP neurons. Relative to locally-anesthetized, paralyzed rats, ketamine-anesthesia reduced the firing rate of both cell types, but did not alter the firing patterns or the direction of response of each cell type to apomorphine. Thus, two distinct GP cell types have been identified based on their observed extracellular waveform, and they exhibit differential pharmacological profiles. These data may necessitate a re-evaluation of general theoretical models of basal ganglia function in order to account for different effects of DA receptor stimulation on globus pallidus output.

SPATIALLY SPECIFIC SPREAD OF EXCITATION IN THE MOUSE NEOSTRIATUM IN VITRO

B. Schlösser, R. Hiendl, F. Rucker, B. Sutor and G. ten Bruggencate\*

Institute of Physiology, University of Munich, Germany
The complex organisation of the striatum is believed to provide the basisfor a topographic processing of information. In order to investigate the spread of activity in different regions of the striatum, we performed photometric multisite measurements using voltage-sensitive dyes and laser

scanning microscopy. Coronal slices (400  $\mu$ m) of the mouse neostriatum were incubated for 1 h in artifical cerebrospinal fluid containing the fluorescent dye RH 414 (30  $\mu$ M). Twenty positions for registration of optical signals were arranged within an area of 1x1 mm, covering most of the striatum. The stimulation electrode was placed into the center of the striatum.

Intrastriatally induced optical signals were detected over the entire striatum Intrastriatally induced optical signals were detected over the entire striatum with a strong preference for the ventrolateral direction. This spread of activity was associated with an enhancement of amplitude. All optical responses were reversibly abolished by perfusion with  $Ca^{2+}$ -free solution, by adding TTX (0,6  $\mu$ M) or by the AMPA-receptor antagonist CNQX (10  $\mu$ M). The GABA-A antagonist bicuculline (10  $\mu$ M) did not significantly influence the amplitude of the optical signals but prolonged their duration. This effect was partly and reversibly blocked by the NMDA-antagonist APV

The data demonstrate that intrastriatal stimulation evokes AMPA-receptor dependent and GABA-A modulated synaptic activity which spreads over the striatum in a characteristic pattern.

(Supported by the BMFT, Morbus Parkinson und andere Basalganglien-Erkrankungen and by the DFG, SFB 220).

DOPAMINE-DEPLETION OF THE NUCLEUS ACCUMBENS LEADS TO INCREASED ACTIVATION OF THE LOCAL CIRCUITS.

A.B. Mulder, I. Manshanden, W.J.A.J. Smeets\*, P.E. Yos#, and F.H. Lopes da Silva

Dept of Exp. Zoology, Univ. of Amsterdam, Amsterdam, The Netherlands. #Rudolf Magnus Institute, Dept of Pharmacol., Univ. of Utrecht, Utrecht, The Netherlands. The Nucleus Accumbens (Acb) or limbic striatum receives important excitatory (glutamatergic) input from the hippocampal formation via the formix fibers and a donaminergic input from the ventral tegmental area. A characteristic field notential in dopartmergic input from the ventual eighenian area. A characteristic field potential in the Acb is evoked by electrical stimulation of the formix fibers. It consists of two positive waves peaking at 10 and 25 ms, corresponding to firing activity of the Acb neurons. To investigate the interaction between the excitatory and the inhibitory input, we examined the effects of denervation of the latter.

we examined the effects of denervation of the latter.

22 male Wistar rats (± 160g) were unilaterally injected with 6-OHDA in the Acb.

The contralateral Acb was sham lesioned. The rats were divided in short-term (ST) and long-term (LT) survival groups of 1-2 weeks and 24 weeks, respectively. Field potentials were measured in the Acb. In ST rats, a striking increase (up to 4 times) of the amplitude of the P10 component at the site of the lesion, compared to the shamlesioned contralateral Acb and to untreated rats, was found. LT rats still displayed an increase of 1.5 to 2 times. In 7 ST, 6 LT and 12 control rats unit-activity was measured using iontophoretical application of L-Glutamate (L-Glu). For each single cell we estimated the threshold ejection current (TEC) for a L-Glu response and the current at which the maximal firing rate (MFR) was obtained. MFR minus TEC was called the effective range (FER). The results (mean+ sem) are given in the table. called the effective range (EFR). The results (mean ± sem) are given in the table

|          | TEC (-nA)  | EFR (-nA)      | MFR <40 Hz (Hz)           | MFR >40 Hz (Hz)       |
|----------|------------|----------------|---------------------------|-----------------------|
| Controls | 24.1 ± 3.1 | $18.8 \pm 1.8$ | 18.4 ± 1.9 (28 cells)     | 56.2 ± 5.6 (6 cells)  |
| St Rats  | 21.8 ± 1.3 | 28.3 ± 2.8     | $24.0 \pm 5.6$ (19 cells) | 78.9 ± 3.4 (25 cells) |
| Lt Rats  | 23.6 + 2.0 | 36.9 ± 5.5     | 26.2 + 2.3 (13 cells)     | 57.7 ± 4.9 (11 cells) |

We conclude that donamine denervation leads to an altered activational state of the Acb, resulting in an increase of the effective range by which higher firingfrequencies can be reached. This is also reflected in the increase in amplitude of the field potential.

COMPARATIVE EFFECTS OF D1 AND D2 DOPAMINE AGONISTS ON SOMATOSTATIN AND NEUROPEPTIDE Y RELEASE IN CULTURED STRIATAL NEURONS. S Garside\*, S Weiss and MF Mazurek. McMaster University Medical Centre, Hamilton, Ontario. University of Calgary, Alberta.

The neuropeptides somatostatin (SS) and neuropeptide Y (NPY) are co-localized in medium-sized spiny neurons of the striatum. These neurons, which also contain nitric oxide synthase and are spared in Huntington's Disease, are known to have dopamine receptors. This study was designed to investigate the effects of D1 and D2 dopamine receptor agonists on SS and NPY release in primary cultures of striatal neurons. The D1 agonist, SKF 38393 had no effect on the basal release of SS and NPY. By contrast, the D2 agonist quinpirole potentiated SS release 3-fold without affecting NPY. The ability of 56mM KCL to provoke a 12-fold increase of SS and a 5-fold increase of NPY was not affected by the D1 agonist but was attenuated by quinpirole. Neither the D1 nor the D2 agonist influenced the kainic acid-induced secretion of SS and NPY, whereas both agents reduced NMDA-stimulated release of SS and NPY. These data indicate that D1 and D2 receptor agonists may produce different responses in the medium spiny neurons of the striatum. They further suggest that SS and NPY release from these neurons may be dissociated under some circumstances.

ELECTROPHYSIOLOGY OF AGING IN THE NEOSTRIATUM: II. SHORT-TERM PLASTICITY. X. Ou\*, S. Bottjer, T. DeFazio, R. Dunia and J.P. Walsh. Andrus Gerontology Center & Department of Biological Sciences, USC, Los Angeles, CA 90089-0191.

Age-related changes in Ca2+ physiology affects many neuronal properties, including the release of neurotransmitter by the presynaptic terminal. A paired-pulse activation paradigm for excitatory corticostriatal afferents was used to determine whether one form of Ca2+-mediated plasticity (pairedpulse potentiation) was altered in the neostriatum of the aged rat. A potentiation index was made by measuring the amplitude of the second synaptic potential relative to the first. Each cell was tested at various interstimulus intervals (150 to 30 msec; 10 msec decrements). examined 14 cells from 10 young rats (3-6 mo) and observed paired-pulse potentiation in 9 cells (at intervals < 100 msec), no change in 3 of the cells, and slight paired-pulse depression in 2 cells (all interstimulus intervals studied). By contrast, paired-pulse depression was observed in all 10 aged neurons (>24 mo) recorded from 8 animals.

We also studied synaptic depression using a 15 pulse paradigm. Afferents received 15 stimuli at interstimulus intervals ranging from 30 msec to 1 sec. In aged rats, the EPSP exhibited, on average, more depression at all inter-stimulus intervals tested. Furthermore, the onset of the synaptic depression was more rapid in the aged animals. Supported by NIA grants AG00093 and AG09793.

ASPECTS OF MORPHOLOGY AND SIGNAL TRANSMISSION OF DOPAMINERGIC, CHOLINERGIC AND GLUTAMATERGIC FLEMENTS IN THE STRIATUM OF THE RAT AND THE LIZARD GEKKO GECKO J.M.L. Henselmans, J.C. Stoof and F.G. Wouterlood. Departments of Anatomy and \*Experimental Neurology, Free University, Amsterdam, The

A characteristic feature of the neostriatum of mammals is that the release of acetylcholine (ACh) can be stimulated by glutamate through activation of a N-methyl-D-aspartate receptor and subsequently inhibited by dopamine (DA) through activation of a D2 receptor. Using a superfusion technique we found that the release of ACh is not significantly inhibited upon D2 receptor activation in the caudomedial part of the nucleus accumbens of the rat nor in the striatal complex of the reptile Gekko gecko. We furthermore investigated the effects of D1 receptor activation and forskolin on the second messenger adenylate cyclase in the presence and absence of D2 receptor activation in the striatum of both species. To study the morphological substrate of dopamine-acetylcholine interactions in the striatal complex of Gekko we conducted single- and dual immunocytochemistry using antibodies against tyrosine hydroxylase (TH) and choline acetyltransferase (ChAT). In addition, we studied the ultrastructural characteristics of dopaminergic fibers and cholinergic neurons using antibodies against dopamine itself and ChAT, respectively. Analysis of our findings suggests that the striatal complex of Gekko bears more similarity to the caudo-medial (shell) part of the nucleus accumbens of the rat than to the rat neostriatum.

ELECTROPHYSIOLOGY OF AGING IN THE NEOSTRIATUM: I. INTRINSIC Ca2+-MEDIATED POTENTIALS. R. Dunia\* and J.P. Walsh, Andrus Gerontology Center & Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191

Evidence supports both age-related increases and decreases in basal levels of intracellular Ca2+ of mammalian neurons. We measured two Ca2+ mediated potentials in the rat neostriatum to determine whether these cells express an age-related change in Ca<sup>2+</sup> physiology. The afterhyperpolarization (AHP) that follows a single action potential or a series of action potentials was examined in young (<6 mo.) and aged rats (>23 mo.). Measurements were made of the peak amplitude and duration of the AHP. Although durations were much shorter than those previously reported in the hippocampus (50% decay =  $5.8 \pm 0.3$  ms; mean  $\pm$  sem; n=30), no significant difference in either amplitude or duration was observed between young (n=22) and old (n=8) rats.

The second Ca2+-mediated potential studied was the plateau potential elicited by a depolarizing current injection in the presence of 30 mM TEA. Peak amplitude and duration were measured. The duration in young rats (n=7) varied from 300 to 1300 msec (800  $\pm$  150 msec). By contrast the duration was significantly reduced in the aged rats (200  $\pm$  70 msec; n=5; p<0.01; Student's T-test). Our results, which show that age-related changes in the  $Ca^{2+}$  physiology lead to decreased  $Ca^{2+}$  influx, are consistent with the hypothesis that the Ca<sup>2+</sup> regulatory mechanism in aged neurons is altered. Supported by NIA grants AG00093 and AG09793.

BENZODIAZEPINE, GLUTAMATE, MUSCARINIC AND DOPAMINE RECEPTORS IN PUTAMEN AND GLOBUS PALLIDUS OF ALZHEIMER'S AND PARKINSON'S DISEASES. JB Penney\*, LS Dure IV, MV Catania, M Carlson, RH Price, Z Hollingsworth and AB Young. Neurology Service, Massachusetts General Hospital, Boston, MA 02114

We used ligand binding autoradiography to measure binding sites.

We used ligand binding autoradiography to measure binding sites for 9nM [3H]mazindol, 10nM [3H]flunitrazepam, 10nM [3H]AMPA, 60nM [3H]kainate, 65nM [3H]glutamate (NMDA conditions), 100nM 60nM [3H]kainate, 65nM [3H]glutamate (NMDA conditions), 100nM [3H]glutamate (metabotropic conditions), 1 nM [3H]QNB, 0.5nM [3H]glutamate (metabotropic conditions), 1 nM [3H]QNB, 0.5nM [3H]SCH 23390, and 0.25nM [3H]spiperone in the lentiform nucleand choline acetyltransferase activity in putamen of 9 control, 9 Alzheimer's (AD), 8 Parkinson's (PD) and 9 AD plus PD brains. Data were analyzed by 2 way ANOVA. There were significant reductions of PD putamen dopamine uptake sites by 83% (96±32 vs 551±41 fmol/mg protein; mean±sem), NMDA sites by 26% (81±7 vs 110±10) and muscarinic sites by 9% (226±±82 vs 248T±72). AD insular cortex NMDA sites were reduced by 39% (214±36 vs 350±40), type 2 metabotropic sites by 33% (222±26 vs 334±45) and muscarinic sites by 17% (1560±123 vs 1875±123). Benzodiazepine sites were increased by 20% (289±17 vs 240±13) in AD putamen and by 25% (183±10 vs 146±13) in AD external globus pallidus. The binding reductions are consistent with the known pathology and binding reductions are consistent with the known pathology and pharmacology of AD and PD. The increases in benzodiazepine binding imply striatopallidal hypoactivity in AD. Current concepts of basal ganglia function suggest that such hypoactivity ought to reduce Parkinsonian symptoms in patients with combined AD and PD. Supported by USPHS Grant AG08671.

A MODEL OF STRIATAL FUNCTION IN HABIT FORMATION, Peter Dominey(1), Jean-Paul Joseph(2)\*, Michael Arbib(1). (1) University of

Southern California, Los Angeles 90089, (2) INSERM Unité 94, 69500 Bron, France.

We hypothesize that sensory activity (from inferotemporal Cx - IT) becomes associated with spatially selective saccade-related cells in the anterior striatum (Str) associated with spatially selective saccade-related cells in the anterior striatum (Str) as a result of learning, by trial and error, to associate central visual cues (colored shapes) with saccades to one of four uniform peripheral targets. Learning, modification of IT-Str synapses, is regulated by reward-related nigrostriatal dopamine activity. This hypothesis is formalized in a model that includes IT, posterior parietal Cx (PP), FEF, Str, substantia nigra, and thalamus (VA, MD).

Cue and target input is provided by a spatial array where each element codes color and shape. Output is in the form of activity in an oculomotor map representing FEF. Spatial/movement selective Str cells receive topographic FEF and PP.

projections, and non-topographic IT projections. The model learns to associate many cues to each spatial target. For a new cue, noise provides initial "guessing" between the four targets. With a correct response, reward related activity strengthens the involved IT-Str synapses. Mistakes yield synaptic weakening. Significant learning dominates guessing effects of noise, and performance approaches 100%. In our model, a new cue produces non-selective Str activity. With learning, the

cue-related activity increases in Str cells having a spatial preference for the correct saccade, and decreases in cells with the non-preferred direction, yielding a net decrease in Str activity. Initial correct saccades that occur before significant learning (guesses) precede these cue-related changes. Different cues associated with the same saccade produce similar activity increases and decreases in cells with the respective spatial preferences and non-preferences. Cue similarity (eg. same color, different spanial protections and non-protections. Cas similarity Cg. Same color, difficulties shape) produces generalization favoring previous associations. Strengthening IT-Str synapses on correct responses without weakening them on errors severely impairs learning conflicting associations, and less severely impairs learning non-conflicting ones, similar to 6-OIIDA nucleus accumbens lesions in rodent. We are now training a monkey in this habit formation task to test these predictions.

MODULAR NETWORK ARCHITECTURE FOR PLANNING AND CONTROLLING MOTOR BEHAVIOR FORMED BY TOPOGRAPHIC PROJECTIONS BETWEEN CEREBELLUM, BASAL GANGLIA AND CEREBRAL CORTEX. J. C. Houk\* and S. P. Wise, Dept. of Physiology, Northwestern University Medical School, 303 E. Chicago Ave, Chicago, Illinois 60611, and Lab. of Neurophysiology, National Institute of Mental Health, P.O. Box 289, Poolesville, Maryland 20837.

We outline a theory of motor behavior that will synthesize recent discoveries concerning the anatomy and physiology of the cerebellum, basal ganglia and cerebral cortex (Houk, J.C., Wise, S.P. *Technical* Report 5. Center for the study of Neuronal Populations and Behavior. Institute for Neuroscience, Northwestern University, 1992). This theory attempts to draw upon diverse knowledge coming from many disciplines of neuroscience. A consideration of regional specializations in neuronal architecture combined with the cellular properties of the principal neurons of these three brain regions leads to the concept that there are a few basic types of information processing module, and that these modules are used iteratively, in a cooperative manner, to control behavior. At one level of iteration, groups of similar modules form modular arrays that solve specific classes of problem. At a higher level of iteration, different types of modular array are interconnected to function in parallel in the control of overt behavior. (Supported by NIMH P50 MH48185 and ONR N00014-90-J-1822.)

### CEREBRILLIIM II

THE ABNORMAL PRENATAL DEVELOPMENT OF THE EGL AND THE CONSEQUENCES IN THE CEREBELLUM OF THE MEANDER TAIL J.A. Napieralski\* and L.M. Eisenman, College MUTANT MOUSE. Jefferson Graduate Studies, Thomas Philadelphia, PA 19107.

Philadelphia, PA 19107.

The cerebellum of the mutant mouse meander tail is characterized by the presence of an apparently normal posterior lobe and an abrupt transition to a disorganized anterior lobe (abnormal foliation, agranular, Purkinje cell (PC) ectopia, and a paucity of Bergmann glial fibers (Ross et al 1990)). An analysis of the postnatal development of the meander tail cerebellum revealed a reduction in the EGL of the anterior portion of the cerebellum as early as the day of birth. This study reports the results of an examination of prenatal cerebellar tissue (E15-E18) from mea/mea and +/mea littermates. The data suggest that differences between the cerebellum of the meander tail and normal mouse are apparent as early as embryonic day 17 (E17) in the anterior apparent as early as embryonic day 17 (E17) in the anterior most portion of the developing cerebellum. At E17 it is clear that there is (1) a thinner EGL and an incomplete migration of this layer over the surface of the cerebellum, (2) an incomplete migration of the PC to form the multilamina normally found beneath the developing EGL, and (3) the continuing presence of fibers in the dorsal and rostral portion of the cerebellum which are last seen in the normal portion of the cerebellum which are last seen in the normal animal at E16. These results suggest that the reduction in GC is due to a problem in cell proliferation in the EGL with a consequent failure to populate the EGL in the anterior lobe of the meander tail cerebellum. Supported by NIH grant NS22093.

CLIMBING FIBER INTERACTIONS WITH PURKINJE CELLS AS REVEALED BY CGRP IMMUNOSTAINING. A. Rosina<sup>1</sup>, S. Morara<sup>1</sup> and L. Provini<sup>2</sup>(SPON: ENA). <sup>1</sup>Ist. Fisiol. Centri Nervosi CNR, 20131 Milano and <sup>2</sup>

Ist. Fisiol. Gen. Chim. Biol., Univ. Milano, 20133 Milano, Italy.

The neuropeptide Calcitonin Gene-Related Peptide (CGRP) is neonatally expressed in the rat olivary afferents to the cerebellum for a short time window, which coincides with the multiinnervation period of Purkinje (Pk) cells by climbing fibers (CFs). CGRP mRNA analysis confirms the time course of this transient expression (see Morara et al., this Meeting). By using doubleimmunostaining and confocal laser-scanning imaging we analyzed the interactions which occur at this developmental stage between CGRP-stained CF terminals and Pk somata, immunostained with Calbindin-D (28 kd).

The results show that from postnatal day (PD) 0 to PD 3, CGRP-positive

terminal boutons design a diffuse net through the multilayer of Pk cells. From PD 4 to PD 12, Pk neurons align in monolayer and protrude perisomatic processes all over their perikaryon, while developing the dendritic tree. As visualized by confocal imaging and 3D reconstruction, CGRP-positive CFs progressively intensify their contacts with the Pk perisomatic processes throughout this period. The boutons first contact the inferior part of Pk soma in the form of a nest, later the whole soma up to the trunk of the primary dendrite. Between PD14 and PD21 the Pk cells adopt their adult morphology and the CGRP-positive boutons are no longer detectable. Thus, CGRP is expressed in the CF terminal boutons at the stage of perisomatic transient synapses, while the selection of a single CF axon collateral, which will form mature dendritic synapses, takes place. The factors underlying this plastic reshaping remain unknown. However, in view of the fact that CGRP receptors are expressed at the Pk cell layer at the same developmental stage, CGRP is a very likely candidate as a transmembrane signalling factor.

DEVELOPMENTAL EXPRESSION OF CGRP mRNA IN THE OLIVOCEREBELLAR SYSTEM OF THE RAT. S. Morara<sup>1</sup>, C. Sternini<sup>2</sup>, L. Provini<sup>3</sup>, A. Rosina<sup>1</sup>(SPON: ENA). <sup>1</sup> Ist. Fisiol. Centri Nervosi, CNR, 20131 Milano, Italy, <sup>2</sup> CURE, Dept. of Medicine, UCLA & VAMC, Los Angeles, CA 90073, 3 Ist. Fisiol. Gen. Chim. Biol., Univ. Milano, 20133 Milano, Italy.

Our previous data showed that CGRP is transiently detected by immunohistochemistry in the rat olivocerebellar system, at a postnatal stage coincident with the "multiinnervation period" of the Purkinje (Pk) cells by the climbing fibers (CFs) (see also Rosina et al., this Meeting). High affinity CGRP binding sites were found neonatally in the Pk cell layer and in the adulthood in the molecular layer. Thus, it was of interest to study the expression of the CGRP mRNA, to analyze a) its time course and distribution in the olivary complex during development, and b) its presence in the adult. "In situ hybridization" with probes for  $\alpha-$  and  $\beta$ -CGRP mRNA was used

The expression of  $\alpha$ -CGRP mRNA in the olivary complex was found to overlap in time the expression of the peptide in the olivocerebellar system, i.e. it was present from birth to the end of the second postnatal week. Moreover, α-CGRP mRNA was found to be expressed in the medial sector of the caudal part of the medial accessory olive, in the caudal part of the beta and dorsal cap nuclei, and in a small medial region of the caudal part of the dorsal accessory olive, i.e. in the same olivary subnuclei as already described by immunohistochemistry. No  $\beta$ -CGRP mRNA was found to be present in the olivary complex either during the development or in the adulthood. The results indicate that the expression of mRNA encoding for CGRP in the olivocerebellar system is developmentally regulated and covers the period of transient CF connections with Pk somata, preceding the stage of CF climbing on the mature Pk dendritic tree. Thus, a role for the peptide in the plastic processes taking place in the cerebellum during development is confirmed.

CEREBELLAR PROJECTIONS TO THE FORELIMB RECIPIENT ZONE OF THE CAT DORSAL ACCESSORY OLIVE ARE GABAERGIC. H.H. Molinari\*. Department of Anatomy, Albany Medical College, Albany, N.Y. 12208

Most of the inferior olive receives GABAergic inputs from either the deep cerebellar nuclei or the lateral vestibular nucleus (Nelson and Mugnaini, 1989). Within the dorsal accessory olive (DAO) of rat, however, the hindlimb recipient zone receives such input but the forelimb recipient zone does not. The present study sought to determine whether the forelimb recipient zone of cat DAO likewise fails to receive GABAergic input from the deep cerebellar nuclei.

Wheat germ agglutinin conjugated to horseradish peroxidase was injected into the deep cerebellar nuclei of adult cats. The anterogradely transported tracer was visualized with tetramethylbenzidine. The tissue was trimmed to include only the forelimb recipient zone of DAO, embedded for EM, and processed for GABA immunocytochemistry.

The vast majority of cerebellar terminals identified to date were also GABA-immunogold labeled. Thus, in contrast to rat, GABAergic terminals in the forelimb recipient zone of the cat DAO arise, at least in part, from the cerebellum. The terminals contacted dendritic shafts and dendritic spines in a ratio of about 2:1, the same ratio described by de Zeeuw et al. (1989) for cerebellar terminals in other olivary regions. These data indicate that input from the cerebellum serves a common function throughout much of the inferior olive (NSF-BNS-8809840 and NIH-1R55NS29771).

PALE CELLS OF THE FLOCCULO-NODULAR LOBE ARE CALRETININ POSITIVE. A. Floris, M.E. Dunn, A.S. Berrebi \* D.M. Jacobowitz and E. Mugnaini, Lab. of Neuromorphology, Univ. of Connecticut, Storrs, CT 06269-4154 and Lab. of Clinical Science, Bidg. 10-3D48, NIMH, Bethesda, MD 20892. Immunostaining with antiserum to the calcium binding protein calretinin (CR)

revealed no immunoreactivity within cerebellar Purkinje cells and stellate/basket cells of the molecular layer, but showed moderate staining of the granule cells and, more conspicuously, intense staining of non-granular neurons in the granular layer that are enriched in the ventral folia (I,IX,X). By their features, these densely stained cells were correlated with Lugaro and Golgi cells (Arai et al., J. Comp. Neurol. 310, 21-44, 1991). In this immunocytochemical light and electron microscopic study we demonstrate for the first time, in both rat and mouse, that densely CR-like immunoreactive cells in the flocculo-nodular lobe and the dorsal cochlear nucleus have features previously attributed to the so-called pale cells. Pale cells are a particular type of neuron situated in the granular layer of the cerebellar cortex. They occur at the highest density in the caudal cerebellum. Altman and Bayer (Exp. Brain Res. 29, 265-274, 1977) discovered that they are generated rather late in ontogeny (E19-P2 in the rat). We show that CR-like immunoreactive cells in the caudal cerebellum have dendrites which are laden with non synaptic evaginations and form conspicuous synaptic contacts with mossy fibers. These dendrites have special intermediate filaments and a rich complement of mitochondria; they also contain a fair number of dense core vesicles and occasional clusters of clear synaptic vesicles, suggesting some sort of paracrine function. The CR-positive dendrites receive symmetrical synapses from boutons containing pleomorphic vesicles, similar to Golgi cell axonal boutons Neurons resembling pale cells were also identified in dissociated cerebellar cultures. In the cerebellum of the reeler mutant mouse, where cell migration is impaired, pale cells collect near the roof of the fourth ventricle, supporting the notion that they originate from the ventricular epithelium and not from the external granular layer. in part by grant NS 09904.

IMMUNOCYTOCHEMICAL LOCALIZATION OF L-BACLOFEN-SENSITIVE GABAB BINDING SITES IN CEREBELLAR CORTEX. G.R. Holstein G.P. Martinelli and B. Cohen. Departments of Neurology, Cell Biology/Anatomy, Surgery and Physiology/Biophysics, Mount Sinai School of Medicine, CUNY, New York, N.Y. 10029.

Radiohistochemical studies have indicated that GABAB receptors are predominant in the

Radiohistochemical studies have indicated that GABAg receptors are predominant in the molecular layer of rat cerebellar cortex, and may be located on Purkinje cell dendrites, as well as parallel fiber and/or climbing fiber terminals. These observations are supported by pharmacologic and physiologic data suggesting the existence of both pre- and post-synaptic GABAg sites. We have used an immunocytochemical approach to study the synaptic interactions involving L-baclofen-sensitive GABAg binding sites in rat (Sprague-Dawley) and monkey (M. fascicularis) cerebellar cortex. Experimental animals received an im- injection of L-baclofen-HCI (5 mg/kg); controls received an equal volume of saline. Ninety min. post-injection, animals were sacrificed by perfusion. Fifty µm vibratome sections were exposed to a monoclonal antibody raised against L-baclofen, and then further processed with the unlabeled antibody PAP procedure.

i.m. injection of L-baclofen-HCI (5 mg/kg); controls received an equal volume of saline. Ninety min. post-injection, animals were sacrificed by perfusion. Fifty µm vibratome sections were exposed to a monoclonal antibody raised against L-baclofen, and then further processed with the unlabeled antibody PAP procedure.

Saline-injected control animals exposed to primary antibody showed no immunoreactivity, and there was no immunostain in sections from experimental and control animals that were incubated in a solution lacking primary antibody. Immunoreactivity was present only in the drug-injected animals. At the light microscopic level, the molecular and Purkinje cell layers were markedly immunostained. Some of this staining appeared to be associated with the Purkinje cell dendritic trees. In addition, the granular layer showed pale immunoreactivity which was particularly evident in the cerebellar islands. At the ultrastructural level, the reaction product was manifest as dense deposits adherent to the inner plasma membrane of immunostained profiles. The label was also present on the outer membranes of cisternae and mitochondria. Most of the stained profiles were less than 0.5 µm in diameter. In general, these immunoreactive profiles exhibited dendritic morphology, and occasionally appeared to occupy postsynaptic sites. These results suggest that GABAg receptors are present on Purkinje cell dendrities. Aided by NIH Grants # NS-24656, NS-00294. L-baclofen was generously provided by Ciba-Geigy, Ltd.

AUTORADIOGRAPHICLOCALIZATION OF CHOLECYSTOKININ (CCK) BINDING SITES IN ADULT OPOSSUM CEREBELLUM. <u>P.C. Madtes Jr., G.A. Bishop and J.S. King\*</u>. Neuroscience Program, The Ohio State Univ., Columbus, OH 43210 A previous study has shown that CCK immunoreactive mossy fibers are

A previous study has shown that CCK immunoreactive mossy fibers are present in the granule cell layer throughout the opossum's cerebellar cortex (King and Bishop, 1990, JCN 298:373). The intent of the present study is to localize CCK binding sites in the cerebellum. Serial frozen sections were analyzed using the method of Akesson et al. (Neuroendocrinology 1987, 45:257). Specific binding was determined using [125]I-labeled sulfated CCKg by subtracting nonspecific binding (measured in the presence of unlabeled sulfated CCKg) from total binding (measured in the absence of unlabeled sulfated CCKg). Binding sites were localized by apposing Kodak X-OMAT AR film to the sides for specific time periods. The films were processed and analyzed using a computer-based densitometry system. The Kpvalue (0.1nM) agrees with values reported for CCK receptors in other mammals. CCK binding sites are present in all lobules of the cerebellar cortex. With respect to laminar distribution there is a gradient of binding sites ranging from the highest density in the molecular layer to the lowest in the granule cell layer. Thus, the CCK binding site localization matches the lobular distribution of the peptide; however, there is a receptor-peptide mismatch with respect to the molecular layer which suggests CCK could act through volume transmission. That is, CCK may reach receptors in the molecular layer by diffusing through the extracellular space, from its localization in mossy fiber terminals within the granule cell layer. Preliminary findings based on the iontophoresis of CCK and extracellular recordings indicate that this peptide primarily has a facilitatory effect on the glutamate- and aspartate-induced firing rate of neurons in the cerebellar cortex. These data suggest that CCK may act as a neuromodulator within the opossum cerebellum. (Supported by NS 08798).

EVIDENCE FOR THE PRESENCE OF THE NUCLEO-OLIVARY PROJECTION AT E18 IN THE MOUSE. M.A. Urban\* and L.M. Eisenman. College of Graduate Studies, Thomas Jefferson University, Philadelphia, PA 19107.

The nucleo-olivary system is the reciprocal projection of the olivocerebellar system and displays a similar topographic pattern. The postnatal development of this GABA-ergic projection has been investigated immunohistochemically in the rat using antibody to glutamic acid decarboxylase (Gotow and Sotelo, '87). Fibers immunopositive to GAD were localized almost exclusively to perinuclear and interlamellar regions at PO, progressively invading the nuclear groups between PO and P5. This study suggested that the projection reaches the olive at birth, but is established postnatally. Recent neuroanatomical tracing studies performed in E18 mice using applications of horseradish peroxidase crystals into the dentate nucleus reveal the presence of labelted fibers ascending in the brachium conjunctivum, crossing in the decussation of the superior cerebellar peduncles, running caudally in the descending limb of the brachium and into and among the cells of the contralateral principal olive. HRP application into the fastigial nucleus resulted in labelted fibers traversing the same course but which terminated in the ipsilateral medial accessory olive. These studies demonstrate the presence of nucleo-olivary fibers in the inferior olive prenatally and suggest that the projection is established prior to birth in a pattern comparable to that of the adult.

SAGITTAL ORGANIZATION OF THE LATERAL RETICULO-CEREBELLAR PROJECTION IN THE MOUSE: A COMPARISON WITH THE MOSSY FIBER COLLATERAL SYSTEM BY DOUBLE ANTEROGRADE TRACING. <u>J.A.Heckroth</u>\* Indiana University School of Medicine Terre Haute Center for Medical Education Terre Haute. IN 47809

Medicine, Terre Haute Center for Medical Education, Terre Haute, IN, 47809.

Mossy fiber afferents which arise from the lateral reticular nucleus of the medulla (LRN) have been shown to terminate in the cerebellar cortex in a longitudinally organized pattern in several species. The present study compares this pattern with the organization of the mossy fiber collateral system previously demonstrated by Heckroth and Eisenman (J. Comp. Neurol. 270:385-394, 1988). Adult B<sub>6</sub>CBA mice received pressure injections of 1% WGA-HRP in the LRN, and injections of 20% rhodamine conjugated dextran (Molecular Probes) in lobule VIII of the cerebellum. Serial frozen sections were processed by the DeOlmos, Harding and Heimer TMB method and examined by epifluorescent and bright-field illumination. Sagittal stripes of the granular layer containing rhodamine labeled mossy fiber rosettes (from lobule VIII) were observed in the anterior lobe, and were compared in the same sections with the organization of TMB labeled mossy fibers (from LRN). Comparison of labeled regions and boundaries indicates that these two mossy fiber systems respect common sagittal boundaries which extend throughout the longitudinal extent of the cerebellar anterior lobe. Even where TMB labeled mossy fibers occupied two contiguous zones, the boundary between the zones remained visible as a thin label-free raphe. These results provide direc evidence that the cerebellar granular layer is divided by fixed sagittal boundaries into longitudinal compartments, each of which receives a unique combination of afferents

THE ORIGIN OF SEROTONINERGIC PROJECTIONS TO THE CEREBELLAR NUCLEI OF THE CAT. P.H. Kitzman and G.A. Bishop. The Department of Cell Biology, Neuroblology, and Anatomy. The Ohlo State University. Columbus, OH 43210

Serotoninergic (5-HT) axons are present throughout the granule cell layer and the cerebellar nuclei of the cat cerebellum, where they form a dense beaded plexus. In a previous study, 5-HT axons in the cortex were found to arise from neurons located in the paramedian reticular nucleus, lateral reticular nucleus, peri-olivary reticular formation, and the lateral tegmental field (Kerr and Bishop, 1991, JCN. 304:502). As the source of the 5-HT fibers in the cerebellar nuclei is unknown, the medial, interpositus, and lateral cerebellar nuclei were selectively injected with either rhodamine or fluorescein-labeled latex microspheres which were retrogradely transported to brainstem neurons. Transverse sections of the brainstem were processed for immunohistochemistry with a primary antibody to 5-HT and secondary antibody tagged with either rhodamine or fluorescein. The location of neurons containing both serotonin-like immunoreactivity and retrogradely transported microshperes was plotted. All three of the cerebellar nuclei receive 5-HT afferents from the nucleus locus coeruleus, the dorsal nucleus of the raphe (median division), the dorsal tegmental nucleus (pericentral division), and the central superior nucleus. In addition, the medial nucleus receives projections from the nucleus raphe pallidus and the interpositus nucleus receives afferents from the lateral tegmental field. These brainstem sources of 5-HT to the cerebellar nuclei are distinct from the more caudal brainstem origins of 5-HT afferents to the cerebellar cortex. In a previous study, 5-HT was shown to have a suppressive effect on cortical neurons (Kerr and Bishop, 1992, Brain Res. in press). At present, the effect(s) of 5-HT on neurons in the cerebellar nuclei are unknown. (Supported by NS18028).

MORPHOLOGICAL CHARACTERISTICS AND SYNAPTIC RELATIONSHIPS OF BASKET CELLS IN THE CAT'S CEREBELLUM. G.A. Bishop\*, Y.F. Chen and J.S. King, Dept. of Cell Biology, Neurobiology and Anatomy and Neuroscience Program. The Ohio State University. Columbus. OH 43210

Program. The Ohio State University, Columbus, OH 43210
The Intent of this study is to analyze the distribution and synaptic relationships of basket cell axons and to quantify the number of GAD immunoreactive terminals on their somata. Basket cells were intracellularly filled with horseradish peroxidase or neurobiotin. The axons of most basket cells distribute either toward the base or the apex of the folium; only rarely are cells found that have a bilateral distribution of the axon around the cell of origin. The parent axons extend 232-682  $\mu$ m (mean = 348  $\mu$ m) from the parent cell body and give rise to 5-11 (mean = 8) collaterals that descend to arborize around subjacent Purkinje cell bodies. Descending collaterals that arise in proximity to the parent cell body (within 73-100 µm) arborize extensively forming a complex terminal "pinceau". Descending collaterals that arise distally from the parent cell are much simpler in form. Fine beaded branches (mean 4/cell) arise from the axons of most basket cells and ascend into the molecular layer. Ultrastructurally both labeled and unlabeled basket cell axons are evident around the somata of Purkinje cells. Few synaptic specializations have been identified. The number of GAD positive terminals surrounding the basket cell body was determined from ultrastructural experiments in which a monoclonal antibody was used. On average, 16% of the synaptic contacts on the basket cell body are GAD positive, whereas 84% have the morphological characteristics of parallel fibers. In summary, these data indicate that 1) collaterals of a basket cell axon arborize to a greater degree around Purkinje cells located close to the parent basket cell; 2) Purkinje cells receive input from more than one basket cell; and 3) the predominant input to basket cell bodie appear to be derived from excitatory afferents. Reticular Projections of the Cat Lateral Cerebellar Nucleus P.L.E. van Kan.\* B. van Duin, A.R. Gibson, K.M.Horn, and J. Voogd. Barrow Neurol. Inst., Phoenix, AZ, 85013

Organization of cerebellar output follows a general schema whereby outputs of medial regions are directed more caudally than outputs of lateral regions. Medial nucleus projects mainly to medullary and pontine reticular formations, interpositus projects mainly to magnocellular red nucleus and cerebral cortex via thalamus, and lateral nucleus projects mainly to cerebral cortex via thalamus. Major exceptions to this schema are the nucleus reticularis tegmenti pontis and inferior olive, which receive input from interpositus and lateral nuclei.

Here we report anatomical evidence for another, less recognized, exception to the schema: The cat lateral nucleus projects to extensive regions of the posting and medullary reticular formation.

regions of the pontine and medullary reticular formation.
We injected WGA-HRP into brainstem regions or cerebellar nuclei and analyzed the pattern of retrogradely labeled nuclear cells or anterogradely labeled brainstem terminations. Injections into pontine or medullary reticular areas labeled cells in the medial nucleus and dorsal regions of lateral nucleus. The same injections labeled few cells in interpositus. Anterograde tracing confirmed the retrograde results: Injections into dorsal regions of lateral nucleus resulted in widespread terminal label throughout brainstem reticular regions; injections into ventral regions of lateral nucleus produced little reticular label.

The reticular projections suggest that dorsal regions of the lateral nucleus are functionally distinct from its more ventral regions as well as from adjoining regions of interpositus.

PROJECTIONS OF INDIVIDUAL PURKINJE CELLS OF IDENTIFIED ZONES IN THE RABBIT FLOCCULUS TO THE VESTIBULAR AND CEREBELLAR NUCLEI. C. J. De Zeeuw\*, P. L. DiGiorgi, D. R. Wylie, D. Wang, E. Marsh, and J. I. Simpson, Dept. Physiology & Biophysics, NYU Med. Ctr., New York, N.Y. 10016.

The rabbit flocculus can be divided both anatomically and physiologically into three large zones (1, 2, and 3) and two small zones.

The rabbit flocculus can be divided both anatomically and physiologically into three large zones (1, 2, and 3) and two small zones (4 and C2). The projections of Purkinje cells (Pcells) in the three large zones were studied using biocytin as an anterograde tracer. The zones were identified by determining whether the Pcell climbing fiber response to moving visual patterns was best for rotation about particular horizontal axes (zones 1 and 3) or the vertical axis (zone 2). Small extracellular injections of biocytin resulted in intracellular labeling of only a few Pcells, the axons of which could be traced from the cell body to the terminals in the vestibular and cerebellar nuclei. To confirm anatomically the identification of the injected zone, some sections were stained for acetylcholinesterase. The Pcells of zone 1 projected to the ventral dentate nucleus, group y, and the superior vestibular nucleus (SVN); the Pcells of zone 2 projected to the magnocellular and parvocellular parts of the medial vestibular nucleus; and the Pcells of zones 3 projected to group y and the SVN. Some axons of Pcells of zones 1 and 3 branched and innervated two nuclei. The branching axons from zone 1 either innervated both the ventral dentate nucleus and group y or both group y and the SVN. The branching axons from zone 3 innervated both group y and the SVN. The terminals of individual Pcells were apposed to cell bodies of different shapes (round, triangular, and fusiform). In summary, Pcells of each of the large floccular zones project to a specific set of nuclei and an individual Pcell can innervate more than one nucleus.

ELECTRON MICROSCOPIC IDENTIFICATION OF PONTOCEREBELLAR AXON TERMINALS IN THE CEREBELLAR NUCLEI OF THE RAT. G. A. Mihailoff\*, Department of Anatomy, Univ. of Mississippi Medical Center, Jackson, MS 39216-4505.

Previous studies in this laboratory have used a light microscopic anterograde axonal transport method, Phaseolus vulgaris leucoagglutinin (PHAL) to demonstrate in rats that axons which arise from neurons in the basilar pontine nuclei (BPN) or nucleus reticularis tegmenti pontis (NRTP) distribute to the cerebellar cortex (CTX) and the cerebellar nuclei (CN). Those axons that reached the granular layer of the CTX exhibited the morphology typical of mossy fibers while those distributing to the CN formed thin preterminal fibers that gave rise to small round boutons which have no apparent resemblance to the large, lobulated terminals in the granular layer of the CTX. Further, Shinoda et al. (J. Neurophys. 67:547) using intraxonal recording and filling with HRP have shown that single BPN axons distribute to both the CTX and CN. The objective of the present study then was to use electron microscopy to characterize the boutons formed by BPN and NRTP axon collaterals in the CN. PHAL was iontophoretically injected into the BPN or NRTP of rats and 7 to 12 days later the animal sacrificed, the CN sectioned on a vibratome and the sections reacted immunocytochemically and processed for electron microscopy to visualize the orthogradely labeled CN and CTX boutons. PHAL labeled boutons were observed in the medial and lateral CN, as well as the anterior and posterior interposed nuclei. Such boutons were ovoid or elongate in shape, appeared to contain round clear vesicles, and formed asymmetric synaptic contacts primarily with small dendritic profiles. The labeled boutons in the CN were smaller than those observed in the CTX which clearly exhibited the typical features of mossy fiber terminals. These observations confirm the existence of synaptic terminations in the CN formed by axons of BPN and NRTP origin. Supported by NIH grant NS12644.

ORGANIZATION OF RAT CUNEOCEREBELLAR PROJECTIONS ANALYZED IN 2-D UNFOLDED RECONSTRUCTIONS OF THE ANTERIOR LOBE. <u>D.L. Tolbert\*, C. Skillington, P. Puckett, J.M. Alisky and B.R. Clark.</u> Department of Anatomy and Neurobiology, St. Louis University School of Medicine and Program in Physical Therapy, Washington University School of Medicine, St. Louis, MO. 63104.

Cuneocerebellar topography was studied using an image analysis system (Bioquant PM, R&M Biometrics) which graphically unfolds sagittal sections of the anterior lobe while maintaining spatial relationships between labeled terminals and the 2-D reconstructed cortex. WGA-HRP injections into the rat internal and/or external cuneate nuclei labeled mossy fiber terminals in the cerebellar cortex. Cuneocerebellar projections were primarily directed to the ipsilateral hemicerebellum. Projections from the internal cuneate nucleus were mainly localized to a discontinuous, sagittally oriented stripe which extended from the vermis in lobules I and II laterally through lobules III and IV to the lateral paravermis in lobule V. In lobule V an additional stripe was present laterally near its junction with lobule VI. Medially, outside the stripe a relatively small number of labeled terminals were present in the vermis. Injections of both the internal and external cuneate nuclei labeled additional terminals within the sagittally oriented stripe that was only partially labeled by the internal cuneate nucleus injections. The sagittal organization of cuneocerebellar projections is significantly different from the transverse organization of lower thoracic-upper lumbar segmental spinocerebellar projections. Supported by NIH grant NS20227.

DIFFERENCE OF AFFERENT AND EFFERENT CONNECTIONS OF MONKEY FLOCCULUS AND VENTRAL PARAFLOCCULUS AND ITS RELEVANCE TO OCULOMOTOR FUNCTIONS.

S. Nagao, N. Nakamura, J. Yamada\*¹¹ and T. Kitamura¹¹. Dept. of Physiol., Jichi. Med. Sch. and Dept. of Anatomy, Nippon Med.

Our recent unit recording study suggests that the primate flocculus (FL) and ventral paraflocculus (vPFL) control differentially reflex and smooth pursuit eye movements. This view is also supported by the present anatomical investigation. WGA-HRP solution was injected locally into the FL or vPFL in 4 anesthetized monkeys. After survival periods of 3-4 days, they were perfused by saline, followed by a standard fixative. Frozen sections of brains were prepared frontally at  $60 \mu$  m, and reacted with tetramethylbenzidine or diaminobenzidine. The mossy fiber inputs to the FL came mainly from neurons of the vestibular ganglion, vestibular nuclei, and nucleus reticularis tegmenti pontis (NRTP), while those to the vPFL came mainly from neurons of the pontine nuclei and NRTP. The sources of climbing fiber inputs were similar. The efferents from the FL terminated mainly in the vestibular nucleus, while those from the vPFL terminated mainly in the dentate and interposed nuclei of the cerebellum.

THE PRIMATE FRONTAL EYE FIELD IS THE TARGET OF NEURAL SIGNALS FROM THE SUBSTANTIA NIGRA, SUPERIOR COLLICULUS, AND DENTATE NUCLEUS. J.C. Lynch\*1, J.E. Hoover, and P.L. Strick². Depts. of Anatomy and Ophthalmology, University of Mississippi Medical Center, Jackson, MS 39216¹ and VAMC and Depts. of Neurosurgery and Physiology, SUNY-HSC, Syracuse, NY 13210².

We used transneuronal transport of herpes simplex virus, type 1 (HSV-1) to label second-order neurons that send information to the frontal eye field (FEF) in monkeys (Cebus apella). The FEF was localized using lowamplitude (< 50µA) intracortical stimulation and then injected with a strain of HSV-1 that is transported transneuronally in the retrograde direction. Thalamic nuclei and cortical regions that are known to project to the FEF contained many neurons labelled with virus-specific antigen. In addition, we found neurons labelled by retrograde transneuronal transport in three subcortical sites: laterally in pars reticulata of the substantia nigra; ventrally in posterior portions of the dentate nucleus of the cerebellum; and in the optic and intermediate gray layers of the superior colliculus. All three of these regions are known to project to the thalamic subdivisions which contained labelled neurons and are known to contain neurons related to eye movements. These observations provide evidence that the output of the FEF is the product of neural signals originating in the substantia nigra. superior colliculus, and dentate nucleus, combined with input signals originating in other cortical areas.

A LIGHT AND ELECTRON MICROSCOPIC EXAMINATION OF THE LIGHT EVOKED BLINK REFLEX PATHWAYS IN THE MACAQUE. Paul J. May\* Depts. of Anatomy and Ophthalmology, Univ. of Miss. Med. Ctr., Jackson, MS.

In the cat, there is evidence of a pathway from the olivary pretectal nucleus to the facial nucleus that subserves the light evoked blink reflex. The circuitry mediating this reflex in the primate was investigated by simultaneously injecting the pretectum, levator palpebrae muscle and orbicularis oculi muscle with WGA/HRP. The pretectal injection retrogradely labeled numerous cells and scattered terminals in the contralateral pretectum, mainly in the nucleus of the optic tract. However, with respect to consensual responses to light, no labeled elements were present in the contralateral olivary pretectal nucleus. Labeled axons were present rostrally in the ventral periaqueductal gray, in and around the Edinger-Westphal nucleus. Caudally, however, these anterogradely labeled axons appeared to avoid the retrogradely labeled levator motoneurons. Similarly, examination of the facial nucleus did not reveal a labeled terminal field overlying the labeled orbicularis oculi motoneurons, although labeled axons were present ventromedial to the facial nucleus and the inferior olive contained dense terminal label. The ultrastructure of these labeled levator and orbicularis motoneurons was investigated in order to confirm the lack of a monosynaptic pretectal input. Initial examination had revealed that both motoneuron populations exhibited the same three basic terminal types in synaptic contact with labeled somata and dendrites: profiles with 1. spherical vesicles, 2. pleomorphic vesicles, and 3, both pleomorphic and dense-cored vesicles. However, axosomatic contacts were more numerous on orbicularis motoneurons. Following a pretectal injection, no labeled terminals were observed contacting either type of motoneuron. These results suggest that in primates, the light evoked blink reflex must be subserved by polysynaptic excitatory and inhibitory CNS pathways to the orbicularis oculi and levator palpebrae motoneurons, respectively. Supported by NEI grant EY07166.

# 358.5

TOWARD A FUNCTIONAL ANATOMY OF THE CAT EDINGER-WESTPHAL NUCLEUS. <u>Jonathan T. Erichsen<sup>1</sup>, Craig Evinger<sup>2</sup> and Paul J. May<sup>3</sup>. Depts. of Neurobiology & Behavior<sup>1,2</sup> and Ophthalmology<sup>2</sup>, SUNY Stony Brook, Stony Brook, NY and Depts. of Anatomy and Ophthalmology<sup>3</sup>, U. of Mississippi Med. Ctr., Jackson, MS.</u>

In the cat, the preganglionic parasympathetic motoneurons that subserve pupilloconstriction and lens accommodation have been difficult to investigate because they do not form a discrete nucleus. We have therefore attempted to better specify their organization. Ciliary ganglion injections retrogradely labeled cells: 1. within (20.1%) and ventrolaterat to (29.5%) the anteromedian nucleus [AM]; 2. within the Edinger-Westphal nucleus [EW] (6.8%) and the surrounding supraoculomotor area (10.7%); and 3. beneath the oculomotor nucleus (32%). Morphological analysis disclosed two populations: fusiform cells (8x25 um) found primarily in AM, and multipolar neurons (15-20 um), which were the major cell type at other locations. Labeled dendrites were observed crossing the midline, providing a possible basis for conjugate lens and pupil responses. In a series of transsynaptic experiments, WGA was injected either into the anterior chamber or the ciliary muscle to label preferentially the pupil and lens preganglionic neurons, respectively. In anterior chamber cases, the transsynaptically labeled motoneurons had a rostral distribution, i.e., more cells were in and lateral to AM. In contrast, ciliary muscle injections produced much higher levels of transsynaptic labeling caudally, in and around EW and beneath the oculomotor nucleus. Thus, a functional subdivision of the preganglionic motoneurons appears to exist along the rostrocaudal axis, in which pupilloconstriction is rostral and lens accommodation is caudal.

in which pupilloconstriction is rostral and lens accommodation is caudal. Supported by EYO4587 (JTE), EY07391 (CE) and EY07166 (PJM).

### 358 2

RECIPROCAL CONNECTIONS BETWEEN THE ZONA INCERTA AND MIDBRAIN IN THE CAT. Wensi Sun''. Paul J. May'. and William C. Hall<sup>3</sup>. Depts. of Anatomy', and Ophthalmology<sup>2</sup>, Univ. of Mississippi Med. Ctr., Jackson, MS, and Dept. of Neurobiology<sup>3</sup>, Duke Univ., Durham, NC. The relationship between the zona incerta (ZI) and saccadic eye movements

was examined by tracing pathways connecting the ZI with the dorsal midbrain of cats. Following ZI injections, both retrograde and anterograde label was consistently found in the insilateral pretectal area and superior colliculus. In the pretectum, the labelled cells and terminals were located mainly in the anterior nucleus, and to a lesser extent in the posterior, and medial pretectal nuclei. In the superior colliculus, labelled terminals and a few labelled cells were found in the intermediate and deep grey layers. These pathways were further examined by making injections into the superior colliculus and pretectum. The collicular injections produced retrogradely labelled cells located predominantly in the ventral incertal sublamina and scattered terminal labelling throughout ZI. Following pretectal injections, the labelled cells were again concentrated in the ventral sublamina. However, the density of labelled terminals was much greater following pretectal injections, particularly in the ventral lamina. Following collicular, pretectal and medial ZI injections, labelled cells and terminals were observed curving from ZI dorsolaterally toward the thalamic reticular nucleus. Caudally, terminal and cell labelling continued into the ventral lateral geniculate nucleus (VLGn). This pattern of labelling may indicate that the extent of the cat ZI and/or VLGn is greater than previously recognized. In conclusion, these results indicate the presence of reciprocal connections between ZI and both the pretectum and superior colliculus in the cat. Thus, ZI may contribute to midbrain control over head and eye

STRIATE CORTICOPRETECTAL PROJECTIONS IN THE GUINEA PIG. F. Lui, R.A. Giolli\*, R.H. Blanks, Y. Torigoe and S.V. Pham Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717 U.S.A.

Guinea pig has a significant nasotemporal component of horizontal optokinetic nystagmus (hOKN) when tested in monocular vision (Hayes & Ireland, 1969; personal observation). This functional finding raises the question, whether the nucleus of the optic tract (NOT) and its associated dorsal terminal nucleus, the recognized braistem centers for hOKN, receive any relevant input from the visual cortex, as Hoffmann (1986) postulated necessary for a nasotemporal hOKN response.

In order to answer this question, 15 guinea pigs were injected into the visual cortex with the tracers biocytin or horseradish peroxidase; after 48-72 hr. survival the guinea pigs were intracardially perfused and coronal sections of the brains (first preincubated with HRP-Avidin D in biocytin injections) were reacted using TMB as a chromogen.

The present study shows the usual projections of the striate cortex of mammals to the thalamus, tectum and pons; the projection to the pretectal complex is restricted to a single zone of pericellular terminals situated in the deep sector of the caudal portion of the NOT and/or in the more lateral portion of the posterior pretectal nucleus; contrary to reports in other species, no terminations are observed in the anterior pretectal nucleus.

F. L. is recipient of the G. Moruzzi Fellowship awarded by the Fidia Research Foundation. Research funded by the Fidia Research Foundation and by an Academic Senate Research Grant, University of California, Irvine.

DIVERGENT AXON COLLATERALS FROM PONTINE PRECERBELLAR REGIONS TO MID-VERMIS OF THE CAT. H. Sato and R. Noda. School of Optometry, Indiana University, Bloomington, IN 47405.

In the macaque, neurons in the fastigial oculomotor region (FOR) project to saccade-related nuclei of the contralateral brainstem, while they receive bilateral mossy-fiber input from pontine precerebellar neurons and ipsilateral input from Purkinje cells of the oculomotor vermis, lobules VIc and VII (Noda and Yamada, 1989; Noda et al., 1990). However, it is not known if the same cells project to the cerebellar oculomotor vermis of both sides or if different cells project to each side, possibly intermingling in the pontine regions. After injecting fast blue into the right half and diamidino yellow into the left half of the lobule VII of cats, and vice versa, topographical differences in the distribution of double- or single-labeled neurons were examined in the pontine precerebellar structures, pontine nuclei and nucleus reticularis tegmenti pontis (NRTP) of both sides. Single-labeled cells were distributed in the NRTP and four longitudinal columns of pontine nuclei, the dorsolateral, peduncular, lateral and medial (median and paramedian) pontine nuclei. The majority of single-labeled cells were found in the dorsolateral and peduncular pontine nuclei confirming an early observation (Hoddevik et al., 1977). Each nucleus contained a mixture of cells which project to either the left or the right vermis. Several cells in the dorsolateral and peduncular pontine nuclei and a few neurons in the NRTP, lateral and medial pontine nuclei send axon collaterals to both sides of the mid-vermis. (Supported by NIH grant EY04063).

EXCITING THE BLINK THROUGH INHIBITION. BASAL GANGLIA CONTROL OF THE BLINK REFLEX AND THE SUPERIOR COLLICULUS.

M.A. Basso'1 and C. Evinger<sup>2</sup>. Depts of 'Psychology, <sup>2</sup>Neurobiology & Behavior and Ophthalmology, SUNY Stony Brook, Stony Brook, NY 11794.

and Ophthalmology, SUNY Stony Brook, Stony Brook, NY 11794.

Lesions of the nigrostriatal dopamine system produce an increase in blink reflex magnitude and excitability. This effect on the blink reflex presumably results from an increase in the activity of the inhibitory projection neurons of the substantia nigra pars reticulata (SNr). We tested this hypothesis by examining the consequences of reducing SNr activity with muscimol injections.

In urethane anesthetized rats, we elicited reflex blinks before and after injection of muscimol, a GABA-A agonist, into the SNr. We quantified blink reflex magnitude and excitability by presenting paired electrical stimuli to the cornea and measuring the amplitude of the orbicularis oculi EMG (OOemg) response. At short interstimulus intervals (<800ms), the OOemg response to the second stimulus was always less than that to the first. In animals injected with 6-OHDA, which should increase SNr activity, the blink evoked by the second stimulus was often larger than normal rather than suppressed. In contrast, injection of muscimol  $(0.1\mu g)$  into the SNr which should decrease its activity, transiently increased blink reflex suppression and decreased blink reflex magnitude. We tested the possibility that the SNr modulated the blink reflex excitability and magnitude through the SNr's inhibitory, GABAergic input to the superior colliculus.

We monitored the magnitude and excitability of the blink reflex following injection of  $0.1\mu g$  of muscimol into the superior colliculus. This inhibition of collicular activity transiently increased the magnitude of the blink reflex but inconsistently altered blink reflex excitability. This result suggests that there are multiple pathways through which the basal ganglia can regulate the magnitude and excitability of the blink reflex, one of which is the superior colliculus.

THE NUCLEUS OF THE OPTIC TRACT (NOT) IN THE OPOSSUM (Didelphis marsupialis aurita): AFFERENTS, EFFERENTS, IMMUNOCYTOCHEMISTRY FOR GABA AND DOUBLE LABELLING ANALYSIS. Vargas, C.D., Volchan, E., Hokoc, J.N.\*, Bernardes, R.F., Rocha-Miranda, C. E.; Instituto de Biofísica Carlos Chagas Fo'(UFR), 21944, Brazil.

The NOT afferents and efferents were investigated by means of WGA-HRP injections. The injection sites attained the NOT, DTN, other pretectal nuclei and the anterior portion of SC. Labelled cells and terminals were present in contralateral NOT-DTN, LTN, INFSp, vLGN and ipsilateral MTN, LTN, vLGN and INFSp. Labelled cells and terminals could be distinguished bilaterally in praepositus hypoglossus and in medial and lateral vestibular nuclei. Labelled terminals were present bilaterally in the inferior olive and ipsilaterally in NRTP. These and eletrophysiological evidences suggest for the opossum's NOT a role in the horizontal OKN comparable to that of other mammals. The presence of GABAergic cells and terminals in NOT-DTN, MTN, INFSp and LTN was verified immunocytochemically. To investigate the existence of commissural GABAergic cells, rhodaminebeads were injected in the NOT and brainstem slices were processed for GABA. Double labelled cells were not found in the opposite NOT. A density analysis of GABAergic and retrogradely labelled cells in NOT-DTN showed that they superimpose in the posterior half of the complex, where the density of GABAergic cells is highest. These results suggest that the inhibitory modulation between the NOT and its opposite counterpart verified in eletrophysiological experiments might be mediated by GABAergic interneurons. CHANGES IN HORIZONTAL OPTOKINETIC NYSTAGMUS (HOKN) FOLLOWING HEMILABYRINTHECTOMY. R.H.Blanks, C. G. Fowler, C. A. Zizz, Y. Torigoe, F. Lui and S. R. Whitaker. Depts. Anat. and Otolaryngol, Univ. of Calif. Irvine, CA 92717 and Audiol, VA Med. Cent. Long Beach, CA 90822.

HOKN was examined in 6 patients with acoustic neuromas and 17 controls with normal health, hearing and vision. Eye position was recorded with conventional electrooculography. Full-field optokinetic stimuli (projected 15°0 vertical stripes) consisted of velocity steps (15-60°/s) lasting 20-60s. With controls, eye velocity matched stimulus velocity (i.e., gain = 1.0) in all conditions (monocular, binocular) through 45°/s, but decreased to a gain of 0.8-0.9 in the range 45-60°/s. The excursion of the eye during a slow phase increased with stimulus velocity, e.g. 5-15°0 at 15°0/s; 5-40°0 at 60°/s. Maximum eye velocity was achieved quickly (<3-4 s). Optokinetic afternystagmus (OKAN) was of low gain (<1.5-2) or absent in total darkness and, therefore, provided an unreliable indicator of vestibular pathology. The gain in all six patients was asymmetrical. Before surgery values were normal with stimuli towards the side of the tumor, but reduced for high stimulus velocities towards the contralateral side. Following the initial phases of compensation (no spontaneous nystagmus, ca. 11 days postoperation), there was a reduction in the HOKN gain to both sides. All patients showed fewer number of slow phase eye movement of slow velocity gain to ipsilateral stimulation, whereas contralateral stimulation remained low. At this late postoperative period, there was an increase in the number of slow phase eye movements and a recovery of the full range of slow phase excursions. These findings confirm the asymmetry was present only under monocular conditions. Finally, the partial recovery of slow velocity gain by day 42 and the near complete recovery of eye movement excursions during slow phase HOKN suggest that there is a late vestibular compensation which long outlasts the cessation of nystagmus.

INTRACOLLICULAR PROJECTIONS OF THE SUPERFICIAL GREY LAYER IN THE TREE SHREW. P. Lee, W. C. Hall\*, D. Fitzpatrick, and I. T. Diamond. Department of Neurobiology, Duke University, Durham. N.C. 27710.

The correct explanation of the physiological differences between the layers of the superior colliculus depends on precise knowledge of their interconnections. The tree shrew, with its large and distinctly laminated superior colliculus, is a good choice for studies of these connections. We have examined the projections of the superficial grey layer, stratum griseum superficiale, in this species after small extracellular injections of biocytin. The main intracollicular projection of neurons in the superficial grey layer is to the optic layer, stratum opticum. By comparison, the projection from the superficial grey layer to the layers beneath the optic layer is extremely sparse. The projections from the superficial grey layer to the optic layer have a columnar organization; the vast majority of the terminals are restricted to the sector of the optic layer that is immediately ventral to the injection site. These results indicate that a direct pathway from the superficial grey layer is unlikely to be responsible for the visual responses of cells in the deep layers, and suggest either that the cells of the optic layer serve as a relay between the superficial and deep grey layers, or that visual information reaches the deep layers primarily by indirect pathways through the cortex and basal ganglia. THIRD NERVE EFFERENTS TO THE ORBIT AND THE RETINA IN THE RAT. P.M. Young, F. Mullin, & J. Robertson-Rintoul\*. Dept. of Psychology, University of Central Lancashire and \*Dept. of Biol. & Preclin. Med., University of St. Andrews, U.K. (Spon: Brain Research Association.)

The subdivisions of the oculomotor nuclei of the rat projecting to the orbit and the retina were demonstrated by simultaneous unliateral injections, under tribromethanol general anaesthesia, of  $10\,\mu$ l of 2% Fluoro-gold, and  $10\,\mu$ l of cholera toxin-HRP conjugate. One injection was made to the posterior chamber of the eye and one to the orbit, with or without optic nerve section. Animals were sacrificed twenty four to seventy two hours later and  $80\,\mu$ m frozen sections were processed according to the technique of Mesulam using TMB as the chromogen. Fluoro-gold was visualised on a Leitz Diaplan using a wide band U.V. excitation filter. Five or six axonal fascicles 50-70  $\mu$ m in diameter and 70-80  $\mu$ m apart project ventrolaterally from the oculomotor nucleus to form several radicles emerging from the base of the cerebral peduncles. Dendritic processes were largely orientated rostro caudally and horizontally. A significant population of branching processes passes through the supracoculomotor central gray, through the parvocellular oculomotor nucleus to terminate close to the cerebral aqueduct and throughout the central gray. A subpopulation of oculomotor neurons was labelled following intravitreal injection, and tracer labelled-fibres were found apparently leaving the ventral component of the medial terminal nucleus of the accessory optic tract

Head braking and release during gaze shifts in the monkey. <u>I.Q.</u> Phillips\*, <u>L. Ling. C. Siebold, and A. F. Fuchs.</u> Departments of Psychology and Physiology and Biophysics, University of Washington, Seattle, WA 98195

Physiology and Biophysics, University of Washington, Seattle, WA 98195

It is not known how head-free gaze shifts are controlled. Vestibular signals may play an important role, but it is not clear when and/or how these signals can influence the gaze movement. To address this issue, we perturbed head movements during natural gaze shifts by unexpectedly stopping and/or releasing the head before, during, and following primate gaze movements to a visual target.

If the head is stopped during a large (up to 80 deg.) gaze shift, we observe a brief, compensatory, re-acceleration of the eye 10-12 msec following the perturbation. Eye movement amplitudes do not increase significantly, so gaze falls well short of the terret indicating that the eye/gaze burst generator does not

If the head is stopped during a large (up to 80 deg.) gaze shift, we observe a brief, compensatory, re-acceleration of the eye 10-12 msec following the perturbation. Eye movement amplitudes do not increase significantly, so gaze falls well short of the target, indicating that the eye/gaze burst generator does not compensate for the decreased amplitude of the head movement. The animal does, however, produce corrective saccades that bring the eye on target without further head movement. This shows that orbital mechanics are not limiting the initial gaze shift

If the head is stopped near the end of the eye saccade, the eye does not reaccelerate. This suggests that the vestibular interaction during the ongoing gaze movement may occur at the level of the eye/gaze burst generator, which is no longer driving the eye at this point. If the head is stopped after the gaze shift is over, the compensatory counter-rotation of the eye stops following a delay of 10-12 msec. This eye movement is vestibular in origin.

If, during fixation of a stationary target, the head is rotated passively away from the target and then released, a high velocity head movement results and gaze remains stable. If a target step accompanies the release, an accurate gaze shift begins with a decrease in the compensatory counter rotation of the eye in the orbit. A saccadic eye movement only occurs well into the ongoing gaze shift. Gaze movement and eye saccades can, therefore, be initiated and controlled independently.

These results can be explained by a limited gaze control mechanism in which the VOR is titrated by a signal proportional to gaze error.

METABOLIC ACTIVATION OF THE VESTIBULO-OCULOMOTOR SYSTEM BY INTRAVENTRICULAR ENDOTHELIN-1: MEDIATION BY CALCIUM L-CHANNELS. S.W. Shaver', R.J. Beninger, H.M. Lawler, D.S. Wainman, D.F. Weaver, F.J. Espinosa and P.M. Gross, Departments of Psychology, Surgery, Medicine, Chemistry & Physiology, Queen's University & Kingston General Hospital, Kingston, Canada K71. 3N6

Intracerebroventricular (icv) injection of endothelin-1 (ET) in rats produces oculoclonus, nystagmus and barrel-rolling convulsions, responses indicating that vestibulo-ocular systems are stimulated. Nuclei controlling proprioception and extraocular muscles have appreciable quantities of ET receptors (Kohzuki et al., Neuroscience 42:245, 1991). We examined whether rates of glucose metabolism in oculomotor and visual-vestibular nuclei would be elevated by lov ET, and whether such stimulation was regulated by dihydropyridine-sensitive Ca<sup>2+</sup> L-channels as shown previously in other brain regions (Neuropeptides 21:211, 1992). Male albino rats bearing a lateral ventricular cannula for icv injection were studied by use of the autoradiographic [¹⁴C]deoxyglucose method for measuring regional rates of brain glucose metabolism (GM). The effects of saline (3 µl) or ET (9 pmol) were studied alone or after icv treatment with a Ca<sup>2+</sup> L-channel antagonist, nimodipine (72 nmol in 1 µl). In comparison to saline treatment, ET evoked: 1) significant locomotor alterations assessed by an automated activity monitor, and 2) metabolic stimulation of oculomotor neurons, including the n. of the Illrd, IVth, and VIth cranial nerves (+38-80%), interstitial n. of Cajal (+45%), Edinger-Westphal and Darkschewitsch n. (+46-80%), and the medial terminal n. of the accessory optic tract (+104%) in which ET receptors are particularly dense. Visual-vestibular structures, including the superior colliculus, prepositus hypoglossal n., inferior olivary n., cerebellar flocculus, and medial and superior vestibular n., had elevated GM following ET. All these stimulatory effects were attenuated or abolished by nimodipine. The findings indicate Ca<sup>2+</sup>-sensitive behavioral and metabolic stimulation by ET of vestibulo-oculomotor nuclei that appear to be part of an intrinsic ETergic neural system.

EFFECTS OF FUNCTIONAL ABLATION OF IRREGULAR AFFERENTS ON SECONDARY VESTIBULAR NEURON ACTIVITY IN ALERT SQUIRREL MONKEYS C.J. Chen-Huang\* , R.A. McCrea, L.B. Minor and J.M. Goldberg Comm. Neurobiology, Univ. of Chicago, Chicago, IL 60637

Anodal galvanic currents, applied to both ears, can be used to functionally ablate irregular vestibular-nerve fibers. The procedure shows that there is no net irregular input to the vestibulo-ocular reflex (VOR) (<u>I\_Neurosci.</u>, 11: 1636). To understand the cellular basis for this finding, the responses of horizontal canal-related neurons in the vestibular nuclei during passive sinusoidal vestibular stimulation (0.5 and 2.0 Hz, 20-40% peak velocity) were compared in the presence and absence of the ablating currents. Position-vestibular-pause (PVP) neurons were studied as they are major contributors to the VOR.

The currents decreased the spontaneous firing of PVP neurons from typical values of 100 ± 40 to 60 ± 50 spikes/s. Because the polarizing currents decrease background discharge, they increase inhibitory saturation and decrease the peak-to-peak modulation in firing during rotations. On average, the decrease in modulation amounted to 10-15%, which might be expected to decrease VOR gain. Since the reflex is unaffected, there must be some central compensation for inhibitory saturation. Head-velocity gains were estimated from records corrected for eye-position and saccade-related activity and for inhibitory saturation. While the mean gain for the population was unaffected by the currents, individual units could have their gains changed by up to 60%. Half the units showed gain decreases; the other half, gain increases. The gain changes show that, despite the fact that the VOR is unaffected when irregular afferents are ablated, these afferents contribute to the firing of presumed VOR neurons, most likely by way of inhibitory and/or excitatory multisynaptic pathways (Supported by NIH Grants DC 00070 and EY 08041 and by NASA Grant NAG 2-148).

SPATIAL ORIENTATION AND DYNAMIC CHARACTERISTICS OF POSTROTATORY AND OPTOKINETIC AFTER-NYSTAG-MUS FOLLOWING PASSIVE HEAD TILTS: II. VERTICAL AND TORSIONAL VOR AND OKN. D.E. Angelaki\* and B.J.M. Hess. Neurology Dept, University Hospital, CH-8091 Zürich, Switzerland.

Vertical and torsional VOR and vertical OKN were elicited in rhesus monkeys implanted with dual search coils for 3d eye movement recordings. Rotation of the animal in ear down and supine or prone position about the earth-vertical axis (± 90 °/s) elicited vertical and torsional VOR, respectively; rotation of the visual surround (± 60 °/s) generated vertical OKN in ear down position. At termination of the velocity step, animals were tilted within < 1 s in the roll plane during vertical VOR /OKN, in the pitch plane during torsional VOR, and in the yaw plane during both vertical VOR/OKN and torsional VOR. The time constant of vertical afternystagmus was smallest in the upright and in prone or supine positions. Similarly, decay of torsional nystgmus was fastest in upright and ear down positions. In addition to a transient VOR, an orthogonal eye movement component was elicited during vertical or torsional afternystagmus whose magnitude and direction depended on the angle and direction of tilt and tended to align eye velocity with the spatial vertical. Such property maintains the direction of stored angular velocity aligned with earth-vertical, and has not been described for the vertical and torsional system during static tilt (Dai et al, JNP 1991). Thus, dynamic canal and/or otolith activity appear to be necessary to specify the plane of the head tilt and to stabilize the axis of Supported by SNF # 31-32484.91. the velocity storage in space.

SENESCENCE OF HUMAN VISUAL-VESTIBULAR INTERACTIONS (VVI). G.D. Paige\*. Dept. of Neurology and Ctr. for Visual Sci., Univ. of Rochester, Rochester, NY 14642.

Visual and vestibular inputs work together to maintain target fixation and spatial orientation throughout life, but these tasks are compromised as age increases. Horizontal eye movements were recorded (search-coils) from subjects 18-89 years of age in response to visual (smooth pursuit, SP, and optokinetic, OK), vestibular (VOR), and combined stimuli (0.025-4 Hz, 50°/s peak). Effects of aging on the VOR were small and largely limited to a decline in performance at  $\leq 0.1$  Hz. SP and OK responses were closely correlated, and both deteriorated progressively with aging across all frequencies. OK trials at 0.025 Hz produced circular vection. The effect became increasingly robust with aging, suggesting that visual influences on equilibrium are enhanced in the elderly, perhaps in compensation for vestibular deterioration. VVI with an earth-fixed scene more closely approached perfect compensation than the VOR, SP, or OK alone, but performance declined slightly with aging at low frequencies. VVI with a head-fixed scene closely resembled the VOR at 4 Hz, where visual suppression is ineffective, but vision increasingly overpowered the VOR as frequency decreased. Visual suppression became progressively less effective with aging, in concert with the general deterioration of visual following. Other VVI mechanisms (e.g. mental set, context) may also deteriorate with aging. Suppt. by NIH Grants RO1-AG06442, P30-EY01319.

### 358.16

SPATIAL ORIENTATION AND DYNAMIC CHARACTERISTICS OF POSTROTATORY AND OPTOKINETIC AFTER-NYSTAGMUS FOLLOWING PASSIVE HEAD TILTS: I. HORIZONTAL VOR AND OKN. B.J.M. Hess\* and D.E. Angelaki. Neurology Dept, University Hospital, CH-8091 Zürich, Switzerland.

If optokinetic afternystagmus is elicited about the yaw axis while the animal is in a static tilt position, the central vestibular system tends to align the eye rotation axis with the earth-vertical (Dai et al, JNP 1991). We examined the spatial characteristics and dynamics of postrotatory (PRN) and optokinetic afternystagmus (OKAN) following short-lasting (< 1s) passive head tilts away from the earth-vertical which were delivered immediately after cessation of rotation about the yaw axis (±90 °/s for VOR and ±60 °/s for OKN). Rhesus monkeys were implanted with dual scleral coils for measuring horizontal, vertical, and torsional eye position. The head tilt evoked a transient VOR in the appropriate head plane (e.g., roll induced a torsional, and pitch a vertical response) and decreased the time constant of horizontal PRN and OKAN. In addition, an orthogonal eye movement component was elicited during PRN or OKAN whose magnitude was proportional to the tilt angle. The direction and relative amplitude of the orthogonal component were such that the resultant three-dimensional eye velocity vector moved toward alignment with the spatial vertical. As to the horizontal system, the spatial and dynamic properties of the velocity storage appear to be similar under static and dynamic conditions during both VOR and OKN. SUPPRESSION OF THE VESTIBULO-OCULAR REFLEX DURING ACTIVE GAZE PURSUIT T.E.Belton\*, R.D. Tomlinson and R.A. McCrea Comm. on Neurobiology, Univ. of Chicago, Chicago, Ill 60637 and Dept. Otolaryngol., Univ. of Toronto

We have examined the gain of the vestibulo-ocular reflex (VOR) in squirrel monkeys during combined eye-head tracking of a visual target. While tracking a predictably moving target that was moved at  $40^{\circ}$ /s the monkeys' head movement was perturbed by a high acceleration transient generated by a brushless torue motor linked to the monkey's head. The perturbations caused the head to be accelerated  $1,100-24,000^{\circ}$ /s $^2$  (peak velocity  $22-350^{\circ}$ /s) either in the same or in the opposite direction of pursuit. The gain of the VOR evoked by the perturbations was close to

The gain of the VOR evoked by the perturbations was close to 1.0 when eye velocity during gaze pursuit was near zero, or in the opposite direction of the pursuit movement. On the other hand, the VOR was usually suppressed at a short latency (20 - 35 msec) when the purturbation occured while monkeys were pursuing targets with a combination of smooth pursuit eye and head movements and the head velocity was less than gaze velocity. Peak VOR gain in these instances ranged from .04 to .8. These observations were similar, regardless of the direction of the perturbation. They suggest to us that the VOR operates at a normal gain during gaze pursuit if the target is moving predictably and can be tracked with a head movement alone. However, if the speed of head movement during gaze pursuit is inadequate to maintain target stability on the retina, the VOR is reduced by a short latency mechanism.

THE NEUROCHEMISTRY OF THE MOTONEURONS OF THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS. C. Priest, P. Popper and P. E Micevych. Dept. Anatomy and Cell Biology, Laboratory of Neuroendocrinology, UCLA School of Medicine, Los Angeles, CA 90024.

Because of its sensitivity to testosterone, the spinal nucleus of the bulbocavernosus (SNB)-target muscle system is a convenient model in which to study the regulation of expression of molecules used by motoneurons in intercellular communication. It has been shown that the number of gap junctions and the levels of preprocholecystokinin mRNA are decreased in the SNB following castration and are restored by testosterone. The expression of αCGRP is increased in the SNB motoneurons following castration because of decrease in the activity of the target muscles. In an effort to further characterise the neurochemistry of the SNB, we investigated the regulation by testosterone of the expression of choline acetyltransferase (ChAT) and galanin, a neuroactive peptide which also is expressed in α-motoneurons. Adult, male Long-Evans rats were castrated or castrated and implanted with testosterone-containing Silastic<sup>TM</sup> capsules (40 mm). Four weeks later, the rats were perfused with 4% paraformaldehyde and 20 µm thick sections through the SNB were processed for in situ hybridization with radiolobeled RNA probes complementary to the mRNAs coding for ChAT and galanin. Castration decreased, and testosterone replacement restored, the levels of ChAT mRNA in SNB motoneurons, as well as in motoneurons of the RDLN. Since the activity of the skeletal muscles innervated by RDLN motoneurons does not change following castration, this indicates that the effect of testosterone on the expression of ChAT mRNA is at the level of the neurons. Supported by NS21220.

PHARMACOLOGICAL PROPERTIES OF NUCLEUS GIGANTOCELLULARIS NEURONS: AN IN VITRO STUDY IN GUINEA PIG BRAINSTEM SLICES.

M. Serafin\* and M. Mühlethaler. Dept. de Physiologie, CMU, 1 rue Michel-Servet, 1211 Genève 4, Switzerland. Nucleus Gigantocellularis neurons (NGCn), located in the medullary reticular formation, belong to networks subserving heterogeneous functions. In a first step, two main neuronal cell types, A and B NGCn, differing by their intrinsic membrane properties, were reparation or brainstern slices (Serafin et al., Soc. Neurosci. Abstr. 1987, 239.6; Serafin et al. 1990, Neurosci. Letters 120, 5-8). Moreover, intracellular injections of Lucifer Yellow have shown that both A and B NGCn were gigantocellular neurons. Thusfar, no attempts have been made to study the neuromodulation of these cells in vitro. Therefore, we recently undertook to study their response to different neurotransmitters.

Preliminary results indicated that monoamines such as serotonine, noradrenaline and histamine reversibly depolarized and excited A and B NGCn. Excitatory amino acid agonists such as NMDA, AMPA or trans-ACPD, also appeared to play a crucial role in controlling the activity of A and B NGCn. Indeed, their bathapplication resulted in a reversible membrane depolarization of these approximation restricted in a reversion in their firing rate. In contrast, both A and B NGCn were hyperpolarized and inhibited by GABAA and GABAB agonists (muscimol and baclofen respectively). (Supported by grants no 3.288-0.85, 3.560.0.86 and 31-26495.89 from Swiss NSF).

# 359.5

AN IN VIVO MICRODIALYSIS STUDY OF THE RELEASE OF SEROTONIN IN THE SPINAL CORD VENTRAL HORN OF TREADMILL-RUNNING RATS. GERIN, L. MARLIER, A. LEGRAND and A. PRIVAT. D.P.V.S.N., INSERM U-336, Case Courrier 106, U.S.T.L., Place E. Bataillon, 34095 Montpellier, Cedex 05,

The ventral horn of the spinal cord is profusely innervated by 5-HT terminals that presumably modulate locomotor activity through motoneurones (Roberts et al., 1988). We have monitored with microdialysis the release of 5-HT and 5-HIAA in the sp cord of rats spontaneously running on a treadmill.

A loop-shaped dialysis probe was implanted stereotaxically in the anterior horn of adult rats. Eight days later, the rats underwent a microdialysis session of four hours, divided in three parts: rest (90 min.), exercise (60 min.), post-exercise rest (90 min.). Samples were collected at fifteen minutes' intervals and 5-HT and 5-HIAA were monitored by HPLC-EC. The animals were sacrificed 30 to 40 days after the implantation of the probe, and the spinal cord was serially sectioned for the location of the probe and immunocytochemical detection of GFAP and 5-HT.

In most of the animals (n=6) the probe was located in the ventral horn, the glial reaction appeared moderate, and 5-HT neuritis were present at the contact of the probe. These animals did not show a significant difference of 5-HT and 5-HIAA levels inbetween rest and exercise. At variance, levels were significantly decreased of respectively 36% and 23% in-between rest and post-exercise. In two animals, where the probe was partly located in the white matter of ventral funiculi and surrounded by many 5-HT fibers, releases of 5-HT and 5-HIAA were respectively increased of 287% and 482% during exercise, and returned to almost basal values thereafter.

It is hypothesized that during exercise, the release of 5-HT or 5-HIAA is increased in the ventral horn, but that this increase is buffered in the grey matter, whereas such buffering does not occur in the white matter. This increase is then followed by a compensatory post-exercise decrease Supported by I.R.M.E. and A.F.M.

### 359.2

α-CGRP mRNA EXPRESSION IN MOTONEURONS IS RELATED TO MYOSIN HEAVY CHAIN COMPOSITION OF SPECIFIC RAT HINDLIMB MUSCLES. C. E. Blanco", P. Popper, and P. E Micevych. Dept. of Anatomy & Cell Biology, Laboratory of Neuroendocrinology, UCLA School of Medicine, Los Angeles, CA 90024.

The purpose of this study was to investigate whether the percentage of motoneurons within defined motor pools expressing the mRNA for  $\alpha$ -calci gene-related peptide (CGRP) was associated with the myosin heavy chain (MHC) composition of the target muscles. Motoneurons innervating the soleus (SOL), extensor digitorum longus (EDL) and contralateral tensor fascia latae (TFL) muscles of male rats (body weight approximately 300 g) were identified by injecting each muscle with a fluorescently labelled retrograde tracer (Fluorogold fluororuby and Fluorogold<sup>117</sup>, respectively). In the rat, the SOL muscle expresses the MHC-S (80%) and the MHC-IIA (20%) isoforms, the EDL expresses the MHC-IIA (25%) and MHC IIB (75%) isoforms and the TFL only expresses the MHC-IIB isoform. The animals were killed by transcardial perfusion under pentobarbital anesthesia 10 days after the retrograde tracers were injected and processed for CGRP in situ hybridization using a 3S-labelled ribonucleic acid probe. CGRP mRNA positive motoneurons constituted 23% of the SOL motor pool, 82% of the EDL motor pool and 85% of the TFL motor pools. These observations suggest that CGRP mRNA positive motoneurons innervate muscle units where the constitutive fibers express MHC-IIB isoform. Furthermore, we have previously reported that approximately 10% of phrenic motoneurons (13% MHC-IIB in the diaphragm) and 90% of the spinal nucleus of the bulbocavernosus innervating the bulbocavernosus/levator ani muscles (100% MHC-IIB). DIFFERENTIAL GLUTAMATERGIC AND CHOLINERGIC PROJECTIONS TO THE PONTINE INHIBITORY AREA. Y.Y. Lai\*, J.R. Clements and J.M. Siegel. Dept Psychiatry, UCLA VAMC, Sepulveda, CA 91343 and Dept Vet Anat, Texas A&M Univ, College Station, TX 77843.

We have found that both glutamatergic (glut) and cholinergic (Ach) mechanisms in the pontine inhibitory area (PIA) are involved in the suppression of muscle tone. Glut is co-localized with Ach in the neurons of dorsolateral tegmental (LDT) and pedunculopontine nucleus (PPN) in rat (Clements et al., 1991). We investigated whether the glut and Ach afferents of PIA originate from the same neurons. WGA-HRP was microinjected into the PIA of either the decerebrated or intact cat (n=8). Ach neurons were identified by NADPH-diaphorase and glutamate-like immunoreactive cells were identified with a glut antibody. Of the LDT neurons projecting to PIA, 15% were cholinergic while 29% were glutamatergic. Of the PPN neurons projecting to PIA, 8% were cholinergic and 44% were glutamatergic. A few WGA-HRP/glut-labeled neurons in caudal PPN also contained NADPHd staining. These neurons may not be cholinergic since the NADPH-d staining is weak. We conclude that Ach and glut afferent inputs to PIA in the cat originate from separate neuronal populations. The coordinated activation of these populations may be responsible for REM sleep atonia.

RAT SPINAL CORD NEURONS CONTAIN NITRIC OXIDE SYNTHASE. S. Saito, G. J. Kidd, D. F. Hanley\*, D. S. Bredt, T. M. Dawson, D. Wilson, R. J. Traystman, and S. H. Snyder. Dept. of Anesth. & CCM and Neurology, The Johns Hopkins Medical Institutions, Baltimore, Maryland 21205.

Nitric oxide (NO) produced from arginine by nitric oxide synthase (NOS) has been identified as a neuronal messenger in the brain, but its presence an possible functions in spinal cord is not clear. In this study we investigated the distribution of NOS containing neurons in the rat spinal cord, using immunocytochemistry to identify NOS containing neurons. Uptake of the tracer Fluoro-Gold into preganglionic sympathetic parasympathetic neurons was used to characterize NOS positive neurons. NOS intensity reactive neurons were found in Laminae 1-IV, and X throughout the spinal cord. Neurons in the intermediolateral cell column of the thoracic to sacral spinal cord were also intensely stained for NOS, and some neurons in Lamin V, VI, VII, and VIII were weakly stained. Colocalization of NOS and Fluoro-Gold in the intermediolateral cell column indicated that some sympathetic and parasympathetic neurons contained NOS. In addition, punctate NOS staining throughout Laminae 1-111 and surrounding some motor neurons suggested the ence of NOS at synap

Localization of NOS containing neurons in the spinal cord suggests that NO may paly role in spinal cord neurotransmission, including sympathetic, parasympathetic, sensory, motor, and possibly visceral pathways

TRH AND 5-HT REGULATION OF ONUF'S NUCLEUS MOTONEURONS. G.M. Holmes, R.C. Rogers, J.C. Bresnahan and M.S. Beattie. Departments of Cell Biology, Neurobiology and Anatomy, and Physiology, Ohio State University, Columbus, OH,

Recent anatomical and physiological evidence suggests supraspinal peptidergic and aminergic control of lumbosacral cord motoneurons (MNs). These neuroeffector substances include thyrotropin releasing hormone (TRH) and serotonin (5-HT) which are co-localized in terminals in the ventral horn. The individual and interactive effects of these systems upon the external anal sphincter (EAS) MNs of Onuf's nucleus were studied in adult female cats

Composite multibarrelled micropipettes containing artificial CSF plus 0.01% bisulphate preservative vehicle (VEH), TRH (10mM), 5-HT (0.136 mg/ml) and the TRH analog RX77368 plus 5-HT (0.025 HT (0.136 mg/ml) and the TRH analog RX77368 plus 5-HT (0.025 and 0.136 mg/ml, respectively) were lowered into Onuf's nucleus following laminectomy. Once EAS MNs were identified by electrical stimulation (25-100 uA, 3Hz, 5 sec trains) nanoliter volumes of VEH, TRH, 5-HT, or RX77368+5-HT were injected. Compared to VEH injections, TRH elevated EAS pressure (measured by rectal manometer) within 5 min of injection. 5-HT, alone, did not produce any appreciable effects. Preliminary results of RX77368+5-HT injections indicate a marked reduction in EAS haseline muscle tension. These results indicate that EAS MNs are baseline muscle tension. These results indicate that EAS MNs are modulated by TRH and 5-HT and that these substances may be involved in the CNS regulation of continence.

terminals in close association to motioneurons have been described. In order to study possible molecular differences between different types of synapses on motioneurons we have chosen to analyze the distribution of three synaptic vesicle proteins in two, not overlapping, transmitter identified systems that both have a substantial input to motioneurons, namely the 5-hydroxytryptamine (5-HT) and the gamma-aminobutyric acid (GABA) systems. Thus, the distribution of synapsin-, synaptophysin- and rab5-like immunoreactivity (LI) was studied in the grey monkey (Macaca fasicularis) spinal cord ventral horn by use of indirect immunofluorescence, peroxidase-antiperoxidase and immunogold techniques. Double labeling immunofluorescence experiments were performed in order to study co-localization with 5-HT and glutamic acid decarboxylase (GAD), which is the synthesizing enzyme for GABA. A dense punctate labeling of synaptophysin-, synapsin-and rab5-LI was found around the motioneurons as well as in the neuropil in the ventral horn. The density of synaptophysin-immunoreactive (IR) profiles was higher than that of synapsin which was in turn higher than for rab3. Preliminary results from double labeling experiments indicate that 5-HT-IR varicosities in the ventral horn also contain rab3-LI to a low degree, while no synapsin- or synaptophysin-LI was detected. On the other hand, GAD-IR varicosities seemed to harbor synapsin- and synaptophysin-LI to a high degree but no rab3-LI. The results of this study suggest that, in the ventral horn, 5-HT nerve terminals differ from GABA terminals with respect to their content of synaptic vesicle proteins.

PATCH CLAMP RECORDINGS OF NEURONS AROUND THE CENTRAL CANAL IN THICK SLICES OF RAT SPINAL CORD: EFFECTS OF SEROTONIN AND N-METHYL-D ASPARTATE. S. Hochman\* M.W. Salter, C. A. Livingston L.M. Jordan and J.F. MacDonald, Dept. of Physiology, Univ. of Toronto, Toronto, ON., Canada M5S 1A8. Dept. of Physiology, Univ. of Manitoba, Winnipeg MB., Canada R3E 0W3.

