# SOCIETY FOR NEUROSCIENCE

# **ABSTRACTS**

VOLUME 18, PART 1

22ND ANNUAL MEETING ANAHEIM, CALIFORNIA OCTOBER 25–30, 1992

# 1992 © Society for Neuroscience

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0-916110-38-9
Part 2 ISBN 0-916110-39-7
Both parts ISSN 0190-5295
Library of Congress Catalog Card Number 75-7761

# Proper citation form for this volume:

Soc. Neurosci. Abstr., Vol. 18, Part 1, p. xxx, 1992.

Published by: Society for Neuroscience 11 Dupont Circle, N.W. Suite 500 Washington, D.C. 20036

# 1992 Program Committee

Stanley J. Watson, Jr., M.D., Ph.D. Chairperson University of Michigan School of Medicine

Dennis W. Choi, M.D., Ph.D. *Incoming Chairperson*Washington University School of Medicine

David G. Amaral, Ph.D. The Salk Institute

Martha C. Bohn, Ph.D. University of Rochester Medical Center

Andrew G. Bulloch, Ph.D. University of Calgary Health Science Center

Marc G. Caron, Ph.D. Duke University Center

Roland D. Ciaranello, M.D. Stanford University School of Medicine

Antonio R. Damasio, M.D., Ph.D. University of Iowa College of Medicine

Stephen M. Highstein, M.D., Ph.D. Washington University School of Medicine

Janice M. Juraska, Ph.D. University of Illinois

Harvey J. Karten, M.D. University of California School of Medicine

James E. Krause, Ph.D. Washington University School of Medicine

Irwin B. Levitan, Ph.D. Brandeis University

James O. McNamara, M.D. Duke University Medical Center V.A. Medical Center Mary L. Oster-Granite, Ph.D. University of California

Urs S. Rutishauser, Ph.D. Case Western Reserve University School of Medicine

S. Murray Sherman, Ph.D. SUNY, Stony Brook

Roger P. Simon, M.D. University of California, San Francisco

Gerard P. Smith, M.D. New York Hospital, Cornell Medical Center

W. Thomas Thach, Jr., M.D. Washington University School of Medicine

Leslie G. Ungerleider, Ph.D. National Institutes of Health

Charles J. Vierck, Ph.D. University of Florida Health Science Center

Monte Westerfield, Ph.D. University of Oregon

Robert D. Wurster, Ph.D. Loyola University of Chicago

Richard E. Zigmond, Ph.D.

Case Western Reserve University School of Medicine

Joseph T. Coyle, M.D., ex officio Harvard Medical School

Ira B. Black, M.D., ex officio UMDNJ-Robert Wood Johnson Medical School

Story C. Landis, Ph.D., ex officio Case Western Reserve University School of Medicine

# **CHRONOLOGICAL LIST OF SESSIONS**

(See page xvi for Thematic List of Sessions)

|---|--|-----|
| SUNDAY, OCTOBER 25  | Poster Sessions — 8:30 a.m.                              |     |
| SONDAI, GETOBER 23  | 20. Genesis of neurons and glia I                        | 29  |
| Decade of the Brain Lecture — 8:00 p.m.                         | 21. Cell shape and differentiation I                     | 31  |
| The Human Brain and Behavior: Insights From Modern              | 22. Axon guidance mechanisms and pathways I              | 34  |
| Imaging Techniques  | 23. Formation and specificity of synapses I              | 39  |
| M.E. RaichleNo Abstract   | 24. Ion channels: development                            | 41  |
|   | 25. Neuronal death: apoptosis                            | 43  |
| MONDAY OCTOBER 26   | 26. Neuronal death: toxins                               | 45  |
| MONDAY, OCTOBER 26  | 27. Neuronal death: axotomy                              | 47  |
| Symposia — 8:30 a.m.  | 28. Neuronal death: retina                               | 48  |
| 2. Emerging Principles of Organization Within the Midbrain      | 29. Neuronal death: morphology                           | 49  |
| Periaqueductal Gray Matter                                      | 30. Neuronal death: sympathetic neurons                  | 49  |
| Chaired by: M.T. Shipley and R. Bandler1                        | 31. Neuronal death: cellular response                    | 50  |
| 3. The Computational Neuron                                     | 32. Molecular and pharmacological correlates             |     |
| Chaired by: T.J. Sejnowski1                                     | of development I   | 52  |
|   | 33. Sensory development: auditory and olfactory          | 54  |
| Special Lecture — 10:00 a.m.                                    | 34. Sensory development: somatosensory                   | 56  |
| 4. Olfactory Mechanisms in an Insect Model                      | 35. Transplantation: Parkinson's—fetal tissue            | 58  |
| J.G. HildebrandNo Abstract                                      | 36. Transplantation: Parkinson's—adrenal, PC12           | 61  |
|   | 37. Neuroglia and myelin I                               | 63  |
| Special Lecture — 11:45 a.m.                                    | 38. Cytoskeletal transport and membrane targeting        | 66  |
| 5. The Molecular Basis of Electrical Excitability in the Brain: | 39. Gene structure and function I                        | 69  |
| Structure, Gating and Neuromodulation of Sodium Channels        | 40. Calcium-activated potassium channels                 | 72  |
| W.A. CatterallNo Abstract                                       | 41. Potassium channels: physiology and molecular biology | 74  |
|   | 42. Acetylcholine: neuronal nicotinic receptors I        | 78  |
| Slide Sessions — 8:30 a.m.                                      | 43. Excitatory amino acids: excitotoxicity I             | 81  |
| 6. Biological rhythms and sleep I                               | 44. Excitatory amino acids: pharmacology I               | 85  |
| 7. Monoamines and behavior: human disease                       | 45. Excitatory amino acids: receptors I                  | 87  |
| and animal models3  | 46. Serotonin receptors: 5HT <sub>1A</sub> subtypes      | 90  |
| 8. GABA receptors: structure and function4                      | 47. Interaction between neurotransmitters I              |     |
| 9. Catecholamine receptors: dopamine I6                         | 48. Regional localization of receptors and transmitters: |     |
| 10. Calcium channel toxins I8                                   | biogenic amines, misc                                    | 97  |
| 11. Visual cortex: functional circuits and oscillations I10     | 49. Regional localization of receptors and transmitters: |     |
| 12. Nerve growth factor I                                       | peptides and GABA  | 100 |
| 13. Invertebrate learning and behavior I                        | 50. Second messengers I                                  | 102 |
| 14. Cell lineage and determination I                            | 51. Behavioral pharmacology: ethanol, GABA, et al        | 107 |
| 15. Degenerative disease: Alzheimer's—ß-amyloid I19             | 52. Hypothalamic-pituitary-gonadal regulation:           |     |
| 16. Opioid and sigma receptors21                                | neuropeptides  | 110 |
| 17. Catecholamines  | 53. Hypothalamic-pituitary-gonadal regulation: steroids  |     |
| 18. Control of posture and movement I25                         | 54. Neuroendocrine regulation: prolactin                 | 114 |
| 19. Oculomotor I  | 55. Hypothalamic-pituitary-gonadal regulation:           |     |
|   | I HRH and I H I  | 116 |