Locomotor activity can be elicited in the *in vitro* rat spinal cord (Kudo and Yamada, Neurosci. Lett. 75:43-48, 1987). Interneurons controlling locomotion must be capable of rhythmic acitivity and be under descending modulation. Recent evidence suggests that neurons near the central canal (lamina X and dorsomedial lamina VII) are activated during locomotion (Dai et al., Soc. Neurosci. Abstr. 16:368.9) and may generate rhythmic bursting (Jordan and Noga, Soc. Neurosci. Abstr., 17:484.6). The present study involves an analysis of the effects of serotonin (5-HT) on the genesis of bursting behaviour in similarly located interneurons

Neurons near the central canal (laminae X, VII and VI) were recorded in the whole cell configuration in transverse sections (400 µm) of caudal lumbar and rostral sacral spinal segments of 12-21 day rats. Bath application of 5-HT (100 µM) and NMDA (20 µM) produced an initial membrane hyperpolarization followed by depolarization and rhythmic fluctuations in membrane potential. Membrane conductance was increased. Further membrane depolarization increased the frequency of rhythmicity ultimately leading to sustained firing. In 3/4 cases the afterhyperpolarization following the action potential was reduced. These observations occurred in the presence of APV (40 µM) or by application of 5-HT alone (50μM). Local pressure applications of NMDA (250μM with 1 μM glycine) in voltage-clamped neurons produced I-V relations with a negative conductance and peak inward current at -20mV. Bath application of 5-HT was found to decrease the inward current evoked by NMDA by 27% ( $V_h$  -40mV). Supported by Canadian Networks of Centres of Excellence.

GABA-IR AXONAL BOUTONS IN THE VENTROLATERAL MOTOR NUCLEUS OF THE CAT SI SPINAL SEGMENT. Brun Ulfhake\* and Vania Ramirez, Department of Anatomy, Karolinska Institutet, S-104 01 Stockholm, Sweden,

The motoneurons (MNs) in the upper sacral spinal segments of the cat are grouped in 3 nuclei, namely: the dorsolateral (DL), the ventrolateral (VL) and the ventromedial (VM). The dendrites of the MNs in the VL are arranged in rather dense rostro-caudally oriented bundles, a property that simplifies ultrastructural analysis of their synaptic input. A number of studies have provided data on peptidergic and aminergic innervation of the VL nucleus. In this study we describe the innervation pattern of GABAimmunoreactive (IR) axons and the fine structure of GABA-IR axonal

Tissue specimens from adult cat spinal cord were used. Transverse

Tissue specimens from adult cat spinal cord were used. Transverse vibratome sections were incubated according to the peroxidase-antiperoxidase (PAP) technique (Sternberger et al., 1970) using a rabbit anti-GABA serum (Chemicon, Temecula, CA, USA) as primary serum. The VL nucleus receive an extensive innervation of GABA-IR axons, surrounding both cell bodies and dendritic profiles. The fine structure analysis revealed that GABA-IR axonal boutons contained flat or pleomorphic small agranular vesicles and often also a number of large dense-core vesicles. The synaptic complex appeared to be asymmetric and the postsynaptic membrane specialization was often rather thin. A frequent finding was that one and the same GABA-IR bouton made synaptic contact with two adjacent dendrites. This type of synaptic synaptic contact with two adjacent defidines. This type of synaptic arrangement in conjunction with the frequent dendro-dendritic contacts among these MNs may be of importance for synchronizing their activity. Taken together, the present results indicate that GABA may be used as a transmitter by a large fraction of the synaptic input to the sacral MNs.

STUDIES OF SYNAPTIC EXCITATION IN THE RAT SPINAL CORD AT LOW-CALCIUM SOLUTIONS. M. Pinco & A. Lev-Tov\*, Dept. of Anatomy, The Hebrew University Medical School, Jerusalem, Israel. Monosynaptic transmission in the neonatal rat spinal cord is

characterized by a prolonged depression which is evident at stimulation intervals as long as 30-50 seconds. This depression has been shown to be of presynaptic nature and can be partially alleviated by reduction in the basic level of transmitter release induced by decreasing the Ca<sup>2+</sup>/Mg<sup>2+</sup> ratio of the bathing medium or by addition of low concentration of baclofen (Lev-Tov & Pinco, J. Physiol, 447: 149-169, 1992). In the present study we characterized monosynaptic transmission between dorsal root afferents and α-motoneurons using sharp-electrode intracellular recordings from hemisected spinal cord preparations of the neonatal rat bathed in low-Ca2+ high-Mg<sup>2+</sup> Krebs saline. Double-pulse stimulation under these conditions transformed the synaptic depression into short term (50-60 ms) facilitation with maximal values (R2/R1) of 1.3-1.4. The facilitated responses could be further augmented by short (5-pulse) tetanic trains applied at 20-60 ms interpulse intervals. At longer intervals potentiation was over dominated by tetanic depression. Tetanic stimulation (5-20Hz) at longer durations (200 impulses) revealed much lower tetanic depression than that observed in normal Krebs saline. This low-level depression was accompanied by substantial post-tetanic potentiation lasting up to 5-10 minutes. These findings show that facilitation, potentiation and post-tetanic potentiation of monosynaptic excitation are developed at early postnatal stages, but cannot be expressed normally due to a complete masking imposed by the prolonged synaptic depression. Supported by grant #363/90 from the Israel Academy of Sciences and Humanities, Jerusalem, Israel.

ULTRASTRUCTURAL EVIDENCE FOR SEROTONERGIC INPUT TO CHOLINERGIC NEURONS IN THE LATERODORSAL TEGMENTAL NUCLEUS IN THE RAT. T. Honda\* and K. Semba, Dept. of Anatomy, Dalhousie Univ., Halifax, N.S. B3H 4H7 Canada.

We have recently shown that application of serotonin (5HT) decreases excitability and markedly modulates the discharge pattern of cholinergic bursting neurons in the laterodorsal tegmental nucleus (LDT) [Luebke et al., PNAS, 89(1992):743]. In the present study, we used electron microscopy to investigate synaptic relations between serotonergic axon terminals and cholinergic LDT neurons, by combining PAP-DAB preembedding immunohistochemistry for choline acetyltransferase (ChAT), and post-embedding immunogold staining for 5HT. ChAT-immunoreactive somata were mostly medium-sized and appeared oval, triangular or multipolar. Their somatic surface was covered by glial processes and both myelinated and unmyelinated axons. ChAT-positive neurons received many synaptic contacts on somata, dendrites and dendritic spines. In postembedding immunogold-stained material, deposition of gold particles was seen in some of these axon terminals in contact with ChAT-immunoreactive neurons. These serotonergic synaptic contacts appeared to occur more frequently with somata and proximal dendrites than with distal dendrites or dendritic spines. The presence of serotonergic synaptic contacts predominantly with the somata and proximal dendrites of cholinergic LDT neurons is consistent with the suggested role of serotonin in modulating rapid eye movement sleep phenomenology through its action on cholinergic neurons in the mesopontine tegmentum.

Neuronal NADPH-diaphorase are related to survival and regeneration after severe neuronal damage. <u>Wutian Wu\*</u>, Microsurgical Research Center, Department of Plastic Surgery, Eastern Virginia Medical School, Norfolk, VA 23501

The function of the enzyme nicotinamide adenine dinucleotide phospate diaphorase (NADPH-d) in central nervous system is still unknown. Using a histochemical method, the present study has, for the first time, discovered that some groups of spinal neurons, which are normally NADPH-d negative, turn into NADPH-d positive during the time period of regeneration in a severe peripheral and/or central nervous lesion animal model (rat). With peripheral lesion, spinal motoneurons began to appear positive NADPH-d reaction seven days following ventral root avulsion and reached the maximum in 2-3 weeks after the lesion Regrowing NADPH-d positive neurites were found far away from the cell bodies to the white matter and gray matter. These NADPH-d positive motoneurons existed for a few weeks and disappeared 3-4 months after the lesion. No NADPH-d positive motoneurons were found when root lesions (axotomy or crush) were made more than 0.5 cm distant from the cord. In central lesion, seven days following hemisection in low thoracic spinal cord, neurons with their regrowing neurites in ipsilateral lamina IV, V, and nucleus dorsalis, and interneurons in bilateral lamina VII and VIII, became NADPH-d positive. These NADPH-d positive neurons only existed for a few days and disappeared 2-3 weeks after the lesion. Heavy NADPH-d positive fibers were also observed within the lateral and ventral funiculus of the lesion side. Some of those fibers were apparent from the neurons of the nucleus dorsalis and the preganglionic sympathetic neurons in the intermediolateral cell column. The latter are normally NADPH-d positive neurons.

Results of this study indicate that neuronal NADPH-d are closely related to survival and regeneration after severe neuronal lesion. Mechanism of NADPH-d on neuronal regeneration needs to be further studied. Supported by the Department of Plastic Surgery, Eastern Virginia Medical School.

ENDOGENOUS LECTIN (RL-29) EXPRESSION OF THE SPINAL AUTONOMIC PREGANGLIONIC NEURONS IN THE RAT. M.J. Park, A.A.Cameron, W.D.Willis, S.H. Barondes, H. Leffler and K.Chung\*. Sch. Allied Health Sci. & Marine Biomed. Inst., Univ. Texas Med. Branch, Galveston, TX 77550.

Med. Branch, Galveston, TX 77550.

Recent studies have demonstrated that an endogenous lactose-binding lectin RL-29 was selectively expressed in subsets of embryonic and postnatal DRG neurons and their fibers in the superficial dorsal horn of the spinal cord. The present study tested the possibility of RL-29 expression in other spinal neurons. Four adult normal male albino rats were perfused with 4% paraformaldehyde in 0.1 M phosphate buffer. Various segments of the spinal cord were removed, vibratome sectioned, and immunostained for RL-29 by the ABC method. The antibody to RL-29 was used at a concentration of 1:3,000 for immunoreaction. We report that a subset of spinal motor neurons, parasympathetic and sympathetic preganglionic neurons, selectively demonstrate intense immunoreactivity to anti-RL-29. Although the functional implications of RL-29 in spinal autonomic pregnalionic neurons are not known, the data suggest that RL-29 is a useful marker for these neurons. (supported by NS11255)

DETECTION OF mRNAs ENCODING THE TWO ISOFORMS OF GLUTAMIC ACID DECARBOXYLASE IN THE RAT SPINAL CORD. S. Feldblum\*, A. Dumoulin, A. Joyeux, C. Maurin-Richaud, F. Sandillon and A. Privat. Insern U336, Montpellier, France, 34000.

Recently we have demonstrated that GABA synthesis in the

Recently we have demonstrated that GABA synthesis in the CNS depends on two forms of glutamic acid decarboxylase (GAD), differing in size, subcellular location and affinity for the cofactor pyridoxal-5'-phosphate. We have suggested that GABA may serve functional roles other than as a neurotransmitter. To further investigate the role of the two GAD isoforms, GAD<sub>65</sub> and GAD<sub>67</sub>, we have studied their distribution in the spinal cord where coexist different types of inhibition (recurrent, reciprocal, presynaptic, post-synaptic). Using in situ hybridization to mRNAs encoding GAD<sub>65</sub> and GAD<sub>67</sub>, we have identified, with both probes, labeled cells scattered through layers 1 to V of the dorsal horn, in the intermedio-medial column and in the ventral horn. GAD<sub>67</sub> mRNA levels were higher than GAD<sub>65</sub> mRNA levels, as reported in most CNS structures. GABA-immunoreactivity confirmed this cellular distribution. Labeled cells of the ventral horn, of larger size (20-30  $\mu$ m) than cells of the dorsal horn (10  $\mu$ m), were, however, visible after a colchicine treatment only, suggesting that they may be projection neurons. We are currently investigating wether this cell type might be motoneurons, as reported in others mammals, or intersegmental neurons. Supported by the Garches and IRME fundations to SF.

SUBSTANCE P MODULATES GLUTAMATE-ACTIVATED SYNAPTIC POTENTIALS BUT NOT SEROTONIN-INDUCED EXCITATION IN NEONATAL MOTONEURONS.

P. Hernandez\*, B.S. Seebach, and L. Ziskind-Conhaim. Dept. Physiol. and Ctr. Neurosci.,
Univ. of Wisconsin, Madison, WI 53706.

Substance P (SP) and serotonin (5-HT) coexist in medullary

Substance P (SP) and serotonin (5-HT) coexist in medullary neurons that descend to rat spinal cords. To determine whether SP modulates 5-HT- or glutamate-mediated neuronal excitation, its effects were recorded intracellularly in motoneurons of newborn rats. SP (1 µM) generated an average depolarization of 13 mV, which was associated with a 40% increase in membrane resistance and an increase in the frequency of synaptic potentials. The induced depolarization was reduced following inhibition of synaptic activity. SP reduced, however, the amplitude of dorsal root-evoked potentials, and this reduction persisted despite motoneuron desensitization. Preliminary results suggest that the effect of SP on dorsal root-evoked potentials is probably not due to its action on glutamate receptors.

SP-mediated neuronal responses are similar to those induced by 5-HT (Ziskind-Conhaim and Newcomer, Soc. Neurosci., 1990, 16:727). However, our data suggest that there is no interaction between the postsynaptic mechanisms of their actions. SP and its analogues had no effect on 5-HT-evoked potentials. Therefore, SP and 5-HT independently modulate synaptic activity in the spinal cord. Supported by RCDA (NS01314) and NS23808 to LZ-C.

EFFECTS OF TREADMILL SPEED AND INCLINE ON THE WALKING PATTERN OF NORMAL AND SPASTIC PARETIC SUBJECTS. A. Pépin and H. Barbeau. School of Physical and Occupational Therapy, McGill University. Montréal, Ouébec, Canada. H3G 1Y5.

The purpose of this study was to investigate the changes on the locomotor pattern of spastic paretic (SP) subjects as a result of changes in speed and incline during treadmill walking. Electromyographic (EMG) activity of lower limb muscles, angular displacements and temporal-distance (T-D) parameters were recorded for three SP subjects and two normal subjects evaluated at comparable ranges of speed (0.1 - 0.7 m/s) and upward incline (0-15%). It was noted that the long cycle duration and large stance to swing ratio observed in SP subjects' comfortable speed (0.2 - 0.3 m/s) were also present in normal subjects for matched speed. For normal subjects, knee flexion during early stance and ankle plantarflexion at push-off were greatly reduced at low speeds, as observed in SP subjects. Changes in T-D parameters with increased speed were similar for all subjects. In addition, EMG activity showed greater amplitude with generally preserved timing for normal subjects. In SP subjects, the increase in the amplitude of EMG activity was limited, and mostly, the recruitment pattern was changed, with longer burst duration and increased stretch activation in the triceps surae. For all subjects, the T-D data did not change with the incline. In normal subjects, the amplitude of the EMG activity was increased in triceps surae and other extensor muscles, whereas such increase was limited in SP subjects. Our results suggest that some characteristics of the gait of SP subjects cannot be solely attributed to their deficit and are associated in part with their low walking speed. Adaptation to changes in speed and incline is limited in SP subjects and we are in the process of further quantifying those Supported by MRC Canada. limitations.

COMPARISON OF THE EFFECTS OF CYPROHEPTADINE, CLONIDINE AND BACLOFEN ON LOCOMOTOR PATTERN IN INDIVIDUAL SUBJECTS WITH SPASTIC PARESIS. K.E. Norman and H. Barbeau. School of Physical and Occupational Therapy, McGill University. Montréal, Qué. Canada. H3G 1YS.

Studies from our laboratory have shown that cyproheptadine and clonidine can improve locomotion in spastic paretic subjects. In this study, we compared the effects of these two drugs, and of baclofen, a standard antispastic drug, on locomotor pattern in subjects at least one year postspinal-cord-injury. Evaluations were conducted for each subject at entry to the study, after three weeks on each drug, after each two-week washout period, and after a period of a drug combination. Treadmill locomotor pattern was analyzed by means of electromyographic and kinematic data. Overground locomotion was also evaluated when possible. Most subjects used wheelchairs full-time and they were able to perform limited stepping on the treadmill only with a partial support harness, parallel bars, and minimal speed. Two subjects made gains in treadmill speed and extent of locomotor independence in response to cyproheptadine. The improvement was associated with a reduction in muscle stretch activation and coactivation of antagonists, as well as changes in hip, knee and ankle kinematic patterns These two subjects also showed a reduction in stretch activation during gait in response to baclofen, although triceps surae clonus was still present, and functional changes in gait pattern were less evident. A third subject showed no changes in muscle activation patterns during drug periods although there was an improvement in gait speed in response to baclofen. These preliminary findings show different effects on locomotor pattern associated with each drug. We are in the process of quantifying these differences

Supported by NCE Canada, MRC, and the Man in Motion Legacy Fund.

ADAPTATION OF THE LOCOMOTOR PATTERN TO NEURO-MUSCULAR LESIONS IN NORMAL AND CHRONIC SPINAL CATS.

L. Carrier, E. Brustein, J. Provencher and S. Rossignol\*. Cntr for Res. in Neurol.

Sci., Fac. of Med., U. de Montréal, Québec, Canada H3C 317.

This work presents preliminary data on the adaptation of the locomotor pattern of cats walking on a treadmill after inactivation of the ankle flexor muscles on one side, first in the intact condition and, in one cat, after spinalization. Four cats were implanted chronically with Electromyographic (EMG) electrodes inserted, under general anesthesia, in hindlimb muscles. EMGs synchronized to video images were recorded in all sessions. One cat had a distal tenotomy of TA (Tibialis Anterior) and EDL (Extensor Digitorum Longus) and 3 cats had a neurectomy of TA and EDL. One of these was, in addition, spinalized at T13. 51 days after the neurectomy. The tenotomized cat adapted rapidly. However, the autopsy revealed that the TA and EDL tendons had regrown. The three other cats showed a remarkable adaptation of locomotion soon after the neurectomy. The kinematics showed a small increase in hip and knee flexion as well as some degree of abduction during swing so that the cats brought their limb forwards using an increased flexion mainly of the knee and some circumduction. These kinematic changes were accompanied by a consistent increase in the hip flexors such as Iliopsoas and Sartorius anterior as well as the knee flexor Semitendinosus. Most of the contralateral extensor muscles were also increased in amplitude. The one spinal cat showed some remarkable differences compared to the usual spinal cats. On the neurectomized side, the cat made shorter steps, landed on the dorsum of the toes and hyperflexed its knee during swing but could not bring its foot forward. The increased in activity of contralateral extensors also disappeared. It is concluded that locomotor adaptive mechanisms to neuromuscular deficits involve mainly supraspinal structures although some aspects of the adaptation (i.e. knee hyperflexion) may be due to some long-lasting changes in the spinal cord. (Supported by the MRC, the NCE and the FCAR).

## 360.5

POSTURAL RESPONSES DURING REACHES TO CONTRALATERAL TARGETS FOLLOWING STROKE. D.R. Fogal, M.C. Verrier, C.D. MacKinnon\*, J. Howe, and C. Diep. Departments of Rehabilitation Medicine and Physiology and the Queen Elizabeth Hospital, University of Toronto, Toronto, Ontario, Canada M5T 1W5.

The successful execution of reaching movements while standing requires anticipatory responses to stabilize posture. Posture is maintained by counteracting centre of mass displacements of the reaching arm and reaction moments created by the focal musculature. Following stroke, patients demonstrate altered sensorimotor processing that impairs the integration and performance of postural and focal tasks.

This study investigated the relationships between posture and reaching to central and contralateral visually illuminated targets (n=4) at 2 velocities (ballistic and self-paced) in patients following stroke (n=5) and matched normals. The kinematics, kinetics and muscle activations associated with the task were studied using 3D body coordinates (Selspot II), ground reaction forces (GRFs) and multichannel EMG (n=13).

Analysis revealed postural responses that were target and velocity dependent in normals. Anticipatory muscle activation and subsequent GRF generation were related to the execution of the reach. Focal movements were initiated at the time of the peak vertical GRF and displayed stereotypical position/velocity profiles. Anticipatory muscle activations and GRFs were markedly delayed in patients following stroke. A loss or degradation of normal response patterns and large increases in variability across trials were evident. Decreased excursion of the centre of pressure (COP) in the anterior/posterior directions and towards the paretic side is indicative of poor weight transference during the execution of a dynamic upper extremity task.

# 360.7

THE ONTOGENY OF MOVEMENT SEQUENCES IN JIMPY (MYELIN DEFICIENT) MICE. V.J. Bolivar\*, K. Manley and J.C. Fentress. Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4J1.

The Jimpy (jp) mutant mouse expresses severe hypomyelination in the CNS. This sex-linked mutation is due to a single base change within the myelin proteolipid protein (PLP) gene. Jimpy mice exhibit tremors, weak hind limbs and tonic-chronic seizures by weaning age. Numerous studies have examined the genetics, biochemistry, and physiology of these mice. However, the behavioral aspects of this genetic deficiency have not been well documented. Due to the progressive nature of the mutation it is important to examine the behavior ontogenetically. We selected supported swimming as a behavioral assay due to the difficulty these mice have with normal quadrupedal locomotion. Mutant jimpy males and littermate controls were videotaped (30 fps) at 2 day intervals from the 3rd to the 21st day postpartum. Videotapes were analyzed using two methods: 1) interlimb coordinations were determined by frame-by-frame analysis and 2) trajectories, accelerations and velocities of specific limb points were calculated using the PEAK Motion Measurement System. Our results indicate both subtle and gross differences between mutant and control mice and that mutants were not able to swim as efficiently as littermate controls. Our data confirm the importance of detailed behavioral documentation if we are to understand how gene expression affects motor development. (Supported by MRC grant MA7660 to J.C.F.).

SENSORY-ORGANIZATION TRAINING FOR OLDER ADULTS WITH BALANCE IMPAIRMENTS. S. Moore\*, M-S Hu, MH
Woollacott. Dept. Exercise and Movement Science, University of

Oregon, Eugene, OR 97403.

The problem of falling in older adults is multifactorial. In order for intervention to be effective, contributing factors which are modifiable must be identified. The primary hypothesis of this study is that impaired CNS processing of information from the balance senses (vision, somatosensory, vestibular) is a fall factor for some older adults. The secondary hypothesis for this study is that this factor is modifiable.

A group of older adults without balance problems (n=18, mean 75 and a group with balance problems in circumstances such as standing up, turning a corner and walking on uneven surfaces (n=14, mean 76 years), were tested for their ability to minimize postural sway when sensory information was manipulated (Nashner, 1982). The symptomatic group demonstrated 5-7 percent more sway on each sensory condition. Symptomatic older adults are participating in an 8week individualized training program which emphasizes central processing of different combinations of information from the balance senses. Preliminary pre/post test results (n=6) demonstrate a reduction in instances of loss of balance (LOB) from 8 to 0 when somatosensory information is altered, and a reduction in LOB from 13 to 7 when both somatosensory and visual information were altered.

It appears that impaired CNS processing of sensory information from the balance senses may be a modifiable fall factor for older

CLINICAL CORRELATES OF PACED VOLUNTARY POSTURAL TASK IN PATIENTS WITH PARKINSON'S DISEASE (PD) D.J. Beckley\*, V.P. Panzer, M.P. Remler and L. Ilog, Dept. of Neurology, U.C. Davis CA 94553.

In this study we asked if movement amplitude abnormalities in PD correlate with direction of movement and which clinical features best reflect changes in amplitude scores. Ten PD patients (mean age 61.9, range 47-75) performed A-P and M-L weightshifting at slow, medium and fast speeds. Movement amplitude scores were analyzed at 3 speeds (1s, 2s & 3 s), off-on medications, and in 4 directions (R, L, Fwd., Bwd.,). Changes in movement amplitude scores were correlated with modified UPDRS motor scores. We found that patients did better on right lateral weight shifts, while on medication, and that this correlated with improved postural instability and right-sided bradykinesia scores. There was a medication effect but no directional effect for A-P movements and improvement in A-P performance correlated only with improved postural instability scores. We conclude that paced voluntary movement abnormalities in PD exhibit a directional effect for lateral but not for A-P movements. Improvements in these abnormalities correlate with postural instability and bradykinesia scores but not with tremor or rigidity scores.

# 360.8

COMPARISON OF THE SYNCHRONIZATION OF HUMAN MOTOR UNITS DURING THE VOLUNTARY CONTRACTION OF THE WRIST EXTENSOR MUSCLES IN THE PREFERRED OR THE NON-PREFERRED ARM.

A. Schmied, J.P. Vedel\* and S. Pagni, UPR CNRS Neurobiologie et Mouvements, 31, Ch. Joseph aiguier, 13402 Marseille cedex 9, France The synchronization of motor unit (MU) discharges can reveal the activity of branching axons shared by the motoneurons (short-term synchronization) and/or the activity of distinct inputs that are presynaptically synchronized (long-term synchronization). Milner-Brown, Stein and Lee (1975) showed that repeated muscle exercise could enhance MU synchronization, possibly as a result of a strengthening of corticomotoneuronal pathways. We documented the dependence of MU synchronization on muscle use with regard to the preferred arm of the subjects. MU synchronization was analyzed in the left arm of 9 righthanded and 6 left-handed subjects by cross-correlating the discharges of pairs of MUs recorded independently and differentiated as "slow" "fast" on the basis of their force recruitment threshold and their twitch contraction time. The subjects tested with their preferred arm presented a significantly higher incidence of MU synchronization, affecting similarly the pairs of 'slow' and 'fast' MUs as well as the mixed pairs. The area of the narrow cross-correlogram peaks (<7,5 ms) reflecting most likely MU short-term synchronization tend to be larger for all types of MUs pairs in the left arm of left-handed subjects. This suggests an increase in the efficiency of common inputs controlling "slow" as well as "fast" MUs in the preferred arm. Broader peaks likely to involved longterm synchronization components were significantly more numerous for pairs including one or two "fast" MUs. The dependence of MU synchronization on arm preference is confirmed by preliminary data obtained in the preferred and the non-preferred arm in the same subject.

MODELING DYSKINESIA: I - DEVELOPMENT OF A DYNAMIC MODEL. JB Lohr and MP Caligiuri, Department of Psychiatry, UCSD Department of Psychiatry, and San Diego VA Medical Center, San Diego, CA 92161

Center, San Diego, CA 92161

Choreoathetoid dyskinesias have long been known to consist of random-appearing patterns of abnormal movement. Recently, DeLong and others (DeLong, 1990) have suggested that choreoathetoid dyskinesias may result from abnormal reduction in output from the internal segment of the globus pallidus and substantia nigra pars reticulata, in part related to an abnormal reduction in output from the subthalamic nucleus. We conjectured that, rather than a simple reduction in glutamatergic output from the subthalamic nucleus, there may in fact be erratic output, and that this erratic output could possibly be the result of chaotic behavior of the basal ganglia circuitry involved in dyskinesia. To follow-up on this idea, we modeled a modified version of the circuitry proposed by DeLong. The model presented gives evidence of chaotic behavior when certain critical parameters are varied. The results are consistent with the notion that chaotic dynamics may underlie the clinical appearance of abnormal movements induced by L-dopa and dyskinetic disorders such as neuroleptic withdrawal-emergent dyskinesia and tardive dyskinesia.

TREMOR AS A FACTOR IN DELAYED REACTION TIME G. Staude  $^1$ , W. Wolf  $^1$ , M. M. Wierzbicka  $^*$   $^2$ , R. Dengler  $^3$   $^1$ Bundeswehr University, Munich, Germany,  $^2$ West Roxbury VA Medical Center & Harvard Medical School, Boston MA,  $^3$ University of Bonn, Bonn, Germany.

We have recently shown (Soc. Neurosci. Abstr. 17:1032, 1991) the existence of a systematic phase relationship between resting tremor and the onset of rapid voluntary contraction in patients with Parkinson's disease (PD). The present study was undertaken to see whether this phase relationship contributes to the prolongation of reaction time in PD. Control subjects and PD patients produced fast index finger abductions to a visual target under a simple reaction time condition. Force/displacement and surface EMG from the first dorsal interesseus muscle were recorded. We used a new technique for on-line analysis of tremor to present the "GO" stimulus at certain phases of the actual tremor cycle. In PD significant differences were found in mean reaction times calculated separately for different locations of the "GO" stimulus within the tremor cycle in both isometric and isotonic conditions. Reactions with an expected onset during the first half of the EMG tremor cycle were delayed in comparison to trials with an expected onset during the second half of the EMG tremor cycle. Similar effects were also found for physiological tremor but they had less influence on reaction time because of the higher tremor frequency. We concluded that attraction of the onset of the voluntary motor response to the tremor oscillator contributes to a delay in reaction time which extent depends on tremor

frequency. (Supported by DFG grant)

MODULATION OF CUTANEOUS INPUT DURING PREPARATION AND EXECUTION OF MOVEMENT IN THE ELDERLY. Arseneau C.A. and Forget R.\* Hôpital Hôtel-Dieu de Montréal et Ecole de réadaptation, Univ. de Montréal, C.P. 6128 succ. A, Montréal, Canada, H3C 3J7
Sensor (input modulation and motor output were studied in 20 healthy elderty subjects (v. – 64 + 5 vers.) Responses to readom electrical etimoletics.

Sensory input modulation and motor output were studied in 20 healthy elderly subjects (x= 64 ± 5 years). Responses to random electrical stimulation of the digits which were involved in a forewarned motor task were compared between 5 conditions: 1) 3250 ms and 2) 500 ms before the go signal during a 4 sec preparatory period, 3) during the holding period of an isometric force task, 4) during feedback processing and 5) at rest after the release of force. Recordings included: somatosensory evoked potentials (SEP) at 5 scalp locations (3 cm anterior and posterior to C3 and C4 and at C2), EMG of finger flexors and neck muscles and the median neurogram at the wrist.

During movement execution, amplitudes of contralateral early SEP components were decreased by 35% (N2D930) and 50% (P22N30) at parietal and frontal locations respectively. Intermediate component P4SN70 was also

components were decreased by 35% (N20P30) and 50% (P22N30) at parietal and frontal locations respectively. Intermediate component P45N70 was also decreased by 20% during movement. These components also showed a significant gating, but to a lesser extent, at the end of the preparatory period (500 ms before the go signal). However, the late component P100N140, which had a bigger amplitude at Cz (over SMA area) was not affected during movement but was significantly increased before movement and during feedback processing after movement. Recording of the median n. and EEG subtraction of stimulated and non-stimulated trials showed that the modulation of SEP amplitudes was not due to a change in the afferent volley and/or contamination by cerebral motor activity (CNV, BP, MP). In some subjects the stimulation of the digits evoked a reflex contraction which was decreased during movement. It is concluded that in the elderly: 1) gating of early SEP stimulation of the digits evoked a renex contraction which was decreased uting movement. It is concluded that in the elderly: 1) gating of early SEP components begins at the end of preparatory period and is strongest during execution of movement, 2) a dissociation between early and late SEP components is found in the preparatory period, 3) reflex activity is inhibited during execution of movement. (Supported by the FRSQ)

MODELING DYSKINESIA: II - QUANTITATIVE CLINICAL STUDIES IN PARKINSON'S DISEASE. MP Caligiuri and clohr Motor Function Laboratory, VA Medical Center, UCSD Department of Paychiatry, San Diego, CA 92161

Nonlinear dynamic models are useful tools for examining the neural circuitry involved in abnormal motor behavior such as tremor (Beuter et al., 1991) and dyskinesia (Lohr and Caligiuri, 1992). These models suggest an interaction among tremor, akinesia, and dyskinesia as parameters of the model change. Purpose The aim of this study was to examine the interactions between tremor, akinesia, and dyskinesia with time post-drug as a critical parameter. Methods PD patients with Peak dose dyskinesia with time post-drug as a critical parameter. Methods PD patients with peak dose dyskinesia were evaluated during six 5-minute segments 30 minutes prior to and following a single dose of Sinemet. Orofacial and hand dyskinesia and tremor were quantified using isometric procedures; bradykinesia was quantified by obtaining the peak velocity associated with rapid ballistic wrist flexion. Results Inspection of temporal interactions between dyskinesia and parkinsonism indicated that increased dyskinesia coincided with dopa-induced changes in movement velocity, but not tremor amplitude. Conclusion These findings contribute to ongoing efforts to model the time-dependent dynamic interactions between dyskinesia, bradykinesia, and tremor in PD patients exhibiting drug-induced dyskinesia. dvskinesia.

OVERCOMING MOVEMENT RESTRICTIONS IMPOSED BY HYPERTONUS THROUGH ANTAGONIST MUSCLE ACTIVATION. S. Wolf\*, P. Catlin S. Blanton, J. Edelman, N. Lehrer, D. Schroeder. Dept. of Rehabilitation Medicine, Division of Physical Therapy

Emory University School of Medicine, Atlanta, GA 30322.

A traditional perspective on the rehabilitation of patients with spasticity presumes that hyperactive muscles must first be relaxed before antagonists are recruited if effective motion about a joint is to occur. To examine this concept, eight subjects with chronic stroke (greater than one year) received feedback to retrain the triceps in the presence of biceps spasticity. Eight additional subjects received conventional movement training. Ten training sessions were given using functional tasks of elbow extension. Measurements included range of motion, speed of movement, and triceps and biceps EMG during triceps contraction. Between group comparisons showed no significant differences. Within group comparisons showed significant increases in triceps EMG output during more measures in the feedback group than in the conventionally trained group. Passive and active range of motion in both groups also increased significantly, while biceps cocontraction persisted. This differentiation suggests that functional improvements at the elbow may have been due to biomechanical (peripheral) rather than neuromuscular (central) changes about the joint. Furthermore, subjects can be trained to increase movement without first specifically inhibiting activity in the spastic muscle

BRADYKINESIA IN ALZHEIMER'S DISEASE: STAGE-DEPENDENT OVERLAP WITH PARKINSON'S DISEASE <u>IC Morris\*, VD Buckles, SA Sahrmann, MC Smith, M Storandt, JD Baty, P Amrhein, Alzheimer's Disease Research Center, Washington University Sch Med., St. Louis, MO 63110; Dept</u> Psychology, Univ New Mexico, Albuquerque, NM 87131

Advanced Alzheimer's disease (AD) is associated with extrapyramidal dysfunction resembling that of Parkinson's disease (PD). We studied subjects in milder stages of AD for presymptomatic parkinsonian dysfunction. There were 4 study groups: very mild AD (n=35; x age=72.7y); mild-moderate AD (n=19; x age=72.4y); PD (n=42; x age=69.5y); and controls (n=46; x age=73.5y). Mean Northwestern Disability composite score for PD subjects was 1.05 (equivalent to Hoehn and Yahr score of 2) and negligible for the other 3 groups (no clinical parkinsonism). Antiparkinsonian medications were withheld in PD subjects for 12 hours prior to motor testing. Subjects were assessed psychometrically (measuring aspects of memory, language, and psychomotor performance) and motorically (temporal measures of gait by motion analysis, finger-tapping, and paradigms for reaction time [RT] and movement time [MT]). Using age and education as covariates, the PD and control groups had generally similar psychometric performance profiles and performed significantly better than the AD groups. The mild-moderate AD group demonstrated bradykinesia comparable to the PD group on gait velocity, fingertapping, and MT; both groups were impaired on these measures relative to the very mild AD and control groups. The mild-moderate AD subjects, but not the PD or other subjects, were impaired on RT. We conclude that preclinical bradykinesia is present in mild-moderate AD and is qualitatively similar to that of PD. However, it appears to have distinct pathophysiologic correlates: bradykinesia in AD is associated with both the presence and severity of cognitive dysfunction.

MOTOR CONTROL DIFFERENCES IN ALZHEIMER'S AND PARKINSON'S DISEASES. V Diggles-Buckles\*, JC Morris, and JD Baty. Dept. of Neurology, Jewish Hospital and Div. of Biostatistics, Washington Univ. Sch. of Medicine., St. Louis, MO 63110.

Motor control differences in simple, discrete movements were observed in patients with Parkinsons's Disease (PD, n=39) and Alzheimer's Disease (AD) as compared with controls (n=36). ADs were divided into 2 groups according to dementia severity: questionable, (n=24) and mild-moderate, (n=13). In a Fitts type task, subjects made discrete movements to a series of 4 targets of varying sizes at a distance of 60 cm from the start position, following an auditory 'go' signal. Index of Difficulty (ID in bits) for each target was calculated and individual, median reaction times (RT) and movement times (MT) were analyzed in repeated measures ANOVAs. RT results revealed a significant group main effect in which measures ANOVAS. R1 results revealed a significant group main effect in which the mild-moderate ADs were significantly slower than all other groups. A surprising group x ID interaction was present in which mild-moderate ADs took longer to program low difficulty movements. A learning/familiarization effect may explain this result, since the larger targets (lower difficulty) were first. MT results revealed significant main effects of group and ID (MT increased with ID). MTs of PDs and ADs averaged 80 and 170 ms slower, respectively, than controls and questionable ADs. Conclusions: Questionable ADs performed essentially the same as controls on this task; slowing in the AD group ocurred only in the more severely demented. Mild-moderate ADs took longer for motor preparation (RT) than the other groups. PDs and mild-moderate ADs showed differences in motor system efficiency as indicated by baseline differences in MT. All groups produced the linear relationship between MT and ID that Fitts predicted, and slopes of the regression lines were not significantly different, indicating that the information processing rates (increase in time per bit of information) of the motor control system are comparable between all groups. THE EFFECTS OF GLUCOSE DEPRIVATION TRANSMISSION AND METABOLITE LEVELS IN HIPPOCAMPUS. K. A. Heldman\*, N. A. Veyna, R. B. Marchase, and M. J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham AL 35294.

Glucose is important in permel annual a LTERNATIVE SUBSTRATES

Glucose is important in normal synaptic transmission in the mammalian brain. It is considered the primary energy source, although alternative substrates have been suggested (Cox & Bachelard, Exp. Brain Res. 69:368-372, 1988; Schurr et al., Science 24:1326-1328, 1988). In addition to producing energy, glucose supports pools of UDP-glucose and UDP-N-acetylglucosamine, which are necessary for the synthesis of and UDP-N-acetylglucosamine, which are necessary for the synthesis of complex glycoconjugates. In order to determine which roles of glucose are necessary for synaptic transmission, we investigated the 1) effects of glucose deprivation, 2) the adequacy of alternative energy substrates such as lactate and pyruvate, and 3) the routing of exogenous radiolabeled glucose during synaptic activity. The Schaffer collateral pathway was stimulated (0.05-0.10 Hz) in submerged, warmed hippocampal slices prepared from anesthetized guinea pigs. Normal synaptic efficacy (evaluated by ratios of rise time of the field EPSP to amplitude of the afferent volley) was maintained in glucose (5.5 or 11.0 mM, n=6), pyruvate (11 mM, n=4) and lactate (11 mM, n=4). Synaptic efficacy was greatly reduced in 0 mM glucose (n=5), 5 mM lactate (n=2) and 5 mM pyruvate (n=1), although the afferent volley was unaffected. In slices deprived of adequate substrate, UDP-glucose levels were more dramatically decreased than were ATP levels.

DOSE-RELATED EFFECTS OF THE ANXIOLITIC BUSPIRONE ON REGIONAL CEREBRAL GLUCOSE METABOLISM (rCMRglc) IN AWAKE RATS. U. Freo\*, M. Dam. G. Pizzolato, P. Pietrini#, A. Morico, S. Ruggero, L. Battistin. Neurology Dept., University of Padua Medical School, & # Psychiatry

Battistin. Neurology Dept., University of Padua Medical School, & # Psychiatry Dept., University of Pisa Medical School, Italy.

The relation to dose of rCMRglc was determined in awake 3-month-old male Fisher-344 rats after administration of the 5-HT1A receptor agonist buspirone, clinically used as an anxiolitic. Using the quantitative autoradiographic [14C]2dcoxyd-glucose technique, rCMRglc was measured in 47 brain regions 10 min after administration of buspirone 0.2, 4, and 20 mg/kg i.p., respectively.

Buspirone 0.2 mg/kg i.p. significantly (p< 0.05) reduced rCMRglc in 21 (42%) brain regions (average decline: −219%), mostly in the limbic areas (dorsal and ventral hippocampus) and raphe nuclei (median and dorsal), which contain the highest 5-HT1A receptor densities. Buspirone 4 and 20 mg/kg i.p. reduced rCMRglc in 35 (74%) and 36 (76%) brain regions, respectively, including cortical, basal ganglia, diencephalic and cerebellar areas (average rCMRglc decline: −30%) and increased rCMRglc in the lateral habenula (mean increase: +55%). As we recently reported [Freo et al., Biol Psychiatry, 29 (11S): 204, 1991], rCMRglc is reduced in the raphe-hippocampal system also by administration of low-dose clomipramine, a clinical hippocampal system also by administration of low-dose clomipramine, a clinical antidepressant. This is intriguing because buspirone is an atypical anxiolitic with no muscle relaxant and anticonvulsive activities, unlike benzodiazepines, and with a slow onset of action like tryciclic antidepressant. Both clomipramine and buspirone are clinically employed in the treatment of psychopathological conditions with coexistent anxiety and depression.

The pattern produced by high doses of buspirone (widespread rCMRglc reduction and isolated rCMRglc increase in the lateral habenula) is similar to those induced by dopaminergic antagonists such as haloperidol, and is in agreement with the reported antidopaminergic activity of buspirone.

### 361.2

STIMULATION OF THE DORSAL RAPHE NUCLEUS WITH KAINATE BUT NOT L-GLUTAMATE INCREASES CORTICAL CEREBRAL BLOOD FLOW IN RAT. M.J. Bakalian\*, M.D. Underwood, V. Arango and J.J. Mann. Labs of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213

Electrical stimulation in the rostral portion of the dorsal raphe nucleus (DRN) elicits decreases in cortical blood flow (CBF), while stimulation in caudal DRN elicits decreases in cortical blood flow (CBF), while stimulation in caudal DRN neurons, but not fibers of passage, by chemical stimulation with the excitatory amino acids L-glutamate (L-glu) and kainate (KA). Studies were performed in 23 adult male Sprague-Dawley rats anesthetized with isoflurane (1 - 5% in 100% O<sub>2</sub>) and α-chloralose (30 - 40 mg/kg, s.c.). Animals were paralyzed and artificially ventilated to maintain arterial blood gases in physiological ranges. Parietal CBF (perfusion units, PU) was continuously monitored by laser-Doppler flowmetry. L-glu (0,1 - 10 nmol/100 nL) or KA (0.005 - 5 nmol/100 nL) were microinjected (15 - 100 nL) over 30 - 60 sec into the DRN using a stereotaxically-guided Hamilton syringe. Injection stress were marked with fast open day and perconstructed from Nissl stained commal 30 - 60 sec into the DRN using a stereotaxically-guided Hamilton syringe. Injection sites were marked with fast green dye and reconstructed from Nissl stained coronal sections. The DRN was mapped with L-glu (1 nmol) in 1 mm increments and no effect was observed from either the DRN (ΔCBF: 4 ± 3 PU; ΔMAP: -2 ± 2 mmHg) or 1 mm above the DRN (ΔCBF: 0 ± 3 PU; ΔMAP: 1 ± 4 mmHg)(p > 0.05). Decreases in MAP (-12 ± 2 mmHg) and CBF (-6 ± 4 PU) were elicited from the median raphe nucleus located ventrally (p < 0.05). In the DRN, L-glu did not affect CBF or MAP at any dose examined (p > 0.05). The effect of microinjection of KA (0.005 nmol to 0.5 nmol) into the DRN on CBF or MAP did not differ from saline (p> 0.05). DRN microinjection of 5 nmol KA increased CBF (19% ± 10%) and MAP (8% ± 4%) 2 min following the onset of microinjection. The CBF elevation (p> 0.05). DRN microinjection of 5 nmol KA increased CBF (19% ± 10%) and MAP (8% ± 4%) 2 min following the onset of microinjection. The CBF elevation was sustained for 5 min, maximal (28% ± 10%; p < 0.05) at min 3 and returned to baseline levels 7 min following microinjection onset. The MAP increase was maximal at min 7 (Δ18 ± 7 mmHg) and remained elevated beyond the 10 min of observation. Decreases in CBF or MAP were not consistently observed. We conclude that stimulation of DRN neurons, but not fibers of passage, increases CBF in excess of increases of arterial pressure. Supported by NARSAD to MDU and MH46745.

# 361.4

THE CONSEQUENCES OF ESTRADIOL INCREASING CEREBRAL GLUCOSE UTILIZATION. J. Bishop and J.W. Simpkins. Center for the Neurobiology of Aging, University of Florida, Gainesville, FL 32610.

We have previously shown that a single dose of estradiol increases glucose utilization in the CNS by as much as 220%. To assess the physiological consequence of this estradiol-modulated increase in cerebral glucose utilization, we evaluated two conditions in which estradiol may significantly affect glucose transport: (i) hypoglycemia, (ii) neuroglucopenia induced by morphine withdrawal. We measured ACTH as an index of the sympathetic response to changes in brain glucose availability. Rats were ovariectomized and treated with estradiol or oil. We provoked an insulin-induced hypoglycemia or a naloxoneinduced increase in brain glucose utilization. There was no estradiol effect on plasma glucose levels as the animals responded to either insulin or naloxone. In both studies, however, estradiol significantly decreased basal ACTH levels. In response to the naloxone-induced hyperglycemia there was an ACTH response equivalent in the two groups for the first 30 minutes. In estradiol treated animals, we observed the expected return toward basal levels over the 120 minute period. In oil treated animals ACTH remained at peak levels for 2 hours. These results suggest (i) estradiol reduces the sympathetic response to neuroglucopenia and (ii) ovariectomized animals fail to respond to the enhanced availability of glucose with an appropriate termination of the stress response (Supported by NIHAG 10485).

Dual-label autoradiographic comparison of glucose and deoxyglucose regional blood-brain transport kinetics.

J.L. Lear and R.F. Ackermann\*. Nuclear Medicine, Health Sciences Center, Denver CO 08262; Nuclear Medicine, UCLA School of Medicine, Los Angeles CA 90024.

The deoxyglucose (DG) method for quantifying brain glucose metabolism assumes a fixed relationship (the "lumped constant" [LC]), between net DG and glucose (GLC) extraction. Although the LC can be affected by the rate of bloodto-brain DG transport relative to that of GLC, the regional uniformity of the DG vs. GLC transport-rate relationship is not well-studied. Here, we used dual-tracer autoradiography to directly compare the transport rate constant  $(K_1)$  of radiolabeled DG and GLC, in both normal and kainate-activated rat brains. Each rat received a 45 sec i.v. infusion containing both <sup>18</sup>F-fluorodeoxyglucose (FDG) and <sup>14</sup>C-GLC, then was immediately decapitated, and its brain sectioned Two tracer concentration images, one for autoradiography. representing FDG and the other GLC, were generated from each brain section. Each image was digitized and converted by computer into images of  $K_1$  value. Overall  $K_1$  values for FDG and GLC did not differ significantly, but certain areas such as hippocampus showed distinctly different patterns of FDG vs. GLC transport. Although kainate-activation changed the overall  $K_1$  values, differences between hippocampal FDG and GLC transport pattern nevertheless persisted. Thus, the assumption of uniform DG vs. GLC transport throughout the brain is not entirely correct. Hence, the LC may differ substantially from a global norm in specific brain regions.

FEASIBILITY OF IN-VIVO BRAIN CHEMILUMINESCENCE UNDER PHYSIOLOGICAL AND PATHOPHYSIOLOGICAL CONDITIONS. U.Dirnagl, U.Ködel, W.H.Örtel', H.W.Pfister, L.Schleinkofer, A.Villringer. Dept.of Neurology, University of Munich, 8000 Munich 70, F.R.G.

The aim of this study was to test the feasibility of counting photons generated by free oxygen radical species in brain cortex in vivo. Anesthetized and ventilated rats were equipped with a closed cranial window over the parietal cortex (0.25 cm<sup>2</sup> exposed). Intracranial pressure (ICP), mean arterial blood pressure (MABP), body temperature, endexspiratory pCO<sub>2</sub>, and blood gases were monitored. The animals were housed in a dark box. The detector was a cooled photon counting camera (Hamamatsu Photonics). Chemiluminescence was enhanced with 10<sup>-2</sup> M lucigenin i.v. The dark count was 234  $\pm$  14 CPM (counts per minute  $\pm$  SD, n=10 rats). 672  $\pm$  196 CPM (n=10) from the brain were counted. I.v. infusion of lucigenin (no effect on MABP, ICP, cerebral blood flow, blood gases etc.) led to an enhancement to 969  $\pm$  346 CPM (n=10). Hyperoxia (100 % O<sub>2</sub>, n=2) increased the count from 1153  $\pm$  652 to 1647  $\pm$  716 CPM within 25 minutes. Treatment with the free radical scavengers superoxide-dismutase (Cu-Zn-SOD) or catalase decreased the hyperoxic count. Hypoxia (5% O2, 95% N2, n=2) for 5 minutes led to an immediate drop in the count rate from 1374  $\pm$  56 CPM to 1014  $\pm$  260 CPM, followed by a delayed increase to 1771  $\pm$  130 CPM within 60 Global forebrain ischemia (n=2) for 10 minutes followed by reperfusion led to an increase in the count rate from 720  $\pm$  12 CPM to 1238  $\pm$ 382 CPM. Pneumococcal meningitis (n=2) raised the count from 817  $\pm$  160 to 1417 ± 143 CPM within 220 minutes, treatment with Cu-Zn-SOD decreased the count to 1238 ± 382 CPM. We conclude that it is feasible to monitor biophotons from the living, exposed brain of experimental animals, and that the system may enable continuous detection of oxygen free radical production in vivo.

COMPUTER-DIRECTED COREGISTRATION OF MULTISLICE FUNCTIONAL AND ANATOMIC BRAIN IMAGES WITH FIXED EXTERNAL FIDUCIALS. R.T. Malison\*. E.G. Miller. R. Greene. G. McCarthy. and R.B. Innis. Yale University School of Medicine and CORITechs, Inc., New Haven, CT

Using fixed external fiducials, we have developed and validated in a phantom a method of computer-assisted coregistration for multislice SPECT and MRI brain images. Reusable markers were fabricated from nylon-based plastic and consisted of two parts: a base which may be attached to the skin with adhesive; and a removable, spherical-cavity insert (5 mm i.d.). The markers can be filled with contrast agents appropriate for multiple imaging modalities. Skin dosimetry is reduced because the spherical insert can be removed between studies (and later exactly repositioned into the base). A set of markers internal and external to a 3D brain phantom provided a means of quantifying the accuracy of the coregistration. A computer algorithm, with precautions against local minima, was used to derive transformation matrices for image sets by minimizing the mean squared deviations obtained from differing permutations (n=10) of increasing numbers (range 3-11) of corresponding external SPECT/MRI point-pairs. As defined by the mean (±SEM) root mean square (RMS) values of non-coregistered internal fiducials, the minimal accuracy was 2.5±0.4 mm for three coregistration points. The absolute accuracy (likely greater than the RMS) was not significantly improved by using greater than 7.8 markers (RMS=2.3±0.3 mm), at which point internal and external RNS values asymptotically converged. This corresponded roughly to the largest SPECT (2.4 mm) and/or MRI (2.2 mm) voxel dimension(s). That is, the coregistration appeared nearly perfect and was confirmed by transformation of two MRI (or SPECT) that sets, measures of test/retest- (RMS=0.5±0.1 and 0.5±0.1 mm, respectively) and internater-reliability (0.5±0.3 and 0.8±0.1 mm) were analogously obtained, establishing the method as highly reproducible and objective. Preliminary results in humans suggest its feasibility for clinical studies.

### THERMAL MAPPING OF RAT CORTICAL FUNCTION

E.M.Santori\*, S.Narayan, A.M.Gorbach, and A.W.Toga Laboratory of Neuro Imaging, Dept of Neurology, UCLA Los Angeles, CA 90024

Digital processing of images captured by infrared cameras has made it feasible to map small changes in cortical temperature that may be associated with altered functional activity <sup>1</sup>. We have sought to examine the capabilities of thermoencephaloscopy (TES) by studying thermal responses to direct intracortical electrical stimulation.

Infrared radiation at the dorsal skull surface of urethane anesthetized rats was detected with an Amber 4128 Focal Plane Array detector. Stimulation of forelimb sensorimotor cortex with 1 second train of 0.2 msec electrical pulses delivered at 500 HZ induced a focal thermal increase contralaterally. The thermal response started approximately 0.5 seconds after the end of the stimulus and lasted one to two seconds. This effect could be observed without digital averaging or subtraction.

These results suggest that TES could provide a powerful new method for studying rapid changes in cortical function.

NONINVASIVE MONITORING OF LOCAL CEREBRAL BLOOD VOLUME AND TISSUE OXYGENATION DURING COGNITIVE TASKS IN MAN USING NEAR INFRARED SPECTROSCOPY. <u>A.Villringer</u>, <u>K.Bötzel, C.Hock', L.Schleinkofer, U.Dirnagl</u>, Dept. of Neurology and Psychiatry, University of Munich 8000 Munich 70 FR.G.

University of Munich, 8000 Munich 70, F.R.G.

The purpose of this study was to evaluate near infrared spectroscopy (NIRS) for the assessment of cerebral hemodynamic responses and alterations in tissue oxygenation during performance of cognitive tasks. 10 healthy human subjects (age 25 - 45) were examined. We used a Hamamatsu NIRO 500 system. The light from the Laser diodes (wavelengths 775, 825, 850, 904 nm) is guided through a fibre optic bundle, the end of which (the optode) is placed on the left forehead, another optode leading to the photomultiplier is placed at a distance of 3.5 to 5 cm. Depending on the absorption of the near infrared light at the various wave lengths in the brain tissue, changes in the local concentration of hemoglobin [Hb], oxygenated hemoglobin [HbO<sub>2</sub>] blood volume (BV=Hb+HbO2) and oxygenated cytochrome oxydase  $[Cyt-O_2]$  are determined. The maximal temporal resolution is 0.5 seconds. The experimental protocol included periods of rest with eyes closed (6 min), eyes open (2 min), calculating (2 min), and rest with eye closed (6 min). Sufficient signal to noise was obtained in all subjects. Eye opening did not significantly affect the hemodynamic and tissue oxidation parameters. During calculating, [HbO2] and BV increased and [Hb] decreased; Cyt-O<sub>2</sub> either increased or remained unchanged. We conclude that alterations in local brain tissue blood volume and oxygenation during cognitive tasks can be monitored noninvasively using NIRS. In combination with evoked potential techniques this method may become an important tool in stuying the interaction of cerebral function, hemodynamics, and energy metabolism.

CORTICAL AND SUBCORTICAL METABOLIC PATTERN MAPPING BASED ON FUNCTION/ANATOMIC FUSION IMAGING FROM REGISTERED PET AND MR IMAGES H.L. Loats\*, E.A. Gastineau, T. Rippeon, M. McIver, S. Loats, H. Holcomb, C. A. Tamminga, Loats Associates, Inc., Westminster, MD 21157, University of Maryland, MPRC, Baltimore, MD 21228, Johns Hopkins Medical Institutes, Baltimore, MD 21205

The interpretation of functional images is generally impeded by the relatively limited anatomic information provided by the functional image. A rapid method for construction of cortical surfaces from registered MR images has been developed. This technique additionally permits construction of functional surfaces from registered PET data sets. Quantitative fusion of functional and anatomic images provides a tool for brain function mapping. Gyral and sulcal features are visually identified from the MRI cortical surface projections for right/left sagittal, anterior and posterior views. These serve as measurement templates for subsequent redirected sampling performed on a series of functional images. Cortical metabolic patterns are produced by projecting onto the cortical surface the average metabolic concentration measured from the surface to a depth of the cortex. Metabolic values for subcortical anatomic features are produced from volumetric shapes derived from volume MRI data sets. The change in cortical metabolic patterns with haloperidol have been analyzed in a series of eight on/off medicated patients. Volumetric metabolic activity and spatial correlation over specific cortical areas have been measured using the MRI cortical surface and the functional images. Accurate fusion of structure-function cortical surfaces provides a unique analytic method for resolving spatially complex, physiological changes.

DETECTION OF PHYSIOLOGICAL (PET) SIGNALS IN INDIVIDUAL SUBJECTS. J.T. Metz\*, C.-T. Chen, M. Jiang, J.-S. Chou, M. Cooper. University of Chicago, Chicago, IL 60637.

Or Chicago, Chicago, IL 00637.

Current methods for detecting metabolic or blood flow changes associated with behavioral or cognitive events ("signals") depend largely on averaging PET images across a number of subjects. Typically, some form of average image based on differences between activation and reference scans is used to define regions of increased activation. Although useful, this approach suffers from imprecision due to individual differences in brain anatomy and in spatial localization of activations.

to individual differences in brain anatomy and in spatial localization of activations. It also has limited usefulness about possible abnormalities in individual subjects. We have identified five steps which can be added to the conventional methods to overcome these limitations. We begin by defining an appropriate group for across subject averaging. Each member of the group must meet behavioral criteria (obtained at the time of scanning) for inclusion in the group (1). All normalized PET images obtained from each subject are then correlated with the subject's MRI and other PET images (2) prior to pixel-by-pixel subtraction of activation and reference scans. Difference images are converted to stereotactic space and averaged across subjects. Thresholding on statistical criteria is used to define regions of increased activation. Each subject is then re-examined for evidence of an activation in close proximity to the group-defined average location (3). The an activation in close proximity to the group-defined average location (3). The likelihood of defined signals occurring in an individual subject, disregarding other activations which may also be present in the subject, is thus determined; this can be used to establish the importance of a lack of signal in some subjects. Repeated presentation of the same reference and activation conditions can improve sensitivity minimizing spurious activations through within-subject averaging (4). Improved methods of interpolation and elastic warping can also reduce blurring when averaging access exhibitors.

methods of interpolation and elastic warping can also reduce ordining when averaging across subjects (5).

The importance of each of these steps depends on the relative size of the physiological signal under study. Experiments using only methods 2 and 4 indicate that signals of about 3 standard deviations from the mean difference level can be detected in individual subjects.

SINGLE CASE ANALYSIS OF CEREBRAL ACTIVATION IN POSITRON EMISSION TOMOGRAPHY (PET). R. J. Seitz<sup>1\*</sup>, U. Knorr<sup>1</sup>, G. Schlaug<sup>1</sup>, Y. Huang<sup>1</sup>, H. Steinmetz<sup>1</sup>, H. Herzog<sup>2</sup>, B. Nebeling<sup>3</sup>. <sup>1</sup>Department of Neurology, Heinrich-Heine-University, 4000 Düsseldorf 1, Institutes of

<sup>2</sup>Medicine and <sup>3</sup>Radiochemistry, Research Center Jülich, FRGermany. Areas of cerebral activation present as regions of interest (ROIs) in subtraction images calculated from PET images of a specific stimulation task and an appropriate control condition. We developed a new algorithm to identify task-specific signals in individual subjects. Our algorithm employs an exponential ranking of ROIs automatically drawn at a 30% isocontour of the maximal pixel value in subtraction images. The algorithm was validated by a cylindrical phantom with low activity in the background compartment and high activity in six spheres of different size. Noise was induced by subtraction of sequential PET-scans of the phantom utilizing the inhomogeneity of the PET images reconstructed with the back projection technique. Spheres with a diameter larger than 25 mm were identified as specific signals (threshold rank = 0.98) in subtraction images with a 100% noise using the SCX PC4096 PET-camera and a reconstruction filter of 6 mm (FWHM).

We applied this method on measurements of the regional cerebral blood flow (rCBF) with <sup>15</sup>O-butanol in five healthy subjects during execution of simple motor tasks in comparison to rest. After spatial alignment and integrated display of PET and high-resolution magnetic resonance (MR) images, the task-specific rCBF increases were identified accurately in the contralateral sensorimotor cortex and in additional cerebral motor structures of both hemispheres. Our results indicate that single case analysis of PET activation studies identifies the common essential areas of activity changes and other task-specific activation sites with individual distributions.

BRAIN DEVELOPMENT IN VERVET MONKEYS: A PRELIMINARY PET STUDY. B. Jacobs\* H.T. Chugani, V. Allada, G.C. Harris, S. Chen, M.E. Phelps, D.B. Pollack, and M.J. Raleigh. UCLA School of Medicine, Los Angeles, CA 90024.

This positron emission tomography (PET) study examined age-related

changes in local cerebral metabolic rates for glucose (LCMRglc) in 6 vervet monkeys (Cercopithecus aethiops sabeaus) ranging in age from 0.13 to 4.38 monkeys (Cercopithecus aethiops sabeaus) ranging in age from 0.13 to 4.38 years. The 2-deoxy-2[<sup>18F</sup>] [Juoro-D-plucose (FDG) technique was performed on the CTI-713 tomograph (CTI/Siemens), which acquires 15 slices at 3.4mm spacing and has a practical in plane resolution of 4.5mm. Monkeys were anesthetized with ketamine (12 mg/kg/hr) and midazolam (0.17 mg/kg/hr) (animal approval #92-075). After FDG injection, arterial blood samples were obtained to determine the arterial input function. A total of 20 brain regions were drawn for each animal; LCMRgle were expressed in µmol/min/100gm.

Metabolic rates across all monkeys were highest in basal ganglia and fearable resolutions.

frontal areas (e.g., anterior cingulate gyrus, sensorimotor and dorsolateral cortices). Lowest LCMRglc were found in the thalamus, cerebellum, brainstem and neocortical white matter. LCMRglc appeared to peak for most structures in the 0.25 year old monkey (Mean LCMRgle = 55.35). This peak in LCMRgle corresponds with the developmental spine density peaks observed in the primary visual cortex of Macaca nemestrina (Booth et al., 1979, J. Comp. Neurol., 186:473-490) and with synaptic overproduction in the sensorimotor, prefrontal and visual cortices of Macaca mulatta (Rakic et al., 1986, Science, 232:232-235). There was a steady age-related decline in LCMRgle in all regions after 0.25 years such that metabolic rates were an average of 57% lower in the oldest monkey (Mean LCMRglc = 23.79). Although preliminary, these findings are consistent with the metabolic changes reported in humans (Chugani et al., 1987, Ann. Neurol., 22:487-497), cats (Chugani et al., 191, J. Cereb. Blood Flow. Metab., 11:35-47) and Macaca mulaita (Kennedy et al., 1982, Ann. Neurol., 12:333-340). (Supported by DOE #DE-FC03-87-ER-60615.)

INTER-SUBJECT VARIABILITY OF CEREBRAL ACTIVATION IN MOTOR LEARNING. G. Schlaug\*, U. Knorr, R. J. Seitz. Department of Neurology, Heinrich-Heine-University, 4000 Düsseldorf 1, FRGermany

Learning of a right hand finger movement sequence in healthy, right-handed volunteers has recently been shown on spatially standardized and averaged positron emission tomography (PET) images to be associated with a significant increase of the mean regional cerebral blood flow (rCBF) in left primary sensorimotor areas, premotor cortical areas, right cerebellum and with a significant augmentation of the mean rCBF in the left basal ganglia during learning (Seitz and Roland, Eur J Neurosci 4: 154-165, 1992). We applied now a new algorithm for the analysis of the individual task-specific cerebral activation patterns in each of the nine volunteers. As validated in a phantom study, task-specific activation areas are identified by exponential ranking of all activity changes in PET subtraction images

The individual analysis on integrated PET and high-resolution magnetic resonance images revealed a consistent task-specific activation in all nine subjects only in the contralateral sensorimotor cortex after learning. There was a positive correlation (r = 0.879) between the size of the activation area in the left motor and premotor cortex and the mean duration of the electromyographic bursts recorded from the right forearm muscles. Further task-specific activations in lateral and medial premotor, parietal, prefrontal, and cingular cortical areas, and subcortical structures of both cerebral hemispheres were present in all subjects but varied in distribution from case to case. Thus, apart from the motor cortical output area with small anatomical and functional inter-subject variability, single case analysis revealed a profound heterogeneity of the cerebral activation sites between the individual subjects which was obscured in the average PET images.

### 361.14

MAPPING INDIVIDUAL BRAIN FUNCTION TO INDIVIDUAL

MAPPING INDIVIDUAL BRAIN FUNCTION TO INDIVIDUAL BRAIN ANATOMY. H. Steinmetz\*, Y. Huang, U. Knorr, R.J. Seitz. Department of Neurology, Heinrich-Heine-University, W-4000 Düsseldorf 1, FRGermany. Individual variability of brain anatomy and brain function are important factors in studies on structural-functional relationships. Using positron emission tomography (PET), these factors are underestimated systematically when image analysis is based on data averaged across subjects and mapped to 'standard' anatomy.

In a first step towards individual image analysis we have developed a head surface matching

lysis we have developed a head surface matching algorithm which allows the retrospective integration of PET and morphometric magnetic resonance (MR) datasets. Validation studies using an anthropomorphic phantom demonstrated high 3-D accuracy limited by spatial PET resolution only (XY-,XZ-,YZ-PET/MR misalignment: 2.2 to 2.3mm).

Employing this method in the localization of

Employing this method in the localization or changes in regional cerebral blood flow (rCBF) induced by manual activity in 5 healthy subjects undergoing PET, the maxima of task-specific rCBF increases were precisely allocated to grey matter in primary sensorimotor and non-primary cortices identified individually by MR. The technique allows the topographical evaluation of individual patterns of functional activation.

# 361.16

DIFFERENCES IN THE DISTRIBUTION OF BRAIN ACTIVITY DURING HEARING AND IMAGINING AN AUDITORY EVENT AS MEASURED WITH [150]WATER AND POSITRON EMISSION TOMOGRAPHY (PET). H. Szechtman, J.M. Cleghorn', List, C. Whelton, R. Kaplan, S. Ballagh, S. Franco, B. Szechtman, K. Bowers<sup>1</sup>, E. Woody<sup>1</sup>, G. Firnau, C. Nahmias and E.S. Garnett. Depts of Biomedical Sciences, Psychiatry, and Nuclear Medicine, McMaster Univ, Hamilton, Ontario, L8N 3Z5, and <sup>1</sup>Dept of Psychology, Univ of Waterloo, Waterloo, Ontario, CANADA.

The present study asks whether, in terms of the underlying neural mechanisms, imagining an event is equivalent to the experience of perceiving it. Cerebral blood flow (CBF) was measured in 8 normal volunteers under 3 conditions: at rest, listening to a taped message, and imagining hearing the taped message, followed by a repetition of the 3 conditions in reversed order. The subjects' eyes were covered throughout. Statistical analysis using the method of Friston et al (JCBFM, 11:690, 1990) revealed the expected activation of auditory cortex during hearing. During imagining, however, there was no activation of the auditory cortex but reduced CBF in the posterior temporal cortex and increased regional CBF in the visual cortex (compared to baseline), implicating different brain regions in the generation of auditory imagery. (Supported by OMHF. HS is a Research Associate of OMHF).

CORTICO-STRIATO-THALAMIC CIRCUITS AND BRAIN GLUCOSE
METABOLIC ACTIVITY IN 70 UNMEDICATED MALE SCHIZOPHRENIC PATIENTS. B.V. Siegel, Jr.\*, M.S. Buchsbaum, J.C. Wu, S.G. Potkin and W.E. Bunney, Jr. Dept. of Psychiatry, University of California, Irvine, CA 92717.

The cortico-striato-thalamic circuit modulates sensory

processing and thus may be involved in the sensory dysfunction in schizophrenia. 18-fluoro-2-deoxyglucose positron emission tomography was used to measure glucose metabolic activity in the structures making up this metabolic activity in the structures making up this circuit in seventy male schizophrenic patients after a period of at least four weeks off of neuroleptic medication and in thirty age-matched male normal controls. Analyses revealed decreased metabolism in medial frontal cortex, cingulate gyrus, medial temporal lobe, corpus callosum, and ventral caudate. Medial frontal cortical and thalamic activity correlated negatively with total Brief Psychiatric Rating Scale score and with positive while lateral frontal cortical activity did not correlate with symptoms or show group effects.

Significant findings in medial frontal and temporal

lobes, thalamus, and striatum are consistent with cortico-striato-thalamic circuit dysfunction in schizophrenia. These findings are also more suggestive of medial frontal than of dorsolateral prefrontal cortical dysfunction in schizophrenia.

## 361.19

NEURAL NETWORKS IN PATTERN RECOGNITION ANALYSIS OF FUNCTIONAL BRAIN IMAGES. J. D. Hidary\*, J. Hsiao, R. Litman, W. Hong, D. Pickar. Experimental Therapeutics Branch, NIMH, NIH, Bethesda, MD 20892.

In this study we examine the utility of neural networks in the identification of functional patterns in dynamic PET and MRI data. We utilize both O15 and F18-deoxyglucose data of schizophrenic and normal subjects. In this approach, we first match the PET scans to their structural MRI. We then place each fused set into a canonical space so that group comparisons can be made without region of interest analysis. Next, we feed the scans into various types of neural networks. Once each network is trained, a number of scans are fed in to test it. Finally, we extract the hidden layer information from the network to determine precisely which patterns serve to discriminate pathological and non-pathological states.

ABUSE K. Bell and E. DeMet. Long Beach VA Medical Center, Long Beach, CA 90822 and University of California, Irvine, Irvine, CA, 92717.

SPECT is a potential diagnostic tool in psychiatry. Enduring psychosis after drug abuse may represent unmasking of schizophrenia or a toxic effect of abused drugs on the brain. Sixteen patients were divided into 3 groups: 5 chronic schizophrenics with and 6 without history of polysubstance abuse antedating their illness; 5 substance abuse psychosis at the time of scan who presented to the hospital with psychotic symptoms; and 6 controls. SPECT images were taken in the resting condition two weeks after hospitalization. The non-psychotic patient group had symptom-free intervals off medication and psychotic episodes after drug use. Patients were male, right-handed and of similar age (p=NS) to controls. All patients except 2 were on medication; Haldol(4), (p=ns) to controls. All patients except 2 were on medication, halloot(4), Phenothiazine(8), Moban(1), and Clozaril(1). Pilot data analysis restricted the number of regions of interest to left superior frontal, right parietal, left lateral temporal, and right superior frontal. MANOVA revealed a significant group (N=4) by region (N=4) interaction (F=2.01; df=12,40; p<0.05), due mostly to the left superior frontal (F=4.45; df=3,18; p<0.02) and right superior frontal (F=2.7; df=3.18; p<0.08) regions. BPRS scores showed a trend toward negative correlation with the flow to the left superior frontal (rho=-.5, p<0.07) and the left lateral temporal lobe (rho=-.4, p<0.07). SPECT imaging may distinguish a subgroup of schizophrenia.

GLUCOSE ADMINISTRATION ATTENUATES COLD-INDUCED IMPAIRMENT OF DELAYED MATCHING-TO-SAMPLE PERFORMANCE IN RATS. S.T. Ahlers. D. Shurtleff, J.R. Thomas. and F. Paul-Emile. Naval Medical Res. Inst., Bethesda, MD 20889-5055.

Administration of glucose has been shown to enhance performance in a variety of test situations in which memory is impaired by some amnestic treatment. In the present study, the effects of glucose were examined on a working memory deficit produced by exposing rats to cold air stress using a delayed matching-to-sample (DMTS) task. In the DMTS task rats were required to respond on one of two levers cued by an illuminated light above the lever on the front wall of an operant chamber. Following a variable delay ranging from 1-16 sec, both lights were illuminated and rats were required to correctly respond on the lever previously cued for a food reward. Rats responded on the back wall lever during the delay interval to prevent position bias. Glucose (25-500 mg/kg) or saline, administered (ip) in a mixed sequence, were given one hour before a 75 minute session in which rats performed the DMTS task (180 trials). During test sessions the ambient air temperature was either 23°C or 2°C which varied unsystematically. Administration of glucose during exposure to 23°C did not effect matching accuracy across the delays. Exposure to 2°C produced a parallel downward shift in the delay gradient in that matching accuracy was impaired at all delay intervals. Glucose dose-dependently improved cold-induced impairment of matching accuracy at the short delays but was ineffective at the longer delay intervals. Selective modulation of cold-induced impairment of working memory at the short delays suggests that glucose preferentially enhanced stimulus acquisition.

THE CALCIUM CHANNEL BLOCKER AMLODIPINE ENHANCES MEMORY CONSOLIDATION IN MICE. A. Hawxhurst, D. Quartermain\* and J. Puente. Lab. of Behavioral Neurology, New York Univ. Med. Ctr., New York, NY 10016 and Pfizer Inc., New York,

Amlodipine (Am) is a calcium antagonist of the 1,4dihydropyridine class, structurally related to nifedipine.

The effects of this drug on memory were studied using passive avoidance and conditioned suppression paradigms.

In a single trial passive avoidance task, mice were injected s.c. with Am (0,3,5,7 and 9 mg/kg) pre-training (1 hr), post-training (immediate, 1,3 or 6 hr) or pretesting (30 min, 1 hr or 3 hr). Memory enhancement (significant increase in step-through latency) occurred only when Am (5,7 and 9 mg/kg) was given immediate posttraining.

In a conditioned emotional response lick suppression task, Am (7 mg/kg) given immediately after CS-UCS (toneshock) training significantly enhanced conditioned suppression.

These findings suggest that Am may facilitate memory consolidation.

ENHANCED ACQUISITION OF REVERSAL TRAINING IN A SPATIAL LEARNING TASK IN RATS TREATED WITH CHRONIC NIMODIPINE.

LEARNING TASK IN RATS TREATED WITH CHRONIC NIMODIFINE.

K. McMonagle-Strucko\* and R.J. Fanelli. Inst. for
Preclin. Pharmacol., Miles Inc., West Haven, CT 06516.

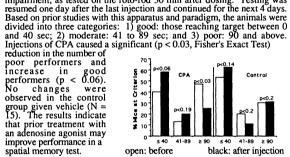

Nimodipine, a dihydropyridine calcium channel antagonist, has been shown to facilitate learning performance. The effects of chronic nimodipine, using 40 mg controlled timed-release pellets, on the performance of young middle-aged and aged rats were studied in the Morris water maze. Animals were trained 3 sessions per day with a 60 sec ITI to locate a submerged platform. The latency to escape was recorded. Every 6th trial was a probe trial, during which the platform was removed and rats were placed in the maze for 30 sec. Time spent in each quadrant was recorded. After 6 days of initial training, the goal was moved to the opposite quadrant for an additional 6 days. Plasma levels of nimodipine measured following training were approximately 13 ng/ml.

During initial training, there were clear age-related acquisition deficits in place training, with no effects of chronic nimodipine. Nimodipine did, however, enhance performance during the probe trials of reversal training. Time spent in the goal quadrant by the nimodipine-treated rats was approximately 35% longer than that of the placebo-treated rats. The selective enhancement of performance by nimodipine suggests that nimodipine improves memory required to perform a complex discrimination, rather than altering simple reference memory.

### 362.5

EFFCTS OF ADENOSINE AGONISTS AND ANTAGONISTS ON SPATIAL MEMORY IN MICE. Dag von Lubitz, <sup>1</sup> Ian A. Paul, <sup>1</sup> Raymond T. Bartus, <sup>2</sup> Kenneth A. Jacobson, <sup>1\*</sup> <sup>1</sup> NIDDK, NIH, Bethesda MD 20892 and <sup>2</sup>Cortex Pharmaceuticals, Inc., Irvine CA. The effect of adenosine agonists in spatial memory are poorly known. Therefore, we have examined the effect of treatment with Nocyclopentyladenosine (CPA) on spatial memory acquisition in the Morris water maze. Mice (C57/BL6 JAX strain) were trained daily for 120 sec in a 1 m diameter maze with an invisible target (8 cm dia.). After 10 trials, training was interrupted, and one group (N = 15) received i.p. injections of CPA (20 µg/kg, daily) for 7 days. At this dose there was no motor impairment, as tested on the roto-rod 30 min after dosing. Testing was resumed one day after the last injection and continued for the next 4 days. Based on prior studies with this apparatus and paradigm, the animals were

spatial memory test.

EFFECTS OF GINKGO BILOBA EXTRACT EGb 761 ON LEARNING IN TWO INBRED STRAINS OF MICE. B. Martin<sup>†</sup>, G. Chapouthier<sup>†</sup>, F. Clostre<sup>‡</sup> and Y. Christen<sup>‡</sup>\*. † Génétique, Neurogénétique et Comportement, UFR Bioméd., 45 rue Sts-Pères, 75006 Paris - FRANCE. ‡ Institut IPSEN, 30 rue Cambronne, 75015 Paris - FRANCE. Ginkgo biloba extract EGb 761 (Tanakan®, Institut

IPSEN) is known to have various different actions including learning/enhancing effects in mice. We have tested female mice of two different inbred strains (C57BL/6J and DBA/2J) at two ages (15±5 and 65±3 weeks) to investigate whether age or strain.could alter the effect of EGb 761. C57BL/6J is a strain known to retain good learning ability in old age whereas DBA/2J mice show learning-deficiencies in old age. The learning task was a discrimination between a lit and a dark alley in a T-maze with negative reinforcement (50 µA-2 sec footshock) in the lit side. Mice were submitted to 10 trials per day during 6 successive days, the 3 first days after i.p. administration of 40 mg/kg EGb 761 (treated) or saline (controls). Results show that in C57BL/6J mice, EGb 761 is devoid of any major effect. On the contrary, in DBA/2J mice, EGb 761 enhances learning, especially in learning-deficient older subjects.

POTENTIAL COGNITION-ENHANCING ACTIVITY OF THE ADENOSINE A1 RECEPTOR ANTAGONIST MDL 102,234 IN SPATIAL LEARNING AND HIPPOCAMPAL LONG-TERM POTENTIATION MODELS. J.M. Hitchcock\*, S.F. Chaney, J.M. Zwolshen, H.J. Ketteler, N.P. Peet, and S.M. Sorensen, Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd, Cincinnati, OH 45215.

Adenosine antagonists acting at the A1 receptor enhance the release of various neurotransmitters, including acetylcholine, and may have potential for cognitionenhancing effects. MDL 102,234 (R)-1.3-diproply1-8-(1-phenylpropyl), santhinel, a potent and selective A1 antagonist (Dudley et al., Soc. Neurosci. Abstr., 1992), was tested in in vitro and in vivo models of learning and memory.

Long-term protentiation (I.TP) in the hippocampul slice has been suggested as a

Long-term potentiation (LTP) in the hippocampal slice has been suggested as a model for events that might occur at a cellular level during learning and memory processes. MDL 102,234 increased the basal population spike and augmented LTP recorded in hippocampal CA1 neurons. Similar results were found with another A<sub>1</sub> antagonist, KFM-19.

In order to assess central bioavailability, the compounds were tested for their ability to antagonize the reduction in spontaneous motor activity in mice induced by the  $A_1$  agonist R-PIA. A water maze task was used to assess effects on learning. In the A<sub>1</sub> agonits K-1A. A water maze task was used to assess effects on learning. In this spatial learning model, rats are required to use distal spatial cues around a circular water tank to navigate to a hidden platform. The cholinergic antagonist scopolamine dose-dependently impaired acquisition of the water maze task. MDL 102,234 and KFM-19 significantly antagonized the scopolamine-induced learning impairment. These compounds had inverted U-shaped dose-response curves; intermediate doses were most effective, and low or high doses were ineffective, which appears to be a

common pattern with potential cognition-enhancing compounds.

The present studies indicate that the adenosine A<sub>1</sub> antagonist MDL 102,234 has potential cognition-enhancing effects both in vitro (hippocampal LTP) and in vivo (spatial learning). MDL 102,234 thus may have potential as a treatment for cognitive

## 362.6

EFFECTS OF REPEATED CAFFEINE TREATMENT ON HYPERLOCOMOTION AND CONDITIONED PLACE PREFERENCE. Ernest N. Damianopoulos\* and Robert J. Carey. Res. and Devel. Serv. -151, VA Medical Center, Syracuse, NY 13210

Rats were administered 7 sessions of caffeine treatment either 10 or 50 mg/kg ip depending on group assignment once every four days interspersed with non drug trials. For one half of each dosage level, the animals were injected 20 min prior to test environment placement (paired group) while for the other half, injection occurred 30 min after removal from the test environment (unpaired group). Test environment placement during the drug and non drug state occurred in one of two flat black, clothlined chambers of equal area which were alike in every respect except for circular vs. square shape differentiation. The two chambers were connected by a pasageway which remained closed except during tests for conditioned place preference (CPP). Locomotor behavior was monitored by two separate computer-assisted camera tracking systems. All animals on separate days were initially given two 20 min habituation trials on each chamber followed by a test for CPP. CPP was measured as percent of time spent in each chamber relative to the total time spent in the two chambers. This CPP baseline assessment phase was followed by 7 sessions of caffeine treatment. After a 7-day drug withdrawal period, all animals were given a single non drug test to evaluate CPP. Following 3 additional reacquisition trials with caffeine and after a 7-day drug withdrawal, all animals were given two 20 min trials on each test chamber on senarate days in a counterbalanced sequence. After another caffeine reacquisition trial, the animals were tested once with 10 mg/kg cafeeine and once with 50 mg/kg caffeine on separate days in a counterbalanced sequence to assess sensitization/tolerance effects. The results showed a selective hyperlocomotion effect in the paired group and a complex interaction of drug dose and CPP.

# 362.8

EFFECTS OF INDELOXAZINE HYDROCHLORIDE, A CEREBRAL ACTIVATOR ON PASSIVE AVOIDANCE RESPONSE IN GERBILS SUBJECTED TO REPEATED CEREBRAL ISCHEMIA BY CAROTID ARTERY M. Yamamoto\*, K. Takahashi, H. Takeuchi, S. Yatsugi. Applied Pharmacology & Development and Cen Research Laboratories, Yamanouchi Pharmaceutical Co. Itabashi-ku, Tokyo 174, Japan. Applied Pharmacology & Development and Central

Effects of indeloxazine hydrochloride, a cerebral activator on disturbance of passive avoidance learning in gerbils subjected to repeated brief episodes of cerebral ischemia were examined. Latency of step-through in passive avoidance learning was shortened for the entire 4day period when gerbils were trained at 3 days after 3 episodes of carotid artery occlusion for 2 min each at 60min intervals. Reacquisition was also impaired for 9 weeks when gerbils were retrained on day 14 after the repeated occlusion. Neuronal degeneration in the CAl regions of the hippocampus was observed 4 and 17 days after occlusion. A close correlation was seen between latency and neuronal degeneration. Administration of indeloxazine was started from day 3 after carotid artery occlusion and repeated once a day for 12 days. Indeloxazine (10 mg/kg po) prolonged the shortened latency of step through without affecting spontaneous motor activity and pain response. These results suggest that this cerebral ischemic gerbils model is useful for quantitatively measuring functional changes in the chronic phase of repeated cerebral ischemia and that indeloxazine can be used for treatment of stroke patients in the chronic phase.

THE COGNITION-ENHANCING AGENT, DM-9384, FACILITATES RATE AND LEVEL OF ACQUISITION OF CLASSICAL CONDITIONING IN OLDER RABBITS. D. S. Woodruff-Pak\* & Y.-T. Li. Deptartment of Psychology, Temple University, Philadelphia, PA 19122.

The effects of the pyrrolidone derivative, DM-9384, were examined at three levels (1, 3, 10 mg/kg sc) in 40 older (21-40 mo.) New Zealand white rabbits classically conditioned for 90 trials/day for 10 days in the delay nictitating membrane (NM)/eyeblink conditioning paradigm with a 750 msec interval between the tone conditioned stimulus and corneal airpuff unconditioned stimulus. Older rabbits administered 10 mg/kg of DM-9384 took a mean of 463 trials to learning criterion, whereas the vehicle group attained criterion in 746 trials. Rabbits administered 1 and 3 mg/kg of DM-9384 reached criterion in 654 and 569 trials, respectively. These differences in learning rate were statistically significant as were the differences observed in percentage of conditioned responses (CRs), CR amplitude, and response latency. The motor unconditioned response was not affected by the compound. Rabbits tested at 10 mg/kg attained the highest learning rates we have ever observed for older animals (80% CRs). This rate is comparable to optimal performance in young rabbits. It was concluded that DM-9384 facilitates learning in NM/eyeblink classical conditioning, a behavior on which human patients with Alzheimer's disease are seriously impaired.

AIT-034 EFFECTS ON SOMATOSTATIN BINDING AND WORKING MEMORY, A. Glasky\*, F. DeLeon-Jones, and R.F. Ritzmann. Advanced ImmunoTherapeutics, Irvine, CA, and Olive View Medical Center, Sylmar, CA

AIT-034, a derivative of the purine hypoxanthine, has been evaluated for its effect on working memory and on somatostatin binding to brain receptors. The neuropeptide somatostatin has been implicated in Alzheimer's disease (ALZ) since its depletion in the brain of ALZ patients is correlated with the degree of dementia. Somatostatin has been shown to stimulate the release of acetylcholine in the hippocampus, the area of the brain involved in working memory. It is of interest to develop a somatostatin-related therapy for ALZ. AIT-034 was evaluated in vitro as a modulator of somatostatin binding to brain membrane receptors. AIT-034 was demonstrated to be a potent non-peptide ligand for the somatostatin receptor, producing a 68% displacement at 10-7M and 82% at 10-5M. AIT-034 was evaluated in mice in the win-shift paradigm, a test for working memory employing the T-maze. In normal adult C57/BL mice, AIT-034 (30 mg/kg, i.p.) increased the duration of memory trace to over 210 seconds when comparable to 120 seconds in control subjects. AIT-034 increased the latency time to leave the start box in the T-maze and prolonged running time but had no effect on spontaneous locomotor activity. AIT-034 also increased the duration of the memory trace in Swiss Webster mice at 0.5 mg/kg. In summary, AIT-034 is one of the first small molecular non-peptide entities that inhibits somatostatin receptor binding in vitro and produces a working memory enhancing activity which is comparable to tacrine in two strains of mice.

EFFECTS OF CONTINUOUS INFUSION OF TRH ON LEARNING AND MEMORY IMPAIRMENTS IN ANIMAL MODELS. M. Miyamoto\*, Y. Kiyota, K. Hirai, H. Takahashi and A. Nagaoka. Biol. Res. Lab., Takeda Chem. Ind. Ltd., Osaka 532, Japan.

Effects of continuous infusion of TRH on learning and memory impairments in animal models were studied. Behavioral tasks were conducted between 3 to 12 days after subcutaneous administration of sustained-release dosage form of TRH. TRH (0.04 and 0.2 mg/kg/day) markedly ameliorated scopolamine-induced amnesia in mice. TRH improved the impairment of water maze learning in rats with AF64Ainduced lesions. The effects of TRH on emotional disturbance and learning impairment in senescence-accelerated mouse (SAM) were also studied. In the elevated plus-maze test, SAM-P/8 mice showed low anxiety-like behavior as demonstrated by an increase in the number of entries into open arms and increase in time spent on open arms as compared with SAM-R/1 control mice. TRH (0.05 and 0.2 mg/kg/day) reversed the low anxiety-like behavior in SAM-P/8 mice. Continuous infusion of TRH ameliorated the impairment of the water maze task and shuttle avoidance task in SAM-P/8 mice, although a single administration of TRH had no significant effect. Furthermore, TRH (0.05 and 0.2 mg/kg/day) improved learning and memory impairments in aged rats, which were assessed by the step-down type passive avoidance and water maze tasks. These findings indicate that continuous infusion of TRH improves memory deficits in animal models at low doses, imply that TRH may be useful for therapy of dementia including Alzheimer's disease.

LINOPIRDINE (DuP996) FACILITATES THE RETENTION OF AVOIDANCE TRAINING AND IMPROVES PERFORMANCE OF SEPTAL-LESIONED RATS IN THE WATER MAZE. J.D. Brioni \* F. Curzon, M.J. Buckley, S.P. Arneric and M.W. Decker, Neuroscience Department, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL 60064.

Linopirdine (DuP996) is a novel compound presently being evaluated in Phase III clinical trials for the treatment of Alzheimer's disease (Cook et al., Drug Dev. Res. 19:301, 1990). Linopirdine releases ACh, DA and 5-HT from brain slices and at the behavioral level it facilitates the performance of rodents in memory tests. We investigated the behavioral effects of linopirdine on locomotor activity and on the inhibitory avoidance task in mice. Furthermore, we evaluated the effects of linopirdine on acquisition of spatial discrimination in the Morris water maze in septal-lesioned rats, a model of the cholinergic hypofunction characteristic of AD.

Linopirdine significantly enhanced retention of the inhibitory avoidance response in mice (0.026 µmol/kg, IP, n=12, p<0.05) and produced a small decrease in locomotor activity in an open field at a slighter higher dose. Septal lesions significantly impaired the performance of rats in the spatial discrimination version of the Morris water maze (errors: control=1.1 vs. lesioned=3.7), and linopirdine facilitated the performance of lesioned animals at 0.026 µmol/kg, IP (errors=1.5). At this dose, no effects were observed on septal-induced hyperactivity in an open field or in normals rats tested on the elevated plus-maze anxiolytic test. Our studies extend previous findings of facilitatory effects of linopirdine on memory by demonstrating improved spatial learning on septal-lesioned rats. Our results further demonstrate that this effect is not accompanied by a reduction of the hyperactivity characteristic of septal lesions suggesting a dissociation between the effects of linopirdine on the cognitive and non-cognitive effects of septal lesions. (Linopirdine was generously supplied by DuPont-Merck).

REVERSAL BY SUBSTANCE P OF DEFICITS IN SPATIAL MAZE PERFORMANCE IN RATS WITH BASAL FOREBRAIN LESION. <u>J.D. Stoehr. C.P. Cramer\* and W.G. North.</u> Depts of Physiology and Psychology\*, Dartmouth Medical School and Dartmouth College\*, Hanover, NH 03756, USA

Excitotoxic lesions of the nucleus basalis magnocellularis (NBM) and medial septum (MS) result in respective reductions in cortical and hippocampal cholinergic activity. Such animals have accompanying behavioral deficits in tasks designed to evaluate learning and memory. However, few studies have employed pharmacological manipulations aimed at reversing these behavioral deficiencies. Bilateral lesions of both NBM and MS in male Long-Evans rats were induced by 1 µl injections of 6µg/µl of ibotenic acid into each brain area. One week following surgery, rats were trained in the Morris Water Maze (place-learning task) for 5 consecutive days followed by paired reversal trials (goal-relocation task) and probe tests (goal-removal task). Lesioned animals showed significant performance deficits throughout place learning and in the first and second paired reversal and probe trials. For the last set of paired trials, lesioned animals received 50 µg/kg I.P. of substance P 30 min prior to testing. Lesioned rats subsequently showed no significant differences from controls in swim latencies or in probe trial performance. These preliminary studies support the notion that forebrain cholinergic functioning plays a role in spatial learning and that the peripheral administration of substance P may reverse behavioral deficits associated with hypocholinergic activity.