| Session<br>Number & Title                                | Page    | Session<br>Number & Title Paş                                    | ge |
|--|---------|--|----|
| 56. Neuroendocrine regulation: hypothalamus/pituitary    | 119     | Presidential Special Lecture — 4:15 p.m.                         |    |
| 57. Neuroendocrine regulation: limbic system             | 122     | 89. Molecular Biology of the Dopaminergic System                 |    |
| 58. Respiratory regulation: central networks/patterns    | 123     | O. CivelliNo Abstrac   | :t |
| 59. Regulation of autonomic function: genitourinary      | 126     |  |    |
| 60. Somatic and visceral afferents I                     | 129     | Slide Sessions — 1:00 p.m.                                       |    |
| 61. Spinal cord  | 131     | 90. Hypothalamic-pituitary-gonadal regulation191                 | 1  |
| 62. Pain modulation: hyperalgesia                        | 133     | 91. Peptides: biosynthesis, metabolism, biochemistry 1193        | 3  |
| 63. Retina and photoreceptors I                          | 136     | 92. Biological rhythms and sleep II195                           | 5  |
| 64. Subcortical visual pathways: LGN                     | 139     | 93. Degenerative disease: Alzheimer's—other197                   | 7  |
| 65. Subcortical visual pathways: retina and colliculus   | 142     | 94. Pain: pharmacology199  | 9  |
| 66. Visual cortex: physiology of extrastriate cortex     | 146     | 95. Psychotherapeutic drugs201                                   | 1  |
| 67. Auditory system: central physiology I                | 149     | 96. Stress   | 3  |
| 68. Brain metabolism and blood flow I                    | 152     | 97. Degenerative disease: Alzheimer's—                           |    |
| 69. Genetic models I                                     | 156     | neuropharmacology and neurotransmitters I205                     | 5  |
| 70. Epilepsy: human studies and animal models I          | 158     | 98. Formation and specificity of synapses II207                  | 7  |
| 71. Epilepsy: basic mechanisms I                         | 162     | 99. Visual cortex: functional organization of striate cortex 208 | 8  |
| 72. Degenerative disease: Alzheimer's—ß-amyloid II       | 164     | 100. Molecular biology of serotonin receptors210                 | Э  |
| 73. Degenerative disease: Huntington's disease           | 167     | 101. Subcortical visual pathways212                              | 2  |
| 74. Trauma: behavioral studies                           | 169     | 102. Oculomotor II214  | 4  |
| 75. Trauma: mechanisms of injury and healing             | 171     | 103. Motor systems and sensorimotor integration: cortex I216     | 6  |
| 76. Trauma: transmitters                                 | 172     |  |    |
| 77. Trauma: cellular reaction                            | 173     | Poster Sessions — 1:00 p.m.                                      |    |
| 78. Trauma: metabolic changes                            | 175     | 104. Process outgrowth, growth cones and sprouting I218          | 8  |
| 79. Trauma: drug treatment                               | 176     | 105. Axon guidance mechanisms and pathways II221                 | 1  |
| 80. Trauma: glia/blood-brain barrier                     | 178     | 106. Other factors and trophic agents: BDNF, NT3, NT4224         | 4  |
| 81. Trauma: hypothermia                                  | 179     | 107. Other factors and trophic agents: trks227                   | 7  |
|  |         | 108. Hormones and development: non-gonadal hormones228           | 3  |
| (History and Teaching Posters will be                    |         | 109. Hormones and development: gonadal hormones I230             | Э  |
| posted the entire week.)                                 |         | 110. Hormones and development: gonadal hormones II234            | 4  |

| 284. Hypothalamic-pituitary-adrenal regulation:               | WEDNESDAY, OCTOBER 28  |
| POMC, ACTH, other factors668                                  | Symposia—8:30 a.m.   |
| 285. Hypothalamic-pituitary-gonadal regulation:               | 310. Strategies for the Study of Alzheimer Amyloidosis Using |
| LHRH and LH II  |  |
| 286. Neuroendocrine regulation: osmotic regulation 1          |  |
| 287. Neural-immune interactions: behavior and stress          |  |
| 288. Neural control of immune functions679                    | <del>-</del> '   |