# 362.14

BEHAVIORAL EFFECTS OF A TRH ANALOGUE, RGH 2202, ON MOTOR AND COGNITIVE ALTERATIONS OF THE RAT F. Drago\*, M. Grassi, A.A. Genazzani, G. Coppi\*\* Institute of Pharmacology, University of Catania Medical School, and Poli Pharm. Company, Rozzano (Milan)\*\*, Italy

TRH is known to improve cognitive and motor deficit in a number of behavioral models and to stimulate various endocrine systems. This study was undertaken to evaluate the effects of a TRH analogue that has no influence on TSH. L-6-ketopiperidine-2-carbonyl-leucyl-L-prolinamide (RGH 2202). This peptide restored learning and memory capacity altered in 24 month-old male rats or reduced by hypoxia, injection of scopolamine or prenatal exposure to methylazoxymethanol, both in active and passive avoidance tests. These effects were statistically significant when the drug was administered at the doses of 5 and 10 mg/kg. ability to interact positively with cognitive processes was also shown in a radial maze, demonstrating spatial memory is modulated as well. The TRH analogue was also able to augment motor performance of aged rats in the open field test and of adult rats in the rotorod test. These results suggest that RGH 2202 may be applied in the treatment of those diseases that result in motor and cognitive alterations.

INTRA-AMYGDALA POST-TRAINING INJECTIONS OF OXYTOCIN ENHANCE RETENTION OF AN INHIBITORY AVOIDANCE TASK K. Coleman\* & J. L. McGaugh, Center for Neurobio of Learning & Memory and Dept. of Psychobio. U.of Calif., Irvine, CA 92717

and Dept. of Psychobio. U.of Calif., Irvine, CA 92/17
There is evidence that the neurohypophyseal peptides vasopressin (VP) and oxytocin (OT) are involved in learning and memory. In general, when given either systemically or in the brain, post-training administration of VP has memory enhancing effects while OT has memory impairing effects. When OT is administered directly into limbic structures involved in memory, results are mixed. OT administered into the hippocampus or dorsal raphe results are mixed. Of administered into the hippocampus or dorsal raphre nucleus following an aversive step-through task impairs memory. Yet, given in the dorsal septal nuclei, memory in this task is enhanced. Several lines of evidence implicate the amygdala as a primary candidate for the integration and modulation of memory. Although the central and basolateral nuclei of the amygdala are rich in OT receptors, OT has been reported to have no effect on memory when administered in the amygdala post-training have no effect on memory when administered in the amygdala post-training at a dose of 25 pg. However, this dose has been reported to be effective in modulating memory in other brain regions. In this study, Sprague-Dawley male rats (250-300g) were implanted bilaterally with cannulae aimed at the central nucleus of the amygdala. Animals were trained in a step-through inhibitory avoidance task. After training, animals received intra-amygdala injections of saline or OT dissolved in saline, at doses of 1, 3, 10, 30, 100, or 300 pg. Retention was tested 48-h after training. The retention latencies of animals given 10 pg were significantly longer than those of all other groups. These results suggest that the amygdala is a site of memory modulation by OT.

modulation by OT.

### 362.16

REVERSIBLE POSTTRAINING INACTIVATION OF THE NUCLEUS OF THE SOLITARY TRACT IMPAIRS RETENTION PERFORMANCE IN AN INHIBITORY AVOIDANCE TASK. C. L. Williams\* and J. L. McGaugh, Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine,

Although it is well documented that peripheral administration of hormones or pharmacological agents which affect their release facilitate memory processes, it is not known how these substances influence the brain since they do not freely pass the blood-brain barrier. Visceral sensory information from peripheral glands and organs is carried by afferent vagal fibers to specific nuclei within the nucleus of the solitary tract (NTS). These neurons in turn, transmit information from the periphery to brain structures such as the amygdala which is involved in regulating memory formation. In view of the anatomical relationship between these two structures, it is possible that the NTS may mediate the effects of peripheral physiological influences on memory. To examine this hypothesis, male Sprague Dawley rats (175-200 g) were trained in a one-trial inhibitory avoidance task (0.35 mA footshock for 0.5 sec) and given immediate or delayed (2 hours) microinjections of buffer or 2% lidocaine into either the NTS, 4th ventricle, or the cerebellum. The effects of posttraining inactivation of these structures on retention of the avoidance training was assessed

48 hours later.

The retention latencies of rats receiving lidocaine into the NTS was significantly lower than those of animals given injections of a buffer solution, delayed injections of buffer or lidocaine, or injection of lidocaine into either the 4th ventricle, which is medial to the NTS, or into a region of the cerebellum just dorsal to this nucleus. These findings suggest that the impaired retention performance observed following idocaine administration into the NTS is due to effects produced within this nucleus rather than to the spread of drug to adjacent brain regions, and further, indicate that the NTS plays an important role in mediating neural input from the periphery to limbic system structures that encode and store memory traces.

# NRURAL PLASTICITY III

## 363.1

THE PROXIMITY OF AXOTOMY DETERMINES THE CHANGES OF DENDRITIC ARBORS OF ADULT RAT RUBROSPINAL NEURONS. G.-F. Tseng\* and M.-E. Hu, Dept. of Anatomy, Col. of Med., National Taiwan Univ., Taipei, Taiwan, R.O.C.

The effect of axonal injury on adult mammalian CNS neurons remained to be investigated. Studies showed that distally axotomized corticospinal neurons were active electrophysiologically and maintained a pyramidal shape (Tseng and Prince, 89, 90, 91), but the model is inappropriate for examining the effect of distance of lesion since a proximal axotomy (PA) would have involved deafferentation. To explore this, we chose lumbar spinal cord-projecting rubrospinal neurons(-NRs) since an upper cervical(C2-4) and lower thoracic(T8-10) tract lesion would represent PA and distal axotomy (DA) in this model.

Lesions were performed on 4 week old rats. A Golg-aidehyde protocol (Berbel, '86) was used to study the soma-dendritic morphology of neurons. Retrograde labelling(Fast blue) showed that I-NRs were located mainly contralaterally in the ventrolateral caudal nucleus and in a thin ventral zone and lateral horn of the middle nucleus. Thus only neurons from these areas were analyzed with the Sholl's method (Sholl, '55) with concentric circles drawn at 25 μm increment steps.

Like normal, both PA and DA neurons maintained a multipolar shape, but the number of dendritic branches were significantly higher(α<0.05) in PA(n=34) than DA(n=27) starting from 75 to 150 μm from the center of the soma. When compared to normal counterparts(n=45), DA neurons have less (at 175μm) and PA neurons more dendritic branches(at 100μm, α<0.025). Thotal dendritic length of normal counterparts(n=45), DA neurons have less (at 175μm) and PA neurons more dendritic complexicity. The results show that, in contrast to the dendritic regression caused by DA, PA signals CNS neurons to increase, or the least maintain, their dendritic complexicity. The results show that, in contrast to the dendritic regression caused by DA, PA signals CNS neurons to incr

# 363.3

BRAIN PLASTICITY AFTER CORTICAL LESION IN THE RAT. M.Bajčetić, A.Milošević and N.Zečević\*, Inst.biolog.res. University of Belgrade, Belgrade 11000, Yugoslavia.

Plasticity of dendritic arborization was examined after unilateral lesioning of rat somatosensory cortex at postnatal day 3 (P-3) or P-10. The P-3 lesioned animals were sacrificed at P-17 (group P3/17) or at P-60 (P3/60), while P-10 lesioned animals were sacrificed only at P-60 (P10/60). After Golgi impregnation morphometric measurements of total dendritic length (TDL) of II/III layers pyramidal neurons in ipsi- and II/III layers pyramidal neurons in ipsicontralateral somatosensory cortex were done. In the first group of the early lesioned and early sacrificed animals (P3/17) TDL did not differ between ipsi-and contralateral sides, but both had smaller values than control animals (p<0.05). In the group P3/60 neurons from the lesion side had TDL smaller than these from contralateral side (p<0.05) or controls (p<0.01). In the group Pl0/60 ipsilateral neurons had smaller TDL than neurons in both contralateral side and controls (p<0.01).

It seems that the early effect of the lesion was expressed on both ipsi- and contralateral sides. Two month later contralateral side recovered completely while ipsilateral side lag behind even more in TDL.

### 363.2

ACOUSTIC IMPRINTING DOES NOT INFLUENCE SPINE FREQUENCY IN THE VISUAL ECTOSTRIATUM OF DOMESTIC CHICKS.

E. Wallhäußer-Franke, H. Scheich and G. Langner\*.

Inst. of Zoology, Technical University, 6100 Darmstadt, FRG.

In a previous study it was shown that spine frequency in a an area of the chicken forebrain (MNH) decreases substantially after acoustic imprinting (Wallhäußer & Scheich, Dev. Brain Res. 31, 1987). To test the specifity of this effect the morphology of the ectostriatum was investigated in Golgi-Cox impregnated tissue from animals of the MNH-study. The chicks differed in their ages (0-20 d posthatch) and in exposure to an acoustic imprinting stimulus (social, isolated-imprinted, isolated-unimprinted). In accordance with a study of Tömböl et al. (J. Hirnforsch. 29, 1988) two neuron types were found in the ectostriatal core. Both have intermediate to large somata, being mostly oval or triangular for the first and round for the second type. While type I has about 5 thick and spiny dendrites, type II has more, but thin and smooth dendrites. The most remarkable feature of type I neurons are numerous spine-like processes at the axon cone. A quantitative analysis was carried out at intermediate dendritic segments of type I neurons (48 brains, 960 neurons). There is a slight decrease in spine frequency within the first week posthatch. No difference in spine frequency was observed within the ectostriatum no matter whether the chicks were imprinted or not, kept isolated or not. This is in contrast to the significant influence of acoustic imprinting on MNH neurons.

SEX AND ENVIRONMENT AFFECT BEHAVIOURAL RECOVERY AND DENDRITIC GROWTH AFTER NEONATAL FRONTAL LESIONS IN RATS. B. Kolb\*, M.Buday, G. Gorny, and R. Gibb. Dept of Psychology, University of Lethbridge, Lethbridge, Canada, T1K 3M4

Rats given prefrontal lesions at 7 days of age were raised in enriched environments along with littermate controls for 3 mo beginning at weaning. The animals were trained at paw reaching and at the Morris water task. The brains were processed for Golgi-Cox staining and the dendritic arborization and spine density measured in layer II/III pyramidal cells in Par 1 and Oc 1. Behaviourally, there were effects of lesion (operates were impaired), sex (male frontals and controls better than comparable female groups), and environment (enriched better in each case) on behavioural measures. Normal males had more dendritic branches than females and showed a greater enrichment effect than females. Frontal females had more dendritic arbor than female controls but equivalent spine density. In contrast, frontal males did not differ from controls in dendritic arbor but had an increase in spine density. Further, frontal males showed an enrichment effect, whereas females did not. The results show that males and females have different anatomical changes in response to neonatal cortical injury and environmental stimulation. These differences may explain the sex differences in behavioural outcome following neonatal cortical injury.

PHENOBARBITAL DELAYS RECOVERY FROM CORTEX DAMAGE. <u>T.D. Hernandez\* and L.C. Russell</u>. Department of Psychology, University of Colorado, Boulder, CO 80309

The usefulness of anti-convulsant prophylaxis following brain injury has been the focus of much debate. Not only is there concern about how effective certain drugs are at preventing post-traumatic epilepsy, but also how these drugs might affect behavioral recovery from the brain damage itself. Results from the animal literature suggest that certain anti-convulsants, like diazepam, interfere with behavioral recovery, while mild, infrequent seizures (including partially kindled seizures) facilitate behavioral recovery following unilateral cortex damage. In addition, there are provocative data from a clinical study which suggest that the use of anti-convulsants following brain injury may not be beneficial for behavioral recovery, and may, indeed, be detrimental. The present studies were undertaken to investigate the effect of phenobarbital on behavioral recovery following unilateral frontal cortex damage in rats. Forty-eight hours after electrolytic lesion, a 7-day phenobarbital or saline regimen was initiated. Anticonvulsant doses of phenobarbital were administered twice daily. Recovery from somatosensory asymmetry (as measured by the bilateral tactile stimulation test) was significantly delayed in the phenobarbital group: saline treated animals recovered within 2 weeks, while the phenobarbital treated group did not recover until 8 weeks after surgery. Given the dramatic and opposing ways in which phenobarbital and kindled seizures individually affect behavioral recovery, it will be interesting to assess whether anti-convulsant administration interferes with seizure-associated changes in recovery patterns when the two treatments are combined, or if their effects balance each other out.

## 363.7

EARLY MK-801 TREATMENT PREVENTS THE REINSTATEMENT OF FORELIMB PLACING DEFICITS FOLLOWING UNILATERAL CORTICAL LESIONS IN THE RAT. S. Barbay\*. T. D. Schmanke and T.M. Barth. Department of Psychology, Texas Christian University, Ft. Worth, TX. 76129.

A previous experiment suggested that administration of MK-801 had both beneficial and detrimental effects on the recovery and maintenance of function following damage to the rat somatic sensorimotor cortex (SMC). For example, a regimen of MK-801 beginning 12-16 hr after the lesion accelerated recovery from somatosensory asymmetry, but had no effect on the rate of recovery from forelimb placing deficits. In contrast, when a single injection of MK-801 was given after recovery, there was a reinstatement of forelimb placing deficits that endured for up to 7 days. The facilitation of somatosensory recovery was linked to MK-801 preventing the degeneration of neurons in the striatum and substantia nigra pars reticulata following the cortical injury. In contrast, a potential anatomical correlate to the reinstatement effect has not yet been explored. The present experiment was designed to investigate whether the neuroprotective effects of early MK-801 treatment can prevent the reinstatement of forelimb placing deficits.

of forelimb placing deficits.

Rats received a regimen of MK-801 (1mg/kg) or saline beginning 16 hr after a unilateral lesion in the SMC. The animals were allowed to recover from somatosensory and forelimb placing deficits and then given two successive injections of MK-801. Rats in the Saline-MK-801 group showed a reinstatement of the contralateral placing deficits following MK-801 treatment. In contrast, treatment with MK-801 during the recovery period prevented the reinstatement effect. These data support the idea that the detrimental effects of MK-801 on the maintenance of function may be blocked by early treatment with the drug. Specifically, the reinstatement effect may be related to the transneuronal degeneration in subcortical structures that typically follows damage to the SMC.

# 363.9

LONG-LASTING ADAPTATION TO IMPOSED ACTIVITY IN REGENERATED CRAYFISH MOTONEURONS. <u>B.A. Stewart</u>, H.L. Atwood, H.C. Kwan.\* Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada M5S 1A8

Can axonal terminal age affect the ability of a neuron to express activity-dependent changes in synaptic transmission? Imposing activity on the phasic motoneuron to the claw closer muscle leads to reduced initial transmitter release and greater fatigue resistance (FR). This long-term adaptation (LTA) is age dependent; it is expressed in young but not old animals. Since LTA is known to depend on somally-regulated mechanisms, we sought to separate the central and peripheral effects of age by examining LTA in animals with regenerated claws where the axonal terminals are younger than the centrally located cell body. We used a conditioning protocol of 5 Hz stimulation for 2 h/day for 3  $\,$ consecutive days and measured excitatory postsynaptic potentials (EPSP) with standard intracellular techniques. Initial EPSP amplitude was reduced and FR increased in conditioned non-regenerated claws compared to non-conditioned contralateral controls in young. but not in old animals. Conditioned regenerated limbs of old animals exhibit increased initial EPSP amplitude and reduced FR compared to non-conditioned regenerated controls. Conditioning of regenerated limbs of intermediate sized animals led to less FR but no change in initial EPSP amplitude. We conclude that limb regeneration does not restore normal LTA in old animals; such limbs exhibit a novel form of long-lasting plasticity opposite to that observed in non-regenerated limbs.

### 363.6

THE AMELIORATIVE EFFECT OF REPEATED INJECTIONS OF SCOPOLAMINE HYDROBROMIDE ON RECOVERY FROM BRAIN DAMAGE: AN ANALYSIS OF GENERALITY AND MECHANISM. A.M. Schneider\*, E. Thomas, M. Jacobs, P. Oishi, R.J.Meagher, P. Asmann. Depts. of Psychology and Biology, Swarthmore College, Swarthmore, PA. 19081 and Bryn Mawr College, Bryn Mawr, PA. 19010

In an earlier study we found that septal lesions produce neophobia and

In an earlier study we found that septal lesions produce neophobia and that repeated injections of scopolamine hydrobromide, prior to surgery, ameliorate the neophobic effects of the lesions. The purpose of the present series of experiments was threefold: (a) to replicate the ameliorative effect using a more conventional test of neophobia, the elevated-plus maze; (b) to extend the generality of the effect to another cholinergic system—the nucleus basalis magnocellularis (NBM)—and to another type of behavioral loss—amnesia as measured by a standard passive-avoidance stepthrough procedure; (c) to characterize the underlying mechanism by correlating the decay of the ameliorative effect with the decay of upregulated muscarinic receptors in the hippocampus and cortex.

The results confirmed the generality of the effect and, indeed, implicated upregulated receptors as the underlying mechanism. The results were as follows: (a) repeated injections of scopolamine ameliorated the behavioral effects of subsequent lesions regardless of the site, septal area or NBM, or the type of behavioral loss, neophobia or amnesia; (b) both the ameliorative effect and the upregulation of muscarinic receptors decreased as the interval between drug and lesion and between drug and assay increased from 12 hrs. to 8 days.

Supported by grants from the Howard Hughes Medical Institute and the Pew Foundation.

TACTILE-EXTINCTION FOLLOWING UNILATERAL LESIONS IN THE RAT ANTEROMEDIAL CORTEX: THE EFFECTS OF A CONTRALATERAL CUE. T.M. Barth\*. B. Marks and L.S. Young. Department of Psychology, Texas Christian University, Ft. Worth, TX 76129. A previous experiment showed that restricted unilateral lesions in two

A previous experiment showed that restricted unilateral lesions in two subdivisions (i.e. anteromedial cortex [AMC]; caudal forelimb area [CFL]) of the rat somatic sensorimotor cortex (SMC) produce an ipsilateral asymmetry on a bilateral tactile stimulation test. The bias may be similar to the neglect or extinction phenomenon observed in people with right parietal lobe damage. Historically, the nature of extinction has been attributed to inattention, increased sensory thresholds or hypokinesia. The attentional hypothesis has been supported by the finding that a salient cue to the contralateral side may overcome the neglect. The present experiment was designed to investigate whether a contralateral cue presented before the simultaneous presentation of bilateral tactile stimuli, would neutralize the ipsilateral asymmetry observed after unilateral lesions in the AMC or CFL.

Rats received unilateral electrolytic lesions in either the AMC or CFL.

Rats received unilateral electrolytic lesions in either the AMC or CFL.

One or two days after surgery, the animals were tested for an ipsilateral bias on
the bilateral tactile stimulation test. Small adhesive patches were placed on the
the radial aspect of each forepaw and the order of contact and removal (i.e. ipsi vs
contra) was recorded. Animals in both groups contacted the patch ipsilateral to
the stimulus before the contralateral patch (i.e. an ipsilateral bias). The rats were
then cued by placing a patch on the contralateral forepaw and allowing them to
contact and remove the stimulus. Following a cue-trial time interval (5-30s), the
animals were again presented with bilateral patches. In animals with AMC
lesions the contralateral cue neutralized the ipsilateral bias, whereas the cue had
no effect on animals with CFL lesions. These data suggest that the ipsilateral
bias observed in AMC damaged animals may reflect an impairment in attention.

# 363.10

ENDURANCE EXERCISE MODULATES NEUROMUSCULAR JUNCTION OF C57BL/NNIA AGING MICE. Mohamed A. Fahim\* Faculty of Medicine, UAE University, Al Ain, United Arab Emirates.

Remodelling of neuronuscular junctions (NMJs) appears to be a lifelong process, as indicated by ongoing outgrowth, retraction, constriction and expansion. This morphological turnover of NMJs may be modulated by activity depending on age and muscle fiber type. To further study these phenomena the effect of age and endurance exercise on the structure and function of gluteus maximus NMJs from 10 and 28 month old C57BL/NNia mice were assessed under identical conditions. This muscle has mixed fibers in the mouse and is recruited to maintain posture and for locomotion. Animals were exercised at 28m/min for 60 min/day 5 days/wk for tweleve weeks. Camera lucida drawings made from ZIO-stained NMJs and conventional intracellular recordings for measuring spontaneous and evoked transmitter release of control and exercise gluteus maximus were assessed. Repeated measures multivariate analysis of covarience was used to test for differences in nerve terminal area, perimeter, extent length, fiber diameter, spontaneous and evoked transmitter release between ages and test conditions. There were significant increase in nerve terminal area, perimeter, length and quantal contents in old compared to young mice. Endurance exercise prevented physiological and morphological age related changes. This suggests that the integrity of mouse NMJ during aging is well maintained through regular physical activity.

MUSTARD OIL APPLICATION INCREASES PERSISTING HIND LIMB FLEX-ION (SPINAL FIXATION) IN RATS. M.M. Patterson\*, M.J. Bartett, T.Jackson, & E.S. Johnson, Dept. of Psychology and College of Osteopathic Med., Ohio University, Athens, OH 45701.

Persisting hind limb flexion may be induced by applying approximately 40 mins of 2-4 mA electrical stimulation to spinalized rats' hind limbs, thus inducing a spinal fixation of the reflex alterations. Woofe and Wall (J. Neurosci, 6.1433-1442, 1986) reported that increased c-fiber input could increase spinal cord responsiveness for up to 3 hours. The present study examined the effects of mustard oil induced c-fiber activation on the production of spinal fixa-

tion. We surgically anesthetized (50 mg/kg ip) 20 rats and randomly assigned them to mustard oil or saline control groups. We then transected the rats' spinal cords at T7 and placed them in the stimulation apparatus. Twenty min prior to stimulation, we applied mustard oil to the experimental rats' right hind feet and saline to the control rats' right hind feet. Immediately following 30 min of 1.5 mA (100pps) stimulation to the right hind limb, we assessed the spinal fixation by measuring the weight needed to remove the right hind limb flexion.

The mustard oil application significantly (p<.0005) increased the fixation, from 5 g in the control group to 19 g in the mustard oil group, thus indicating that c-liber activation enhances fixation. We suggest that the enhancement of fixation by c-fiber activation is mechanistically similar to the sensory and motor changes which result from tissue injury. Tissue injury activates c-fibers which in turn enhance the spinal processes which store and maintain excitability alterations. These spinal processes may partially modulate pain persistence and could be implicated in chronic pain, phantom limb pain and other chronic syndromes. TYROSINE HYDROXYLASE POSITIVE CELLS PROJECT FROM DORSAL AND MEDIAL RAPHE TO NUCLEUS ACCUMBENS AND VENTRAL FOREBRAIN SUGGESTING A ROLE FOR BRAINSTEM DOPAMINE IN SPARING ADULT REWARD FUNCTION IN NEONATAL 6-OHDA TREATED RATS. K.S. Sidhu\*, R. Sikes, and J.R.Stellar Departments of Psychology and Physical Therapy, Northeastern University, Boston, MA 02115.

Three day old pups, pretreated with DMI (25mg/kg, s.c.), were given ICV administration of 6-OHDA (100ug) or it's vehicle. At 90-100 days postnatal, all animals received injections into the Nucleus Accumbens of anatomical retrograde tracers Fluoro-Gold or True Blue or both. After one week, brain sections were taken, processed for Tyrosine Hydroxylase (TH) immunoreactivity and examined with fluorescence microscopy for single and double-labeled cells.

In comparison to controls, neonatal 6-OHDA treated rats showed an expected severe reduction in the number of TH+ cells and double labeled cells in the ventral tegmental area (VTA). However, an additional population of double labled cells located in the Raphe nuclei, paticularly the Median Raphe (MR), were less effected by 6-OHDA. These results raise the possibility that some of the residual dopamine known to exist in neonatally 6-OHDA treated rats may originate from the Raphe not the VTA.

DIFFERENTIAL EXPRESSION OF IMMEDIATE EARLY GENES IN CEREBELLAR SLICES. K. Nakazawa, L. Karachot and T. Yamamori\*. Lab. of Neural Networks, Frontier Research Program, RIKEN, Wako, 351-01, Japan

In order to investigate the molecular basis of cerebellar plasticity (specially for long-term depression: LTD), we have examined the induction of immediate early genes (IEGs) in rat cerebellar slices by application of \( \alpha \)-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid (AMPA: as a substitute for parallel fiber stimulation) and 8-bromo cyclic guanosine monophosphate (Br-cGMP: substituting for climbing fiber activation). The sensitivity of cerebellar Purkinje cells to AMPA is persistently reduced for several hours when combined with Br-cGMP (M. Ito and L. Karachot, Neuroreport, 1, 129-132, 1991).

IEG induction has been detected with in situ hybridization and immunohistochemistry. In Purkinje induction and immunonistic cells, AMPA application induced c-fos expression, while induction of other IEGs was less prominent. Br-cGMP application alone had little effect. Other types of neuronal and glial cells in the cerebellum also displayed differential expression of IEGs in response to AMPA and/or Br-cGMP application although the patterns of expression differed from those observed in Purkinje This study thus may reveal a dynamic pattern of IEG expression in neuronal circuitry of the cerebellum.

ENVIRONMENTAL STRESSORS INCREASE PERSISTING HIND LEG FLEXION (SPINAL FIXATION) IN RATS. M.J. Bartelt. F.S. Johnson, T. Jackson, & M.M. Patterson. Dept. of Psychology and College of Osteopathic Med., Ohio University, Athens, OH 45701

We have demonstrated that stimulating a spinalized rat's leg for approximately 40 min induces a flexion which persists for at least 3 days (Steinmetz, Cervenka, Robinson, Romano, & Patterson, JCPP, 95, 548-555, 1981). Because the excitability producing this leg flexion fixates in the spinal cord, it has been termed spinal fixation. In the present studies, we investigated the development of fixation following exposure to the stressors of swimming and noxious noise

In the first study, we placed the experimental rats into a water bath and forced them to swim for 8 min. In the second study we exposed the experimental rats to white noise (approx 85 db) for 12 hours. Following exposure to either the control or the stress condition, we surgically anesthetized the animals (Nembutal 50 mg/kg ip), and performed spinal transections. Following the 30 min of right hind leg stimulation (3-4 mA, 100pps), we assessed the fixation by measuring the weight required to remove the right leg flexion.

In both studies the environmental stressors increased the fixation (p<.0005). The swimming stress group's (n=9) fixation was 36 g compared to their control group's (n=9) of 28 g, while the noise stress group's (n=16) fixation was 38 g

compared to their control group's (n=16) of 32 g.

These findings confirm that generalized organismic stressors enhance the induction of spinal reflex excitability. Exposure to stressors increases responsiveness to pain and may also increase long-term spinal excitability. We suggest that these excitability alterations may be induced by somatic and vis-ceral malfunctions and may in turn contribute to the development of chronic pain and other syndromes such as phantom limb pain. PLASTIC CHANGES IN RAT HYPOTHALAMO-NEUROHYPOPHYSIAL NEURONAL-GLIAL RELATIONS INDUCED BY RESTRAINT STRESS. G.H.Beagley\* and G.I. Hatton, Alma College, Alma, MI 48801 and University of California, Riverside, CA 92521-0146.

Nerve terminal contact with the basal lamina (BL) of the posterior pituitary has been shown to increase, with a decrease in glial occupation, in response to stimuli that elevate neuropeptide release (e.g. parturition, lactation and dehydration by water deprivation or systemic injection of hypertonic NaCl). Increased contact with the BL by oxytocin (OX) and vasopressin (VP) terminals is thought to facilitate hormone release. Systemic adrenalin has been shown to play a crucial role in this phenomenon, suggesting stressful stimuli that cause sympathetic adrenalin release should lead to increased neural apposition with the BL. In the present study 100 day old male rats were confined in Plexiglass restrain tubes for 4 - 5 h and sacrificed immediately after release from confinement. Posterior pituitaries of confined rats (n = 8) were compared to those of unrestrained control rats (n = 6). Morphological analysis of electron micrographs revealed confined rats had greater neural apposition with the BL than control rats (51% vs. 35%, p<.001). These data suggest that, in rats, a stressful stimulus such as prolonged confinement can cause rapid pituicyte withdrawal from the BL as effectively as parturition or hypertonic saline induced dehydration. Supported in part by NS09140.

A HSV-I VECTOR EXPRESSING AN UNREGULATED PROTEIN KINASE C FROM THE TYROSINE HYDROXYLASE PROMOTER CAUSES ROTATIONAL BEHAVIOR FOLLOWING STEREOTAXIC INJECTION INTO THE SUBSTANTIA NIGRA COMPACTA OF UNLESION RATS. Song Song\*, Dean Hartley, John Bryan, Donna Ulirey, Oliver Ashe, Karen O'Malley, Rachael Neve, Alfred Geller, and Mathew During. Div. Endocrinol., Children Hosp., Boston MA. USA 02115; Yale U. Sch. Med., New Haven CT. USA 06510; Wash. U. Sch. Med., St. Louis MO. USA 63110; McClean Hosp. Belmont MA. USA.

We devised a genetic intervention strategy to determine if the protein kinase C (PKC) pathway in substantia niera pars compacta (SNC) neurons controls donamine

We devised a genetic intervention strategy to determine if the protein kinase C (PKC) pathway in substantia nigra pars compacta (SNc) neurons controls dopamine release, and therefore rat motor behavior. We exploited our defective HSV-1 vector system (Science, 1988 241,166; TINS 1991, 14, 428) which can deliver genes into neurons. We have established that expression of the PKC catalytic domain, encoding an unregulated enzyme that is always active, causes an activity dependent increase in neurotransmitter release from cultured sympathetic and cortical neurons (Soc Neurosci Abs 1991 17, 603). Based on these results, we designed an approach to selectively increase dopamine release from SNc neurons in the brain: The vector pTHpkc places the rat PKC BII catalytic domain under the control of the rat tyrosine hydroxylase (TH) promoter; pTHpkc virus was unilaterally injected into the SNc of unlesioned adult rats. Our expectation was the TH promoter should limit expression of PKC to dopamine release from these neurons, perhaps affecting rat motor behavior. In initial experiments, pTHpkc was injected into the SNc of adult male Sprague Dawley rats. Starting two weeks after surgery, the rats were tested for rotational behavior following injection with apomorphine. Ten of 24 rats demonstrated long-term ipsilateral rotational behavior. Control rats injected with pTHlac (expresses E. coli & galactosidase), or PBS, did not show rotational behavior. One month after injection, rats were sacrificed and PKC expression from pTHpkc was demonstrated by immunohistochemistry; most PKC expression was localized to the SNc by staining adjacent sections for TH. Preliminary microdialysis data show an increase in dopamine levels in the striatum of rats injected with pTHpkc.

INDUCTION OF THE IMMEDIATE EARLY GENE NGFI-C IN CORTEX AFTER SEIZURES AND PHYSIOLOGICAL STIMULATION S. Chang, S.D. Yi, P. Mack, H.S. Schutta, and K.J. Mack University of Wisconsin, Madison WI.

NGFI-C is an early response gene which encodes a Cys<sub>2</sub>/His<sub>2</sub> zinc finger protein. NGFI-C has been demonstrated by Northern blotting to be inducible in PCI2 cells after NGF stimulation, and in whole brain after a pentylenetetrazol induced seizure. This study sought to localize this gene in somatosensory cortex, and investigate its possible induction by seizure and physiological stimuli

In situ analysis using digoxigenin labelled cDNA probes from non-homologous regions demonstrated NGFI-C containing neurons throughout the somatosensory cortex. Qualitatively, it appeared that staining was darker in post-seizure animals than controls.

To investigate the inducibility of NGFI-C, RT-PCR was performed on mRNA extracts from somatosensory cortex. Increased NGFI-C mRNA levels were seen after a single injection of pentylenetetrazol in a dose dependent manner. Similarly, kindled animals also showed an elevated expression of NGFI-C.

Physiological stimulation of the barrel cortex was also studied. In lightly anesthetized animals, vibrissae were stimulated by an artists paint brush. This resulted in an increased level of NGFI-C expression in the contralateral barrel cortex.

These studies indicate that NGFI-C is a neuronal zinc finger gene that is inducible in response to seizure or physiological stimuli. These findings delineate another pathway of transcriptional activity that may follow neuronal stimulation.

IS SCHIZOPHRENIA A RESULT OF EARLY DAMAGE TO THE HIPPOCAMPAL FORMATION? A BEHAVIORAL STUDY IN PRIMATES. M. Beauregard\*, L. Malkova and J. Bachevaller. Dept. Neurobiology and Anatomy, Univ. Texas, Houston, TX 77225 and Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

We reevaluated the socioemotional behavior of adult monkeys with neonatal hippocampal lesions and compared it with previously reported analysis of their behavior at 2 and 6 months (Bachevalier et al., Innovations In autism. DeLong & Bauman Eds, 1992). Four animals had received hippocampal lesions (H) neonatally, 4 were normal controls (N/H) reared with monkeys from Group H, and six were normal controls reared together (N/N). At 7 years, each H animals was paired in a play cage with its agematched control, and their behavior was observed for 2, 5-minutes intervals during 5 consecutive days. Similarly, each N/N was paired with another N/N. Monkeys in the N+H dyads displayed a lack of social interaction and an increase in locomotion and manipulation as compared to monkeys in the N+N dyads. In addition, H monkeys showed more motor stereotypies than either normal controls (N/H or N/N). Since only mild behavioral changes were seen in H monkeys at 2 and 6 months of age, the data indicate that early damage to the hippocampus and parahippocampal gyrus yields behavioral disturbances that become more severe when the animals reach maturity. The developmental time course and the nature of these disturbances closely resemble those seen in schizophrenia.

### 364.2

EFFECTS OF AMANTADINE ON PLAY AND OTHER SOCIAL EMOTIONAL PROCESSES. J. Panksepp\*. W. Klimesch, E. Nelson, and C. Nociar. Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403.

Brain dopamine (DA) release increases psychomotor activity and social play is characterized by such behavior. To analyze this relationship, we evaluated the effects of amantadine (AMANT), a DA releasing agent, on basic social processes, including rough-and-tumble play in rats and separation distress vocalizations (DVs) in domestic chicks. AMANT produced dose dependent reductions in play as measured by pins as well as overall rough-and-tumble motor activity (reductions of about 25%, 36% and 67% at 10, 20 & 40 mg/kg) lasting for about two hours. Solicitations (as mean by dorsal contacts) were reduced by 30% only at the highest dose. Repeated daily injections of 50mg/kg inhibited play completely with modest tolerance seen by day 4. Established play dominance was not modified when dominant rats received 20 mg/kg AMANT, but submissive rats receiving AMANT seemed more dominant. This wa largely due to the dorsal contacts of control animals becoming less effective in producing pins. This pattern was even more evident if drug treatment was initiated at the very beginning of play testing. AMANT inhibition of play was not modified by pretreatment with .25 mg/kg haloperidol, which itself also reduced all aspects of play. The results suggest that vigorous play is sustained only in the presence of phasic DA activity, with both tonic release and blockade of DA being incompatible with rough and tumble ludic activities. Modifications in play and play dominanace appeared to be due to the ability of AMANT to decrease overall social responsivity, and social choice tests indicated normal animals prefered to socialize more with vehicle than AMANT treated animals. The decrease in social-emotional responsivity by AMANT was affirmed by the ability of the drug to reduce separation DVs in domestic chicks (at 50-100 mg/kg), suggesting that DA release in the brain may decrease social motivation and increase social dominance (a non-playful state) in animals.

TESTOSTERONE EFFECTS ON SOCIAL BEHAVIOR IN CHICKS. L.Normansell\*, T. McCollister, C. Hélie, T. Bateson, and K. Gerecke. Department of Psychology, Muskingum College, New Concord, OH 43762.

Testosterone administration has long been known to affect morphological and behavioral development in chicks. The present series of studies investigated its effects on a variety of social behaviors. For a three week period, male and female chicks received daily injections of testosterone propionate (TP; 2.5mg) or oil control.

TP-treated chicks took longer to approach the flock than controls, with females generally having longer latencies than males. TP induced crowing, with males affected more than females. During the period of testing, no control chicks ever crowed. When like-treated mixed-sex groups were placed in a testing arena, TP chicks were more aggressive towards the other flock members, pecking the other birds over twice as often as controls. TP males were more aggressive than TP females but there were no gender differences in the control animals.

Effects of various drugs were assessed in some of these testing conditions. Morphine (Img/kg) completely eliminated crowing, but had no effect on aggressive pecking. Diazepam (Img/kg), the prototypical anxiolytic, modestly reduced both pecking and crowing. Scopolamine (Img/kg), a muscarinic cholinergic antagonist, reduced aggression. Although scopolamine didn't affect the number of crows emitted, it disrupted many of the behaviors associated with crowing including neck and body extension and wing fluffing.

# 364.4

SOCIAL ENCOUNTERS WITH CONSPECIFICS ELICIT SELECTIVE HIGH-FREQUENCY (35-70 kHz) ULTRASONIC VOCALIZATIONS IN RATS. R.J.Blanchard', S.M.Weiss, E.B.Yudko, H.K.Taukulis'. Bekesy Laboratory of Neurobiology and Dept. of Psychology, Univ. of Hawaii, Honolulu, HI 96822; Dept. of Psychology, 'Univ. of New Brunswick-Saint John, New Brunswick, Canada E2L 4L5.

Colony-housed rats emit ultrasonic vocalizations in the 35-70 kHz range when one of the residents is reintroduced after a period of absence from the colony. The calls increase in number as a function of the length of the interval between removal and replacement. Singly-housed animals will also emit these calls when confronted with an anesthetized, same-sex conspecific, and females will produce a greater number than males. Reliably more vocalizations will occur when the animals are intruders into, rather than residents in, the test cage. Morphine, gepirone (1.0, 10.0 mg/kg), and diazepam (3.0 mg/kg) were found to attenuate this behavior, while ethanol (0.6, 1.2 g/kg) had no effect. This model presents a simple technique for eliciting high-frequency (35-70 kHz) ultrasounds unaccompanied by calls of the "22 kHz" variety. It may have potential utility as an index of social defense or anxiety.

PILOCARPINE REDUCES THE NOVEL INDUCED GROOMING BEHAVIOR IN TWO INBRED SUBLINES OF SPRAGUE-DAWLEY RATS. E. Doger\*,

PILOCARPINE REDUCES THE NOVEL INDUCED GROOMING BEHAVIOR IN TWO INBRED SUBLINES OF SPRAGUE-DAWLEY RATS. E. Doger\*, A. Moyaho, A.M. Cajica and J.R. Eguibar, Dept. Ciencias Fisiológicas, Instituto de Ciencias. UAP. México.

It is well known that ACTH and related peptides intraventricularly injected induce excessive grooming behavior and stretching-yawning syndrome in rats. These effects are blocked by systemic injection of muscarinic antagonists (atropine and scopolamine). We reported recently two inbred sublines of Sprague-Dawley rats which differ in their spontaneous yawning behavior (Behav., Brain Res. 40:29,1990). These animals also differ in their grooming scores under different experimental conditions. The purpose of these experiments was to explore the effects of pilocarpine, a cholinergic muscarinic agonist, in novelty and water immersion-induced grooming. Novelty-induced grooming was higher in high yawning rats (HY) than in low yawning (LY) animals (pc0.002, t test). The different grooming components: face washing (FW), body grooming (BG), genital grooming (GG), paw licking (PL) and scratching (S) showed also significant differences between both sublines (F/df 1,210; 15.09 ANOVA). The systemic administration of pilocarpine produced a dose-dependent inhibition on grooming scores in both sublines. The HY animals were more sensitive, with an ED50 of 2.14 mg/Kg than the LY with 3.39. In HY rats pilocarpine affected all the components, except S; on the other hand LY rats only FW was affected (pc 0.01 Duncan's test). Preliminary observations also demonstrated a clear reduction in the water immersion-induced grooming by this drug. These data suggest a direct participation of muscarinic receptors in the expression of grooming behavior.

# 364.7

VALIDATION OF THE DORSOMEDIAL HYPOTHALAMIC (DMH) GABA BLOCKADE MODEL OF "PANIC" WITH ANTI-PANIC DRUG TREATMENTS. A.Shekhar\* and J.S. Katner Dept. of Psychiatry, Indiana Univ. Med.Ctr., Indianapolis, IN 46202.

Blockade of GABAA receptors with bicuculline methiodide(BMI) in the DMH of rats elicits a "panic" like response characterized by increases in heart rate(HR), blood pressure(BP), Respiration(RR) and measures of "anxiety" such as the conflict, elevated plus-maze and social interaction(SI) tests. The present study was aimed at testing the validity of this response as a model of panic drugs by chronically treating the animals with anti-panic attacks imipramine (5 & 15 mg/kg), clonazepam (5 mg/kg) and vehicle intra-periotoneally. Rats were implanted with bilateral microinjection cannulae in the DMH and arterial catheters. Rats were then randomized to chronic imipramine (7 days), clonazepam (3 days) and placebo injections. All treatments were double-blind and the HR BP and SI responses to BMI injection (25 ng/250 Nl) into the DMH were recorded. Imipramine and clonazepam but not vehicle treated rats showed significant decreases in the effects of GABA blockade into the DMH. These results support the validity of GABA blockade in the DMH as a model of panic attacks. (Supported by R29 MH45362).

# 364.9

EFFECTS OF REPEATED RESTRAINT ON THE TIME-DEPENDENT RESPONSES OF MESOLIMBIC DOPAMINE SYSTEM TO STRESS Stefano Puglisi-Allegra 1. Assunta Imperato<sup>2</sup>, and Simona Cabib<sup>3</sup>, <sup>1</sup>dept of Psychology Univ. of Rome "La Sapienza", <sup>2</sup>dept of Neurosciences, B.B. Brodie, Univ. of Cagliari, <sup>3</sup>Isnt of Psicobiologia e Psicofarmacologia (C.N.R.), Roma, Italy

During exposure to either restraint or footshock stress a biphasic evolution of 3-Methoxytyramine (3-MT) concentrations (increase followed by decrease) is observable in the nucleus accumbens septi (NAS) of mice. Moreover, in vivo microdialysis data show biphasic changes in DA outflow (increase followed by decrease) in rats exposed to restraint. Taken together, these results support the hypothesis that biphasic alteration of DA transmission in the mesolimbic system is a general response to stress and suggest that the initial increase of DA release represents an arousal response while the subsequent decrease in DA release may be related to coping failure. Repeated exposure to restraint abolishes the increase in 3-MT concentrations in the NAS of mice as well as the increase in DA otflow in the NAS of rats. On the other hand, the decrease of DA outflow induced by prolonged restraint is anticipated in rats repeatedly exposed to the stressor. Finally, repeated restraint has strain-dependent effects on the decrease in 3-MT levels produced by stress in mice. In fact, while this response is unchanged in repeatedly stressed DBA/2 mice an anticipation of the response is evident in C57BL/6 mice.

These results point to a different effect of repeated stressful experiences on the two phases which characterize the response of the mesolimbic system to stress. While the phase of arousal characterized by increased DA release undergoes tolerance, the stress phase characterized by decreased DA release show sensitization possibly modulated by genotype-dependent factors.

#### 364.6

REPEATED INJECTION OF THE GABA-A ANTAGONIST BMI INTO THE BASOLATERAL AMYGDALA (BLA) "KINDLES" EXPERIMENTAL ANXIETY IN RATS. S.K. Sanders\* and A. Shekhar. Program in Medical Neurobiology and Dept. of Psychiatry, Indiana University Sch. of Medicine, Indianapolis, IN 46202.

Sch. of Medicine, Indianapolis, IN 46202.

We have previously reported that GABA blockade in the region of the anterior basolateral amygdala (BLA) elicits increases in heart rate (HR) and blood pressure (BP) as well as experimental anxiety. In addition, repeated injections of BMI into the BLA augments this cardiovascular response. In the present study, we have found that repeated injections of a subthreshold dose of BMI (6pmol/250 nl) into the BLA sensitizes the rats similar to kindling such that this same dose now increases HR and BP as well as experimental anxiety in the conflict and social interaction (S.I.) paradigms. Further, the BLA contains a high density of benzodiazepine (BDZ) receptors and may represent an important site of action for this anxiolytic class of drugs. We have found that the anxiolytic effects of chlorodiazepoxide (2.5 mg/ml, i.p.) may be reversed by injection of 6 pmol BMI into the BLA in the S.I. test and 6 pmol flumazenil in the conflict model of anxiety. These results suggest that the GABA/BDZ receptor complex in the BLA may be important in developing anxiety and mediating the anxiolytic effects of BDZ. (Supported by R 29 MH 45362-02 and the IUPUI Research Investment Fund)

## 364.8

AUTONOMIC ORIGINS OF CARDIOVASCULAR RESPONSES TO NONSIGNAL STIMULI IN RATS TREATED WITH FG 7142. K.S. Quigley\*, S. Faber, M. Sarter and G.G. Berntson. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

To assess the autonomic correlates of the putative anxiogenic effects of the benzodiazepine receptor partial inverse agonist FG 7142 (FG), heart rate and blood pressure were recorded in freely moving rats under both baseline and mildly evocative stimulus conditions. Effects on vagal and sympathetic activity were determined by co-administering antagonists of either input. FG only minimally affected baseline heart rate and blood pressure. However, FG significantly increased stimulus-induced acceleration of heart rate responses. This effect appeared to be based on a shift in the autonomic control of the heart. While the stimulus-induced autonomic response appeared to result from a coactivation of sympathetic and vagal innervation of the heart in control animals, the FG-induced augmentation of this response was due to a reciprocal pattern of sympathetic activation and vagal withdrawal. These results suggest that a profound shift in the autonomic control of cardiovascular responsivity represent a component of the putative anxiogenic effects of FG. Additionally, these findings indicate that the assessment of putative cardiovascular effects of inverse agonist-like drugs requires the analysis of autonomic responsivity to behaviorally significant stimuli.

# 364.10

ANTIPREDATOR DEFENSE, FEAR, AND ANXIETY IN THE LABORATORY MOUSE D.C.Blanchard, S. Parmagiani, S.M. Weiss, J.K.Shepherd, and H.K. Taukulis. Bekesy Laboratory of Neurobiology and Department of Psychology, University of Hawaii, Honolulu, HI 96822.

The antipredator defense repertoire of the laboratory and wild rat is comprised of a number of behaviorally and neurologically distinct response patterns. We have described a similar defensive repertoire in the laboratory mouse when it is confronted with a predator or is exposed to situations associated with predatory threat.

Swiss-Webster mice show clear patterns of flight from and avoidance of an approaching human. When presented with an anesthetized rat, defensive vocalizations and bites at the rat's snout occur. When exposed to a cat for 15 minutes in visible burrow systems, the mice show behavioral changes that last for 22 hours. The reactions include initial patterns of flight, followed by risk assessment, with a prolonged (12-hour) period of freezing. The animals exhibit avoidance of the surface area and inhibition of non-defensive behaviors for the remainder of the 22-hour period.

We have devised two sets of procedures, a fear/defense test battery and an anxiety/defense test battery, designed to isolate and maximize these behaviors in contexts that are useful to the psychopharmacologist. To illustrate this, the effects of yohimbine, ethanol, and imipramine on the behaviors elicited by these procedures will be described. Yohimbine, for example, shows a clear potentiation of flight and avoidance with a reduction of freezing. These results support Deakin and Graeff's conceptions of flight behavior and its modulation by panicogenic compounds.

SEX DIFFERENCES AND DEVELOPMENTAL CHANGES IN PREDATOR-INDUCED ANALGESIA IN MEADOW VOLES.

L.A.M. Galea, M. Kavaliers, K.-P. Ossenkopp and R. Shivers\*. Dept. Psychology, Univ. British Columbia and Dept. Psychology, Univ. Western Ontario, London, Canada.

Although there is substantial evidence for sex differences in predatorinduced responses of adult rodents, little is know about the responses of young animals. The present study examined developmental changes in predator-induced analgesia in male and female meadow voles, Microtus pennsylvanicus. The nociceptive responses of 8-18 day old (pre-weaning) and 20-30 day old (post-weaning) male and female voles exposed to a garter snake (a natural predator of young meadow voles) were examined. Brief (30 sec) exposures to the snake induced significant analgesic responses that were inhibited by the 5-HT<sub>1A</sub> agonists 8-OH-DPAT and buspirone, and were insensitive to the opiate antagonist naloxone. Longer (15 min) exposures to the snake elicited lower amplitude opioidmediated naloxone sensitive responses. Pre-weaning female voles displayed significantly greater 5-HT<sub>1,a</sub>-mediated analgesic responses than pre-weaning males, with no significant sex differences in the opioid mediated responses. In all cases, the levels of snake-induced analgesia declined during development, with post-weaning voles displaying lower amplitude responses than pre-weaning voles. These results show that there are sex differences in 5-HT<sub>1A</sub> mediated predator-induced analgesia in young meadow voles. They also indicate that responses to predators can change developmentally according to the risk posed by the predator.

## 364.13

AXON-SPARING LESIONS OF THE MEDIAL NUCLEUS OF THE AMYGDALA SELECTIVELY DECREASE AFFILIATIVE BEHAVIOR IN PRAIRIE VOLES. B. Kirkpatrick\*. C.S. Carter. T.R. Insel. Lab. Neurophysiology, NIMH, Poolesville, MD 20837. Previous studies in several mammalian species have shown lesions of the amygdala decrease non-mating, non-

shown lesions of the amygdala decrease non-mating, non-maternal social behaviors; however, it is not clear which anatomical division of the amygdala might be involved, and whether these effects are due to the loss of amygdala neurons or damage to fibers of passage. In two studies, we used the axon-sparing neurotoxin n-methyl-d/l-asparate (NMA) to make lesions in the prairie vole, a gregarious, monogamous rodent that exhibits high levels of male parental care. Partial bilateral lesions of the medial nucleus of the amygdala were made in adult males. With no more than 50% volume loss in the anterior half of the nucleus. Lesioned males exhibited a decrease in paternal nucleus, lesioned males exhibited a decrease in paternal nucleus, lesioned males exhibited a decrease in paternal behavior compared to controls. Lesioned animals showed no decrease in autogrooming, motor activity, sexual behavior, or social contact, and no increase in aggression. NMA lesions of the <a href="https://whole.medial.nucleus resulted">whole</a> medial nucleus resulted in a decrease of both paternal behavior and social contact. Lesioned animals did not differ from control animals relative to level of motor activity, sniffing conspecifics, autogrooming, ability to find buried food, body temperature, or several other species-typical behaviors. These results and other studies implicate the medial nucleus in mammalian social behaviors. medial nucleus in mammalian social behaviors.

EFFECTS OF LESIONS OF THE TEGMENTAL PEDUNCULO-PONTINE NUCLEUS (PPN) ON FEEDING INDUCED BY LATERAL HYPOTHALAMIC ELECTRICAL STIMULATION. W. Trojniar and R. A. Wise.\* Ctr. Stud. Behav. Neurobiol., Dept. Psychol., Concordia University., Montreal, Canada.

PPN receives inputs from nucleus accumbens septi (NAS) and appears to play a role in at least two behavioral functions associated with NAS circuitry: locomotor activity and the rewarding effects of such things as food, amphetamine, morphine, and lateral hypo-thalamic (LH) brain stimulation. NAS also appears to be involved in feeding induced by LH stimulation; the present study was designed to determine if PPN might play a role in this behavior as well.

Rats that fed in response to LH stimulation were given twostage electrolytic lesions of PPN. The first lesion facilitated the behavior, decreasing the feeding threshold and increasing the speed of feeding with supra-threshold stimulation. Ipsi- and contra-lateral lesions were each effective; contralateral lesions were more consistent. The second-stage lesions impaired stimulation-induced feeding; the effects ranged from a slight increase in threshold to a complete cessation of feeding. These findings suggest a complex and bilateral interaction between PPN and mesolimbic motivational circuitry.

DOES MEDIATION OF AGGRESSIVE AROUSAL BY THE HAMSTER CORTICO MEDIAL AMYGDALA INVOLVE AN LTP-LIKE EFFECT? M.Potegal\* Dept Med.Neurosci., Walter Reed Army Inst. Res., Wash. DC

"Priming" a hamster by allowing it one attack on a conspecific increases its aggressive arousal, eg., reduces its attack latency on a subsequent trial. This arousal persists for at least 30 min. We previously reported two lines of evidence that the corticomedial amygdala (CMA) is part of the neural circuitry mediating the temporal persistence of aggression: 1) c-fos expression was increased in the CMA but not other brain regions of attack primed hamsters; 2) CMA lesions reduced aggression without affecting a number of other behaviors (Potegal et al, Soc. Neurosci., 1991,17, 877)

We now report a third line of evidence: Brief stimulation of the CMA through chronic electrodes with currents ≤100 uA reduces hamsters' latencies to attack a subsequently presented conspecific. Time course studies are now determining the optimal stimulation-test interval but it is already clear that this is a delayed effect consistent with the hypothesis that the CMA mediates aggression persistence. The optimal stimulation parameters appear similar to those which induce LTP. Studies of AMPA and NMDA receptor mediation of this effect are also underway. In so far as trans-ient increases in aggressive arousal in rodents bear any relevance to affective state in humans, it can be conjectured that a non-associative, LTP or STP-like activation of the medial amygdala may underlie our experience of anger.

MORPHINE AND AMPHETAMINE-INDUCED FEEDING DERIVED FROM THE NUCLEUS ACCUMBENS: SIMILARITIES AND DIFFERENCES. F.J. Vaccarino\* and R. Gadzovski. Depts of Psychology and Psychiatry, University of Toronto, 100 St. George Street, Toronto, Ontario.

Morphine (MOR) and amphetamine (AMP)-induced feeding derived from the nucleus accumbens (N.Acc) are believed to be an expression of N.Acc opiate and dopamine reward functions, respectively. In an effort to behaviorally dissociate opiate and dopamine reward processes, the present study compared the behavioral profile of AMP- and MOD intend fooding domined from the N.Acc. MOR-induced feeding derived from the N.Acc.

METHOD. Male wistar rats implanted with cannulae aimed at the N.Acc were tested for their feeding/exploratory responses to intra-N.Acc microinjections of MOR (4.0 ug), AMP (1 ug) and saline.

RESULTS AND CONCLUSIONS: Consistent with previous results, intra-N.Acc injections of MOR and AMP stimulated sugar intake in rats. Further behavioral analyses indicated that AMP increased rate of eating while MOR increased time spent eating. In addition, MOR increased exploration, while AMP tended to decrease exploration during feeding. These results suggest that N.Acc. opiate and dopamine reward signals are behaviorally dissociable and demonstrate that analysis of natural behavior profiles may be an effective method for distinguishing the behavioral relevance of different reward signals. NEGATIVE CONTRAST ASSOCIATED WITH REINFORCING STIMULATION OF THE BRAIN. C. D. Anderson\*, R. J. Ferland and M. D. Williams. Dept. of Psychology, Providence College, Providence, RI 02918.

When periods of behavior are being reinforced by events of a given quantity, quality, or temporal density, and alternate periods begin to occur that offer an improved reinforcement, work output for the original behavior is often decreased, a change called negative contrast. The present study attempted to maximize negative contrast by training rats on an FR-10 schedule for standard pellets of food, then introducing alternate periods of reinforcement by electrical stimulation of the lateral hypothalamus (0.1 s train of 50 Hz square wave pulses, 0.4 ms per pulse). Periods of reinforced behavior lasted 90 s and were signaled by a salient light. Reinforcement periods were separated by nonreinforcement intervals signaled by a 6000 Hz tone; pausing for 30 s was a contingency for shifting to the next reinforcement condition. Six rats trained on this procedure showed varied amounts of negative contrast, with drops to about 6% of the original response rate. Control conditions were used to discount satiation as an alternative hypothesis. The extremes of negative contrast observed here have not been seen with conventional reinforcers.

GENETIC INFLUENCE ON + MAZE PERFORMANCE IN MICE. Dudley Peeler.\* Department of Neurosurgery, University of Mississippi

Medical Center, Jackson, MS 39211.

Recombinant inbred (RI) mouse strains have been used to investigate possible major gene determinants of behaviors reflecting learning, memory and emotion. Major single gene influences have been described for various measures of activity and learning. In this study, male mice of the CXB set of 7 RI strains and their BALB/cBY and C57BL/6By progenitors were tested for exploration in a + maze. The crossed arms and center area of the maze were totally exposed except for crossed arms and center area of the maze were totally exposed except for opaque shelters (walls and top) positioned at the ends of two (opposed) arms. Mice were allowed to explore the maze for 5 min. in each of two sessions separated by 48 hrs. The first session was under bright illumination, the second under dim illumination. Approximately half the mice were tested in both sessions between 7:00 and 9:00, the other half between 13:00 and 15:00. Analysis of variance reveals a complex interaction of strain, illumination level and time of day (TOD). All strains exhibit greater movement out of the center area in dim than in bright illumination, but some (BALB/c, CXBD, CXBG & CXBH) as a function of TOD. All strains, when venturing out of the center area, spend less time in open than enclosed arms, but C57BL/6 consistently visit open arms more in dim than in bright light. BALB/c and CXBE show this illumination effect only in aftermoon hours while CXBH do so only in the morning. There is no concordance between strain distribution patterns for these behaviors and CNS variations among these strains. Adequate assessment of genetic influences upon behavior and underlying neural substrates requires a multifactorial approach. and underlying neural substrates requires a multifactorial approach.

MAUDSLEY REACTIVE (MR) AND NON-REACTIVE (MNRA) RATS: PERFORMANCE IN AN OPERANT CONFLICT PARADIGM. R.L. Commissaris\*, L. Franklin, J.S. Verbanac and H.J. Altman. Depts. Pharmaceutical Sciences and Psychiatry, Wayne State University, Detroit, MI 48202.

As a result of selective breeding experiments in the 1960s, there exist two strains of Maudsley rats: Reactive (MR; "anxious") and NonReactive (MNRA; "nonanxious"). The present studies compared the behavior of these MR and MNRA rats in a modification of the Geller-Seifter multiple-schedule operant conflict paradigm. In the absence of a tone, every 30th lever press resulted in the delivery of a 45 mg food pellet. In the presence of a tone, each lever press resulted in both food and foot-shock (0.20 mA for 500 msec). Tone periods were 27 sec in duration and were presented on a VI-120 sec schedule (approx. 20 tones/40-min session). Conflict testing was conducted 5 d/wk for 35 wks. Initially, punished responding in the MR and MNRA rat strains did not differ dramatically. However, over the course of many weeks of conflict testing, rats of the MNRA strain came to accept significantly more shocks than did subjects of the MR strain. Additional experiments revealed that the difference in conflict behavior was not due to strain differences in shock sensitivity. The mechanism for this time-dependent difference in conflict behavior between the MR and MNRA rats remains undetermined. (MH #47181).

THE MOTIVATION PRODUCED BY FOOD AND MORPHINE ARE ISOMORPHIC: APPROACHES TO SPECIFIC MOTIVATIONAL STIMULI ARE LEARNED, K. Nader\* and D. van der Kooy, Neurobiology Research Group,

Dept. of Anatomy, Univ. of Toronto, Ontario, MSS 1A8.

Using an unbiased place conditioning paradigm, we have identified two double dissociable motivational systems that generalize across different rewarding stimuli, but define a boundary between non-deprived and deprived motivational states.

Lesions of the brainstem tegmental pedunculopontine nucleus (TPP) block only a non-deprived (food sated or opiate naive) rat's normal preference for an environment paired with either food or morphine, respectively. In contrast neuroleptic pretreatment blocks only a deprived (food deprived or opiate withdrawn) animal's preference for an environment paired with food or morphine, respectively. The generalization of these motivational systems across stimulus boundaries begs the question of why food deprived animals specifically approach food and not other motivational stimuli in the environment. We asked if morphine can serve as a reward for a food deprived animal in the same way food does. We conditioned opiate naive rats such that one environment was paired with 22hr food deprivation, while the other environment was paired with 22hr food deprivation, while the other environment was paired with 22hr food deprivation and morphine (20mg/kg i.p.). On the test day, rats showed a large preference for the side paired with morphine and hunger. This preference was uneffected by bilateral ibotenic acid lesions of the TPP, but was completely blocked by neuroleptic pretreatment with *cis*-flupentixed (0.8mg/kg i.p.) two and a half hours before each conditioning session. The failure of TPP lesions to attenuate the preference suggests that the rewarding effects of morphine occurring in opiate naive, animals were not mediating the preference. Moreover, since the rats were opiate naive, the rewarding effects of morphine in opiate withdrawn animals could not be mediating the preferences. We conclude that morphine can substitute for food as a reward in food deprived animals. Thus, approaches to specific motivational stimuli are not an inherent property of motivational systems, but rather are learned during the ontogeny of the behaving animal.

FOS-LIKE IMMUNOREACTIVITY IN BRAIN OF PRIMIPAROUS RATS AFTER MOTHER-LITTER INTERACTIONS. A. S. Fleming\*, B. Rusak and E. J. Suh. Dept. of Psych., Erindale College, Univ. of Toronto, Mississauga, ON L5L 1C6 and Dept of Psych., Dalhousie University, Halifax, N.S.

The expression of the immediate-early gene c-fos in neurons is regulated with great anatomical specificity by a variety of pharmacological and environmental stimuli. The distribution of Fos protein in the brain can be used as a marker to help map functional neural systems involved in sensory processing and behavior. In this study, we examined the pattern of Fos-like immunoreactivity (Fos-lir) in the brains of primiparous female rats after their first sustained interaction with pups

Pups were removed from their dams at parturition. parturition, one group of dams (n=9) were presented with six 1-3 day-old pups for 1 hr. A second group (n=6) were presented with a novel food (chocolate) for 1 hr. to control for offactory stimulation and arousal, while another control group (n=11) were left undisturbed. All dams were sacrificed at the end of the 1 hr. period and their brains were fixed and prepared for immunohistochemical detection of Fos-lir in 40u frozen coronal sections.

Brain regions known to be involved in the processing of olfactory

information and regulation of maternal behavior were studied. Exposure to pups significantly increased Fos-lir in the olfactory bulbs and bed nucleus of the stria terminals compared to the undisturbed control group but not the food exposed group. Compared to both control groups, pup-exposed dams showed increased Fos-lir in the MPOA, cortical and medial amygdala and piriform cortex. Fox-lir levels in other hypothalamic nuclei (SCN, VMN, SON), thalamic nuclei and the hippocampus did not differ significantly among the groups.

These results indicate that the sensory or behavioral changes associated with exposure of recently-parturient rats to pups increases nuclear Fos-lir in structures previously shown by other methods to mediate maternal behavior.

DEVELOPMENT OF THE HUMAN RETINOHYPOTHALAMIC TRACT.

DEVELOPMENT OF THE HUMAN RETINOHYPOTHALAMIC TRACT.

S.T. Glotzbach\*, P. Sollars², R.L. Ariagno¹ and
G.E. Pickard². Dept. of Pediatrics, Stanford
Univ., Stanford, CA 94305 and Dept. of Psychiatry,
Univ., Pennsylvania, Philadelphia, PA 19104.

It is presently unknown how and to what extent
photoperiodic modulation may affect the development and coordination of circadian rhythms in
premature or term infants. It is now possible to
examine the development of the retirobypothalamic premature or term infants. It is now possible to examine the development of the retinohypothalamic tract (RHT) in post-mortem tissue using the fluorescent tracer Di-I. Small crystals of Di-I were placed directly into the cut surface of the optic nerve in fixed tissue from preterm and full term infants of varying gestational and post-gestational ages. Sixteen-24 months after Di-I application, hypothalamic tissue was sectioned on a vibratome and examined for the presence of Di-I labeled retinal fibers in the region of the suprachiasmatic nucleus (SCN). Tissue from a 36 week preterm infant had evidence of only a few labeled retinal fibers dorsal to the optic chiasm whereas tissue from a 5 month old full term infant had numerous labeled retinal fibers in the region of Analysis of additional tissue at earlier gestational ages will supplement these preliminary results. Supported by NIH NS 21165 and HD 24315.

ORGANIZATION OF THE RAT SUPRACHIASMATIC NUCLEUS USING DII INJECTIONS. I.H. Tang. D. M. Murakami\* and C. A. Fuller. Department of Animal Physiology, University of California, Davis, California 95616-8519.

Davis, California 95616-8519.

This study examines the general organization of the SCN by making small injections of Dil into specific portions of the nucleus. Male Wistar rats were sacrificed and perfused with 4% paraformaldehyde, brains removed, and a specific part of the SCN injected with Dil with the aid of a dissecting microscope.

Brains were stored for approximately 3 months, coronally sectioned at 100µ, and examined with an Olympus fluorescence microscope or BioRad confocal microscope. Injections of DiI into the dorsomedial SCN extensively labelled axons in the dorsal and medial portions of the SCN. However, very little labelling was found in the ventrolateral portion of the SCN. Densely labelled axons were found to course both dorsally along the wall of the third ventricle to the region ventral to the PVN, and laterally toward the SON, avoiding the ventrolateral SCN. Injections of Dil into the dorsolateral SCN also failed to densely label the ventrolateral SCN. Densely labelled axons project dorsally to the regions ventral to the PVN, but course lateral to the third ventricle. The lateral projection courses toward the SON. An injection into the ventrolateral SCN revealed extensive lateral projections, but light dorsal projections. These results suggest that the rat SCN exhibits an organization that may reflect distinct functional specialization within the nucleus. This research was supported in part by NASA Grant NAGW-2195

GENERATION OF IMMORTAL ASTROCYTE CELL LINE FROM RATISCN Laurel L. Haak\*, Fred W. Turek, and Joseph S. Takahashi Department of Neurobiology and Physiology, Center for Biological Timing

Northwestern University, Evanston, IL 60208

All mammalian cellular clock studies to date have of necessity used primary cell cultures. A cell line derived from the suprachiasmatic nucleus (SCN) that could be grown in culture indefinitely would be tremendously useful, as it would greatly enhance our ability to study the cellular and molecular basis of circadian clock function. Dispersed cells have already been used to restore circadian rhythms in vivo (Silver et al., 1991) and to demonstrate circadian

rhythms in vitro (Murakami et al., 1991).

We introduced a temperature-sensitive (ts) oncogenic retrovirus (U19-tsA) into primary cultures of embryonic rat SCN cells using recombinant Moloney murine leukemia virus. This virus is replication deficient and has been manipulated to code for the ts SV40 large T antigen and neomycin (G418) resistance genes. Only cells that have incorporated the retrovirus will grow in the presence of the antibiotic G418. Dispersed cell cultures were prepared from E15 rat SCN. Cultures were infected with U19-tsA, and the resultant colonies were grown under G418 selection. Several colonies were isolated from each infection. One such G418-resistant colony showing multiple phenotypes was expanded and has been in continuous culture for over 4 months. Cell staining with antibodies to galactocerebroside, neurofilament, and GFAP has shown these cells to react only with GFAP, indicating they are astrocytes. When grown at a temperature non-permissive to oncogene function, the cells still stain only with GFAP antibody, although cell adhesion and growth seem to be enhanced in low levels of serum. The study of the role of these cells in expression of circadian rhythms may prove interesting.

PROJECTIONS OF THE SUPRACHIASMATIC NUCLEUS TO STRESS

PROJECTIONS OF THE SUPRACHIASMATIC NUCLEUS TO STRESS RELATED AREAS IN THE RAT HYPOTHALAMUS: A LIGHT AND ELECTRONMICROSCOPIC STUDY USING Pha-L TRACING AND FOS IMMUNOCYTOCHEMISTRY. R.M. Buijs\*, M. Markman, S. Shinn and Y.X. Hou. Neurosciences Loeb Medical Research Institute, Ottawa, Canada.

A diurnal pattern for corticosteroid and ACTH release has been reported in a number of separate studies. This involves both a diurnal difference in basal levels as well as in the response to stressful stimuli. The structure responsible for the control of ACTH and corticosteroid release is the paraventricular nucleus of the hypothalamus (PVN) where the corticotrophin releasing factor (CRF) neurons are located. Since the suprachiasmatic nucleus (SCN) most likely is the sole source for all diurnal rhythms in mammals, it is to be expected that connections between the SCN and the PVN may explain this diurnal rhythm in ACTH secretion. However, previous anatomical studies in which the projections of the SCN were investigated could not provide evidence for such direct pathways. Therefore, the present study aimed to investigate the anatomical basis for the control of the SCN on ACTH and corticosteroid secretion. Pha-L tracings from the SCN were undertaken and revealed the sites of interaction between the SCN and Fos stained neurons involved in stress. LM and EM studies indicated a direct innervation of Pha-L labelled fibers with parvocellular neurons in the periventricular and caudal PVN, not in the part with putative CRF cellbodies. A high interaction was found also in the DNH, suggesting that interneurons are used to transmit the message of the SCN to CRF secreting neurons.

RETINAL AFFERENTS AS DEMONSTRATED WITH UNCONJUGATED CHOLERA TOXIN J. C. Speh\* and R.Y. Moore Department of Psychiatry, University of Pittsburgh, Pittsburgh, PA 15261

The retinal afferents to the hypothalamus and thalamus of the rat have been demonstrated with many neuroanatomical tract tracing techniques. Using the localization of anterograde transport of unconjugated cholera toxin (CT) with a sensitive immunocytochemical technique, we here demonstrate a more extensive array of projections to these areas than has been previously reported (Johnson et al, '88; Levine et al, '91).

Previously undescribed retinal projections to the organum vasculosum lamina terminalis, dorsal hypothalamic area, perifornical area, midline and ventral thalamic areas, subparaventricular zone of the hypothalamus, lateral dorsal thalamic nucleus, periaqueductal gray, reticular formation and an additional anterior accessory optic nucleus will be described. More extensive projections to the medial and lateral preoptic areas, lateral hypothalamic area, anterior hypothalamic and retrochiasmatic areas, the suprachiasmatic and intergeniculate leaflet nuclei, zona incerta and the ventral surface of the basal forebrain are demonstrated. In addition, a small number of retrogradely labeled cells are seen at the lateral border of the lateral habenula, in the medial pretectal area and the periaqueductal gray. This pattern of projections is more extensive than that reported for the hamster (Johnson, et al, '88). The functional significance of such a complex and extensive distribution of retinal afferents remains to be elucidated. (Supported by NIH grant #NS-16304)

#### 365.4

SOMAL APPOSITIONS IN THE VENTROLATERAL SUPRACHIASMATIC NUCLEUS OF THE RAT. A.S. Elliott\* S.M. Krauchunas and A.A. Nunez. Dept. of Psych., Neuroscience Program, Michigan State University, East Lansing, MI 48824.

It has been reported that cells in the dorsomedial portion of the suprachiasmatic nucleus (SCN) are often in apposition, forming "chains of neurons" (J. Comp. Neurol. 1980, 191:661-702). The ventrolateral SCN (vISCN) receives the bulk of retinal input to the nuclei and also contains peptide producing cells. Circadian fluctuations in the amount of direct neural membrane appositions may play a role in the pacemaker function of the SCN. These data are a preliminary report of the types of appositions in the vISCN. They were collected from animals entrained to a 12:12 LD cycle and sampled at midday, a time when glucose utilization in the SCN is high (Science 1977, 197:1089-1091). We measured the amount of somal membrane in apposition to glia (astrocytes and astrocytic processes), neural membrane (synapses, adjacent somas, unmylinated axons and dendrites), and other components of the neuropil (oligodendrocytes, myelinated axons) from electron micrographs. The initial data show that for cells in the ventrolateral SCN, 55% of somal membrane is in apposition to glia, 26% is in apposition to neural membrane, and 19% is in apposition to other aspects of the neuropil. In addition, every cell had an invaginated nucleus, with an average of 2.5 invaginations. Supported by grants BNS8908576 from NSF and NS 07279 from NIH

#### 365.6

EFFERENT PROJECTIONS OF THE RAT INTERGENICULATE LEAFLET (IGL): A PHASEOLUS VULGARIS LEUCOAGGLUTININ (PHA-L) STUDY. R.P.Weis\*, J.C.Speh and R.Y.Moore, Depts. of Psychiatry Univ. of Pittsburgh, Pittsburgh PA 15261.

The IGL is a distinctive anatomical and functional subdivision of the lateral geniculate complex that is a component of the circadian timing system. In this study, we examined the efferent projections of the IGL using PHA-L in the rat. PHA-L injections were localized to IGL, IGL and dorsal lateral geniculate (DLG) and IGL and ventral lateral geniculate (VLG). The major bundle of IGL projections runs rostrally and ventrally along the optic tract to form a dense terminal plexus in the ventrolateral suprachiasmatic nucleus (SCN). Other fibers extend through the SCN to terminate in sparse plexuses in the adjacent anterior hypothalamic area, subparaventricular zone, retrochiasmatic area and lateral hypothalamic area. These projections are bilateral but greater on the ipsilateral side. Another large group of fibers continues to run through the supraoptic commissure to terminate in the contralateral IGL. A smaller group of fibers extends medially from the IGL into the zona incerta and a small bundle of fibers runs rostrally along the lateral surface of the thalamus to terminate in the anterior nuclei. Another limited bundle, not entirely separate from VLG projections, runs over the dorsal thalamus into the pretectal area, periaqueductal gray and posterior hypothalamus. (Supported by NIH grant NS-16304.)

# 365.8

EFFERENT CONNECTIONS OF THE RETROCHIASMATIC AREA IN THE RAT. M.M. Moga\* and R.Y. Moore. Dept. Psychiatry, Univ. Pittsburgh Medical Center, Pittsburgh, PA 15261.

A major question in circadian biology is how the circadian rhythm of the suprachiasmatic nucleus (SCN) is transmitted throughout the brain when the efferent connections of the SCN are sparse and limited to only a few nuclei. The retrochiasmatic area (RCh) receives direct input from the SCN and may relay circadian information to nuclei not connected with the SCN. To examine this possibility, we placed iontophoretic injections of PHA-L into the RCh. After injections into the medial part of the RCh, located immediately caudal to the SCN, many labeled fibers with terminal boutons were observed in the bed nucleus of the stria terminalis (particularly in the sexually dimorphic posteromedial subnucleus), the medial preoptic area, the septohypothalamic nucleus, and the periventricular hypothalamic nucleus. injections into the lateral part of the RCh, which extends laterally over the optic tract, labeled fibers were particularly numerous in the preoptic subnucleus of the bed nucleus of the stria terminalis, the paraventricular thalamic nucleus, the perifornical lateral hypothalamus and the periaqueductual gray. These results suggest that circadian information may reach additional nuclei via the retrochiasmatic area. (Supported by NIH grant # NS-16304)

ULTRASTRUCTURAL LOCALIZATION OF NERVE GROWTH FACTOR-RECEPTOR-LIKE IMMUNOREACTIVITY IN THE SUPRACHIASMATIC NUCLEUS OF THE RAT. K.G. Bina<sup>1</sup>\*, T. Honda<sup>2</sup>, B. Rusak<sup>1</sup> and K. Semba<sup>2</sup>, Depts. of <sup>1</sup>Psychology and <sup>2</sup>Anatomy and Neurobiology, Dalhousie Univ., Halifax, N.S., Canada.

Heavy nerve growth factor receptor-like immunoreactivity (NGF-R-ir) has been localized in the suprachiasmatic nucleus (SCN) of the hypothalamus, a site responsible for the generation of circadian rhythms and for photic entrainment. At the light microscopic level, NGF-R-ir is located in the ventrolateral aspects of the SCN, an area that receives retinal afferents. Previous studies conducted in our laboratory revealed that NGF-R-containing neurons in the basal forebrain and the retina project to the SCN. Although no detectable levels of NGF-R mRNA have been reported in the SCN, at the light microscopic level some of the NGF-R-ir appears to be located on the surface of SCN neurons. This study was conducted to determine whether NGF-R-ir in the SCN was exclusively located on axon terminals or whether some of the NGF-R-ir is also located on SCN neurons. Both pre-embedding PAP-DAB and post-embedding immunogold staining techniques were used. NGF-R-ir was found to be located on axon terminals as well as on neuronal somata and dendrites within the SCN. In the neuronal somata and dendrites NGF-R-ir was associated with cell organelles such as microtubules and endoplasmic reticulum. These results suggest that NGF-R are not only transported anterogradely from the basal forebrain and retina but are also synthesized within the SCN.

SINGLE UNIT RESPONSES OF RAT SUPRACHIASMATIC NUCLEUS NEURONS TO SUBSTANCE P AND GLUTAMATE IN VITRO. T. Shirakawa\* and R. Y. Moore. Depts. of Psychiatry and Behavioral Neuroscience, Center for Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15261.

The suprachiasmatic nucleus (SCN) of the hypothalamus is a circadian pacemaker in the mammalian brain. It receives entraining input from the retina via the retinohypothalamic tract (RHT). Although RHT axons have been thought to produce glutamate (GLU), a recent study (Takatsuji et al. 1991) has shown that some RHT fibers contain substance P (SP). In this study we examined the responses of SCN neurons to SP and GLU using single unit recording from a hypothalamic slice preparation.

hypothalamic slice preparation.

Neurons were recorded predominantly in the ventrolateral SCN. Approximately, 25% of neurons recorded showed an excitatory response (increased firing rate) to perfused SP (1,10,100,1000nM) and 6% showed an inhibitory response. In a number of instances, these acute effects were followed by long excitatory effects that persisted for minutes after washout of SP from the bath. GLU (10,100,1000µM) evoked excitatory responses from more than 80% of SCN neurons in a dose-dependent manner. There was no interactive effect of GLU and SP on SCN neurons. Supported by NIH grant NS-16304.

NICOTINIC RESPONSES OF SUPRACHIASMATIC NEURONS IN INTACT AND OVARIECTOMIZED HAMSTERS RECORDED IN VITRO. L.R. Waldman and C.A. Fuller\*. University of

California, Department of Animal Physiology, Davis, CA 95616-8519. The effects of nicotine and mecamylamine, a nicotinic antagonist, on neurons in the suprachiasmatic nucleus (SCN) of intact and ovariectomized (ov-x) female hamsters was examined. Three groups were studied: intact, ov-x and ov-x with estradiol implants. 500µ hypothalamic slices, including the SCN, were cut and incubated in artificial cerebrospinal fluid. As intact and ov-x animals with implants showed comparable blood levels of estradiol, they comprised a single control group; ov-x animals had non-significant blood levels. Rate vs. time histograms were constructed. Of the control groups, 63% (n=60) of the cells given 30 mmol nicotine showed a change in firing rate and the ratio of neurons that were stimulated to those that were inhibited was 1.3. The mean absolute value of 't' score for the changes in firing rate was high; t=6.864, p<.0001. In the ov-x group, 65% (n=51) of the cells exhibited changes in firing rate but the ratio of cells stimulated to those inhibited was 0.76. The mean absolute t score was also high, t=6.024, p<.0001. Forty three percent (n=26) of the cells given microtine in the control groups were given mecamylamine (100 mmol mecamylamine with 30 mmol nicotine). Mecamylamine effectively blocked the nicotine response in 77% (n=20) of these cells. Of the ov-x group, 33% (n=17) received the mecamylamine/nicotine mixture. In this group, however, mecamylamine was effective in only 29% (n=5) of the cells. In conclusion, while nicotine effected both ov-x and intact hamsters, mecamylamine, was not as effective in the ov-x group as it was in the control animals.

EFFECTS OF PREOPTIC-ANTERIOR HYPOTHALAMIC WARMING ON THE WAKING DISCHARGE OF POSTERIOR LATERAL HYPOTHALAMIC NEURONS. B.L. Krilowicz 1, R. Szymusiak 2, 3\* and D. McGinty 2, 4. 1Dept. Biol., Cal. State Univ., Los Angeles, CA 90032, <sup>2</sup>V.A. Medical Center, Sepulveda, CA 94343, <sup>3</sup>Dept. Anat. Cell Biol. and <sup>4</sup>Dept. Psychology, Univ. Calif., Los Angeles, CA 90024.

Interactions between sleep-wake regulation and the

Interactions between sleep-wake regulation and the thermoregulatory system are well known, suggesting that preoptic/ anterior hypothalamic (POAH) thermosensitive neurons may participate in the regulation of brain mechanisms of sleep and arousal. To test this hypothesis, we examined the effects of local POAH warming on spontaneous and evoked activity of neurons in the posterior lateral hypothalamus (PLH) of cats during waking and sleep. In response to POAH warming, 46% of 50 PLH cells decreased spontaneous discharge rates by 16-92%, 26% increased activity by 18-140%, and 28% exhibited minimal changes (-14-3%) in discharge rate. Cells that increased activity during POAH warming tended to have low firing rates during active wakefulness, while the other two classes of cells had high discharge rates when cats were active. Orthodromic responses evoked by brainstem or cortical stimulation were also examined. Cells that were most responsive to POAH warming (±25% change in spontaneous waking discharge rate) exhibited changes in waking evoked excitability during POAH warming that were similar to those evoked during normal slow-wave sleep. These results suggest that POAH thermosensitive neurons participate in the regulation of sleep and wakefulness via inhibition and/or disfacilitation of arousal systems.

THE EFFECT OF NEUROPEPTIDE Y AND OPTIC NERVE STIMULATION ON SPONTANEOUS DISCHARGE RATE IN THE SUPRACHIASMATIC NUCLEI. T.E. Hermida and M.E. Harrington\*, Dept. of Psychology, Smith College, Northampton, MA USA.

The circadian pacemaker in the suprachiasmatic nuclei (SCN) receives retinal input via the retino-hypothalamic tract (RHT). A second photic pathway, the geniculo-hypothalamic tract (GHT) arises from neuropeptide Y-immunoreactive neurons in the intergeniculate leaflet. We studied the role of the GHT by examining how neuropeptide Y and electrical stimulation of the optic nerves altered SCN cell discharge rate.

Extracellular single unit activity was recorded from the SCN in horizontal slice preparations with the optic nerves attached. Optic nerve stimulation was applied through a suction electrode. Neuropeptide Y was added to the bath in two minute intervals, and post-stimulus responses were recorded until the firing rate returned to baseline.

SCN cell responses to both neuropeptide Y and to optic nerve stimulation were both excitatory and inhibitory, with changes in firing rate of up to 200%. Some cells responded to neuropeptide Y with a long lasting (e.g., 2 h) oscillation in firing rate, while responses to optic nerve stimulation were of a much shorter duration. Application of neuropeptide Y could alter the response to optic nerve stimulation.

These results indicate that application of one putative neurotransmitter of the GHT can induce long-lasting oscillations in discharge rate of SCN neurons and can alter responses of SCN neurons to direct stimulation of the RHT.

BRAINSTEM-PROJECTING NEURONS IN THE HYPOTHALAMIC

BRAINSTEM-PROJECTING NEURONS IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS DECREASE THEIR SPONTANEOUS ACTIVITY FOLLOWING STIMULATION OF THE SUPRACHIASMATIC NUCLEUS. M.L.H.J. Hermes and L.P. Renaud\*. Neuroscience Unit, Ottawa Civic Hospital, Ottawa, Canada KIY 4E9.

Several lines of evidence indicate that in mammals the circadian rhythm in many behavioral, neuroendocrine and autonomic functions is generated by a pacemaker located within the suprachiasmatic nucleus (SCN). The efferent projections of this nucleus to the medial hypothalamus and thalamus are likely involved in the mediation of rhythmic information to the rest of the brain. Recently, applying extracellular electrophysiological techniques, we have observed that electrical stimulation in the SCN influences the excitability of identified neurosecretory neurons in the hypothalamic paraventricular nucleus (PVN). In view of the presence of caudally-projecting neurons in the PVN that are involved in the regulation of autonomic functions, we also studied the effect of electrical stimulation in the SCN on the excitability of PVN neurons that could be antidromically activated from the dorsal vagal complex (DVC).

In pentoparhital anesthetized male Long-Evans rats. PVN

(DVC).

In pentobarbital anesthetized male Long-Evans rats, PVN neurons projecting to the DVC showed a reduction in excitability after SCN stimulation. Mean latency of onset was 17.0 ± 2.7 ms; mean duration of effect was 132.2 ± 39.5 ms. These results support the idea that the SCN influences sympathetic and parasympathetic outflow through the PVN and may, via this pathway, induce rhythmicity in certain autonomic functions. This research was supported by the International Human Frontier Science Program Organization.

IRRADIANCE CODING BY SUPRACHIASMATIC NUCLEUS AND INTERGENICULATE LEAFLET NEURONS. M.E. Harrington, J. Meijer and B. Rusak\*, Dept. of Psychology, Smith College, Northampton MA, USA, Physiology Dept., Leiden University, Leiden, THE NETHERLANDS, and Dept of Biomedical Sciences, McMaster University, Hamilton, Ontario, CANADA.

Cells in the suprachiasmatic nuclei (SCN) and intergeniculate leaflet (IGL) have been shown to alter their firing rates in response to changes in diffuse illumination. Firing rate changes are intensity-related and often sustained for the duration of retinal illumination. We examined whether responses of SCN and IGL neurons to manipulation of light irradiance and duration resemble phase-shifting responses

Male golden hamsters were removed from a light:dark (14:10) cycle, anesthetized with urethane (2g/kg), and prepared for electrophysiological recording (see Brain Res., 554 (1991) 95-104). The photic stimulus was either a full spectrum light (to halogen lamp) or the same light source filtered to produce monochromatic light (500nm, BW=25nm, Corion Corp.).

SCN cells showed irradiance coding with response thresholds at about 10-14 photons/cm $^2$ s. Cells in the IGL and anterior ventral lateral geniculate nucleus showed similar thresholds ( $10^{-13}$  to  $10^{-15}$  photons/cm $^2$ s). Response thresholds as measured by firing rate changes in anesthetized animals were several log units higher than those measured in behavioral experiments (J. Physiol., 439 (1991) 115-45), perhaps as a result of the urethane anesthesia.

For geniculate cells, irradiance-response curves for the first 5 s of a light stimulus were shifted toward lower irradiances as compared to responses over longer durations (e.g., 300 s). Irradiance-responses of SCN cells did not vary with light duration These results suggest that the duration-dependence of phase-shift responses at CT19 might be mediated beyond the level of the photoreceptor.

# FUNCTIONAL ORGANIZATION OF THE HAMSTER SCN VISUALIZED WITH VOLTAGE-SENSITIVE DYES

D.M.Senseman\*, K.Hart, J.Solis, G.Gonzalez, and M.A.Rea. Division of Life Sciences, University of Texas at San Antonio, San Antonio TX, 78249 and Armstrong Laboratory, Brooks AFB, TX, 78235.

How afferent input from the retinohypothalamic tract (RHT) can phase shift the circadian oscillator is still largely unknown. Spatial difference: in SCN field potentials have been observed in response to optic nerve stimulation (Shibata et al., Brain Res. 12: 377, 1984) suggesting a possibile functional organization to the SCN's intrinsic neural circuitry that might be related to the entrainment process. To investigate this possibility, we are using multiple-site optical recording techniques (Obaid et al., Neurosci. Abstr. 16: 1185, 1990) to visualize and map spatiotemporal differences in neuronal activity in the hamster SCN. The figure below shows three (of 124) optical traces recorded from a 400 um horizontal slice stained with the dye RH155 following electrical stimulation of the optic nerve. These traces were recorded from adjacent 120x120 um regions of the SCN and illustrate the degree of spatiotemporal variation Supported by: RDL 18, GM 08194, GM07717 & AFOSR 2312W6 observed.

SPONTANEOUS FIRING PATTERN OF NEURONS IN THE CAUDO-LATERAL PERIBRACHIAL AREA. S.Datta J.Quattrochi and J.A.Hobson. Lab. of Neurophysiology, Dept. of Psychiatry, Harvard Medical School, Boston, MA 02115.

Cholinergic stimulation of the caudo-lateral peribrachial nucleus of the pons produces immediate state-independent ipsilateral LGB PGO waves and enhancement of SP and REM sleep lasting for seven days. state-independent PGO waves persists for 3-4 days. In the present study neurons were recorded during the wakesleeping cycles in normally behaving cats. About 79.5% of the cells increased or began firing (median around 40 Hz) during PGO related states (SP and REM). Of these PGO state-on cells 27% discharged high frequency (300-500 Hz) spike bursts 30-40 ms before each thalamic PGO wave, upon a background of tonically increased firing rates during the PGO related states. Another 9.5% of the cells fired (15 Hz)tonically during waking and slow wave sleep without PGO but stopped or decreased firing during the PGO related states. The remaining 11.0% cells fired (10 Hz) tonically but were unrelated to the wake-sleep state. This correlative evidence indicates that the caudolateral area is a candidate for PGO generation and driving element of the rostral peribrachial PGO-related transferring neurons. EFFECTS OF SHORT TERM EXPOSURE TO CONSTANT ILLUMINATION ON THE HYPOTHALAMO-NEUROHYPOPHYSIAL SYSTEM (HNS). M.L. Weiss\*, J.E. Smith. Sohanjan, P. Rusch and G.I. Hatton. Neuroscience Program, Michigan State University, E. Lansing, MI 48824-1117

It has been inferred that the suppression of 24 hr water intake induced by exposure to continuous environmental illumination (LL) is due to increased release of vasopressin from the posterior pituitary (e.g., Glantz, Physiol. Behav. 2: 49-54, 1967). We wanted to determine if LL could induce the same pattern of plastic changes produced in the HNS by other stimuli which activate the system, such as 10 d lactation. Twenty four male Sprague Dawley rats, housed in pairs, were randomly distributed into three groups: short term exposure to LL (24 hr), long term LL (48 hr) and control (12:12 L:D). Body weight and 24 hr water intake (for each pair) were recorded daily prior to the onset of the experiment. After exposure to experimental conditions for the appropriate time, half of the animals in each group were decapitated and trunk blood collected for plasma measurements of oxytocin (OX) and vasopressin (VP); assayed by J. Verbalis, U. Pittsburgh, osmolality, and sodium and potassium concentrations. The remaining animals were perfused with fixative and prepared for light and EM morphometric analysis of the HNS. We confirmed the suppression of growth curve and water intake for the first 24 hr of LL and found concomminent changes in the posterior pituitary (similar to what has been found with other stimuli of the HNS). There were no changes in cell or nuclear size of magnocellular neurons in the HNS. Plasma osmolality, ion centrations, and OX and VP were not different between groups. Thus, the behavioral and morphological findings were supportive of an increase in VP release, but plasma hormone levels and cell size of supraoptic neurons were not affected by short term LL. We conclude that the suppression of water intake seen during short term LL is most likely due to other factors, possibly stress, and that long term LL nay be needed to produce activation of HNS. PHOTOPERIOD-INDUCED DECREASES IN MEDIAN EMINENCE DOPAMINE CONCENTRATIONS IN MALE SYRIAN HAMSTERS ARE NOT DUE TO A CHANGE IN TYROSINE HYDROXYLASE ACTIVITY. K. Krajnak Manzanares<sup>2</sup>, K.J. Lookingland<sup>2</sup>, and A.A. Nunez<sup>1</sup>. Department of Pharmacology/Toxicology, and Neuroscience Program, Michigan State University, East Lansing, Michigan 48824.

Steady-state stores of dopamine (DA) are maintained in tuberoinfundibular (TI) neurons by the coupling between neurotransmitter synthesis, rele sm. Exposure of male Syrian hamsters to a short photoperiod is median eminence (ME) DA concentrations (Biol. Reprod. 1982, 26:437), but has no effect on concentrations of its primary metabolite 3,4dihydroxyphenyl-acetic acid (DOPAC; Krajnak et al., 1992, Soc. Biol. Rhythms). Thus, photoperiod-induced decreases in the amount of DA stored in TI neurons is not due to an increase in intraneuronal metabolism of DA. In the present study, the effect of photoperiod on the synthesis of DA in TIDA neurons was estimated by measuring the activity of tyrosine hydroxylase (accumulation of 3,4-dihydroxyphenylalanine [DOPA] in the ME following administration of the L-aromatic amino acid decarboxylase inhibitor NSD 1015) male hamst Animals were housed in either a long (LD; 16L:8D) or short photoperiod (SD; 6L:18D) for 12 weeks. On the day of sacrifice, each animal was injected with NSD-1015 (100 mg/kg; i.p.) 30 minutes prior to decapitation. The ME was microdissected from frozen brains and assayed for DOPA and DA by HPLC. Exposure to short photoperiod decreased DA concentrations in the median eminence, but had no effect on the accumulation of DOPA. These results reveal that photoperiod-induced decreases in DA stores in the ME in male Syrian hamsters are not due to an alteration in the synthesis of DA in TIDA neurons. DO PRESYNAPTIC MELATONIN HETERORECEPTORS MODULATE CATECHOLAMINE RELEASE IN AREAS OF RABBIT BRAIN POSSESSING HIGH LEVELS OF 2-[125]-IODOMELATONIN BINDING SITES? M.L. Dubocovich, S. Iacob, J.G. Hensler, F.B. Cutting, and M.I. Massna'. Dept. Pharmacol, Northwestern Univ. Med. School, Chicago, Illinois 606II.

2-[125I]-Iodomelatonin (100 pM) binding sites were localized in coronal rabbit brain sections using in vitro autoradiography (50 mM Tris buffer, pH 7.4). Specific binding defined with 1 uM melatonin was unevenly distributed throughout the rabbit brain. The highest levels of specific binding were found in the dorsal hippocampal commissure (23 fmol/mg protein), followed by the retrosplenial cortex, dorsolateral thalamus, frontal, parietal and occipital cortex, cingulate girus, corpus callosum, suprachiasmatic nucleus, superior colliculus, caudate and ventral hypothalamus (4 fmol/mg protein). Brain slices prepared from hippocampus, frontal cortex, caudate or hypothalamus were labeled with either <sup>3</sup>H-dopamine (DA) or <sup>3</sup>H-norepinephrine (NE) and superfused with Krebs solution (1.3 mM calcium). In the caudate melatonin (1 pM - 10 uM) did not modify the calcium dependent release of DA elicited at 3 Hz (20 mA, 2 msec), in contrast to the rabbit retina where this hormone is a potent modulator of DA release (IC<sub>50</sub> = 17 pM). In slices of frontal cortex and hippocampus, melatonin did not affect the release of NE, while in hypothalamic slices, melatonin inhibited release only at 1 uM. These results suggest that melatonin receptors in the rabbit brain do not function to modulate the release of DA or NE. Supported by USPHS Grant MH-42922 to MLD.

2-[125]-IODOMELATONIN BINDING IN LAYERS OF CHICK OPTIC TECTUM MEASURED OVER THE DIURNAL CYCLE. D.N. Krause\*1, F.B. Cutting² and M.L. Dubocovich², Depts. of Pharmacology, ¹Univ. of Calif., Irvine, CA 92717 and ²Northwestern Univ. Med. Sch., Chicago, IL 60611.

We have shown specific, high affinity 2-[125]-iodomelatonin (2-IMEL) binding to be unevenly distributed

We have shown specific, high affinity 2-[1251]-iodomelatonin (2-IMEL) binding to be unevenly distributed throughout the major layers of chick optic tectum (Krause et al., 1992). Tectal 2-IMEL binding was further studied in coronal brain sections from chicks (3.5 week old) kept on a 14:10 light: dark cycle until sacrifice at either 07:00 or 18:00 hrs. Saturation analysis using quantitative autoradiography showed that 2-IMEL (1-500 pM) bound to the various tectal layers with similar picomolar affinities. The highest binding densities were found in the retinorecipient layer, stratum griseum et fibrosum superficiale (SGFS; Kd, 86 ±12 pM; Bmax, 201 ± 10 fmol/mg protein, n=3, determined at 18:00 hrs.), as compared to the underlying stratum griseum centrale (SGC; 123 ±16 fmol/mg) and the optic fiber layer, stratum opticum (SO; 26 ±2 fmol/mg). No significant differences between the two time points were found for tectal binding (Kd or Bmax) in any layer. Thus the sensitivity of tectal melatonin receptor binding sites appears to be the same at the beginning and end of the daily nocturnal peak in melatonin levels. These findings contrast with the dramatic decreases in 2-IMEL binding we have seen previously in SGFS and SO following optic nerve transection. (Supported by USPHS Grant MH-42922 to MLD.)

# 366.7

MELATONIN RESETS THE SCN CIRCADIAN CLOCK IN <u>VITRO</u> WITHIN A NARROW WINDOW OF SENSITIVITY NEAR DAWN. A.J. McArthur\* and M.U. Gillette. Dept. of Physiology & Biophysics and Dept. of Cell and Structural Biology, Univ. of Illinois, Urbana-Champaign, IL 61801.

We have previously reported that melatonin (MEL) acts directly on the SCN in vitro, phase advancing the time-of-peak in neuronal activity only when applied near the day-night transition (McArthur et al., 1991). Animal studies suggest that mammalian circadian systems have a second period of sensitivity to MEL just prior to dawn. MEL treatment at this time increases SCN metabolism (Cassone et al., 1988) and induces c-Fos (Kilduff et al., 1990). High affinity MEL receptors in the SCN demonstrate maximal density at late subjective night (Laitinen et al., 1989). Brain slices were prepared from 8 wk old male Long Evans rats

Brain slices were prepared from 8 wk old male Long Evans rats housed in a 12L:12D cycle. Slices were treated with MEL (10<sup>9</sup> M) for 1 hr, and measurements of phase were made by determining the time-of-peak in neuronal activity. While MEL treatment at CT 22 has no effect on the SCN clock, the same treatment at CT 23 results in a near 4 hr phase advance (n=4) in the rhythm of electrical activity on days 2 and 3 in vitro. These results suggest 1) that MEL can regulate the SCN at both transition points in the environmental lighting cycle, and 2) that even in constant conditions in vitro, sensitivity to MEL is modulated over time. (Supported by NIH Grant 5T32GM07143 to A.J.M. and NINDS Grant NS-22155 to M.U.G.)

#### 366 4

PHARMACOLOGICAL AND BIOCHEMICAL CHARACTERIZATION OF MELATONIN BINDING PROTEINS IN HAMSTER BRAIN. J.B. Hogenesch, R.C. Brown, M.L. Dubocovich. Dept. Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

In Djungarian hamster brain 2-[128]-iodomelatonin (2-IMEL) labels a site (ML-2) with binding and pharmacological characteristics distinct from the well characterized ML-1 receptor. The specific binding of 2-IMEL to the ML-2 site shows rapid association at 0°C, with maximal binding at 5 min. It is reversible and saturable (Kd=1.5 ± 0.3 nM) (Duncan et al., Endoc. 125: 1011, 1989). The aim of this study was to identify putative melatonin binding proteins in hamster brain. Washed synaptosomal membranes were labelled with the irreversible ligand 2-[125]-bromomelatonin (Laudon and Zisapel, FEBS Lett. 288: 105, 1991) (BIM, 55 pM) by incubation at 0°C in 50 mM Tris (pH 7.4) with 10 mM MgCl<sub>2</sub>. The association of BIM was time dependent (0 to 60 min), although specific binding (melatonin,  $10~\mu M$ ) was only observed up to two minutes. The concentration of melatonin (IC<sub>50</sub>) necessary to protect the binding of BIM (55 pM) to hamster brain membranes was 115 nM. This value is similar to the value obtained when membranes were labeled with 2-IMEL (IC<sub>50</sub> 90.7 ± 26.7 nM n=6). BIM-labeled membranes were processed by SDS-PAGE, and autoradiography showed five labeled proteins of approximate molecular weights of 40, 55, 58, 107, and >200 kD, whose binding was protected by melatonin (0.1-10  $\mu$ M). Current pharmacological experiments are aimed at establishing the identity of these proteins with the 2-IMEL binding site (ML-2). Supported by USPHS grant MH 42922 (MLD) and training grant NS-07140 (RCB).

CIRCADIAN RHYTHM OF MELATONIN SECRETION FROM INDIVIDUAL PINEAL CELLS OF ANOLIS CAROLINENSIS DEMONSTRATED USING A REVERSE HEMOLYTIC PLAQUE ASSAY. G.E. Pickard\* and W. Tang. Department of Psychiatry, Univ. Pennsylvania, Phila., PA 19104

It is not known whether individual vertebrate

It is not known whether individual vertebrate cells function as circadian oscillators or whether circadian rhythms occur as an emergent property of a large number of interacting cells. This issue was addressed by examining melatonin secretion from individual pineal cells from the lizard Anolis carolinensis using a modified reverse hemolytic plaque assay. Dispersed cells maintained in culture demonstrated rhythmic secretion of melatonin for up to 10 days while maintained under a 12:12 LD cycle at 32 °C. When chambers prepared from a single pineal gland were cultured in constant dark for successively longer periods before melatonin secretion was assayed, a circadian rhythm was detected. Mean plaque area from individual cells, assayed over a 12 hr interval, was greater during the subjective night than during the subjective day for at least 3 cycles (72 hrs). These data suggest that individual pineal cells function as circadian oscillators and rhythmically secrete melatonin. Supported by a grant from the Whitehall Foundation, Inc.

MEASUREMENT OF SPECIFIC 2-[1251]-IODOMELATONIN (IMEL) BINDING SITES IN SIBERIAN HAMSTERS AFTER PINEALECTOMY OR SHORT PHOTOPERIOD EXPOSURE.

M.J. Duncan\*, C.C. Purvis and M.H. Stetson. Dept. of Anatomy & Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY and Dept. of Life and Health Sciences, Univ. of Delaware, Newark, DE.

These studies examined whether treatments which alter the secretion of melatonin affect specific

These studies examined whether treatments which alter the secretion of melatonin affect specific IMEL binding sites in the pars tuberalis (PT) of Siberian hamsters. In Exper. 1, adults (N=8/group) were sacrificed 1 week after pinealectomy (PINX) or sham-surgery (SHAM). IMEL binding sites were measured by saturation studies ([FREE]= 8-370 pM IMEL) using quantitative autoradiography. No difference was found in the affinity (K<sub>d</sub>) or density (B<sub>max</sub>) of IMEL sites (SHAM: K<sub>d</sub>=14.2±4.7 pM, B<sub>max</sub>= 1.69±0.15 fmol/mg; PINX: K<sub>d</sub>=17.4±4.4 pM, B<sub>max</sub>= 1.99±0.12 fmol/mg). In Exper. 2, 18 d old hamsters were exposed to short days (SD, 10L:14D, N=11) or long days (LD, 16L:8D, N=9) for 2 weeks. SD inhibited testes and body weight but did not significantly affect the K<sub>d</sub> (SD: 36.9±7.5 pM; LD: 17.3 ±2.04 pM) or B<sub>max</sub> (SD: 2.46±0.19 fmol/mg; LD: 2.39 ±0.13 fmol/mg) of the IMEL sites. These results suggest that IMEL sites may not be regulated by chronic ligand exposure. (Supported by NIH DK42056 to M.J.D.)

DAILY PROFILES OF <u>IN VIVO</u> 5-HIAA AND GLUTAMATE RELEASE IN THE AMYGDALA OF THE FEMALE SYRIAN HAMSTER. <u>U.E. Hauser, I. Van den Beukel and J.D. Glass\*</u> Dept. Biological Sciences, Kent State

HAMSTER. U.E. Hauser, I. Van den Beukel and J.D. Glass\* Dept. Biological Sciences, Kent State University, Kent, OH 44224.

The amygdaloid complex is involved in various cyclic functions, including behavior, sleep-wake patterns, and reproduction. The presence of extensive serotonergic and putative contents of extensive serotonergic and putative contents. glutamatergic projections prompted us to examine the daily pattern of extraneuronal 5-hydroxyindolacetic acid (5-HIAA) and glutamate (GLU) in freely-behaving animals using micro-dialysis. Intact female hamsters were outfitted with microdialysis probes in or near the medial amygdaloid nucleus, and hourly samples were collected. A GLU release pattern was clearly visible, showing low levels during the day, and 3- to 5- fold increases soon after lights off. 5-HIAA release increased in anticipation of darkness, and reached peak levels (1.2- to 1.5-fold over daytime levels) about one hour before the GLU peak. This pattern appears to be location-specific. It is of interest that comparable GLU and 5-HIAA profiles are seen in the suprachiasmatic region, and therefore might be related to circadian function. RESERPINE ABOLISHES THE PHASE-SHIFTING EFFECT OF TRIAZOLAM ON LOCOMOTOR ACTIVITY RHYTHMS OF GOLDEN HAMSTERS. P.D.Penev\*, P.C.Zee# and F.W. Turek. Dept. Neurobiology and Physiology, and #Dept. Neurology, Northwestern University, Evanston, IL 60208.

Injections of the short-acting benzodiazepine triazolam (Tz) 6 h before activity onset (CT6) produce large phase advances of locomotor activity circadian rhythms (CR) in young hamsters. The phase-shifting effect of the drug is absent or attenuated in old animals. Decreased monoamine transmitter levels, recentor densities and neuronal populations are associated with impairment of major integrative systems during senescence. The objective of this study was to determine if monoamine depletion with reserpine (Res) will change the phase-shifting effect of Tz on CR in young hamsters. Wheel running activity of 12 male golden hamsters (8 wks old) was continuously monitored in constant darkness. After a stable free-running circadian rhythm was established 6 animals were injected with Res (2.5 mg/kg s.c.), the rest received vehicle (Veh). Eight to ten days later all animals were injected with Tz (1 mg i.p.) at CT6 and the rhythm was monitored for 2 more weeks. Chi-square periodogram and ANOVA were used to evaluate data. Daily wheel-running activity was reduced by 83.3 +/- 8.4% after reserpine treatment (p < 0.001). A free-running CR persisted (Chi-square, p < 0.05) both after Res (period T = 24.25 + 1.007h) and Veh (T = 24.1 + 1.004h) treatment. Triazolam treatment at CT6 produced phase advances that were larger than 20 min in all vehicle-treated animals and in 1 reserpine treated hamster. The mean phase shifts for the control (83.3 +/- 18.4 min) and reserpine (12.3 +/- 25.6 min) groups were significantly different (p<0.05) from each other. Our results suggest that: 1. Free-running activity CR persists with reduced amplitude after Res treatment. 2. Reserpine significantly eliminates the phase shifting effect of Tz on activity CR. 3. Reserpine application to young hamsters produces changes in the circadian system similar to those observed with aging.

366.13

A CHOLINOCEPTIVE SITE IN THE BASAL FOREBRAIN IS INVOLVED IN CANINE NARCOLEPSY. S. Nishino, J. Shelton, M. S. Reid, J. M. Siegel, W. C. Dement\* and E. Mignot, Psychiatry Dept., Stanford University Sch. of Med., Palo Alto, CA. Psychiatry Dept., UCLA Sch. of Med., Los Angeles, CA.

Narcolepsy is a REM sleep disorder may result from abnormalities in both the cholinergic and monoaminergic systems. Pharmacological studies on canine narcolepsy have shown that systemic administration of muscarinic agonists, α1 antagonists and D2/α2 agonists aggravate cataplety, a pathological manifestation of REM sleep atonia in narcolepsy. A possible site of action for these effects might be the pontine reticular formation (PRF), a region where carbachol, a muscarinic agonist, induces muscle atonia in narcoleptic and control canines (M. S. Reid, personal). the pointne reticular formation (PKP), a region where caracanol, a musicannic agonist, induces muscle atonia in narcoleptic and control canines (M. S. Reid, personal communication). In this study, we have investigated the effects of locally injected monoaminergic and cholinergic compounds on cataplexy (by a behavioral assay) and polygraph recordings. Carbachol (1-10 nmol), prazosin, an  $\alpha$ 1 antagonist, (1-100 nmol) and BHT-920, a D2/ $\alpha$ 2 agonist, (1-10 nmol) were first administered to the narcoleptic Dobermans into the lateral ventricles, and only carbachol injections (10 nmol) indeed attains and a lateral properties model. narcoleptic Dobermans into the lateral ventricles, and only carbachol injections (10 mol) induced status cataplecticus and a long-lasting muscle atonia with desynchronized EEG. This effect was completely antagonized by the administration of an  $\alpha 2$  antagonist, yohimbine (96  $\mu g/kg$  i.v.), in direct contrast to the effect of carbachol injection (10 mmol) into the PRF (Nucleus reticularis pontis oralis), where yohimbine did not modify the carbachol-induced muscle atonia. These results suggest that cholinoceptive sites other than the PRF are involved in the regulation of cataplexy and/or REM steep atonia in narcoleptic canines. We therefore injected carbachol into several brain structures and found that carbachol (10 mmol) injected unilaterally or bilaterally into the basal forebrain (diagonal bundle) induced status cataplecticus and a long-lasting muscle atonia with desynchronized EEG, while cataplecticus and a long-lasting muscle atonia with desynchronized EEG, while carbachol injections into the lateral preoptic area, lateral septum and amygdala had no clear effect. Yohimbine also antagonized this carbachol effect in the basal forebrain. Histological confirmation of the sites of drug injection will be performed when the animals are sacrificed. Our current results represent the discovery of the most rostral cholinoceptive site involved in REM sleep atonia in a pathological model.

DISCRETE INFLUENCES OF ACETYLCHOLINE ON THE CHOLINERGIC, NORADRENERGIC AND SEROTONERGIC NEURONS IN THE ANESTHETIZED RAT BRAINSTEM.

Y.Koyama and Y.Kayama\*. Dept. of Physiology, Fukushima Med. Col., Fukushima 960-12, Japan. Cholinergic neurons in the laterodorsal teg-

mental nucleus (LDT), noradrenergic neurons in the locus coeruleus (LC) and serotonergic neurons in the dorsal raphe (DR) are major components of the brainstem systems controlling activity of the upper brain. To clarify the cholinergic influences on these projection systems, acetylcholine (ACh) was applied ionophoretically to LDT, LC and DR neurons of urethane-anesthetized rats during single unit recording. ACh had an inhibitory effect on about half of the LDT and DR neurons generating broad spikes, which were postulated to be cholinergic or serotonergic, respectively. None of them were excited by ACh. Of the LC neurons, about one third were excited by ACh, while others were not influenced except only one neuron inhibited. These results suggest that the LDT neurons were inhibited via autoreceptors, and that neurons in the LC and DR, which were similar in that they cease firing during paradoxical sleep, are under the different control by cholinergic neurons. Influences of noradrenaline and serotonin on these neurons were also examined.

GABAERGIC AGENTS WHICH PREVENT LIGHT-INDUCED PHASE SHIFTS OF THE CIRCADIAN SYSTEM DO NOT INHIBIT THE PHOTIC REGULATION OF FOS-LIKE IMMUNO-REACTIVITY IN THE HAMSTER SUPRACHIASMATIC NUCLEUS. C.M. Kaufman\*, K. Shimomura, C.S. Colwell, and M. Menaker. NSF Center for Biological Timing, Dept. Biology, Univ. of Virginia, Charlottesville, VA 22901.

Previous studies have shown that agents which alter GABA receptor function can prevent light-induced phase shifts of the circadian rhythm of locomotor activity in hamsters. The GABA antagonist bicuculline prevents light-induced delays, but not light-induced phase advances1. Conversely, the pnase deays, our not ingui-induced pnase advances. Conversely, the benzodiazepine diazepam, which can potentiate GABA activity, blocks only light-induced phase advances<sup>2</sup>. In the present study, we found that these agents did not interfere with photic induction of Fos-like immuno-reactivity (Fos-LI) in the suprachiasmatic nucleus (SCN). By themselves, these agents did not cause an induction of Fos-LI in the SCN. These results suggest either that Fosinduction occurs at a point in the light input pathway upstream from where these drugs are acting or that Fos-induction is not part of this light signal transduction cascade.

THE INJECTION OF CHOLINERGIC DRUGS INTO THE SAME SITE IN THE BRAINSTEM RETICULAR FORMATION RESULTS IN DIFFERENT

THE INJECTION OF CHOLINERGIC DRUGS INTO THE SAME SITE IN THE BRAINSTEM RETICULAR FORMATION RESULTS IN DIFFERENT RESPONSES WHICH DEPEND ON THE ANIMAL'S PRIOR BEHAVIORAL STATE. F. López-Rodríguez\*, K. Kohlmeier, F.R. Morales, and M.H. Chase. Dept. of Physiology, Dept. of Anatomy and Cell Biology, and the Brain Research Institute. UCLA School of Medicine, Los Angeles, CA 90024.

The microinjection of cholinergic drugs into the pontine reticular formation elicits active sleep-like states that are comprised of either some or all of the principal physiological patterns of activity that characterize spontaneous active sleep, i.e., PGO waves, EEG desynchronization, atonia and rapid eye movements. The different patterns of activity that cocur have been attributed to the site of injection (Vanni-Mercier et al., Arch. Ital. de Biol., 1989, 127: 133-164). However, we have observed that different states arise even when cholinergic drugs are injected into the exact same location (Sleep Research, 1992, 21:8). The present study was conducted to explore the basis for the differences in the effect of the drug. A combination of acetylcholine (2M) and neostigmine (2M) was injected by microiontophoresis into the pontine reticular formation for three minutes with currents of 300-700 nA in four chronic, unanesthetized cats. Injections were applied into the site with the shortest latency of effect (bid.), which corresponded to the dorsal region of the nucleus pontis oralis. Two injections into the exact same location were carried out on each experimental day; a minimum of four hours elapsed between injections. With identical injections on the same day, the state of the animal at the time of injection appeared to be the key factor in determining the response. When the animal was awake, cholinergic injections first resulted in a dissociated state in which the animal remained awake with a desynchronized EEG, even though atonia and occasionally PGO waves were present; sometimes this state was followed by slow waves in the EEG, with the an

VERAPAMIT. INCREASES WAKEFULNESS AND SUPPRESSES REM SLEEP IN RATS. Ticho\*, S. Ehrenpreis, and M. Radulovacki. Dept. of Pharmacology, University of Illinois, College of Medicine, Chicago, IL 60612.

The dose-response effect of intraperitoneal administration of verapamil, a calcium channel blocker. on sleep in rats was examined. 5mg/kg dose had no significant effect on sleep, but the 10mg/kg dose increased wakefulness during the first 3 hours following drug adminisration. This dose also increased REM sleep latency and suppressed REM sleep during the 6 hours of EEG recording. The findings suggest that doses of verapamil used for their cardiovascular effects in humans may also be responsible for deleterious effects on CNS.

Pharmacological heterogeneity of basal forebrain neurones, P. Fort\*, A. Khateb, A. Alonso°, B.E. Jones°, and M. Mühlethaler, Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and °Montreal Neurological Institute, McGill University, Canada H3A 2B4

In a recent study, we demonstrated that cholinergic neurones within the substantia innominata, display a very homogeneous responsiveness to the major neurotransmitters contained in the afferent fibers that originate in the brainstem. Their responses include most notably a depolarization to noradrenaline and a hyperpolarization to muscarine and serotonin (Khateb et al., 1991). Another class of neurones within the same area, which displays 40 Hz oscillations and may represent non-cholinergic cells (Mühlethaler et al., this meeting), responds differently from the cholinergic neurones to the same neurotransmitters. This other class of cells can be further subdivided into two major subclasses according to their differential sensitivity to the neurotransmitters. One subclass of cells was hyperpolarized by noradrenaline and had very homogeneous responses to the other neurotransmitters, being consistently and strongly hyperpolarized by both muscarine and serotonin. In the second subclass, all the cells were depolarized by noradrenaline but showed variable responses to the other neurotransmitters. In particular, one subset of neurones was hyperpolarized by muscarine, while another subset was depolarized by muscarine. This pharmacological heterogeneity suggests that these presumed non-cholinergic neurones may possess heterogeneous receptors and perhaps also neurotransmitters, and may thus play different functional roles in determining the state modulated activity of their target structures. (Swiss NSF, Fondation Fyssen, Lyonnaise des banques and Canadian MRC).

INHIBITION OF NITRIC OXIDE (NO) SYNTHESIS SUPPRESSES SPONTANEOUS SLEEP AND TRANSIENTLY DELAYS INTERLEUKIN-1 (IL-1)-INDUCED SLEEP BUT NOT FEVER Levente Kapás\*. Masaaki Shibata, James M. Krueger Dept. Physiology, Univ. Tennessee, Memphis, TN 38163

The effects of a competitive NO synthase inhibitor, Nω-nitro-Larginine methyl ester (L-NAME), on sleep, and on sleep and febrile responses induced by IL-1 were studied. Male New-Zealand rabbits were injected with L-NAME iv (10, 100 mg/kg) or intracerebroventricularly (icv, 0.05-5 mg). In separate experiments L-NAME was injected icv (5 mg) or iv (100 mg/kg) 30 min before icv injection of 20 ng IL-1β. Sleep-wake activity and brain temperature (T<sub>br</sub>) were determined for 6 h after treatments. Iv and icv injections of L-NAME dose-dependently suppressed non-rapid-eye-movement-sleep (NREMS) and REMS without treatments. Iv and icv injections of L-NAME dose-dependently suppressed non-rapid-eye-movement-sleep (NREMS) and REMS without affecting T<sub>br</sub>. IL-1B induced NREMS and fever when injected alone. If animals were pretreated either iv or icv with L-NAME then given IL-1B the somnogenic actions of IL-1B were delayed 2-3 h but not the pyrogenic actions of IL-1. The suppression of sleep after L-NAME indicates that NO may contribute to sleep-promoting mechanisms. Since higher doses of L-NAME increase blood pressure and decrease cerebral blood flow it is also possible that the arousal response to L-NAME is due to hemodynamic changes. Current data suggest that NO has little to do with icv IL-1B-induced fever. induced fever

NORDIHYDROGUAIARETIC ACID, AN INHIBITOR OF LIPOXYGENASE IN ARACHIDONIC ACID METABOLIC PATHWAY, PHASE-SHIFTS THE APLYSIA EYE RHYTHM. U. Raju and A. Eskin\*. Dept. of Biochem. and Biophys. Sci., Univ. of Houston, Houston, TX 77204.

A number of proteins in the eye of *Aplysia* have been identified as putative oscillator proteins (POPs) based on their responses to light, cGMP, serotonin (5-HT) and cAMP. One of the POPs, POP-1, is a 40-kDa (pl 5.6) protein whose synthesis was decreased by light and cGMP and increased by 5-HT treatments. As a first step to investigate the function of this protein, we obtained a partial amino acid sequence of it. We discovered from this sequence and subsequent immunoblot analysis that the 40-December is constant to the contraction of the protein of the p The we discovered from this sequence and subsequent minimionion analysis that the 40-kDa protein is an annexin (probably annexin-1). Annexins are a unique family of  $Ca^{2+}$ /phospholipid binding proteins. Annexins may modulate arachidonic acid metabolism by their ability to inhibit phospholipase A2 activity. Some other proposed functions of annexins are regulation of some second meesengers, serving as  $Ca^{2+}$  channels, and controlling membrane protein-cytoskeletal linkages and

Identification of POP-1 as an annexin led us to hypothesize that arachidonic acid metabolism plays a role in the *Aplysia* eye circadian system. To test this hypothesis, we examined the ability of several inhibitors of enzymes in the arachidonic acid metabolic pathway to perturb the eye rhythm. Pulse treatments of isolated eyes with a lipoxygenase inhibitor, nordihydroguaiaretic acid (NDGA), phase-shifted the rhythm. The phase response curve (PRC) obtained using NDGA appears to be an "all-delay" PRC. The phase-shifting ability of NDGA suggests that arachidonic acid and some of its metabolites may play a role in the eye circadian system. Also, further evidence has been obtained for a role of POP-1 in the eye circadian system. With these results we have closed an "experimental loop" in which physiological properties of the circadian system were used to find POPs and now properties of POPs are beginning to yield new information about the nature of the circadian system. Oscillatory bursts in basal forebrain cholinergic neurons induced by NMDA, A. Khateb\*, M. Mühlethaler, A. Alonso\* and B.E. Jones\*, Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and \*Montreal Neurological Inst., McGill University, Canada H3A 2B4

We recently described the distinct electrophysiological properties of a major class of basal forebrain neurons recorded within the substantia innominata in guinea-pig brain slices. These cells were characterized by the presence of a strong A current and low threshold calcium spikes. When depolarized from rest, they fired at a slow tonic rate (maximum 10-15 Hz). When stimulated from a hyperpolarized level, they gave rise to a burst of 2-3 high frequency spikes (>100 Hz) followed by a long after-hyperpolarization (>200ms). Following intracellular filling with biocytin, the recorded cells displaying this burst activity were shown by immunohistochemistry to contain choline acetyl transferase (ChAT) and thus to be cholinergic. Glutamate agonists (NMDA, AMPA and trans-ACPD) were all found to depolarize cholinergic cells. Moreover in the case of NMDA, sustained slow oscillatory bursts (1-5 Hz) were elicited by the continuous application of the agonist when the membrane was held at or slightly below rest. These oscillations persisted in the presence of TTX, and their frequency was voltage dependent. They were blocked We recently described the distinct electrophysiological properties of a neid at or slightly below rest. These oscillations persisted in the presence of TTX, and their frequency was voltage dependent. They were blocked in a reversible manner by the application of the NMDA antagonist, D-AP5. These results suggest that glutamate, which could be released from putative glutamate containing neurons of the cerebral cortex and brainstem reticular formation that project to the basal forebrain, may stimulate an oscillatory burst firing mode in cholinergic basal forebrain neurons. In this mode, the cholinergic cells could in turn drive their cortical target neurons in a delta or these that the of certifielt. COMPARISONS OF CALL AMPLITUDE AND AUDITORY SENSITIVITY IN ANURAN AMPHIBIANS. J. H. Fox: Dept. of Psychology, University of Texas, Austin, TX 76712.

It is unclear how call amplitude and auditory sensitivity should interrelate interspecifically. Three possibilities were considered: (1) Species become specialized for longer or shorter range communication by increasing or decreasing both factors together. (2) One factor compensates the other, such that, for instance, species with low amplitude calls have enhanced auditory sensitivity. (3) The two factors are unrelated, evolving under dissimilar selection pressures. A database was compiled from published sources and analyzed, in order to address this and other issues. Low, nonsignificant correlations were found between call amplitude and estimated toral multiunit sensitivity for amphibian papilla (r = 0.035, n = 28, p > 0.8) basilar papilla (r = 0.056, n = 28, p > 0.75), and combined (r = 0.060, n = 27, p > 0.75) frequency ranges. These results suggest that call amplitude and auditory sensitivity evolve in response to dissimilar selection pressures. For example, no environmental predictors of auditory sensitivity are known, but certain habitat differences may affect call characteristics. Modeling results indicate that in heavily vegetated environments, benefits from higher amplitude calls are wasted, and lower amplitudes are more efficient. As predicted, call intensity and foliage density are negatively correlated (r = -0.275, n = 43, p < 0.05). Body size is the only factor known to predict both call amplitude (r = 0.441, n = 64, p < 0.0002) and auditory sensitivity (e.g. combined, r = 0.737, n = 41, p < 0.0001). METABOLIC MAPPING USING CYTOCHROME OXIDASE HISTOCHEMISTRY IN FROG BRAIN AREAS ASSOCIATED WITH AUDITORY PROCESSING AND REPRODUCTIVE BEHAVIOR. C. A. Marler\*, W. Wilczynski and F. Gonzalez-Lima. Depts. of Zoology and Psychology, University of Texas, Austin, TX

Cytochrome oxidase stain was used to map metabolic activity in breeding gray treefrogs, Hyla chrysoscelis. Brainstem auditory areas, including the dorsolateral nucleus, superior olivary nucleus, and torus semicircularis, were darkly stained indicating high metabolic capacity. In contrast, two forebrain systems, receiving auditory input, showed differential staining. The interconnected areas of the central thalamic nucleus, striatum, and ventral hypothalamus were lightly stained, whereas the interconnected areas of the anterior nucleus, medial pallium, septal and preoptic areas were darkly stained. Furthermore, within the latter system, preliminary results indicate that there are sex differences. For example, the preoptic area, which is associated with male reproductive behavior, and the septal area stain more darkly in We are also currently examining whether experimental manipulations in testosterone levels can cause changes in areas of the brain where sex differences are found. JAW MUSCLE (EMG) ACTIVITY AND AMPLITUDE SCALING OF JAW MOVEMENTS DURING EATING IN THE PIGEON. R. G. Bout and H. P. Zeigler\*. Organismal Zoology, Leiden Univ., Netherlands and Biopsychology Program, Hunter College (CUNY), New York, NY, 10021.

Amplitude scaling of gape size to object size is a prominent feature of eating in pigeon, and involves both visual and somatosensory inputs. Kinematic and neuromotor mechanisms of scaling were examined by correlating variations in interbeak distance (gape) with jaw muscle EMG activity during the ingestion (grasping, stationing, intraoral transport) of food pellets (3.9, 6.4, 8.7 mm). A magnetosensitive transducer was used to monitor variations in gape; conventional EMG techniques were used to record jaw muscle activity in the upper and lower jaw openers and several jaw closer Kinematic analysis indicates that the motor control strategy mediating amplitude scaling involves the modulation of both jaw opening velocity and jaw opening rise time, but their contribution differs for each phase. EMG analysis showed that, although both maxilla and mandible are moveable in pigeon, scaling involves primarily variations in the amplitude and duration of lower jaw-opener (depressor) activity. These are produced by modulating agonist burst duration and the onset of antagonist (pterygoid) activity. Scaling mechanisms are discussed in relation to task requirements and compared with mechanisms mediating amplitude scaling in humans. (Supported by the Program in Neurobehavioral Morphology, Leiden

University and by Grants (NSF) BNS88-10722; (NIMH) MH-08366;RSA MH-00320 to HPZ)

CENTRAL AND PERIPHERAL SEX DIMORPHISMS IN MALE AND FEMALE CRICKET FROGS, ACRIS CREPITANS. B. E. McClelland' and W. Wilczynski, Dept. of Psychology, University of Texas, Austin, TX 78712. Anuran reproductive behavior is highly sexually dimorphic, with vocalizations usually exhibited solely by males. We measured the volumes of laryngeal components, as well as the preoptic area (POA) and the ventral hypothalamus (VH) of male and female cricket frogs (Acris crepitans) to establish and compare sexual dimorphism in the peripheral and central areas establish and compare sexual dilinorphish in the peripheral and certifial areas associated with vocalization in these frogs. Following snout-vent length (SVL) and head width measurements, the heads of 7 males and 7 females were isolated and cut at 10 or 25 µm. The areas of the larynx, POA and VH were measured every 10 slices and the volumes and brain size were calculated. The females were larger than the males [all MALE vs FEMALE (SVL:2.204 vs 2.576; temales were larger than the males (all MALE vs FEMALE (SVL:2:204 vs 2:5/6; HEAD::63 vs.793; all cm)), however, estimates of brain size derived from representative sections show a non-significant trend toward larger brain size in males. The volumes of the laryngeal components were significantly larger in males (ARYTENOID CARTILAGE::612 vs. 046; VOCAL CORDS::045 vs. 004; CONSTRICTOR MUSCLE::516 vs. 064; DILATOR MUSCLE::194 vs. 023; all CONSTRICTOR MUSCLE:.516 vs. 064; DILATOR MUSCLE:.194 vs. 023; all mm<sup>3</sup>). However, neither the POA nor the VH volumes were different between the sexes (POA:.066 vs. 060; VH:.056 vs.062; all mm<sup>3</sup>), even after correction for brain size differences. The sexual dimorphism in the laryngeal anatomy size is functionally related to vocalization behavior, although the POA and VH do not show a significant degree of difference in size between the sexes. In many vertebrate species, the POA and VH have separate functions in males and females and are sexually dimorphic. However, in amphibians the POA may be responsible for both male calling and female phonotaxis behavior. Our results show that an obvious sexual dimorphism in peripheral anatomy does not necessarily predict a concomitant degree of sexual dimorphism in forebrain areas responsible for the control of behaviors involving those peripheral structures. (Research supported by NSF BNS-9021185.)

## 367.4

TRIGEMINAL DEAFFERENTATION DISRUPTS BOTH THE LOCATION AND GRASPING COMPONENTS OF PREHENSION IN THE PIGEON. R. Bermejo\* and H. P. Zeigler. Dept of Psychology, Hunter College (CUNY), New York, NY, 10021.

The pigeon's pecking response functions to transport a prehensile effector organ (the jaw) towards biologically significant objects such as food. During pecking at food, the transport component (head movement) is precisely localized and the grasp component (jaw movement) is scaled to the size of the object. To examine the kinematics of pecking in the pigeon, a head mounted accelerometer and a magnetosensitive jaw movement transducer were used in conjunction with a touch-sensitive device attached to the computer's monitor. Subjects were food reinforced for pecks made to a computer-generated circular stimulus. During testing, both the position and the size of the stimulus were randomly varied on successive trials. The locations of pecks made to the stimulus and the temporal organization of head and jaw movements during conditioned and ingestive pecks were monitored on each trial. Preoperatively subjects tracked the location of the stimulus on successive trials with great precision. Following trigeminal deafferentation, which disrupted tactile but not proprioceptive inputs from the jaw, both peck location and the grasping and manipulation of food pellets were significantly disrupted. The effects upon the head transport (localization) component are similar to the effects of limb deafferentation upon prehensile behaviors in primates.

THE EFFECT OF ELEVATED DIETARY TRYPTOPHAN ON CENTRAL LEVELS OF SEROTONIN AND ITS METABOLITES IN BIRDS. M.M.S.Moore', W.J. Kuenzel and IN BIRDS. M.M.S.Moore, W.J. Kuenzel and J.A.Mench. Dept. of Poultry Sci., Univ. of Maryland, College Park, MD 20742.

Supplemental dietary tryptophan (TRP) has been shown to decrease aggression in developing

and mature fowl(<u>Gallus domesticus</u>). To investigate whether this effect is mediated through central serotonergic transmission, cannulae were surgically implanted into the <u>cisterna magna</u> of six adult birds. Using a switch-back design, birds were fed high TRP (1.5%TRP) and control (.19%TRP) diets. Sample volumes of 50-200ul of cerebrospinal fluid were drawn from the <u>cisterna magna</u> of each bird. Samples were analyzed for 5-hydroxytryptophan, samples were analyzed for 5-hydroxytryptophan, serotonin, and 5- hydroxyindoleacetic acid using high performance liquid chromatography. Results showed a significant difference (p<.01) in the rate of serotonin turnover in TRP treated birds while actual serotonin levels remained constant.

EFFECTS OF ECTOSTRIATAL LESIONS, WULST LESIONS AND HEMISPHERECTOMY UPON VISUAL CONCEPT OF FOOD IN PIGEONS. S. Watanabe\*. Dep. of Psychol., Keio Univ., Tokyo, Japan.

Pigeons were trained on visual discrimination between four kinds of grains and four non-edible objects in an operant chamber. In Experiment I the birds received surgery of the ectostriatal lesions or Wulst lesions after they learned the discrimination. Either lesion did not impair the discrimination. Experiment II pigeons were trained on the same task but received hemispherectomy after they learned the When they used the eye contralateral to the ablated hemisphere, they showed deficits in food discrimination. Whereas they maintained the discrimination with the eye ipsilateral to the A feeding test with screws and ablated hemisphere. hemp seeds also demonstrated a similar lateralized deficits in visual discrimination of food. results suggest 1) either the ectostriatum or Wulst alone successfully process visual discrimination of food, and 2) damages to both structure impaired the discrimination.

MEDIAL GENICULATE NEURONS IN THE SQUIRREL MONKEY SENSITIVE TO COMBINATIONS OF COMPONENTS IN A SPECIES-

SENSITIVE TO COMBINATIONS OF COMPONENTS IN A SPECIES-SPECIFIC VOCALIZATION. J.F. Olsen\* and J.P. Rauschecker. Neuroethology Unit, LNP, NIMH, Poolesville, MD 20837. We are investigating the neural mechanisms in the squirrel monkey for processing species-specific calls. The chuck is a stereotyped, broadband call beandwidth > 19 kHz) that consists of an initial, upward frequency modulated component, followed immediately by a downward frequency modulated component and a constant frequency component (Winter et al., Exp. Brain Res. 1:359, 1966), respectively called the flag, mast, and cackle. Individually, the components of the chuck are acoustically similar to vocalizations produced in other contexts, thus presenting a discrimination problem to the monkey. As a possible neural mechanism for solving this problem, we sought neural sensitivity to combinations of the flag, mast, and cackle in the medial geniculate. The chuck was modeled on a computer and the components were presented, singly or in combination, from a free-field speaker to a halothaneanesthetized monkey while neural responses were recorded extracellularly. Thirt anesthetized monkey while neural responses were recorded extracellularly. Thirty neurons were found that responded reliably to the model chuck presented at 70 dB SPL; of these, 8 responded only poorly to the three components presented individually. When two or more components were combined as found in the natural chuck, these 8 neurons were facilitated; gating the components separately or introducing more than 5 ms of delay between them abolished the facilitated or introducing more man 3 ms or delay between them adousted the actinated responses. By contrast, we found 5 other neurons that responded well to the cackle alone and poorly to the cackle preceded by the mast, for cackle amplitudes up to 24 dB louder than the mast. The results suggest that combination-sensitivity may be a neural mechanism for categorizing acoustically related vocalizations that differ in their behavioral significance

FUNCTIONAL CONNECTIVITY WITHIN THE FM-FM AREA IN THE AUDITIORY CORTEX OF THE MUSTACHED BAT. M. Kanou. T. Shimozawa, J. S. Kanwal and N. Suga\*. Dept. of Biology, Washington Univ., St. Louis, MO 63130.

The FM-FM area in the auditory cortex of the mustached bat (Pteronotus parnelity is 1.8 mm long along the rostro-caudal axis of the brain and consists of 3 subdivisions: FM1-FM2, FM1-FM3 and

FM1-FM4. In each subdivision, FM-FM combination-sensitive FM1-FM4. In each subdivision, FM-FM combination-sensitive neurons tuned to particular echo delays are systematically arranged for the representation of target distances from 7 to 310 cm (Suga & O'Neill 1979; O'Neill & Suga 1979). The aim of the present research is to explore (1) whether different types of FM-FM neurons with identical best delays interact through excitatory synapses to improve the representation of distance information, (2) whether FM-FM neurons with different best delays interact through inhibitory synapses to enhance the representation of distance information, and (3) whether FM-FM neurons show synchronized after-discharges which represent the integration of neural activities evoked by a single target.

after-discharges which represent the integration of neural activities evoked by a single target.

Simultaneous recording of action potentials were made from two FM-FM neurons at different locations in the FM-FM area, and Joint peristimulus time histograms (JPSTHs) and predicted-JPSTHs (Aertsen et al. 1989) were plotted to examine the temporal relation in discharges between them. Out of 34 pairs of neurons (300-600 µm apart) studied, four pairs (1246) showed correlated activities which might be due to the common (shared) inputs. No direct interaction between paired neurons was observed even though the paired neurons were separated only by 300 µm. Unlike the cat's visual cortex, no oscillatory after-discharges were observed in the FM-FM area of the auditory cortex.

MORPHOLOGICAL ALTERATIONS OF NEURONS DUE TO SOCIAL ENVIRONMENT CHANGES ARE RESTRICTED TO "AROUSAL" AREAS IN THE ZEBRA FINCH FOREBRAIN. A. Rollenhagen and H.-J. Bischof\*. Universität Bielefeld, Fakultät Biologie, Postfach 8640 W-4800 Bielefeld 1, Germany.

2-Deoxyglucose studies (Bischof and Herrmann 1986) show that four areas of the forebrain of zebra finch males are selectively activated in arousing situations. We likewise showed that neuron morphology of these areas is affected by rearing conditions and by short social experience in adulthood (Rollenhagen and Bischof 1991). In this study we investigated whether these neuronal reactions to changing social conditions is a special feature of these "arousal" areas.

Rearing the birds in isolation decreases the density of spines, compared to social rearing, in the "arousal" areas ANC (Archi-Neostriatum caudale) and the visual wulst. The acoustic field L and the visual ectostriatum showed only slightly decreased spine densities. Short social contact (7 days) after isolated rearing enhanced spine densities only in the "arousal"

Our results clearly demonstrate that neurons of the "arousal" areas can react quickly to changes of the social environment, whereas the other areas can't. We suggest that these alterations are in some way linked to changes of activation by arousing stimuli.

ENCODING SIGNAL REPETITION RATE AND DURATION BY INFERIOR COLLICULAR AND AUDITORY CORTICAL NEURONS OF THE FM BAT, EPTESICUS FUSCUS. M. Wu, T. T. Hou and P. H-S Jen\*. Division of Biological Sciences, University of Missouri-Columbia, Mo 65211

Under free field stimulation conditions, we studied encoding of signal repetition rate and duration characteristic of different phases of hunting by the inferior collicular and auditory cortical neurons of the big brown bat. For each recorded neuron, the best frequency (BF) and the minimum threshold (MT) were first determined. The neuron's intensity minimum threshold (M1) were first determined. The neuron's linensity at which the neuron fired maximally. Train stimuli (150 ms duration delivered at 1-2/s) consisted of 2 pulses (10ms duration,100ms interpulse-interval = 10/s) or 6 pulses (4ms duration, 25ms interpulse-interval = 40/s) or 15 pulses (1.5 ms duration, 10ms interpulse-interval) and (10/s) pulses (1.5 ms duration, 10ms interpulse-interval). =100/s) were respectively delivered at the best intensity and the number of impulses of the neuron was recorded. Our data show that both inferior colliculi and auditory cortex contain different populations of neurons which responded maximally to one of the presented train stimuli. There were also neurons which responded equally to either two or all train stimuli. However, neurons in these two auditory centers encode these three train stimuli in different manners. While inferior collicular neurons generally responded in an one-to-one fashion to each pulse within a train stimulus, the cortical neurons only responded to 1-2 pulses within a train stimulus. Such responsive differences may be due to the different recovery cycles among neurons in these two auditory centers (supported by NIH DC 247).

RESPONSES OF CORTICAL AND THALAMIC FM-FM AND CF/CF NEURONS OF THE MUSTACHED BAT TO SPECIES-SPECIFIC COMMUNICATION SOUNDS. K.K. Ohlemiller\*, J.S. Kanwal and N. Suga. Dept. Biol., Washington University, St. Louis, MO 63130.

The central auditory system of the mustached bat is specialized for echolocation. Over 60% of its auditory cortex is devoted to neurons sensitive to combinations of biosonar pulse and echo. For communicating with conspecifics in the dark, this species also uses a diverse array of calls. It is of interest whether biosonar-specialized neurons also process these calls, and thus serve a dual function. We examined this question by comparing the responses of FM-FM and CF/CF neurons in the auditory cortex and thalamus to biosonar sounds and to calls.

Calls were digitized at 250 kHz and classified based on their spectrograms. Eight call classes were presented. The 1-3 most effective calls were then used for further analysis. Minimum thresholds (MTs) and best amplitudes (BAs) in dB SPL, and maximum response (MR) were compared for calls and biosonar signals. For biosonar, MT and BA were taken to be that of the echo in the presence of the pulse. Since the temporal characteristics of the two stimulus types were different, MR was taken to be the largest sum of spikes in any 10 ms window.

Results appeared similar in cortex (n=57) and thalamus (n=10), and for FM-FM (64%) and CF/CF neurons: Neurons were typically not selectivity varied from neuron to neuron. Biosonar sounds were clearly the preferred stimulus. MTs averaged 25.4±11.9 dB SPL for biosonar and 59.0±14.3 dB SPL for calls. That is, neurons were -50 times more sensitive to biosonar than to calls. While responses to biosonar showed BAs averaging 49.9±12.1 dB SPL, calls responses had BAs of 77.9±8.8 dB SPL. 37% of the neurons did not show a BA to calls. The MR to biosonar showed BAs averaging 49.9±12.1 dB SPL, and presumably mediate social interactions over short distances. These neurons may therefore function in call discrimination by graded respo

INHIBITION SHAPES RESPONSE LATENCIES IN THE INFERIOR COLLICULUS OF THE MUSTACHE BAT

G.D. Pollak\* and T.J. Park. Dept. Zoology, Univ. Texas, Austin, TX 78712

Two types of combination sensitive neurons in the mustache bat's medial geniculate nucleus are though to be created by the convergence of projections from generate nucleas are unough to be created by the convergence or projections must two frequency contours of the inferior colliculus. One type, the so called CF/CF neurons, discharge weakly to tone bursts but fire vigorously when two tone bursts having different frequencies are presented together. The other type, the delay tuned neurons, also require two frequencies, but in addition, they require that the two tone bursts be presented in a specific temporal order. The delay tuned properties are a consequence of the latency differential with which the inputs evoked by each of the

two frequencies arrive at the geniculate neuron.

Here we report that there is an orderly arrangement of latencies in the 60 kHz Here we report that there is an orderly arrangement of latencies in the 60 kHz isofrequency contour of the mustache bat's inferior colliculus. There were three salient features of the latency arrangement: 1) neurons in the dorsal colliculus had, on the average, longer latencies than neurons located ventrally; the average median latency in the more dorsal part of the colliculus was 15.4 ms which decreased to an average of about 9.8 ms in the more ventral region. 2) The latencies recorded dorsally, within 200-400  $\mu$  of the colliculus surface, ranged from 30 to about 6 ms, whereas the latencies at depths from 1000-1300  $\mu$  ranged from 5 to 10 ms. 3) a similar distribution was seen in the monaural, E-1 and E-E subregions of the contour. We also investigated the effect of GABAcrgic inhibition on the latencies of collicular cells with intophoretic application of bicuculline, an antagonist specific for GABAA receptors. Bicuculline caused a latency decrease in many cells, and latency changes ranged from 1-15 ms. These values are consistent with the range of latency differences among collicular neurons.

latency changes ranged from 1-15 ms. These values are consistent with the range of latency differences among collicular neurons.

The ordering of latencies in collicular isofrequency contours could provide the topographical substrate for the generation of the combinatorial properties in geniculate neurons. Furthermore, the data suggest that GABAergic inhibition is an important mechanism for producing the wide range of latencies expressed by collicular neurons. Supported by NIH grant DC 00268.

RESPONSE PROPERTIES OF NEURONS IN THE PALLID BAT INFERIOR COLLICULUS THAT RESPOND SELECTIVELY TO MULTIPLE FEATURES OF THE BIOSONAR PULSE . Z. M. Fuzessery.\* Depts. of Zoology and Psychology, Univ. of Wyoming, Laramie, WY 82071

The pallid bat relies on passive listening to capture ground-dwelling prey, and uses its biosonar system only for general orientation. Consequently, this bat must simultaneously process two different modes of auditory input while hunting. Perhaps in response to a need to partition these sensory channels, some inferior colliculus neurons tuned to the biosonar pulse are remarkably selective for the spectrum, FM sweep direction and the duration of the biosonar pulse, which sweeps downward from 55 to 30 kHz over a period of 3-6 msec. These cells are located within the 30-45 kHz layers of the tonotopically organized region of inferior colliculus. Within this neuronal population, some neurons respond to FM sweeps in both directions, others respond only to the normal downward FM sweep, but none respond selectively to upward FM sweeps. The most selective of these neurons respond only to FM sweeps, and cannot be driven by single tones within the sweep. Some FM sweep-selective neurons also act as band-pass filters for the normal sweep duration, and cease responding when the sweep duration exceeds 15 msec. While the mechanisms that underlie the response selectivity of these cells is not yet clear, this abstract presents evidence that suggests that these neurons may integrate acoustic information over periods of 5-10 msec before responding.

ANTERIOR MEDIAL CORTICAL LESIONS IMPAIR PERFORMANCE IN A JUMPING TASK IN THE MONGOLIAN GERBIL. C. Ellard, Dept. of Psychology, University of Waterloo, Waterloo, Ont.

In a jumping task, gerbils can be trained to estimate the size of a gap with precision. Previous studies have suggested that one means by which gerbils compute distance is by using retinal motion information generated by vertical head movements. In the present experiment, we trained gerbils to jump across a gap varying randomly in size from 10 cm to 40 cm. Following this, animals were either subjected to a sham procedure or received aspiration lesions of anterior medial cortex (AMC). Following surgery and a short recovery period, gerbils were tested at randomly varying distances ranging from 10 to 34 cm. AMC animals not only produced fewer head movements prior to jumping, but also produced less accurate jumps, particularly at longer distances. These results suggest that a frontal cortical system is involved in the production of head movements that are used to generate retinal motion information.

This research was funded by a grant from the Natural Sciences and Engineering Research Council of Canada.

SELECTIVE REPRESENTATION OF CALL-SYLLABLES IN THE DSCF AREA IN THE PRIMARY AUDITORY CORTEX OF THE MUSTACHED BAT. J. S. Kanwal\*, K. K. Ohlemiller, and N. Suga. Dept. of Biology, Washington University, St. Louis, MO 63130.

Mustached bats emit a diverse array of complex communication sounds (calls) in addition to the stereotypic biosonar pulses. In contrast to biosonar, however, nothing is known about the neural processing of calls. DSCF neurons in the primary auditory cortex of the mustached bat, Pteronous parnellii, overrepresent 61 and 22-28 kHz frequencies and show facilitation to combinations of these non-harmonic frequency components. While the DSCF area is important for target detection and characterization, our recent findings suggest that neurons in this area harmonic frequency components. While the DSCr area is important to target detection and characterization, our recent findings suggest that neurons in this area may also process calls, which range between 7 and 90 kHz and contain either constant or modulated frequencies, or noise bursts, or their combinations. To test this hypothesis we recorded single unit responses from the DSCF area of awake, restrained bats to CF tones, to broadband noise and to call-syllables. Bats'

awake, restrained bats to CF tones, to broadband noise and to call-syllables. Bats' calls were tape-recorded, classified and digitized using SIGNAL (Engineering Design Inc.) prior to playback as stimuli. DSCF neurons responded either non-selectively ("generalists") to 6 or more of the 10 call-syllables presented or selectively ("specialists") to the 1 or 2 biosonar-like syllables that contained energy in the 61 kHz region in addition to the 25 kHz region. While best amplitudes were not generally observed, both the generalists and the specialists showed upper and lower thresholds to calls and did not respond to noise bursts. For paired CF tones, DSCF neurons exhibited a wide range in the width of facilitative tuning (200 Hz to 6 kHz at 30 dB SPL above threshold) that was flanked by inhibitory regions. For single CF tones, neurons were tuned either to the 61 kHz (Type I neurons) or 25 kHz (Type II neurons) or responded to both (Type III neurons) frequency components. The generalists (Types II or III) exhibited broad tuning in the 25 kHz region, while the specialists (Types I and III) exhibited relatively broad tuning in the 61 kHz region. Neurons with narrow tuning in the 61 kHz region did not show any response to calls. Thus, DSCF neurons process both biosonar signals and calls and call-selectivity is shaped by excitatory, facilitative and inhibitory tuning. (Supported by NIH grants NS07057 to J.K., DC00076 to K.O. and DC00175 to N.S.)

THE DEVELOPMENT OF MOTOR PATTERNS IN WEAVER MUTANT MICE. J.C. Fentress\*, V.J. Bolivar, W. Danilchuk and K. Manley.

MICE. J.C. Fentress\*, V.J. Bolivar, W. Danilchuk and K. Manley. Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4J1.

Although the weaver mouse has been extensively studied in terms of biochemistry and physiology, few detailed behavioral studies examining the development of these animals exist. This mutation results in deficiencies in cerebellar Purkinje, granule, and Bergmann glia cells, as well as a dopamine deficiency due to cell loss in the substantia nigra. Behavioral symptomology includes ataxia, tremors and poor limb coordination. We have examined the ontogeny of grooming in this neurological mutant mouse. Studies have documented that rodents perform a stereotypic, highly structured set of movements during grooming. Any deviation from this set of movements may indicate an effect of the weaver mutation. Double recessive and littermate control pups were videotaped (30 fps) in a warmed container at 2 day intervals from the 3rd to the 21st postnatal day. We report data obtained from frame-by-frame analysis of videotapes, including number and mean duration of grooming bouts and amount of time spent grooming. In addition, the PEAK Motion Measurement System was used to analyze trajectories, accelerations, velocities and angles used to analyze trajectories, accelerations, velocities and angles of limb movements. Mutant animals displayed larger numbers of short duration bouts and in general spent less time grooming. The two groups also displayed differences in the general style of grooming. These observed differences between mutant and littermate controls indicate behavioral manifestations of the weaver mutation. (Supported by MRC grant MA7660 to J.C.F.).

The role of the striatum in organizing complex behaviors as revealed by play in neonatally 6-OHDA depleted rats. Sergio M. Pellis, Ian Q. Whishaw, Mario M. McKenna and Eddie Castañeda. Dept. Psychology, Univ. Lethbridge, Lethbridge, AB T1K 3M4 and Dept. Psychology, Arizona State Univ., Tempe, AZ 85287.

What is the role of the striatum in complex actions? If decorticated

neonatally juvenile rats can still perform complex sequences of playful behavior as juveniles, suggesting that both the behavioral elements and their sequencing are organized subcortically. Other complex behavioral sequences, such as grooming, have been shown to depend upon the striatum. In this study, neonatal ventricular injections of 6-OHDA were used to disrupt the development of striatal mechanisms. Although juvenile 6-OHDA rats are smaller in size, probably reflecting impairments in feeding, they appeared relatively normal in their exploratory and locomotor behaviors. Play, however, was severely impaired. All the behavioral elements were present and indeed were more frequent, but they were not correctly sequenced. For example, playful nape contact was more likely to lead to allogrooming or mounting and thrusting, rather than the leaping away of intact rats. That is, immediate stimuli were more likely to redirect their behavior away from completing the play sequence. These findings support the hypothesis that striatal mechanisms are involved in the organization of complex sequences of behavior.

MARKED FALL IN EXTRANEURONAL DOPAMINE DURING BEHAVIORAL DESPAIR IN RATS. Z.L., Rossetti\*, Y., Hmaidan, M. Lai and G.L., Gessa. Dept. of Neuroscience, Univ. of Cagliari, 09124 Cagliari, Italy.

Accumulating evidence indicates that abstinence from drugs of abuse is

accompanied by a marked inhibition of dopamine (DA) output in the mesolimbic system. Given the role of mesolimbic DA in reward mechanisms, the suppression of DA release has been hypothesized to constitute a common neurochemical correlate for the anhedonic and depressive state associated with abstinence syndromes. Prolonged, inescapable stress is also known to result in an anhedonic and depressive state. To study the effect of inescapable stress on DA neurotransmission, we measured by microdialysis the changes in extraneuronal DA concentrations in the ventral striatum of rats exposed to the forced swimming test ("behavioral despair test"). Rats were forced to swim into plexiglas cylinders containing water at 22-24 °C. Perfusate DA concentration was measured at time intervals during the test (1 hr) and 4 hr thereafter. Body temperature was monitored through a rectal catheter. Exposing the animals to the test resulted in a dramatic fall in extraneuronal DA to about 20% of pre-exposure (baseline) values. When animals were returned to their home cages DA output progressively returned to baseline values in about 4 hr. Manipulation of water level and temperature ruled out possible hypothermic effects on DA release. Furthermore, chronic treatment with the antidepressant imipramine (20 mg/kg/day for 3 weeks) significantly reduced (-40%) both the magnitude and the duration of the inhibition of DA output. These results support the hypothesis that an inhibition of DA release may constitute a neurochemical correlate for anhedonic and depressive states.

UNILATERAL LESION IN BARREL CORTEX INDUCES ASYMMETRIES IN BEHAVIOR AND NIGROSTRIATAL DOPAMINE: CORTICAL INTERACTION WITH BASAL GANGLIA F.S. Adams, R.K.W. Schwarting, J.A. Nagel\*, J.P. Huston Inst. Physiol. Psychol. I, Univ. of Düsseldorf, Germany

Previous experiments from our laboratory have shown time-dependent lateralized changes in behavior and nigrostriatal anatomy and neurochemistry following unilateral removal of the mystacial vibrissae of rats. The present experiment investigated the time-dependent effects of unilateral radiofrequency lesion of the cortical barrel fields in light of these results. We measured lateralized changes in behavior as well as the tissue content of dopamine and serotonin plus their metabolites, in neostriatum and substantia nigra, between 1 and 16 days post-lesion. Asymmetries in exploratory behavior (thigmotactic scanning) and neostriatal metabolite/serotonin ratios that lasted from 4 to 7 days were seen. In substantia nigra, time-related asymmetries in dopamine concentrations were found with higher ipsilateral values on day 3 and higher contralateral values on day 6. On day 6, the animals had recovered from these acute effects, and thereafter, neostriatal metabolite/dopamine ratios became asymmetrical. Also after day 6, an ipsiversive bias in spontaneous and apomorphine-induced turning was seen. Finally, neostriatal serotonin was bilaterally elevated on day 16. These results parallel some of the effects previously seen following unilateral removal of the vibrissae, indicating that functional interaction between the vibrissae and basal ganglia is routed via cortico-striatal connections.

DEVELOPMENT OF ALTERED D1-D2 RECEPTOR INTERACTIONS FOLLOWING DA DEPLETIONS IN NEONATAL RATS. E.McCone and J.P.Bruno\*. Neuroscience Program and Dept. of Psychology, Ohio State Univ., Columbus, OH 43210

Our recent data suggest that the normal ability of selective dopamine (DA) D1 or D2 antagonists to block behavior induced by the converse agonist is lost in adults depleted of DA as neonates. The present study determined the emergence of these altered receptor interactions as a function of time after the DA depletion. Rats received either 6-OHDA (100  $\mu$ g) or its vehicle on postnatal Day 3 and were tested on postnatal Day 10. The D1 agonist SKF 38393 induced sniffing, grooming, licking, and modest locomotion whereas the D2 agonist quinpirole induced sniffing, mouthing, and locomotion. These profiles were similar in vehicle- and 6-OHDAtreated pups. Unexpectedly, vehicle- and 6-OHDA-treated animals also looked similar with respect to the ability of antagonists to block these effects. Only the D1 antagonist SCH 23390 blocked the SKF 38393-induced behaviors whereas only the D2 antagonist clebopride blocked the quinpirole-induced behaviors. These results suggest that the effect of the neonatal DA depletion may be to preserve an earlier developmental form of D1-D2 receptor interaction rather than to induce a new one

#### 368.2

SKF 82958, A SELECTIVE DOPAMINE  $D_1$  AGONIST, POTENTLY INDUCES ROTATION IN 6-OHDA-LESIONED RATS.

J.D. Belluzzi\*, P. Sheth and S. Pham, Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

Our current understanding of the relative involvement of dopamine D<sub>1</sub> receptor activation in motor control is based heavily on the use of the prototypical D<sub>1</sub> agonist, SKF 38393. While quite selective for the D<sub>1</sub> receptor, its behavioral actions often appear weak, suggesting a minor role for  $D_1$  receptors. However, SKF 38393 is only 45% efficacious and it poorly penetrates the blood brain barrier. The purpose of this study was to evaluate the effects of a fully efficacious D<sub>1</sub> agonist SKF 82958 on rotation in rats with unilateral 6-OHDA lesions. Net contralateral rotations were recorded every 5 min during a 60-min test period. SKF 82958 (0.01-1.0 \(\mu\)mol/kg, s.c.) induced vigorous rotation which was completely antagonized by pretreatment with the D<sub>1</sub> antagonist SCH 23390 (0.3 mg/kg), but only partially antagonized by pretreatment with the D, antagonist eticlopride (0.1 mg/kg). SKF 38393 had no effect in the same dose range (0.1-1.0 \(\mu\text{mol/kg}\), but did induce rotations at 17.1 \(\mu\text{mol/kg}\). At this high dose, pretreatement with SCH 23390 completely suppressed rotations, whereas pretreatment with eticlopride had no effect. agonist quinpirole (0.033-3.3 \(\mu\text{mol/kg}\)) induced turning behavior that was completely antagonized by eticlopride. However, SCH 23390, at a dose that completely antagonized SKF 82958, only partially blocked the effects of quinpirole. These results indicate that a full D, agonist potently induces rotation, and that both D<sub>1</sub> and D<sub>2</sub> dopamine receptors play an important role in motor performance.

# 368.4

D1 AND D2 RECEPTOR MEDIATION OF MOTOR BEHAVIOR IS ALTERED FOLLOWING DOPAMINE DEPLETIONS IN NEONATAL BUT NOT IN WEANLING RATS. D.Abrams E.McCone. and J.P.Bruno. Neuroscience Program & Dept. of Psychology, Ohio State Univ.,Columbus, OH 43210

Coactivation of D1 and D2 dopamine (DA) receptors appears necessary for the expression of certain motor behaviors in normal rats. This can be illustrated by the ability of a DA antagonist (i.e. D1) to block the behavioral effects of the counter DA agonist (i.e. D2). Our previous data indicate that D1 and D2 receptors can mediate motor behavior independently in adult rats depleted of DA as neonates. This study focused on the ability of DA antagonists to block agonist-induced locomotion and stereotypy in adult rats treated with 6-OHDA (100 µg) or its vehicle on postnatal Day 3 or 20. The D2 agonist quinpirole produced low levels of stereotypy and locomotion in all 3 groups. In vehicles and rats depleted on Day 20, these effects were blocked by either the D1 antagonist SCH 23390 or the D2 antagonist clebopride. However, in rats depleted on Day 3, these effects could only be blocked by clebopride. The D1 agonist SKF 38393 produced no obvious motor effects in controls or in rats depleted of DA on Day 20. This drug produced a moderate stereotypy and locomotion in rats depleted on Day 3. These effects were fully blocked by SCH 23390 but not by clebopride. Thus, the D1-D2 mediation of motor behavior is qualitatively changed following DA depletions during early but not later stages of development.

# 368.6

D1 AND D2 RECEPTOR-MEDIATION OF STRIATAL ACETYLCHOLINE RELEASE IN RATS DEPLETED OF DOPAMINE AS NEONATES. <u>B.Johnson\* and J.P.Bruno.</u> Dept. of Psychology and Neurosci. Program, Ohio State Univ., Columbus, OH 43210

We have reported that the D1 and D2 receptor-mediation of sensorimotor behavior is qualitatively changed in adult rats depleted of dopamine (DA) as neonates. Activation of either D1 or D2 receptors is sufficient for the expression of normal behavior in rats depleted as neonates, whereas coactivation of both receptor subtypes is necessary for these behaviors in intact animals. Given that striatal DA and acetylcholine (ACh) interactions are necessary for normal sensorimotor behavior, we compared the effect of D1 and D2 receptor ligands on striatal ACh release in adults treated with 6-OHDA (100  $\mu$ g) or its vehicle on postnatal Day 3. Striatal ACh efflux was determined in freely moving animals using in vivo microdialysis. We unexpectedly found that the D1 and D2 mediation of striatal ACh release was similar in controls and rats depleted of DA as neonates. Systemic administration of D1 receptor agonists or D2 receptor antagonists stimulated ACh release, whereas D2 receptor agonists or D1 receptor antagonists inhibited release. These in vivo release data are in marked contrast to the behavioral data and suggest that the compensations underlying the sparing from deficits in rats depleted of DA as neonates are not at the level of striatal ACh neurons.

MICRODIALYSIS OF STRIATAL DOPAMINE IN FREELY MOVING RATS: EFFECTS OF COCAINE AND COCAINE METHIODIDE. I.A. Ivens, P.H. Janak, S.B. Rodriguez\*, and J.L. Martinez, Jr. Dep. of Psychology, UC Berkeley, Berkeley CA 94720.

The effect of peripherally and centrally administered cocaine on striatal dopamine levels was investigated. Microdialysis probes were implanted in the caudate nucleus and microdialysis was performed in freely moving rats. Cocaine (5.5, 7.5, and 15.0 mg/kg IP) produced a dose-dependent increase in extracellular dopamine concentrations, while cocaine methiodide (19.6 mg/kg IP, equimolar to the 15.0 mg/kg dose of cocaine), a cocaine analog with limited ability to cross the blood-brain barrier, was without effect on central dopamine levels. Previous studies in rats indicated that 5.5 mg/kg IP of cocaine modulates both aversively- and appetitively-motivated conditioning, while an equimolar dose of cocaine methiodide is without effect. Dialysis of either cocaine (0.5 mg/ml cocaine in perfusate, 2 ul/min perfused) or cocaine methiodide (in equimolar concentration) directly into the caudate nucleus produced a marked elevation of dopamine levels. Thus changes in striatal dopamine levels could be associated with the changes in conditioned performance produced by peripherally administered cocaine, and cocaine methiodide's inability to alter conditioning may be associated with its failure to cross the blood-brain

INDIVIDUAL DIFFERENCES IN DOPAMINE BUT NOT SEROTONIN RECEPTORS ARE RELATED TO THE LOCOMOTOR RESPONSE TO NOVELTY. M. S. Hooks,\* J. L. Juncos, and J. B. Justice, Jr., Departments of Chemistry and Neurology, Emory University, Atlanta GA, 30322.

High (HR) and low (LR) locomotor responding rats to a novel environment show differences in their vulnerability to drugs of abuse. In the current experiments, the nucleus accumbens (NACC), striatum (STR), and the medial frontal cortex (MFC) were removed 7-10 days after subjects were screened for novelty response. Both the density and affinity were determined for the dopamine uptake sites (DA-UP), D₁ receptors, D₂ receptors, serotonin uptake sites (SHT-UP), SHT₂ receptors, and SHT₁A receptors with in vitro radioactive ligand binding in tissue homogenates. The B<sub>max</sub> (fmol/mg protein) and Kp (nM) were determined from 3-6 pooled tissue homogenates run in duplicate using 9 concentrations of radioactive ligand.

There were fewer D₂ binding sites in HR rats in both the NACC (B<sub>max</sub> = 268±26, p < 0.05) and STR (B<sub>max</sub> = 412±42, p < 0.005) than in LR rats (B<sub>max</sub> = 548±49 and 711±62 the NACC and STR, respectively). HR rats (B<sub>max</sub> = 780±27) showed a greater (p < 0.05) number of D₁ inding sites in the NACC (B<sub>max</sub> = 260±27) showed a greater number (p < 0.05) of DA-UP binding sites in the NACC than LR rats (B<sub>max</sub> = 883±41). However, HR rats (B<sub>max</sub> = 2301±113) had a lower number (p < 0.05) of DA-UP sites in the STR than LR rats (B<sub>max</sub> = 2771±114). No differences in B<sub>max</sub> for any of the dopamine receptors were observed in the MFC between HR and LR rats in the NACC than LR rats (B<sub>max</sub> = 700±25). There were no differences between HR and LR rats in affinity for any of the dopaminergic receptors were observed in the STR than LR rats (B<sub>max</sub> = 7771±114). No differences in M<sub>max</sub> for any of the dopaminergic receptors were observed in the STR than LR rats (B<sub>max</sub> = 700±25). There were no differences between HR and LR rats in the NACC than the regions examined. Furthermore, there did no

A BEHAVIORAL ANALYSIS OF D1 and D2 RECEPTOR SYSTEMS. L.D. Middaugh,\* B.P. Jackson, and G.D. Gentry. Dept. of Psychiatry, Medical University of South Carolina, Charleston, S.C. 29452

D1 and D2 receptor function was assessed by determining the discriminability of specific D1 (SKF-38393) and D2 (quinpirole) agonists and by determining their effects on motor activity of naive and habituated C57 mice. The mice learned to discriminate both of the agonists in an operant drug discrimination paradigm. D1 receptor activation appeared to be necessary for discrimination of the D1 agonist since its discriminative stimuli did not generalize to those of a D2 agonist, and its discrimination was blocked by a D1 antagonist. The D2 agonist produced a mono-tonic reduction in motor activity of nonhabitu-ated mice relative to vehicle levels. The D1 agonist at low doses reduced the activity of non-habituated mice relative to vehicle levels; however, activity increased with increasing dose. nowever, activity increased with increasing dose. Activity levels of habituated and nonhabituated mice injected with the D1 agonist were similar. Because vehicle injected habituated mice were less active than nonhabituated mice, the D1 agonist elevated or reduced activity relative to basal activity levels of habituated and nonhabituated with the constitution. uated mice, respectively. (Supported by AA06611)

EVIDENCE FOR DOPAMINE-DEPENDENT REHAVIORS IN MICE WITH LOW DENSITIES OF STRIATAL DOPAMINE RECEPTORS. E.Tirelli\* and J.M.Witkin. Psychobiology Laboratory, NIDA Addiction Research Center, P.O. Box 5180, Baltimore, MD, 21224-5180. Several reports indicate that DBA/2 mice may have a lower density of

striatal dopamine (DA) receptors than C57Bl/6 mice and are unresponsive to postsynaptic DA agonists (e.g. apomorphine, APO). To evaluate whether this apparent insensivity is due to a peculiar expression of postsynaptic DA activity, we studied simultaneously several behaviors (full climbing, leaning against the wall, gnawing). Mice were tested in wire mesh cages and their behaviors scored using a time-sampling technique. We compared the effects of APO, and its modulation by cocaine (COC), in DBA/2 and C57BI/6 mice. C57 mice showed a dose-dependent increase in APO-induced climbing, and little leaning. DBA mice however, showed sustained leaning, and only at a high dose of APO some climbing. Both strains showed strong gnawing, though DBA mice were less responsive at low doses. COC potentiated APO-induced climbing and gnawing at high APO doses in DBA and at all doses in C57 mice. APO-induced leaning was not substantially changed by COC in either strains. In addition, the potency of APO in inducing convulsions and lethality (at very high doses) were comparable in both strains. Thus, although showing a different drug potency for APO-induced climbing, DBA mice still respond behaviorally to APO, but in an idiosyncratic way.

368.10

THE EFFECTS OF THE DOPAMINE D2 AGONIST, QUINPIROLE, ON MEMORY, FINE MOTOR PERFORMANCE AND "HALLUCINATORY-LIKE" BEHAVIOR IN RHESUS MONKEYS. A.F.T. Arnsten\* and P.S. Goldman-Rakig. Section of Neuropiology, Yale Medical School, 333 Cedar St., New Haven, CT 06510-8001.

Chronic, high dose amphetamine use can cause hallucinations in humans and "hallucinatory-like" behavior (HLB) in monkeys. These abnormal behaviors in monkeys include swatting and other organized responses to what appear to be imaginary or nonexistent objects. In the current study, monkeys were injected with the D2 agonist, quinpirole (0.0001-1.0 mg/kg), and tested on a working memory task, spatial delayed response, and a fine motor task; in separate experiments they were rated for behavioral changes in their home cage. An acute, high dose of quinpirole was found to produce HLB in young and aged monkeys; middle-aged monkeys required higher dose (1.0 mg/kg) treatment than younger or aged monkeys (about 0.05 mg/kg). Other behavioral changes included vacuous chewing, fear grimacing and agitation. Fine motor performance was impaired at the highest and lowest doses but not in the middle dose range; the low dose effect could result from preferential actions at presynaptic receptors.

Unexpectedly, delayed response performance was unchanged or actually improved by high doses which induced HLB. As D1 stimulation has been implicated in cognitive enhancement but not in HLB, it is possible that the D2 family of receptors underlies the generation of HLB. Receptor mechanisms are currently being investigated. Furthermore, preserved delayed response performance in monkeys exhibiting HLB suggests that the prefrontal cortical circuits necessary for working memory may not play a central role in HLB.

# 368.12

ACUTE ADMINISTRATION OF HALOPERIDOL AND RESERPINE INCREASES VACUOUS JAW MOVEMENTS IN YOUNG AND AGED RATS. R.E. Steinpreis\* and J. D. Salamone. Psychology Dept., Univ. of Connecticut, Storrs, CT 06269-1020.

An experiment was conducted to examine the effects of two neuroleptics, haloperidol (HP) and reserpine (RES), on vacuous jaw movements in rats at three different age levels. Rats were given a single IP injection of either vehicle (VEH), 0.4 mg/kg HP, or 5.0 mg/kg RES. The age groups included young (3 mos), middle aged (6-9 mos) and aged (12-15 mos) rats. ANOVA revealed a significant elevation of vacuous jaw movements with increasing age. There was also a significant effect of drug treatment, with both HP and RES producing significant increases in vacuous jaw movements. The age x drug interaction was not significant, indicating that the combined effects of age and neuroleptic drugs were additive under the conditions tested. These results demonstrate the acute interference with dopamine systems by receptor blockade or terminal depletion can increase vacuous jaw movements. In addition, the present study indicates that age is an important variable in the production of vacuous jaw movements.

Variations in the Behavioral Responses Produced by Apomorphine in Different Strains of Rats. W. D. Essman\*, P. McGonigle and I. Lucki. Depts. of Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA, 19104.

Experiments in inbred strains of rats and mice have suggested

potential genetic contributions to the behavioral responses produced by drug administration. Dopamine systems associated with mechanisms of reward have provided one focus for these experiments in an attempt to identify genetic factors related to drug abuse. The present experiments compare the behavioral responses produced by the direct dopamine receptor agonist apomorphine (APO) in five inbred strains of rats; Brown Norway (BN), Lewis (LEW), Fisher (F-344), Buffalo (BUF) and DA. Examination of locomotor activity during repeated acclimation sessions and activity and stereotypy elicited by APO revealed strain-specific patterns of behavior. BN rats were most resistant to acclimation. Low doses of APO (0.1 and 0.32 mg/kg) produced a flat body posture in LEW animals which was generally not observed in the other strains. A higher dose of APO (1.0 mg/kg) markedly increased activity in F-344 rats compared to the other four strains. BUF animals showed licking during saline sessions, and also demonstrated the greatest increase in gnawing at higher doses of APO. DA rats were generally less responsive to the behavioral effects of APO. Autoradiographic analyses of dopamine receptors in the five strains of rats revealed region-specific differences in the density of D1 receptors labelled by 3H-SCH 23390 and D2/D3 receptors labelled by 125I-NCO 298 in the caudate-putamen and nucleus accumbens. The results from these studies are discussed in terms of the neurochemical basis for differences in APO behavioral responses between strains. Supported by USPHS grant GM34781.

COMPARISON OF DOPAMINE RELATED BEHAVIORS AND DOPAMINE RECEPTORS IN MESOCORTICOLIMBIC REGIONS OF C57BL AND DBA MICE. <u>D.E. Womer, V.G. Erwin\* and A.D. Campbell</u>. School of Pharmacy, University of Colorado Health Sciences Center, 4200 E. 9th Ave., Denver CO, 80262.

School of Pharmacy, University of Colorado Health Sciences Center, 4200 E. 9th Ave., Denver CO, 80262.

Previous studies have shown that C57BL/6lbg (C57) and DBA/2lbg (DBA) mice differ in cocaine and ethanol induced behaviors, e.g. locomotor activity and stereotypy. The present studies were undertaken to further characterize these strain differences in cocaine and ethanol related motor activities. Locomotor activation and stereotypy were more pronounced in DBA than C57 mice after administration of 15 mg/kg cocaine or 1.5 g/kg ethanol. The selective D2 antagonist, epidepride (.03 mg/kg), greatly attenuated cocaine and ethanol induced motor behaviors of DBA mice, but not of C57 mice. Dopamine receptors (D1 and D2) and the uptake transporter were characterized in specific brain regions of C57 and DBA strains. Values for KD or Bmax for the D1 receptor labelled with the antagonist, [3H]SCH 23390, were similar in C57 and DBA brain membranes. In the companies of the c

PROFILE OF BEHAVIOURAL CHANGES DURING THE COURSE OF CHRONIC TREATMENT WITH D-2 AGONIST QUINPIROLE. D. Eilam\*, H. Talangbayan, H. Dai, G. Canaran and H. Szechtman. Dept. Biomedical Sciences, McMaster Univ, Hamilton, Ont. CANADA L8N 3Z5.

This report extends our initial observation that chronic treatment with quinpirole produces profound sensitization of activity with compulsive and rigid locomotion along few paths, confined to a small region of a large open field [1,2]. The number of rats tested has been increased to 22 and the number of repeated quinpirole administrations to as many as 90. A separate group of animals (N=18) received an equivalent number of drug administrations in their home cage but were not tested in the open field (160 x 160 cm) until the final test day. Results indicate that the most profound sensitization of activity in the open field is produced when treatment with quinpirole is administered in the test environment.

Moreover, the profile of response to quinpirole appears related to the animal's baseline reaction to the open field. (Supported by MRC. DE is an Allon Fellow and HS is a Research Associate of the Ontario Mental Health Foundation).

ENVIRONMENTAL ENRICHMENT ALTERS THE BEHAVIORAL RESPONSE TO AMPHETAMINE BUT NOT TO ELECTRICALLY-EVOKED DOPAMINE RELEASE. S.L. Bowling, J.K. Rowlett, M. Bradley, L.P. Dwoskin & M.T. Bardo\*, Dept. Psychology & Coll. Pharmacy, University of Kentucky, Lexington, KY 40506.

Psychology & Coll. Pharmacy, University of Kentucky, Lexington, KY 40506.

Rats were raised from 21 days of age in either an enriched condition (EC) or isolated condition (IC). At age 50 days, locomotor activity and conditioned place preference (CPP) were assessed following amphetamine (0, 0.1, 0.3, or 1.0 mg/kg). Separate groups of EC and IC rats were also used to examine electrically-evoked release of dopamine in vitro in the presence of the D2 agonist pergolide. Only EC rats showed significant CPP. EC rats also showed a greater locomotor responsiveness to amphetamine than IC rats. In a separate experiment, amphetamine pre-exposure abolished these behavioral differences between EC and IC rats. The neurochemical results revealed no significant differences between EC and IC rats in dopamine release within the nucleus accumbens or striatum, suggesting that the altered behavioral response to amphetamine does not reflect a change in stores of dopamine which are releasable by electrical stimulation. (Supported by USPHS grant DA05312).

THE EFFECTS OF SEPARATE AND COMBINED ADMINISTRATION OF

THE EFFECTS OF SEPARATE AND COMBINED ADMINISTRATION OF DOPAMINE D-1 AND D-2 AGONISTS ON KEY-PECKING IN THE DEVELOPING CHICK. J. M. Dose and J. F. Zolman. Physiology and Biophysics, Univ. of Kentucky, College of Medicine, Lexington, KY 40536.

In rodents, stimulation of either the dopamine D-1 or D-2 receptor elicit receptor-specific behavioral profiles yet these receptors are often functionally coupled (see Clark & White, Synapse, 1, 1987). A coactivation effect of these two dopamine receptors has also been reported in 7-day and older chicks (Zarrindast & Amin, Psychopharmacology, 106, 1992). We have studied the ontogeny of this functional coupling using the developing chick. One- and 4-day-old chicks of two different strains were rewarded with heat in a key-peck autoshape task of 24 discrete trials. Twenty minutes prior to testing, reserpine pretreated (5mg/kg, sc, 18 hr prior) chicks were given ip injections of either distilled water, 10mg/kg SKF 38393, 2mg/kg quinpirole, or a combined dose of SKF 38393 and quinpirole. Chicks of both ages responded on more trials when given the combined administration of both drugs compared with chicks given either distilled water or single drug injections. Hence, functional coupling D-1 and D-2 receptors is evident within 1-day after hatching. This coactivation effect was found in both strains of chicks indicating that the effect is not strain specific.

RATS SENSITIZED TO D-2 AGONIST QUINPIROLE SHOW PERSEVERATION IN A SPATIAL LEARNING TASK. H. Einat and H. Szechtman\*. Dept. Biomedical Sciences, McMaster Univ, Hamilton, Ont. Canada L8N 3Z5.

The present study examines whether behavioral sensitization induced by quinpirole produces longterm changes in undrugged behavior. Rats received 10 injections of quinpirole (0.5 mg/kg; N=12) or saline (N=12) spaced at 4 day intervals, in Omnitech activity cages. Quinpirole induced a 4-6 fold increase in various measures of locomotion and rearing. Following the sensitization phase, both groups of rats were trained on a spatial learning task in the Morris water maze, without the injection of any drugs. During acquisition, sensitized animals showed better retention from training day 1 to day 2, but both groups performed equally well by the 3rd day of training. During extinction, sensitized rats stayed significantly longer in the (empty) training quadrant. This perseveration in spatial bias continued even into the initial trials of reversal learning. These results suggest that the process of sensitization to quinpirole has longterm consequences for undrugged behavior

368.19
DISCRIMINATIVE STIMULUS PROPERTIES OF THE D<sub>1</sub> DOPAMINE AGONIST, DIHYDREXIDINE. Q.D. Walker\*1, M.H. Lewis<sup>1,2,3,\*</sup> A.M. Perkins³, D.A. Eckerman³, D.E. Nichols⁵ and R.B. Mailman¹, 2,4. Curr. in Tox¹, Depts. of Psychiatry², Psychology³ and Pharmacol⁴. UNC, Chapel Hill 27599, NC and Dept. of Mcd. Chem., Purdue University⁵, West Lafayette, IN 47907
Dihydrexidine (trans-10,11-dihydroxy-5,6,6a,7,8,12b-hexahydrobenzo-[a]phenanthridine) is a high potency full efficacy D<sub>1</sub> dopamine agonist with some D<sub>2</sub> affinity (10-fold less than D<sub>1</sub>). Because dihydrexidine (DHX) is a useful neuropharmacological probe, as well as a potential antiparkinsonian drug, we have studied its actions in vivo using the drug discrimination paradigm. The hypotheses tested were that DHX would function as a discriminable stimulus, and that the cue would be mediated specifically by D, receptor stimulation. Using a two-lever milk would be mediated specifically by D<sub>1</sub> receptor stimulation. Using a two-lever milk reinforced operant task (FR20), rats were trained to discriminate 2.0 mg/kg DHX (15 minutes prior to testing, se) from its vehicle. Rats acquired this discrimination in an average of 67 test sessions. The training dose engendered 98% drug lever responding. Substitution of 0.5 and 1.0 mg/kg in animals trained to 2.0 mg/kg produced only 10 and 55% drug appropriate responding, respectively. The time course of substitution of the training dose indicated that rats selected the vehicle lever 2.5 and 240 min of the training dose indicated that rats selected the vehicle lever 2.5 and 240 min after dosing, but the drug lever 5-120 min after dosing. The receptors involved in this cue were investigated by administering dopamine antagonists. All rats pretreated with the  $D_1$  antagonist SCH23390 (5  $\mu g/kg$ , sc) responded exclusively on the vehicle appropriate lever in the first trial, with only a 10% decrease in response rate. Conversely, the  $D_2$  antagonist removipride (0.2 or 0.45 mg/kg, sc) did not attenuate DHX lever selection (>80% DHX responding), and decreased response rates 30%. Agonist substitution experiments demonstrated that only high doses of the mixed agonist apmorphine (50  $\mu g/kg$ , sc) produced partial (60%) generalization. Initial observations suggest that 8.0 mg/kg SKF 38393 (a partial  $D_1$  agonist) substitutes completely, and that the selective  $D_3/D_2$  agonist, quinpirole, does not substitute for DHX. Together these data indicate that DHX produces a robust interoceptive cue mediated selectively by  $D_1$  receptor stimulation. Animals trained to recognize DHX in this behavioral paradigm will be used to study functional interactions of dopamine receptor subtypes and to identify other  $D_1$  agonists.