| Session<br>Number & Title                               | Page     | Session<br>Number & Title                                    | Page   |
|---|----------|--|--------|
| Special Lecture — 11:45 a.m.                            |          | 350. Pain pathways: supraspinal                              | 831    |
| 312. New Insights Into Synaptic Signal Termination: The |          | 351. Pain modulation: supraspinal                            | 834    |
| Neurotransmitter Transporter Gene Family                |          | 352. Retina and photoreceptors: photoreceptors,              |        |
| S.G. AmaraNo  | Abstract | horizontal and bipolar cells                                 | 837    |
|   |          | 353. Auditory system: central physiology III                 | 840    |
| Slide Sessions — 8:30 a.m.                              |          | 354. Chemical senses: peripheral mechanisms—taste            | 844    |
| 313. Visual cortex: theoretical studies                 | 740      | 355. Motor systems and sensorimotor integration: cortex IV   | 846    |
| 314. Ingestive behavior: salt appetite and food intake  | 742      | 356. Basal ganglia and thalamus V                            | 849    |
| 315. Human cognition: neuropsychology                   | 744      | 357. Cerebellum II   | 852    |
| 316. Somatosensory system                               | 746      | 358. Oculomotor IV   | 855    |
| 317. Serotonin neuropharmacology                        | 749      | 359. Spinal cord and brainstem IV                            | 858    |
| 318. Presynaptic mechanisms IV                          | 750      | 360. Control of posture and movement:                        |        |
| 319. Hypothalamic-pituitary-adrenal regulation          | 752      | clinically related studies                                   | 860    |
| 320. Cardiovascular regulation I                        | 754      | 361. Brain metabolism and blood flow III                     | 863    |
| 321. Excitatory amino acids: excitotoxicity IV          | 756      | 362. Learning and memory: pharmacology—other I               | 866    |
| 322. Drugs of abuse: alcohol, barbiturates and          |          | 363. Neural plasticity III                                   | 869    |
| benzodiazepines II                                      | 758      | 364. Motivation and emotion II                               | 872    |
| 323. Long-term potentiation III                         | 759      | 365. Biological rhythms and sleep III                        | 875    |
| 324. Peptides: physiological and behavioral effects     | 761      | 366. Biological rhythms and sleep IV                         | 878    |
| 325. Degenerative disease: Alzheimer's—ß-amyloid IV     | 764      | 367. Neuroethology: tetrapods—bat echolocation               | 882    |
| 326. Neural-immune interactions                         | 766      | 368. Monoamines and behavior: striatum and DA receptors      | 885    |
|   |          | 369. Hormonal control of reproductive behavior I             | 888    |
| Poster Sessions — 8:30 a.m.                             |          | 370. Hormonal control of reproductive behavior II            | 890    |
| 327. Genesis of neurons and glia II                     | 768      | 371. Hormonal control of reproductive behavior III           | 892    |
| 328. Development of neurotransmitter systems:           |          | 372. Hormonal control of reproductive behavior IV            | 894    |
| catecholamines and neuropeptides                        | 771      | 373. Neuropeptides and behavior II                           | 895    |
| 329. Nerve growth factor IV                             | 774      | 374. Neuropeptides and behavior III                          | 898    |
| 330. Development of cerebral cortex and limbic system I | 777      | 375. Drugs of abuse: interaction of cocaine,                 |        |
| 331. Transplantation: gene therapy and cell lines       | 781      | DA-altering drugs and the VTA                                | 900    |
| 332. Neuroglia and myelin III                           | 784      | 376. Aging and behavior I                                    | 901    |
| 333. Gene structure and function V                      | 787      | 377. Epilepsy: human studies and animal models III           | 905    |
| 334. Presynaptic mechanisms V                           | 790      | 378. Epilepsy: basic mechanisms III                          | 908    |
| 335. Potassium channels: pharmacology and effects       |          | 379. Schizophrenia: neurochemistry                           | 911    |
| of transmitters   | 793      | 380. Neurotoxicity: amphetamine                              | 913    |
| 336. Ion channel modulation II                          | 797      | 82. History of neuroscience                                  | 180    |
| 337. Acetylcholine: neuronal nicotinic receptors II     | 801      | 83. Teaching of neuroscience: undergraduate and graduate     |        |
| 338. Excitatory amino acids: anatomy and physiology II  | 803      | education  | 183    |
| 339. Peptides: anatomical localization—human and primat | te805    | 84. Teaching of neuroscience: computer-assisted              |        |
| 340. Ontogeny of serotonin receptors                    | 807      | instruction  | 186    |
| 341. Second messengers V                                | 809      | 85. Teaching of neuroscience: elementary                     |        |
| 342. Behavioral pharmacology: benzodiazepines, et al    | 813      | and secondary grades   | 189    |
| 343. Receptor modulation, up and down regulation II     | 815      |  |        |
| 344. Hypothalamic-pituitary-gonadal regulation: other   | 818      | Symposia — 1:00 p.m.   |        |
| 345. Neuroendocrine regulation: other                   | 820      | 381. Mechanisms of HIV-related Injury in the Central Nervous | System |
| 346. Neuroendocrine regulation: osmotic regulation II   | 822      | Chaired by: S.A. Lipton                                      | 914    |
| 347. Regulation of autonomic function: other            | 825      | 382. Cognitive and Neurobiological Consequences of Norma     | l      |
| 348. Respiratory regulation: chemoreception             | 826      | Aging: From Rats to Primates                                 |        |
| 349. Somatic and visceral afferents: touch              | 829      | Chaired by: C.A. Barnes                                      | 914    |

| Session Number & Title Page                                  | Session Number & Title Page  |
|--|--|
| Presidential Special Lecture — 1:00 p.m.                     | 421. Uptake, storage, secretion and metabolism III                                   |
| 383. Nitric Oxide: A Novel Neuronal Messenger                | 422. Second messengers VI  |
| S.H. Snyder  | 423. Hypothalamic-pituitary-adrenal regulation: stress—                              |
| 3.11. 3Hyder10 / Maddet                                      | developmental aspects  |
| Special Lecture — 4:15 p.m.                                  | 424. Neural-immune interactions: innervation and other 1009                          |
| 384. Specification of the Zebrafish Body Axis                | 425. Neural-immune interactions: interleukin-1                                       |
| C.B. Kimmel  | 426. Cardiovascular regulation: lower brainstem I                                    |
| C.D. Killinet  | 427. Subcortical somatosensory pathways: lemniscal and                               |
| Slide Sessions — 1:00 p.m.                                   | spinothalamic  |
| 385. Interactions between neurotransmitters III915           | 428. Pain modulation: spinal I   |
| 386. Limbic system IV  | 429. Pain modulation: spinal II  |
| 387. Other factors and trophic agents: BDNF, NT3918          | 430. Pain modulation: behavior   |
| 388. Potassium channel permeation and gating                 | 431. Retina and photoreceptors: amacrine, ganglion                                   |
| 389. Visual development: neuronal and                        | and glial cells1027  |
| synaptic development922                                      | 432. Subcortical visual pathways: cortico-tectal, Accessory                          |
| 390. Cell migration and motility I                           | Optic System, centrifugals1030   |
| 391. Receptor modulation, up and down regulation III926      | 433. Visual cortex: motion processing I  |
| 392. Neuroendocrine regulation I                             | 434. Auditory system: neurochemistry   |
| 393. Transplantation I                                       |  |
| 394. Human cognition: blood flow/metabolism                  | 435. Auditory system: anatomy I  |
| -  | 436. Chemical senses: pathways—gustation   |
| 395. Degenerative disease: Parkinson's I                     | 437. Basal ganglia and thalamus VI       1042         438. Cerebellum III       1045 |
| 396. Ingestive behavior: NPY, galanin and insulin            |  |
| 397. Motor systems and sensorimotor integration: cortex V938 | 439. Vestibular system: behavioral responses   |
| 398. Invertebrate learning and behavior IV940                | ·  |
| Postor Cossions 1.00 p.m.                                    | 441. Control of posture and movement II  |
| Poster Sessions — 1:00 p.m.                                  | 442. Circuitry and pattern generation II   |
| 399. Process outgrowth, growth cones and sprouting IV943     | 443. Learning and memory: systems  |
| 400. Formation and specificity of synapses V                 | and functions— misc. I   |
| *  | 444. Learning and memory: systems  |
| 402. Other factors and trophic agents: IGF                   | and functions— misc. II  |
| 403. Other factors and trophic agents: FGF                   | 445. Learning and memory: physiology IV  |
| 404. Pattern formation, compartments and boundaries II955    | 446. Ingestive behavior: taste aversion and neural                                   |
| 405. Glia and other non-neuronal cells III                   | mechanisms1066 447. Monoamines and behavior: behavioral effects                      |
| 407. Regeneration III  | of dopamine  |
| 408. Staining, tracing and imaging techniques II966          | 448. Drugs of abuse: alcohol, barbiturates and                                       |
| 409. Calcium channel toxins II969                            |  |
|  | benzodiazepines III  |
| 410. Calcium channels: physiology II                         | 450. Drugs of abuse: cocaine and dopamine neuronal                                   |
|  |  |
| 412. Excitatory amino acids: receptors V                     | systems  |
| 413. GABA receptors: function III                            | 451. Degenerative disease: Parkinson's II  |
| 414. Peptides: biosynthesis and metabolism II                |  |
| 415. Peptides: physiological effects II                      | 82. History of neuroscience  |
| 416. Peptides: physiological effects III                     | 83. Teaching of neuroscience: undergraduate and graduate                             |
| 417. Opioids: anatomy and physiology I                       | education  |
| 418. Catecholamines: receptors II                            | 84. Teaching of neuroscience: computer-assisted instruction                          |
| 419. Purines: adenosine                                      | nistruction  |

SYMPOSIUM: EMERGING PRINCIPLES OF ORGANIZATION WITHIN THE MIDBRAIN PERIAQUEDUCTAL GRAY MATTER (PAG). M.T. Shipley, Univ. Cincinnati & R. Bandler, Univ. Sidney (Co-Chairpersons); A. Beitz, Univ. Minnesota; T. Lovick, Univ. of Birmingham; H. Fields, Univ. of San Francisco, (Discussant),

Research during the past two decades has led to the recognition that the midbrain periaqueductal gray region (PAG) plays a pivotal executive role in an organism's responses to threatening stimuli. Such responses include rapid and coordinated skeletal and autonomic adjustments, associated with significant alterations in "pain" thresholds. Roles for PAG in the regulation of pain and aversion, defensive and sexual behavior, and cardiovascular and respiratory functions have been firmly established. The use of sensitive anatomical and neurochemical techniques has also yielded much new information about the afferent and efferent connections and the neurotransmitters of the PAG. The aim of this symposium is to provide a much-needed venue for reassessing our current understanding of the neural organization of this important brain region. Consideration will be given to the hypothesis that organization within the PAG can be largely subsumed under a single fundamental principle. Namely, that anatomical and functional specificity is expressed in the form of discrete longitudinal neuronal and afferent columns extending along the rostrocaudal axis of the PAG. Individual presentations will focus on different aspects of PAG function, anatomy and neurochemistry, in order to examine the different manifestations of longitudinal columnar organization within the PAG, e.g., the extent to which afferent input columns co-distribute with functionally and anatomically defined output columns; somatotopic and viscerotopic organization of longitudinal columns; intrinsic and extrinsic linkages between longitudinal columns. The goal of the symposium, thus, is to provide a precise and up-to-date understanding of the organization within the PAG that underlies the integrated expression of its vital functions.

SYMPOSIUM. THE COMPUTATIONAL NEURON. T.J. Sejnowski, Howard Hughes Medical Institute and The Salk Institute, La Jolla, CA (Chairperson); C. Koch, Caltech, Pasadena, CA; R. J. Douglas, Oxford University, Oxford, England; W. W. Lytton, Neurology Department, University of Wisconsin, Madison, WI; A. Bell, Free University of Brussels, Belgium.

Nonlinear properties of neurons due to voltage-sensitive ionic currents and synaptic conductances have important consequences for how neurons compute. Detailed computer models of single neurons based on anatomically-reconstructed morphologies, known synaptic strengths, and measured channel kinetics are presented that illustrate new computational principles. In the introduction, <u>Sejnowski</u> will motivate the need for modeling single neurons and outline the computational techniques that are available. Koch will show that synaptic conductances can dynamically modulate the properties of dendrites in cortical pyramidal neurons; Douglas will demonstrate models of neurons implemented in analog VLSI silicon circuits that vastly enhancing the speed of these models; <u>Lytton</u> will present simulations of synaptically-driven entrainment of thalamocortical neurons and cortical pyramidal neurons. Bell will examine the question of why dendrites have active currents, making a provocative prediction for their self-organization during development. From these modeling studies a new view of computational processing is emerging in which the intrinsic dynamical properties of neurons interact with network properties to produce large-scale coherent activity in neural populations.

MEASUREMENTS OF ELECTRICAL COUPLING BETWEEN CIRCADIAN PACEMAKER CELLS OF THE BULLA EYE. Michael E. Geusz\* and Gene D. Block. NSF Center for Biological Timing, University of Virginia, Gilmer Hall, Charlottesville, VA 22901.

A pacemaker in the eye of the mollusk Bulla gouldiana generates a circadian

rhythm in the frequency of compound action potentials (CAPs) in the optic nerve. The CAPs are produced from the synchronous firing of a population of about 100 cells known as the basal retinal neurons (BRNs). The BRNs are believed to be electrically coupled because CAPs persist in media with low Ca<sup>2+</sup> concentrations and dye coupling between BRNs has been shown.

To assess the strength of the electrical coupling between the BRNs,

simultaneous intracellular recordings were made from pairs of BRNs while -0.5 nanoamp current pulses were injected into either cell. Coupling coefficients, measured using discontinuous current clamp, averaged  $0.66\pm0.15$  S.D. (n=12 pairs), indicating that strong coupling occurs. There was no obvious rectification when current was passed in either direction. Strong coupling was found during both the subjective day,  $0.68 \pm 0.17$  S.D. (n=7), and the subjective night, 0.64 $\pm 0.14$  S.D. (n=5)

Pair-wise recordings between BRNs and the H-type cells of the retina, which hyperpolarize transiently in response to light, did not show evidence of electrical coupling (n=5). Similarly, pair-wise recordings between H-type cells did not reveal electrical coupling.

Treatments that block gap junctional conductances in other systems did not block electrical coupling between BRNs. CAPs and coupling persisted in 1 mM 1-octanol, or when extracellular pH was below 5.0. Coupling persisted in 1heptanol at 1 mM, although CAPs were blocked. Heptanol at 10 mM caused irreversible loss of CAPs. Both alcohols were administered in 0.5% by volume dimethyl sulfoxide. Supported by NS08806 to MEG and NS15264 to GDB.

DISSOCIATED PACEMAKER CELLS OF BULLA EXPRESS CIRCADIAN RHYTHM IN MEMBRANE CONDUCTANCE

S. Michel\*, M.E. Geusz, J.J. Zaritsky and G.D. Block. NSF Center for Biological Timing, University of Virginia, Charlottesville, VA 22901 The eyes of the marine snail Bulla gouldiana express a circadian rhythm of

compound action potentials (CAP) in vitro driven by endogenous changes in membrane potential of basal retinal neurons (BRN), which are believed to be the pacemaker cells. Using single electrode current clamp in a semi-intact eye, it has been shown that BRN membrane conductance decreases at subjective dawn and increases at subjective dusk. These changes appear to be mediated by a modulation of a potassium current.

We now report that the circadian control of membrane conductance is retained in dissociated BRNs. The cells were obtained from surgically reduced eyes. The basal part of the Bulla retina was dispersed in culture dishes containing modified L-15 medium and kept in constant conditions. We used morphological criteria previously confirmed with Lucifer Yellow injections to identify BRNs in dispersals. Due to the low cell density most cells did not connect with each other, although neurite outgrowth was observed after 24 h. Intracellular recordings from these unconnected neurons were performed at ZT 19 and ZT 3 on the first (n=5) and second (n=8) circadian cycles using the same methods as in the semi-intact retina. Current-voltage relations were obtained after applying current pulses with the discontinuous current clamp technique. Predawn (ZT 19) and postdawn (ZT 3) I/V curves were significantly different in slope (p<0.01) during both of the first two cycles in culture. The decrease in conductance near subjective dawn was consistent with results found in the semi-intact preparation. These results support the hypothesis that an individual neuron can function as a circadian pacemaker. Supported by DFG Mi 328/1-1 to SM, NS08806 to MEG and NS15264 and NSF DIR8920162 to GDB.