INTRACEREBRAL INJECTIONS OF THE FULL EFFICACY D, AGONIST DIHYDREXIDINE: BEHAVIORAL EFFECTS IN THE RAT. T. I. Schmitt<sup>1</sup>, S. B. Southerland<sup>2</sup>, R.B. Mailman<sup>1,2,3,4,4</sup> D.E. Nichols<sup>5</sup>, and M. H. Lewis<sup>1,2,3</sup> Toxicology Curriculum<sup>1</sup>, Brain and Development Research Center<sup>2</sup>, Departments of

Toxicology Curriculum', Brain and Development Research Center', Departments of Psychiatry<sup>3</sup> and Pharmacology,<sup>4</sup>, University of North Carolina, Chapel Hill, NC, 27599 and School of Pharmacy<sup>5</sup>, Purdue University, West Lafayette, IN, 47907. Dihydrexidine (DHX) has been characterized as a potent, full efficacy D<sub>1</sub> agonist that has a ten-fold selectivity for D<sub>1</sub> vs. D<sub>2</sub> binding sites. We recently reported significant increases in grooming, locomotion and sniffing in rats systemically injected with DHX. The purpose of the present study was to identify specific brain regions important in the mediation of these DHX-induced behaviors. Male Sprague-Dawley rats had cannulae implanted stereotaxically in the caudate nucleus or nucleus occurbers and were allowed to recover at least earner days are in Associated. accumbens, and were allowed to recover at least seven days prior to behavioral testing. DHX was intracerebrally injected (1.0, 3.0, and 10.0 µg). Discrete behavioral topographics (e.g., rearing, grooming, locomotion, etc.) were quantified by direct observation. The frequency of grooming was increased by 1 and 3  $\mu$ g DHX in both brain regions, with a decline toward control values observed at the highest dose. DHX significantly increased vacuous chewing at all doses when injected into the nucleus accumbens, but had no effect when injected into caudate nucleus. The nucleus accumbens, but had no effect when injected into caudate nucleus. The frequency of locomotion was significantly increased by all three doses of DHX in the caudate nucleus, whereas in the nucleus accumbens, locomotion was not increased at any dose. Sniffing behavior was not significantly different from control values in either brain region, at any of the DHX doses tested. Particularly when injected into the nucleus accumbens, DHX was observed to induce a marked hyperreactivity to both auditory and tactile stimuli, despite extensive pre- and post-operative handling. These data provide new information concerning the functional roles of select populations of dopamine receptors in the mediation of behavior, and suggest an important role for D<sub>1</sub> receptors in mediating reactivity. (Supported, in part, by PHS Grants MH40537 and MH42705).

# HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR I

INFLUENCE OF VOMERONASAL ORGAN ON LORDOSIS AND LUTEINIZING HORMONE-RELEASING NEURONAL SYSTEM IN FEMALE RATS. G. HORMONE Dept. Physiol., Univ. Rajendren\*, C.A. Dudley and R.L. Moss. Dept. 1 Texas Southwestern Med. Ctr., Dallas, TX 75235-9040.

The vomeronasal system influences reproduction in mammals. the present experiments the role of the vomeronasal organ (VNO) in mediating the effects of conspecific males on lordosis behavior and on the luteinizing hormone-releasing hormone (LHRH) neuronal Ovariectomized rats were system in female rats was studied. Ovariectomized rats were subjected to VNO removal (VNX) (n=5) or sham (VN-Sham) surgery Forty eight hours after estrogen priming, the females were subjected to repeated mating (15 min mating followed by 15 min resting) for 180 min. For each female, the increase in lordosis quotient (LQ) was calculated by subtracting LQ during the first test (0-15 min) from that of the last test (150-165 min). At 180 min, the brains were fixed and were double labelled for Fos protein and LHRH. LHRH neurons with or without Fos immunoreactivity were counted in sections obtained from a block of brain encompassing AP bregma +0.2 mm through bregma -0.8 mm (cf. Paxinos and Watson, 1986). The enhancement of lordosis following repeated mating was significantly reduced in the VNX females as compared with the controls (p=0.006). Similarly, the proportion of LHRH neurons controls (p=0.000). Similarly, the proportion of Linkin leurons exhibiting Fos-like immunoreactivity was significantly lower in the VNX females than in the VN-Sham controls (p=0.049). There was a significant positive correlation between LQ and the proportion of Fos positive LHRH neurons (r=0.859; p<0.01). The present results demonstrate a close link between lordosis behavior and the accessory olfactory-LHRH systems in rats. Supported by MH41784.

HIPPOCAMPAL ELECTRICAL ACTIVITY IN THE FEMALE RAT: THE ESTROUS CYCLE, COPULATION, PARTURITION, AND PUP RETRIEVAL. L.A. Mead and C.H. Vanderwolf. Dept. of Psychology, University of Western Ontario, London, Ontario, CANADA N6A 5C2.

Hippocampal electrical activity was examined in female rats across the four phases

e estrous cycle, as well as during copulation, parturition, and pup retrieval. Possible hormonal effects on hippocampal activity were examined by recording daily during struggling and immobility throughout five estrous cycles. No differences in the characteristics of rhythmical slow activity (RSA), large-amplitude irregular activity (LIA), or their relation to behavior were found between the phases of the estrous cycle.

Behaviors examined during copulation were lordosis, hopping, and ear wiggling. Lordosis and ear wiggling were both accompanied by irregular waves, with some low frequency RSA also present during lordosis. Hopping was accompanied by RSA which was higher in amplitude and frequency than RSA during walking. Pre-parturition behaviors examined included body extensions, genital or pup licking, and body flattening". Body extensions were found to be associated with irregular activity, and appeared to be a Type 2 behavior. Interestingly, sudden suppress of the hippocampal record lasting 1-5 s often preceded body extensions. Irregular hippocampal activity was present at all times during genital and pup licking. Body flattening was typically accompanied by very high amplitude irregular waves although the rats were awake, resembled a sleeping hippocampal pattern. Pup retrieval involved walking and was thus always accompanied by RSA.

These experiments provide additional information on the relationship between hippocampal activity and behavior in rats by documenting the hippocampal electrical activity accompanying several exclusively female conditions and behaviors.

PROGESTERONE - OXYTOCIN INTERACTIONS: BEHAVIOR AND PHYSIOLOGY. D. S. Janowsky\*, J. D. Caldwell, J. M. Johns, and C.A. Pedersen; BDRC & Dept. of Psychiatry, School of Medicine, Univ. of North Carolina, Chapel Hill, NC 27599-7250

Oxylocin (OXT) and progesterone (P) interact at several levels to achieve sexual receptivity. We have found that infusions of the OXT antagonist PM-OXT into the medial preoptic area (MPOA) of rats immediately before injection of 500  $\mu$ g P (4 hr before testing) results in increased frequency and duration of punch/kicks and vocalizations. Giving PM-OXT immediately before testing also increased rejection behaviors such as punch/kicks, vocalizations and mounts without lordosis. Microdialysis found that while estrogen pretreatment increased OXT release in surges in the MPOA, peripheral injection of  $500\,\mu g$  P initially suppressed these surges but resulted in a larger peak of OXT recovered about four hours after P injection. Recoveries of OXT using push-pull cannulas found that P linked to albumin (P-BSA) when perfused through the MPOA-AH, VMH or near the PVN significantly increased OXT recoveries (levels increasing from 1-3 pg/ $\mu$ l to 40-50 pg/ $\mu$ l over a 50  $\mu$ l collection). OXT recoveries increase immediately and return to basal levels for subsequent perfusions, indicating an immediate and transient effect of P-BSA. Push-pull perfusions with equimolar BSA had no effect on OXT recoveries. Since P-BSA is not believed to penetrate the cell membrane, it appears that P releases OXT by an extracellular mechanism. Such an effect might explain the ability of P to increase OXT receptor number in the MPOA and move OXT receptors in the VMH as well as its ability to augment the capacity of OXT to facilitate female sexual receptivity.

5,7-DHT INFUSIONS INTO THE MEDIAL HYPOTHALAMUS FACILITATE LORDOSIS IN PREWEANLING RATS. G. S. Benedict\*and C. L. Williams. Departments of Psychology, Columbia University and Barnard College, New York, NY 10027.

During the first week of life, lordosis and ear wiggling are

displayed by both male and female rats without need for prior hormone priming (Williams, <u>Behav. Neurosci.</u>, 1987). Work from our lab has shown that lordosis and ear wiggling become sexually dimorphic and more dependent on ovarian hormones for elicitation by postnatal days (PD) 10-18. Defeminization ultimately results from the presence or absence of perinatal testicular androgen, although behavioral consequences are not manifested until one week later perhaps following the maturation of inhibitory neural system(s). Serotonergic innervation of the ventromedial hypothalamus (VMH), Serotonergic innervation of the ventromedial hypothalamus (νικιτη, established by PD 9 (Ugrumov et al., Dev. Brain Res., 1983), may contribute to this developing suppression. We infused 5 μg of the neurotoxin 5,7-dihydroxytryptamine (5,7-DHT) into a site dorsolateral to the VMH of 9-day-old male and female Sprague-Dawley rats and tested them for lordosis 10 days later. Although 5,7-MB and the state of th Dawley rats and tested them for lordosis 10 days later. Although 5,7-DHT did not alter ear wiggling frequencies, the infusion significantly increased lordosis frequencies of both males and females even without hormone priming. Furthermore, females generally displayed lordosis more frequently than males, and priming with estradiol benzoate (1 or 100 µg) and progesterone (0.5 mg) increased lordosis and ear wiggling frequencies of males and females. The behavioral data suggest that sentences of ference to the VMH may behavioral data suggest that serotonergic afferents to the VMH may contribute to the defeminization and hormonal dependence of

30-OH-DHP AND 50-THDOC IMPLANTS TO THE VTA FACILITATE SEXUAL RECEPTIVITY IN HAMSTERS AFTER PROGESTERONE PRIMING TO THE VMH. C.A. Frye and J.F. DeBold\*. Psychology Department, Tufts University, Medford, MA 02155.

Progesterone (P) stimulation to both the ventral medial hypothalamus (VMH) and the ventral tegmental area (VTA) is necessary to facilitate sexual receptivity in the female hamster, in spite of the sparse population of estrogen (E) induced P receptors found in the VTA. Recently we have found that P may act instead at neuronal membranes in the VTA. These P effects may be mediated by progestin actions on the GABA<sub>A</sub>-benzodiazepine receptor complex (GBR). Many progesting metabolites have a greater effect on benzodiazepine binding and Cl flux than P. If P's actions are due to metabolism to a progestin more potent at the GBR, then applying one of those progestin metabolites directly to the VTA should facilitate receptivity, if coupled with P to the VMH. Similarly, progestin metabolites with eater effectiveness on GBR might have an enhanced effect on behavior, independent of affinity for the P receptor.

To test this hypothesis three P metabolites, in decreasing order of activity at the o test this hypothesis time e r metabolities, in decreasing order of activity at the GBR, were tested: 5α-pregnane-3α-α, 21-diol-20-one (5α-THDOC) and 5β-pregnane-3α, 21-diol-20-one (5α-THDOC) and 5β-pregnane-3α, 21-diol-20-one (5β-THDOC). Ovariectomized hamsters were implanted with chronic cannula, one aimed about the VMH and the other over the contralateral VTA. Animals were E primed and tested for sexual receptivity 4 hours after a P containing insert was applied to the VMH and a progestin containing insert was applied to the VTA. The following week the contents of the tubes were reversed. Facilitation of receptivity occurred week the coments of the tubes were reversed. Facilitation of receipting occurred only when P was applied to the VMH and either P or a metabolite was applied to the VTA. The reversed treatment was not effective. The progestin metabolites in order of behavioral effectiveness were: 3α-OH-DHP, 5α-THDOC, 5β-THDOC, this rank order is consistent with efficacy at the GABA A-benzodiazepine receptor

SEPTAL REGION AND PARAVENTRICULAR NUCLEUS: TWO NEURO-ANATOMICAL SUBSTRATES CONTROLLING MATERNAL BEHAVIOUR IN

SHEEP. A.Da Costa, K.Broad, R.Guevara and K.M.Kendrick Dept Neurobiology, AFRC, IAPGR, Babraham, Cambridge CB2 4AT, UK; UNAM In order to identify the neuroanatomical substrates involved in controlling the induction of maternal behaviour in sheep, and the formation of the selective ewe/lamb bond, the changes in the expression of the immediate early gene, c-fos, were mapped. In addition, in vivo neurochemical changes were monitored, using microdialysis, in two areas found to express high levels of c-fos expression during the induction of maternal behaviour and the formation of the selective bond.

Changes in the expression of c-fos mRNA in the brains of Clun Forest ewes were investigated using in situ hybridization histochemistry using a specific <sup>35</sup>S labelled, 45 mer oligonucleotide probe. High levels of expression were found in both the

septal region(SR) and paraventricular nucleus(PVN) in maternal but not control ewes.

Microdialysis sampling used CMA microdialysis probes (Sweden, CMA-10) inserted into 18 gauge guide tubes which were surgically implanted (under halothane anaesthesia) in the skull over the septal region and PVN. Ringer was pumped through these probes at 5µl/min using battery driven syringe pumps attached to the animal's backs and samples collected at 5 min intervals during parturition.

Aspartate, glutamate and GABA concentrations were measured by HPLC with fluorescence detection. In the SR, aspartate, glutamate and GABA increased around parturition and a second peak of release occured at around 2h post-partum whereas in the PVN, these neurotransmitters showed identical increases around parturition but

only glutamate demonstrated a second peak of release at around 2h post-partum.

The results suggest that the increase in the neurotransmitters measured around parturition may be related with the induction of maternal behaviour whereas the increase at around 2h post-partum may be related with the formation of the selective olfactory memory between the ewe and its lamb.

This work was in part financed by JNICT, Portugal.

SEXUAL BEHAVIOR OF MALE RATS IS AFFECTED BY CELL BODY LESIONS OF THE VENTRAL PREMAMMILLARY NUCLEUS. S.G. Truitt, C. Ulibarri, and T. R. Akesson. Dept of Vet & Comp Anatomy, Pharmacology, & Physiology, Washington State Univ, Pullman, WA 99164.

Through its afferent and efferent connections, the ventral premammillary nucleus (PMv) interacts with more-extensively studied nuclei that make up a system that controls sexual behavior. The nucleus accumulates some estrogen, but mainly androgen; it contains cells that produce peptides that are known to influence sexual behavior; and although the size of the nucleus is similar in males and females, there is a sexually dimorphic density of neurons immunoreactive for substance P. Taken together, these findings suggested to us that the PMv may have a role in the regulation of sexual behavior.

Castrated, testosterone-supplemented adult male Sprague-Dawley rats were tested with ovariectomized estrogen- and progesterone-primed receptive female rats through two ejaculations to establish baseline sexual behavior. Bilateral cell body lesions were generated by infusing ibotenic acid into the PMv in one group of rats (n = 13). The control group (n = 11) received sham surgeries using only vehicle infusate. Behavior testing was repeated every 4 days following surgery for 4 test periods. Post-testing, lesions placement was verified histologically. Data were analyzed using univariate ANOVA for a block design with repeated measures with a 2 x 2 factorial treatment.

In rats that received bilateral lesions of the PMv, mount number and intromission number increased and intromission latency and ejaculation latency increased as compared to control rats. There were no significant differences in mount latency, postejaculatory interval, copulatory rate, or copulatory efficiency between treatment and control groups. Thus the PMv may be important in the completion of copulatory behavior. Supported by HD22869 (TRA) and BSN9112097 (CU).

OPIATE RECEPTOR BLOCKADE ENHANCES THE DISPLAY OF PROGESTERONE-FACILITATED LORDOSIS IN JUVENILE FEMALE GUINEA

OPIATE RECEPTOR BLOCKADE ENHANCES THE DISPLAY OF PROGESTERONS-FACILITATED LORDOSIS IN JUVENILE FEMALE GUINFA PIGS. D.H. Olster\*. Department of Psychology, University of California, Santa Barbara, CA 93106.

In adult female guinea pigs, administration of morphine, an exogenous opiate, inhibits the display of steroid-induced lordosis; however, treatment with naloxone, an opiate receptor antagonist, does not facilitate receptivity, suggesting the absence of tonic inhibition of lordosis by endogenous opiate peptides in adult females (Nock and Cicero, 1991). In contrast to adults, juvenile female guinea pigs are not behaviorally responsive to estradiol and progesterone (Olster and Blaustein, 1989). In light of the reported opiate effects in adults, the present study was designed to test the hypothesis that endogenous opiates tonically inhibit the display of steroid-induced lordosis in juvenile females. Hartley guinea pigs were ovariectomized at 9-10 days of age and treated with estradiol benzoate (EB, 10 µg) at 15 days of age. Approximately 40 hours later, animals received naloxone (2 mg/kg) or vehicle, or progesterone (P, 0.5 mg). The EB+P-treated females then received naloxone (2 mg/kg) or vehicle 4.5 h after the P injection. None of the animals which received naloxone or vehicle 40 h after EB displayed lordosis (n=6/group). Among the groups that received EB and P, 73% displayed lordosis following naloxone treatment, while only 23% were sexually receptive following vehicle injection (P < 0.05, n=11-13/group). These data suggest that endogenous opiates do tonically inhibit the display of progesterone-facilitated lordosis in juvenile female guinea pigs and are consistent with the theory that pubertal maturation may include a release from endogenous opiate inhibition of steroid-induced sexual behavior. (Supported by NIH HD 23483.)

NEURONS LOCATED IN THE LATERAL HABENULA MEDIATE THE HORMONAL OWSET OF MATERNAL BEHAVIOR IN RATS. K.P. Corodimas, J.S. Rosenblatt, M.E.Canfield and J.I. Morrell. Rutgers University, Institute of Animal Behavior, Newark, NJ 07102.

Previously we demonstrated that radiofrequency lesions of the entire habenular complex made on day 12 of pregnancy severely disrupted the hormonal onset of maternal behavior (MB). This study explored the importance of neurons in the lateral habenula (Lhb) for the onset of MB. On day 12 of pregnancy bilateral axon-sparing lesions were produced by injecting kainic acid (1.0ug) into the Lhb, or as a control, just dorsal in the medial hippocampus. Animals were hysterectomized-ovariectomized and given 20ug/kg estradiol benzoate on day 16 of pregnancy, then tested 48h later with pups for MB. Following 10d of behavioral testing, the retrograde tracer Fluoro-Gold (FG) (0.2ul) was injected into the ventral midbrain (where many Lhb and medial habenula (Mhb) neurons project). FG labeling demonstrated that Lhb cells were lesioned, whereas Mhb cells were intact. We are examining the number of FG labeled neurons in limbic areas that project through the Mhb to verify intact axons-of-passage. Complete Lhb lesions (>95% cell loss) severely disrupted all components of MB without any recovery. Activity and body weight changes were similar between groups. These results suggest that Lhb neurons are important for the onset of MB. (HD22893 to JIM)

# 369.10

EPIGENETIC FACTORS IN PERSISTENT MATING BY CASTRATED MICE. A. <u>Coquelin</u>\*. Dept. of Cell Biology & Anatomy, Texas Tech

University Health Sciences Center, Lubbock, Texas 79430. Sexual activity of male mice ordinarily depends on the presence of their testes, yet B6D2F1 hybrid males may perform the entire copulatory sequence indefinitely after castration. Two experiments examined whether sexual experience or presence of the testes during puberty is experience or presence of the testes during puberty is required for persistent mating by B6D2F1 males. In the first, sexually naive males (n=14) were castrated at 2.5 months of age; behavioral testing began 5 months later. The males were tested 3 times at weekly intervals, then they cohabited with 3 different, mature females for 5 days apiece, and finally they were tested 3 more times. Half the males mounted, 29% intromitted, and 14% "ejaculated" before combalitation; 64% mounted, 50% intromitted, and 29% "ejaculated" afterwards. In the second experiment, juvenile males were castrated or received sham surgeries at 1 month of age, before their pubertal rise of androgens (n=10 per group). At 3 months of age the males cohabited with 3 females as above. Subsequent behavioral tests revealed no sexual activity in the castrated males, whereas all the intact males mounted and intromitted, 80% ejaculated. Together these results demonstrate that sexual experience prior to castration is unnecessary but the testes must be present during pubertal maturation for B6D2F1 males to initiate or maintain copulation. (Supported by NSF BNS-9104425.)

**BEHAVIORAL RESPONSES TO ANABOLIC STEROIDS.**A. S. Clark\* and D. M. Barber. Dept. of Psychology, Dartmouth College, Hanover, NH 03755

Anabolic steroids are synthetic compounds which are often taken in massive quantities by athletes with the intention of enhancing muscular appearance and/or physical strength. Although it has been speculated that these compounds have significant neurobehavioral effects, few studies have systematically examined the influence of anabolic steroids on the brain or behavior. The present studies focus on the impact of anabolic steroids on reproductive behavior and aggression.

Sexual behavior was tested weekly in castrated adult male rats

Sexual behavior was tested weekly in castrated adult male rats receiving daily injections of anabolic steroids or vehicle. Testosterone cypionate and methyltestosterone were as effective in maintaining male sexual behavior after castration as testosterone propionate. Treatment with either stanozolol or fluoxymesterone was ineffective in maintaining male sexual behavior in castrated males. Intermale aggression was assessed in anabolic steroid-treated and control, castrated male rats which were housed with intact female rats. Aggressive responses of the resident male to "intruder" male rats were examined weekly for 3 weeks. Rats treated with methyltestosterone and testosterone propionate had elevated levels of intermale aggression relative to controls. In contrast, stanozolol treatment failed to stimulate intermale aggression. Variations in the chemical structure, metabolic fate and/or neural receptor potency of anabolic steroids may account for their distinct behavioral profiles. Supported by NS 9109687 and the Hitchcock Foundation.

ALTERATION OF SNB MOTONEURON SOMA SIZE AFTER TWO WEEKS OF ANDROGEN TREATMENT. Barbara A. Padgett, Louise M. Freeman and S. M. Breedlove,\* Depts. of Neurobiology and Psychology, Univ. California, Berkeley, CA 94720.

Androgen treatment increases soma sizes of motoneurons in the rat spinal nucleus of the bulbocavernosus (SNB). A decrease in soma size has been demonstrated in males four weeks after castration. We examined whether such an effect can be seen as early as two weeks following castration. We castrated adult male rats and subcutaneously implanted either blank or testosterone propionate (TP) filled Silastic capsules, which were left in place for two weeks. Animals were overdosed and perfused with saline and buffered formalin. Spinal cords were cross-sectioned at 50  $\mu$ m and stained with thionin. At least 25 SNB cells were drawn from each animal using a camera lucida and computer digitizing tablet. As expected, the difference in cross-sectional soma area between the two groups was smaller than has been reported after four weeks, but still marginally significant (p<.05, one tailed). The TP treated animals' cells had a mean area of 1509.1 ± 55.2  $\mu \text{m}^2$  (SEM, N=8), while the cells of the animals with blank capsules had a mean of 1388.9  $\pm$  32.6  $\mu \text{m}^2$  (N=7). These results demonstrate that an androgen regimen as short as two weeks can alter SNB soma size.

ABSENCE OF MORPHOLOGICAL CHANGES IN PERINEAL MOTONEURONS WITH INTRATHECAL TESTOSTERONE. L.M. Freeman\*, E.P. Monaghan, J.W. Hershey & S.M. Breedlove, Psychology Department, Univ. California, Berkeley, CA 94720.

Motoneurons of the spinal nucleus of the bulbocavernosus (SNB) mediate "cup-like" erections in the male rat, while the motoneurons of the dorsolateral nucleus (DLN) mediate penile lips. Castration eliminates penile reflexes and also causes shrinkage of SNB cells. Last year we reported that testosterone (T) administered (14.4  $\mu$ g/day, 2 weeks) to the lumbosacral spinal cord via osmotic minipumps attached to intrathecal catheters (ITT) maintained low levels of penile flips in castrated adult rats. However, giving the same dose of hormone peripherally in combination with intrathecal vehicle (ITveh) was equally effective in maintaining the reflexes. We measured soma size of both SNB and DLN cells of the rats in the behavioral study to see if cell morphology was influenced by the hormone treatment. Cross-sectional soma areas are given in  $\mu$ m<sup>2</sup>  $\pm$  SEM.

ITT (n=7) ITveh (n=6) GNX (n=5) SNB 1050±55 1001±41 1104±41 DLN 751±39 724±40 731±47

There were no significant differences between the treatment groups. This suggests that either T does not act in the spinal cord to alter motoneuron size or that we failed to provide sufficient localized T treatment. Supported by NIH #NS28421 and an NSF predoctoral fellowship.

# 369.14

ULTRASTRUCTURAL CHANGES IN GNRH CELLS AS A FUNCTION OF AGE AND OVARIECTOMY. M.-T. Romero\*, A.-J. Silverman. P. Wise1.and J.W. Witkin. Dept of Anat. & Cell Biol., Columbia University, New York, N.Y. 10032.. 1Dept. of Physiology, U. of Maryland, Baltimore, MD 21201

Synaptic input to GnRH perikarya is significantly increased with age in virgin male rats (Witkin, Neurosci. 22: 1003, 1987). We addressed the question of whether similar changes occur in female rats and whether ovariectomy (ovx) had any added effects. Virgin female rats aged 3 (young) or 20 (old) months were divided into 4 groups: 1. Young intact, 2. Young short term ovx (4 weeks), 3. Old short term ovx, and 4. Old long term ovx (9 months). Coronal sections of preoptic area were immunostained for GnRH and subsequently processed for electron microscopy. Total plasma membrane length and that percent of membrane with synaptic modifications were quantified using a morphometric program. The volume fraction of various organelles was estimated by point counting. Preliminary data indicate that synaptic input to the soma of GnRH cells does not change significantly as a function of age or gonadal steroid milieu. The volume of rough endoplasmic reticulum (RER) was significantly decreased in young females following ovx and in old females after long term ovx (Mann-Whitney U, p<.01). This later finding may indicate a general decline in protein synthesis. However, short term ovx of old females had no effect on the volume of RER when compared to young intact females. A group of old intact females is presently under study to determine whether the differences observed are due to steroid hormonal milieu or to age. Supported by \$T32AG00189 and AG05366

GONADAL STEROIDS REGULATE IMMUNOREACTIVE TACHYKININ IN THE VENTROMEDIAL NUCLEUS OF THE FEMALE BUT NOT THE MALE RAT. T.R. Akesson\*. Dept of VCAPP. Wash State Univ. Pullman. WA.

MALE RAT. T.R. Akesson\*. Dept of VCAPP, Wash State Univ., Pullman, WA. Tachykinin-immunoreactive (TACir) neurons are found in all subdivisions of the ventromedial nucleus of the hypothalamus and in the ventrolateral subdivision (VMHvI), many of them concentrate estrogen. A substance P-specific projection to the midbrain periaqueductal gray may represent a component of circuitry essential to lordosis since injections in the periaqueductal gray facilitate this behavior. SP injections in the preoptic area (POA) facilitate male sexual behavior and the POA is filled with TACir fibers, however, the VMH and its connection with the POA is not considered to be an important participant in circuitry mediating male sexual behavior.

| Sex      | N | Treatment #                  | # TACir cells in the VMHv |
|----------|---|------------------------------|---------------------------|
| ♂        | 5 | Intact                       | 1174 ± 45                 |
| ਰਾ       | 4 | Castrate - 3 wk              | 1139 ± 39                 |
| ş        | 5 | Ovex - 2 wk                  | 1079 ± 28                 |
| <b>Q</b> | 4 | Ovex - single injection of l | EB 1334 ± 83              |
| 0        | 4 | Over - E concule 2 mk        | 1557 + 62                 |

Significant differences in numbers of tachykinin immunoreactive cells were found in the VMHvI such that: \*cap > \*tinj > \sigma\_v\*\*. \*Tachykinin cells in the anterior 1/3 of the VMH, as well as the central and medial subdivisions of the posterior 2/3 did not respond to changes in steroid levels. In the posterior ½ of the VMH (VMHp), staining intensity of TACir fibers varied with treatment. In intact males, castrated males, and ovex females, fibers were lightly stained. In ovex-injection rats they were moderately intense, and in ovex-capsule females, they formed a darkly stained plexus. Thus TACir cells in the VMHvI and fibers in the VMHp respond to gonadal steriods in a sexually differentiated manor. Supported by HD22869.

SEX STEROID REGULATION OF PEPTIDERGIC TRANSMISSION IN THE FEMALE RAT. T. Smock\*. S. Amold. P. Emerson. K. Burrows. J. Garrilano. C. Sanson. W. Derber, and D. Albeck. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

The medial amygdala modifies the output of the hippocampus using a peptide transmitter similar to vasopressin and oxytodin in structure (Brain Res., 1990, 511.7 and 15). The synthesis of the peptide is steroid-dependent and the system probably plays a role in the generation of sexual behavior in males. The function of the system in females is unclear. Here we report our preliminary studies of the peptidergic network in female rats.

The strength of the peptidergic signal in the hippocampus was measured

The strength of the peptidergic signal in the hippocampus was measured with field potential recording techniques in six males and six females. No difference in signal strength could be detected between the genders. Then 25 males and 22 females were castrated and the intensity of the signal evaluated in groups of 3 to 7 individuals at 3-week intervals. The signal remained strong in males for 6 weeks and then declined quickly, approaching zero at 15 weeks. The signal in females remained strong for 3 weeks and then declined towards zero at 15 weeks. Estradiol replacement (for females) and testosterone replacement (for males) restored the signal to the baseline condition.

The estrous cycle of rats is only four days long. The fact that total removal of gonadal steroids has no effect until after 3 weeks strongly suggests that steroid fluctuations during the estrus cycle should have no impact on the peptidergic transmission. We tested this by recording the signal in 37 females and subsequently determining stage of estrus with vaginal smears. No difference was found between the proestrus, estrus, metestrus and diestrus conditions. Thus, physiological investigation of the system in females can proceed without concern for stage of estrus.

SITE SPECIFIC EFFECTS OF NEUROKININS ON MALE RAT COPULATORY BEHAVIOR. Krista Vink, William M. Struthers, Christopher Barrett, and Wayne A Dornan'. Dept. of Psychology, Illinois University, Bloomington, IL 61701.

In this study, a four part experiment was done. Experiment 1a was conducted in an attempt to replicate the neurokinin K (NKK) induced inhibition of male copulatory behavior following bilateral injections into the Medial Preoptic Area (MPOA) observed previously in this lab. In experiment 1b, the effects of another neurokinin, neurokinin y (NKy), on male copulatory behavior was assessed. Experiment 1c examined the question of whether the effects observed previously are specific to the MPOA by assessing the effects of bilateral injections of NKK into the Caudate Putamen (CP) and Bed Nucleus of the Stria Terminalis. Lastly, in order to ascertain whether the effects on male copulatory behavior were mediated via a neurokinin receptor (NK-2), animals were pre-treated with a selective NK-2 antagonist ([Try<sup>5</sup>, D-Trp<sup>6,8,9</sup>, Arg<sup>10</sup>]-Neurokinin A (4-10)) followed by bilateral injections of saline, NKy, or NKK into the MPOA (experiment 1d). In support of a previous study, our results indicated that bilateral injections of NKK inhibited the expression of male copulatory behavior when compared to injections of saline (p < 0.001). In contrast, bilateral injections of NKy failed to effect the expression of male copulatory behavior of sexually vigorous male rats when compared to control injections. Bilateral injections of NKy did, however, produce marked increases in intromission and mount latencies, although only intromission latencies were statistically significant. No other parameter of male copulatory behavior was affected. Injections of NKK into the CP failed to affect male copulatory behavior. Injections of NK-2 receptor antagonist failed to block the effect of injections of NKK into the MPOA, while antagonist injections were successful in blocking effects of NKy

MATING BEHAVIOR AND AGGRESSION RESULT IN A DIFFERENTIAL PATTERN OF FOS INDUCTION IN THE MALE SYRIAN HAMSTER BRAIN. S.S. Kollack\* and S.W. Newman. Department of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109-0616.

Mating behavior results in a selective pattern of fos expression within the medial nucleus of the amygdala (Me), the bed nucleus of the stria terminalis (BNST), and the medial preoptic area (MPOA) (Soc. Neurosci. Abstr., 17: 1059). The specificity of the mating-induced pattern of fos expression was determined by comparing fos induction after mating behavior with fos induction comparing fos induction after mating behavior with fos induction after aggressive behavior. Both of these behaviors are dependent upon chemosensory cues and gonadal steroids. Adult male hamsters were divided into three groups: (1) 10 min mating, (2) 10 min aggression against a male intruder, and (3) isolated controls. All hamsters were perfused with 4% paraformaldehyde; brains were cut into 40 um sections and immunostained for fos protein (Ab-2; Oncogene Sciences). Fos expression was increased within Me and posteromedial BNST in males following mating behavior or aggression, relative to isolated males. In contrast, only mated hamsters showed increased fos immunostaining in medial preoptic nucleus (MPN) and magnocellular MPN. These data demonstrate that two social behaviors, both dependent upon chemosensory cues and gonadal steroids, result in distinctly different patterns of neuronal activation. (Supported by NIH NS 20629 to SWN) comparing fos induction after mating behavior with fos induction

INDUCTION OF FOS-IMMUNOREACTIVITY IN THE BRAIN FOLLOWING MATING IN FEMALE RATS. M.J. Tetel\*, D.C. Celentano and J.D. Blaustein, Neurosci. and Behav. Program, Univ. of Massachusetts, Amherst, MA 01003.

To determine the neuroanatomical areas which respond to mating, we visualized Fos-immunoreactivity (Fos-IR) in three groups of ovariectomized, estradiol and progesterone-treated rats: 1) "Mated" animals were mated with three males, consecutively, for a total of 30-36 intromissions, 2) "AIM-exposed" were exposed to an anesthetized, intact male and 3) "Home Cage" remained in their cage and were not exposed to males or the testing arena.

Mating resulted in a dramatic increase in Fos-IR cells in the medial preoptic area, bed nucleus of the stria terminalis, posterodorsal medial amygdaloid nucleus and midbrain central gray within 1 hour of exposure to the males when compared with AIM-exposed and Home Cage animals. There were no differences between AIM-exposed and Home Cage groups, suggesting no effect in these areas of stimuli associated with exposure to an anesthetized, intact male. In an estrogen-receptor rich area ventrolateral to the ventromedial nucleus of the hypothalamus, AIM-exposed animals had an increase in Fos-IR cells when contrasted with Home Cage animals, while mating did not potentiate this effect. Although Fos-IR cells were observed in some other areas, such as the lateral habenular nucleus, no consistent differences among the three groups were detected.

All the areas discussed above, which respond to mating stimuli, contain estrogen-sensitive neurons as well. Thus, this technique may allow investigation of the possible integration among somatosensory and hormonal factors involved in female sexual behavior.

LESIONS OF THE ACCESSORY OLFACTORY BULB (AOB) REDUCE LORDOTIC RESPONSIVENESS AND DECREASE C-FOS IMMUNOREACTIVITY IN THE ACCESSORY OLFACTORY SYSTEM (AOS) OF FEMALE RATS. R.L. Moss, C.A. Dudley, and R.N. Rosenberg\*, Depts. Physiology and Neurology, UT Southwestern Med. Ctr., Dallas TX 75235-9040

The gradual increase in the lordosis-to-mount (L/M) ratio observed in ovariectomized (OVX), estrogen(E)-primed female rats as a consequence of repetitive mating is thought to be partially due to pheromonal cues processed through the AOS. Repetitive matinginduced increases in L/M can be blunted by removal of the romeronasal organ (Rajendren et al., 1990) and are associated with induction of fos-like immunoreactivity (fosIR) in several AOS sites (Dudley et al., 1992). The present study examined the contribution of the AOB to these effects. OVX, E-primed rats were repeatedly mated before and 10 and 20 days after AOB lesion or SHAM surgery. At 10 days post-surgery, the L/M scores in both groups were significantly lower than their pre-surgery values. By 20 days, lordotic responsiveness in SHAM animals had returned to pre-surgery levels while the L/M ratios in AOB-lesioned animals remained significantly depressed. Some SHAMS and AOB-lesioned rats underwent a third mating test 2 to 3 months after surgery. Immediately after 3 hr of repetitive mating, they were sacrificed and their brains were processed for fosIR. The number of fosIR neurons in several AOS structures was significantly higher in SHAM animals than in AOB lesioned animals. The results suggest that the AOB contributes to increased lordotic responding observed during repetitive mating and that centrifugal projections of the AOB also participate. Supported by MH41784.

## 370.6

C-FOS PROTO-ONCOGENE ACTIVITY INCREASES IN THE AMYGDALA AND PREOPTIC AREA OF THE FEMALE RAT AFTER CERVICAL STIMULATION: ROLE OF AFFERENT INPUT VIA THE PELVIC NERVE. M.S. Erskine\* and D.W. Rowe. Department of Biology, Boston University, Boston, MA 02215

Cervical stimulation (CS) received during mating in the female rat is required for induction of the twice-daily prolactin (PRL) surges of early pregnancy. In order to identify brain areas which receive afferent genitosensory input and may be important for induction of PRL surges, we compared FOS immunoreactivity (FOS-IR) in brains of estrous females who received CS (15 intromissions from males, INTR) or mounts-withoutintromission (MNTS); these mating treatments induced PRL surges in 100% and 0%, respectively, of females in a separate experiment. Brain FOS-IR was also examined after bilateral pelvic n. transection in separate INTR and MNTS groups. Brains taken 1 hr after mating onset were cut and processed for FOS-IR. Darkly-stained FOS-positive cells were counted at 50X using a camera lucida. In intact animals, significantly greater numbers of FOS-IR cells were seen in the POA and AMYG of INTR animals than of MNTS animals. Pelvic n. transection completely eliminated the response to CS in these two areas, and FOS-IR levels in nerve-transected INTR and MNTS animals were similar to those seen in intact MNTS females. FOS-IR did not differ between groups in the paraventricular nucleus of the hypothalamus or in the central tegmental field/peripeduncular area. These data demonstrate that afferent input via the pelvic nerve activates cell groups within the POA and AMYG, and suggest that these areas may be involved in initiation of CS-induced PRL surges. (HD21802)

SIMILAR INCREMENTS IN LIMBIC AND PREOPTIC C-FOS IMMUNOREACTIVITY AFTER MATING IN MALE AND FEMALE RATS. S.R. Wersinger\*, M.J. Baum and M.S. Department of Biology, Boston University, Boston, MA 02215

Significant increments in FOS immunoreactivity (IR) are induced in the medial preoptic area (mPOA), medial amygdala (MA), bed nucleus of the stria terminalis (BNST), and midbrain central tegmental field (CTF) of male rats after mating (Baum and Everitt, 1992). We compared nuclear FOS-IR in these same brain regions from mated and unmated male and female rats in order to determine if this genetic response to mating is sexually dimorphic. Rats of both sexes were gonadectomized and treated with estradiol benzoate for 5 days followed by progesterone 4h prior to testing. Males and females were either placed alone in a testing chamber for 10 minutes or were paired until one ejaculation was observed. Animals were killed  $\hat{1}$  hour after the test ended. Significant, mating-induced increments in FOS-IR occurred in the mPOA, MA, BNST, and CTF of both sexes, suggesting that the neural processing of sensory stimuli (olfactory and genital/somatosensory) derived from mating is similar in male and female rats. (supported by HD21094; HD02971 and MH00392)

EQUIVALENT LEVELS OF MATING-INDUCED NEURAL C-FOS IMMUNOREACTIVITY IN CASTRATED MALE RATS GIVEN ANDROGEN, ESTROGEN, OR NO STEROID REPLACEMENT. M.J. Baum\*. S.R. Wersinger, and J.C. Alvarez. Dept. of Biology, Boston University, Boston, MA

Previous research (Baum & Everitt, 1992) showed that c-fos immunoreactivity is augmented in neurons of the medial preoptic area (mPOA), medial amygdala (MA), and midbrain central tegmental field (CTF) of male rats following mating. An experiment was conducted to determine whether circulating testosterone or either of its reduced or estrogenic neural metabolites play a role in this process. Equivalent numbers of FOS immunoreactive neurons were counted in the medial preoptic area, medial amygdala, and central tegmental field of sexually experienced, castrated male rats which were injected with either testosterone days propionate dihydrotestosterone propionate, estradiol benzoate, or vehicle and then were killed 1h after achieving 8 intromissions with an estrous female. Sex steroids appear to contribute little to the ability of sensory stimuli (olfactory and genital/somatosensory) associated with mating to promote c-fos expression in the male rat brain. (supported by HD21094 and MH00392)

FOS AND JUN EXPRESSION IN THE FEMALE RAT FOREBRAIN FOLLOWING HORMONE TREATMENT AND SEXUAL STIMULATION. J.G. Pfaus\*, S.P. Kleopoulos, C.V. Mobbs, R.B. Gibbs, & D.W. Pfaff, The Rockefeller University, New York, NY 10021.

Regions of the brain that concentrate estrogen and progesterone are thought to regulate feminine sexual behavior by altering gene expression and neural sensitivity to afferent stimulation. We used immunocytochemistry and in situ hybridization to examine the expression of Fos and Jun within estrogen-concentrating regions of the forebrain as a function of various types of sexual stimulation with or without hormone treatment. Ovariectomized rats (n=20) received injections of estradiol benzoate (10 µg) 48 hr and progesterone (500 µg) 4 hr before testing. Control rats (n=20) that had been ovariectomized at least 5 months before testing did not receive hormone treatment. Rats were then either placed into bilevel chambers with sexually vigorous males (n=5), received manual stimulation of the flanks (n=5), received vaginocervical stimulation with a glass rod (n=5), or were left in their home cages (n=5) for one hour prior to sacrifice. A dramatic induction of c-fos mRNA and Fos-like immunoreactivity (IR) was detected in estrogen-concentrating regions of the medial preoptic area, bed nucleus of the stria terminalis, ventromedial hypothalamus, and medial amygdala, as well as regions in the neocortex, lateral septum, paraventricular nucleus of the hypothalamus, and lateral habenula, following copulation with intromission and ejaculation in hormone-treated rats or stimulation of the vaginal cervix in both hormone-treated and control rats. Mechanical stimulation of the flanks produced a much smaller induction in these rats, whereas hormone treatment alone had no effect on Fos expression (consistent with Gibbs et al. (1991) Mol & Cell Neurosci, 1, 29). In contrast, Jun-like IR was detected in these regions but did not appear to be altered by sexual stimulation. These data demonstrate that afferent sensory sti

#### 370.10

EXPRESSION OF FOS PROTEIN IN PERIAQUEDUCTAL GRAY (PAG) NEURONS BY ELECTRICAL STIMULATION OF THE MEDIAL PREOPTIC ARRA (MPO). M.T. Shipley\*, T.A. Rizvi, M Jiang, M.N. Lehman and M Ennis. Dept. Anatomy, University of Cincinnati, College of Medicine, Cincinnati, OH 45267.

We have recently shown that MPO robustly innervates discrete, longtudinallyorganized columns running through the rostrocaudal axis of PAG (Rizvi et al., 92). The neurons targeted by these MPO inputs are unknown. Intense synaptic stimulation can induce the expression of the immediate early gene, c-fos, in activated target neurons. Thus, we used immunocytochemistry to map the distribution of PAG neurons that express FOS protein following stimulation of the MPO->PAG pathway.

Focal electrical stimulation (30 Hz; 5 sec on-3 sec off; 500 uA; 1 hr) of MPO in anesthetized male rats dramatically increased the number of PAG cells staining for FOS compared to sham controls. Neurons expressing FOS were organized into 2-3 longitudinal columns extending along the rostrocaudal axis of PAG. Columns of FOS+ cells corresponded remarkably well to the afferent terminal columns from MPO. Double labeling studies show that some FOS+ PAG neurons are immunopositive for estrogen receptors (Mab H222). Additional studies indicate that some FOS+ cells are retrogradely labeled by injections of Fluorogold in the ventral medulla (VM).

MPO, which is strongly modulated by olfactory stimuli, is critical to sexual behavior and neuroendocrine function. Activation of PAG induces analgesia, autonomic changes and the expression of specific sexual postures. The present results suggest that the MPO->PAG->VM circuit reported here, may coordinately regulate neuroendocrine, motor and autonomic components necessary to the elaboration of sexual behaviors. ## 370.12

MATERNAL BEHAVIOR IN FEMALE RATS IS ASSOCIATED WITH INCREASED NUMBERS OF FOS CONTAINING NEURONS IN THE MEDIAL PREOPTIC AREA. M. Numan\* and M.J. Numan. Dept. Psychology, Boston College, Chestnut Hill, MA 02167.

Lesion and hormone implant studies have suggested a central role for the medial preoptic area (MPOA) in the neural circuitry of maternal behavior. In this study we used Fos immunocytochemistry to support the view that MPOA neurons are activated during maternal behavior, and to localize the anatomical distribution of such neurons. behavioral method used took advantage of the fact that virgin female rats can be induced to show maternal behavior after several days of cohabitation with pups. Therefore, virgin female rats were exposed to pups on a daily basis until maternal behavior was displayed for 2 hr. Each of these maternally behaving females was yoked to a control female that was concurrently exposed to pups but had not yet displayed maternal behavior. Using standard immunocytochemical procedures it was found that the MPOA of maternal females had significantly more Fos labeled neurons than did the MPOA of control females. This difference was especially evident in the more lateral aspects of the MPOA. The Fos mapping procedure will also be used to uncover novel regions in the maternal behavior circuit. We are currently investigating the location of brainstem neurons that may be activated during maternal behavior.

# HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR III

TYROSINE HYDROXYLASE NEURONS IN THE MALE HAMSTER FOREBRAIN CONTAIN ANDROGEN RECEPTORS. S.E. Asmus and S.W. Newman, Dept. of Anatomy and Cell Biology, University of Michigan, Ann Arbor, MI 48109.

The male Syrian hamster relies on chemosensory and hormonal signals for mating. Chemosensory signals are relayed through the medial amygdaloid nucleus (Me), bed nucleus of the stria terminalis (BNST), and medial preoptic area (MPOA), regions that accumulate gonadal steroids. Neurons immunoreactive for tyrosine hydroxylase (TH-IR), a catecholamine biosynthetic enzyme, are located in Me (Brain Research 575:199-207), posteromedial BNST (BNSTpm) and the lateral part of caudal MPOA in colchicine-treated hamsters. The present study investigates whether TH-IR neurons in these areas also produce androgen receptors (AR). Colchicine-treated hamsters (n=3) were perfused with 4% paraformaldehyde, and the brains were cut at 40 um. Sections were processed for The male Syrian hamster relies on chemosensory and the brains were cut at 40 um. Sections were processed for immunocytochemistry using an AR antiserum (G.S. Prins) with NiCl<sub>2</sub>-intensified DAB and subsequently with a TH antibody (Incstar) visualized with unintensified DAB. Colocalization of TH and AR was most abundant in subdivisions of Me and BNST containing the highest number of steroid-concentrating neurons. In posterior Me and BNSTpm, approximately 80% of the TH-IR neurons contained AR-IR nuclei, whereas a smaller percentage of TH-IR neurons contained AR in anterior Me (30%) and MPOA (5%). (Supported by NIH NS 20629 to SWN)

RESTRICTION OF METABOLIC FUEL AVAILABILITY DECREASES ESTROGEN RECEPTOR-IMMUNOREACTIVITY IN VENTROMEDIAL HYPOTHALAMUS OF FEMALE SYRIAN HAMSTERS. H.-Y. Li\*and G. N. University of Massachusetts, Amherst, MA 01003.

Metabolic fuel availability is essential for initiation and maintenance of reproductive function in female Syrian hamsters. Decreased fuel availability induced by food restriction, metabolic inhibitors, or redirection of fuels into storage interests according to the control of the control

induced by food restriction, metabolic inhibitors, or redirection of fuels into storage interrupts estrous cycles. Steroid-induced lordosis is suppressed by 48h of food deprivation or treatment with metabolic inhibitors. The neuronal changes responsible for deprivation-induced suppression of estrous behavior are unknown, but a reduction in neural steroid binding is one possibility. Since ventromedial hypothalamus (VMH) is an important site of estradiol action on sexual behavior in female rodents, immunocytochemistry for estrogen receptor was used to examine the response of estrogen receptor-immunoreactive (ER-IR) cells in the VMH to

the response of estrogen receptor-immunoreactive (ER-IN) cells in the VMII to changes in the fuel supply.

We have developed an immunocytochemical technique to localize ER-IR cells in female Syrian hamster brain. ER-IR cells were found in the medial preoptic area, bed nucleus of the stria terminalis, amygdala, periventricular hypothalamus, paraventricular hypothalamus, VMII, and the arcuate area. ER-IR cells were also detected in the midbrain central gray and the nucleus of the solitary tract (NTS) in the hindbrain.

The number of ER-IR cells in the VMH was reduced following 48h of food The number of ER-IR cells in the VMH was reduced following 480 of tood deprivation or treatment with inhibitors of glucose and fatty acid oxidation compared to ad lib.-fed animals. However, no significant effect of these metabolic manipulations on ER-IR cells was observed in the NTS, which relays visceral information from the periphery to the central nervous system. These results are consistent with the hypothesis that metabolic fuel availability affects estrous behavior by altering VMH estrogen receptor content. (Supported by NS10873, DK32976, and MH00321)

DOWN-REGULATION OF ESTROGEN RECEPTOR-LIKE IMMUNOREACTIVITY IN THE FEMALE BRAZILIAN OPOSSUM BRAIN. P.L. Pearson, L.R. Ross, and C.D. Jacobson. Molecular, Cellular, and Developmental Biology Program & Dept. of Veterinary Anatomy, Iowa State University, Ames, IA 50011

Previous studies in this laboratory have described estrogen binding and estrogen receptor-like immunoreactivity (ER-LI) in the brain of the Brazilian opossum, Monodelphis domestica. This study focused on regulation of ER-LI by estrogen in the adult female opossum lateral septal This study focused on nucleus, ventral part (LSV); medial preoptic area (MPA); bed nucleus of stria terminalis, medial division (BSTM); and the medial amygdaloid nucleus (MeA). Female opossums were gonadectomized and two weeks later given subcutaneous silastic implants containing estradiol benzoate (EB) mixed with cholesterol (EB group), or cholesterol (control group). Another group contained intact female opossums in estrus (estrus group). Estrogen receptors (ER) were detected by an indirect immunohistochemical technique, using the H222 monoclonal antibody (a gift of Abbott Laboratories). Image analysis was used to quantify the percent area displaying ER-LI in each of the four brain regions. Prolonged EB treatment reduced ER-LI levels when compared to the control group. In addition, ER-LI was lower in the LSV, MPA, and MeA, in the EB group vs. the estrus group. In the estrus group, ER-LI was lower in the MPA and BSTM when compared to the control group. These results support a down-regulatory role of estrogen in relation to expression of ER. Also, these results indicate that ER may be differentially regulated in the brain, allowing for sensitive modulation of estrogen responsiveness

NEONATAL INTRACEREBRAL INFUSION OF ANTISENSE DNA TO

NEONATAL INTRACEREBRAL INFUSION OF ANTISENSE DNA TO ESTROGEN RECEPTOR MRNA ALTERS ESTROGEN-DEPENDENT PARAMETERS IN ADULT RATS. M.M. McCarthy', E. Schlenker and D.W. Ptaff, Rockefeller University, 1230 York Ave, New York, NY 10021 Androgen treatment of neonatal females produces masculinization via estrogen (E) derived from aromatized testosterone binding to neuronal Ereceptors, a process also necessary for masculization in males. Normal feminization also depends on gondal steroids. Therefore, we tested the hypothesis that hypothalamic E-receptor gene expression is involved in sexual differentiation. On day 3 of life, Sprague-Dawley pups were cold anesthesized before bilateral hypothalamic infusion (1µµ'side; 2µg DNA) with either antisense DNA (AS) spanning the translation start codon for the E-receptor, scrambled sequence control DNA (SC) or vehicle (VE; oil). Groups were females (FE), females androgenized with 50 µg TP (AND), and males (MA). Daily vaginal smears indicated trends toward disruption of estrous cyclicity in FE-AS, and a protection against persistent estrus in AND-AS, with ovaries significantly heavier in AND-AS females vs controls (pc.05). After ovariectomy and treatment with EB-P (10µg, 2 days, P 4 hr prior), 77% of AND-AS exhibited lordosis, vs. 23% and 15% for AND-SC and AND-VE (pc.05). Lordosis quotient also differed significantly (33.1% vs. 9.2% and 9.2% for controls, pc.05). Open field testing of EB-treated females (5µg 4.8 hrs prior) indicated a significant increase in # of crossings by FE-AS vs controls (pc.05). Intact males given three tests for sexual behavior on alternating days exhibited behavioral differences as a result of treatment. Mount latency was significantly greater and the mount to intromission ratio was significantly this pattern

exhibited behavioral differences as a result of treatment. Mount latency was significantly greater and the mount to intromission ratio was significantly less in MA-AS compared to the other two groups on the first test, with this pattern reversing by the third test so that MA-AS had a significantly shorter latency and higher mount to intromission ratio (pc.05). Preoptic area analyses showed total volume of the SDN/POA to be significantly smaller by 26% in AND-AS vs AND-SC and AND-VE (p<.05). Results from other groups and brain nuclei will be reported on.

# 371.7

MATING ACTIVATES ANDROGEN RECEPTOR-CONTAINING NEURONS IN THE BRAIN OF THE MALE SYRIAN HAMSTER. R.I. Wood\* and S.W. Newman. Reproductive Sciences Prog., Dep't of Anatomy & Cell Biology, Univ. of Michigan, Ann Arbor, MI 48109. Mating in the male Syrian hamster activates a specific population of neurons in the medial amygdaloid nucleus (Me), bed nucleus of the stria terminalis (BNST), and medial preoptic area (MPOA) as determined by the pattern of fos immunoreactivity (Soc Neurosci Abstr 17:1059, 1991). Fos-immunoreactive neurons are present in subnuclei that relay chemosensory information and contain receptors for gonadal steroid hormones, as determined by lesion studies and steroid autoradiography. Both hormonal and chemosensory stimuli are essential for copulation in the male hamster. The present study determined if neurons activated during mating behavior contain androgen receptors. Adult male hamsters (n=6) were allowed to mate with a sexually receptive female for 30 min. They were perfused one h later with 4% paraformaldehyde and 40 um frozen sections were processed for immunocytochemistry using antibodies against c-fos (Cambridge Research Biochemicals) and the androgen receptor (G.S. Prins). Three males were perfused as non-mated controls. Mating dramatically increased the number of fos immunoreactive neurons in Me, BNST, and MPOA relative to controls. These nuclei contain abundant androgen receptors, as determined by immuno-cytochemistry. A subpopulation of fos-immunoreactive neurons in each of these regions also contained androgen receptors. This suggests that chemosensory input or changing steroid concentrations during mating in the male hamster activate neurons that contain gonadal steroid hormone receptors. (Supported by NIH NS 20629 to SWN and HD 070514 to RIW)

EFFECTS OF HYPOTHALAMIC ADMINISTRATION OF ANTISENSE DNA FOR PROGESTERONE RECEPTOR MRNA ON LORDOSIS BEHAVIOR AND PROGESTERONE RECEPTOR IMMUNOREACTIVITY. Sonoko Ogawa\*, Ursula E. Olazábal & Donald W. Pfaff. University, New York, NY 10021. The Rockefeller

Reproductive behavior of female rats can be correlated with estrogen (E)-induced increase of progestin binding in hypothalamic neurons (Parsons & Pfaff, Current Topics in Neuroendo., 5:103, 1985). E increases progesterone receptor (PR) mRNA in the ventromedial nucleus (VMN) of hypothalamus of genetic females (Romano et al., Mol. Endo., 3:1295, 1989).
If PR mRNA increases help cause facilitation of reproductive behavior, then effective PR antisense sequences might decrease this behavior and PR effective PR artisense sequences might decrease this behavior and PR immunoreactivity. Antisense (AS) oligonucleotides (15 bases) were chosen to span the translation start site. Control (SC) oligomers were composed of the same nucleotide bases in scrambled order. For behavioral studies, E was injected s.c. at hour 0 to ovariectomized female rats implanted with bilateral cannulae directed at VMN; then AS or SC oligomers were microhjected at hour 12 or 24; finally progesterone (P) was given s.c. at hour 44, four hours before behavioral test. Antisense effects were specific as to time of administration and strongest for a specific P-dependent behavior. When given 12hr, but not 24hr after E, AS (vs. SC) significantly reduced fordosis behavior measured as a reflex (44% J. p.c.0.5) or in a behavior. When given 12hr, but not 24hr after E, AS (vs. SC) significantly reduced lordosis behavior measured as a reflex (44%), p<0.05) or in a mating behavior test (73%), p<0.01). Occurrence of proceptive behavior, known to be P-dependent, was greatly reduced (80%), p<0.01) by AS oligomers (vs. SC). For immunocytochemical studies, E was injected s.c. to ovariectomized female rats. 12hr later, AS oligomers were administered near VMN on one side of the brain, and the other side received SC or vehicle control. 48-50hr after E, PR-immunoreactive cells on AS side were decreased (27-42%), p<0.005). Interrupting gene expression for PR, a transcription factor, can have behavioral and immunocytochemical effects.

**DISTRIBUTION OF ANDROGEN RECEPTOR-LIKE** IMMUNOREACTIVITY IN THE BRAIN OF MALE SYRIAN HAMSTERS. D.C. WHITMAN, A.N. CLANCY, AND H.E. ALBERS. Lab. of Neuroendocrinol. & Behav., Depts. Biol. & Psychol., Georgia State Univ. Atlanta, Ga. 30303; Dept. of Psychiat., Emory Univ. School of Med., Atl., Ga. 30322.

The immunocytochemical distribution of androgen receptors (AR) was examined in male hamster brain using a rabbit poly-clonal anti-androgen receptor antibody raised against a fragment of the human AR (Affinity Bioreagents PA1-110) (Chang, et al, Endocrinol. 125, 1097, 1989). Coronal sections (40  $\mu$ M) from castrated and gonadally intact males were compared after processing by the peroxidaseavidin-biotin complex method. AR-like immunoreactivity (ARir) in both castrate and intact males was observed in the septum, bed nucleus of stria terminalis, amygdala, hippocampus, thalamus, preoptic area, and several hypothalamic nuclei including the paraventricular, supraoptic, and ventromedial nuclei. The distribution of AR-ir was found to be similar to the pattern of androgen binding previously reported with [H3] dihydrotestosterone autoradiography in male hamster brain (Doherty, & Sheridan, Brain Res. 219, 327, 1931). Supported by NSF BNS-8910863 and The Emory University Research Committee.

INCREASES IN ESTROGEN RECEPTOR mRNA IN THE MEDIAL PREOPTIC AREA OF THE MALE RAT FOLLOWING LONG-TERM CASTRATION. R.F. McGivern\*, M.R. Bollnow, J.A. O'Keefe, and R.J. Handa. Dept. of Cell Biology, Neurobiology and Anatomy, Loyola Univ., Stritch School of Medicine, Maywood, IL and Dept. Psychology, San Diego St. Univ., San Diego CA.

To explore the role of estrogen in neural function of the male, we have begun studies examining the hypothesis that estrogen receptor (ER) synthesis is autologously regulated in the male rat brain. Male Sprague/Dawley rats (Charles River, Portage, MI) were castrated at 25-28 days of age and sacrificed at 5-6 mos. of age. Littermate controls were left intact. Animals were group housed from weaning and were experimentally naive at the time of sacrifice. Following sacrifice, brains were removed, frozen in isopentane and sectioned at 16 u for subsequent analysis of steady state ER mRNA density using In Situ hybridization (ISH) histochemistry. ISH was performed using a 171 base 35S labelled cRNA probe corresponding to the 3'end of the ligand binding domain of rat ER mRNA. Northern blot analysis showed that this probe hybridizes to a single 6.2 kb species of mRNA in rat brain. Film autoradiograms and emulsion coated slide autoradiograms were analyzed for hybridization density using NIH image analysis software. ER mRNA density was increased by over 150% in the medial preoptic area and bed nucleus of the stria terminalis of castrated males as compared to intact controls (n=7; p<0.01). These data suggest that testosterone or an estrogenic metabolite of testosterone are involved in the regulation of estrogen receptor synthesis in the male rat brain. GRRH CDNA SEQUENCE FROM THE SEXUALLY POLYMORPHIC TELEOST FISH, PORICHTHYS NOTATUS. M.S. Grober\*, A. Bass and D. Myerst. Section of Neurobiology and Behavior, Cornell University; and Laboratory for Pregnancy and Newborn Research, New York State College of Veterinary Medicine, Ithaca, New York, 14853.

The plainfin midshipman, Porichthys notatus, exhibits two alternative male reproductive morphs (TINS 15:139, 1992). Since gonadotropin releasing hormone (GnRH) regulates the onset of sexual maturation, we are examining GnRH gene expression in this sexually polymorphic species. Using PCR technology utilizing degenerative oligonucleotide (21 mer) primers derived from the GnRH sequence of salmon and cichlid fish, we have identified two amplification products of 200 and 300 bp hybridizing with an oligonucleotide probe that is complementary to the ba ice for amino acid positions 1-7 of the GnRH decapeptide. The presence of two distinct PCR products suggests a molecular basis (e.g. alternate splicing or different GnRH genes) for the existence of multiple forms of GnRH within species.

We have cloned and partially sequenced the 200 base pair cDNA. There is a high degree of homology for amino acid (AA) and cDNA sequences (NA) for GnRH (AA:100%; NA:83%) and GnRH-associated peptide (GAP; AA&NA:>81%) within the fishes. Between fish and mammals there is a high degree of homology for GnRH (AA:80%; NA:73-80%), but less homology for GAP (AA:6-13%; NA:28-33%). It has been proposed that GAP functions as a biologically active peptide and/or dictates secondary structure necessary for processing of GnRH. As with AA and NA sequence data, hydrophobicity profiles based on GAP AA sequences suggest conservation of secondary structure within, but not between mammal and fish GAP. Thus, unlike the GnRH decapeptide, GAP may have different biological roles across the vertebrate taxa, but conserved functions within taxa.

## 372.3

AROMATASE-IMMUNOREACTIVE CELLS IN THE QUAIL PREOPTIC AREA: SEX DIMORPHISM AND EFFECTS OF TESTOSTERONE A Foidart\*. A, De Clerck, N, Harada, and J, Balthazart Lab. Biochemistry, Univ. Liège, B-4020 Liège, Belgium and Molec. Genetics, Fujita Health Univ., Toyoake, Aichi 470-11, Japan. We previously demonstrated that testosterone (T) increases aromatase activity (AA) and that AA is sexually dimorphic (males>females) in the quail preoptic area (POA). The precise anatomical localization of these effects is however impossible to obtain by the product-formation assay even when samples are dissected by the Palkovits punch technique. We were recently able to set up an immunocytochemical (ICC) procedure that permits visualization of aromatase-immunoreactive (ARO-ir) cells in the quail brain. This showed that the ARO-ir cells of the quail POA are all located in the sexually dimorphic medial preoptic nucleus (POM) which is actually outlined by this neurochemical marker. This ICC technique was used here to analyze at a cellular level of resolution the sex dimorphism of the quail preoptic aromatase and the localization of T effects on ARO-ir cells. In experiment 1, the number of ARO-ir cells was counted in one section every 100 μm throughout the rostral to caudal extent of the POM in 6 pairs of males and females. This showed that the POM of males contains more stained cells than the POM of females but only in a restricted region located just rostral to the anterior commissure (AC). In experiment 2, the same of males contains more stained cells than the POM of females but only in a restricted region located just rostral to the anterior commissure (AC). In experiment 2, the same procedure was used to study the effect of increasing doses of T (silastic implants of 5, 10 or 20 mm) on the number of ARO-ir cells. These T-treatments produced a doserelated increase in the sexual behavior of the birds and they increased the number of ARO-ir cells in POM, especially in the region rostral to the AC. In experiment 3, the number of ARO-ir cells was determined in the POM of males and females that had been gonadectomized and treated with a same dose of T (40 mm). No sex difference in the number of ARO-ir cells could be detected in these conditions. This suggests that the sex difference in AA that had been previously observed in T-treated birds results either from a difference in aromatase concentration or activity in a similar number of positive cells or from a difference in the number of ARO-ir cells that is very discrete from the anatomical point of view. These experiments also indicate that ARO-ir cells in the region of POM located just rostral to AC are sexually dimorphic and T-sensitive which suggests their involvement in the control of male sexual behavior. This conclusion is also supported but our recent studies based on electrolytic lesion and stereotaxic implantation of T in POM.

ARGININE VASOTOCIN (AVT) EFFECTS ON VOCAL BEHAVIOR IN CRICKET FROGS (ACRIS CREPITANS). L. Chu. C. A. Marler, and W. Wilczynski\*. Depts. of Psychology and Zoology, University of Texas, Austin, Texas. 78712.

AVT induces courtship and clasping behavior in male urodeles (Moore & Miller, Peptides, 4:97-102, 1983). We investigated whether AVT similarly increases male reproductive behavior in frogs, where courtship displays take the form of advertisement calls. After their calls were recorded, male cricket frogs in a breeding chorus were injected with AVT (10µg/g BW, IP) or saline, or handled without injection, and replaced on their call sites. After 30 min., advertisement calls were recorded for 5 min. AVT injected frogs were significantly more likely to call than saline injected or handled frogs ( $\chi^2$  test, p<0.025), indicating that as in newts AVT induces male courtship behavior in frogs. Spectral and temporal call characteristics change in a graded fashion when male cricket frogs engage in aggressive interactions with conspecific males (Wagner, Ethol., 82:27-45, 1989). Preliminary results suggest that AVT treated frogs produce calls with temporal features indicative of higher aggression levels than control frogs, including a lower rate of calls within call groups, an increase in call group duration, and a decrease in call group rate. These preliminary results suggest that AVT not only increases the likelihood of calling, but may also increase the aggressive nature of those calls that are produced. (Supported by NIMH R01 MH45350 and NIMH NRSA F32 MH10204).

SYNERGISM BETWEEN ANDROGEN AND ESTROGEN IN THE INDUCTION OF AROMATASE IN THE QUAIL BRAIN: IMMUNOCYTOCHEMICAL AND RT-PCR STUDIES J. Balthazart\*. A. Foldart, R. Loeffen, S. Dohmae, and N. Harada Lab. Biochemistry, Univ. Liège, B. 44020 Liège, B. Belgium and Molec, Genetics, Fujita Health Univ., Toyoake, Aichi 470-11, Japan.

It is established that testosterone (T) increases aromatase activity (AA) in the quail brain and that this induction of AA represents a limiting factor in the activation of male copulatory behavior (Balthazart et al., 1990, 47:83-94). This action of T presumably results from an induction of aromatase synthesis since the number of aromatase-immunoreactive (ARO-ir) cells increases (Balthazart et al., 1990, Brain Res. 514:327-333) and in parallel, there is an increase in aromatase mRNA as measured by reverse transcriptase-polymerase chain reaction (RT-PCR) technology (Harada et al., 1992, Molec. Brain Res., in press). The specific role of androgenic and estrogenic metabolites of T in this induction is not yet clear but product-formation assays suggest that both types of compounds synergize to increase AA (Schumacher et al., 1987, C.R.Acad. Sci. 305:569-574). We have analyzed this question by studying both the aromatase protein by immunocytochemistry and the aromatase (ARO) mRNA by RT-PCR in castrated quail that had been treated with T or its androgenic metabolite. 5α-dihydrotestosterone (DHT) or its estrogenic metabolite, estradiol-17β (E2) or both DHT and E2 simultaneously. A specific quantitative PCR technique using a modified aromatase as internal standard was developped for this purpose. T increased the number of ARO-ir cells both in the preoptic area (POA) and in the tuberal hypothalamus (POA-aHYP) and in the posterior hypothalamus (pHYP). E2-treated birds had more ARO-ir cells in the POA and tuber, their ARO mRNA concentration was significantey increased in the POA-aHYP but this effect did not reach significance in the pHYP. DHT by itself had no effect on either the number ARO-ir cells or

## 372.4

HORMONAL CONTROL OF SEX DIFFERENCES IN THE BRAIN, BEHAVIOR AND ACCESSORY SEX STRUCTURES OF WHIPTAIL LIZARDS. J. Wade<sup>1\*</sup> and D. Crews<sup>1,2</sup> Departments of <sup>1</sup>Psychology and <sup>2</sup>Zoology, and the Institute of Reproductive Biology, University of Texas, Austin, TX 78712.

Austin, TX 78712.

The effects of steroid hormones on sexual dimorphisms in the accessory sex structures, behavior and brain were investigated in two species of whiptail lizards. The studies were conducted both in adults and hatchlings of a sexually reproducing species, Cnemidophorus inornatus, and an all-female species, C. uniparens, which displays "sexual" behaviors typical of males and females. Androgens and estrogen stimulated somatic structures in all animals at both time periods. The hormones also stimulated courtship and copulatory behaviors in many of the adult animals. However, testosterone in adult males of the sexual species was the only treatment which produced parallel effects on the volume of the anterior hypothalamus-preoptic area (AH-POA) and the ventromedial hypothalamus (VMH) and the behaviors which the areas control. Steroid hormones did not (VMH) and the behaviors which the areas control. Sterior horhories during the elicit parallel effects on the volume of the two brain areas and behaviors in female *C. inornatus* or parthenogenetic *C. uniparens* in adulthood. Further, hormones did not affect the volume of either brain area in hatchlings of either species. The data on males add *C. inornatus* to the list of species in which steroid hormones alter behavior and the volume of brain of species in which steroid normones after behavior and the volume of brain regions in adulthood. However, the data from females and parthenogens indicate that the size of brain regions and the frequency with which behaviors are produced may not be directly linked.

SOCIAL FACILITATION OF SPHINCTER CLOACAE MUSCLE MOVEMENT IN MALE JAPANESE QUAIL.

MUSCLE MOVEMENT IN MALE JAPANESE QUAIL. C.M. Seiwert\* and E. Adkins-Regan. Department of Psychology, Cornell University, Ithaca, NY 14853.

Male Japanese quail (Coturnix japonica) produce a stiff meringue-like foam that is transferred to the female during copulation. This foam may be produced by rhythmic "spontaneous" movements (SMs) of the sphincter cloacae muscle (mSC), which overlies, and is interdigitated with, the proctodeal gland. As a complement to anatomical and physiological studies of mSC and the motoneurons which innervate it, this experiment investigates the possibility that social stimulation. this experiment investigates the possibility that social stimulation enhances expression of SM, and that response to females is greater than that to males. On each of 2 days, mSC movement was monitored in reproductively naive males when the subject was isolated (baseline), when a conspecific was present in the arena but separated from the subject by wire mesh (screen), and when the barrier between subject and stimulus was removed (contact). Subjects were presented with either male or female stimuli on a given day, and order of presentation was counterbalanced [male Day 1 (n=12), female Day 1 (n=12)]. Contact with conspecifics of either sex facilitates expression of SM. Presentation of a stimulus animal significantly increa SM, number of SMs, and number of SM bouts, while latency to begin SM significantly decreases. The level of SM in screen and contact SM significantly decreases. The level of SM in screen and contact conditions is significantly greater than in baseline, and screen and contact conditions are equally effective in eliciting the behavior. Females are a more potent stimulus than are males. Furthermore, presentation of females enhances subsequent response to males. [Supported by NSF # BNS 88-09441.]

NEUROPHYSIOLOGICAL EFFECTS OF CORTICOSTERONE RELATED TO BEHAVIOR AND REPRODUCTION IN AN AMPHIBIAN. J. D. Rose\* and F. L. Moore Dept. of Psychology, Univ. Wyoming, Laramie, WY 82071 and Dept. of Zoology., Oregon State Univ., Corvallis, OR 97331.

Stress-induced corticosterone (CORT) release blocks courtship clasping by male rough-skinned newts (Taricha granulosa) by an effect involving a neuronal membrane receptor. We studied CORT effects on brain activity in male newts by recording through fine-wire microelectrodes chronically-implanted in forebrain regions rich in CORT receptors (e.g. hippocampal primordium) and in rostral brainstem sites. Neural activity consisted mainly of small spikes, with large spikes occurring during strong sensory stimuli or pronounced movements. Systemic CORT in behaviorally-effective doses elevated forebrain activity in 2-5 min. This effect lasted for several min and was followed by a sustained activity decline. During these activity changes, forebrain neural responses to food or other newts and activity associated with reflexive clasping in response to cloacal stimuli were reduced or abolished. Thus, CORT attenuated forebrain neural responses to stimuli significant for reproductive behaviors and neuroendocrine function. Supported by NIH grant NS13748 (J.R.) and NSF grant BNS8909173 (F.M.).

DISTINCT HIGH-AFFINITY BINDING SITES FOR ALDOSTERONE AND CORTICOSTERONE ON NEURONAL MEMBRANES. F.L. Moore\*, C.S. Bradford, and M. Orchinik. Dept. of Zoology, Oregon State Univ., Corvallis, OR 97331.

Rapid, inhibitory effects of stress on

Rapid, inhibitory effects of stress on reproductive behaviors in the urodele amphibian Taricha granulosa appear to involve membranebound corticosteroid receptors that are coupled to G proteins (Orchinik et al. Science 252: 1848-1851,'91; Proc. Natl. Acad Sci. in press,'92). We recently conducted equilibrium saturation binding studies with radiolabeled aldosterone ([ $^3$ H]ALDO) or corticosterone ([ $^3$ H]CORT) and synaptic membranes from Xenopus laevis. Synaptic membranes from Xenopus were found to contain high-affinity and saturable binding sites for [ $^3$ H]CORT (K<sub>d</sub> = 0.2 nM; B<sub>max</sub> = 85 fmol mg¹ protein), as found previously in Taricha, and for [ $^3$ H]ALDO (K<sub>d</sub> = 4.1 nM; B<sub>max</sub> = 46 fmol mg¹ protein). These findings suggest that in distantly related amphibians there are distinct mineralocorticoid and glucocorticoid receptors in neuronal membranes. Supported by NSF grant BNS8909173.

## NEUROPEPTIDES AND BEHAVIOR II

#### 373.1

ANXIOLYTIC-LIKE ACTION OF NEUROPEPTIDE Y (NPY) IN THE RAT: MEDIATION BY THE AMYGDALA. K.T. Britton' (1), G.F. Koob (2) and M. Heilig (2), 1: Dept. of Psychiatry, San Diego VAMC and UCSD 2: Dept. of Neuropharmacology, The Scripps Res. Inst., 10666 N. Torrey Pines Rd., La Jolla, CA 92037

Disturbed NPY transmission has been suggested in depression. Anxiety is a core symptom of the depressive syndrome. NPY concentrations in CSF of depressed patients have been reported to correlate inversely with anxiety scores. In experimental animals, previous results have suggested that centrally administered NPY at low doses may have anxiolytic properties, while higher doses in addition produce sedation.

may have anxiolytic properties, while higher doses in addition produce sedation.

We have used an established, pharmacologically validated animal model of anxiety, the Geller-Seifter test, to further examine the anxiolytic properties of NPY. Animals were trained to press a lever for food reward. Drug effects were then tested in sessions consisting of an unpunished component (pressing the lever followed by reward only), and a punished component (reward accompanied by mild electric footshock, incremented with consecutive responses). Unpunished responding reflects effects unrelated to anxiety, e.g. on appetite or locomotor performance. Punished responding is selectively increased by anxiolytic drugs. Intracerebroventricular injection of NPY in freely moving rats (0.2 - 5.0 nmol) dose-dependently increased punished responding, probably reflecting the orexigenic action of NPY. Bilateral injection of NPY into the amygdala also increased punished responding by up to 100%, required only 50 pmol/side for maximum effect, and was effective within 15 min. No effect on unpunished responding or food intake was present. Current data are in agreement with previous observations suggesting NPY to be an endogenous anxiolytic. Further, the anxiolytic-like and orexigenic actions of NPY seem to be anatomically dissociated.

#### 373.2

EFFECTS OF NPY AND NPY<sub>2-36</sub> ON BODY TEMPERATURE AND FOOD INTAKE FOLLOWING ADMINISTRATION INTO DISCRETE HYPOTALAMIC NUCLEI. <u>S. M. Bouali<sup>28</sup>A. Fournier<sup>1</sup> and F. B. Jolicoeur.</u> Depts of Psychiatry and Pharmacology, University of Sherbrooke, Sherbrooke, Québec. Canada, J1H 5N4 and <sup>1</sup>INRS-Santé, Pointe Claire, Qué, Canada.

Our previous in vivo structure activity studies suggested that the putative receptors mediating the effects of NPY and NPY2.36 on food intake and body temperature following ICV administration are pharmacologically different (Jolicoeur et al. 1991b, Brain Res. Bul 26: 309). In the present study, we examined and compared dose related effects of NPY and NPY2.36 on ad libitum food intake and rectal temperature after administration into discrete hypothalamic nuclei in the rat. Results indicate that NPY and NPY2.36 have opposite effects on body temperature when injected into the lateral preoptic area, hypothermia and hypothermia respectively, and into the anterior lateral hypothalamus, hyperthermia and hypothermia respectively. However, when administered into the paraventricular nucleus, both increased body temperature. Into the third ventricle, NPY produced a biphasic effect, hypothermia at low doses and hyporthermia at high doses. Similar effects were obtained with NPY2.36 but in an inverse dose related fashion. In the arcuate nucleus, NPY induced significant hypothermia whereas NPY2.36 had no effect. Finally, neither peptide affected body temperature when injected into the ventromedial and perifornical sites. For feeding, both NPY and NPY2.36 increased food intake after injection in all regions examined. In general, NPY was more potent and efficacious than NPY2.36. The present results clearly dissociate the effects of NPY on food intake and body temperature. Furthermore, data suggest that the putative receptors underlying the effects of NPY and NPY2.36 on food intake are similar, whereas those mediating effects on body temperature are pharmacologically different.

temperature are pharmacologically different.

SCN/MPOA MICROINJECTION OF GRF AND NPY PREFERENTIALLY INCREASE THE CONSUMPTION OF SUGAR-SWEETENED CHOW IN RATS: SIMILARITY TO MORPHINE EFFECT SUGGESTS COMMON UNDERLYING REWARD MECHANISM. S.A. Josselyn and F.J. Vaccarino. Dept Psychology, University of Toronto, Toronto, Canada, MSS 1A1

Previously, this lab has demonstrated growth hormone releasing-factor (GRF) stimulates chow intake when microinjected into the suprachiasmatic nuclear or medial preoptic (SCN/MPOA) areas of non-deprived male rats. In addition, data suggest GRF's orexigenic action may be mediated by opiates and reflect an enhancement of the food's reward value. The present experiment was designed to explore the consequence of GRF administration on the intake of foods that differed in hedonic value [sugar/chow (10% sugar), saccharin/chow (0.018% saccharin) or unsweetened chow] and further, to compare with the effect of a similar administration of neuropeptide Y (NPY). Non-deprived male rats with SCN/MPOA cannulae were given free access to the food choices. The quantities of foods eaten, microstructure of meal patterns and general locomotor activity were measured following establishment of a stable baseline and microinjections of vehicle (0.01% ascorbic acid, 0.5 ul), GRF (1.0 pmol) and NPY (2.0 nmol). Preliminary results indicate that both GRF and NPY, when microinjected into the SCN/MPOA, produce an augmentation in sugar/chow consumption without accompanying changes in locomotor activity. As baseline measures revealed rats initially preferred the sugar/chow alternative, GRF and NPY preferentially increased intake of the preferred food choice. This pattern is consistent with that obtained following systemic morphine in a similar choice paradigm and implicates a shared underlying reward mechanism.

TESTS OF AGONIST EFFECTS OF NPY ANALOGS. S. Sheriff, A. Balasubramaniam, J. Krstenansky and W. Chance\*. Dept. Surgery, Univ. Cincinnati Med. Ctr., Merrel-Dow & VA Med. Ctr., Cincinnati, OH. Neuropeptide Y (NPY) is an extremely potent stimulator of feeding. This feeding effect is mediated by Y1 receptors, requiring nearly the whole sequence of NPY for biological activity. To develop agonists to NPY, we have synthesized several analogs modified at the C-terminal. These analogs were tested for NPY binding and adenylate cyclase activity in rat hypothalamic membranes as well as for feeding effects following their injection into the perifornical hypothalamic area of adult, male, SD rats. The potencies of the analogs on these tests were: NPY NPY 32-PRO > NPY CYS CYS > NPY 36-D-TRP > NPY 36-D-TRP(CHO) > NPY 34-D-TRP. Although the order of potencies for adenylate cyclase and feeding were similar, the feeding response was lost as adenylate cyclase activity was reduced to 50% (NPY 36 D-TRP(CHO)) of NPY. None of the centrally-modified analogs (AOC-8-17-NPY, C2, C5) obtained from Merrel-Dow stimulated feeding significantly. These results indicate that although partial agonist effects remain for adyenlate cyclase following C-terminal modifications of NPY, feeding behavior is lost.

INTRAHYPOTHALAMIC INJECTION OF NEUROPEPTIDE Y REDUCES INCREASES RATE AND BEHAVORIAL THERMOREGULATION. C.L. Bivens and H.J.Carlisle Dept. of Psychology, University of California, Santa Barabara, CA 93106

Neuropeptide Y, a potent orexigenic neurochemical, has been observed to decrease core temperature in rats when administered centrally. We investigated the hypothesis that NPY may alter the "set point" for body temperature. Hat-Human neuropeptide Y was injected in various doses (0, 78, 1.7, 235 pmoles) into the perifornical and preoptic areas of the hypothalamus of male Sprague-Dawley rats while metabolic rate, behavioral thermoregulation, and food intake were measured. In the perifornical hypothalamus, metabolic rate decreased significantly in a dose-dependent manner from 12% to 25% after injection of rNPY in the absence of food. Metabolic rate increased if food was available, with the increase being related to the amount of food consumed (r=.99 for both control and rNPY treated rats). Behavioral thermoregulation increased by 30% to 80% in a dose-dependent manner after injections into the perifornical hypothalamus. Thermoregulatory behavior also increased following preoptic administration of rNPY.

These results indicate that NPY reduces energy expenditure, but not by lowering the set point since thermoregulatory behavior increased so as to oppose the fall in temperature.

## 373.7

# BLOCKADE OF FATTY ACID OXIDATION INCREASES THE NUMBER OF VAGAL SENSORY NEURONS CONTAINING GALANIN mRNA AND hnRNA. N.Y. Calingasan\* S. Ritter and P.W. Kalivas. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520. Mercaptoacetate (MA)-induced lipoprivic feeding is mediated by the property of the prope

by vagal sensory neurons. Since we previously showed that these by vagal sensory neurons. Since we previously showed that these neurons synthesize galanin (GAL), a peptide which stimulates feeding when injected intracranially, vagal GAL may participate in lipoprivic feeding. Therefore, we examined the effect of MA-induced lipoprivation on GAL gene expression in the nodose ganglion using in situ hybridization with a 45-base oligonucleotide probe complementary to nucleotides 259-303 of rat preproGAL mRNA. Rats maintained on a fat-supplemented diet were injected with 600 maintained on the control of the co was infinital to 0 at 1a-supplemented the well enjected with 000  $\mu$ mol/kg MA, 200 mg/kg 2-deoxy-D-glucose (2DG), 4  $\mu$ g/kg cholecystokinin (CCK) or saline (n=4/group) and killed 2 hr later. We found that MA significantly increased the percentage (mean  $\pm$  SE) of GAL mRNA-labeled cells to 75.9  $\pm$  5% compared to saline (16.8  $\pm$  6%), 2DG (21.3  $\pm$  5%) or CCK (16.5  $\pm$  4%). The number of the NRNA belief cells was also confidently increased by MA (70.2). hnRNA-labeled cells was also significantly increased by MA (79.2  $\pm$  2%) but not saline (24.9  $\pm$  7%), 2DG (25  $\pm$  2%) or CCK (19.4  $\pm$  4%). The absence of significant effect of 2DG which, like MA stimulates feeding, and CCK which, like MA acts through vagal sensory neurons, suggests specificity of MA effect. Thus, GAL is a potential neurochemical participant for vagal responses to lipoprivation.

# 373.9

PRESSOR RESPONSES TO MICROINFUSION OF AMINOPEPTIDASE M INTO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS IN NORMOTENSIVE AND HYPERTENSIVE RATS. C.M. Batt\*, L.L. Jensen, J.W. Harding and J.W. Wright, Departments of Psychology and

Veterinary and Comparative Anatomy, Physiology and Pharmacology, Washington State University, Pullman, Washington 99164.

Experiments were designed to address the potential role of leucine aminopeptidase M (APM) as a therapeutic hypotensive agent in normotensive and hypertensive rat models. In earlier reports from normotensive and hypertensive rat models. In earlier reports from this laboratory blood pressure was reduced in normotensive Wistar-Kyoto (WKY) rats and to a greater degree in spontaneously hypertensive rats (SHR) when APM was microinfused into the lateral ventricles of anesthetized animals (Jensen et al., 1992). It has also been shown that microinjections of angiotensin II (AII) into the paraventricular nucleus (PVN) of the hypothalamus results in pressor responses in anesthetized (Brosnihan et al., 1987; Diz et al., 1985) and alert (Jensen et al, in press) rats.

dose response relationship between APM and hypotension was established in both WKY and SHR rats, with WKY showing maximum mean (±SEM) pressor changes of -38.4±5.3 mmHg in anesthetized and -36.8±2.6 mmHg in alert, free-moving subjects. SHR animals showed changes of -71.2±6.6 mmHg in anesthetized and -76.5±6.0 mmHg in alert animals. Pretreatment with the specific angiotensin receptor antagonist Sar<sup>1</sup>Thr<sup>8</sup>-AII (sarthran) greatly diminished the APM-induced depressor responses, strongly suggesting the responses are angiotensin-dependent.

A NEUROENDOCRINE SYSTEM REGULATING EGG-LAYING BEHAVIOR IN THE NUDIBRANCH ARCHIDORIS MONTEREYENSIS. B.L. Wiens\* and P.H. Brownell. Oregon State University, Corvallis, OR. 97331 In the gastropod molluscs Aplysis californice and Lymnees stagnalis egg-laying is a long-lasting behavior triggered by discrete populations of peptide-secreting neurons, the bag cells (BCs) and the caudo-dorsal cells (CDCs), respectively. We describe here a group of neurons in the cerebral ganglia of the nudibranch mollusc Archidoris montereyensis cerebral ganglia of the nudibranch mollusc Archidoris montereyensis that exhibit morphological, immunological, and behavioral similarities to the BCs and CDCs. These intercerebral white cells (ICWCs) are distributed in bilateral clusters each comprised of approximately 50 small (20 µm) cells that appear white under epi-illumination. The location of these clusters, immediately posterior to the cerebral commissure and adjacent to vascular spaces, is identical to that of the CDCs. The ICWCs and their processes in the intercerebral commissure CDCs. The ICWCs and their processes in the intercerebral commissure and cerebral ganglia are immunoreactive for alpha bag cell peptide ( $\alpha$ BCP) but not alpha caudo-dorsal cell peptide. Each pleural ganglion contains an additional immunoreactive neuron ( $60~\mu$ m) reminiscent of the ectopic BCs and CDCs. These cells appear to be electrically silent, with resting potentials of approximately -60mV, and refractory to discharge of action potentials when focally stimulated. Like the BCs and CDCs, the ICWCs appear to contain hormones that stimulate eggliuing lighting in the containt the conta and CDCs, the ICWCs appear to contain hormones that stimulate egglaying. Injection of cerebral ganglia (6 trials, p<.01; Fisher exact probability test) or ICWC homogenates (3 trials, p<.05) cause resting animals to lay eggs within 4 hours. Thus, the ICWCs of *Archidoris* have properties similar to the neurons that trigger egg-laying behavior in Aplysia and Lymnaea, providing further support for the hypothesis that the neuroendocrine mechanism controlling this behavior is common to all gastropods. # 373.8

INCREASED PROENKEPHALIN mRNA IN SPECIFIC HYPOTHALAMIC AREAS DURING LACTATION. M.A. Ottinger<sup>1\*</sup>, K.T. Margaretten, K.L. Rosewell, and P.M. Wise, <sup>1</sup>Dept. Poultry Sci, U. of Maryland, College Park, MD and Dept. of Physiology, U. of Maryland School of Medicine, Baltimore, MD 21201

Enkephalin appears to modulate several aspects of reproductive function in rats and steroids influence the level of gene expression (Romano <u>et al</u> 1989 Mol Brain Res 5:51). In addition,  $\beta$  endorphin content changes in response to lactation (Hammer & Bridges 1987 Brain Res 420:48). The purpose of this experiment was to determine whether lactation influences proenkephalin mRNA levels in specific brain regions known to be involved in maternal behavior and prolactin secretion. Rats were sacrificed on diestrous day 1 (D1), day 3 (Lac3) or day 10 (Lac10) of lactation. Eight micron sections were subjected to <u>in situ</u> hybridization using an <sup>35</sup>S-labelled riboprobe complementary to rat proenkephalin (gift of James Douglass). mRNA levels per cell were analyzed in rostral and mid-arcuate nucleus, magnocellular and parvocellular aspects of paraventricular nucleus and ventromedial nucleus. We observed a highly significant (p<.0001) increase in proenkephalin mRNA levels in the mid-arcuate nucleus in both Lac3 and Lac10. mRNA levels increased (p<.05) in the rostral arcuate nucleus in Lac10 compared to D1, Lac3 was intermediate. We are currently analyzing mRNA levels in the other brain regions, including the medial preoptic nucleus and corpus striatum. These data provide evidence that enkephalins may play a role in the endocrine and behavioral changes that characterize the lactational state.

# 373.10

ENDOGENOUS OPIOIDS AUGMENT LOCOMOTION VIA A MUI OPIOID RECEPTOR AFTER DOPAMINE DEPLETION IN THE NUCLEUS ACCUMBENS. L. Churchill and P.W. Kalivas. Dept. of Veterinary & Comparative Anatomy, Pharmacology, & Physiology, Washington State University, Pullman, WA 99164-6520.

Kelatorphan, a mixed peptidase inhibitor that blocks enkephalin degradation, stimulates locomotion when microinjected into the nucleus accumbens (NA). After bilateral lesion of the dopaminergic innervation to the NA with 6-hydroxydopamine (4  $\mu g/\mu l$  free base in 0.25 mg/ml ascorbic acid in sterile saline), kelatorphan augments the horizontal and vertical locomotor activity in a dose-dependent fashion relative to sham-lesioned rats. A specific  $\mu l$  antagonist, naloxonazine (10 mg/kg, i.p., 10-12 hrs prior to the microinjections in the NA), blocks the kelatorphan-induced augmentation over the sham-lesioned controls without affecting the kelatorphan-induced responses in the sham-lesioned rats. Similarly, naloxonazine blocks the locomotor augmentation induced by microinjection of the  $\mu$ -selective opioid peptide, Tyr-D-Ala-Gly-NmePhe-Gly-OH (DAMGO) at 1 nmol/0.5  $\mu$ l after dopamine depletion in the NA. These results indicate that endogenous opioids also produce an augmented locomotor response and that the  $\mu 1$  opioid receptor is involved. The molecular mechanism and that the proposed response in the indeed an inechanism that underlies this behavioral augmentation has not been elucidated yet. Although [H]phorbol ester binding to protein kinase C has been increased in the NA after dopamine depletion, an inhibitor of protein kinase C activity, 1-(5-isoquinolinesulfonyl-2-methylpiperazine dihydrochloride (H7), does not block the behavioral augmentation to DAMGO, suggesting that the translocation of protein kinase C to the membranes is not a necessary step in this augmentation.