TRYPTOPHAN HYDROXYLASE MESSENGER RNA LEVELS EXHIBIT CIRCADIAN RHYTHMICITY IN XENOPUS LAEVIS RETINA. C. B. Green and J. C. Besharse\*. Dept. of Anatomy and Cell Biology, University of Kansas

J. C. Besnarse: Dept. of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS 66160.

Tryptophan hydroxylase is the rate-limiting enzyme in melatonin synthesis in Xenopus laevis retina (Cahill and Besharse, J. Neurochem. 54:716-719). Melatonin is synthesized rhythmically in photoreceptors with elevated levels during the night (Cahill and Besharse, Visual Neuroscience 8:487-490, 1992). This pattern of synthesis is controlled by light and a retinal circadian clock. In order to determine whether tryptophan hydroxylase is expressed in photoreceptors and whether this expression is rhythmic, we analyzed tryptophan hydroxylase methods. ryptophan hydroxylase mRNA by Northern blot analysis and in situ hybridization.

hypordization.

A Xenopus retinal cDNA library was constructed and screened, under conditions of low stringency, using rabbit tryptophan hydroxylase cDNA (Grenett et al., Proc. Natl. Acad. Sci. USA 84:5530-5534, 1987)as a probe.

A cDNA clone coding for Xenopus tryptophan hydroxylase was isolated and characterized. This clone was used as a probe for analysis of retinal tryptophan hydroxylase mRNA. Retinas were dissected throughout the normal 12 hour light: 12 hour dark cycle or throughout a 24 hour period of constant darkness. Northern blot analysis of total retinal RNA showed that the tryptophan hydroxylase message levels are low in the day and higher during the night. This expression of tryptophan hydroxylase mRNA appears to be under circadian control since rhythmic changes are also seen in constant darkness, with elevated levels during the subjective night. Preliminary results from in situ hybridization suggest that the tryptophan hydroxylase mRNA in the retina is located in photoreceptors. Our observations suggest that rhythmic expression of tryptophan hydroxylase many be important in the generation of the melatonin rhythms.

CULTURED NEURONS AND PHOTORECEPTORS OF THE APLYSIA CIRCADIAN PACEMAKER. <u>J.W. Jacklef</u> Dept. Biol. Sci., Neurobiology Research Center, SUNY Albany, Albany, NY 12222.

An antiserum against a 48kD eye specific protein stains certain cells and fibers of the <u>Aplysia</u> retina, which contains a circadian pacemaker. It also stains the optic nerve, the optic tract of the cerebral ganglion and other central ganglia. Myomodulin antiserum stains other specific fibers, neuropil and cells of the retina including several large neurons, whose axons project in the optic nerve to the optic tract of the cerebral ganglion. The lateral terminus of the optic tract stains with both antisera and is a putative synaptic exchange area. In order to identify cells and fibers containing the antigens and preparatory to other types of analysis, the retinas were dissociated, using conventional enzymatic digestion, and cells were plated in cell culture using defined medium. Many cell types survived, grew neurites and interacted, including monopolar and bipolar neurons; large microvillous, large tufted and small fusiform photoreceptors. The monopolar and bipolar neurons are putative pacemaker neurons, which produce the CAP activity that exhibits a circadian rhythm. They have cell bodies 12-18µm in diameter and survived for more than a week in culture. Under certain conditions they extended neurites for hundreds of micrometers and interacted with other cell types by neurite association and putative synapse formation. Preliminary electrical recordings revealed several voltage sensitive outward and slow inward currents. Supported in part by NSF BNS-8819773; University Calgary Visiting Scientist and Alberta Heritage Foundation Funds; thanks to University Calgary Neuroscience Faculty.

AN EFFECT OF THE PERIOD GENE ON A CIRCADIAN RHYTHM IN VISUAL SENSITIVITY IN DROSOPHILA. Peter S. Auerbach and Kathleen K. Siwicki\*.
Biology Department, Swarthmore College, Swarthmore, PA 19081

The period (per) gene, which controls the period of circadian rhythms in Drosophila melanogaster, is highly expressed in the fly nervous system. Drosophila head sections stained with anti-per antibody revealed high levels of per protein in the compound eyes and the optic lobes of wild-type flies, but no detectable per protein in per <sup>01</sup> mutants. The effects of per on visual physiology were investigated with electroretinogram (ERG) recordings from wild-type and per <sup>01</sup> flies. Responses to 1-sec flashes of light (peak wavelength 565 nm) revealed no effects of the per 01 mutation on the ERG waveform. A daily rhythm in visual sensitivity was detected in chronic recordings (12 to 33 hours) in visual sensitivity was detected in chronic recordings (12 to 33 nours) from wild-type flies, however, with the photoreceptor response to 0.5-sec flashes of light peaking in the middle of the subjective night. For these experiments, flies (1-10 days old) were reared in a 12h: 12h light-dark cycle, then kept in darkness for 12-27 hours prior to recording. Conditions of constant darkness were maintained for the duration of the experiment, except for 0.5-sec light pulses every 30 minutes. No rhythm was detected in chronic recordings from per 01 flies, suggesting that the *per* gene regulates this physiological circadian rhythm in the visual system. This result raises the possibility of a link between physiological rhythms and rhythmic *per* expression within the photoreceptor cells.

MELATONIN IS DEGRADED WITHIN THE VERTEBRATE PINEAL GLAND AND BRAIN. Michael S. Grace\* and Joseph C. Besharse. Departments of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS 66160, and Emory University School of Medicine, Atlanta, GA 30322.

Melatonin is deacetylated within the eyes of several species, and melatonin deacetylase activity occurs at sites of melatonin action within the African clawed frog Xenopus laevis (Grace, M.S. et al., 1991, Brain Res. <u>559</u>:56-63). The vertebrate pineal gland synthesizes melatonin, and contains all of the non-melatonin methoxyindoles generated by the retinal melatonin deacetylase. We therefore set out to determine whether melatonin deacetylase activity exists within the pineal gland and elsewhere within the central nervous system. We now report the metabolism of exogenous melatonin to 5-methoxytryptamine (5MT) and 5-methoxyindoleacetic acid (5MIAA) by cultured pineal glands and brains of the lizards Anolis carolinensis and Sceloporus jarrovi. After incubation of pineal glands or whole brains with 100nM [3H-methoxy]-melatonin (specific activity 83.3Ci/mmol), 3H-5MT and 3H-5MIAA were detected and quantified by HPLC with fluorescence detection and flow scintillation spectrometry. The production of <sup>3</sup>H-5MT and <sup>3</sup>H-5MIAA accounted for all <sup>3</sup>H-melatonin loss. Melatonin breakdown in all cases was inhibited (80-95%) by the retinal melatonin deacetylase inhibitor eserine at 100µM. Subsequent 5methoxytryptamine deamination was inhibited by the monoamine oxidase inhibitor pargyline at 100µM. Melatonin catabolism in the pincal is rapid; the Sceloporus pincal gland deacetylated 37.7pmol of melatonin/mg protein/hr, while the eyecup and brain deacetylated 2.1 and 1.1pmol melatonin/mg protein/hr, respectively. These results directly demonstrate melatonin breakdown within the pineal gland and brain, and suggest that degradation may help regulate production and release of pineal melatonin. Melatonin deacetylation within the central nervous system may generate functional methoxyindoles, and may regulate levels of melatonin at its sites of action. Support: NIH Grant EY02414 (JCB); Sigma Xi Grant-in-Aid (MSG).