MEDIATION OF OPIOID EFFECTS IN THE MD AND PPN BY GABA AND MESOLIMBIC DOPAMINE. M.A. Klitenick\* and P.W. Kalivas. Dept. of VCAPP, Washington State University. Pullman. WA 99164-6520.

Mashington State University, Pullman, WA 99164-6520.

The results from a number of recent studies provide evidence suggesting a role for the dorsomedial nucleus of the thalamus (MD) and the pedunculopontine nucleus (PPN) in the expression of locomotor activity induced by enhanced transmission within the mesocorticolimbic system. The present experiments examined the role of the ventral tegmental area (VTA) in the mediation of the motor stimulant effects of opioid injections into either the MD or PPN. In the first experiment it was found that injection of the μ-opioid agonist DAMGO into either the MD or PPN elicited a dose-dependent increase in locomotor activity. Peripheral administration of haloperidol, at a dose that attenuated amphetamine- but not caffeine-induced locomotion, blocked the motor stimulant effects of DAMGO in the MD as well as in the PPN. However, whereas intra-VTA injection of the GABAB agonist baclofen attenuated the motor response elicited by DAMGO in the PPN, baclofen did not block the locomotion elicited from the MD following DAMGO. These data suggest that although the opioid-induced behavioral response elicited from the MD and PPN are dopamine-dependent, only the activity elicited from the PPN appears to be mediated, in part, by the VTA. Neurochemical experiments utilizing in vivo microdialysis are currently in progress to further assess the involvement of the VTA in the motor stimulant response to opioids in the MD and PPN.

#### 373.13

THE EFFECT OF ADRENALECTOMY AND FOOD DEPRIVATION IN THE PORSOLT SWIM TEST. <u>D. Jefferys\* and J.W. Funder.</u> Baker Medical Research Institute, Prahran, Victoria, Australia 3181.

In the Porsolt swim test intact animals become progressively immobile over a 15 min test period, and on retest 24h later remain immobile for ~70% of the 5 min retest period. Adrenalectomy (ADRX) blocks retention of the response, with animals immobile for ~35% of the retest period, an effect reversed by dexamethasone (6µg) or ketocyclazocine (1mg/kg). When the antiglucocorticoid RU38486 (3.75mg) is administered alone to intact animals it is without effect, as is MR2266 (1mg/kg) a kappa opioid antagonist, administered alone. In contrast, when RU38486 and MR2266 are simultaneously administered to the intact animals they behave like ADRX on retest.

Recently we have shown that glucose (100mg/kg) reverses the effect of adrenalectomy. Secondly, animals food deprived for 24h behave like ADRX animals on retest, an effect not seen with 48h food deprived animals. In the present study we show that simultaneous administration of RU38486 and MR2266 reverses the effect of 48h food deprivation; administered alone, neither agent is effective. We have also shown that glucose reverses the effect of the simultaneous blocking of glucocorticoid and kappa opioid action in 48h food deprived animals. The results from the present studies provide additional support for the role of metabolic factors in modulating retention of the behavioral responses. They also suggest that in the 48h food deprived animal both adrenal signals facilitating retention are restored.

# 373.15

THE EFFECTS OF ANGIOTENSIN II IN WATER ABSORPTION RESPONSE BEHAVIOR IN THE SPADEFOOT TOAD, SCAPHIOPUS COUCHII. C.R. Propper, W.E. Johnson, and D.J. Prior. Department of Biological Sciences, Northern Arizona University, Flagstaff, Arizona 86011.

In vertebrates, angiotensin II (A-II) is a potent inducer of drinking behavior in many species. Instead of oral drinking, anuran amphibians obtain water by placing their ventral pelvic region on a moist substrate. The purpose of this investigation was to determine whether A-II induces water absorption response behavior in the spadefoot toad, Scaphiopus couchii. We determined 1) the dehydration rate, 2) whether dehydration induces a behavioral water absorption response, 3) whether A-II activates a behavioral water absorption response in fully hydrated animals, and 4) whether A-II antagonists or angiotensin converting enzyme inhibitors block the water absorption response in dehydrated animals. It took toads 3 hours to dehydrate to 90% of their ad libitum weight. Dehydrated animals spent significantly more time displaying water absorption response behavior than did fully hydrated toads (P < 0.01). Angiotensin II at 10  $\mu$ g/ 100g of toad induced water absorption behaviors in fully hydrated toads compared to saline treated controls (P < 0.01). However, saralasin, an A-II antagonist, and captopril, an angiotensin converting enzyme inhibitor, had no significant effect on blocking the water absorption response behavior in dehydrated animals These results suggest that exogenous, but possibly not endogenous, A-II may influence water absorption response behavior in amphibians. THE ACTH(4-9) ANALOG ORG2766 MODULATES NMDA RECEPTOR ACTIVITY. <u>Berry Spruijt</u>\*. University of Utrecht, IMB, Padualaan 8, 3584 CH, Utrecht, The Netherlands.

In studies on senescent and fimbria fornix lesioned rats the ACTH(4-9) analog ORG2766 has been demonstrated to improve hippocampal functioning. These results have suggested that functional recovery is due to protection against consequences of damage or stimulation of compensatory processes. It is hypothesized that these beneficial effects are due to modulation of NMDA receptor activity which is known to be involved in neuronal protection as well. The modulatory action on NMDA receptor activation is addressed by studying the interaction between ORG2766 and NMDA or its antagonist AP5, on locomotor activity and spatial orientation in a Morris maze. Intracerebroventricularly (icv) injected NMDA (300 ng) induced a dramatic increase in locomotor activity. This enhanced locomotion could be antagonized by AP5 (3µg icv) and equally potent by ORG2766 (10 µg sc). ORG2766 also counteracted the NMDA antagonist-induced impairment in performance in the Morris water maze test. ACTH(4-9) alone in these tasks did not result in behavioral changes. The present results indicate a very potent indirect modulation of NMDA receptor activity by the ACTH(4-9) analog.

## 373.14

TONIC NEURONAL INHIBITION BY ANGIOTENSIN II REVEALED BY IONTOPHORETIC APPLICATION OF A SPECIFIC ANGIOTENSIN II TYPE I RECEPTOR ANTAGONIST. S.N. Thormton\*—F.P. Martial and S. Nicolaidis. CNRS URA 637, Neurobiologie des Régulations, Collège de France, 11 pl. Marcelin Berthelot, 75231 Paris CEDEX 05, France.

Deoxycorticosterone acetate (DOCA) pretreatment enhances neuronal activity and sensitivity to angiotensin 11 (All) in the septum and medial preoptic regions of rats. Using 7 barrelled micro-iontophoretic (Io) electrodes sealed to a recording electrode we have investigated extracellularly neuronal responsiveness to Io application of AlI, of the specific AlI type 1 receptor non-peptidergic antagonist losartan potassium (DUP-753), of atrial natriuretic peptide (ANP) and of aldosterone in two groups of urethane anaesthetised male Wistar rats. The animals in each group, controls (non-pretreated) or experimentals (pretreated, DOCA 0.5 mg/kg s.c.) also had their femoral arteries catheterised for blood pressure recording. Unit activity was also recorded down through the stria terminalis to the central nucleus of the amygdala.

In the above mentioned regions losartan could block the excitatory responses to All but not those to ANP nor to aldosterone. However, not all the neurons had their responsiveness to All blocked by losartan. Similar results were found in the stria terminalis but not in the amygdala. Losartan also showed an effect by itself since it could induce an activation lasting as long as the lo application in DOCA pretreated rats, and a prolonged and dramatic activiation in the non-pretreated rats.

Therefore, it could be proposed that in these regions AII exerts a tonic inhibitory action on an as yet unidentified population of neurons via a type 1 receptor. However, not all neurons in these areas appear to have type I AII receptors.

# 373.16

WATER ABSORPTION RESPONSE BEHAVIOR IN THE GREAT PLAINS TOAD, <u>BUFO COGNATUS</u>: EFFECTS OF ANGIOTENSIN II, SARALASIN, AND CAPTOPRIL. <u>W.E. Johnson\* and C.R. Propper.</u> Department of Biological Sciences, Northern Arizona University, Flagstaff, Arizona 86011.

Angiotensin II (A-II) induces rehydration behavior in vertebrates. Desert amphibians such as Bufo cognatus display water absorption response behaviors in order to rehydrate after exposure to xeric conditions. The following experiments examined the putative role of A-II in water absorption response behavior of B. cognatus. We determined 1) the dehydration rate over five hours, 2) water absorption response in dehydrated toads, 3) whether A-II induces water absorption response in hydrated animals, and 4) whether an A-II antagonist, saralasin, or an angiotensin converting enzyme inhibitor, captopril, blocks water absorption response in dehydrated toads. Bufo cognatus lost 90% of their ad libitum weight in 5 hours via dehydration. When presented with water, dehydrated toads exhibited significantly more water absorption response behavior than hydrated toads (p < 0.02). Hydrated toads injected with 100 ug A-II/100g. toad showed more water absorption response behavior than saline injected controls (p < 0.02). Neither saralasin or captopril induced significant blockade of water absorption response behavior in dehydrated toads. These results suggest that exogenous A-II promotes water absorption response The role of endogenous A-II in water absorption behavior is not clearly defined for B. cognatus.

Supported by NSF Grant# BNS-9110045 to CRP

The Effect of Alpha-MSH and MCH on Auditory Sensory Gating C.L. Miller\*\(^1.2\). \(^1.

Auditory gating refers to the decrease in amplitude of tone-evoked CNS potentials that can be measured when two identical tones are presented in rapid succession to the ear. Studies of auditory gating have been carried out in scalp EEG recordings of humans and have been extended to depth recordings in a rat model. Within approximately 50 msec after a tone, an auditory evoked potential occurs in both humans (50 + /- 10 msec) and rats (40 + /- 10 msec). The ratio of the response evoked by the 2nd tone (presented 500 msec after the 1st) to that evoked by the 1st is termed the testing/conditioning (T/C) ratio and is a measure of the effectiveness of gating. Using the rat model, the peptides alpha-MSH and MCH (rat and salmon sequence) were administered icv in a continuous flow system to chloral hydrate (400 mg/kg ip) anaesthetized rats. Depth recordings were carried out in the dorsal hippocampus and T/C ratios were collected both during peptide administration and during infusion with the vehicle alone, both pre- and post-peptide. The effect of alpha-MSH administered alone was to improve auditory gating via an increase in the response to the 1st tone. The effect of MCH was to worsen auditory gating via a decrease in the response to the 1st tone. The maximally effective response was attained at 200 uM for alpha-MSH and 125 uM for MCH. When MCH (125 uM) was administered prior to alpha-MSH (200 uM), the effect of alpha-MSH was blocked. Thus, the two peptides appear to be functional antagonists. These results may be relevant two periodes appear to be unicitorial arriagorinss. These results may be recorded to behavioral disorders characterized by impaired attention to and defective processing of environmental stimuli, specifically schizophrenia, for which numerous studies have now demonstrated a deficit in auditory sensory gating. Supported by VAMRS&USPHS Grants MH44212, MH38321.

Opiate antagonist effects of the Tyr-MIF-1 family of peptides and their analogs in lizards. J. E. Rickels, E. L. Simmons, A. J. Kastin, J. Erchegyi, G. A. Olson, and R. D. Olson\*. Department of Psychology, University of New D. Olson\*. Department of Psyc Orleans, New Orleans, LA 70148

Previous work suggests that Tyr-MIF-l (Tyr-Pro-Leu-Gly-NH $_2$ ) and MIF-l (Pro-Leu-Gly-NH $_2$ ) act as opiate antagonists. Based on the structure of the newly isolated peptide, Tyr-Pro-Trp-Gly-NH2, new analogs were created by substituting Trp for Leu. All compounds were then combined factorially with a free acid (OH) or a amide (NH $_2$ ) at the C-terminus and injected IP in 450 lizards at six doses: 0.0001, 0.001, 0.01, 0.1, 1.0 and 10.0 mg/kg, each with a constant dose of 2.0 mg/kg of morphine. A diluent control group and a morphine control group were also tested. Tail-flick latenices were obtained 15 min. after injection. ANCOVA performed on the data yielded a triple interaction for Peptide x Analog x C-terminus, p < .05, as MIF-1 with Leu was more effective with an amide while with Trp it was more effective with a free acid; the opposite was true for Tyr-MIF-1. Peptide x Dose x C-terminus was also reliable, p<.05, with the relationship varying as a function of dose. Finally, Dunnett's test indicated that four treatments significantly reduced tail-flick latencies below those associated with morphine: Pro-Leu-Gly-NH<sub>2</sub> (0.0001 mg/kg), Pro-Trp-Gly-OH (0.0001 and 1.0 mg/kg), and Tyr-Pro-Trp-Gly-NH<sub>2</sub> (0.1 mg/kg). Under optimal conditions, some compounds may function as opiate antagonists.

# 374.5

ANTAGONISM OF CRF RECEPTORS IN THE CENTRAL NUCLEUS OF THE AMYGDALA ATTENUATES SHOCK-INDUCED FREEZING BEHAVIOR IN RATS. A. H. Swiergiel\*, N. H. Kalin, W. W. Rubin, and L. K. Takahashi. Dept. Psychiatry, Univ. Wisconsin, Madison, WI 53792.

Extrahypothalamic corticotropin releasing factor (CRF) is involved in mediating stress-induced behavioral responses. Studies conducted in this laboratory demonstrated that intracranial administration of CRF antagonist attenuated shock-induced freezing behavior in rats. The amygdala has a high density of CRF receptors and is integral to the expression of fear-related behavioral responses.

The present study examines the effect of administration of the CRF antagonist into the central nucleus of the amygdala on shock-induced freezing. The CRF antagonist, alpha-helical  $\mathsf{CRF}_{9\text{-}41}$ , was infused bilaterally into the nucleus of the amygdala of adult Sprague-Dawley rats. The duration of electric foot-shock induced freezing was measured in a 15 min test.The antagonist at a dose of 200 ng per animal decreased duration of freezing by 51% (p < 0.01). These results suggest that CRF receptors in the central nucleus of the amygdala participate in the expression of fear-related behavioral patterns. Supported by NIH grant # MH 40855.

MELANIN-CONCENTRATING HORMONE AND α-NEOENDOR-PHIN IMMUNOREACTIVE NEURONS IN THE LATERAL HYPO-THALAMUS PROJECT TO THE PARABRACHIAL AREA OF THE RAT. K. Touzani, G. Tramu. J.L. Nahon¹ and L. Velley. Lab. Neurosci. Comport. Cognitives, CNRS URA 339, Univ. Bordeaux I, 33405 Talence France and ¹ Institut Pharmacol. Moléc. Cellulaire, CNRS UPR 411, 06560 Valbonne France.

In previous studies we showed that the ibotenic acid lesion of the neurons of the lateral hypothalamus (LH) 1) suppressed self-stimulation in the medial part of the parabrachial area (PBm), the second gustatory relay station, 2) increased the preference threshold for saccharin, 3) altered the

station, 2) increased the preference threshold for saccharin, 3) altered the modulation of taste by morphine. In the present study, by coupling retrograde transport and immunohistochemistry, we attempted to identify some of the neuropeptides implicated in the LH-PBm projection. We found that 55-60% of the LH neurons projecting to the PBm are immunoreactive to the melanin-concentrating hormone antiserum. These neurons are localized in the middle and posterior parts of the LH, mainly in juxtacapsular position. In the perifornical area, 28% of the neurons projecting to the PBm are labelled by  $\alpha$ -neoendorphin antiserum. In the PBm, a great number of terminals immunoreactive to one or the other antisera was observed. The colocalization of the two immunoreactivities in the same LH neuron projecting to the PBm was examined.

projecting to the PBm was examined.

THE ANORECTIC EFFET OF FENFLURAMINE INJECTED IN PVN IS MEDIATED BY CRF NEURONS. J. P. Max. A. Burlet.\*J. P. Nicolas and C. Burlet INSERM U. 308. F 54000 Nancy France

Centrally administered d-fenfluramine (dff) decreases food intake when injected into the hypothalamic paraventricular nuclei (PVN). This diminution is specifically due to the reduction (34±3.2% p<0.001) of the carbohydrate and the fat (9±0.4%) intake, the protein one being slightly increased when Long Evans rats have free access to pure macronutrients. At the same time the release of CRF increases (J. P. Max et al. Int. J. Obes. 14 sup. 2, p. 164 1990) suggesting the involvement of this neuropeptide in the anorectic effect of dff after PVN injection. We have previously demonstrated that intracerebral administration of a monoclonal antibody to neuropeptide together with ricin A chain and monensin resulted in a long term inhibition of the biological function

of the peptidergic neuron (A. Burlet et al Neuroendocrine Res. Methods1991) We tested the effects of dff PVN injections on feeding behaviour of Long Evans rats after immunolesion of CRF neurons. The lesion was induced by injection of a mixture of toxin [(ricin A chain (230 μg/ml) and monensin (50 nM)] and CRF-monoclonal antibody (generously given by F. G. H. Tilders and J. W. A. M. Van Oers) above PVN (0.25 µl/nucleus). 300 n moles of dff in 0.5 µl of synthetic CSF were injected at the end of the light period, macronutrient selection was measured 24 hours after injection. In these conditions, compared to CSF, dff did not modify food intake and body weight evolution.

These results indicate that fenfluramine needs intact CRF neurons to promote anorectic effect after PVN injection. The ability of rats to select macronutrients is complex and may involve neurotransmitters but also neuropeptides. Our results are in favour of the necessary involvement of CRF in the anorectic effects of dextrofenfluramine when centrally injected.

SUPPRESSION OF CORTICOTROPIN-RELEASING FACTOR ACTIVITY IN THE PARAVENTRICULAR NUCLEUS ENHANCES FEEDING INDUCED BY NEUROPEPTIDE Y. S.C. Heinrichs\*, E. Merlo Pich, F. Menzaghi, R.L. Hauger1 and G.F. Koob. Scripps Research Institute, Dept. of Neuropharm. CVN7, 10666 N. Torrey Pines Rd., La Jolla CA 92037 and <sup>1</sup> VA Medical Center, Dept. of Psychiatry 0603, 9500 Gilman Dr., La Jolla CA 92093.

Brain feeding circuits which control meal initiation or rate of food intake may balance the strength of stimulatory signals arising from Neuropeptide Y (NPY) containing pathways and inhibitory input produced by Corticotropin-Releasing Factor (CRF) systems. Since the anatomical and physiological correlation of these two neuropeptides is apparent in the paraventricular nucleus of the hypothalamus (PVN), the present studies examined the effect of both intracerebroventricular (ICV) and intra-PVN administration of a CRF antagonist, α-helical CRF<sub>9-41</sub>, on NPY-induced hyperphagia. Administration of 1  $\mu$ g, but not 5 or 25  $\mu$ g, ICV doses of the CRF antagonist enhanced significantly the hyperphagia induced by a 5  $\mu$ g ICV dose of NPY. Intra-PVN pretreatment with 250 ng, but not 125 or 500 ng, doses of  $\alpha$ -hel CRF potentiated significantly the feeding induced by a 500 ng intra-PVN dose of NPY. No effect of either peptide or their interactive effect was observed following administration into the central nucleus of the amygdala. Systemic pretreatment with the synthetic glucocorticoid, dexamethasone (100 µg/kg), also enhanced appetite stimulated by intra-PVN administration of NPY. These results suggest that endogenous, hypothalamic CRF pathways inhibit feeding evoked by NPY and that both direct neurotropic and peripheral steroid feedback onto CRF neurons serve to modulate short term food intake.

PHENELZINE POTENTIATES THE ANXIOGENIC EFFECTS OF INTRACEREBROVENTRICULAR CORTICOTROPIN RELEASING FACTOR IN THE RAT. H. Ward, D. Cottrell, I. Goodman, A. Azzaro\* Depts. of Behavioral Med./Psych., Neurology, and Pharmacology/Tox., West Virginia University School of Medicine, Morgantown, WV 26506

There is growing evidence for the role of extrahypothalamic corticotropin releasing factor (CRF) in the neurobiology of anxiety. A defensive withdrawal assay of rat behavior is often used as an animal model that supports the anxiogenic effects of this neuropeptide, and can be antagonized by benzodiazepines. We used a modified form of this assay to confirm these anxiogenic effects and compared 1.0 microgram intracerebroventricular (i.c.v.) CRF to i.c.v. injection of artificial cerebrospinal fluid. CRF treated rats reared less than controls (p < .001), spent more time in a withdrawal chamber (p < .001), and made fewer passages into a lighted open field (p < .01). (N = 11) Phenelzine (Nardil) is effective in the treatment of various pathologic anxiety states including panic disorder and social phobia. It was anticipated that chronic pretreatment with this agent would "protect" the animals from the effects of i.c.v. CRF. However, 3.0mg/kg/day subcutaneous administration of this nonselective monoamine oxidase inhibitor for up to six weeks augmented these behavioral findings, thought to represent anxiety in this model. These surprizing results may be explained by a pertubation of normal monoaminergic transmission by phenelzine as opposed to a corrective action of this agent in clinical states of anxiety.

EFFECTS OF CCK<sub>A</sub> AND CCK<sub>B</sub> ANTAGONISTS ON AMPHETAMINE (AMP)-INDUCED BEHAVIOR IN RATS. <u>G.A. Higgins\*</u>, <u>D.M. Tomkins</u>, <u>T.L. Sills+</u>, <u>E.M. Sellers and F.J. Vaccarino+</u>. Departments of Pharmacology, Medicine and Psychology+, University of Toronto and Clinical Research and Treatment Institute, Addiction Research Foundation, Toronto, Ontario M5S 2S1, Canada
The neuropeptide CCK is closely associated with the dopamine

(DA) mesolimbic system. In order to examine any functional interaction between these neurotransmitter systems, we examined the effects of a  $\operatorname{CCK}_A$  antagonist (devazepide) and a  $\operatorname{CCK}_B$  antagonist (L365-260) against AMP-induced locomotor activation (LMA), stereotypy, place conditioning and palatability-induced feeding. Devazepide (0.001-0.1 mg/kg) failed to modify any of the behaviors elicited by AMP pre-treatment. L365-260 (0.01-0.1) produced a mild but non-significant increase in AMP-induced LMA. However, previous research has shown marked individual differences between rats with respect to AMP-induced behavior (Piazza et al. Science 245: 1511-1513, 1989; Sills and Vaccarino. Psychopharmacol 105: 329-334, 1991). L365-260 produced a significant potentiation of AMP-induced LMA in low AMP responders (veh = 611  $\pm$  52; L365-260 0.1 = 1182  $\pm$  223; p < 0.05) but not in high AMP responders (veh = 1032  $\pm$  44; L365-260 0.1 = 1062  $\pm$  95). L365-260 was also found to potentiate sugar intake in low but not high baseline feeders. Furthermore, L365-260 potentiated a sub-effective dose of AMP to produce a conditioned place preference, but had only inconsistent effects against AMP-induced stereotypy. Taken together, these studies suggest that L365-260 may potentiate certain DA-dependent behaviors, at least under conditions of low baseline responding

MODULATION OF 8-OHDPAT-INDUCED HYPERPHAGIA AND MODULATION OF 8-OHDPAT-INDUCED HYPERPHAGIA AND ANXIOLYSIS BY CCK-4 AND CCK-8S. H. Fink, A. Rex. Th. Barth and C. A. Marsden# (sponsor: Brain Research Association), Inst. Pharmacol. Toxicol., Charité, Humboldt University, Berlin 1040, Germany. # Dept of Physiology & Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, UK.

Cholecystokinin (CCK) receptors can be divided into CCK-A and CCK-B/gastrin receptors. CCK-A receptors show an enhanced sensitivity to CCK-8s, while those of CCK-B type display a high affinity for CCK-4 and CCK-8s. The aim of the present study was to investigate the influence of these CCK fragments on 5-HT<sub>1A</sub> receptor-mediated behavioural effects 5-HT1A agonists such as 8-OHDPAT induce hyperphagia and anxiolytic effects in suitable rat models. In contrast CCK-A receptor stimulation is known to induce hypophagia while CCK-4 has been shown to produce a proconflict effect in a test based on novelty-induced suppression of feeding in rats.

of feeding in rats.

In the present study, both CCK-4 (2 - 50 μg/kg i.p.) and CCK-8s (1 - 25 μg/kg i.p.) suppressed hyperphagia induced by 8-OHDPAT (300 μg/kg s.c.) in freely feeding rats. The anticonflict effect of 8-OHDPAT (30 μg/kg/i.p.) was also abolished by CCK-4 (2 - 100 μg/kg i.p.) and CCK-8s (0.4 - 100 μg/kg i.p.). These data indicate that CCK-4 and CCK-8s modulate 5-HT<sub>1</sub>A receptor-mediated hyperphagia and anxiolysis, respectively, and suggest a complex interaction between 5-HT<sub>1A</sub> and CCK mechanisms.

EFFECTS OF ELECTROCONVULSIVE (ECS) AND KINDLING (KIN) SHOCK ON TRH-PEPTIDES & FORCED-SWIM TEST (FST). A. Sattin\* & A.E. Pekary. Endocrinol. Rsrch, Wadsworth-UCLA & \*Antidepressant Neuropharm. Rsrch, Sepulveda-UCLA, Sepulveda, CA 91343-2099.

Both ECS and invasive electrical KIN induce synthesis of TRH and its mRNA in rat limbic forebrain regions (rev. MJ Kubek et al, Ann NY Acad To examine possible TRH-peptide roles in the antidepressant (AD) effects of seizures (SZ), we now include RIA of related tetrapeptide, TRH-Gly & FST as one measure of AD efficacy. Age 60da male S-D rats (n = 19) got sham ECS, corneal ECS or corneal KIN (Skeen et al, Soc Neurosci'90); alternate days x 3. Sequential ECS current: 50, 100 & 167 mA x 0.6s; for each KIN: 8mA x 4.0s. All ECS gave max. GM SZ. KIN rats all reached Racine stage 3/4. The 15 min pre-swim in 30cm depth, 36°, occurred 24h before 1st Rx; post-swim (5 min, 15cm): at 48h & sacrifice at 72h after last Rx. FST immobility times  $[Mean(sec) \pm SEM(N)] : Sham, 223 \pm 11(6); KIN, 267 \pm 5(5); ECS, 181 \pm 35(6)$ (KIN > Sham, p < 0.05, 2-tail t test). Increased immobility supports expected pro-depressant effect of KIN. Predicted anti-immobil. effect of ECS was too variable. This is the first report of TRH-GlyLI in hippocampus (HC): 8.3±1.1(7) & pyriform/olfactory ctx. (PYR): 28.9±9.6(7)pg/mg tissue. Like earlier reports of TRH in HC, TRH-Gly increased to 12.7±3.5(6) after KIN; to 24.1±3.1(6) after ECS. Both Rx's increased TRH-Gly to ca. 50(6) in PYR (not signif.). In present results, TRH-Gly exceeded TRH > 10-fold in PYR & > 3-7-fold in HC. Both steady-state & SZ-related processing of TRH-peptides appears to differ in these two limbic regions. THE CCK<sub>B</sub> RECEPTOR ANTAGONIST, L-365,260 DOES NOT SUBSTITUTE FOR COCAINE OR MORPHINE IN RAT MODELS OF DRUG ABUSE. F.D. Tattersall, A. Jackson, G. Bentley and M.D. Tricklebank Merck Sharp and Dohme Research Laboratories, Neuroscience

Research Centre, Terlings Park, Harlow, Essex CM20 2QR, U.K.
The CCK<sub>B</sub> receptor antagonist, L-365,260 has been reported to enhance the analgesic effect of morphine in rodents. In order to assess the ability of L-365,260 to enhance the stimulus properties of drugs of abuse, we have examined the effects of the compound in rats trained to (a) discriminate morphine from saline and (b) self-administer the stimulant, cocaine

Male Sprague-Dawley rats were trained to discriminate morphine (5 mg/kg, i.p.) from saline using a food reinforced operant technique. In substitution tests, L-365,260 (0.063 - 4 mg/kg, i.p., suspended in ethanol/carboxymethylcellulose) failed to induce morphine-appropriate responding. When given immediately before morphine (0.63 - 5 mg/kg, i.p.), L-365,260 (1 mg/kg, i.p.) also did not alter the potency of morphine to induce drug-lever responding.

For self administration studies, male Wistar rats were implanted with a chronically indwelling jugular catheter. During daily 2 h training sessions, the pressing of a lever in an operant chamber elicited a 0.1 ml injection of cocaine (0.25 mg per injection). When response rates had stabilised on an FR5 schedule of reinforcement, L-365,260 (0.3 - 10 mg/kg, dissolved in polyethylene glycol 300) was administered via the catheter immediately before the test session. Response rates were not altered by L-365,260.

Thus, the results suggest that L-365,260 is unlikely to have the stimulus properties often associated with drugs of abuse.

BLOCKING CCK-ELICITED HYPOACTIVITY IN HAMSTERS. P. Schur\* M. Espinoza, R. Flores. Dept. of Psychology, Univ. So. Colo., Pueblo, CO 81001.

Previous research has demonstrated that cholecystokinin (CCK) inhibits locomotor activity in hamsters and that CCK is co-localized in dopaminergic neurons. The present work was designed to test the effects of selective CCK and dopamine receptor antagonists on CCK elicited hypoactivity. In Experiment 1, the effects of devazepide, a CCK, receptor antagonist, and of L365,260, a CCK, receptor antagonist, and of L365,260, a CCK, receptor antagonist, on CCK elicited inhibition of running wheel activity were investigated. Group CCK (n=16) received an IP injection of CCK (25 ug/kg). Group SAL (n=16) received an IP injection of saline. On four test days, half of the animals in each group received an IP injection of devazepide (0, 0.1, 0.5, 1 mg/kg) and half received an IP injection of L365,260 (0, 0.1, 0.5, 1 mg/kg) and half received an IP injection of CCK or saline. Results indicated that devazepide attenuated CCK elicited hypoactivity in a dose related manner, but that L365,260 had no effect. Neither receptor antagonist alone affected locomotor activity. The same design was used in Experiment 2 to test the effects of SCH23390 (0, 0.1, 0.2, 0.5 mg/kg), a D<sub>1</sub> receptor antagonist, and of sulpiride (0, 5, 10, 20 mg/kg), a D<sub>2</sub> receptor antagonist, on CCK elicited hypoactivity. The results indicated that sulpiride, at a dose of 5 mg/kg, attenuated CCK elicited hypoactivity. At other doses, however, sulpiride had no effect on CCK elicited hypoactivity at any dose tested, but alone, SCH23390 suppressed locomotor activity. These results indicate that CCK's inhibitory effect on locomotor activity. These results indicate that CCK's inhibitory effect on locomotor activity. These results indicate that CCK's inhibitory effect on locomotor activity. These results indicate that CCK's inhibitory effect on locomotor activity is mediated, in part, by CCK, receptor subtypes. EFFECTS OF CHRONIC EXPOSURE TO AMPHETAMINE AND NICOTINE ON THE RESPONSE OF THE MESOLIMBIC DOPAMINE SYSTEM TO COCAINE: AN IN VIVO MICRODIALYSIS STUDY B.A. Horger. A. Valadez and S. Schenk, Dept. Psychology, Texas A&M Univ., College Station, TX 77843.

We have previously reported that preexposure to the psychostimulants amphetamine or nicotine facilitated the acquisition of cocaine self-administration by rats. In the present study we investigated whether this behavioral sensitization could be explained by a neurochemical sensitization in the mesolimbic dopamine system. Rats were preexposed with 9 daily injections of d-amphetamine SO4 (1.0 mg/kg, IP), nicotine bitartrate (0.6 mg/kg, base weight, SC) or the saline vehicle. On the tenth day a microdialysis probe was inserted into the ventral striatum and following a number of baseline dopamine determinations (1-3 pg/35 ul) the rats received an injection of cocaine HCl (15 mg/kg, IP). Samples were collected at 20 min intervals for 60 min post injection. Dopamine levels in saline pretreatment potentiated this effect. For these rats, cocaine -induced increases in synaptic dopamine levels peaked at about 450% of baseline values. In contrast, nicotine preexposure failed to potentiate the neurochemical correlate of cocaine. Rather, these rats were slightly less responsive to cocaine's ability to increase dopamine in the ventral striatum. Thus, this neurochemical correlate of cocaine cannot explain the sensitized response to cocaine's reinforcing effect produced by preexposure to nicotine.

CHRONIC COCAINE (COC) ADMINISTRATION (7 DAYS) INCREASES TYROSINE HYDROXYLASE (TH) mRNA AND ACTIVITY IN THE RAT NIGROSTRIATAL AND MESOLIMBIC DOPAMINE PATHWAYS. S.L. Vrana\*, K.E. Vrana, J.E. Smith and S.I. Dworkin. Center for Neurobiology of Drug Abuse, Dept. of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

Cocaine (COC) is a potent catecholamine reuptake blocker and has dramatic effects on neurochemical, neurophysiological and neurobehavioral characteristics of dopamine (DA) pathways. Since TH catalyzes the ratelimiting step in DA synthesis, we have investigated the consequences of COC administration on TH gene expression. Fischer 344 rats were implanted with chronic, indwelling jugular catheters through which they received saline or COC (1 mg/inf) every 8 min for 6 hr daily. This schedule of drug delivery is similar to those seen during self-administration studies Following 7 days of treatment, TH activity was significantly increased (75%) in the ventral tegmental area (VTA; mesolimbic) and 40% in the substantia nigra (SN; nigrostriatal) by cocaine treatment. Activity levels were not significantly changed in the terminal fields (nucleus accumbens and corpus striatum) by COC. Messenger RNA levels (assessed by northern blot analysis) were increased in both the VTA (65%) and SN (60%) by COC administration. These results indicate that COC can increase TH expression (mRNA and protein) in the cell bodies of the mesolimbic and nigrostriatal pathways, however, this increase is not reflected in the terminal field regions. Since the nigrostriatal pathway has not previously been implicated in COC reinforcement, these effects (in the VTA and SN) may reflect physiological responses indirectly related to the abuse potential of COC. ACTIONS OF DRUGS OF ABUSE ON REWARD-RELATED ACTIVITY IN NEURONS OF THE VENTRAL TEGMENTAL AREA AND PREFRONTAL CORTEX IN THE RAT. Kosobud, A.E.' Harris, G.C. and Chapin, J.K. Hahnemann University, Philadelphia, PA. 19102, USA.

Hahnemann University, Philadelphia, PA. 19102, USA.

Using chronically implanted microwire electrodes, the activity of multiple single neurons can be recorded simultaneously in awake, behaving animals. In the present experiments, multiple bundles containing 4-6 microwire electrodes were chronically implanted in the ventral tegmental area (VTA) and prefrontal cortex (PFC) of male rats, 450-500g. Following recovery from surgery, recordings were obtained from rats pressing a lever for sucrose reward on a fixed-ratio schedule of reinforcement. In both the VTA and PFC, units were found that showed activity changes around the time of reward, consistent with the involvement of these brain regions in reward processes. Cocaine (10 mg/kg i.p.) produced a significant increase (p<.01) in baseline firing rates in cellipercorded in both VTA (18%, n=5) and PFC (53%, n=2). These increased firing rates did not seem to be directly related to enhanced dobamine (DA), since acute injections of apomorphine (1 mg/kg i.p.) produced a significant (p<.01) decrease (36%, n=6) in baseline firing rates (VTA) and no change in PFC. Cocaine enhanced both excitation and inhibition related to reward in both brain areas (n=8, p>.01), while apomorphine enhanced activity just prior to reward onset, in VTA only (n=6, p<.01). Ethanol (.5 g/kg i.p.), like cocaine, sharpened reward-related activity, but this effect was less pronounced. Smaller changes in basal rates and patterns of reward-related activity were also observed in the VTA (23%, p<.01, n=4) during control sessions with or without saline injections, suggesting that endogenously released DA had effects similar to those seen following drug-mediated DA release. Consistent with this interpretation, haloperiol (30 μg/kg i.p.) blocked these changes. Supported by grants NS26722, AA06965, K02-AA00089 and AFOSR 90-0266.

#### 375.2

CHRONIC COCAINE TREATMENT DECREASES COCAINE-INDUCED EXTRACELLULAR DOPAMINE OVERFLOW IN THE VENTRAL TEGMENTAL AREA: IN VIVO MICRODIALYSIS STUDIES. R. Marmur, J. Chen, A. Pulles, W. Paredes, P.A, Vincent and E.L. Gardner, Departments of Psychiatry and Neuroscience, Albert Einstein College of Medicine, New York, NY 10461

We previously reported that cocaine sensitization, as manifested by enhanced extracellular nucleus accumbens (Acc) donamine (DA) content to acute cocaine challenge, does not appear to involve local neural mechanisms within the Acc (Chen et al., Soc. Neurosci. Abstr. 17:323, 1991). The present work sought to assess possible involvement of somatodendritic DA efflux in the ventral tegmental area (VTA) in the development of cocaine-induced sensitization. We treated rats with cocaine (20 mg/kg/day, i.p.) for 16 days followed by 7 days wash-out. On the 24th day rats were challenged with 40 mg/kg cocaine i.p. and extracellular DA in the VTA was measured by in vivo microdialysis. Rats treated with chronic cocaine for 16 days showed significantly decreased somatodendritic VTA DA overflow when challenged with acute cocaine as compared to drug-naive rats similarly challenged with acute cocaine. Since it has been previously suggested that increased VTA DA levels mediate the cocaine-induced inhibition of the electrophysiological activity of mesoaccumbens DA neurons (Einhorn et al., J. Neurosci. 8:100-112, 1988), the present data may indicate that cocaine sensitization is partially mediated by attenuation of recurrent inhibition produced by somatodendritic DA release in the VTA (Supported by a research grant from the Aaron Diamond Foundation).

CHRONIC COCAINE INCREASES TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE VENTRAL TEGMENTAL AREA S.Y. Chen and P.W. Kalivas\*. Department of VCAPP, Washington State University, Pullman, WA 99164-6520

We examined the levels of tyrosine hydroxylase (TH) in the ventral

We examined the levels of tyrosine hydroxylase (TH) in the ventral tegmental area (VTA), substantia nigra (SN), nucleus accumbens (NA), striatum (STR) and medial prefrontal cortex (mPFC) in occaine-sensitized rats. In the first experiment, the control group received 7 days of saline, and the remaining groups received either 6 days of saline or 6 days of cocaine (15 or 30 mg/kg, 1,p.) followed by cocaine on day 7 (15mg/kg, 1,p.). Animals were sacrificed at 2 or 24 hr after the last injection. In an additional experiment rats were given the same pretreatments but the cocaine challenge was given 3 weeks after the last daily injection and animals sacrificed 24 hr later. Locomotor activity measured on day 1 and the challenge day showed an augmented behavioral response to the cocaine challenge in all chronic cocaine treated groups. In the first experiment, Western blot analysis of TH levels showed no changes 2 hr after either acute or chronic cocaine treatment in the brain areas tested, including the VTA and NA. However, at 24 hr, both chronic cocaine-treated groups showed a 25% elevation of TH levels in the VTA. This change was seen only in the VTA and not in the SN, NA, STR or mPFC. In the late withdrawal group, there were no differences between treatment groups in TH levels in the VTA or NA. These results demonstrate that rats sensitized to cocaine show increased TH levels in the VTA 24 hr after the last injection but that levels return to normal after a 3 week withdrawal period.

# 375.6

THE EFFECTS OF COCAINE AND MORPHINE ON MESOLIMBIC NEURONS IN THE RAT. H. Zhang\* and E.A.Stein, Depts of Pharmacology and Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226.

Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226.

The mesolimbic system has been ascribed a critical role in the reinforcing properties produced by both psychomotor stimulant and opiate drugs. A common neural substrate (eg, nucleus accumbens (NAS) and olfactory tubercle (olf tub) has been suggested. However, while NAS plays an important role in both cocaine and opiate reinforcement, the critical opiate receptor(s) mediating reinforcment may be postsynaptic to the dopamine (DA) terminal. Thus, a neural circuitry of reward beyond the DA terminal appears warranted. Significant efferent projections from both the NAS and olf tub to the ventral pallidum (VP) have been described and investigations into this output have established the VP as a critical component in the expression of behaviors produced by stimulants. Thus, we examined the effects of IV cocaine (1.0 mg/kg) and morphine (0.5 mg/kg) on the spontaneous discharge rate of neurons in 2 ventral tegmental (VTA) terminal fields: NAS and olf tub, and their major efferent projection field, VP in urethane anesthetized rats. The ability of VTA stimulation to drive recorded mesolimbic neurons allowed subsequent subgroup division. In all 3 regions, neurons both excited and inhibited by VTA stimulation were observed. After systemic cocaine, excitatory and inhibitory responses seen in the NAS apparently corresponded to the VTA stimulation response direction. In olf tub, while both excitatory and inhibitory responses were seen to VTA stimulation, most of these cells showed no response to either systemic cocaine or morphine. Finally, VP neuron responses to both drugs were predominantly excitatory. Supported in part by DA 06485 to EAS.

LISURIDE REDUCES COCAINE SELF-ADMINISTRATION AND AMPHETAMINE WITHDRAWAL IN RATS L. Pulvirenti\* and G.F. Koob Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA.

The maintainance of intravenous (IV) self-administration of psychostimulant drugs in rats seems to depend upon activation of dopamine (DA) receptors within mesolimbic areas, while the withdrawal phase is thought to be associated with a state of relative DA hypofunction. The effects of administration of lisuride (a direct DA D2 receptor agonist) were therefore studied in rats trained to lever press for IV cocaine self-administration (0.75 mg/kg/inj.; 3hr/day) and during withdrawal from self-administration of high doses of amphetamine. Acute pretreatment with lisuride (0; 0.025; 0.1; 0.2; 0.4 mg/kg IP) produced a dose-dependent decrease in cocaine intake. Lisuride also prevented the increase in responses observed when saline was substituted for cocaine. Rats withdrawing from chronic exposure to high doses of amphetamine (15hr/day x 10 days; average intake 7.37 mg/kg/day) experienced a state of psychomotor retardation as measured by reduction of spontaneous locomotor activity and increased catalepsy 48 and 96 hrs after discontinuation of access to the drug. Subchronic administration of lisuride during the withdrawal phase (0.2 mg/kg IP twice daily) prevented the occurrence of such changes. These results suggest that lisuride may reduce cocaine-seeking behavior and some behavioral signs of amphetamine withdrawal and warrant further studies on the effect of lisuride in psychostimulant addiction in humans.

## 375.9

THE EFFECT OF HALOPERIDOL DECANOATE AND ALPHA-FLUPENTHIXOL DECANOATE ON COCAINE SELF-ADMINISTRATION IN RATS. N.R. Richardson\*, A.M. Smith and D.C.S. Roberts. Department of Psychology, Carleton University, Ottawa, Canada, K1S 5B6

The effect of decanoate forms of haloperidol (HAL) and alpha-flupenthixol ( $\alpha$ -FLU) on cocaine self-administration were evaluated using FR 1 and progessive ratio (PR) schedules. Rats were implanted with chronically indwelling IV cannulae and trained to self-administer cocaine (0.6 mg/inj) during daily 5 h sessions until a stable baseline was established. A single IM injection of either HAL (2.5 mg) or  $\alpha$ -FLU (2.0 mg) produced an increase in cocaine intake on an FR 1 which was maximal after 3-4 days and diminished slowly over the next several days. Separate groups of animals showed a decrease in breaking points on the PR schedule with a similar time course.

The PK schedule with a similar time course. These data demonstrate that one injection of the decanoate form of either HAL or  $\alpha$ -FLU can reduce the reinforcing effects of cocaine for up to a week. While the use of neuroleptics in the treatment of cocaine abuse remains controversial, the use of a depot administration circumvents one issue, that of patient compliance. (Supported by NIDA contract no. 271-90-7401)

MODELING COCAINE SELF-ADMINISTRATION IN RATS WITH REWARDING MFB STIMULATION: EFFECTS OF RACLOPRIDE AND SCH23390. E. McCaskill\*, A. Foster, and J.R Stellar, Dept. of Psychology, Northeastern University, Boston, MA. 02115.

Recently it has been established that self-administration behaviors can be modeled with rewarding medial forebrain bundle (MFB) stimulation administered in an unconventional like waveform (Franklin et Abstracts:15:1092,1989 and McCaskill et al. NSAbstracts: 17:489.11,1991). We challenged rats working in this paradigm under various stimulation parameters (current, waveform duration) with D1 and D2 blocking drugs (SCH23390, .002-.025 mg/kg; Raclopride, .003-.08 mg/kg). In comparison to rats running on the standard rate-frequency curve-shift method, rats engaging in self-administration of self-stimulation appear to be more sensitive to either D1 or D2 receptor blockade. Evidence for the classic self-administration response enhancing effects of dopamine receptor blockade was found and is related to changes in stimulation current which was also previously reported to increase response rate and therefore average stimulation density. The effects of dopamine receptor blockade are also discussed in terms of other changes in response pattern and in relation to aversive side-effects of MFB stimulation.

ROLE OF DOPAMINE RECEPTOR SUBTYPES IN THE DEVELOPMENT OF COCAIME-INDUCED BEHAVIORAL SENSITIZATION. B. A. Mattingly\*. T.Hart, K. Lim, and C. Perkins. Department of Psychology, Morehead State University, Morehead, KY 40351.

Previous research indicates that the development of behavioral sensitization to amphetamine and apomorphine may be prevented by concurrent treatments with dopamine D,, but not D,, antagonists. The objective of the present study was to extend this receptor analysis to include the development of behavioral sensitization to cocaine. In two experiments, male Wistar rats (250-350g) were injected daily for 4 to 7 days with either cocaine (15 mg/kg, IP) or vehicle in combination with either the D, dopamine antagonist, SCH 23390 (0.3 or 0.5 mg/kg) or the D, dopamine antagonist, sulpiride (100 mg/kg, IP). After the daily injections, the rats were tested for locomotor activity in photocell arenas. At the conclusion of this sub-chronic pretreatment phase, all rats were tested for locomotor activity following a challenge injection of cocaine (15 mg/kg) alone. Consistent with previous results, cocaine produced a progressively greater increase in activity over the first few treatment days. Moreover, this acute cocaine-induced increase in activity was blocked by concurrent treatments with either SCH 23390 or sulpiride. In contrast to previous work with amphetamine and apomorphine, however, concurrent SCH23390 treatments did not prevent the development of behavioral sensitization. That is, rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine did not differ from rats pretreated with SCH 23390 and cocaine for 4-7 days when given a cocaine challenge

# AGING AND BEHAVIOR I

DO DEVELOPMENTAL BRAIN LESIONS HASTEN AGING IN BRAIN FUNCTION? M.H. Lee and A. Rabe. New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

In experimental animals, perturbations during prenatal or early postnatal brain development by teratogenic agents can lead to increased functional impairment in old age. The age-associated decline may be either premature appearance of functional decline typical of normal aging, or recurrence of specific symptoms that appeared after treatment but from which the animal recovered.

(1) Rats with micrencephaly, resulting from prenatal exposure to methylazoxymethanol, showed exaggerated decline in spatial navigation during the second half of their lives. This age-associated decline could be partially prevented by normal neocortical tissue transplants given in infancy. (2) C57BL/6 mice, exposed to a single dose of ethanol in utero, exhibited an augmented retention deficit of spatial location at middle-age (Rabe & Dumas, Soc. Neurosci. Abstr. 1992). (3) Wallace et al. (*Dev. Psychobiol.* 5:35, 1972) reported recurrence in old age of abnormalities in motor and emotional behavior which had appeared following neonatal cerebellar irradiation, but from which the rats had recovered. These phenomena appear to be related and suggest that developmental lesions reduce "redundancy" in the brain (Glassman, Neurosci. Biobehav. Rev. 11:275, 1987), and thus hasten functional aging. Structural disorganization resulting from the early treatment may play an additional role in the accelerated functional decline.

ANALYSIS OF AGE-RELATED MOTOR ACTIVITY IN SQUIRREL MONKEYS. L.E.DeLanney<sup>10</sup>, B.Tabrizi<sup>2</sup>, J.W.Langston<sup>1</sup>, <sup>1</sup>California Parkinson's Foundation, San Jose, CA 95128; <sup>2</sup>Dept. Indust. Engineering, Stanford University, CA 94045.

MPTP-treated squirrel monkeys provide a model strikingly similar to idiopathic Parkinson's disease, an age-associated affliction. However, development of parkinsonian behavioral traits is more subtle in squirrel monkeys than in humans and some Old World monkeys. Therefore a monkeys than in humans and some Old world monkeys. Inerefore a principal objective was to assess motoric behavior in untreated and treated monkeys of various ages. To achieve this objective two devices were designed and built. The first was an infra-red beam, computerized activity cage to record movements per minute (mpm). The second device was a grasp-and-pull treat retrieval apparatus (tr).

The results obtained through the use of these two techniques to date are:

a) Each animal has its own characteristic mom, unvarying with the time of day or year. b) Caged MPTP-treated animals that might not show overt parkinsonism, show significant and persistent drops in their mom; c) Moms of naive animals can be correlated with their ages, when known, and may become predictive of ages of feral animals. d) Young animals (3 yr) master the tr task in as short a time as 2 hours of training and retain memory, on re-challenge, for as long as 3 months to date. e) Each animal's technique to retrieve is unique. f) MPTP-treated animals without prior training have been refractory to tr learning. g) A future objective is to assess tr in older

We conclude that from these two systems we obtain quantifiable data to permit correlations of movements with age, with MPTP treatment and with neurochemistries and neuropathologies, and permit analysis of refined motor performance achieved after mastery of the treat retrieval.

COGNITIVE FUNCTION AND AGING IN THE DOG E. Head, E. Weiner, T. Yearwood, C. Reid, E. Thomas and N.W. Milgram\* Life Sciences Division, Scarborough Campus, U. Toronto, Scarborough, Ontario Canada, M1C 1A4

Although it is widely believed that cognitive function deteriorates during aging in the dog, no previous studies have been addressed to this topic. We first compare old (> 8 years), middle aged (5-8), and young (< 5) dogs on tests of object discrimination learning, reversal learning and recognition memory using a delayed non-matching-to-sample (DNMS) paradigm. As has been found with other species, there were no significant age differences in discrimination learning - but there was considerably greater variability in the oldest group of animals, and the correlation between chronological age and errors to criterion was also significant. Again, sistent with work on other species, we did find significant differences betw old and young animals in reversal learning. In DNMS testing there were more marked differences, and none of the oldest group (n=7) were able to learn the task when the delay was set at 10 seconds. In contrast, 7 out of 8 young dogs and 6 out of 8 middle aged dogs successfully achieved criterion levels of accuracy at a 10 second delay. Examination of the response patterns revealed that dogs typically tested position strategies in their attempts to solve the problems presented. The aged dogs were often much more unwilling to discard this strategy and this counted for some of the age differences

We have also tested dogs on a spatial version of the DNMS test involving presentation of a sample stimulus, followed by a test in which the correct resp is to approach the side opposite to that of the sample. Overall, this proved to be a much easier task for dogs, and some of the oldest animals have already achieved a high degree of accuracy (>80% correct) at delays as high as 90 seconds. For the dog, in contrast to the primate, the spatial memory task appears to be much easier than the object recognition task.

BRAIN CHOLINERGIC, NORADRENERGIC AND OPIOID CORRELATES OF SPATIAL MEMORY IMPAIRMENT IN AGED RAT. T.D. Smith\*1, M. Gallagher2 and F.M. Leslie

<sup>1</sup>Dept. of Pharmacology, University of California, Irvine, CA 92717 and <sup>2</sup>Dept. of Psychology, University of North Carolina at Chapel

Age-related alterations in the density of cholinergic, noradrenergic and opioid receptor (sub)types and/or reuptake binding sites were simultaneously examined in discrete forebrain regions of Long-Evans simultaneously examined in discrete forebrain regions of Long-Evans rats using quantitative autoradiography. Spatial memory performance was assessed in the Morris water maze. Age-associated neurochemical changes were distinguished from specific memory-dependent alterations by correlating density of binding sites with behavioral performance of aged rats. Regionally widespread age-related changes were observed in density of muscarinic and nicotinic cholinergic binding sites, white significant differences in noradrenergic markers were limited to limbic structures. Although the density of some binding sites decreased, others remained constant or even increased. With respect to the opioid receptors, the only significant change observed was a decrease in the density of mu binding sites in the basal ganglia. Thus, these data argue against a hypothesis that a generalized decline in neurochemical integrity occurs with advancing age. Furthermore, an increased density of cholinergic M1 and age. Furthermore, an increased density of cholinergic M1 and age. Purtnermore, an increased density of cholling in η and noradrenergic β2 binding sites in hippocampal subfields and piriform cortex, respectively, was correlated with impaired spatial memory. These results indicate that synergistic changes in cholinergic and noradrenergic systems may, in part, lead to impairments in mnemonic

CORRELATION BETWEEN MORPHOLOGICAL AND BEHAVIORAL DEFICITS IN AN ADULT RAT MODEL FOR AGING.

DEFICITS IN AN ADULT RAT MODEL FOR AGING.

T. Kadar, I. Arbel, S. Dachir, M. Silbermann, and A. Levy Faculty of Medicine, Technion, Haifa. Israel Inst. for Biol. Res., Ness-Ziona, ISRAEL. The use of old rats in the study of age related cognitive deficits does not enable a follow up of the aging changes as they evolve, and is impaired by physical incapacitation of part of the subjects. Using the radial arm maze, we have shown recently high correlation between cognitive impairments and morphological impairments and morphological alterations at the hippocampal formation, in Wistar rats aging 3 to 24 months. In an attempt to establish the adult rat as an animal model for the study of progressive aging processes, the present study monitored the acquisition of the Morris water maze in a large group of 12 months old Fischer rats, in comparison to a group of 3 months old rats. Two distinguished populations of impaired vs unimpaired rats were found among adult rats. The degree of behavioral impairment was correlated in individual animals with the severity of hippocampal damage, quantitative morphometric analysis based the morphometric analysis in the hippocampus. It is suggested that the adult 12-months old rat may serve as a preferred animal model for the study of the mechanism of agerelated cognitive and morphological deficits.

DISCRIMINATION AND EXPECTANCY IN ADULT AND OLD RATS. A. Caprioli\*, O. Ghirardi, A. Pietromarchi, M.T. Ramacci, #L. Angelucci, Institute for Research on Senescence, Sigma Tau, Pomezia; #Pharmacology II, La Sapienza Univ. of Rome, Italy

The role of aging in discrimination and expectancy was measured in an independent two-choice reaction time test in Fischer-344 adult (5-7 months) and old (22-24 months) rats. Each rat discriminated between two stimuli, light and tone (Exp. 1), and between 4000Hz Tone 1 (T1) and 12000Hz Tone 2 (T2) (Exp. 2) by releasing one of the two correspondent levers, left or right. Expectancy to each stimulus was modified by varying the probability of stimulus occurrence (10%, 50%, 90%, 100%). Reaction time (RT), percent of correct responses (CRs), discriminability (D) and response bias criterion based on CRs were measured. In Exp. 1, between two different stimulus modalities, the auditory RT in old rats was slower than in adult rats, but there was no difference in the other measures between the two age groups. In Exp. 2, within the tone modalities, the CRs and D were lower in old rats than in adult rats. Stimulus probability influenced RTs and CRs in both experiments and in both age groups. In fact, RTs and CRs to the more probable stimulus were faster and higher, respectively, than those to the less probable stimulus for both visual and auditory stimuli and T1 and T2 stimuli. The results demonstrated that rats developed an expectancy about the probability of future events. Rats shifted their response bias and decreased RT to the more probable stimulus. Expectancy was not remarkably different between the two age groups.

AGE-RELATED CHANGES IN THE PHARMACOLOGI-CAL IMPROVEMENT OF RETENTION IN SENESCENCE ACCELERATED MOUSE (SAM). I.F. Flood\*and J.E. Morley, Geriatric Research Education and Clinical Center (GRECC), VA Medical Center and Department of Internal Medicine, Division of Geriatric Medicine, Louis University School of Medicine, St. Louis, MO 63106.

The P/8 line of the senescence accelerated mouse (SAM) model exhibits characteristics of aging early in its lifespan including an early onset of impaired learning and memory which becomes progressively worse with age. Age-matched controls of the R/1 line do not show impaired learning and memory. We now report age-related changes in the drug dosage needed to improve one week retention in the P/8 but not R/1 line. The results indicate that 8 month old P/8 mice show a reduced sensitivity to memory enhancing doses of cholinomimetics and an increased sensitivity to a serotonin antagonist compared to 4 month old mice. By 12 months of age, improvement of retention required higher doses of cholinomimetics and lower doses of the serotonin antagonist. Higher doses of an opioid antagonist and a dopamine agonist were needed to improve retention in 12 month old mice. A GABA antagonist and an alpha noradrenergic agonist improved retention at the same dose in mice 4, 8 and 12 months of age.

COMPLEX ENVIRONMENTAL CUES AND EXTENDED TRAINING AMELIORATE AGE-RELATED SPATIAL LEARNING DEFICITS IN F-344
RATS. C.F. Mactutus\*, H.L. Black and R.M. Booze. College of Pharmacy, Tobacco
& Health Res. Inst. & University of Kentucky Medical Center, Lexington, KY 40546-0236

Age-related deficits in spatial learning are often interpreted as reflecting a decline in the capacity to acquire and/or utilize spatial information. Conflicting reports on the influence of simplification of extramaze environmental cues on spatial learning prompted us to examine the role of visual disability as a contributing factor. The demonstration of an improvement in spatial learning as a function of complex and/or redundant environmental stimuli would strongly argue against a major role of visual decline in cognitive processing. Aged Fischer-344 male and female rats, were trained in the Morris water maze task, beginning at 28 months of age. Animals were trained under enriched and standard environmental cue conditions in a cross-over design to permit assessment of the factors of cue complexity, extended training, and their interaction. For each training condition one male and one female from each litter (ns=8) received 8, 8, and 4 training trials on three consecutive days followed by a probe test trial at the end of every day. Cue complexity condition did not differentially affect the decrease in training trial latency, although the decline in latency was primarily linear, without any quadratic component typical of young adult animals. Quadrant preference scores, although not reflecting an effect of cue complexity during an animals' initial training cue condition, demonstrated an enhancement as a function of cue complexity and continued training. Annulus crossings demonstrated a similar, though not statistically significant, pattern. In sum, although neither cue complexity or extended training increased performance to that expected of young adult animals, the influence of cue complexity is counter to a functional role of visual impairment in the aged-related decline in spatial learning capacity. (Supported by UKMCRF and AG 10747).

AIT-082 MODULATES WORKING MEMORY IN NORMAL MICE AND MICE WITH AGE-INDUCED MEMORY DEFICITS, R.F. Ritzmann\*, B. Pirzadeh, C. Melchior and A. Glasky. Advanced Immuno-Therapeutics, Irvine, CA, and Olive View Medical Center, Sylmar, CA

Since working memory has been shown to be impaired in early and middle stages of Alzheimer's disease, it is of therapeutic interest to develop a drug that can restore working memory. The win-shift foraging paradigm is a single trial T-maze learning model of working memory. By increasing the interval between successive trials, the length of time a mouse can remember can be determined (i.e. duration of memory trace). AIT-082 is a derivative of the purine hypoxanthine that has been evaluated for its effects on working memory in the win-shift model.

for its effects on working memory in the win-shift model.

In young adult Swiss Webster mice, AIT-082 increased the duration of the memory trace from 60 seconds to 120 seconds. AIT-082 is active over a dose range from 0.5 to 60.0 mg/kg with the optimal effect at 20 mg/kg. The onset of action is rapid (1 hour) and lasts for more than 7 days after a single administration of 60 mg/kg. Tolerance does not develop after 18 days of treatment and the memory enhancing effects are blocked by atropine, a known cholinergic antagonist. AIT-082 also increased the duration of the memory trace in young adult C57BI/6 mice

increased the duration of the memory trace in young adult C57Bl/6 mice In 11 month old Swiss Webster mice, we found (a) 70% of these mice had a moderate deficit, (b) 15% had a mild deficit and (c) 15% could not remember at 10 seconds. AIT-082 increased the duration of the memory trace in subjects with a mild and moderate working memory deficits.

trace in subjects with a mild and moderate working memory deficits.

In summary, the win-shift foraging model can detect strain and age-induced differences in working memory which are reversed by ATT-082.

INCREASED SENSITIVITY TO AVERSIVE MOTIVATION IN MICE FOLLOWING SHORT- AND LONG-TERM DIETARY RESTRICTION.

M. J. Forster\* and H. Lal. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107.

Male C57BL/6NNia, DBA/2NNia and B6D2F1 mice fed ad libitum or reared under dietary restriction (60% of ad libitum beginning at 4 months) were tested for sensitivity to aversive motivation when approximately 9, 19, or 27 months old. In order to estimate the contributions of short- and long-term diet restriction, half of the mice within the ad libitum (A) and chronic restricted (R) conditions were switched to the opposite condition one month prior to the test (yielding RR, RA, AA, and AR groups). Aversive motivation was measured according to a spatial preference procedure [Biomed. Environ. Sci., 4:144, 1991] in which seven intensities of scrambled, constant current shock (from 0 to 0.24 mA) were presented through the grid floor of a small chamber in durations of up to 20 s. The mouse could minimize shock in the chamber by moving a short distance (8 cm or less) to the opposite side and remaining there for the rest of each shock period. Comparison of aversion functions (% safe time x current intensity) failed to suggest remarkable changes with age for any of the genotypes or diet groups. However, there was a profound (2-5-fold) increase in shock aversion for RR groups relative to AA groups within all age x genotype combinations. Comparison to AR and RA groups suggested that both long- and short-term restriction of diet contributed to the overall differences These findings indicate that diet restriction may substantially modify neural processing of aversive stimuli and, thereby, influence the outcome of studies of learning and an memory processes using aversively-motivated behavioral paradigms. Supported by NIA grants AG07695 (HL) and AG06182 (MJF).

AGE RELATED CHANGES OF SOCIAL MEMORY/RECOGNITION IN MALE FISCHER 344 RATS. X.-B. Guan\* and D.E. Dluzen. Department of Anatomy, Northeastern Ohio Universities College of Medicine, Rootsown, OH 44272. Two different habituation-dishabituation test paradigms were used to

evaluate differences in social memory/recognition among 3, 15 and 22 month old male Fischer 344 rats (N=8/group). In Experiment I, males received three 2 minute exposures to the same stimulus ovariectomized female, followed by three 2 minute exposures to a different stimulus female with an inter-trial interval of 6 minutes. Investigation (mean ± SEM in seconds) of the stimulus animal upon first exposure (trial 1) was not significantly different among the three groups: 19.56±4.04, 22.93±4.02 and 28.14±2.02 for the 3, 15 and 22 month old animals, respectively. All groups showed a habituation response with investigation times decreasing on trials 2 and 3. Investigation times were not significantly different among the 3 groups on trial  $3:9.47\pm3.34, 5.66\pm2.88$  and  $3.30\pm1.11$ , respectively. Introduction of a different stimulus female on trial 4 resulted in significant differences with investigation times of the 3 month animals (22.83 ± 4.09) being significantly greater than both the 15(12.77 ± 2.40) and 22(5.27±1.09) month animals. The 15 and 22 month animals failed to differ statistically. In Experiment II, all animals received two trials with different stimulus females used in each trial. Respective investigation times for the 3, 15 and 22 month animals on trial 1 vs 2 were  $14.02\pm2.71$  vs  $22.76\pm4.00$ ,  $19.91\pm2.10$  vs  $11.33\pm1.75$  and  $24.79\pm1.55$  vs  $5.65\pm0.94$ . Taken together, these results demonstrate that the 22 month old rats show habituation, but markedly defecient dishabituation responses compared to the 3 month old animals, while the performance of the 15 month animals was intermediate. These results suggest an age dependent decrement in social memory/recognition processes in the male Fischer 344 rat.

## 376.10

EMBRYONIC ALCOHOL EXPOSURE AND AGING: A DELETERIOUS FUNCTIONAL INTERACTION. A.Rabe\* and R.Dumas. NY State Institute for Basic Research in Developmental Disabilities. Staten Island. NY 10314.

An embryonic exposure to alcohol produced a deficit in longterm memory that became prominent already at middle-age. No readily obvious brain abnormalities accompanied the functional defect. Young adult (3 mo), middle-aged (12 mo) and old (24 mo) C57Bl/6J mice of both sexes were trained on a place learning task in a cross-shaped water maze. The alcohol groups (n=62) of these three ages were offspring of dams who had been exposed to a single teratogenic (5.8 g/kg) dose of ethyl alcohol by gavage on gestation day 9 (plug = GD 1). The 3 control groups (n=54) came from dams exposed to dextrose. Testing consisted of (a) 6 acquisition trials a day for 6 consecutive days, and (b) 6 retention trials on a single day 24 days later. The middle-aged and old alcohol-exposed mice displayed a marked retention deficit on 3 different measures of performance, whereas the young alcohol animals showed only a modest loss on one measure. No alcoholexposed group was inferior to controls on the acquisition trials, nor did they show a retention loss after a 24-hour interval.

## 376.12

INTERACTIONS BETWEEN THE EFFECTS OF AGE AND OF BENZODIAZEPINE RECEPTOR LIGANDS ON ATTENTION: TAXING PROCESSING CAPACITY. J. McGaughy and M. Sarter. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

We have previously demonstrated that the performance of differently aged rats in simple and choice reaction time tasks shows considerable face validity in terms of modelling the effects of human aging and practice on vigilance performance. However, in contrast to the human situation, performance in the choice reaction time task did not more powerfully separate age-related differences, and the effects of age did not reliably interact with the effects of compounds known to augment the age-related attentional deficits in humans. As it is assumed that inadequate task demands on processing capacity formed the basis of these limitations, differently aged rats were trained and tested in a signal detection paradigm that required the animals to detect differently salient signals and, in addition, to process propositional response rules. Performance in this task varied with age, treatment with benzodiazepine receptor ligands affected performance, and these effects interacted with age. These results suggest that by increasing the demands on processing capacity, more valid behavioral paradigms of the agerelated impairments in attentional abilities can be developed. Such paradigms are required for the examination of hypotheses about the neuronal basis of age-related impairments in cognitive abilities.

CHRONIC INFUSIONS OF GABA INTO THE MEDIAL PREFRONTAL CORTEX INDUCE SPATIAL ALTERNATION DEFICITS IN AGED RATS. S. Meneses <sup>1</sup>, Galicia, O., Hernández, E. and S. Brailowsky.\* Instituto de Fisiología Celular and <sup>1</sup> Facultad de Psicología, U.N.A.M., 04510 México D.F., MEXICO.

Lesions of the prefrontal cortex (PFCx) may produce severe deficits in spatial delayed alternation tasks (DAT). Previous experiments have demonstrated that GABA infusions into the PFCx of young rats affect the execution of a spatial DAT learned before the infusion (Behav. Brain Res., 40:81, 1990). It has been proposed that functions associated with the PFCx could change as a consequence of aging. In the present study we investigate wether chronic infusions of GABA into the PFCx of aged rats induce deficits similar to that observed in young rats in a spatial DAT.

Fifteen 26-month old rats were trained to alternate the arms in a T-maze (win-shift paradigm); after the criterion for acquisition was reached, cortical infusions of GABA (50  $\mu$ g/ $\mu$ l/hr) or saline were applied through osmotic minipumps for 7 days. Rats were tested on the T-maze during this period.

The results indicate that old rats need more sessions to acquire the task than young rats. GABA infusion into the PFCx produce severe deficits in spatial alternation tasks similar to that observed in young rats. After the infusion period the performance rapidly recovered.

The results can be taken to suggest that the PFCx in aged rats is important for the retention of previously learned spatial delayed alternation tasks.

THE EFFECT OF LONG TERM DEPRENYL ADMINISTRATION ON BEHAVIOR AND BRAIN FUNCTION IN AGED RATS P. C. Bickford\*, C. Heron, G.M. Rose, N. Miniclier, K. Poth, A.M-Y. Lin, M. Friedemann, and G.A. Gerhardt Medical Research Service, VAMC; Depts. of Pharmacology and Psychiatry, and Neurosciences Training Program UCHSC, Denver, CO 80220.

Deprenyl has been shown to increase the longevity of rats. This study was undertaken to examine the effects of deprenyl on behavior and was indictated to examine the effects of depends on behavior and brain function. Twenty F344 rats were treated with I-deprenyl (0.5 mg/kg/day) via the drinking water starting at 12 months of age, twenty age-matched rats served as controls. The mean lifespan was extended in the deprenyl group from  $51.5 \pm 3.7$  months to  $59.0 \pm 1.4$  months (p<0.05 two-tailed Student's t-test). At 18 months of age, the rats were tested on a series of motor coordination tasks and a motor learning task that involves learning to negotiate unevenly spaced pegs on a runway. Performance on these motor coordination and learning tasks was not different between l-deprenyl and control aged rats. There was also no difference when the rats were tested for spatial learning in the Morris water maze at 24 months of age. At 28 months of age the remaining rats (6 deprenyl and 4 controls) were studied with *in vivo* electrochemistry using carbon fiber electrodes coated with nafion. The clearance of exogenously applied norepinephrine (NE) from the extracellular space of the cerebellar cortex was not different between the two aged groups. The ability of nomifensine to increase the t<sub>1/2</sub> of the NE signal, however, which is normally lost in aged controls was intact in the deprenyl treated group. (Supported by Vet.Admin. Med. Res. Service, USPHS grants AG04418, AG10755, AG06434, AG00441 and AFAR).

AGE-ASSOCIATED CHANGES IN PROPERTIES BASAL FOREBRAIN NEURONS PROJECTING TO THE J. Tanaka\* M. Nomura, FRONTAL CORTEX IN THE RAT J. Nishimura and F. Kimura. Dept. of Physiol., Saitama Med. Sch., Saitama 350-04, \*Dept of Physiol., Yokohama City Univ. Sch. of Med., Yokohama 236, Japan

We recorded extracellular single-unit activities of neurons that were antidromically activated by electrical stimulation of the frontal cortex, in the nucleus basalis area of urethane-anesthetized young (4-5 months old) and aged (30 months old) male rats, and compared them in an attempt to find changes with age in various electrophysiological properties of these neurons. Post-antidromical orthodromic excitatory responses were found, and the number of neurons showing such an orthodromic excitation was significantly smaller in aged rats. There was no significant difference in the threshold, latency or the conduction velocity of antidromic activation, or in the spontaneous firing rate of driven cells between the two groups of subjects. The absolute cells between the two groups of subjects. The absolute refractory period was significantly longer and the incidence of successful antidromic propergation into the somatodendritic complex was significantly lower in aged rats. The data provide evidence that cortically projecting putative cholinergic neurons in the nucleus basalis area undergo dramatic changes with age in their physiological properties.

NICOTINIC MODULATION OF RAT HIGH VOLTAGE SPINDLING AND EEG. R.J. Radek\*, S. Rvu, Neuroscience, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, II. 60064-3500

Increased incidence of a spike and wave pattern termed high voltage spindling (HVS) has been observed from the EEG of 8 and 22 month old rats and may be associated with cognitive deficits of aged rats. Since nicotine improves cognitive performance in rats, this study sought to determine whether nicotinic agents modulate HVS activity in a way consistent with effects on learning and memory tasks. Wistar (10 month) rats were surgically implanted with recording electrodes over the frontal and parietal cortices. HVS were identified from EEG recordings as regular

60 minute recording sessions. Rats were administered (i.p.) either nicotinine, mecamylamine or dimethylpiperazinium (DMPP) immediately before recordings commenced.

Nicotine desynchronized the EEG in all rats. Nicotine at 0.62 and 1.9  $\mu$ Mol/kg lowered HVS time 83% and 94% from baseline (p<0.05, n=9), respectively. Cotinine (0.62, 1.9  $\mu$ Mol/kg), a major metabolite of nicotine, had no effect on Cotinine (0.62, 1.9 µMol/kg), a major metabolite of nicotine, had no effect on spindling (n=9). Mecamylamine (15.0 µMol/kg), a nicotinic antagonist which impairs rat water maze performance (Decker and Majchrzak, Psychopharm., in press), increased HVS time 76% from baseline (p<0.05, n=6). A lower dose of mecamylamine (5.0 µMol/kg) did not significantly increase HVS but blocked nicotine (0.62 µMol/kg) induced attenuation of HVS. DMPP (0.62, 1.9, and 6.2 µMol/kg), a nicotinic agent which does not cross the blood brain barrier, had no effect on HVS (n=6). Cotinine, Mecamylamine, and DMPP had no pronounced effect on EEG amplitudes during non-spindling EEG. These results suggest that HVS are sensitive to those centrally active nicotinic agenties and antagonists that possess. sensitive to those centrally active nicotinic agonists and antagonists that possess specific cognitive enhancing or impairing properties.

BEHAVIORAL DEFICITS AND MORPHOLOGICAL CHANGES IN RENAVIONAL DEFICITS AND MORPHOLOGICAL CHANGES IN FRONTOPARIETAL CORTEX AFTER BASAL FOREBRAIN LESIONS IN ADULT AND AGED RATS. C.L. Wellman\*, S.F. Logue, and D.R. Sengelaub. Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405. Regressive changes in aging may interact with other degenerative processes to produce unique neuropathologies. We are using basal

processes to produce unique neuropathologies. We are using basis forebrain lesions in adult and aged rats to determine the contribution and potential interaction of age and depletion of cholinergic input on frontoparietal morphology and function. Six-, 13-, and 21-month-old rats received sham or ibotenic acid lesions of the basal forebrain. One month after surgery, rats were trained in a radial arm maze task, which has been shown to be sensitive to alterations in the forebrain cholinergic system, until of their first 5 visits were to baited arms on 4 of 5 consecutive trials. Number of trials to criterion and average between-trials errors did not vary with age. However, lesioned rats took significantly longer to reach criterion and made more between-trials errors than did sham-lesioned rats. Lesioned and made more between-traits errors rain did sham-lesioned rats. Lesioned aged rats entered significantly fewer arms per trial and were significantly slower than were the other groups. Average within-trials errors were unrelated to either age or treatment. Three months after surgery, cellular changes in frontoparietal cortex (Frontal I and Parietal I) were assessed in frozen sectioned, cresylecht violet stained material. Neuronal soma area in frozen sectioned, cresylecht violet stained material. Neuronal soma area in amina II-III increased from 9 to 16 months of age, but decreased from 16 to 24 months of age. Across groups, basal forebrain lesions differentially affected smaller neurons. Lesions increased soma size in lamina IV of both cortical areas of 9-month-old rats, and decreased soma size in lamina II-III in both areas and lamina IV of parietal cortex in 16-month-old rats. In 24-month-old lesioned rats, soma size increased in lamina IV in both areas and decreased in lamina IV of parietal cortex. Thus, while changes in soma size across ages are unrelated to maze performance, basal forebrain lesions produce correlated changes in cortical morphology and behavior.

EEG CORRELATES OF AGE RELATED BEHAVIORAL IMPAIRMENTS P. Curzon\* M.W.Decker, R.J. Radek, Neuroscience, Pharmaceutical Products
Division, Abbott Laboratories, Abbott Park, IL. 60064-3500

EEG changes related to senesence have been identified in humans and in animal

models of aging. Increased incidence of a spike and wave pattern termed high voltage spindling (HVS) has been observed in the EEG record of aged rats. Aged rats have impairments in a variety of learning and memory tasks, but as yet there is no established link between increases of HVS and these impairments. The purpose of this study was to determine whether HVS in 8 (mature) and 22 (aged) month old rats is associated with deficits on a spatial discrimination version of the Morris water

Wistar rats were surgically implanted with recording electrodes over the frontal and parietal cortices. After recovery, the rats were trained for 5 days in the water maze to distinguish between a visible escape platform and a platform that sank under the weight of the rat. Contacts with the incorrect (sinking) platform were scored as

weight of the rat. Contacts with the incorrect (sinking) platform were scored as errors. After completion of the water maze experiments, 60 minute EEG recording sessions were conducted during which HVS durations (in sec.) were determined for each rat. Spindles were identified as regular 6-10 hz burst complexes.

Mean errors on days 4 and 5 of water maze training in mature (n=9) and aged (n=10) rats were 2.0±0.3 and 3.7±0.6, respectively (p<0.05). Mean HVS times of mature and aged rats were 50.3±25.9 and 58.4±13.5, respectively (p>0.05). Two rats in the mature group expressed high levels of spindling which substantially increased the mean for this group. Correlation coefficient (r) from linear regression analysis between HVS and day 4/5 water maze errors was 0.73 (p<0.05) for aged rats, and 0.43 (p>0.05) for mature rats. The 2 mature rats with high spindling times had the poorest training performance among rats in the mature group. These results suggest the existence of a correlation between increased incidence of HVS in aged rats and behavioral impairments in a soatial discrimination water maze task. behavioral impairments in a spatial discrimination water maze task.

MAGNETIC SOURCE IMAGING (MSI):

MAGNETIC SOURCE IMAGING (MSI):
DIRECT INTRA-OPERATIVE VERIFICATION OF NEUROMAGNETIC LOCALIZATIONS OF SOMATOSENSORY EVOKED AND SLOW WAVE FIELDS USING A LARGE ARRAY BIOMAGNETOMETER. C.C. Gallen\*, B.J. Schwartz, T. Waltz, B. Copeland, D.S. Sobel, M. Aung and F.E. Bloom The Scripps Research Institute (TSRI), La Jolla, CA 92037

Presurgical localization of critical brain functional and dysfunctional control of the control of th

al regions potentially allows more effective planning to avoid imporan regions potentiarly amove more effective planning to avoid important regions in the surgical approach to pathology. Noninvasive neuro-magnetic localization of the postcentral gyrus in humans was accomplished using a large array (37-channel) biomagnetometer in a rapid (60-120 min) procedure allowing localization of the large 45-70 evoked field generated by a painless tactile stimulus. These localiza-tions computed in a 3-dimensional Cartesian coordinate system were then merged with Magnetic Resonance Imaging (MRI) scans of the subjects via common fiducial points to allow visualization of functional and dysfunctional activity relative to brain structures and le-sions in a procedure referred to as Magnetic Source Imaging (MSI). Five subjects were subsequently taken to surgery and intraoperative corticography was used for localization of the central sulcus, median nerve somatosensory or motor stimulation and slow wave activities. In all cases neuromagnetic and corticographic methods agreed completely on the localization of the central sulcus relative to lesion. The MSI and corticographic localizations of the median nerve area agreed within 3-15 mm. Areas implicated as producing slow wave activity on MSI were verified intraoperatively. These combined data proved useful in presurgical planning.

P300 ACTIVATION TIME: A NON-INVASIVE TOOL FOR PRE-SURGICAL EVALUATION IN TEMPORAL LOBE EPILEPSY I. D. Dunn\*, A. Rupert, R. Leroy, and G. Moushegian. Electrophysiology Lab, Parkland Memorial Hospital,

Dallas, TX 75235 Evidence suggests that the P300 long-latency auditory evoked response is related to activity in the temporal and Okada, Kaufman, & Williamson, 1983). These areas are often the source of focal abnormalities in epileptic orten the source of focal adhormalities in epileptic patients. This study describes a new measure, "P300 Activation Time" (AT), that varies according to the hemisphere of epileptic pathology, and identifies left temporal lobe patients with better accuracy than absolute

P300 AT was calculated for each hemisphere in 20 normal subjects, 19 left temporal lobectomy (LTLs), and 8 right temporal lobectomy (RTLs) patients prior to surgery. Absolute latencies at 18 electrode sites did not differ between groups at any site. However, the difference in AT between the hemispheres varied significantly between groups (df=2, p $\langle$ .0005). Eleven (58%) of the LTLs had a left hemispheric AT that extended more than 10 ms over the right hemispheric AT. None of the normal subjects, and only 1 (12%) of the RTLs exhibited this pattern. These findings suggest that the non-invasive measure, P300 AT, is potentially more useful in the pre-surgical evaluation of epilepsy patients than absolute latency.

CORPUS STRIATUM ABNORMALITY IN MAGNETIC RESONANCE IMAGING (MRI) AND N-ACETYL-ASPARTATE (NAA) IN THE URINE AS A CAUSE OF CONVULSIONS IN A 2 YEAR OLD BOY. P.B.Toft, O.Pryds, O.Kiehn\*, E.Christensen, H.Lou, O.Henriksen. Danish Research Center of Magnetic Resonance, KKHH, DK-2650 Hvidovre.

A nine mo old boy presented with febrile, generalized, tonic-clonic convulsions. Unprovoked convulsions from the age of 15 mo. He sat alone 9 mo old and walked 18 mo old. Electroencephalogram was normal and seizures could be controlled with valproat. Urine examination at the age of two y showed large amounts of NAA (6.1 g/L urine). He was suspected to have a mild form of Canavan disease and MRI and 1H-MR-spectroscopy (MRS) were done to reveal the white matter changes typical for this disease. MRI showed perfectly normal white matter, but the globus pallidus, putamen and caudate nucleus gave high-signal intensity in the T2 weighted images. MRS of 8 mL occipital lobe gave [NAA]=11.9 (9.5), [creatine]=5.4 (6.3), [choline]=0.9 (1.6) mmol/L brain tissue, results from a four year old boy with non-metabolic convulsions in (). The elevated NAA/Cho is consistent with earlier findings in Canavan disease but the classical form is excluded by the normal white matter pattern in MRI. This case suggests that the corpus striatum may have an influence on seizure susceptibility. Urine examination for NAA should be done in children with seizures.

THE HUMAN EPILEPTIC FOCUS STUDIED BY SIMULTANEOUS LASER DOPPLER FLOWMETRY, MICRODIALYSIS AND ELECTROCORTICOGRAPHY. E.Ronne-Engström<sup>1+</sup>, H.Carlson<sup>1</sup>, S.Blom<sup>2</sup>, R.Flink<sup>2</sup>, B.Spännare<sup>1</sup>, U. Ungersted<sup>13</sup> and L.Hillered<sup>1</sup> Depts.of Neurosurgery<sup>1</sup>, Clin. Neurophysiology<sup>2</sup>, University of Uppsala and Dept. of Pharmacology3, Karolinska Institute, Stockholm, Sweden.

Stockholm, Sweden.

The aim of this study was to monitor pathophysiological changes in the human epileptic focus by the combination of laser doppler flowmetry (LDF), intracerebral microdialysis (MD) and electrocorticography (ECoG).

Five patients with medically intractable epilepsy, undergoing resection of the epileptic focus, were included in the study. The preoperative localization of the focus was confirmed intraoperatively by ECoG together with electrical stimulation of the cortex. A combined subdural electrode and LDF probe was placed at the focus. During the ECoG and blood flow measurements MD from the epileptogenic

Electrical stimulation elicited epileptiform activity with a duration of 12-120 sec in all the patients. Epileptiform activity was associated with changes in the regional cortical blood flow of 0,7-7 times the basal leves. In four patients there were increases and in one patient a decrease of blood flow. The blood flow returned to preseizure levels within 2-6 min. Heart rate and systemic blood pressure remained constant. MD was performed in cortex of the temporal lobe in one patient, hippocampus in three patients and in both cortex and hippocampus in one patient. Epileptiform activity with a duration of 40 sec or longer, was associated with an increase in aspartate, glutamate and serine, with a maximum of 2.6, 2.1 and 2.5 times the basal level, respectively.

In conclusion, the combination of LDF, MD and ECoG appears to be a

powerful tool for studying temporal relationships between changes of blood flow transmitter release and electrophysiological events in the human epileptic focus.

## 377.4

REGIONAL CEREBRAL BLOOD FLOW MAPPING IN EPILEPTICS USING TECHNETIUM-99M-HMPAO SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY. J. S. Cheon\*, Department of Neuropsychiatry Kosin Medical College and Gospel Hospital, Pusan 602-702,

The cerebral blood flow in the epilepsy was reported to be increased during ictal phase and decreased during interiotal period, while others insisted of interiotal hyperperfusion due to subictal neuronal hyperactivity.

In this study, the cerebral blood flows of seventeen idiopathic epileptics were compared with those of twelve neurotic controls measured by 99m Tc-HMPAO SPECT to observe the perfusion changes in the interictal phase.

As compared to the controls whose activity counts per frame were decreased to 5.5±3.3%(mean±S.D.), 29.4% of idiopathic epileptics showed hyperperfusion to 10.9  $\pm$  7.2% (P(0.05), and 70.6% showed hypoperfusion to  $10.8\pm3.3\%$ P(0.001). Most foci of maximal blood flow change were located at the right hemisphere and posterior part. The foci in the anterior part could be found more in controls (33.3%), while posterior foci in epileptics(88.2%). The degree of EEG abnormalities was not correlated with the activity counts per frame, while the abnormal findings mostly composed of high voltage(88.9%) spike or slow waves re notified more in the hyperperfusion group(80.8%) than in the hypoperfusion group(41.7%).

# 377.6

DIFFERENCES IN LONG-TERM RECOGNITION BETWEEN LEFT AND RIGHT TEMPORAL EPILEPTICS AFTER SODIUM AMYTAL INJECTION. J. Robidoux\*, I. Rouleau, & R. Labrecque. Neurology Service, Notre-Dame Hospital, Montréal and Université du Québec à Montréal.

The intracarotid sodium amytal test (ISA) was used in 51 patients with intractable unilateral temporal lobe epilepsy (LT=30, RT=21) prior to surgery. To bypass the problem of aphasia and to enable comparison of performance after left and right injection, common objects were presented visually (color pictures) and tactually, and their naming was prevented. Memory was assessed by yes/no recognition. Two measures were obtained for each patient: (1) short-term recognition (STR) of stimuli presented and recognized during the effect of the drug; (2) long-term recognition (LTR) of the same stimuli when normal brain function has resumed (20min after the injection). Statistical analysis revealed that, although both LT and RT patients' scores improved from STR to LTR after the injection ipsilateral to the epileptic focus and worsened after contralateral injection, both effects were more pronounced in LT patients. The present findings suggest that the use of color pictures and concrete objects presented tactually, although theoretically amenable to dual coding, is more discriminative for LT than for RT patients. The hemispheric processing of these stimuli is discussed as a function of the sensory modality of presentation, language dominance and methodological factors such as the duration of stimulus presentation and the level of sedation at the begining of memory testing assessed by the percentage of delta waves on EEG.

COHERENCE IN HUMAN SURDURAL EEG HAS FINE STRUCTURE IN SPACE AND TIME. T.H. Bullock\*, J.Z. Achimowicz and M.C. McClung. Dept. Neurosci. & Neurobiology Unit, Scripps Inst. Oceanog., U.C.S.D., La Jolla, CA 92093-0201.

Analyzing EEGs from subdural strips of 8 electrodes 5-10 mm apart in epileptic

patients, power, phase and coherence (C) spectra were computed in alert, sleep and seizure states, none with sharp peaks in power. C was averaged for bands 2-5, 5-8, seizure states, none with sharp peaks in power. C was averaged for bands 2-5, 5-8, 8-13, 13-20, 20-35, 35-50 Hz. Spatial fine structure is suggested by pooling C values for all pairs of the same electrode distance. C vs distance falls from 1.0 within a small distance to 0.5-0.7 at 5 mm, 0.3-0.5 at 10 mm, 0.2-0.4 at 20 mm, approaching at 50-70 mm the level for 2 independent noise sources. Variance is high in 5 s samples but means are reproducible in 30-120 s samples. Different bands are remarkably similar. Higher frequency (F) bands tend to show slightly lower C values at a given distance. Slow wave sleep has slightly higher values in all F bands but the visual impression of synchronization is due mainly to a difference in power spectrum, not to true population synchrony. Seizures show markedly higher C values at all Fs. The highly local nature of C is also shown by maps of values for adjacent electrode pairs 10 mm apart in strips of 8, values may be quite difference in coordingus pairs but consistent over time of 8. values may be quite different for continguous pairs but consistent over time of 8. values may be quite different for continguous pairs but consistent over time. of C is also shown by maps of values for adjacent electrode pairs 10 mm apart in strips of 8: values may be quite different for contiguous pairs but consistent over time. Remarkably, the profile of values along a strip is similar across bands. Steepness of fall with distance is also locally different and similar between bands. Temporal fine structure was studied by computing C with autoregressive models in 1 s epochs and examining the time series of values over 100-200 s for given pairs and states. Histograms of values in sleep, alertness and seizure are unimodal and quasi-normal. Variation of C over time is high but often departs from the null hypothesis of being a totally random sequence. By first lag auto-correlation and by comparing the power spectrum of the time series with shuffled versions, we find most 10 mm pairs have significant power at one, two or there periods between I s and 60 s less often in time series from of the time series with stuffined versions, we find most 10 mm pairs have significant power at one, two or three periods between 7 s and 60 s, less often in time series from higher bands. Maps show some adjacent pairs have peaks at the same periods, but most do not. Low-passed time series of C values from different EEG bands show high cross-correlation; from adjacent pairs some do, many do not. Ccan be quite local and change slowly over many seconds. The similarity in Cacross bands in several respects does not support an EEG model of discrete oscillators.

## 377.9

Kindling Characteristics and Susceptibility to Status Epilepticus of Various Temporal Lobe Structures. <u>D. C. McIntyre\*C. Dufresne, M. E. Kelly and P. Mohapel.</u> Dept. of Psychology, Carleton Univ., Ottawa, Canada, KIS 5B6.

Previously Le Gal La Salle (<u>Kindling 2</u>, 1981) demonstrated heterogeneity between various amygdala nuclei in their rates of kindling. We extend this observation by comparing the kindling profiles of 3 amygdala nuclei (basolateral, central, medial), and the piriform (Pir) and perirhinal (Prh) cortex. Thirty Sprague-Dawley rats were stimulated daily from one site until 6 generalized stage-5 convulsions were triggered. The different sites were compared for local afterdischarge (AD) thresholds, kindling rates and convulsion characteristics, including latency and duration of clonus and AD duration. Susceptibility to status epilepticus (SE) was then assessed for each of the 5 structures by subjecting the kindled site to 60 min of electrical stimulation at an intensity 10% above the AD threshold.

The rate of kindling in the Prh was significantly faster than The rate of kinding in the Prh was significantly laster than either the basolateral or medial n., and only slightly faster than the central n. and Pir. In addition, the latency to onset of forelimb clonus was significantly shorter in the Prh, suggesting it may be functionally closer to the mechanisms of secondary generalization than the amygdala nuclei or the Pir. Despite being slower to kindle than the other structures, provocation of the basolateral n. most easily triggered SE. These data suggest that the mechanisms and circuits associated with development of kindling and SE likely are not the same. same.

TWO TYPES OF NEUROPLASTICITIES IN THE KINDLING PHENOMENON II, PHARMACOLOGICAL STUDY. Y. MINABE\* and K. EMORI. Toyama Med. & Pharma. Univ. and Tanino Gozan Hospital, Toyama 930-01, Japan.

Using the low-frequency kindling technique, we studied the effects of chronic MK-801 (0.05 and 0.1 mg/kg/day i.p.), scopolamine (SCOP, 0.5 and 1.0 mg) and methamphetamine (MAP, 6 mg) administration on hippocampal kindling seizure development. The number of stimulating pulses required for the triggering of epileptic afterdischarge (pulse-number threshold, PNT) was used as an indicator of the seizure threshold. PNT, afterdischarge duration (ADD) and behavioral seizure stage (BSS) of each induced seizure in the initial stage of kindling, kindling rate, seizure parameters at the completion of kindling were recorded and compared to the values of each saline-treated control group.

MK-801 administration prior to each electrical stimulation selectively and significantly increased PNT in the initial stage of kindling without affecting other seizure parameters. Although SCOP 1.0 mg/kg increased PNT at the 5th stimulation compared to control, no other significant changes of the seizure parameters were found by

1.0 mg/kg increased PNI at the 5th stimulation compared to control, no other significant changes of the seizure parameters were found by SCOP. Chronic pretreatment of MAP caused a selective and significant decrease of PNT of the first two stimulations in the kindling process. Taken together with the previous studies, these fesults support our findings that physiological and pharmacological characteristics of the reduction of seizure threshold, but not of the development of induced seizures in the hippocampal kindling process are quite cimiler to those of long term perturbations. are quite similar to those of long-term potentiation.

INFORMATION PROCESSING DURING ABSENCE EPILEPSY IN RATS. W.H.I.M. Drinkenburg, A.M.L. Coenen, J. Duysens', and E.L.J.M. van I Dept. of Psychology, University of Nijmegen, Nijmegen, The Netherlands.

A characteristic of absence epilepsy is the temporary change in consciousness. Processes controlling these changes are largely unknown; however, visual evoked potentials, registered during spike-wave discharges (SWD), showed that sensory transmission, the first part of information processing, is altered.

The present study investigates a second part: stimulus evaluation, which requires also some memory retrieval. For this purpose, 10 male, adult rats of the WAG/Rij strain were permanently implanted with fronto-cortical EEG electrodes and mildly deprived of food. WAG/Rij rats frequently show spontaneously occurring SWD and are considered as a valid animal model for absence epilepsy.

Firstly, all rats were habituated to auditory stimuli of 8kHz with a 20 dB low (L)

and a 45 dB high (H) intensity by repeatedly presenting these tones without any contingencies. Next, these neutral stimuli were presented during SWD and effects on epileptic activity were analyzed. In the second part, conditioning of these tones took place with a classical procedure: for one group (n=5) each presentation of the high intensity tone was followed by a food reward (H\*), while presentation of the low intensity tone was never rewarded (L'). For the other group rewarding was reversed (H and L\*). Tones were then presented during SWD and effects on ongoing epileptic activity were again analyzed.

Only in about 10 % of the presentations of the neutral tones (both H and L) SWD were influenced. After conditioning 77.7% of the H\* and 60.7% of the L\* presentations totally stopped ongoing SWD, whereas the previously not rewarded stimuli H and L stopped SWD in only 37.2 and 36.5%.

It is therefore concluded that, notwithstanding the fact that disturbances in information processing during SWD exist, evaluation of external stimuli to a certain degree still takes place.

TWO TYPES OF NEUROPLASTICITIES IN THE KINDLING PHENOMENON I, EFFECTS OF STIMULUS-INTERVAL. <u>K. EMORI\* and Y. MINABE</u>. Tanino Gozan Hospital and Toyama Med. & Pharm. Univ., Toyama 930-01, Japan.

Recently we reported that pulse-number threshold (PNT), the number of stimulating pulses required for the triggering of epileptic afterdischarge (AD) and the indicator of seizure threshold in the low-frequency hippocampus kindling, dropped profoundly in the initial stage of kindling and the behavioral seizure stage (BSS) developed in the later stage (Brain Res. 509: 355-357, 1990). We assume that there is a possibility that there are two types of neuroplasticities in the kindling appearance, which are independent of each other is the is a possibility that there are two types of neuroplasticities in the kindling phenomenon which are independent of each other, i.e. the early type involving the decrease of seizure threshold and the late type involving the development of BSS. The advantage of our procedure is that we get a quantitative seizure threshold measure during a single stimulation train, whereas the conventional trainintensity procedure requires the delivery of at least several trains and can not neglect the influence of repetitive sub-threshold testing stimuli. In this study we further provided the dissociation of seizure threshold (PNT) changes and the increases in strength in HP kindling. During the kindling process, PNT showed a sudden decrease at the early stage; in contrast, BSS increased in the later stage. After the completion of kindling, a 4week interval elevated PNT significantly compared to the value at the completion of kindling, whereas BSS showed no regression. A 2-week interval after the first 5 AD-triggering stimulations elevated PNT of the 6th stimulation significantly without affecting BSS and AD duration compared to the values of the no-interval group and PNT dropped again by the following a few stimulations. A 2-week interval after 10 AD-triggering stimulations failed to elevate PNT.

# 377 12

ABSENCE OF NEURONAL DEATH IN KINDLING: A STUDY WITH THE CUPRIC SILVER DEGENERATION STAIN. M. Khurgel<sup>1\*</sup>, R.C. Switzer<sup>2</sup>, G.C. Teskey<sup>3</sup>, A.E. Spiller<sup>3</sup>, R.J. Racine<sup>3</sup> and G.O. Ivy<sup>1</sup>. Dept. Anatomy and Cell Biology, Univ. of Toronto, Scarborough, ON M1C 1A4, Neurosci. Assoc., Knoxville, TN 37922 & <sup>3</sup>Dept. Psychology, McMaster Univ, Hamilton, ON L8S 1B9.

It is controversial whether or not kindling results in neuronal degeneration. We have studied this question with a sensitive cupric silver degeneration stain. Rats were implanted with electrodes in the right amygdala and, after 4 weeks, kindled until the first stage 5 seizure. Rats were subsequently sacrificed at 3, 12, 24, 48, 72 hr, and 7 d. Brain sections were stained with the cupric silver method and were processed for GFAP and vimentin (Vim) immunoreactivity (IR). The silver stain revealed a pattern of degenerative changes which was similar for all animals, including electrode implanted controls. Traces of degeneration were, in most instances, unilateral to the implantation site and were confined to fiber tracts: dorsomedial part of corpus callosum, internal capsule and fimbria. There was no evidence of degenerating neurons or their immediate processes anywhere along the neuraxis. Nevertheless, a prominent increase in GFAP and Vim IR was present in astrocytes in the amygdala/piriform region bilaterally. Taken together, the evidence suggests that kindling does not result in neuronal death and that in this preparation astrocytes react with dramatic cytoskeletal changes to signals other than neuronal degeneration. Supported by NSERC.

NORADRENERGIC REGULATION OF ELECTROSHOCK-INDUCED FOREBRAIN AND BRAINSTEM SEIZURES IN RATS. <u>C. Wang\*, P. K. Mishra<sup>1</sup>, P. C. Jobe<sup>1</sup> and R. A. Browning</u>, Dept. of Physiol. Southern Illinois Univ. Sch. of Med., Carbondale, IL 62901 and <sup>1</sup>Dept. of Basic Sci. Univ. of Illinois Coll. of Med. Peoria, IL 61656.

Previous studies have shown that facial and forelimb (F&F) clonic convulsions emanate from the forebrain, while tonic hindlimb extensor (THE) convulsions emanate from the brainstem. Inasmuch as norepinephrine (NE) has been shown to exert seizure attenuating effects in a wide variety of animal models of epilepsy, it was of interest to determine if the noradrenergic terminal fields of the forebrain and of the brainstem exert differential effects on these two types of convulsions. In the present study we examined this question by evaluating electroshock-induced F&F clonus and THE convulsions in Sprague-Dawley and Genetically Epilepsy Prona tats 2 weeks to 2 months after one of the following 6-hydroxydopamine (6-OHDA) treatments: (1) neonatal intracisternal (depleting forebrain and spinal cord NE); (2) dorsal noradrenergic bundle (depleting forebrain Ne only); (4) A-1 medullary (depleting brainstem and spinal cord NE only) and (5) intrathecal (depleting spinal cord NE only). Neonatal intracisternal 6-OHDA significantly increased the incidence of THE convulsions in adult rats. Treatments that depleted forebrain NE predominantly (i.e. dorsal bundle and MFB 6-OHDA) were found to alter neither F&F clonus nor THE convulsions. Depletion of brainstem and/or spinal cord NE (A-1 or intrathecal 6-OHDA) treatments) facilitated THE convulsions. These results suggest that forebrain NE regulates neither electroshock-induced F&F clonus nor THE convulsions, while brainstem and/or spinal cord NE regulates THE convulsions. Inasmuch as whole brain NE depletion has been shown to facilitate eletroshock-induced F&F clonus in other studies, it is possible that brainstem NE regulates both forebrain and brainstem seizures. Such a possibility is currently under investigation (Supported by NHI grant NS 22672).

SEIZURE EXPERIENCE ALTERS THE DEVELOPMENT OF SEIZURE SEVER-ITY IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR). <u>S.M. Lasley\*</u>, <u>M.C. Green and P.C. Jobe</u>. Dept. Basic Sciences, U. Illinois Coll. of Medicine, Peoria. II. 61656.

Past work (Reigel et al., Epilepsy Res., 1989) has shown that the ontogeny of sound-induced seizure activity in GEPRs develops primarily within the 3rd and 4th postnatal weeks when audiogenic stimulation is applied to previously untested (UT) animals. The current study was conducted to determine the effect of repetitive audiogenic seizure (AGS) induction on seizure ontogeny in moderately severe (clonic) seizure GEPRs (GEPR-3s). The moderate nature of GEPR-3 seizures permits a ready discrimination of the enhancing or diminishing effects of repetitive induction. These animals also exhibit a trannt susceptibility to more severe tonic seizures during early development. Male GEPR-3s were exposed once daily to sound stimulation to induce AGS beginning at day 18 and continuing through day 25 with behavior quantified by Audiogenic Response Score (ARS) and latencies to wild running or convulsions. Male littermates of animals receiving daily sound stimulation were exposed to seizure induction once during this age interval to quantify behav-lor in UT animals. In rats receiving daily seizure experience, severity peaked at day 22 (8.6±1.3, N=9) before declining at later ages and was significantly greater than the value in UT animals of this age (5.4±3.0, N=9). However, this difference did not persist over days 23-25. The facilitation of AGS severity from repeated sound stimulation was accompanied by a contrasting effect on latencies to running or convulsions, which were significantly longer in seizure-experienced rats at day 22 than in UT littermates. These results suggest that repetitive seizure induction in young GEPR-3s exacerbates the development of seizure severity, producing a kindling-like effect in this model of brainstern seizures, but prolongs the latency for seizure initiation

ROLE OF HYPERTONICITY IN BLOOD-BRAIN BARRIER (BBB) OPENING AS PART OF THE MECHANISM OF ACTION OF MONOSODIUM GLUTAWATE (MSG) IN AN EXPERIMENTAL MODEL OF GENERALIZED SEIZURES IN THE RAT. A. Ferla-Velasco\*, G.G. Ortiz and M.D. Hulzar-Lara. Lab. of Exp. Neuropath. Centro Invest. Blomed. Occte. Instituto Mexicano del Seguro Social (IMSS), Guadalajara, Jal. and Div. Neurobiol., D.F. Blomed. Res. Ctr. IMSS, México, D. F. MEXICO

MSG has been used to induce convulsions in rodents when administered intraperitoneally (i.p.). Catecholamines and acetylcholine play and Important role in the physiopathology of convulsions in this model. Due to high concentrations of MSG employed by the various authors, the aim of this work was to evaluate the effects of MSG solution (sol) on the integrity of the BBB in correlation with events of the preconvulsive period when MSG is i.p. injected to adult rats. Three groups of adult Wistar rats were i.p. injected with 0.9% NaCl (PSS),MSG (5 mg/g),and NaCl (equimolar to MSG sol),respectively.Plasma osmolarity was measured at 0,15,30 and 45 min after injections in all groups; and Evans blue was injected at those times through the right carotid artery to evaluate the dye passage to brain, and craneotomy was performed under general anesthesia. Normal values osmolarity were seen when PSS was given; while those values progressively increased in the other groups, reaching at 45 min,  $463\pm14$  and  $385\pm8$  mEq/L when MSG or NaCl equimolar to MSG were injected, respectively. When PSS was given, only the areas devoided of BBB were stained at all times studied.Right cerebral hemisphere was progressively stained since 15 mln after MSG injection, while dye was evident at lesser extent in the group injected with NaCl(equimolar to MSG) at 30 and 45 min after the injection. It is concluded that hyperosmolarity of MSG sol opens the BBB allowing its free access to brain parenchyma, exerting a direct excitatory effect and influencing variations in other neurotransmitter systems, resulting in generalized cerebral hyperexcitability and convulsions

EFFECT OF 5,7-DIHYDROXYTRYPTAMINE (5,7-DHT) ON AUDIOGENIC SEIZURES IN GENETICALLY EPILEPSY-PROME RATS (GEPRs). M.A. Statnick\*, C. Wang, M. Maring, J.W. Dailey J. P.C. Jobe J., and R.A. Browning. Dept. of Physiol., Southern Illinois Univ. Sch. of Med., Carbondale, IL 62901 and 1 Dept. of Basic Sci., Univ. of Illinois Coll. of Med., Peoria, IL 61656.

Previous studies have suggested an inverse relationship between serotonin (5-HT)

Previous studies have suggested an inverse relationship between serotonin (5-HT) neurotransmission and audiogenic seizure severity (AGS) exists in the GEPR. Thus, pharmacological treatments that elevate central 5-HT were found to decrease AGS, while treatments that decrease central 5-HT increase AGS. To further assess the role of 5-HT in the regulation of AGS in the GEPR, changes in AGS following destruction of central 5-HT neurons by intracerebroventricular (i.e.v.) administration of 5,7-DHT in protriptyline-pretreated, male, moderate seizure GEPRs (GEPR-3s) were examined. Animals were anesthetized with chloral hydrate (400 mg/kg, i.p.) and injected i.c.v. with either 200 μg 5,7-DHT in saline-ascorbate (30 μl) or vehicle only (30 μl). A significant increase in seizure severity was observed at 2, 3 and 4 weeks following i.c.v. 5,7-DHT (mean scores of 5,1, 4.6 and 4.6, respectively) as compared to vehicle-injected controls (mean scores of 2.9, 2.8 and 2.9, respectively). The increase in severity was reflected by a significant increase in the incidence of tonic convulsions in 5,7-DHT (reated animals over the testing period (average incidence= 53% in treated animals compared to 0% in controls). Although the latency to the running seizure was prolonged (p<.05), no difference was observed in the latency to the clonic-convolsion. The significance of the effect of 5,7-DHT or running latency remains to be determined. Neurochemical analysis revealed significant depletion of 5-HT in structures of the telencephalon (>90%), diencephalon (>60%), midbrain (>75%) and in the pons-medulla (45%). However, no significant reductions in norepinephrine content were observed in any of the regions assayed. The present study provides further evidence that 5-HT exerts inhibitory control of AGS in the GEPR.

DIFFERENCES IN AUDIOGENIC SEIZURE PRONENESS BETWEEN LINES OF CF-1 MICE FROM DIFFERENT SUPPLIERS. <u>J.W. Collins and W.B Iturrian</u>. Pharmacology, Univ. of Georgia, Athens, GA 30602-2356. Environmental noise sensitizes CF1 mice for audiogenic seizures upon

subsequent exposure to the audiogenic stimulus (Lab. Animal Sci., 19:559, 1968). While rederiving an inbred CF1 line from Charles River CF1 parents, we surprisingly obtained 20 day old mice that uniformly exhibit audiogenic seizure proneness (asp) upon the initial auditory exposure (IAS). After failing to find environmental noise contamination, we obtained CF1 mice from another supplier (Harlan Sprague Dawley, Inc.) for comparison. Offspring between 16 and 20 days old were IAS-ed with a 102dB bell in an enclosed, circular, class chamber and tested for sensitization-dependent seizure activity upon reexposure to the same bell 2 or 3 days later. Mice derived from Crl:CF1 BR show 92% asp with 50% tonic-clonic, while those derived from Hsd:NSA (CF1) exhibit 10% asp. The F1 hybrid cross of these lines are 17% asp. Nearly all mice (98%) from all three lines showed sensitization-dependent audiogenic seizures upon the second exposure. These results confirm a genetic anomaly for differences in asp in CF1 lines from different suppliers. Moreover, the study may be of genetic relevance for the asp loci hypothesis since DBA/2 x Crl:CF1 hybrids carry an uniquely high risk for asp and calcerous pericarditis (Pharmacol. 21:144, 1979). Furthermore, 20 day old CF1 mice seizure with a unilateral IAS in the presence of reserpine or naloxone (Fed. Proc. 38:257, 1979). We conclude that the genetics of the audiogenic seizure (and asp) is much more complex and perhaps more relevant to human epilepsy than generally acknowledged. Future genetic studies should examine the linkage of neurotransmitters, calcium binding proteins, and asymmetry in seizure susceptibility.

CARDIAC HYPERTROPHY SECONDARY TO STATUS EPILEPTICUS IN THE RAT. B.K. Rubinstein, N.Y. Walton, and D.M. Treiman\*. Neurology and Research Services, Wadsworth DVAMC and Department of Neurology, UCLA School of Medicine. Los Angeles, CA. 90024.

of Medicine, Los Angeles, CA. 90024.
Status Epilepticus was induced in rats (N = 29) by sequential injections of lithium and pilocarpine. EEG was monitored continuously in the unrestrained rats via epidural screw electrodes. Seizure activity was aborted by administration of 4 mg/kg MK-801 followed by 10 mg/kg diazepam. The duration of status epilepticus varied from a few minutes to three hours. Animals were allowed to recover following status epilepticus for 8-12 days - intensive supportive care was required to enable complete recovery. Intracardiac perfusion was performed using 50 ml of saline followed by 50 ml of formalin. Hearts were excised, and all connective tissue was dissected away as well as both atria and aorta. Hearts were blotted and weighed. The hearts were then dessicated overnight and re-weighed.

Rats which had experienced status epilepticus of any duration had significantly larger hearts than did controls (wet weight t-test = 3.234, p<.01). The dried heart weights were also significantly different (t = 2.524, p<.05). The larger difference in wet versus dry weights suggests that the changes were the result of cellular hypertrophy. Control rats given all of the drugs, but not allowed to seize, did not differ from naive controls.

Cardiac hytpertrophy has not been reported, following either human or experimental status epilepticus and may represent a serious problem which deserves further study.

INCREASED SYNAPTIC NUMBERS IN THE MEDIAL PALLIUM OF FROGS WITH CISPLATIN-INDUCED EPILEPSY. K.S. Blisard\*, D.A. Harrington, K.L. Taylor. Univ. of Cincinnati Med. Ctr., Cincinnati, OH, 45267-0529.

Frogs treated with a single systemic dose (10 mg/kg) of the anticancer agent cisdiamminedichloroplatinum II (cisplatin) develop recurrent generalized seizures 3-5 weeks after the injection. Minimal histologic changes are seen in the brain by light microscopy. We quantitated the number of synapses per 100  $\mu^2$  in the telencephalic medial pallium (analogous to the mammalian hippocampus) in treated vs. control frogs. In frogs with seizures, there was a statistically significant increase in both the total number of synapses (9.7  $\pm$  0.9 for experimental vs. 7.6  $\pm$  1.4 for control) as well as in asymmetric synapses (8.2  $\pm$  0.8 vs. 6.4  $\pm$  1.4, respectively). There was little change in the number of symmetric synapses. These data may suggest that an increased level of excitatory neurotransmission contributes to the epileptic state in this model.

## EPILEPSY: BASIC MECHANISMS III

## 378.1

EFFECT OF MEDIAL SEPTAL AREA INACTIVATION ON C-FOS-LIKE PROTEINS EXPRESSION INDUCED BY SOMAN. M. Denoyer, L. Quintin\* and G. Blanchel. Dept. Neurotoxicology, C.R.S.S.A., B.P. 87, 38702, L. Tronche, France.

B.P. 87, 38702 La Tronche, France.

Status epilepticus induced by the anticholinesterase soman can elicit c-fos production in the rat brain. We have recently reported that intraseptal application of atropine reduces the typical cholinergic signs of soman. We therefore hypothesized that the blockade of convulsions would be followed by a suppression of Fos production. Thus, this study examined the effect of intraseptal injection of atropine on the distribution of c-fos-like proteins immunoreactivity related to soman treatment. Imalgene-anesthetized rats were implanted with a guide canula above the medial septal area. After recovery, atropine were injected into the septum (20 µg/0.2 µl). Twenty min later, 0.9 LD50 soman (83 µg/kg, s.c.) was administred. Two hours later, rats underwent brain perfusion-fixation. The blockade of Fos induction revealed by immunohistochemistry was significant in most of the limbic structures but also in non-limbic areas. Thus, only a very poor labelling in the piriform and entorhinal cortices was still detected. Moreover, the laminar pattern of staining observed in non-treated frontoparietal and cingulate cortices had disappeared. The present data strongly suggest that hyperactivity of the cholinoceptive cells of the medial septal area is responsible for Fos production related to soman.

# 378.3

CORTICAL INFUSIONS OF THE CHOLINERGIC ANTAGONISTS ATROPINE AND PIRENZEPINE INDUCE EPILEPTIFORM SPIKING IN THE RAT. <u>I. Payne</u>, <u>D.K. Bilkey</u>, & <u>C.L. Darlington\*</u>, Department of Psychology and the Neuroscience Centre, University of Otago, Dunedin, New Zealand.

Previous research has suggested a largely facilitatory action for the cholinergic system in epileptiform activity, with atropine and other antimuscarinics retarding or blocking these epileptiform effects. However, in this study, we have found that intracranial infusions (0.5 to 1 ul) of atropine sulphate (1 to 160 mM) into the perirhinal cortex produced high amplitude epileptiform spiking (approx 1-2 Hz) in 6 out of 7 freely moving adult Sprague Dawley rats. Spiking typically occurred within 4 minutes of the onset of the infusion and lasted for up to 4 hours, depending on dose. Similar epileptiform activity was also recorded following infusions into the temporal, frontal and pyriform cortices in 6 out of 9 rats. Concurrent recordings from regions distal to the area of infusion indicated that this activity remained largely isolated to the infused regions, although occasionally, propagation into other regions would occur and behavioural seizures identical in appearance to

Sig 1-5 amygdala kindled seizures were observed.

To determine which muscarinic receptor subtype was mediating this effect, the specific antagonists pirenzepine (M1), gallamine triethiodide (M2), and p-fluoro-Hexahydro-sila-difenidol HCl (M3) were infused. Preliminary results indicate that only pirenzepine was effective in eliciting epileptiform activity. These data suggest a functionally inhibitory (possibly mediated by activation of a GABA interneuron) cortical cholinergic pathway. This pathway appears to utilise the M1 receptor subtype. Blockade of this receptor could result in disinhibition of excitatory pathways and the generation of epileptiform activity.

## 378.2

EFFECT OF TRANSECTIONS ON SEIZURES INITIATED FROM THE DEEP PREPIRIFORM CORTEX OF RATS. R. A. Browning 1. R. Maggio and K. Gale, Dept. Pharmacology, Georgetown Univ. Sch. of Med., Wash. D.C. 20002 and 1 Dept. Physiology, Southern Illinois Univ. Sch. of Med., Carbondale, IL 62901.

Previous studies have shown that brainstem seizures can still occur after transections which separate forberain from brainstem. In the present study we sought to determine whether forebrain-evoked electrographic seizures require brainstem connections for initiation and generalization. Male Sprague-Dawley rats (295-320 g), implanted with epidural electrodes underwent one of the following transections at the pre-, mid-, or postcollicular level: (1) brainstem (core), (2) complete brain, (3) incomplete transections (sparing pathways ventral to the pretectal nuclei) or (4) hemisection. All transections were performed under ether anesthesia and seizures were initiated 3 hours later by focal infusion of bicuculline (BIC, 118 pmoles/120 nl) into the area tempestas (AT) via a previously implanted guide cannula. Bilateral forebrain electrographic seizures were found to occur in the complete absence of connections between forebrain and brainstem, showing that the brainstem is not required for forebrain-evoked seizures. Additionally, it was found that focally-evoked forebrain seizures were suppressed by "complete" transections which also interrupted connections between AT and the caudal telencephalon (entorthinal cortex, subiculum and ventrolateral hippocampus). On the other hand, sensitivity to focally-evoked forebrain seizures was restored in rats with "complete" transections if carbachol was administered together with BIC, suggesting that removal of excitation from the caudal telencephalon is responsible for the effect of the "complete" transection. The finding that "complete" brain transections setween the caudal telencephalon and AT in determining the sensitivity of AT to bicuculline. The present findings support previous studies showing that seizure substrates in the forebrain and brainstem are separable and independent.

# 378.4

ANTICONVULSANT EFFECT OF SYSTEMIC FLUOXETINE ON FOCALLY-EVOKED LIMBIC MOTOR SEIZURES IN RATS. S. Prendiville and K. Gale\* Department of Pharmacology, Georgetown University Medical Center, Washington, DC 20007

Fluoxetine, a serotonin (5HT) uptake inhibitor, was evaluated for anticonvulsant effects in a rat model of limbic motor seizures. Seizures were induced by focal microinjection of the GABA<sub>A</sub> receptor antagonist, bicuculline methiodide (118 pmol) unilaterally into 'area tempestas' (AT), an epileptogenic site in the deep prepiriform cortex of the rat. Fluoxetine (or saline in controls) was administered intraperitoneally 1 hr before seizure induction. Significant dose-dependent seizure protection was obtained with fluoxetine (5,10 and 20 mg/kg), with 50% protection following the 5 mg/kg dose. Suppression of electrographic seizure activity was concomitant with suppression of motor seizures. These findings support and extend recent observations of Dailey et al. (JPET 260:533, 1992) who found that fluoxetine exerted anticonvulsant actions against audiogenic seizures in genetically seizure-prone rats. Thus, pharmacologic enhancement of serotonergic transmission may reduce seizure susceptibility in a variety of experimental models

#### 378 5

ENHANCEMENT OF SEROTONERGIC TRANSMISSION IN SUBSTANTIA NIGRA PRODUCES ANTICONVULSANT EFFECT. A.PASINI\*, A. TORTORELLA, K. GALE. Dept. of Pharmacol., Georgetown Univ. Med. Centr., Washington, D.C. 20007

The influence of serotonin transmission in substantia nigra (SN) was studied using a rat model of focally-evoked complex partial seizures with secondary generalization. A serotonin uptake inhibitor, fluoxetine, was injected into SN. When bilaterally microinjected into SN, fluoxetine (1.75, 3.5 and 7.0 nmol.) protected against convulsive seizures evoked by the focal injection of the GABA-A receptor antagonist, bicuculline methiodide (118 pmol) into a discrete epileptogenic site in the deep prepiriform cortex, area tempestas (AT), of the rat. Injection of fluoxetine unilaterally in SN or bilaterally into a site dorsal to SN was not anticonvulsant. Focal application of a serotonin receptor agonist, TFMPP, bilaterally in SN produced anticonvulsant effects comparable to fluoxetine. The anticonvulsant action of fluoxetine (3.5 nmol.) in SN was not reversed by the application of the GABA-A receptor antagonist, bicuculline methiodide (800 pmol) in SN. These data suggest that serotonergic transmission in SN exerts a seizure suppressing action which is independent of nigral GABA-A transmission. This raises the possibility that in SN, serotonin and GABA may act in an additive and/or mutually compensatory fashion to limit the development and propagation of seizure activity generated in limbic circuits.

### 378.7

EVIDENCE FOR NORADRENERGIC REGULATION OF FOREBRAIN SEIZURES: STUDIES OF DSP-4 IN SPRAGUE-DAWLEY RATS PRETREATED WITH DESI-PRAMINE.

PRAMINE.
P.C. Jobe, R.L. Burger, A.F. Bettendorf, J.W. Dailey, C. Wang, R.A. Browning and P.K. Mishra. Univ. of Illinois College of Medicine at Peoria and SIU School of Medicine, Carbondole, II

The role of norepinephrine in regulating brainstem seizures has been well documented. These seizures are characterized by running/bouncing clonus, and tonic extensor convulsions. Evidence for noradrenergic regulation of brainstem seizures comes partially from studies with genetic models of epilepsy which are characterized by innate noradrenergic deficits, and from selective lesioning of noradrenergic neurons and/or pathways. We have previously reported that the noradrenergic neurotoxin DSP-4 (N-(2-hloroethy)-N-2-bromobenzylamine) reduces the threshold for forebrain and brainstem seizures. The present study was conducted to evaluate whether this effect of DSP-4 is due to its influence on noradrenergic system or through some other mechanism. Sixty female Sprague-Dawley rats (49-55 day old) received DSP-4 (50 mg/kg ip) after a pretreatment of desipramine (a norepinephrine reuptake inhibitor) or saline. A control group of 30 animals received two administrations of the vehicle. Three weeks later, these animals were tested for facial and forelimb clonus (FFC) threshold (convulsive current<sub>60</sub>) via corneal electroshock stimulation.

these animals were tested for facial and forelimb clonus (FFC) threshold (convulsive current, 50 via corneal electroshock stimulation.

The FFC CC<sub>50</sub> thresholds in the animals treated with saline plus DSP-4 were significantly reduced below control (vehicle-vehicle) values. Also the desipramine pretreated group failed to exhibit any reduction in FFC thresholds as indicated by the Litchfield and Wilcoxon test. These observations provide additional support for the noradrenergic hypothesis of forebrain seizure regulation. Supported in part by NIH grant # NS22672.

## 378.9

Medial Thalamus: A possible pacemaker site for the generation of spike and wave discharges induced by gamma-hydroxybutyric acid in rats. P.K. Banerjee\* and O.C. SneadIII, Dept. and Div. pf Neurology, Chilrens Hosp. Of LA, Sch. of Med., USC, Los Angeles, CA 90027.

Gamma-hydroxybutyric acid(GHB) is a naturally occuring compound which induces experimentaly absence seizures in rats(Snead, Epilepsia 29:361, 1988). It is generally believed that the 10% frequency bilaterally synchronous spike wave discharges(SWD) that characterize absence seizures arise due to abnormal thalamocortical oscillations. We have earlier reported that specific thalamic(VPL/VPM, medial and reticularthalamus) and cortical outer layer of frontal ctx) areas which participate in the generation of SWD induced by GHB constitute thalamocortical circuitry for the GHB model(Banerjee et.al, 55 Neurosci. Abs. 1/7, 1606, 1991). The purpose of the present study was to investigate whether any of the thalamic acts as pacemaker site for the generation of SWD. For this porpose we lesioned the SWD from the unle sioned thalamic sand recorded the SWD from the unle sioned thalamic sand recorded the SWD from the unle sioned thalamic sand recorded the SWD from the unle sioned thalamic sand cortical sites; alesions in the subcortical and cortical leads. In tredicular nucleus lesioned animals, SWD was not reduced. In the VPL/VPM lesioned group, neither SWD was abolished nor its duration was affected. These results suggest that MT may act as a pacemaker site in the GHB model of absence seizures.

#### 378.6

CONVERSION OF EEG FROM DISCRETE TO CONTINUOUS SEIZURE ACTIVITY CAUSED BY ELEVATION OF BRAIN GABA DURING EXPERIMENTAL STATUS EPILEPTICUS. N.Y. Walton\* and D.M. Treiman. Neurology and Research Services, Wadsworth DVAMC and Department of Neurology, UCLA School of Medicine, Los Angeles, CA 90024. We have reported that the EEG during untreated status epilepticus

We have reported that the EEG during untreated status epilepticus progresses from a pattern of discrete seizures to one of continuous ictal activity (Epilepsy Res 1990, 5:49-60) and that brain GABA levels increase progressively during status in the rat (Exp Neurol 1990, 108:61-70).

Rats were prepared with recording electrodes and cortical cobalt lesions. When the lesion became epileptogenic status was induced by injection of 5.5 mmol/kg homocysteine thiolactone. Tiagabine was injected IP after the second generalized tonic-clonic seizure (GTCS). EEG was monitored for 30 minutes following tiagabine injection, then the animals were anesthetized and blood and brain samples obtained.

The anticonvulsant effect of tiagabine was evident almost immediately - rats receiving 10 mg/kg or more had no further GTCS. However, within 15-20 minutes, the EEG began to display a continuous ictal pattern, consisting of rhythmic 3 Hz activity as well as spiking. This model rarely converts to a continuously ictal pattern in less than one hour following saline treatment, and the rapid conversion observed here was striking. We hypothesize that GABA receptor desensitization may be responsible for this, and may also cause the conversion in untreated status epilepticus.

IMAGING OF SEIZURE SPREAD ACROSS CORTEX OF THE PERFUSED GUINEA-PIG BRAIN. P. Federico\*, S.G. Borg, and B.A. MacVicar. Neuroscience Research Group. The University of Calvary. Calvary. Alberta 77N 4N1 CANADA.

Research Group, The University of Calgary, Calgary, Alberta T2N 4N1 CANADA.

Neuronal activity in the guinea-pig isolated whole brain preparation is associated with detectable intrinsic optical signals. We used video imaging of reflectance changes combined with extracellular recordings to examine seizure spread across cortex of this preparation. Entorhinal cortex (EC) stimulation (5 Hz, 10 sec) decreased tissue reflectance in the EC in an area 2 - 3 mm around the stimulation site. This reflectance change recovered within 1 min after stimulation. After several stimulation trials in some preparations, seizure activity was evoked along with a persistent, large amplitude optical signal that was initially restricted to the EC for 10 This optical signal then spread over 20 sec to the medial amygdala via the medial EC/subiculum. In some experiments, seizure activity was evoked in the EC or posterior piriform cortex by lateral olfactory tract stimulation (5 Hz, 10 sec). When seizure propagation occurred, it was directed toward the medial amygdala with the same time course as observed previously. Perfusion of the GABA, antagonist bicucculline (20 or 100  $\mu$ M) resulted in spontaneous seizure activity in the EC that spread to the medial amygdala following the same path and time course as seizures evoked by electrical stimulation alone. Occasionally, spontaneous seizures were initiated in the posterior perirhinal cortex which later propagated anteriorly along the perirhinal cortex and also toward the entorhinal, amygdalar, and piriform cortices. Perfusion of the GABA<sub>B</sub> antagonist 2-hydroxysaclofen (100  $\mu$ M) increased the area of a stimulus-induced seizure focus, while having no consistent effect on seizure propagation. Therefore, seizure spread across cortex can be examined using intrinsic imaging techniques. This spread is characteristically directed toward the medial

amygdala and might be shaped by GABA, as opposed to GABA<sub>8</sub> receptor activation.

## 378.10

DIFFERENTIAL PARTICIPATION OF INFERIOR COLLICULUS SUBNU-CLEI IN THE NMDA-DEPENDENT AUDIOGENIC SEIZURES ELICITA-TION. N. Garcia-Cairasco\* and V.C. Terra. Department of Physiology, Ribeirão Preto School of Medicine, University of São Paulo, 14049, Ribeirão Preto-SP-Brazil.

Neurochemical alterations in the inferior colliculus (IC) include both GABA and NMDA, in audiogenic seizure (AS) susceptible rats. Because central (CIC) and cortical (CXIC) IC subnuclei seem to play a different role in AS, the present experiments were developed to compare AS sensitization by NMDA of AS resistant (R) rats and blockade of AS by NMDA antagonists in AS susceptible (S) rats, in CIC and CXIC. AS were evaluated by means of a quantitative behavioral cluster analysis (Garcia-Cairasco et al., Behav.Brain Res.48:49-56,1992, NMDA (2.0, 2.5 and 3.0µg/0.2µl) or phosphate buffer(PB;0.2µl) were microinjected unilaterally into CIC (n=30) and CXIC (n=35) 15 minutes before sound stimulation (110 dB) in R rats. AP7 (3.0 µg/0.2µl) or PB (0.2µl/side) were microinjected unilaterally 1 minute before NMDA in R rats(n=16), and bilaterally, 15 minutes before sound stimulation in S ratis(n=15). NMDa induced spontaneous AS-like behaviors at 2.5 and 3.0 µg/0.2µl(p<0.01). Also 2.5 µg/0.2µl NMDA was best potentiated by the sound, mimicking AS when it was applied into CXIC nucleus. Moreover, NMDA induced contralateral spontaneous tonic AS in CIC and bilateral spontaneous AS in the CXIC. In both subnuclei, the generalization was observed during the sound stimulation. AP7 blocked completely AS in S animals when applied into the CIC(p<0.01) and partially when applied into the CXIC(p<0.01). These results suggest that CIC and CXIC may have a NMDA-dependent epileptogenicity and that they play a different role in the sensorimotor transduction involved in AS.

# IN VIVO MAPPING OF KAINIC ACID INDUCED SEIZURES WITH VOLTAGE SENSITIVE DYE.

D.S. SACKS and R.M. DASHEIFF. Dept. of Veteran Affairs, VAMC, University Dr., Pgh, Pa, 15240 and Univ. of Pittsburgh Epilepsy Center.

The functional relationship between electrical activity and brain function is a central concern in the study of epilepsy. By mapping the electrical activity of the neural pathways involved in the propagation of seizures, new structure-function relationships can be uncovered. The voltage sensitive dye (VSD) diO-C(2)-5 was used as a marker of this electrical activity during kainic acid (KA) induced seizures in awake animals. This technique when coupled with computerized image analysis, (Seizure, in press) allows a histological survey of the brain's neural activity during the dye injection period. The rats received either i.p. kainic acid (12 mg/kg) + saline vehicle, or saline alone prior to dye injection. EEG activity was recorded via hippocampal electrodes and the dye injection timed to coincide with seizure activity. The neural activity of the septum, amygdala, anterior thalamus, hippocampus, mammilary bodies, substantia nigra, and entorhinal, frontal and posterior cortices will be presented.

nigra, and entorhinal, frontal and posterior cortices will be presented.
Previous work had shown that KA induces specific patterns of depolarization in the several neural structures previously surveyed. During the present study, we extend this survey to include other neural structures. It is our contention that the spatial pattern of polarization induced by the KA extend throughout the brain. The acute seizures as well as the chronic pathological changes induced by this agent have been shown to be similar to those seen in human temporal lobe epilepsy. This work lays the foundation to imaging human brain activity with VSD's labelled for PET or MRI.

### 378.13

DEVELOPMENTAL SENSITIVITY OF MODERATE AND SEVERE SEIZURE GENETICALLY EPILEPSY-PRONE RATS (GEPRs) TO FLUROTHYL SEIZURES. <u>C.E. Reigel\*</u>. Department of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

The GEPR currently exists as two independently derived colonies of rats bred to exhibit specific audiogenic seizures (AGS). GEPR-3s exhibit clonic seizures whereas GEPR-9s exhibit tonic seizures in response to sound. GEPRs also exhibit a broad seizure sensitivity to a wide variety of electrical and chemical seizure provoking modalities. A series of developmental studies suggest AGS susceptibility depends on two independent traits, the development of an AGS focus and a more general neuropathological condition functioning as a seizure propagation mechanism. This seizure propagation mechanism is hypothesized to be responsible for the extreme sensitivity of the GEPR to other seizure-provoking manipulations. Franck et al. (Epilepsia 30:1-6, 1989) demonstrated GEPR-9s to be more sensitive to flurothyl seizures prior to the age of AGS susceptibility. The purpose of the present study was to extend the findings of Franck et al. to the GEPR-3, characterize the developmental sensitivity of the seizure propagation mechanism independent of the AGS focus and to determine f the seizure propagation mechanism developmentally precedes AGS. Clonic and tonic flurothyl thresholds were determined in GEPR-9s, GEPR-3s and controls at 13, 17, 21, 25, 30 and 45 days of age, ages preceding AGS susceptibility through maturation to adult AGS traits. Unexpectedly, flurothyl induced tonic seizures in both GEPR-3s and GEPR-9s at all ages, including ages in which GEPR-9s do not exhibit tonic AGS. Flurothyl thresholds were lower in both strains of GEPR than control and lower in GEPR-9s than GEPR-3s at all ages. The seizure propagation mechanism developmentally precedes AGS susceptibility in both strains

## 378.15

CHANGES IN PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR LEVELS IN ADULT GENETICALLY EPILEPSY-PRONE RATS (GEPRs). P. J. Syapin\*, R. Medley and C. E. Reigel. Dept. of Pharmacology, Texas Tech Univ. Health Sci. Center, Lubbock, TX 79430.

The GEPR was derived from Sprague-Dawley (SD) rats by selective breeding for audiogenic seizure (AGS) susceptibility. One strain, the GEPR-9, exhibits full tonic extensor convulsions in response to sound. Recently, it was reported that astrocyte cultures prepared from neonatal GEPR-9 cortex had a reduced number of peripheral-type benzodiazepine receptor (PBR) sites compared to cultures prepared from control cortex (Ducis, et al., Brain Res. 531:318, 1990). We have measured PBR sites in the adult GEPR-9 to determine if the results from astrocyte cultures extend to in vivo conditions. Four days after an AGS, brains, kidneys and adrenals were removed from age-matched male GEPR-9s and SD control rats, quick frozen in 0.32 M sucrose, and stored at -70°C until assayed. To measure PBR sites the samples were thawed, dissected (brain only), weighed, and homogenized in 50 mM Tris-HCl buffer (pH 7.5). A washed membrane fraction was prepared and used to quantify [H<sup>2</sup>]PK11195 (0.3 - 12 nM) binding to the PBR. No statistically significant differences in either the affinity ( $K_D$ ) or binding capacity ( $K_D$ ) was found for the adrenals or cerebellum. A significant 20%-40% ase in  $B_{\text{max}}$  was found in GEPR-9 kidney, hippocampus and cerebral cortex, while a large increase in B<sub>max</sub> was observed in the olfactory bulbs. These results confirm and extend the report of Ducis et al., however the significance of these findings to the development and maintenance of ar epileptic state is presently obscured. The observed CNS changes could be either a cause or an effect of seizure susceptibility, or neither. The decrease in kidney sites may indicate an increase in stress or anxiety in the GEPR-9 line. (Supported in part by grant AA07351 to PJS)

#### 378.12

MODEL OF PARTIAL EPILEPSY IN RAT PIRIFORM CORTEX REVEALS STAGES IN THE TRANSITION FROM FOCAL EPILEPTIFORM ACTIVITY TO ELECTROGRAPHIC SEIZURES, <u>K.L.Keichum\* and L.B.Haberly</u>. Dept. of Anatomy, Univ. of Wisc., Madison, WI 53706.

IO ELECTROCAPHIC SELUCIOS. L.K. Rectaum" and L.B. Habery. Dept. of Anatomy, Univ. of Wisc., Madison, WI 53706.

An acute anaesthetized preparation has been developed in which several characteristics of partial (focal) epilepsy can be consistently reproduced: spontaneous interictal-like activity, slow spreading recruitment of adjacent cortex into the generation of epileptiform activity, and self-sustained ictal-like activity that extends into the recruited area. Afferent shock stimuli were used to pace the frequency of epileptiform events resulting from disinhibition by picrotoxin injection of a focus in ant. piriform cortex (PC) of urethane anesthetized rats. Stimulation at 1/2 Hz evoked interictal-like events similar to those occurring spontaneously at 1/3 Hz. Current source-density (CSD) analysis and multiunit recording indicated that the regenerative process underlying these events was confined to the disinhibited focus. Increasing the rate to 1 Hz resulted in a large stereotyped increase in the amplitude of the epileptiform field potential in successive trials which propagated across post. PC at approximately 0.001 m/s. Following this transition the epileptiform population spike was no longer restricted to the focus; it propagated without decrement across PC at the conduction velocity of the caudally directed association fibers (0.3 m/s). During the transition the field potential within the focus was unchanged, suggesting that a change in excitability occurred outside the focus. At 2 Hz a second, long latency population spike was initiated caudally and propagated back into the focus — a "secondary" initiation site for epileptiform activity developed at a posterior site. Following the delivery of 10 to 20 stimuli at 4 Hz, self-sustaining ictal-like cativity developed throughout PC. The full sequence of changes could be evoked repeatedly during the same picrotoxin application, indicating that they were not a consequence of diffusion of picrotoxin from the injection site. Analysis of the different stages is be

NEUROPATHOLOGICAL ALTERATIONS IN GENETICALLY EPILEPSY-PRONE RATS (GEPRs) FOLLOWING STATUS EPILEPTICUS. F.J. Denaro\* and C.E. Reigel. Depts. of Med. Surg. Neurol and Pharmacol. Texas Tech Univ. Health Sci. Ctr. Lubbock. TX 79430.

One strain of GEPR, the GEPR-9, has been bred to exhibit full tonic extensor convulsions in response to sound. A small percentage of these animals exhibit status epilepticus following an acoustically evoked seizure or a spontaneous seizure. Episodes of status epilepticus occur in both adult and juvenile GEPR-9s. In untreated adults, there is an approximate 50 percent mortality. One week after acoustically-induced status epilepticus without pharmacological intervention, adult GEPR-9s were overdosed with pentobarbital and perfused with formalin. Brains were removed and examined by a battery of histochemical stains (H&E, PAS, Nissi, Luxol Fast Blue, Bielschowsky and GFAP). Diffuse neuronal cell loss was identified in the cortex and striatum. However, in contrast to human findings, no Purkinje cell loss was noted in the cerebellum. Early hypoxic changes were found in the hippocampus. One subject als showed evidence of microhemorrhages and bleeding into the ventricle. In this brain, encrusted neurons were identified. Bielschowsky stain revealed swollen axons in the cortex, but no neurofibrillary changes or inclusions GFAP stain revealed patchy gliosis; glial cells were often swollen and showed evidence of microvacuolation. Similar findings have been reported in animal models of status epilepticus that employ somewhat heroic exogenous manipulations (bicuculline, cobalt or kainate) to induce sustained seizure activity. Significantly, morphological changes observed following status epilepticus in the GEPR brain, a nervous system pathophysiologically epileptic, closely correspond to human neuropathology associated with status epilepticus

THE ROLE OF THE PERIRHINAL CORTEX IN LIMBIC MOTOR SEIZURES. A. Tortorella\*, L. Hu. and K. Gale Department of Pharmacology, Georgetown University Medical Center, Washington, DC 20007.

The area tempestas (AT), an epileptogenic site in the prepiriform cortex, has been demonstrated to be involved in the generation of bilateral limbic motor seizures. Previous studies have shown neural projections from AT to the perirhinal cortex (PRC), an area 6-7 mm caudal to the level of AT, and this area shows marked activation of c-fos expression and glucose utilization in response to AT triggered seizures. In the present study, we have further explored the functional relationship between AT and PRC. Seizures evoked by microinjections of bicuculline-methiodide (236 pmol) into AT were suppressed by microinjections of muscimol (220 pmol) into PRC, but were not suppressed by muscimol injections 2 mm dorsal to PRC. Microinjections of 2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo-(F) quinoxaline (NBQX, 1 nmol), a selective antagonist of AMPA receptors, into PRC also attenuated AT-evoked seizures. Bilateral microinjections of NBQX (2 nmol) into PRC also protected against seizures evoked by systemic bicuculline (2 mg/kg, sc). These observations indicate a role of SABAergic and glutamatergic transmission in PRC for the mediation of seizures evoked from AT as well as for systemically evoked seizures.

RECIPROCAL CONNECTIONS BETWEEN THE AREA TEMPESTAS AND THE PERIRHINAL CORTEX IN THE RAT. N. Sahibzada\*1. 2, W. Chen'. and K. Gale'. 'Dept. of Psychology, Univ. District of Columbia and <sup>2</sup>Dept. of Pharmacology, Georgetown Univ. Medical Center, Washington DC 20007.

The area tempestas (AT) is a functionally distinct epileptogenic site in the deep prepiriform cortex. Previously, we reported that it has connections with a number of structures in the limbic forebrain (Neurosci. Absts. 201.2, 1992). The perirhinal cortex (PRC) is one such structure. The purpose of the present study was to characterize the cells of origin of the AT that project to the PRC, and the distribution of terminals in the AT that arise from the PRC. Using anterograde and retrograde flourescent tracers, bulk as well as discrete injections were made in the PRC immediately dorsal to the rhinal fissure.

Retrograde tracing demonstrated flourescent cells in the ipsilateral AT; following unilateral injection of Fluoro-Gold in PRC. Furthermore, dense label was encountered in the rostral endopiriform nucleus (EN), dorsomedial to the AT. In addition, sparse labeling was observed in external and lateral anterior olfactory nucleus and the lateral part of the intermediate olfactory tract. Anterograde tracing revealed flourescent terminals in AT following application of Fluoro-Ruby into PRC.

These data suggest that a reciprocal connection exists between the PRC and the ipsilateral AT, and to a lesser extent between the PRC and contralateral AT. Moreover, the existence of strong reciprocal connections between PRC and rostral EN raises the possibility that neural information from AT and EN may converge in the PRC.

### SCHIZOPHRENIA: NEUROCHEMISTRY

### 379.1

GAMMA-GLU-GLN AND EXCITATORY AMINO ACIDS (EAA) IN CEREBRO-SPINAL FLUID (CSF) OF UNTREATED SCHIZOPHRENIC PATIENTS. K.Q. Do\*1, C. Lauer², M. Cuenod¹ and F. Holsboer². ¹Brain Res. Inst., Univ. of Zürich, Zürich, Switzerland; ²Max-Planck-Inst. for Psychiatry, Munich, FRG.

Pathophysiological theories of schizophrenia have emphasized dysfunctions in dopaminergic (DA) systems, although a role of EAA systems has also been proposed. Lumbar CSF of 19 patients with schizophrenic disorders (according to DSM-III-R; all patients were off drugs for at least 1 year) and of 16 age- and sex-matched controls were analyzed by optimized precolumn ophtalaldehyde derivatization HPLC. Performing an analysis of covariance with age and sex as covariates, taurine and tyrosine were found to be significantly decreased in the patients. The remaining amino acids evaluated (including aspartate, glutamate and sulfur containing EAA) as well as the catecholamines metabolites did not differ between patients and controls. The level of a compound (P15.5) which we identified as Y-glutamyl-glutamine (as it coeluted with the dipeptide at 3 different pH) was significantly decreased by 13-18% in the patients. While the results do not support a direct involvement of DA or EAA systems in those patients, they point out to a possible role of 8-Glu dipeptides in the pathogenesis of schizophrenic disorders.

## 379.3

MESOPONTINE CHOLINERGIC CELLS AND MESOLIMBIC DOPAMINE FUNCTIONS, INCLUDING SCHIZOPHRENIA. J.S. Yeomans\*, Dept. of Psychology, Univ. Toronto, Toronto, Canada M5S 1A1.

Mesolimbic dopamine systems are believed important for positive symptoms, and cholinergic systems for negative symptoms of schizophrenia, due to the clinical effects of systemic drugs (Tandon & Greden, 1989). Recently, Ch5 and Ch6 cholinergic cells were found in twice normal numbers in a few schizophrenic brains (Karson et al., 1991). Also, increased AChE levels were found in several thalmic nuclei (McGeer & McGeer, 1977). Thus, some schizophrenics may have increased Ch5 cholinergic function. Ch5 cells appear to connect monosynaptically to A9 and A10 dopamine cells (e.g., Bolam et al., 1991; Lacey et al., 1991). We tested whether these connections could activate dopamine-related functions in rats by injecting muscarinic drugs near the Ch5 cells, and near the dopamine cells. Activation of cholinergic cells (e.g., by injecting scopolamine, 100 ug, near medial Ch5 cells) increased mesolimbic dopamine-related functions (i.e., activity, sterectypy, reward sensitivity) by several times, with only slight evidence of nigrostriatal activation (i.e., turning). These increases were blocked by atropine (60 ug) injected near A10 cells. Ch5 cholinergic overactivation may be a causal factor in positive symptoms (via mesolimbic dopamine activation), disorganized thinking (via thalamic activation, Steriade, 1990) and REM sensitivity (via pontine reticular formation connections) in some schizophrenics. (Supported by NSERCC grant to J.Y.)

#### 379.2

CORRELATION OF ALTERED NAAG AND NAALADase LEVELS WITH LEVELS OF GLUTAMATE AND OTHER AMINO ACIDS IN SCHIZOPHRENIC BRAIN. L. A. Passani\*, G. Tsai, J. Kleinman and J. T. Coyle, Dept. of Psychiatry, Harvard School of Medicine / MGH, Boston, MA.

We have previously reported significantly increased N-Acetyl-Aspartyl-Glutamate (NAAG) levels and decreased N-Acetylated Alpha-Linked Acidic Dipeptidase (NAALADase) activity in hippocampus, parahippocampus and orbital frontal cortex of schizophrenic brain. It has been demonstrated that NAAG, a putative neurotransmitter or modulator in glutamatergic pathways, may interact with both nonNMDA and NMDA glutamate (GLU) receptors. From these observations we hypothesized that NAAG may influence GLU-mediated neurotransmission and thereby alter Glu levels. In our present study, levels of GLU, aspartate (ASP), glycine (GLY), taurine (TAU) and GABA were determined by HPLC in eight different regions of schizophrenic, neuroleptic control and normal control brains using the specimens previously analyzed for NAAG and NAALADase (Tsai, et al., 1991). Preliminary results indicate significant decreases in GLU levels in hippocampus, orbital frontal cortex and cerebellum as compared to normal and neuroleptic controls. We also found decreases in the levels of ASP, GLY, TAU and GABA in several regions of schizophrenic brain. The fact that we observed close regional correlations between GLU and NAAG/NAALADase alterated areas suggest a possible causal link between levels of NAAG/NAALADase and GLU in disease-affected regions of schizophrenic brain.

## 379.4

NEUROPSYCHOLOGICAL IMPAIRMENT IN MONOZYGOTIC TWINS DISCORDANT AND CONCORDANT FOR SCHIZOPHRENIA. T. E. Goldberg\*, E. F. Torrey, J. M. Gold, D. R. Weinberger. Clinical Brain Disorders Branch, National Institute of Mental Health, Washington, D.C. 20032

In this study, we examined neuropsychological performance in monozygotic (MZ) twins discordant (N=20) and concordant for schizophrenia (N=8) and normal MZ twins (N=7). We first contrasted unaffected and affected twins from the discordant pairs in order to assess disease specific impairment. The affected group performed significantly worse on tests of executive function, secondary memory, attention, psychomotor speed, and IQ. The profile of performance was suggestive of fronto-temporal dysfunction. Matched pair hit rate analyses suggested that cognitive impairment was not restricted to a group of outliers but was present throughout the distribution. Next, we contrasted affected twins from the discordant group and twins from the concordant group. No differences were observed. This result does not support the idea that putatively "genetically" determined concordant cases have more severe deficits than putatively "sporadic" cases in the discordant group. In the final comparison, designed to assess genetic risk for cognitive impairment in schizophrenia, we contrasted unaffected and normal twins. We observed subtle differences favoring the normal twins on tests of executive and memory function.

BRAIN PATHOMORPHOLOGY IN FIRST EPISODE SCHIZOPHRENIA. J.A.Lieberman\*, G.DeGreef, M.Ashtari, B.Bogerts, R.Bilder. Dept. of Psychiatry, Long Island Jewish Medical Ctr. Albert Einstein College of Medicine, Glen Oaks. NY 11004.

The aims of this study were: 1) to characterize brain morphology in young first episode schizophrenics (SCZ) prior to drug treatment or the effects of chronic illness; 2) to determine the clinical correlates of brain pathomorphology; 3) to determine if brain pathomorphology was progressive in the course of SCZ.

Brain MRIs were acquired in 70 first episode treatment naive SCZ and matched normal subjects at hospital admission and 18 months follow-up on a Siemens Magnetom (1.0t) with a gradient echo pulse sequence (FLASH) providing 63 contiguous 3.1mm slices in the automated mensuration system. Results indicate that SCZ have significant volume differences in the hippocampus, temporal lobe and caudate nucleus (decreased), and the lateral and third ventricles (increased) which were greatest in the left hemisphere and in males. Temporolimbic volumes were correlated with positive psychotic symptoms while lateral ventricular enlargement was associated with primary negative symptoms and poor treatment response. Repeat MRIs are being analyzed.

Current findings multifocal pathology specifically associated with clinical features and are consistent with a neurodevelopmental etiology of SCZ.

Abnormal Serine-Glycine Metabolism in the Mesial Temporal Lobes of Schizophrenics.

R. Waziri\*, S. Baruah & A.D. Sherman. Dept. of Psychiatry, Univ. of Iowa Coll. Med., Iowa City, IA 52242.

High serine and glycine concentrations and decreased serine hydroxymethyl transferase (SHMT) activity in the plasma are biological markers for schizophrenia & psychosis (Waziri, et al., 1984). The purpose of this study is to find out whether these variables are also biological markers in the autopsied brains of schizophrenics. The present results are from samples of frozen autopsied brains obtained from the Wadsworth VA Hospital in Los Angeles and the MacLean Hospital in Belmont, MA. Conventional biochemical and HPLC techniques were used to assay SHMT and serine and glycine levels. LineWeaver-Burke plots were constructed to determine the apparent  $K_{\rm m}$  of the enzyme. Serine and glycine concentrations in Brodmann area (BA) 34 and adjacent areas of brain samples from schizophrenics was significantly higher than those found in brains from controls (p <0.0005 and p <0.001, respectively). Serine and glycine concentrations in BA 22 did not differentiate between the brains of schizophrenics and controls. The apparent  $K_{\rm m}$  of SHMT (for serine as substrate) in BA 34 and adjacent areas was significantly higher than in controls (p <0.002). Abnormalities in the levels of the above variables could not be attributed exclusively to either the left or right hemisphere of the brain. These results provide evidence of abnormal serine and glycine metabolism in the mesial but not lateral temporal lobes of schizophrenics.

Conclusion: Because glycine and serine can enhance glutamatergic neurotransmission and neurotoxicity at the NMDA site, these results suggest that abnormally high levels of these amino acids may be a factor in the frequently observed neuropathology of mesial temporal lobes in schizophrenia, particularly in the vulnerable areas of limbic structures.

REDUCTION IN (<sup>3</sup>H)FLUNITRAZEPAM BINDING IN CINGULATE CORTEX AND HIPPOCAMPUS OF POSTMORTEM SCHIZOPHRENIC BRAINS. R.F. Squires, E. Saederup. A. Laitha, and M. Palkovits, N.S. Kline Institute, Orangeburg, NY 10962

Cerebral atrophies and neuronal loss are seen in many cases of

Cerebral atrophies and neuronal loss are seen in many cases of schizophrenia. Benes et al. have reported loss of small (inter)neurons from the anterior cingulate cortex (Arch. Gen. Psychiat., 48:996, 1991a) and loss of pyramidal cells from the CA1 region of the hippocampus (Schizophrenia Bull., 17:597, 1991b). We report here a 50% reduction of [HI[unitrazepam (FLU) (0.2 nM) binding in anterior cingulate cortex (P=0.005), 30% reduction in hippocampus (P=0.025), 38% in cerebellar cortex (P=0.025), and 27% in globus pallidus (P<0.02). In 12 other brain regions there were no significant differences between schizophrenic (n, 2 to 4) and non-schizophrenic (n, 3 to 9) brains with respect to [3H]FLU binding using 10 uM clonazepam to define non-specific binding (which subtracts binding to "peripheral" sites). Cingulate cortex and hippocampus are part of the loop of Papez, together with mammillary bodies and anterior thalamic nucleus (Benes et al., 1991b). We speculated earlier that instances of psychoses may be associated with selective loss of glutamatergic neurons (Squires and Saederup, Neurochem. Res. 16:1099, 1991), and it is known that hippocampal pyramidal cells are glutamatergic. It is known that most of the small interneurons of the cortex are GABAergic, but some are glutamatergic (e.g., granular cells, which may consist partly of very small pyramidal cells). The neurotransmitters used by the small interneurons that disappear from the cingulate cortex of schizophrenic brains are not yet known (Benes et al., 1991a). We speculate that many of them may be glutamatergic and would normally exhibit high densities of [3H]FLU binding sites.

#### 379.6

SCHIZOPHRENIA OR MESOPONTINE NEURONOSIS? Authors: <u>C.Karson\*, R.Mrak, M.Husain, W.Griffin</u> Depts of Psychiatry, Pathology & Pediatrics, UAMS, Little Rock, AR 72205

A preliminary finding of increased NADPH-diaphorase (+) PPN neurons in schizophrenia led to Western immunoblot studies of protein indices of cholinergic activity (ChAT) and neurodevelopment (B-tubulin 2.1) vs degeneration (GFAP) in this disorder. Rostral pons was obtained from 5 deceased schizophrenics, mean age + SD=61+8 years, and the same number of age and sex matched controls. RESULTS: In schizophrenia, pontine [B-tubulin] was increased at both 24 and 66 hrs of exposure (mean + SD=0.06 + 0.03 units of absorption vs  $0.00 \pm 0.00$  units, p<0.05 and  $0.40 \pm 0.16$  units vs 0.10 + 0.03 units, p<0.01, respectively). ChAT and GFAP concentrations were not different between the 2 groups DISCUSSION: The increased concentration of B-tubulin in schizophrenia is consistent with our earlier report of increased neuronal numbers in this brain region and problem(s) in early development. (-) results with ChAT may suggest that many of the NADPH-diaphorase (+) neurons found in schizophrenic PPN are not ChAT (+).

### 379.8

INCREASED NUMBERS OF GLUTAMATE-IMMUNOREACTIVE VERTICAL AXONS IN SUPERFICIAL LAMINAE OF CINGULATE CORTEX OF SCHIZOPHRENIC BRAIN. F.M. Benest, I. Sorensen, S.L. Vincent, E.D. Bird, M. Sathi. Department of Psychiatry and the Program in Neuroscience, Harward Medical School; Mailman Research Center, McLean Hospital Belmont MA 02178

McLean Hospital, Belmont, MA 02178.

A recent post-mortem investigation has suggested that schizophrenia may involve a defect in associative information processing in limbic cortex because vertical processes visualized with antibodies against the neurofilament 200K subunit were increased in layers II and IIIa of anterior cingulate cortex (ACC) of schizophrenias (SZS). To explore this possibility further, an immunoperoxidase localization of glutamate has been found to visualize vertical fibers in superficial layers of ACC and prefrontal cortex (PFC) of normal (N = 15) and SZs (N = 17). Vertical fibers were distinguished according to small or large calibres and were differentially counted with a blind computer-assisted technique. In SZ ACC, the density of small calibre (77.8%; p = 0.0025), and to a lesser extent, large calibre (30%; p = 0.02) fibers was increased when compared to controls. There were no differences in the density of either small or large calibre vertical fibers in PFC. The potential effects of age, post-mortem interval, fixation and neuroleptic exposure do not account for the differences seen in ACC of SZs. Taking together their small calibre, vertical orientation, preferential localization in superficial layers and marked glutamate immunoreactivity, it seems plausible that the fibers showing an increased density in SZs may be glutamatergic afferents, possibly ones that are associative in nature. Overall, the data are consistent with earlier findings based on NFP200-immunoreactive axons and support the hypothesis that alterations of associative processing in ACC and may be one component to the pathophysiology of schizophrenia. Supported by MH00423 and the Scottish Rite Foundation.

EXCITOTOXIC LESIONS IN RAT STRIATUM PROTECT
AGAINST SUBSEQUENT METHAMPHETAMINE-INDUCED
DOPAMINE TERMINAL DAMAGE. S.J. O'Dell\*, F.B.
Weihmuller, R.J. McPherson and J.F. Marshall. Dept. of
Psychobiology, University of California, Irvine, CA 92717.
Repeated administration of methamphetamine (m-AMPH)(4x
4 mg/kg, sc) produces a large increase in striatal dopamine (DA)

overflow and subsequent damage to the DA terminals (measured as an average decrease in striatal DA content of 45% one week after m-AMPH). We have shown that unilateral striatal injections of quinolinic acid (OA) (15 ug/0.5ul) two to three weeks before a neurotoxic regimen of m-AMPH can protect the lesioned striatum from m-AMPH-induced DA terminal injury. In these animals, m-AMPH produced a decrease in striatal DA of 41% in the intact striatum one week later while the DA content of the QA-injected striatum was no different from that of content of the QA-injected striatum was no different from that of control animals not exposed to m-AMPH. The QA lesions themselves had no significant effect on the integrity of striatal DA terminals as indicated by no differences in either DA content or [3H]mazindol binding between QA- and vehicle-injected striata. In previous studies we have found that the amount of DA overflow produced by neurotoxic m-AMPH regimens was positively correlated with the degree of subsequent DA depletions. Treatments which protected against m-AMPH neurotoxicity were found also to reduce m-AMPH-induced DA overflow. We are using in vivo microdialysis to determine if QA lesions also protect against m-AMPH-induced neurotoxicity by reducing the stimulant-induced DA overflow. reducing the stimulant-induced DA overflow.

REGIONAL DIFFERENCES IN THE INDUCTION OF C-FOS mRNA IN GERBIL BRAIN BY METHAMPHETAMINE. B.K.
Tolliver, M.S. Kindy, and J.M. Carney. Depts. of Pharmacology and
Biochemistry, Univ. of Kentucky Col. of Med., Lexington KY 40536.
Methamphetamine (MA) has been shown to induce neuronal

Methamphetamine (MA) has been shown to induce neuronal damage at doses which alter gene expression in the brain. The effects of MA on c-fos proto-oncogene expression in distinct regions of gerbil brain were studied. Levels of c-fos mRNA in cerebral cortex, cerebellum, brainstem, hippocampus, and striatum 60 minutes after i.p. injection of 1.0, 3.2, 10, or 20 mg/kg MA were assayed by Northern blot analysis. Levels of c-fos mRNA were also assayed at 10, 30, and 60 minutes following injection of 20 mg/kg MA. Methamphetamine induced c-fos in all brain regions studied but regional differences were found in the descendence and time. methamphicalmine induced c-tos in an ordan regions studied but regional differences were found in the dose-dependency and time course of induction. In cortex, a dose-dependent induction of c-fos was maximal 60 min after 20 mg/kg of MA (107-fold induction over saline controls), intermediate at 30 minutes (41-fold induction) and saline controls), intermediate at 30 minutes (41-fold induction) and least at 10 minutes postinjection (6-fold induction). Induction of c-fos in striatum was also dose-dependent but was maximal at 30 minutes (23-fold over control) and declined by 60 minutes (7-fold induction). Elevation of c-fos mRNA in cerebellum, brainstem, and hippocampus also peaked at 30 minutes postinjection. The present study therefore demonstrates that methamphetamine rapidly and transiently alters expression of the early inducible gene c-fos in gerbil brain in a dose-dependent fashion. While the precise role of c-fos elevation in response to methamphetamine remains unclear, such changes in gene expression may be involved in the long term such changes in gene expression may be involved in the long term neurotoxic effects of MA.

## 380.5

EFFECTS OF NMDA ANTAGONISTS ON METHAMPHETAMINE-INDUCED SEROTONIN DEPLETION IN VARIOUS BRAIN REGIONS. T.Ohmori\*, T.Koyama, S.Matsubara and I.Yamashita. Dept. of Psychiatry and Neurology, Hokkaido Univ. Sapporo 060 Japan N-methyl-D-aspartate(NMDA) antagonists have been shown to prevent the toxic action of methamphetamine(MA) on the dopaminergic and serotonergic systems in the striatum. To investigate the involvement of NMDA receptors in the MA-induced damage of serotonin (5-HT) nerve terminals in various brain regions, we examined the effects of a non-competitive (MK-801) and a competitive (SDZ EAA494) antagonist on MA-induced 5-HT depletion in the rat frontal cortex (FC), nucleus accumbens (NA), dorsal striatum (ST), cortex (FC), nucleus accumbens (NA), dorsal striatum (ST), anterior hypothalamus (AH), amygdala (AM), and hippocampus

(HI). Four injections of MA (7.5 mg/kg, sc, at 2hr intervals) produced significant reduction in the levels of 5-HT in all areas examined (30-60 % of control values), although the levels of dopamine(DA) was significantly reduced only in ST. The monoamines were measured by HPLC-ECD one week after the MA treatment. Pretreatment with MK-801 (lmg/kg, ip, 30min before and 3.5hr after the first MA injection) or SDZ EAA494 (20 mg/kg, ip, 30min before, 1.5hr after, and 3.5hr after the first MA injection) almost completely reversed the MA-induced 5-HT depletion in all areas. The pretreatments also reversed the reduction of striatal DA levels. These results suggest that exitatory amino acids participate in the MA-induced damage to 5-HT nerve terminals in FC,NA,ST,AH,AM, and HI, as well as DA nerve terminals in ST.

PRETREATMENT WITH L-DOPA MARKEDLY INCREASES METHAMPHETAMINE-INDUCED EXTRACELLULAR STRIATAL DOPAMINE OVERFLOW AND POTENTIATES TERMINAL DAMAGE. F.B. Weihmuller\*, S.J. O'Dell, and J.F. Marshall. Dept. of Psychobiology, University of California, Irvine, CA 92717.

We have recently shown that repeated methamphetamine (m-AMPH) treatments produce a marked overflow in extracellular striatal dopamine (DA) and the extent of this overflow is correlated with the depletion of striatal DA measured one week later (O'Dell et al., 1991). We have tested this relationship by further increasing extracellular striatal DA overflow and observing the consequences on striatal DA content. Rats were pretreated with 70 mg/kg L-DOPA + 17.5 mg/kg carbidopa one hr before a single m-AMPH treatment (4 mg/kg) and DA terminal damage was measured one week later. Microdialysis measurement of striatal DA overflow showed that treatment with L-DOPA + carbidopa alone produced a small (2-fold), but We have recently shown that repeated methamphetamine (m-L-DOPA + carbidopa alone produced a small (2-fold), but consistent increase in striatal DA overflow. However, when this consistent increase in striatal DA overflow. However, when this L-DOPA + carbidopa treatment was followed by m-AMPH, striatal DA overflow increased to as much as 60-fold over basal levels and remained elevated at 20-fold basal for the subsequent 9 hrs. Striatal tissue content measured 1 week later was reduced by 50 - 90% when compared to that of animals given a single, non-neurotoxic injection of m-AMPH. These findings further support the hypothesis that the amount of DA overflow produced by m-AMPH may be an important determinant of the extent of DA terminal injury produced. DA terminal injury produced.

### 380.4

PROTECTION OF AMPHETAMINE-DERIVATIVE-INDUCED NEUROTOXICITY TO SEROTONIN NEURONS BY NITRIC OXIDE (NO) SYNTHESIS INHIBITION OR N-METHYL-D-ASPARTATE (NMDA) RECEPTOR ANTAGONISM. S. Benmansour & D.J. Brunswick, Dept. of Psychiatry, Univ. Pa. Sch. of Med. & VA Med. Ctr., Phila., PA 19104.

Dextromethorphan, an NMDA receptor antagonist, prevents the neurotoxic effects of amphetamine-derivatives on serotonin (5-HT) neurons. Since activation of NMDA receptor sleads to increases in the synthesis of NO, we investigated whether NO is involved in the neurotoxic effects of amphetamine derivatives. Groups of rats were pretreated with either L. NG-nitroarginine (NO2-arg) (50mg/kg) b.i.d. for 2 days), an irreversible inhibitor of NO synthase, or MK-801 (2.5mg/kg), an NMDA receptor antagonist. p-Chloroamphetamine (pCA) (4mg/kg) was administered 40 hours after the last injection of NO2-arg or 13min after MK-801. Other groups received either pCA or saline alone. Rats were killed 7 days after pCA or saline administration and neurotoxicity was assessed by quantitative autoradiography using [3H]cyanoimipramine ([3H]CN-IMI), a radioligand which binds to 5-HT uptake sites. pCA caused significant reductions in binding of [3H]CN-IMI (40-65%) in all serotonergic terminal field areas examined. By contrast, rats treated with both MK-801 and pCA had no significant reductions in [3H]CN-IMI binding. Similarly, in rats given both NO2-arg and pCA, most areas showed no significant reductions in binding. Attenuation of the neurotoxic effects of fenfluramine (20mg/kg) was also seen following pretreatment with NO2-arg. In separate experiments it was determined that the NO2-arg treatment regimen produced 80% inhibition of NO synthase activity at the time of the administration of amphetamine-derivatives. These results indicate that NO may mediate neurotoxic effects of amphetamine-derivatives on 5-HT neurons. (Supported by Research Funds from the Dept. of Vet. Affairs and USPHS grant DA 05317).

## 380.6

INHIBITOR OF NITRIC OXIDE SYNTHESIS REDUCE THE NEUROTOXIC EFFECTS OF METHAMPHETAMINE IN MICE.  $\underline{\mathbf{JA}}$ Clikeman, S Wei, SA Turkanis', and KT Finnegan. Depts of Psychiatry and Pharmacology, Univ. of Utah Sch. Med., Salt Lake City, UT 84148

Glutamate is reported to stimulate the synthesis of nitric oxide (NO) in rat brain slices via an NMDA receptor-dependent mechanism. Glutamate induced neurotoxicity may involve increases in NO, as inhibitors of NO synthesis have recently been shown to prevent the damaging effects of glutamate in cortical cell culture. Methamphetamine (METH) damages CNS dopaminergic neurons in animals, and recent studies indicate that the neurotoxic effects of this agent, like glutamate, can be prevented by NMDA receptor antagonists. Based on these observations, we evaluated the ability of the nitric oxide synthase inhibitor, N\*nitro-L-arginine methyl ester (L-NAME), to block the toxic effects of METH on nigrostriatal DA neurons in mice. Groups of mice (N=10) were treated with saline or 4 doses of METH (10 mg/kg/injection, each injection separated by an interval of 2 h), either alone or in combination with 2 doses of L-NAME (given 3 h apart), and then killed 1 week later for the assay of striatal DA by HPLC-EC. Mice given saline and then treated with METH showed a 65% decrease in the level of striatal DA. Substitution of increasing doses of L-NAME (37.5, 75, or 150 mg/kg/injection) for saline, however, provided a significant dose-related protection against the long-term, DA-depleting effects of the neurotoxin, although complete protection was not observed. In other experiments, pretreatment with the NO-generating compound, isosorbide dinitrate, restored the toxic effects of METH in L-NAME-treated mice. The findings suggest that NO may play an important role in the neurotoxic mechanism of action of METH.

DOPAMINE RECEPTOR (DAr) ANTAGONISTS PROBABLY DO NOT ACT AS DA REUPTAKE INHIBITORS IN THEIR PROTECTION AGAINST AMPHETAMINE INDUCED NEUROTOXICITY. GE Drucker' N Levine' R Song' JH Gordon & JZ Fields. Res Svce 151, VA Hosp, Hines IL 60141.

Continuous exposure (≥ 8 hr) of rodents or primates to amphetamine elicits decreases (-50% to -80%) in striatal DA and in markers for striatal DA terminals. In vivo administration of D2 DAr antagonists prevents this neurotoxicity. The simplest explanation is that the D2 DAr antagonists act at the post-synaptic D2 DAr, although in theory they could protect by inhibiting the DA reuptake pump. Steranka (Naunyn-Schmeid Arch Pharmacol 325 (1984) 198-204) found that i) sulpiride was an effective preventive agent and that ii) (+)-butaclamol (the more potent DAr antagonist) completely prevented neurotoxicity while (-)-butaclamol (the less active stereoisomer), was ineffective at an equal dose. In our studies, in contrast, sulpiride, even at 0.1 mM, failed to inhibit in vitro synaptosomal accumulation of [3H]DA. Second, the two enantiomers of butaclamol had essentially equal potencies in their ability to inhibit [3H]DA reuptake in vitro (IC-50 = 6 uM). Moreover, all of the D2 DAr antagonists tested had low potencies (uM range) for inhibiting [3H]DA uptake relative to their DAr blocking concentrations (nM range). We conclude that DAr antagonists probably do not protect via pre-synaptic DA reuptake inhibition. Since post-synaptic D2 DAr are thus the probable target, the mechanism of amphetamine neurotoxicity must be more complex than a simple direct toxicity to DA terminals. ### 380.9

CAUDATE/PUTAMEN (CPU) DOPAMINE (DA) AND GLUTAMATE (GLU) RELEASE AND CHANGES IN TOTAL DA AND 5HT CONTENT PRODUCED BY METHAMPHETAMINE (METH) ARE AFFECTED BY AGE. B. Gough, R.R. Holson, W. Silkker Jr., G.W. Lipe, G.D. Newport and J.F. Bowyer, NCTR/FDA. Jefferson. AR 72079-9502.

Six and 12 mo. old female Sprague-Dawley rats were given 4 doses (i.p. at 2 hr intervals in a 23°C environment) of METH, and extra-cellular CPU DA, SHT and GLU levels were determined at 20 min intervals using microdialysis and HPLC-EC up to 5 hr after the last METH dose. These rats were then sacrificed either 3 or 14 days after METH to determine total CPU DA and 5HT content. The 6 and 12 mo. old controls did not differ from each other in either total CPU DA and 5HT content or the extracellular CPU amino acids levels. In contrast, basal extracellular CPU DA and 5HT levels were only 50% as great in 12 mo. compared to 6 mo. old rats, and the increase in CPU DA. 5HT and GLU levels evoked by METH was also less than 50% as great in the 12 month old rats. The CPU GLU and Taurine levels did not differ between the controls in the 2 age groups but GLU levels were elevated in METH treated rats towards the end of dosing (particularly in the 12 mo. old rats). No late DA surge after the 4th dose of METH occurred in 6 or 12 mo. old female rats. Despite this blunted response of CPU DA release by METH in 12 mo. old rats, they had significantly greater reductions in total CPU DA and 5HT content 3 and 14 days post METH than 6 mo. old rats. In summary, METH toxicity may not be predicted solely by extracellular DA levels attained during METH exposure: Age and other factors also greatly influence METH toxicity.

LARGE DOSE REGIMEN OF METHAMPHETAMINE PRODUCES LONG LASTING DEFICITS IN THE ACQUISTION AND PERFORMANCE OF A REACTION TIME TASK. M.J. Baggott, J.B. Richards, K.E. Sabol, L.S. Seiden\*. University of Chicago, Department of Pharm/Phys Sci., Chicago, IL. 60637.

Male Sprague Dawley rats were trained to press a lever for a water reinforcer (.05 ml). After initial bar press training the rats were injected with 50 mg/kg of methamphetamine (MA) (3 times, 1 injection/8hr), or saline. After a 2 week recovery period, MA treated rats (N=11) and control rats (N=8) were tested for acquistion and performance of a reaction time (RT) task. The RT task required the rats to hold down a lever for a variable duration until a stimulus light was turned on. Releasing the lever after stimulus light onset was reinforced if the rats reacted faster than a criterion RT value. Reaction time was defined as time elapsed between stimulus onset and lever release. The criterion RT value was adjusted by computer for each rat so that approximately 3 of every 4 lever releases was reinforced. Each training session consisted of 100 trials or 1hr, whichever occurred first. The rats were trained on the task 5 days/week for 9 weeks. During the first week of training the mean RTs were not significantly different between the 2 groups (CONT=0.37±.03s; MA=0.40±.04s) (mean+S.E.M.). During subsequent training, the RTs for the control group became significantly faster while the RTs for the MA group did not change. By week 9 of training the mean RTs for the two groups were: CONT=0.22±.02s; MA=0.37±.03s. The rats were sacrificed 11 weeks after MA treatment. Dopamine tissue concentrations were significantly decreased in the caudate (66%) and nucleus accumbens/olfactory tubercle (67%) (% = treated/control). Serotonin tissue concentrations were significantly decreased in the nucleus accumbens/olfactory tubercle (36%), caudate (31%), somatosensory cortex (4%), amygdala (35%), and hippocampus (10%). MA treatment caused long lasting deficits in both neurotransmitter levels and behavioral output. (Supported by: NIDA DA-00085 and RSA-10562 L. Seiden)

SYMPOSIUM. MECHANISMS OF HIV-RELATED INJURY IN THE CENTRAL NERVOUS SYSTEM. Stuart A. Lipton, Harvard Med. Sch. (Chairperson); Clayton A. Wiley, UCSD; Douglas E. Brenneman, NIH-NICHD; Lynn Pulliam, UCSF; Melvyn Heyes.

Both neuronal and glial injury are involved in the neurologic manifestations of AIDS even though neurons are not infected by HIV-1. Dr. Wiley will present an overview of the neuropathological findings of myelin pallor and neuronal loss with resulting clinical dementia. Dr. Brenneman will describe injury to rodent neurons in culture and in animal models induced by the envelope protein (gp120) of HIV-1. Neuronal damage may be indirect, mediated in part by gp120 effects on astrocytes. The effects of gp120 resemble those associated with antagonists of vasoactive intestinal peptide (VIP). Dr. Pulliam will describe the injury to astrocytes and cytological changes in neurons caused by gp120 in cultured human brain cell aggregates. She will also describe the neurotoxic and glial-toxic effects of as yet unidentified substances released from HIV-infected human macrophages. Dr. Heyes will describe the increase in quinolinic acid (an NMDA-like neurotoxin) measured in the cerebrospinal fluid of AIDS patients with dementia. Dr. Lipton will show that gp120 increases intracellular neuronal calcium levels, with subsequent neuronal injury in both rodent culture systems and animal models. The action of gp120 may be mediated in part by the release of NMDA-like neurotoxins from macrophages. Calcium channel antagonists and NMDA antagonists can protect from this gp120-induced neuronal injury. The findings of the various speakers will be linked by summarizing effects of HIV-related toxins, including gp120, on macrophages, astrocytes, and neurons.

SYMPOSIUM. COGNITIVE AND NEUROBIOLOGICAL CONSEQUENCES OF NORMAL AGING: FROM RATS TO PRIMATES. C. A. Barnes, Univ. of Arizona (Chairperson); M. Gallagher, University of North Carolina; L. de Toledo-Morrell, Rush-Presbyterian - St. Lukes Medical Center; P. R. Rapp. The Salk Institute; M. S. Albert, Massachusetts General Hospital.

This symposium reviews recent advances in understanding the neural basis of cognitive decline in normal aging. One experimental strategy that has proven particularly powerful in this regard involves the combined analysis of behavioral and neurobiological measures in the same subjects. This provides a basis for identifying those brain markers of aging that are most tightly coupled to senescent functional decline. Symposium topics were chosen to provide a focused survey of recent findings from investigations in rodents, monkeys, and humans, that have analyzed both behavioral and neurobiological measures in aged subjects. Rodent models for the study of cognitive decline in aging have focused on spatial learning tasks that are sensitive to the integrity of the hippocampal formation. Neurobiological markers that coincide with impairment are found in neurochemical, morphological, and electrophysiological studies of hippocampal circuitry. Such age-related changes are often region specific, and occur along with sparing of function and evidence for compensatory mechanisms. The cognitive consequences of aging will also be described for the nonhuman primate and related to neuroanatomical changes in the aged monkey brain. Again, individual differences in memory function are a prominent feature of aging that appear to be valuable predictors of the types of neural alterations observed. Finally, studies in healthy adults across the age range (30-80) will be discussed in terms of neuropsychological function, quantified electrophysiology, and measurements of CT and MRI scans. Recent longitudinal data provide additional information on the time course of these changes in humans.

ACTIONS OF NITRIC OXIDE IN THE MICROCIRCUITS OF THE GUINEA-PIG SMALL INTESTINAL MYENTERIC PLEXUS. K. Tamura, M. Schemann and J.D. Wood\*. Tokai Univ., Isehara, Japan; Max-Planck Institut, Bad Nauheim, Germany; Dept. Physiol., The Ohio State Univ., Columbus, Ohio 43210.

Intracellular microelectrode recording was used to

investigate the possible involvement of nitric oxide in the electrical and synaptic behavior of myenteric neurons the electrical and synaptic behavior of myenteric neurons in the small intestine. The nitric oxide synthase inhibitor, L-NAME (100  $\mu$ M) was applied in the bathing medium for 20 min to identify actions on stimulus evoked slow EPSPs and fast nicotinic EPSPs. No effects of L-NAME on fundamental electrical behavior or excitatory synaptic events were found. Sodium nitroprusside was synaptic events were found. Sodium nitroprusside was applied in the bathing solution as a source of nitric oxide. Sodium nitroprusside (10  $\mu$ M to 1 mM) dosedependently and reversibly suppressed or abolished slow excitatory postsynaptic potentials (slow EPSPs) in AH/Type 2 neurons. Slow EPSP-like responses to microejected substance P or serotonin were unaffected by sodium nitroprusside during suppression of the slow EPSPs. Pretreatment with either methylene blue (1 to 5  $\mu$ M) or oxyhemoglobin (0.5 to 10  $\mu$ M) reduced or prevented the inhibitory action of sodium nitroprusside on the slow EPSPs. Sodium nitroprusside did not significantly affect fast nicotinic EPSPs in the neurons. The principal action of nitric oxide in the microcircuits of the myenteric plexus appeared to be suppression of of the myenteric plexus appeared to be suppression of release of neurotransmitters for slow synaptic excitation. NITRIC OXIDE AS A POSSIBLE SYNCHRONIZING FACTOR FOR PULSATILE

NITRIC OXIDE AS A POSSIBLE SYNCHRONIZING FACTOR FOR PULSATILE LHRH RELEASE FROM IMMORTALIZED LHRH NEURONS PERIFUSED IN VITRO. M. Moretto, F. J. López, P. Petrusz\* and A. Negro-Vilar. Reprod. Neuroendocr. Section, LHNN. National Institute of Environmental Health Sciences, NIH. Res. Tri. Pk., NC 27709.

The GT1-7 neuronal cell line secretes LHRH into the incubation medium in a pulsatile fashion, and is responsive to several stimuli. Nitric Oxide (NO) is best known for its relaxing properties as an endothelium-derived relaxing factor. Recent studies have provided compelling evidence indicating that NO may act also as a neurotransmitter depicting unique characteristics. As a gas, NO displays a extremely fast diffusion, which enables it to reach neighboring cells within a limited range. Those features may be important for the synchronization process in some specific neurosecretory systems like LHRH neurons. We tested this hypothesis in a perifusion system. GT1-7 cells were grown for four days on cytodex beads and then transferred to perifusion chambers. They were perifused for 4 h with Krebs-Ringer-Bicarbonate-Glucose buffer either alone or with 3 µM oxyhemoglobin, which binds NO. At the end of this period, cells were depolarized by 56 mM K'-containing medium for 5 min. Fractions were collected at 5 min intervals and assayed for LHRH. The results were analyzed for pulsatility using the algorithm Detect. The continuous infusion of oxyhemoglobin (Hb) induced a marked reduction in pulse frequency without altering quantitative aspects of pulsatile LHRH secretion. In addition, an increased responsiveness to K' was observed in Hb-treated cells. Since Hb binds NO, thereby inhibiting its effects, it is tempting to suggest that NO participates in the genesis of a synchronous release of LHRH from these cells.

## 385.5

RELATIONSHIP OF GABAERGIC AND CHOLINERGIC BASAL FOREBRAIN NEURONS AND THEIR PROJECTIONS TO THE MEDIODORSAL THALAMIC NUCLEUS IN THE CAT. I.Gritti. M. Mariotti and M. Mancia. Institute of Human Physiology II, University of Milan, Milan, Italy I-20133. Multiple lines of evidence indicate that cholinergic and GABAergic neurons located in the basal forebrain and preoptic region may influence cortical activities directly through cortical projections as well as indirectly through the

subcortical connections involving the thalamus. In an effort to understand the potential role of the GABAergic neurons of the basal forebrain, we have investigated in the cat first their relationship to cholinergic neurons, and secondly their projections to the mediodorsal thalamic nucleus. In order to establish the relationship of neurons which synthesize GABA with those which synthesize acetylcholine (ACh) within the basal forebrain regions, a sequential double labelling immunohistochemical procedure was employed to stain glutamic acid decarboxylase (GAD) and choline acetyl transferase (ChAT), respectively. Through the entire basal forebrain, there was no evidence for colocalization of GAD and ChAT in the same cells. However a large population of distinct GAD+ neurons was found intermingled with ChAT+ cells through the cytoarchitectonically defined basal forebrain regions. GAD-immunoreactive neurons appeared to be morphologically similar regions. GAD-immunoreactive neurons appeared to be morphologically similar to ChAT+ neurons although they were concentrated in slightly different positions of each subregion. Following injections of wheat germ agglutnin conjugated to horseradish peroxidase (WGA-HRP) into the mediodorsal thalamic nucleus and combined processing for WGA-HRP and immunohistochemistry, a contingent of basal forebrain projecting neurons was found to contain ChAT, whereas a small contingent was found to contain GAD. These results demonstrate that a distinct population of GABA-synthesizing cells is intermingled with ACh-synthesizing cells across the basal forebrain. They reveal the existence of GABAergic projections from the basal forebrain to the mediodorsal nucleus, which may play an important role in the control of thalamocortical functions during sleep.