INTRACEREBRAL INFUSION OF VIP ANTISENSE OLIGONUCLEOTIDES INTO THE SUPRACHIASMATIC NUCLEI AFFECTS THE CIRCADIAN CORTICOSTERONE PEAK. K. Scarbrough\* & P.M. Wise. Dept. Physiol., U. Maryland Sch. Med., Baltimore MD 21201

Antisense oligonucleotides (oligos), presumably acting through hybridization arrest, have been used successfully in vivo to inhibit mating behavior in rats (McCarthy et al. 1991 Neurosci Abst 197.5). We employed a mixture of two 20mer antisense oligo sequences complementary to separate regions of rat VIP mRNA in an attempt to disrupt neurotransmission of a single neuropeptide that may be important in circadian aspects of suprachiasmatic nucleus (SCN) function. To detect altered SCN function we measured serum important in Citadian aspects of supracinasmatic function. To detect altered SCN function we measured serum corticosterone, a hormone whose circadian pattern of secretion is regulated by the SCN. Female rats were implanted with double guide cannulae (23 g) directed stereotaxically at the SCN. Rats were divided into 3 treatments: antisense oligos (0.5 µg/side), control oligos having the same ATGC content but a scrambled sequence, or vehicle alone. Treatments were infused slowly on Day 0 with rats under ether anesthesia. Beginning at 1800 h (time of lights off) rats were maintained in constant dim red illumination until 1800 h on Day 2 when rats were decapitated within 30 sec of handling. Trunk blood was collected and sera assayed for corticosterone. Brains were sectioned to verify cannulae placement and integrity of the SCN. Preliminary results indicate that antisense treatment of the SCN. was able to significantly suppress (p<0.02) peak corticosterone levels in intact female rats (11.3 ± 21µg/dl), compared to control oligos (24.0 ± 4.5µg/dl), and oil treatment (30.9 ± 3.1µg/dl). Treatments did not adversely affect the hypothalamic-pituitary-adrenal axis because rats could release high levels of corticosterone in response to stress. Additional experiments to characterize more fully the 24 h corticosterone profile are being performed. NIH AG-02224 & HD-15955.

ANTIBODY TO THE *DROSOPHILA PERIOD* PROTEIN IDENTIFIES AN ANTIGEN THAT EXHIBITS A DIURNAL RHYTHM IN THE SUPRACHIASMATIC NUCLEUS (SCN) OF THE RAT. K.L. Rosewell<sup>1</sup>, K.K. Siwicki<sup>2</sup>, J.N. Masters<sup>3</sup> and P.M. Wise<sup>1</sup>. Dept. Physiology, U. Maryland, Baltimore, MD 21201, <sup>2</sup>Biology Department, Swarthmore College, Swarthmore, PA 19081, <sup>3</sup>Onio State University, Columbus, OH 43210.

The *period (per)* gene of *Drosophila melanogaster* is considered an important biological clock gene because it regulates multiple behavioral rhythms. An antibody to the *per* protein, which revealed a circadian rhythm in the *per* protein of the fly nervous system, also recognizes antigens in the SCN of rats. The purpose of this study was to determine whether the rat *per*-like antigens exhibit

also recognizes antigens in the School rats. The purpose of this study was to determine whether the rat per-like antigens exhibit diurnal rhythms. Rats were ovariectomized (day 0), treated with estradiol (days 7-9) and killed at 12 times of day 9. Brains were frozen, sliced and microdissected. Levels of *per*-like antigens were quantified in several brain regions including the SCN, a critical neural pacemaker, by Western analysis. The antibody to *per* protein identifies 3 proteins of approximately 160-170kD and 115kD in all the rat brain regions examined. The largest of these proteins exhibits a diurnal rhythm in the SCN which peaks in the middle of the dark and attains its nadir around lights off; levels during the light are intermediate with a tendency toward a second drop around lights on. The data demonstrate that an antigen similar to *per* exhibits a diurnal rhythm in a critical neural pacemaker region of the rat brain. They suggest that *per*-like proteins may be an important component of the mammalian clock.

#### 6.8

ELECTROPHYSIOLOGICAL EFFECTS OF BOMBESIN-LIKE PEPTIDES ON HAMSTER SUPRACHIASMATIC NUCLEUS (SCN) NEURONS IN VITRO. H.D. Piggins\* and B. Rusak, Dept. of Biomedical Sciences, McMaster

University, Hamilton, Ontario, Canada L8N 3Z5.

The rodent SCN functions as a light-entrainable circadian pacemaker. Gastrin releasing peptide (GRP), the mammalian analog pacemaker. Gastrin releasing peptide (GRP), the mammalian ahalog of bombesin (BN), and its receptors are found in the SCN region receiving photic input. We investigated how micro-ejection of BN-like peptides onto hamster SCN cells in a hypothalamic slice affected extracellularly recorded firing rates. BN, GRP, Neuromedin B (NmB) and Neuromedin C (NmC) in saline/BSA vehicle were micropressure ejected onto SCN cells. In one study, an ejecting electrode containing BN (10<sup>6</sup>-10<sup>-4</sup>M) was positioned 20-60μm away from a recording electrode. Of 72 cells tested with BN, 50 (69.4%) showed significant increases in firing rate, while 3 of 18 cells (16.7%) were activated by pressure-ejected vehicle. In a second study, recordings and pressure ejections were made through a single electrode. Of 52 cells tested, BN (10<sup>-8</sup>-10<sup>-4</sup>M) activated 30 (57.7%) and suppressed firing in 5 (9.6%). Of 213 cells tested with GRP ( $10^{-9}$ - $10^{-4}$ M), 107 (50%) were activated and 3 (1.4%) suppressed. NmC ( $10^{-5}$ - $10^{-4}$ M) activated 12 of 20 cells tested (60%), while NmB (10-4M) activated only 2 of 30 cells

tested (6.7%) and vehicle ejections activated 1 of 26 cells (3.8%). BN-like peptides activate ~50% of hamster SCN cells, apparently via the GRP receptor, and may play a role in photic entrainment. Supported by grants from US AFOSR, NSERC and MRC of Canada, and by an NSERC postdoctoral fellowship to HDP.