INTERACTIVE METABOLIC STIMULATION BY ENDOTHELIN-1 AND NITRIC OXIDE IN THE RAT BRAIN. P.M. Gross, D.F. Weaver, D.S. Wainman, F.J. Espinosa, R.J. Beninger\* and S. Nag, Departments of Surgery, Medicine, Chemistry, Physiology, Psychology & Pathology, Queen's University & Kingston General Hospital, Kingston, Canada K7L 3N6
Endothelin (ET) neuropeptides and biosynthetic mechanisms producing neuronal nitric oxide (NO) may coexist to modify neurotransmission and cellular activity. Using N<sub>2</sub>O-halothane anesthetized rats, we applied the quantitative autoradiographic [<sup>14</sup>C]deoxyglucose technique to assess the influence of ET and NO on focal rates of cerebral glucose metabolism (GM). The design employed lateral ventricular injections in separate rat groups to determine GM responses of individual periventricular structures to: 1) saline (3 µl), 2) ET-1 (9 pmol), 3) the NO donor, sodium nitroprusside (NP, 3 µmol), 4) the NO synthase inhibitor, N°-monomethyl-t-arginine (NMMA, 4 µmol), 5) NP+ET, and 6) NMMA+ET. The main effects of each treatment were: ETintense periventricular hypermetabolism (GM increases as high as +276% in the lateral septal n.) (Neuropeptides 21:211, 1992); NP - marked bilateral stimulation of white matter GM, e.g., corpus callosum (+239%), fornix (+94%), anterior commissure (+161%), and thalamic stria medullaris (+154%). In the ipsilateral choroid plexus, there was a 55% reduction in GM and histological evidence for cell damage: NMMA - no significant regional changes in GM. indicating that NO may not contribute to the basal metabolic state of the brain; NP+ET - topographically heterogeneous patterns of hypermetabolism (80% to 183% increases in GM) in the ipsilateral caudate and lateral septal n.; and NMMA+ET - inhibition of the hypermetabolic response to ET in the lateral septal n., results suggesting that ET may induce release of a metabolically-active NO in this structure. The findings indicate that intraventricular ET and NO have selective stimulatory effects on the GM of gray and white matter structures bordering the lateral ventricle

COLOCALIZATION OF GAD AND PARVALBUMIN IN THE MEDIAL SEPTUM OF THE RAT. G. M. Peterson\* and G. W. Lanford. Dept Anatomy & Cell Biology, East Carolina Univ Sch Med, Greenville, NC 27858

The calcium-binding protein parvalbumin (Parv) is contained within most GABAergic neurons in the cerebral cortex, hippocampus and striatum. Within the medial septum (MS), a substantial number of neurons are immunoreactive for GABA (or GAD). Cells immunoreactive for Parv are similar in number and position to GABAergic cells within the MS, suggesting colocalization of both GABA and Parv. We have employed a double immunofluorescence staining technique to investigate the extent and distribution of colocalization. Sections through the MS were incubated successively in antisera to GAD and Parv. Using a GAD antibody (Chemicon) to the 67 kD form of GAD which does not require pretreatment with colchicine for the visualization of somata, GAD+ somata were labeled with a biotinylated secondary antibody and tagged with Cy3 conjugated to streptavidin (Jackson Labs). To visualize both GAD and Parv in the same section, Parv+ somata were labeled with an AMCA conjugated secondary antibody. Sections were examined throughout the rostral-caudal extent of the MS and the number of GAD only, Parv only and GAD + Parv neurons were counted. It was determined that the percentage of neurons containing both GAD and Parv ranged from 83% near the rostral pole to 43% at the caudal pole. Viewing the MS as a whole, 68% of the GAD+ cells contain Parv. Only a few cells were observed to contain Parv without GAD. These data indicate that, as has been shown for other regions in the forebrain, GAD and Parv are colocalized in the MS, but the extent of colocalization varies within the nucleus. Since most of the septal neurons which project to the hippocampus originate from the caudal half of the MS (Peterson, 1989) it is possible that those GAD cells which do not contain Parv are projection neurons whereas those in which GAD and Parv are colocalized are interneurons. NOREPINEPHRINE RELEASE ELICITED IN VIVO BY LOCAL NMDA RECEPTOR STIMULATION. V. Robine. R. Valentino, G. Aston-Jones and J. Lehmann\*, Division of Neurobiology, Department Mental Health Sciences, Hahnemann University, Philadelphia PA 19102.

Norepinephrine (NE) recovered in microdialysate obtained from frontal cortex of halothane-anesthetized rats was increased when N-methyl-D-aspartate (NMDA) was contained in the microdialysis medium. NE levels increased by a factor of 3.6 compared to prior baseline levels when 1 mM NMDA was applied for 30 minutes. This increase was largely reversible. Subsequent application of aconitine (0.3 mM, 30 minutes), which acts on voltage-sensitive sodium channels, evoked a second release of NE. The NMDA antagonist MK-801 (300 nM) blocked the NMDA-elicited increase but not the aconitineelicited increase. However, this concentration of MK-801 also decreased the spontaneous release of NE, raising the possibility that there may be endogenous excitatory amino acid neurotransmission mediated by presynaptic NMDA receptors.

### 385.9

HALOPERIDOL INCREASES NEUROMEDIN N AS WELL AS NEUROTENSIN CONCENTRATIONS IN SPECIFIC BRAIN REGIONS R. Clement, D. Griff, B. Banks, C. B. Nemeroff, P. Kitabgi and G. Bissette\*. Departments of Psychiatry, Duke University Medical Center, Durham, NC 27710, Emory University Medical School, Atlanta, Georgia 30322, and IPMC, CNR, Valbonne, France

Mammalian gene sequences coding for neuromedin N (NMN) and neurotensin (NT) are contained on the same exon and are separated by a single pair of dibasic residues. It is likely that differential processing can occur, however, as the regional brain distributions of NMN and NT are often distinct. Because several classes of antipsychotic drugs have been shown to selectively increase NT in the rat nucleus accumbens and caudate nucleus, we examined the response of NMN neuronal systems to three weeks of daily haloperidol treatment. The effect of lithium alone or in concert with haloperidol and the effects of a D2 receptor agonist, quinelorane, on regional NMN and NT concentrations were also examined in nine brain regions. Haloperidol significantly increased NMN and NT concentrations in the nucleus accumbens, caudate nucleus and pre-optic nucleus of the hypothalamus and this increase was significantly correlated (p<.0001) between the two peptides. Lithium alone did not alter NMN or NT concentrations in any brain region examined and lithium did not further increase haloperidol's effect when co-administered. Quinelorane did not decrease the regional concentrations of either peptide but did increase both NMN and NT in the nucleus accumbens. Neuroleptic drugs may induce some of their clinical antipsychotic effects through increases in NMN as well as neurotensin.

#### 385 8

N-METHYL-D-ASPARTIC ACID DIFFERENTIALLY REGULATES DOPAMINE, GABA AND GLUTAMATE RELEASE IN THE DORSOLATERAL STRIATUM OF THE HALOTHANE ANAESTHETIZED RAT. AN IN VIVO MICRODIALYSIS STUDY. M. Morari, W. T. O'Connor, U. Ungerstedt and K. Fuxe\*. Depts. of Pharmacology, Histology and Neurobiology, Karolinska Inst., S104-01, Stockholm, Sweden.

The effects of local perfusion with the glutamate (GLU) receptor agonist N-Methyl-D-Aspartic acid (NMDA) and the non competitive NMDA receptor antagonist MK-801 on extracellular dopamine DA, GABA and GLU levels in the dorsolateral striatum were monitored using in vivo microdialysis in the anaesthetized rat. Local perfusion (10 min) with both the 10-3M and 10-4M dose of NMDA increased striatal DA and GABA release while only the (10-3M) dose of NMDA was associated with a small and delayed increase in extracellular GLU levels. The NMDA induced effects were dose-dependently counteracted by simultaneous perfusion with MK-801 (10-6M and 10-5M). Both basal and NMDA (10-3M) induced increases in DA release were reduced in the presence of TTX (10um) and low Ca2+ (0.1mM) while both basal and NMDA stimulated GABA release were unaffected by these treatments. Both the basal and NMDA stimulated GLU release were enhanced following TTX, while perfusion with low Ca2+ reduced basal GLU levels and enhanced and prolonged the NMDA induced stimulation. These data provide evidence for a differential effect of NMDA receptor stimulation on these three striatal neurotransmitter systems, possibly reflecting direct and indirect actions mediated via striatal NMDA receptors

PHYSIOLOGICAL PROPERTIES OF ANATOMICALLY IDENTIFIED AXO-AXONIC CELLS IN THE RAT HIPPOCAMPUS IN VITRO

E.H. Buhl\* Z.-S. Han. Z. Lörinczi and P. Somogyi. Medical Research Council, Anatomical Neuropharmacology Unit, Mansfield Rd., Oxford OX1 3TH, U.K. In hippocampal slices of the rat non-pyramidal cells were physiologically

characterized with biocytin filled electrodes and subsequently identified with correlated light and electron microscopy. Four neurons in area CA1, two in CA3 and two in the dentate area had the distinct appearance of chandelier cells with their axon formi symmetrical synaptic contacts exclusively with the axon initial segment of pyramidal cells, granule cells and mossy cells.

Axo-axonic cells (AACs) had a mean resting membrane potential of -68 mV, an average input resistance of 42 M $\Omega$  and a short time constant (6.3 msec). Short duration action potentials (AP; 0.39 msec at halfamplitude) were followed by a deep shortlatency afterhyperpolarization (8.5 mV mean amplitude) as well as a depolarizing afterpotential which was most prominent in CA1. In response to depolarizing current AACs could fire at up to 388 Hz and showed a varying degree of spike frequency adaptation. AACs in CA1 had a unique firing pattern, displaying numerous "doublets", i.e. one AP followed by another at a very short latency, apparently triggered by the depolarizing afterpotential. In the presence of 1  $\mu$ m TTX and 5 mM TEA depolarizing pulses triggered APs of small amplitude, slow rise and long duration, suggesting that they were mediated by calcium. Electrical activation of the Schaffer collaterals, perforant path fibers and the alveus evoked short-latency EPSPs with a mean rise time of 3.7 msec, while suprathreshold stimuli elicited 1-3 APs. Bath application of the non-NMDA glutamate receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX; 10 μM) reduced the EPSP amplitude by up to 96%. IPSPs were usually comprised of a short latency IPSP-A (max. amplitude at 28.9 msec latency) with a mean reversal potential of -67 mV, while the IPSP-B peaked at 125 msec latency. In conclusion, AACs (a) have a distinct firing pattern (b) receive synaptic input which is largely mediated by non-NMDA receptors (c) and are involved in feedforward inhibition

CALRETININ IN THE PRIMATE HIPPOCAMPUS IS PRESENT IN INTRINSIC INHIBITORY AND AFFERENT EXCITATORY SYSTEMS.

C. Leranth\*(1) and R. Nitsch (2). (1) Dept. of OB/GYN and Section of Neurobiol., Yale Univ. Sch. of Med., New Haven, CT 06510 and (2) Centr. of Morph. Univ. Clinic, Frankfurt, D-6000 Frankfurt/M. 70, FRG.

The calcium-binding protein calretinin (CR) is present in rodent hippocampal non-pyramidal cells including a presumably excitatory cell type specifically associated with the mossy fiber system. Our light and electron microscopic studies on the hippocampus of African green monkeys demonstrated that CR is exclusively present in non-pyramidal cells concentrated in the hilus subjacent to the granule cells and in both sides of the fissure. They showed smooth, aspiny dendrites extending to all hippocampal layers. Colocalization studies revealed that almost all of the hippocampal CR-containing neurons contain GABA. CR boutons were concentrated in the hilus and on both sides of the hippocampal fissure and established symmetric synaptic contacts. Conversely, CR-positive axons which formed a prominent band at the border of the dentate molecular and granule cell layer and in the CA2, established asymmetric contacts, and were found to be immunoreactive for substance P (SP). These axons disappea 10 days after a fimbria-fornix transection. An HRP tracing study revealed their cells of origin in the tuberomammillary nucleus (TBM). These large projective neurons contained both CR and SP. These observations suggest that in contrast to the rat, in the primate hippocampus, there are no intrinsic excitatory CR neurons associated with the mossy fiber system, but rather an intrinsic inhibitory and an extrinsic, hipothalamic, excitatory pathway. Supported by NS26068; MH44866; HD2380; (C.L.) and DFG: Ni344/1-1 R.N.).

THE DEVELOPMENT OF THE MOSSY FIBER PLEXUS IS DELAYED IN THE HILUS OF THE DENTATE GYRUS AS COMPARED TO THAT IN CA3. C.E. Ribak\* and M.S. Navetta. Dept. of Anatomy & Neurobiology, Univ. of Calif., Irvine, CA 92717. Recent studies have shown that mossy fibers, the axons of granule cells, sprout into the inner molecular layer after seizures and hilar cell cells.

death in adult rats, but they do not sprout in 15 day old rats injected with kainic acid. The present study was made to examine the number of mossy fibers in the dentate gyrus at different postnatal ages to determine whether a lack of hilar cell loss and subsequent sprouting in 15 day old whether a lack of final cell loss and subsequent splotting in 13 day of rats is due to a reduced mossy fiber input to hilar neurons. It is interesting to note that mossy fibers form mature synapses in CA3 before 14 days of age. Neo-Timm and electron microscopic preparations from rats at 7, 10, 12, 15, 22 and 30 days of age were examined. The adult pattern of Timm-labeled mossy fiber innervation was found for hilar basket cells at 22 and 30 days, but deep hilar cells were less densely innervated at 22 days than in the adult. At 10 and 15 days, basket cells in the rostral dentate gyrus showed more intragranular mossy fibers than those in the septal pole, and they appeared to be the mossy fibers than those in the septal pole, and they appeared to be the first hilar cell type to become densely innervated by mossy fibers. Electron microscopy of the 7 day hilus showed only a few synapses formed by developing mossy fibers. At 12 and 15 days, the density of synapses formed by mossy fibers with dendrites in the hilus was less than half that found in adults. The relatively sparse innervation of hilar neurons in the 15 day old rat may contribute to their resistance to kainate-induced cell death because these cells have a reduced number of the proposed and for their associated physmate recentlys. The delayed synapses and/or their associated glutamate receptors. The delayed growth of synapses in the hilus between 10-22 postnatal days may be due to this region being a thoroughfare for migrating granule cells.

ENTORHINAL CORTEX (EC) GENERATES 40 Hz HIPPOCAMPAL

S. Charpak\*, D. Paré and R. R. Llinás, Department of Physiology and Biophysics, New York University Medical Center, 550 First Avenue, New York, N.Y. 10016.

Recurring episodes of 40 (± 10 Hz) field potential oscillations can be recorded from the hippocampal formation in anaesthetized guinea pigs (Ketamine-Xylazine). Laminar analyses of these oscillations and of EC-evoked field potentials in the hippocampus revealed that this synchronous oscillatory activity is generated by a rhythmic synaptic input to the stratum lacunosum-moleculare and the stratum moleculare of the fascia dentata. Because these layers constitute the targets of EC afferents, we performed field potential and single unit recordings in the EC. These experiments revealed the presence of 40 Hz EC oscillations accompanied by rhythmic neuronal discharges at the same frequency. Furthermore, injections of tetrodotoxin within EC boundaries abolished ipsilateral hippocampal and EC 40 Hz oscillations but preserved hippocampal synaptic responses to contralateral EC stimulation. In contrast, hippocampal removal sparing only its temporal pole did not suppress the 40 Hz EC oscillation. Moreover, knife cuts interrupting the connections between CA3 and CA1 did not abolish the 40 Hz oscillations recorded in the stratum lacunosum-moleculare Taken together, these results suggest that the 40 Hz oscillations recorded in both the fascia dentata and the CA1 regions originate in the EC and are conveyed by a monosynaptic input. The existence of 40 Hz in the entorhinal-hippocampal circuit. which is linked with the association cortices, raises the issue of temporal binding of perception with the memory-affective axis.

INVOLVEMENT OF A GABAERGIC COMPONENT IN THE INHIBITORY EFFECT INDUCED BY VENTRAL TEGMENTAL AREA STIMULATION ON THE PREFRONTAL CORTEX.

R. Godbout<sup>1</sup>, S. Pirot<sup>2</sup>, J. Mantz<sup>2</sup>, J. Glowinski<sup>2</sup> and A.M. Thierry<sup>2</sup>.

<sup>1</sup>Dép. de Psychiatrie, U. de Montréal, Montréal (Québec) Canada H4J 1C5

<sup>2</sup>Collège de France, INSERM U. 114, 75231 Paris cedex 05, France.

The medial prefrontal cortex (PFC) receives dopaminergic (DA) and non-DA projections from the ventral tegmental area (VTA). The present study sought an electrophysiological evidence for the existence of a GABAergic component in PFC inhibition induced by VTA stimulation or DA iontophoretic application. Experiments were performed under ketamine anesthesia in control rats and in animals treated with aMPT in order to deplete DA stores. The iontophoretic applications of DA and GABA induced an inhibition of spontaneous firing in 70% of 84 cells and 100% of 133 cells, respectively. The DA receptor antagonist sulpiride blocked 89% of DA inhibitions but none of GABA inhibitions; the GABA receptor antagonist bicuculline blocked 100% of GABA inhibitions and 57% of DA inhibitions. Electrical stimulation (1Hz) of the VTA inhibited 86% of 196 cells in control rats (D=112ms); iontophoretic application of sulpiride blocked 54% of VTA inhibitions (n=41); bicuculline blocked 51% of VTA inhibitions (n=68). In αMPT rats, only 66 of 169 PFC cells (39%) were inhibited by VTA stimulation (D=94ms); sulpiride was no longer effective in reversing VTA inhibitions while bicuculline reversed 95% of VTA inhibitions. The present results suggest that: 1) the DA-induced inhibition of PFC cells involves cortical GABAergic interneurones; 2) the non-DA mesocortical system also exerts an inhibitory influence on PFC cells and appears to be GABAergic.

INHIBITORY LATERAL SEPTUM-HYPOTHALAMUS PATHWAY:

A PHA-L TRACING/GABA-IMMUNOGOLD EM STUDY. R.L. Jakab1\* and C. Leranth<sup>1,2</sup>. Dept. of Ob/Gyn<sup>1</sup> & Sect. Neurobiol<sup>2</sup>., Yale University Sch. Med., New Haven, CT 06510

The lateral septum (LS) massively projects to the hypothalamus, and contains a large group of GABAergic somatospiny neurons. This study aimed to test whether the LS-hypothalamus pathway is GABAergic

The anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L) was applied to the location of the somatospiny neurons. Sections from the two major termination fields of PHA-L labeled LS efferents, the anterior and lateral hypothalamic nuclei, were processed for electron microscopy. GABA content of PHAL-labeled axons was determined by processing ultrathin sections for postembedding GABA-immunogold staining. All PHA-L-labeled axon terminals examined were immunoreactive for GABA, and formed symmetric synapses on GABA-positive or immunonegative profiles

This GABAergic LS → hypothalamus projection may be responsible for the septal inhibition of neuroendocrine and autonomic functions. Our previous studies demonstrated that the somatospiny neurons (the parent cells of this inhibitory projection): 1) are strongly controlled by numerous peptidergic pericellular baskets of mostly hypothalamic origin (thus, forming an "autonomic disinhibitory circuit"); and 2) the same cells receive massive excitatory afferents from higher limbic areas, such as hippocampus and amygdala, which can activate the inhibitory LS  $\rightarrow$  hypothalamus projection. This model may explain why septal stimulation suppresses, whereas septal lesion triggers autonomic responses. (Supported by NIH grants NS 26068 and HD 23830, C.L.).

### 386.6

BEFECTS OF VENTRAL HIPPOCAMPAL COMMISSUROTOMY ON RHYTHMIC SLOW - WAVE ACTIVITY (THETA) IN THE URETHANE ANAESTHETISED RAT. A.J. Heynen\* and D.K. Bilkey. Department of Psychology and the Neuroscience Research Centre, University of Otago, Dunedin, New Zealand.

The present study examined the contribution of the hippocampal commissural system in the production of rhythmic slow-wave activity (RSA) in urethane anaesthetised Sprague Dawley rats (n=10). Bilateral recording electrodes were placed in the hippocampus of each hemisphere in order to perform depth profiles of RSA during high frequency stimulation of the nucleus pontis oralis. Stimulating electrodes were also placed bilaterally in the CA3 region in order to activate the commissural/associational projection onto CA1 pyramidal cells. Lesions of the ventral hippocampal commissure (VHC) were performed by sectioning with a scouten knife.

Prior to transection of the VHC, single pulse stimulation of the CA3 region reliably produced field responses in both the ipsilateral and contralateral CA1 regions. Depth profiles of RSA demonstrated a superficial amplitude maximum in stratum oriens and a second deep maximum at the level of the hipppocampal fissure. Following transection of the VHC, field responses were no longer elicited in contralateral recordings, whereas ipsilateral field responses remained unaltered. Depth profiles conducted through the hippocampus of both hemispheres revealed a dramatic reduction of amplitude, or in some cases, a complete loss of RSA recorded in the stratum oriens region. A reduction in amplitude through the fissure remained unaltered. The present results suggest that a major portion of the RSA field recorded from the CA1 region during urethane anaesthesia depends on activity originating in the contralateral hippocampus. (Supported by New Zealand HRC Grant 91/98).

## 386.8

RHYTHMIC SLOW ACTIVITY IN EEG OF REPTILIAN AMYGDALA. J.C. Precht!\* and T.H. Bullock. Dept. of Neurosciences & Neurobiology Unit, Scripps Institution of Oceanography, U.C.S.D., La Jolla, CA. 29093-0201

Homologues of limbic structures have been established in non-mammals from ontogeny, connectivity and cytoarchitecture but little is known of their comparative physiology. The mammalian amygdala is distinguished by slow EEG rhythms that have recently been related to affective behavior. We used pond turtles (Pseudemys scripta) implanted with 6-8 electrodes to examine for an analogous EEG profile in the reptile. Electrode targets were: the central amygdala, the thalamus, the dorsal ventricular ridge (DVR), and the dorsal cortex (DC). The turtles were awake and restrained. Unstimulated EEGs were recorded with a band pass of 0.1-50 Hz. The multi-channel record was examined by eye and culled of movement artifacts after which power spectral analyses were applied.

The power spectrum from electrodes in or near the central amygdala yielded higher densities than those from the DC and DVR placements throughout the 1-15 Hz range and particularly between 1-4 Hz. On average, power density values in the 1-4 Hz range were nearly four times as large as those of DC or DVR, including comparably deep DVR loci. Results of placements in or near the thalamus or ventral part of the medial cortex were varied but always showed less overall power than amygdalar sites. Amygdalar EEGs included two conspicuous rhythms: one of broad (160 ± 8 ms) negative "sharp" waves of 90 ± 5 µV peak-to-peak (p-p) that occurred at a frequency of 4-5 per sec, and another that consisted of smaller but similarly shaped contiguous waves at a frequency of 7-8 per sec. Power spectra of epochs containing exclusively slow or fast amygdalar rhythms show peaks between 1-7 Hz or 7-12 Hz respectively.

DC loci show 17-25 Hz spindles lasting > 900 ms, associated with slow

epochs containing exclusively slow or fast amygdalar rhythms show peaks between 1-7 Hz or 7-12 Hz respectively. DC loci show 17-25 Hz spindles lasting > 900 ms, associated with slow negative shifts. Spindles occur as often as once every 4 sec with 50-100  $\mu V$  (p-p) amplitudes. Spindles cause 12-25 Hz power spectrum peaks exceeding those peaks in the amygdalar spectrum. The spectra from most DVR loci resemble those obtained from DC depths where spindles were not observed. In view of the wide differences in brain morphology and metabolism between mammals and ectotherms, analogous activities are impressive. Autonomic and behavioral measures may uncover functional parallels.

OPTICAL ACTIVITY OF DORSAL HIPPOCAMPUS IN FREELY BEHAVING CATS ASSOCIATED WITH EXTRACEILULAR VOLUME MANIPULATION. G.R. Poe\*, D.A. Nitz, F.M.Bairamova, D.M.Rector and R.M.Harper. Department of Anatomy and Cell Biology and the Interdepartmental Neuroscience Program, UCLA School of Medicine, Los Angeles. CA. 90024.

Application of hyperosmotic solutions to hippocampal slices in vitro increases extracellular volume and decreases cell size, whereas hypoosmotic solutions effect the opposite result. MacVicar and Hochman hypothesized that stimulation-induced changes in 700 nm reflectance in the dorsal hippocampal slice result from cell swelling accompanying increased neural activity. We examined the possibility that reflectance changes found in the dorsal hippocampus of freely behaving animals stem from variations in extracellular space and cell volume which accompany neural activity.

space and cell volume which accompany neural activity. Adult cats were anesthetized and stereotaxically fitted with an optical monitoring device and microdialysis cannulae in the dorsal hippocampus. After recovery, 20 mM sucrose and 100% double distilled  $\rm H_20$  were successively applied to the CA1-CA2 region in the freely behaving cat via passive diffusion through a microdialysis membrane probe. Images were digitized at 3 s intervals with respect to the ECG R-wave. Hypoosmotic ( $\rm H_2O$ ) trials resulted in decreased 700 nm light reflectance relative to baseline Ringer's solution conditions, and hyperosmotic (sucrose) trials resulted in increased reflectance (ANOVA,  $\alpha=0.05$ ). Thus, conditions which increase the extracellular volume fraction and decrease cell size are associated with increased reflectance, whereas circumstances which decrease the extracellular volume fraction and increase cell size correlate with decreased reflectance.

EFFECTS OF INTRA-ACCUMBENS MICROINJECTIONS OF AN NMDA ANTAGONIST IN AN OPEN FIELD TASK <u>C.S. Maldonado-Irizarry \*and A.E. Kelley</u> Dept. Psychology, Northeastern University, Boston, MA 02115.

University, Boston, MA 02115.

Anatomical experiments have demonstrated the existence of a pathway originating in the hippocampal formation (subiculum) and projecting to the nucleus accumbens (NAcc). There is some evidence that this pathway, which is primarily coded by glutamate, plays an important role in mediating locomotion and exploratory behavior (Mogenson & Nielsen, 1984). To further investigate this hypothesis, rats were tested in an open field task following microinjections of amino-5-phosphonovaleric acid (AP-5), a competitive NMDA antagonist (0, 0.05, 0.5, 1.0µg/0.5µl) into the NAcc. In this procedure, rats were previously habituated to the apparatus and locomotion, rearing and grooming were measured. AP-5 significantly decreased peripheral locomotion. No other behaviors were affected. A control experiment indicated a certain degree of site specificity; AP-5 injections into the anterior dorsal striatum did not significantly affect locomotion. Interestingly, this effect may be rate- or environment-dependent; similar NAcc AP-5 infusions increased motor activity in photocell cages. In a further test of exploration of novel objects in the open field, NAcc infusions of AP-5 (0, 0.1, 1.0 µg/0.5 µl) had no effect on exploration of objects (specific exploration). Taken together, these findings suggest that the hippocampal-accumbens projection may mediate diversive exploration (responses that bring the animal into contact with distal stimuli) but does not play a role in specific exploration (investigatory responses to specific stimuli).

ASSESSMENT OF DORSAL HIPPOCAMPAL OPTICAL PROPERTIES CONCURRENT WITH ELECTROPHYSIOLOGICAL MEASURES AT HIGH TEMPORAL AND SPATIAL RESOLUTION. D. M. Rector\*. G. R. Poe. and R. M. Harper. Department of Anatomy & Cell Biology and the Interdepartmental Neuroscience Program, UCLA School of Medicine, Los Angeles, CA., 90024.

Optical measurement of neural tissue activity requires high temporal resolution to ensure adequate correlation with concurrent electrophysiological events occurring at high frequencies. The introduction of inexpensive dedicated image processors allow microcomputers to digitize and store standard video images continuously at a rate of 60 frames/sec. To assess the correlation between slow wave electrical activity and optical density of neural tissue, a 1.6 mm diameter coherent fiber optic imaging probe, with attached macrowires for recording slow wave electrical events, was placed over the dorsal hippocampus in freely behaving cats. A miniature CCD video camera attached to the distal end of the probe generated video images from reflected 700 nm light. Images were digitized continuously at a rate of 60 Hz and saved to a mass storage device. A multiplexer was designed to interlace video signals with up to 32 electrophysiological channels which were simultaneously digitized and stored with the images. Subsequent analysis involved retrieval of images and cross correlation of image characteristics with electrical events. The physiological record was scored for sleep state, and discrete epochs were identified with characteristic patterns of hippocampal rhythmical slow wave activity of REM sleep and low frequency waves of quiet sleep. Reflected light amplitude correlated temporally with individual theta waves (4-7 Hz) during REM sleep and with slow waves (0-3 Hz) during quiet sleep.

and with slow waves (0-3 Hz) during quiet sleep.

## OTHER FACTORS AND TROPHIC AGENTS: BDNF, NT3

## 387.1

NEUROTROPHINS AND MOTONEURON SURVIVAL DURING AVIAN DEVELOPMENT. R. W. Oppenheim\*, D. Prevette, Y. A. Barde, R. Kolbeck. Dept. of Neurobiology and Anatomy, Wake Forest University, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1010, and Dept. of Neurobiochemistry, Max Plank Institute for Psychiatry, Munich, Germany.

Developing spinal motoneurons (MNs) express neurotrophin receptors and retrogradely transport at least some members of the NGF family of neurotrophins. However, previous in vitro studies with NGF, NT-3 and BDNF, as well as <u>in vivo</u> studies with NGF have consistently failed to observe any effect of these agents on spinal MN survival during development. We have used an <u>in vivo</u> bioassay (naturally occurring cell death) to further explore the role of NGF, NT-3. BDNF and NT-4/5 in MN development and survival. In accord with previous (including our own) findings, NGF was without effect on MN survival. Preliminary results indicate that NT-3 is also ineffective in preventing naturally occurring MN death in vivo. By contrast, BDNF not only promoted the in vivo survival of sensory neurons in the dorsal root and nodose ganglia (as expected), but also rescued significant numbers of spinal MNs from cell death. Experiments with NT-4/5 are still in progress and the role of all of these neurotrophins in regulating the cell death of other populations of central and peripheral neurons is being examined. The present data suggest that at least one member of the NGF family of neurotrophins (BDNF) may play a role in the normal in vivo development and survival of neuronal populations (e.g. MNs) other than those in peripheral sensory ganglia.

MULTIPLE PROMOTERS DIRECT TISSUE-SPECIFIC AND SEIZURE-INDUCED EXPRESSION OF THE RAT BDNF GENE. T. Timmusk, K. Palm, M. Metsis\*, M. Saarma and H. Persson. Lab of Mol. Gen., Inst. of Chem. Phys. and Biophys., Akadeemia 23, EE0026 Tallinn, Estonia, Dept. of Med. Chem. (II), Lab. of Mol. Neurobiol., Karolinska Inst., Box 60400, S-10401 Stockholm, Sweden and Inst. of Biotec., Univ. of Helsinki Karyaamokuja 3, SE-00380, Helsinki Finland

Helsinki, Karvaamokuja 3, SF-00380, Helsinki, Finland.
Here we show that the rat BDNF gene spans more than 40 kilobases of genomic DNA and consists of three short 5'-untranslated exons and one 3' protein coding exon. Three similar size mRNAs of approximately 1.6 kb, containing three different 5'-untranslated exons spliced to the same 3'-exon, are transcribed from the BDNF gene. The use of an alternative polyadenylation site in the 3'-exon generates three additional approximately 4.2 kb long mRNAs with the same 5'-ends as the shorter transcripts. The 5'-flanking regions of exons I and Ill contain TATA box-like elements and the 5'-flanking region of exon Il is similar to TATA-less promoters. Several transcription initiation sites were mapped in these regions and transfection of promoter-reporter gene constructs confirmed that these sequences act as promoters. BDNF mRNAs containing exons I and Ill were expressed only, or preferentially, in the brain, while exon Ill containing mRNA is the predominant form in lung and heart. Exon Il containing mRNA was markedly increased in the brain after seizures evoked by injection of kainic acid while only modest increases were seen for the other two forms of the BDNF mRNA. Combined, the data argue that alternative usage of three promoters within the BDNF gene and differential splicing control tissue specific and seizure-induced expression of BDNF mRNA.

**EXPRESSION OF RECOMBINANT HUMAN NEUROTROPHIC FACTORS:** STUDIES OF MUTATED FORMS AND THEIR BIOLOGICAL ACTIVITIES. K. Kullander, A. Kylberg, L. Lärkfors and T. Ebendal\*. Department of Developmental Biology, Uppsala University, Biomedical Center, S-751 23 Uppsala,

PCR was used to isolate DNA fragments encoding nerve growth factor (NGF), neurotrophin-3 (NT-3), brain-derived neurotrophic factor (BDNF) and ciliary neurotrophic factor (CNTF), cDNA from cultured human embryo primary brain cells were used to derive full-length DNA fragments that were subsequently sequenced and subcloned into the vector pXM for transient expression in COS cells. The neurotrophic activities of the various culture media were tested in bioassays using chicken embryo ganglia and found to be similar to those observed in our earlier work with mouse, rat and chicken neurotrophins. In particular, NT-3 strongly stimulated neurite outgrowth from the Remak ganglion but only a weak response was observed in paravertebral sympathetic ganglia. We are now undertaking a study of chimeric proteins where parts of the human NT-3 sequence have been replaced by the corresponding amino acids of NGF in order to determine receptor specificities. These mutations involve differences in chemical character of the replaced amino acids. They may also, from the three-dimensional structure of NGF, involve regions of binding to the trk-family of high-affinity receptors but not to the low-affinity NGF receptor, according to previous data. The human CNTF was not secreted from the COS cells but found in the cell homogenate after was included from the lack of secretion, we have designed a CNTF which includes the 20-amino-acid signal peptide from NGF. Upon transfection, this construct resulted in the secretion of biologically active CNTF. These recombinant trophic factors were also tested for their c-fos induction in cultured E16 rat cerebellar neurons. (Granted by the Swedish Science and Medical Research Councils, and the Swedish EPA).

### 387.5

CHANGES IN THE EXPRESSION OF THE NEUROTROPHINS BDNF AND NT3 MAY MEDIATE THE DEPENDENCE OF HIPPOCAMPAL NEURONS ON GLUCOCORTICOID LEVELS Timothy L. Denton, Millicent N. Dugich-Djordjevic, Nancy R. Nichols, Cynthia J. Davenport\*\*, Caleb E. Finch and Franz Hefti, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089 and \*Central Research Division, Pfizer Inc., Groton, CT 06340

Chronic stress and the elevated levels of glucocorticoids associated with it can cause degeneration in the hippocampal pyramidal neurons of both primates (Sapolsky, 1989) and rodents (Landfield, 1991). This damage resembles the degeneration that is characteristic of the aged human brain. Contrariwise the granule neurons of the dentate in young rats require adrenal steroids for survival (Sloviter, 1990). The highest levels BDNF are expressed in hippocampal pyramidal cells, while NT3 is the principal neurotrophin of the dentate. We investigated the effects of adrenal steroids on BDNF and NT3 mRNA levels. We found that male F344 rats showed a statistically significant decline (36%) in hippocampal BDNF mRNA by Northern blot analysis when treated with corticosterone (CORT) at 10 mg/day for three days compared with intact animals. The decline was confirmed as being in both dentate and pyramidal layers by in situ hybridization analysis. Interestingly, in the same experiment, NT3 mRNA levels show a statistically significant decrease (25%) in response to adrenal ectomy. Our results suggest that BDNF and NT3, by being regulated in different directions, may mediate the degenerative effect of both excessive adrenal cortical hormones, as well as their lack, on hippocampal neurons.

## 387.7

BOTH NMDA-SENSITIVE AND NON-NMDA GLUTAMATE RECEPTOR AGONISTS INCREASE THE BDNF mRNA EXPRESSION IN CEREBELLAR GRANULE NEURONS IN CULTURE. J.M. Rimland\*, M. Favaron, R.M. Maney, M.C. Comelli and H. Maney, FIDIA Research Laboratories, 35031 Abano Terme, Italy.

Laboratories, 35031 Abano Terme, Italy.

We have used primary cultures of rat cerebellar granule neurons to characterize the influence of the excitatory glutamatergic neuronal transmission on the expression of mRNAs for the brain-derived neurotrophic factor (BDNF). 8-12-day old cultures responded to an increased level of KCl in the medium (depolarization) or the removal of Mg<sup>2+</sup> from the medium by enhancing the basal expession of the BDNF mRNAs (4 and 1.6 kb bands). The increase was blocked by MK-801 (the noncompetitive antagonist of N-methyl-D-aspartate (NMDA)-sensitive glutamate receptors. NMDA itself potentiated the expression of the BDNF mRNAs dose dependently. The effect of NMDA was blocked by MK-801, but not by CNQX, the antagonist of the non-MMDA glutamate receptors. In the antagonist of the non-NMDA glutamate receptors. In situ hybridization revealed that this increase occurred situ hybridization revealed that this increase occurred within individual neurons without enhancing the number of cells expressing the mRNA. The levels of the BDNF mRNAs can also be elevated by the non-NMDA agonists kainate, AMPA and quisqualate. Here we showed for the first time that the primary culture of cerebellar granule neurons could be a suitable model to study the mechanisms involved in the regulation of BDNF expression. The model can also be used to evaluate the putative pharmacological approaches.

POTENTIATION OF THE EFFICACY OF DEVELOPING SYNAPSES BY NEUROTROPHINS, A.M. Lohof\*, Z. Xie, N.Y. Ip+ and M-m, Poo. Dept. of Biol. Sci., Columbia Univ., N.Y., N.Y. and + Regeneron Pharmaceuticals, Inc., Tarrytown, N.Y. The neurotrophins are a family of factors with well-known effects

on neuronal survival and neurite growth. In the present study, we examined their actions on synaptic transmission. Spontaneous and evoked synaptic currents were recorded from developing evoked synaptic currents were recorded from developing neuromuscular synapses in *Xenopus* cultures before and immediately after extracellular application of 50 ng/ml of brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) or nerve growth factor (NGF). BDNF and NT-3 induced marked protentiation of spontaneous synaptic activity, while NGF was without effect. The frequency of spontaneous synaptic currents (SSCs) showed an average 6.4 - fold (n=8) and 5.5 - fold (n=5) increase in response to BDNF and NT-3, respectively. The effect of NT-3 had an earlier onset than that of BDNF. The range of SSC amplitudes remained unchanged, indicating that the increase in SSC amplitudes remained unchanged, indicating that the increase in SSC frequency reflects potentiation of spontaneous ACh secretion from the presynaptic nerve terminal rather than changes in the postsynaptic ACh sensitivity. BDNF and NT-3 also potentiated the impulse-evoked synaptic response. During the first hour of exposure to BDNF and NT-3, the mean amplitude of the evoked synaptic currents increased 30 % (n=6) and 32 % (n=5) respectively. currents increased 30 % (n=6) and 32 % (n=5), respectively. These results indicate that neurotrophins can produce acute physiological effects on synaptic functions and may play a role in promoting synapse maturation.

#### 387.6

CUTANEOUS AND MUSCLE AFFERENTS IN VITRO: CUTANEOUS AND MUSCLE AFFERENTS IN VITAGE.
DIFFERENT REQUIREMENTS FOR SURVIVAL FACTORS.
PLoPrestif and S.A.Scott. Dept. of Neurobiology and Behavior,
SUNY at Stony Brook, Stony Brook, NY 11794.
Characterization of the diversity of neurons is essential for

understanding the mechanism by which neuronal diversity arises. One aspect of the diversity of dorsal root ganglion (DRG) neurons is their response to different neurotrophic factors. NGF, BDNF and NT-3 each supports the *in vitro* survival of subsets of DRG neurons, but the identity of the responding subsets is unknown. In this study we ask which neurotrophic factors support cutaneous and muscle afferents in vitro. These populations of DRG neurons have been labeled by injecting fast DiI into either a cutaneous (cutaneous femoralis medialis) or a muscle (femorotibialis/iliotibialis) nerve in E9 chick embryos. We then established cultures of lumbosacral DRG 2 and 3, in which approximately 2% of neurons were labeled. Cultures were supplemented with either NGF, BDNF or NT-3. Survival of labeled and unlabeled neurons was determined at 24 and at 48 hours. Preliminary data suggest that the major survival factor for cutaneous afferents is NGF and to a lesser extent BDNF. In contrast, the major survival but consistent support from NT-3 and NGF.

To determine whether different factors support the same or

separate neurons within cutaneous or muscle afferents, we will test whether the survival effects of different trophic factors are additive. (Supported by NIH NS16067)

## 387.8

Neurotrophin-3 Binds to Brain Sections with High Affinity

Neurotrophin-3 Binds to Brain Sections with High Affinity and with a Topography Distinctly Different from NGF.

C. A. Altar\*, M. Criden, J. A. Siuciak, R. M. Lindsay, P. S. DiStefano, Regeneron Pharmaceuticals, Tarrytown, NY 10591.

The binding of biologically active, [125]-labeled neurotrophin-3 (NT-3) was studied with dry film and emulsion autoradiography. The equilibrium binding of 300 pM [125]NT-3 to rat brain sections was reversible and inhibited by unlabeled NT-3 (IC50 of 420 pM). [1251]NT-3 bound saturably, with high affinity (Kd of 269 pM), and with a capacity (Bmax) of 26 fmol/mg prot that exceeded that of NGF by 3-fold. The association rate constant for [125I]NT-3 was 0.0074 x  $10^9~M^{-1}$  min<sup>-1</sup> and the dissociation rate constant was 19.4 x  $10^{-4}$ min<sup>-1</sup>, yielding a K<sub>d</sub> value  $(k_{-1}/k_1)$  of 227  $\pm$  28 pM. As with NGF [125I]NT-3 bound to a second site with lower affinity (Kd of 2.8 nM) [125]]NT-3 bound to a second site with lower affinity (Kd of 2.8 nM) but with much higher capacity (B<sub>max</sub> of 170 fmol/mg prot). [125]]NT-3 binding was not blocked by NGF, CNTF, K252a, or serum proteins, but was competed for by BDNF in a distinctly biphasic manner (IC50 values of 230 pM and 37 nM). [125]]NT-3 binding topography was clearly different from [125]]NGF. Highest binding was in layers 1 and 2 of rat (and human) neocortex, strata oriens and radiatum of highest parts and radiatum of the protein of the lateral effectory frost. hippocampus, molecular dentate gyrus, nu. of the lateral olfactory tract, entorhinal cortex, olfactory bulb, anteromedial thalamus, and olfactory tubercle. Moderate binding densities were present in retina, layers 4-6 of neocortex, amygdala, substantia nigra, DRG, spinal cord, and in rat and human caudate-putamen. Binding was absent from many brain regions and peripheral organs assessed with whole body autoradiography. [1251]NT-3 binds to CNS structures distinctly unlike [1251]NGF and thus is likely to affect brain and spinal cord regions not affected by NGF.

GLIAL CELLS IN THE MATURE RODENT CNS EXPRESS TRK RECEPTOR PROTEINS. <u>L.F. Kromer\*, R.H. Fryer, and D.R. Kaplan.</u> Dept. of Anat. & Cell Biol., Georgetown University Medical Center, Washington, DC 20007 and ABL-Basic Res. Program, the National Cancer Institute, Frederick, MD 21702

Recently, the trk family of tyrosine kinase receptors have been identified as high affinity receptors for the neurotrophins NGF, BDNF, and NT-3. These trophic factors are thought to be specific for neuronal elements within the CNS which are presumed to possess specific trk receptor subtypes. Thus, the objective of the present study was to determine whether receptors for these neurotrophins also are present on glial cells within the CNS. For these experiments a double immunofluorescence technique was used to colocalize GFAP and trk receptors on astrocytes. Using a pan-trk antibody that recognizes a highly conserved intracellular domain present in trkA, trkB and trkC, it was possible to colocalize trk receptors on CNS astrocytes in the postnatal and adult rat. On the day of birth (P0), most astrocytes lacked GFAP and trk staining except within the glial endfect at the pial border. By P10, astrocytes within white matter tracts strongly stain for GFAP and trk. In the adult CNS all astrocytes that stain for GFAP also possess weak *trk* staining which is concentrated in glial endfect along blood vessels and the ependymal and pial surfaces. Those astrocytes within myelinated pathways expressed the most intense *trk* immunoreactivity. These observations suggest that during the postnatal maturation of astrocytes there is an induction of trk protein that coincides with the expression of GFAP. Current experiments are investigating the functional significance of these receptors.

INDUCTION OF TRUNCATED trkB NEUROTROPHIN RECEPTORS IN HIPPOCAMPAL GLIAL CELLS DURING INJURY-INDUCED AXONAL SPROUTING. Klaus D. Beck\*. Thomas H. McNeill, Caleb E. Finch, Franz Hefti, and Jonathan R. Day. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089.

Neurotrophin receptors are formed by products of trk-related tyrosine protein kinases. At least for NGF, high affinity binding requires trk and the low affinity NGF receptor protein. trkB forms functional BDNF receptors, whereas NT-3 is capable of interacting with trk, trkB, and trkC. NT-5 was reported to bind to trkB and possibly also to trk. BDNF and trkB expression is prominent in the adult brain, particularly in cortex and hippocampus, and may be confined to neuronal cells. To test the hypothesis, suggested by the high abundance of BDNF and trkB mRNA in the hippocampus, that BDNF mechanisms play a crucial role in adult plasticity of this structure, we used defined lesions of hippocampal afferents which cause synaptic rearrangements in the hippocampal dentate gyrus. Combined lesions of perforant path and fimbria remove inputs from entorhinal cortex and septum and produce robust sprouting of axons of the commissural/assocation pathways into the molecular layer of the hippocampal dentate gyrus. We showed that this neuroplasticity correlates in time and place with the induction of trkB mRNA synthesis in non-neuronal cells in the dentate outer molecular layer. The induced mRNA species codes for a truncated trkB receptor lacking the cytoplasmic protein kinase domain. These findings suggest that trkB molecules expressed on the surface of glial cells, possibly serving as neurotrophin presenting molecules, play an important role for axonal growth in the central nervous system.

NEUROTROPHIN-3 RECEPTORS IN THE DEVELOPING RETINA OF THE CHICK. A. Rodríguez-Tébar\*, E. de la Rosa and A. Arribas. Inst. Cajal de Neurobiología, Doctor Arce 37, E-28002 Madrid,

The aim of this study was to characterize the receptor(s) for neurotrophin 3 (NT-3R) in the chick retina at various developmental stages. High affinity binding of [ $^{125}$ I]-NT-3 was found during the stages. Fig. attributes the stage of the st M). Estimation of receptor numbers per cell revealed two distinct beaks of NT-3R expression, one around E6-7 (at the onset of neuron differentiation), and another one at E12-14 (when neuron differentiation is already complete in the chick retina). The NT-3Rs expressed by retinal cells at the age of E7 and E14 may not be identical. This is suggested by differences in the pattern of inhibition with other neurotrophins and by the results of crosslinking experiments. The latter disclosed a 130 kDa band with trk-like immunoreactivity, both at E7 and E14. However, application of [125]]-NT-3 at increasing concentrations showed that this band was a high affinity NT-3R only at E14, but not E7 (kp: 2x10<sup>-11</sup> and >2x 10<sup>-10</sup> M, respectively). Age-dependent differences were found also in physiological actions of NT-3 on critical calls in short were found also in physiological actions of NT-3 on retinal cells in short-term culture. At E7 NT-3 arrested proliferation and stimulated differentiation of neuronepithelial cells. In contrast, trophic support of amacrine and ganglion cells was exerted by NT-3 at E14.

These results suggest that, by diversity of specific neurotrophin receptors, a particular neurotrophin may induce distinct effects on retinal cells at different stages of development.

DOES A SINGLE RESIDUE IN THE PORE DETERMINE SENSITIVITY TO TEA,, SINGLE CHANNEL CONDUCTANCE, AND ION SELECTIVITY OF T-CELL K CHANNELS? S. Grissmer, J. Aiyar, R. Wymore, A. Nguyen, R. Spencer, and K. G. Chandy. Dept. Physiol. & Biophys., UC Irvine, CA 92717. The genes encoding two voltage-gated K channels found in T cells, types n and l,

have been identified as Kv1.3 (Grissmer et al., 1990. PNAS 87:9411) and Kv3.1 (Chandy et al., 1992. Biophysical Journal 61:A257), respectively. These two channel proteins differ by only one residue in the deep pore (P-region).

Kv1.3 W W A V V T M T T V G Y G D D M

Kv3.1 - - - - - - L - - - - -

This residue has been recently suggested to determine sensitivity to TEA, single channel conductance,  $\gamma$ , and ion selectivity of K channels (Kirsch et al., 1992. Neuron 8:499). To test this hypothesis we compared the properties of the native the state of the determines higher K vs. Rb conductance, whereas V (Kv1.3) confers TEA sensitivity. Mutagenesis studies exchanging these residues between Kv1.3 and Kv3.1 are in progress to delineate the properties associated with these residues.

BLOCK BY HYDROXYLAMINE REQUIRES AN INTERACTION BETWEEN A PUTATIVE PORE SITE AND THE N-TERMINAL OF THE SHAKER K+CHANNEL. Andrea Yool\* and Thomas Schwarz, Dept. of Molecular & Cellular Physiol., Stanford Univ. Med. Center, Stanford CA 94305

A single site mutation (T441S) in H5 of the Shaker K+ channel has

A single site mutation (T441S) in H5 of the Shaker K+ channel has been shown previously to alter ion permeation (Yool & Schwarz 91 Nature 349:700) and internal TEA binding (Yellen & al 91 Science 251:939). These results suggest that T441 contributes to the structure of the ionic pore. In support of this hypothesis, we have found that the wild and T441S channels differ in sensitivity to block by the substituted ammonium derivative, hydroxylamine (HONH3+). Channels were expressed in Xenopus oocytes and analyzed by 2-electrode voltage and patch clamp. In the mutant T441S, but not in wild type, HONH3+ appeared to stabilize the inactivated state mediated by the N-terminal. No block by HONH3+ was observed in the non-inactivating mutant ΔN-T441S (N-terminal deletion 6-84). The dose-dependent block of otuward current of T441S was half-maximal with 10 mM external HONH3+ (90mM NaCl), 10mM HONH3Cl, 4.3mM MgCl<sub>2</sub>, 5.0mM Hepes), and correlated with a left-shift (by 10-15 mV) in the prepulse inactivation curve. Both the block of current and the shift in prepulse inactivation for T441S were prevented by the substitution of 2-10 mM external Na+ with permeant ions (K+, NH4+ or Rb+). Our results support the hypothesis that T441S alters the affinity of a putative ion binding site for NH4+ and ammonium derivatives. The interaction between the site T441S, the ion HONH3+, and the N-terminal inactivation particle (a cytoplasmic domain of the channel, Zagotta & al 90 Science 250:568) suggests that the ion is trapped by the inactivation particle at the internal side of the pore. EFFECT OF MUTATIONS IN SHAKER S4-S5
CYTOPLASMIC LOOP AND S5 SEGMENT ON ION
SELECTIVITY P.A. Slesinger\*, E.Y. Isacoff, Y.N. Jan and L.Y.
Jan. Depts. of Biochem. and Physiology, Univ. of Calif. Med. School.

<u>Jan</u>. Depts. of Biochem. and Physiology, Univ. of Calif. Med. School. San Francisco, CA 94143.

Voltage-gated potassium channels transport ions across membranes at extremely fast rates, yet maintain very high specificity by incorporating "selectivity filters" along the ion conduction pathway. Although recent mutagenesis experiments have shown that the H5 (p, SS1/SS2) region connecting S5 and S6 transmembrane domains contains elements important for singlechannel conductance and ion selectivity, it is possible that other regions of the channel comprise part of the ion conducting pore. Because mutations in the cytoplasmic loop connecting S4-S5 segments alter the single-channel conductance, suggesting that this loop lies near the internal mouth of the channel, we examined the effect of mutations in this loop as well as the neighboring S5 segment on ion selectivity. Permeability ratios for Rb and NH4 relative to internal K were determined by measuring the reversal potential in excised patches containing macroscopic currents and using a voltage ramp protocol. Most mutations produced no effect on either PRb/PK (0.64) or PNH4/PK (0.1) ratios, except for L385A & S392C mutations in the loop and G397A in S5 which increased the permeability to Rb but not to NH4. We are currently examining whether other amino acid substitutions at these residues alter Rb selectivity

## 388.7

MODULATION BY cAMP OF THE DELAYED RECTIFIER CHANNEL Kv3 EXPRESSED IN *Xenopus* OOCYTES. J. Acosta-Urquidi. C. Chavkin\*, J. Redell, N. Davidson<sup>§</sup> and H.A. Lester<sup>§</sup>. Dept. Pharmacol. Univ. Washington, Seattle, WA 98195 and <sup>§</sup>Div. Biol. 156-29, Caltech, Pasadena, CA 91125.

Using standard two-electrode voltage-clamp techniques, we studied the effects of the membrane permeable cAMP analogue 8-chlorophenylthio-cAMP (8CPTcAMP), on the cloned delayed rectifier Kv3 (Swanson et al. Neuron 4: 929, 1990). As previously described, Kv3 RNA expresses well in oocytes; its current is steeply voltage-dependent, activates between -35 to -20 mV, and is blocked by 5 mM 4-AP. We found that Kv3 is insensitive to Ba++, reaches peak in 40-50 ms at +20 mV, decays exponentially to steady-state in 2-3 s, and exhibits twin-pulse inactivation requiring 20-25 s rest for 100% recovery. 8CPTcAMP (150-300  $\mu$ M) produced a variable change in peak amplitudes: both increases (19±2.4%, N=13) and decreases (30.6±7%, N=9) were observed. In contrast, 8CPTcAMP consistently slowed the kinetics of activation and of inactivation ( $\tau_{\rm off}$  434 vs. 540 ms, P<0.01, N=5). Steady-state inactivation curves were shifted positive (h<sub>0.5</sub>: -22.8±3, vs -16.5±3.2 mV, P<0.01, N=6). Tail analysis (Erev -70 to -80 mV) revealed a slower decay rate after 8CPTcAMP (30.5±4, vs. 20± 9 ms, P<0.05, N=6). Supported by DA-04123. We thank R. Swanson for generously providing the Kv3 clone.

MUTATIONAL ANALYSIS EXAMINING THE PERMEATION PATHWAY OF THE SHAKER POTASSIUM CHANNEL. G.A. Lopez\*, Y.N. Jan & L.Y. Jan. Howard Hughes Medical Institute and Departments of Physiology and Biochemistry, University of California, San Francisco, San Francisco, CA 94143-0724.

To identify regions of the protein which may contribute to the internal mouth and pore lining structure of the Shaker potassium channel, we have made multiple single amino acid substitution mutations in the proposed sixth transmembrane segment (S6) and adjacent intracellular regions of the protein because sequence comparison reveals that some of the residues in the S6 domain are 100% conserved in all cloned potassium channels. Mutant channels were characterized at the single-channel level using inside-out patches with bi-ionic conditions to determine if the single-channel conductance and/or selectivity profile of the channel had been altered. We have found that several conservative substitution mutations in S6 affect the single channel conductance. For example, mutations at positions L468 and L472 decrease the single channel conductance. In addition to single amino acid substitutions, we have made chimeric channels using the S6 domain from other sub-families in order to identify residues which might contribute to the different single channel conductances observed with rat Shall (Kv4.2) and NGR2 (Kv3.1).

### 388.6

MODULATION OF SLOW INACTIVATION OF Kv3, A DELAYED RECTIFIER TYPE K\* CHANNEL. J. Kupper, S. Marom and I.B. Levitan\*. Dept. of Biochemistry and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Using the patch clamp configuration to record macroscopic currents through Kv3 channels expressed in Xenopus oocytes, we find that the behavior of the channels changes dramatically upon moving from the on-cell to the cell-free mode. In the on-cell mode, when the membrane is pulsed repeatedly to the same depolarized potential, the successive current traces show no change in size and kinetics. In the off-cell mode, the current decreases substantially from one pulse to another. Kv2, a highly homologous channel, does not show this change under the same conditions. One way to describe the macroscopic behavior of the Kv3 channel in the cell-free configuration is to assume that the channel can enter a long-lasting nonconducting state. TEA is known to reduce the rate of slow inactivation in Shaker H4 K+ channels when applied from the outside (Choi, K.L. et al. PNAS 88 (1991)5092-5095). External TEA also interferes with the decrease in Kv3 current with repeated pulses, suggesting that the long-lasting nonconducting state in Kv3 is equivalent to the slow inactivated state in Shaker. Studies with chimeric channels indicate that the structural components involved in this phenomenon are upstream from the pore region.

MUTATIONS OF A SINGLE PORE RESIDUE INTRODUCE FAST INACTIVATION INTO SLOWLY INACTIVATING K\* CHANNELS. M. De Biasi\*, H.A. Hartmann, M. Taglialatela, J.A. Drewe, C.C. Shieh, A.M. Brown and G.E. Kirsch\*. Departments of Molecular Physiology and Biophysics, and Anesthesiology\*. Baylor College of Medicine, Houston, TX 77030.

Fast inactivation was introduced by point mutations at position 369 in Kv2.1 and a chimeric K+ channel (CHM), in which the pore region of Kv3.1 replaced that of Kv2.1. This form of inactivation called pore or P-type inactivation shares with Shaker C-type inactivation the property that extracellular TEA slows inactivation. Additional features of P-type inactivation are its modulation by extracellular K+, its sensitivity to side chain substitutions and its removal by a unique second mutation of pore residue L374 to Val (Kirsch, et al.; this meeting). Side chain substitutions in Kv2.1 and CHM, respectively, accelerated the rate of inactivation in the following order: Leu>>Ser≥Thr>Ile>Tyr>His and Ile≥Ser>Thr>Cys>Val. Although no correlation was found between side chain polarity and the rate of inactivation produced, all the polar residues markedly reduced ouward K+ conductance. These results support the notion that residues lining the pore modulate inactivation gating. Supported by NIH grants NS29473 (G.E. Kirsch) and NS23877 and HL37044 (A.M. Brown).

THE SODIUM CHANNEL III-IV LINKER FUNCTIONS AS AN AMINO TERMINAL INACTIVATION PARTICLE IN THE MK1 POTASSIUM CHANNEL. D.E. Patton J.W. West<sup>2</sup>, W.A. Catterall<sup>2</sup>, and A.L. Goldin<sup>1</sup>. <sup>1</sup>Dept. of Microbiology & Molecular Genetics, U. California, Irvine, CA 92717 and <sup>2</sup>Dept. of Pharmacology, U. Washington, Seattle, WA 98195.

The short cytoplasmic linker that connects domains III and IV of the voltage-gated sodium channel is thought to be involved in the fast inactivation process. One hypothesis is that the linker acts as an inactivation particle in a manner similar to the amino terminal region of the Shaker B potassium channel. To test this hypothesis, we constructed a series of chimeric ion channels using as the parent channel MK1 (Kv1.1), which lacks the fast "N-type" inactivation process. To determine if MK1 possesses a functional receptor for the ShH4 amino terminal inactivation particle, we first constructed a chimeric channel in which the first 57 amino acids of the ShH4 potassium channel were attached to the amino terminus of MK1. Macroscopic currents through these channels expressed in *Xenopus* oocytes were characterized using two microelectrode voltage clamp techniques. The macroscopic inactivation kinetics of the ShH4/MK1 chimera were very similar to the wild type ShH4 potassium channel, suggesting that MK1 contains a functional receptor for the inactivation particle. To test the hypothesis that the sodium channel III-IV linker acts as an inactivation particle, we constructed a chimeric channel in which the sodium channel III-IV linker was attached to the amino terminus of MK1 (NaMK1). This chimeric channel also inactivated with kinetics similar to the wild type ShH4 channel, suggesting that the III-IV linker of the sodium channel and the amino terminal inactivation particle region of the ShH4 potassium channel may serve similar functions in the inactivation process. We are currently introducing mutations in the III-IV linker portion of the NaMK1 chimera which have dramatic effects on sodium channel inactivation to test if the same region of the III-IV linker is essential for fast inactivation in these two channels.

PROTEIN KINASE C ACTIVATORS ENHANCE A MAMMALIAN A-TYPE K <sup>+</sup> CURRENT EXPRESSED IN

XENOPUS OOCYTES.

Covarrubias, M.<sup>1</sup>, Pak, M.<sup>2</sup> and Sorensen, R.<sup>3\*</sup> Departments of Pathology and Cell Biology<sup>1</sup> and Medicine<sup>3</sup>, Jefferson Medical College, Philadelphia, PA 19107 and NIH<sup>2</sup>, Bethesda, MD 20892.

Using Xenopus oocytes as expression system, we have studied the effects of PKC activation on the properties of a mammalian A-type K<sup>+</sup> channel coded by mShal1. In voltage-clamp experiments we found that 12-O-tetradecanoylphorbol 13 acetate (TPA, 10-100 nM) or 1-oleoyl 2-acetylglycerol (OAG, 20 µM) enhance the peak mShal1 current and the effect reaches a maximum 5-10 min after the activators were perfused in the bath solution (%enhancement: 53+32, n=7 and 26+11, n=4, with TPA, 20 nM and OAG, 20 µM, respectively). PKC activation does not affect the kinetics or voltage sensitivity of mShal1 currents. The inactive 40-phorbol ester does not affect the does not affect the kinetics or voltage sensitivity of mShal1 currents. The inactive 4a-phorbol ester does not affect the current and the effect of TPA was inhibited by a 5-10 min pretreatment of the oocytes with a selective PKC inhibitor (Calphostin C, 1 uM). Furthermore, we found that the current coded by Shal2 (the Drosophila homolog) was also enhanced by PKC activation (92%, n=2). This is in contrast to Shaker currents which were only inhibited by TPA (20-100 nM). Currently, we are preparing deletion mutants and point mutations to identify the site most likely associated with the Shal current enhancement induced by PKC activation.

MODULATION OF KINETIC PROPERTIES OF A CLONED MAMMALIAN A-TYPE K CHANNEL BY BRAIN POLY(A) mRNA. L.D. Chabala 1. N. Bakry and M. Covarrubias 2, Depts. of Medicine and Pathology & Cell Biology 2, Jefferson Medical College, Phila., PA 19107.

The mouse brain cDNA clone <u>mShal</u> encodes a transient A-type K\* current that can be expressed in <u>Xenopus</u> oocytes and studied with a two-electrode voltage clamp. Expressed currents show rapid and slow phases of inactivation (A). When  $\underline{mShal}$  cRNA is coinjected along with a low molecular weight (LMW) fraction of brain  $poly(A)^{\dagger}$ mRNA (2-4 kb), currents show mostly a rapid phase 'macto' patch recordings. We did not observe any current size-dependent kinetics for control or coinjected oocytes  $(2<I_p<15~\mu A)$ . Results are consistent with expression of a modulatory factor, such as an enzyme, by LMW poly(A), which is not expressed endogenously by oocytes. The LMW poly(A) also results in sizable up-regulation of mShal current. Oocytes in A and B (same batch) were injected with  $\approx 2$  and  $\approx 0.5$  ng mShal cRNA. Oocyte in B was coinjected with  $\approx 50$  ng LMW poly(A).  $V_c$  = -90 to +50 mV.

CHANGES IN K+ CURRENT IN NORMAL AND PROTEIN KINASE A DEFICIENT CELL LINES. M. M. Bosma\* M. L. Allen, and B. L. Tempel. GRECC, Seattle VA Med. Ctr. and Depts. of Medicine and Pharmacology, U.W. School of Medicine, Seattle, WA 98195.

MK1 K<sup>+</sup> channels were stably transfected into Chinese Hamster Ovary (CHO) cells and their electrophysiological properties studied. Expressed currents were voltage-dependent, activating within 25 ms and showing less than 15% inactivation during a 500 ms pulse to +40 mV. Appreciable current was first seen between -50 and -40 mV, and maximal conductance was reached at 0 mV in mammalian Ringer. Currents were reversibly blocked by external tetraethylammonium (Ki = 5 mM), 4-aminopyridine (Ki = 3 mM) and dendrotoxin (Ki = 2.5 nM). Cells transfected with a control plasmid (vector only) or an antisense plasmid expressed no K+ current.

This channel was also stably transfected into a CHO cell line which is cotransfected with a plasmid containing a dominant mutant regulatory subunit of Protein Kinase A (PKA), causing a reduction of approximately 90% of normal PKA activity . Under these conditions, MK1 current density was up-regulated almost 2.5 fold. The histogram shows current density for 6 different cell lines, three with normal PKA activity (wt), and three with the mutant PKA (AB-). The number of cells is shown above each bar. The molecular mechanism of this regulation is under investigation. Supported by Mellon Foundation, HL44948 and NS27206.

DENSITY GRADIENTS AND LATERALLY DISPLACED DENDRITES OF RETINAL GANGLION CELLS. R. Linden\*, Instituto de Biofisica da UFRJ, Rio de Janeiro, Brazil.

Dendrites of retinal ganglion cells (RGC) in adult mammals tend to distribute mainly towards areas of low RGC density after lesions, and also in the retina of normal cats. In normal rats, however, the dendrites adult RGC do not point away from central retina, which was attributed to a shallow centro-peripheral (C-P) gradient of RGC density. In HRP-labeled whole-mounts of adult rat retinae, we studied the relationship between lateral displacement of dendrites and gradients of RGC density created by lesions of the contralateral optic tract made at birth. After degeneration of RGC with crossed projections, the dendrites of ipsilateral RGC are laterally displaced towards the depleted nasal retina. However, the temporal to nasal (T-N) gradient retina. However, the temporal to nasal (T-N) gradient created by the lesions was less steep than the normal C-P gradient. When RGC density gradients were examined at 5 days after birth (PND5), the induced T-N gradient in operated rats was also less steep than the C-P gradient of normal adults. In normal rat retinae at PND5, ganglion cells are homogeneously distributed. The results indicate that the time course, rather than the magnitude of C-P gradients of cell density determines the appearance of laterally-displaced dendrites in mammalian retinal ganglion cells. (CNPa. FINEP) (CNPq, FINEP) mammalian retinal ganglion cells.

## 389.2

DENDRITIC FIELD DEVELOPMENT OF RETINAL GANGLION CELLS (RGC) IN THE CAT AFTER DAMAGE TO VISUAL CORTEX AT BIRTH. A.J. Weber\*and R.E. Kalil, Waisman Center and Dept. of Comparative Biosciences, Center for Neuroscience and Dept. of Ophthalmology, Univ. of Wisconsin, Madison, WI 53706.

Competitive interactions among RGC dendrites during development are thought to influence their mature organization. Since damage to visual cortex in newborn cats leads to the selective retrograde degeneration of about 75% of beta RGC, we decided to investigate whether this massive degeneration of a single class of RGC in infant cats affects the subsequent dendritic development of spared RGC. Therefore, we labeled more than 110 individual RGC in living retinae with Lucifer Yellow. These cells were sampled from one nondegen erated and 12 degenerated hemiretinae in adult cats with unilateral damage to visual cortex at birth, and the spatial organization of their dendrites was analyzed with video-enhanced microscopy.

Most labeled RGC could be classified morphologically as alpha, beta or gamma cells according to standard criteria. Measurements of dendritic field size and orientation indicate that the arbors of alpha and gamma RGC are not unequivocally abnormal. While dendritic arbors of surviving beta RGC tend to be larger than those of control cells, current sample sizes are small, 8 and 11 cells respectively. In summary, these results suggest that a pronounced loss of beta RGC during infancy may not produce major alterations in the dendritic development of those ganglion cells that are spared.

CORRELATED SPONTANEOUS CALCIUM BURSTING IN THE DEVELOPING . Wong, A. Chemiavsky, S. J Smith and C.J. Shatz, Depts. of Neurobiol., and Molec. & Cell Physiol., Stanford University, CA 94305.

Ganglion cells of the neonatal ferret retina spontaneously fire sodium

cangion ceils of the neonatal terret retina spontaneously lire sodulinaction potentials in rhythmic bursts, which are correlated between neighbors in the form of an excitatory wave (Meister et al, Science, 252:139,1991). To learn more about the spatiotemporal pattern of bursting activity in the retina, we used single wavelength (380 nm exc.) in vitro measurements of Fura-2 stained neonatal retinae (P5-P15) to monitor changes in intracellular calcium. Cells in the ganglion cell layer (GCL) underwent spontaneously generated increases in [Ca++]; that lasted 5 to 8 secs; these increases occured periodically, every 25 to 60 secs. This temporal pattern is identical to that seen with recordings of action potentials. Another similarity to action potential recordings is that the "calcium bursting" of neighbouring cells in the GCL was correlated. Even though not all cells in the GCL were active during periods of spontaneous bursting, the remaining cells could increase curing periods of spontaneous bursting, the remaining cells could increase [Ca++], with perfusion of 100 μM glutamate, indicating they are capable of responding to applied transmitter. Calcium bursting ceased in the presence of 10-25μM tetrodotoxin. By contrast, the pattern of calcium bursting was not altered in the presence of 0.1-1 mM of kynurenic acid, suggesting that glutamate is not involved in sustaining the spontaneous activity. Retinal cells in the inner nuclear layer were also periodically bursting and their activity was correlated with that of cells located in the GCL Taken together, our observations suggest that the spontaneous changes in [Ca++]; require Na+ dependent action potentials and that the correlated activity between developing retinal neurons is likely to be mediated by a specific network of connections rather than by the non-specific release and diffusion of glutamate into the extracellular space. GENESIS OF RETINAL GANGLION CELLS AND THE CHIASMATIC COURSE OF THEIR AXONS IN THE FERRET B.E. Reese\* G.E. Baker², W.F. Thompson¹, and J.D. Peduzzì². Neuroscience Research Institute and Dept of Psychology, University of California, Santa Barbara, CA 93106; Dept of Physiological Optics, University of Alabama, Birmingham, AL 35294 Retinal ganglion cell classes in non-primate mammals differ greatly in their decussation patterns. The axons of medium-sized cells primally decussate at the optic chiasm, so that those from the nasal retina project contralaterally while those from temporal retina project ipsilaterally, whereas the axons of most small-sized cells project contralaterally, irrespective of retinal origin. We have examined the hypothesis that these different decussation patterns are governed by a time-dependent mechanism defining the chiasmatic course of growing optic axons. In one study, fetal ferrets were exposed to ?!!-thymidine at different gestational stages in order to label early and late cohorts of retinal ganglion cells at two months after birth. Early (E-26) and late (E-32) injections of ?!!-thymidine each label ganglion cells across the surface of both the nasal and temporal retina. Early injections label exclusively medium-sized cells while later injections label primarily small-sized cells. Since medium-sized cells of the temporal retina project ipsilaterally while the majority of small-sized cells project contralaterally, time of genesis may determine pathway choice at the optic chiasm.

The axons of recently generated ganglion cells take 3-4 days to reach the optic tract. In a second study therefore, fetuses were fixed with paraformaldehyde on E-30 or E-36, and then given implants of Dil into either one optic tract at the same age retrogradely label beth two eyes or optic tracts, respectively. Implants into the temporal retina to label the two eyes or optic tracts, respectively. Implants into the temporal retina to the temporal retina but only the contralateral nasal retina. In contrast, implan

DEVELOPMENT OF ELECTROPHYSIOLOGICAL MEMBRANE PROPERTIES AND SYNAPTIC RESPONSES OF FERRET LGNd CELLS. A.S. Ramoa\* and D.A. McCormick. Yale Univ. Med. Sch. New Haven, CT

Establishment of the mature pattern of retino-geniculate connectivity requires the development of electrophysiological activity in LGNd (dorsal lateral geniculate nucleus) neurons. In the present study, we used whole cell patch-clamp recordings in vitro to examine the time course of development of the intrinsic membrane properties and synaptic (optic tract) inputs of ferret LGNd cells.

Several changes in electrophysiological properties of LGNd cells were noted between postnatal day 1 (P1) and P25. Although P1-5 cells could generate long-duration (500 msec) and high frequency (up to 50 Hz) trains of action potentials to depolarization, individual action potentials became taller in amplitude, faster in rate of rise and fall, and shorter in duration with age. Early postnatal cells could also generate a high threshold Ca ++ current but not the low threshold Ca++ spike that characterizes cells P5 or older. In addition, P1-5 cells lacked the hyperpolarization-activated cation current Ih. Activation of retinal afferents resulted in longer duration EPSPs earlier in life. IPSPs only appeared several days after birth. Thus, the postnatal development of intrinsic membrane properties and synaptic responses in LGNd neurons is coordinated to enhance synaptic-driven action potential activity at an early age, even before endogenous rhythmic burst firing develops.

JUNCTIONAL COUPLING BETWEEN NEURONS IN THE DEVELOPING MAMMALIAN RETINA. A. A. Penn. R.O.L. Wong and C.J. Shatz\*. Dept. of Neurobiolgy, Stanford Univ. School of Medicine, Stanford, CA 94305 and Dept of Molecular and Cell Biology, UC Berkeley, CA 94720.

The ganglion cells of the developing ferret retina during the first 3 postnatal weeks spontaneously generate waves of electrical activity that travel across the retina in the absence of mature photoreceptors (Meister

et al., Science, 252: 139, 1991). These waves of correlated activity may be generated by a neural circuit in the retina. Here we have explored the possibility that gap junctions could represent a morphological substrate for the correlations. Retinal ganglion cells in a living in vitro preparation from P10 to P30 ferrets were injected with neurobiotin and lucifer yellow, P10 to P30 terrets were injected with neurobiotin and luciter yellow, tracers known to pass through gap junctions. At all ages studied luciter yellow entirely filled the soma and processes of the injected cell only. In contrast, from P12 onwards neurobiotin filled not only the injected cell but also frequently a constellation of other cells within the dendritic tree. When injected ganglion cells were classified by type, alpha cells are seen to be tracer coupled to amacrine cells (including displaced amacrines) and by P21 they were also coupled to other alpha ganglion cells, in a pattern resembling that seen in the adult (Vaney, Neurosci. Lett. 125: 127,1991). Beta cells were apparently not coupled at any time nor to any other cell. These observations indicate that junctions able to pass the lower molecular weight neurobiotin are present in the inner plexiform layer during the period when the firing of retinal ganglion cells is highly during the period when the firing of retinal ganglion cells is highly correlated. Such junctions could play a role in synchronizing the activity of neighboring ganglion cells during development. However, since the junctions are known to exist in adulthood but the waves of activity disappear by P30, other changes in retinal circuitry are likely to contribute to the disappearance of the waves. ACTIVITY-DEPENDENT ENHANCEMENT OF SYNAPTIC TRANSMISSION WITHIN THE DEVELOPING LGN. R. Mooney\*, D.V. Madison and C.J. Shatz. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

The adult pattern of segregated eye input to the mammalian lateral geniculate nucleus (LGN) arises as a consequence of an activitydependent rearrangement of synapses from retinal ganglion cell (RGC) axons, which initially are intermixed with each other. To study the synaptic mechanisms capable of supporting such activity-dependent reorganization, we used an in vitro slice preparation of the neonatal ferret LGN, in which retinogeniculate synaptic transmission could be monitored physiologically. Whole cell voltage-clamp recordings were obtained from LGN neurons with perforated patch techniques. Electrical stimulation of the optic tract elicited both short latency inward currents (at  $V_m$ =-70 mV), which were blocked by a combination of CNOX (10 μM) and D-APV (50 μM), and longer latency currents, which were eliminated by picrotoxin (50-75 μM). To examine the activity-dependent properties of the short latency glutamatergic EPSC, recordings were performed in picrotoxin. Under these conditions, three to six bursts of high frequency stimulation of the optic tract often (17 of 37 cells) produced marked increases in the EPSC amplitude. This enhancement persisted up to two hours, and was observed in slices prepared from P6 to P30 animals. These observations indicate that synapses within the retinogeniculate pathway exhibit activity-dependent changes in strength. Thus, such changes may underlie the process of synaptic rearrangement that accompanies the segregation of RGC axons into eye-specific layers. Supported by H.H. Whitney Foundation to R.M., March of Dimes and NSF IBN 9212640 to C.J.S., and NIHMH 48108 to D.V.M. and CJ.S.

ELECTROPHYSIOLOGICAL PROPERTIES OF DEVELOPING NEURONS RECORDED IN SLICES OF FERRET LGN C.A. White\*, M. Esguerra and M. Sur. Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

Sciences, M.I.T., Cambridge, MA 02139
During the first postnatal month, retinogeniculate axons segregate into eye-specific laminae and On and Off sublaminae. Eye-specific laminae are formed by postnatal day (P) 14 (Linden et al., '81) and On and Off sublaminae a week or more later. Using 4M potassium acetate electrodes, we recorded intracellularly from 45 A-layer neurons in slices of LGN between P7 and P33, during the period of lamination and sublamination. Resting membrane potential (mean=62.4 mV), input resistance (58.5 M $\Omega$ ) and time constant (7.0 ms) did not change significantly during the period. At all ages cells were capable of firing action potentials and had low threshold potentials when excited from hyperpolarized membrane potentials. On the average action potentials hyperpolarized membrane potentials. On the average action potentials became shorter in duration (from 4.4 ms to 1.7 ms) and larger in amplitude (from 56.9 mV to 77.5 mV) with age. In cells recorded with 4M cesium acetate, the spikes broadened significantly and a typical 8-20 ms afterhyperpolarization was not seen. Young and older neurons shared similar spike train characteristics, producing more spikes with shorter latency (maximum frequency 123 Hz) as current intensity increased. Optic tract stimulation produced EPSPs, IPSPs and EPSP-Increased. Optic tract stimulation produced EPSPs, IPSPs and EPSP-IPSP pairs beginning at the youngest ages. Preliminary experiments indicate that the EPSPs are reduced by the NMDA and non-NMDA glutamate receptor antagonists d-APV and NBQX, respectively, and that the IPSPs are reduced by the GABAA receptor antagonist bicuculline methodide. Supported by EY 06297 (C.A.W.) and EY 07023 (M.S.).

GLUTAMATE - INDUCED CALCIUM RESPONSES OF DEVELOPING

GLUTAMATE - INDUCED CALCIUM RESPONSES OF DEVELOPING SUBPLATE CELLS. K. Herrmann\*and C.J. Shatz. Division of Neurobiology, Dept. of Molecular and Cell Biology, U.C. Berkeley, CA 94720. In neocortical development, the subplate is a complex neuropil filled with subplate neurons and synapses, some of which are supplied by waiting thalamic axons. To further understand and characterize the possible interactions between the waiting axons and their postsynaptic partners, we used Fura-2 imaging techniques. Since glutamate is thought to be used by thalamic axons in adults, glutamate-induced changes in the calcium responses of subplate cells were monitored in acute slices of neocortex taken from neonatal ferrets. Many cells in the subplate were well stained with Fura-2, but in acute slices they showed very little spontaneous activity. However, application of 100 µM glutamate induced large increases in the intracellust Ca+++ which could be mignificed by 110 µM intracellular Ca++ concentration [Ca++]i, which could be mimicked by 100 μM NMDA. During application of glutamate and NMDA, some cells responded with a transient rise in  $(Ca^{++}]_i$ , while other cells underwent oscillations. Responses were abolished in the presence of 2.5  $\mu$ M TTX, or upon application of 100 $\mu$ M glutamate in the presence of 50  $\mu$ M APV. These observations indicate that glutamate elicits heterogeneous responses, suggesting the presence of diverse cell types in this zone, as has been demonstrated for the cortical plate in rats (Yuste & Katz 1991, Neuron 6, 333). In addition, these changes in [Ca++] depend upon activation of voltage sensitive Na<sup>+</sup> channels via NMDA receptors. Since migrating neurons are not thought to express NMDA receptors (Lo Turco et al.1991, J. Neurosci 11, 792), and astrocytes are virtually absent until about P4 in ferrets, it is likely that the observed changes in [Ca<sup>++</sup>]<sub>i</sub> originate primarily in subplate neurons. If so, then subplate neurons are capable of responding to release of neurotransmitters such as glutamate during these early developmental times. Supported by the Alzheimer's Association and NIH EY02858.

NEURONAL DOMAINS IN DEVELOPING NEOCORTEX: MECHANISMS OF COACTIVATION.

R. Yuste\*, D. A. Nelson, A. Peinado and L. C. Katz, Dept. of Neurobiology, Duke University, Durham, NC 27710.

Correlations in the spontaneous activity of neighboring neurons may play a critical role in the emergence of cortical connectivity. By imaging slices of neonatal rat visual and somatosensory cortex with the Ca<sup>2+</sup> sensitive dye fura-2, we observe hat discrete regions of neurons spontaneously undergo synchronous [Ca<sup>2+</sup>]<sub>1</sub> changes, defining neuronal "domains," In tangential slices domains have similar sizes, 50 - 120 µm in diameter, discrete borders, and tile the cortex with little overlap with neighboring domains. In coronal slices they have radial shapes, resembling columns. These spatial properties suggests that domains represent modular units in developing cortex that could contribute to the formation of the adult functional architecture

To study the mechanisms responsible for the coactivation of neurons within a domain, we performed high-speed optical recordings (33 msec time resolution). The activation of all neurons in a domain took less than 1 sec; the resulting increases in  $[Ca^{2+}]$ ; persisted for 10 - 25 sec. The rate of spread of the coactivation ranged from 49 to  $382 \ \mu m/sec$  (mean =  $128 \pm 71 \ \mu m/sec$ , n = 27). These speeds are faster than estimates of free ionic diffusion, but are compatible with electrical activation or regenerative second messenger waves (Meyer, Cell 64:675, 1991). Thus, passive diffusion of calcium cannot account for the coactivation. In addition, domains occurred in TTX, suggesting that their coactivation is not due to sodium spikes and conventional synaptic transmission, but may be mediated instead by gap-junctions. In agreement with this, perfusion of 12 slices with the gap-junction blocker 1- octanol (1 mM) reversibly blocked 69 ± 19 % of the domains. Also, consistent with gap-junctional coupling, intracellular injections of the tracer biotin ethylenediamine into single neurons resulted in the labeling of numerous neighboring neurons (see next abstract).

Based on these data, we hypothesize that the domains are due to the spontaneous activation of one or a few "trigger" neurons which in turn activate a restricted number of secondary neurons through gap-junctions.

GROWTH BEHAVIOR OF THALAMIC AXONS ON CORTICAL MEMBRANES STUDIED WITH TIME-LAPSE VIDEO MICROSCOPY. M. Hübener\* 1, M. Götz 1, S. Klostermann², and J. Bolz 1. ¹Friedrich-Miescher Labor der Max-Planck Gesellschaft and ²Max-Planck Institut für Entwicklungsbiologie, Spemannstr., 7400 Tübingen, Germany.

Thalamocortical afferents arrive in the cortex before their target cells in layer 4

are born. The fibers wait in the subplate zone and enter the grey matter only after layer 4 cells have migrated to their final position. It has been shown recently that specific growth promoting molecules up-regulated during cortical development allow thalamic fibers to invade the cortex (Götz et al., Soc. Neurosci, Abstr. 17, 898. 1991). We have now used time-lapse video microscopy to study the growth of thalamic axons on cortical membranes from different developmental stages, and their behavior at borders between different substrates. There were clear differences in the growth behavior of thalamic axons on cortical membranes prepared from embryonic (E16) or postnatal (P7) rats. On P7 membranes fibers grew at an average rate of  $30 \, \mu \text{m/h}$ . Collapse of growth-cones was observed frequently after contact with other axons, but only rarely in the absence of fiber-fiber interactions. In contrast, axons grew slower on E16 membranes (16 µm/h) and growth-cone collapse often occurred without contact with another axon, suggesting that substrate properties are responsible for this behavior. In experiments where thalamic axons were given a choice between alternating lanes of E16 and P7 cortical membranes, a higher number of fibers grew on P7 membranes. Fibers extending on P7 membranes and encountering a border with E16 membranes often reacted with a growth-cone collapse and retraction. In many cases axons performed sharp turns after contact with E16 membranes and continued their growth on P7 membranes. Only a few fibers crossed the borders between the two substrates without any visible change in growth behavior. These observations show that the trajectories of thalamic axons can be oriented by growth-permissive molecules expressed on cortical membranes. Supported in part by DFG.

EXTENSIVE NEURONAL DYE-COUPLING IN NEOCORTE DURING THE TIME WHEN CIRCUITS ARE FIRST FORMED.

A. Peinado\*, R. Yuste and L. C. Katz., Dept. of Neurobiology, Duke University, Durham, NC 27710.

The formation of local circuits in the developing cerebral cortex involves many kinds of neuronal interactions mediated by conventional synaptic transmission. Another way for neurons to transmit signals is through gap-junctions. In cerebral cortex, these have been difficult to observe with conventional gap-junction tracers such as Lucifer yellow (LY), although there are reports of coupling among small groups of up to 9 neurons using LY in rat before day 10 (Connors et al., J. Neurosci, 3:773 '83) and among groups of ventricular zone neuroblasts (LoTurco & Kriegstein, Science 252:563 '91). Using a smaller intracellular tracer, biotin ethylenediamine (BE) (Vaney, Neurosci. Lett., 125:187, 91), in rat visual and somatosensory cortex, we find that coupling is widespread among neurons during the first 2 postnatal weeks. We injected single neurons with BE or LY in cortical slices. BE was visualized

using the ABC method (Vector) and viewed with Nomarski optics. LY was visualized similarly, using a biotin-conjugated anti-LY antibody to amplify its signal.

similarly, using a houn-conjugated anti-L7 anholody to amplify its signal. We find that after injection of biotir ethylenediamine into single neurons, the tracer either remains confined to that cell or spreads to many nearby neurons (range=21-35 cells; mean=27 cells; ages P7-9) where it labels their soma and proximal dendrites. In contrast, LY usually labels a single neuron and occasionally 2 or 3.

Coupling is already extensive by P5, the earliest time tested, and can be seen until P14, but not later. Injections on P5 often generate a columnar arrangement of

labeled cells, 50-70 µm wide, spanning several cortical layers. At later ages most coupled neurons are found either inside the dendritic field of the injected neuron,

where dendro-somatic contacts can be seen, or close enough to it to be within range of dendro-dendritic contact. Coupling is only rarely associated with axons.

These results, together with those in the previous abstract, suggest that exchange of small molecules and ions through dendritic gap junctions may be a means for neighboring cortical neurons to achieve temporal coordination of their responses during the period of circuit formation.

## CRLL MIGRATION AND MOTILITY I

Blochemical Differentiation of Migratory Gonadotropin-Releasing Hormone (GnRH) Cells in the Mouse.

1. Livne\*, M. J. Gibson, and A. J. Silverman. Dept. of Medicine, Mt. Sinai Sch.

of Med., New York, N. Y. 10029 & Dept. of Anat. & Cell Biol., Columbia Univ., New York, N. Y. 10032.

New York, N. Y. 10032.

GnRH cells are first detected in the olfactory placode on E11.5 in the mouse and migrate across the nasal septum on E12.5-E15.5, taking residence within the CNS on E16.5. We have studied several aspects of the biochemical and morphological differentiation of GnRH neurons and the cellular associations that they make during their migratory process. On E12.5, when most of the cells are still in the nasal septum, only 15% of the population can process the pro-GnRH precursor to the amidated decapeptide. Two days later (E14.5), when the majority of GnRH cells have advanced into the can process the pro-GnRH precursor to the amidated decapeptide. Two days later (E14.5), when the majority of GnRH cells have advanced into the forebrain, 79% contain mature GnRH. In keeping with these observations, EM analysis indicated that E12.5 GnRH neurons are only lightly stained and the reaction product is confined to the outer nuclear envelope and the rough endoplasmic reticulum (RER). By E14.5 cells in the nasal septum have more reaction product in the RER and some of the Golgi cisternae are also positive. Immunoreactive neurosecretory granules also appear at this stage. While GnRH neurons migrate in the nasal septum they remain within the confines of the olfactory and vomeronasal (VMO) axonal fascicles. Immunoreactive cells maintain close apposition with each other and with the axons and their associated glia which ensheathe these fascicles. Once in the forebrain, GnRH neurons no longer maintain close association with each other, nor do they associated glia which ensheathe these fascicles. Once in the forebrain, GnRH neurons no longer maintain close association with each other, nor do they follow any defined anatomical structure. These findings indicate that although GnRH cells express their unique neuropeptide early in their ontogeny, their differentiation continues and is coordinated with their migration. The migration of these neurons across the nasal septum relies on axonal fascicles of the olfactory and VMO nerves. In the forebrain, however, GnRH cells must utilize alternative guiding mechanisms to complete their migration. Supported by HD 10665 and NS 20335.

## 390.2

CELLS DESTINED FOR THE OLFACTORY BULB ORIGINATE IN THE TELENCEPHALIC SUBVENTRICULAR ZONE AND REACH THEIR TARGET BY MIGRATING ALONG A RESTRICTED LONGITUDINAL PATHWAY. M.B. Luskin\*, E. Breding, K.E. Miller, M. Maultsby. Dept. of Anatomy and Cell Biology & Program in Neuroscience, Emory Univ. Sch. of Med., Atlanta, GA 30322.

In the neonatal rodent forebrain, glial cells are derived from the subventricular zone (SVZ) which surrounds the lateral ventricles. We are further examining the spatial and temporal patterns of migration of cells originating in different regions of the SVZ.

To determine the course of migration of the neurons and glia arising in the anterior part of the SVZ (SVZa), a retroviral lineage tracer containing the reporter gene E. coli  $\beta$ -galactosidase (lacZ) was injected into the SVZa of rat pups on postnatal day 0 (P0) or P1. Animals were perfused either 1 day or 1 - 5 weeks later and the brains were sectioned and stained with X-Gal to reveal the position of lacZ+ cells.

The number and distribution of lacZ+ cells were dependent upon injection site and survival time. One day after injection, small numbers of lacZ+ cells appeared near the injection site (1.0-1.9 mm lateral to midline, 1.5-2.0 mm anterior to Bregma, 1.5-2.0 mm below the pial surface), whereas after one week, there were numerous lacZ+ cells throughout the subependymal zone (SEZ), which formed a continuous stream of cells extending longitudinally from the injection site to the center of the olfactory bulb (OB). Two weeks after injection, the majority (97%) of lacZ<sup>+</sup> cells had migrated from the SEZ of the OB radially into overlying cellular layers. By 4 weeks, <30 % of the post-migratory lacZ<sup>+</sup> cells were located in the glomerular layer, while the majority (>60 %) populated the granule cell layer. Retroviral injections more posteriorly (0.3-1.0 mm anterior to Bregma) in the SVZ seldom labeled cells in the OB.

Our experiments show that progenitor cells situated in the SVZa generate cells destined for the OB and that their progeny reach the OB by proceeding initially, in a longitudinal direction, along a confined pathway and then proceed radially outward into the OB. Supported by Pew Charitable Trusts, NIH and March of Dimes.