#### 6.10

INDUCTION OF C-FOS DURING SPONTANEOUS WAKE-FULNESS IN THE FOREBRAIN AND DIENCEPHALON: AN IMMUNOCYTOCHEMICAL AND IN SITU HYBRIDIZATION STUDY IN THE RAT. M. Bentivoglio\*. Z.-C. Peng. S. Chen. P. Montagnese°. P. Mandile°. S. Vescia° and G. Grassi-Zucconi°. Institute of Anatomy, University of Verona, "Department of General Physiology, University of Naples," Institute of Cell Biology, University of Perugia, Italy.

The distribution of c-Fos was investigated with immunocytochemistry in rats sacrificed at different times of the sleep-wakefulness cycle monitored with EEG recording. The number of c-Fos-immunoreactive neurons was strikingly increased in the cases with EEG

creative neurons was strikingly increased in the cases with EEG corresponding to prevailing wakefulness up to 4 hrs before sacrifice in respect to those in which a sleep EEG pattern had prevailed at the same interval before sacrifice. This increase was proportional to the percent of duration of wakefulness and was especially pronounced in the cerebral cortex (frontal, cingulate, entorhinal), basal forebrain, hypothalamus, midline and intralaminar thalamus. Preliminary findings based on  $in \ situ$  hybridization indicate a similar distribution of c-fos transcripts in these cases. A double immunocytochemical procedure aimed at visualizing c-Fos and the low affinity nerve growth factor receptor (NGFr) revealed that in the basal forebrain c-Fos was contained in NGFr-immunonegative cell bodies. Since NGFr is expressed by cholinergic neurons in the basal forebrain, these findings suggest that the spontaneous induction of c-Fos during wakefulness may not involve this cholinergic system. Altogether the present data indicate that subsets of forebrain and diencephalic neurons are involved in the genomic expression during the sleep-wakefulness cycle.

D1-DOPAMINE RECEPTOR-MEDIATED ACTIVATION OF C-FOS GENE EXPRESSION IN THE FETAL RAT SUPRACHIASMATIC NUCLEUS.

D.R. Weaver\*, S.A. Rivkees, & S.M. Reppert. Lab. Devel. Chronobiology, Mass. General Hospital, Boston MA, 02114.
The suprachiasmatic nuclei (SCN) function as a biological clock. Studies of neurotransmitter systems in the fetal SCN may reveal mechanisms for the entrainment of the fetal biological clock. We report that an activatable Dl-dopamine receptor system is present in the fetal SCN.
In situ hybridization with 35S-labeled cRNA probes

revealed that D1-dopamine receptor mRNA is highly expressed within the fetal SCN on gestational days (GD) 18 and 20. Cocaine (30 mg/kg) injected into pregnant dams or directly into cesarean-delivered fetuses on GD 20 selectively increased c-fos mRNA expression in the fetal selectively increased c-fos mRNA expression in the fetal SCN. Cocaine did not induce c-fos expression elsewhere in the fetal brain or in the maternal SCN. Cocaine induced c-fos expression in the fetal SCN when administered either during the day or at night. Cocaine-induced c-fos expression in the fetal SCN was mediated in part by Dl-dopamine receptors, as the Dl antagonist SCH 23390 reduced the cocaine-induced induction of c-fos and the Dl-dopamine receptor agonist SKF 38393 induced c-fos expression in the fetal SCN. The presence of an activatable Dl-dopamine receptor system in the fetal SCN provides a mechanism through which maternal signals could provides a mechanism through which maternal signals could entrain the fetal biological clock and may have implications for the development of circadian function in fetuses exposed to psychoactive drugs.

EFFECTS OF LOCAL ADMINISTRATION OF EXCITATORY AMINO ACID AGONISTS ON CIRCADIAN PHASE AND c-fos EXPRESSION IN THE HAMSTER SCN. M.A. Rea\*, A. M. Michel, Laboratory, Brooks AFB, TX 78235.

To further characterize the role excitatory amino acids (EAA) in the photic entrainment of the SCN circadian clock, we investigated the

effects of EAA agonists, on the phase of the free-running activity rhythm, and on *c-fos* expression in the hamster SCN. Male, Syrian hamsters were fitted with intracranial guide cannulae stereotaxically aimed at the SCN and housed in constant darkness in cages equipped with running wheels. At either circadian time (CT)9-10 or CT18-19, hamsters received a 300 nl injection of 1 mM NMDA, 0.01 mM AMPA, or vehicle into the region of the SCN. Some hamsters were returned to wheel cages under constant darkness for 10 - 14 days. Others were deeply anesthetized 2 hours after injection, perfused with 4% para-formaldehyde, and processed for c-fos immunocytochemistry. NMDA induced c-fos expression in the SCN at both CT9-10 and

CT18-19. Expression was limited to the area immediately adjacent to the CT18-19. Expression was limited to the area immediately adjacent to the injection site. However, when the injection entered the third ventricle, the pattern of c-fos expression was similar to that observed after a phase advancing light pulse. AMPA induced c-fos expression in the vicinity of the injection site excluding the SCN. NMDA caused phase delays of the activity rhythm at CT9-10 (vehicle -6+6 min; NMDA=-51+9 min). Neither drug altered phase when injected at CT18-19 (vehicle=-11±10 min; NMDA =-11±8 min; AMPA=5±8). The results show that EAA-induced c-fos expression in the SCN does not result in light-like phase shifts of the SCN circadian clock. Supported by 2312W6 (MAR).

IN VIVO PET IMAGING AND QUANTIFICATION OF DOPAMINE TRANSPORTER SITES WITH 11C-WIN 35,428 IN LESCH NYHAN SYNDROME. DF Wong\* J Harris, B Yung, RF Dannals, HT Ravert, C Chen, M Yaster, J Neumeyer, R Carpenter, W Nyhan, HN Wagner, Jr. MJ Kuhar, G Breese; Johns Hopkins Med Inst, Baltimore, MD 21205, and Research Biochemicals, Lag. Natick MA

Navert. C Chen. M Yaster. J Neumeyer. R Carpenter. W Nyhan, HN Wagner, Jr. MJ Kuhar, G Breese; Johns Hopkins Med Inst, Baltimore, MD 21205, and Research Biochemicals, Inc., Natick, MA.

Lesch Nyhan Syndrome (LNS) is an X-linked recessive, inborn metabolic disorder characterized by infantile onset of choreoathetosis, dystonia, and stereotypical self bitting. Postmortem studies of 3 LNS cases and a transgenic biochemical mouse model indicate that dopamine (DA) and its synthesizing enzymes are substantially reduced in basal ganglia suggesting dopamine deficiency. Based on these studies, we hypothesized that there may be a presynaptic reduction in DA transporter sites in striatum in LNS which might be quantified with the DA reuptake site ligand, \(^{11}\text{C-WIN}\) 35,428 (WIN). Utilizing high specific activity WIN to test this hypothesis, we imaged the dopamine transporter in vivo with PET in a 23 year old with LNS. The Caudate-Gerebellar (CA/CB) ratio at 90 min was 3.7 in the LNS patient and 5.5 in normals. LNS CA/CB ratio and Putamen/CB ratio versus time slope was reduced by 42% and 52%, respectively. Preliminary kinetic modeling demonstrated a several fold reduction in the bound over free ratio (ka/ka), consistent with substantial reduction in presynaptic DA transporter sites in LNS. Our previous studies of the DA system with PET in LNS (Wong et al. Soc. Neurosci. 17:678 1991) found evidence that suggests elevated D<sub>2</sub> DA postsynaptic receptor density (B<sub>max</sub>). This data combined with the current findings may be consistent with postsynaptic DA supersensitivity or upregulation in LNS. Supported in part by HD23042 and HD240061.

#### 7.2

THE RESPONSE OF MESOLIMBIC DOPAMINERGIC NEURONS IS OPPOSITE DEPENDING ON THE AFFECTIVE VALUE OF STIMULUS.  $\underline{\mathbf{A}}$ . Louilot\*, C. Besson and M. Le Moal. Lab. de Psychobiologie des Comportements Adaptatifs. INSERM U. 259 - Université de Bordeaux II - Domaine de Carreire -33077 Bordeaux Cedex - France.

Depending on the affective value of a stimulus, the response of dopaminergic (DA) neurons could be opposite. In order to test this hypothesis we investigated the reactivity of DAergic neurons to an appetitive stimulus before and after an

The DAergic reactivity was studied using the voltammetric measurements of DA and its main presynaptic metabolite, the DOPAC, in the nucleus accumbens of freely moving rats. The separation of the DA and DOPAC signals was obtained by the computed numerical analysis of the catechol signal. Procedure used is as following: animals were placed during one hour in the experimental cage; they is exposed during one hour to an appetitive olfactory stimulus (banana) and received consecutively either an injection of saline (NaCl 0.9%) (control group) or received consecutively eliner an injection to same (vaca 0.5%) (cutous group) an injection of LiCl (0.15 M) (experimental group) and stayed then one more hour in the experimental cage; 72 h later animals were still exposed during one hour to the conditional olfactory stimulus (CS). The following results are obtained: during the 1st presentation of the CS the DA signal in the nucleus accumbens increased progressively to reach about 160% of the basal level after one hour; during the 2nd presentation of the CS a transient decrease in the DA signal of about 30% below the baseline was observed for the experimental group whereas an increase of about 100% above the baseline was obtained for the control group. No significant variations in the DOPAC signal were noticed.

Results of the present study showing an increase in the DAergic signal when the stimulus is appetitive and a decrease when the stimulus is aversive argue for a differential and discriminative involvement of the DAergie neurons reaching the nucleus accumbens in the affective perception of environmental stimulus.

EFFECTS OF ACUTE TRYPTOPHAN DEPLETION IN DRUG-REMITTED OBSESSIVE-COMPULSIVE DISORDER PATIENTS. L. C. Batt. L. H. Price, C. J. McDougle, P. L. Delgado, W. K. Goodman\*. Yale University School of Medicine, New Haven, CT 06519.

The majority of depressed patients remitted on serotonin reuptake inhibitors (SRIs) demonstrate reemergence of depression following acute inhibitors (SRIs) demonstrate reemergence of depression following acute tryptophan depletion (ATD), which is thought to lower brain serotonin. This study examined the effects of ATD in drug-remitted obsessive compulsive disorder (OCD) patients. Methods: 15 OCD patients remitted on SRIs (7 female, 8 male; mean age = 36 ± 2 years; 10 with a lifetime history of major depression) participated in two test sessions: (1) ATD (24hr. 160mg/day, low tryptophan diet followed the next AM by a 16-amino acid drink without tryptophan) and (2) sham depletion (both diet and drink supplemented with L-tryptophan) in random order. Blind ratings of depression and obsessive compulsive (OC) symptoms were obtained. Results: ANOVA revealed significantly (p=.04) increased mean depression ratings on the ATD compared to the sham test day. Paired t-tests showed significant increases in Hamilton Depression Scale ratings at 420 minutes after the amino acid drink compared to 24 hours prior to the drink (p=.004). ATD had no significant effect on mean OC ratings at 420 minutes after the amino acid drink compared to 24 hours prior to the drink (p=.004). ATD had no significant effect on mean OC ratings: only one patient showed an exacerbation of OC symptoms with ATD. Conclusions: This study replicates preliminary findings from a smaller non-overlapping sample that ATD increases depressive, but not OC symptoms, in OCD patients remitted on SRIs. This suggests that maintenance of SRI-induced remission of OC symptoms, unlike remission of depressive symptoms, may not depend upon ongoing symptoms in the symptom of the symptom of the symptoms. availability of serotonin.

AN ANIMAL MODEL FOR STUDYING THE ETIOLOGY OF NEURODEGENERATIVE DISEASES

a.K. Andersson\*, c.B. Bjelke, a.R. Diaz, b.P. Bolme & c.S.O. Ögren.

a.Dept. Internal Medicine and b.Dept Pediatrics, Karolinska Institutet, Huddinge Hospital, 141 86 Huddinge, Sweden, c.Dept. Histology & Marchiselaw, Neurobiology, Karolinska Institutet, Box 60 400, 104 01 Stockholm,

Asphyxia to male Sprague-Dawley rat pups was induced by a delayed cesarean section. An immunohistochemical and functional analysis was carried out on the pups at an age of 3 weeks and 5 months. The monoaminergic nerve cell body regions of substantia nigra, locus ceruleus and raphe region were studied. It was demonstrated that asphyxia timedependently produced an increase in the number of tyrosine hydroxylase immunoreactive (TH-IR) nerve cell bodies of the substantia nigra. This increase was still present in the adult animal. Behavioral recordings of rearing and locomotion indicated a progressive aggravation of disturbances, demonstrating a bimodal curve of events. Mild asphyxia induced increased rearing and locomotion, while severe asphyxia resulted in a reversal of the enhanced rearing and locomotion. The observed behavioural changes may reflect an animal analogue for the attention deficit disorders and hyperkinetic syndrom in MBD-children, which may be related to oxygen deprivation during the human delivery. Since disturbed function in the meso-striatal and meso-limbic dopamine systems are of central importance for the development of schizophrenia and Parkinson's disease the use of this animal model may enlighten the mechanisms behind these neurodegenerative diseases.

DISCHARGE PATTERNS OF DORSAL RAPHE NEURONS AND THEIR COORDINATION ACROSS SEVERAL TIME SCALES. <u>B. Kocsis\* and R.P. Vertes</u>, Center for Complex Systems, Florida Atlantic University, Boca Raton, FL.

Dorsal raphe (DR) nucleus projects throughout widespread regions of the forebrain and is capable of influencing numerous and diverse structures of the forebrain. It contains a morphologically and electrophysiologically heterogeneous population of cells with firing rates distributed over more than two orders of magnitude (from 0.5-1 Hz to 70-100 Hz). We recorded extracellularly 30 DR neurons in 8 unanesthetized freely moving rats during different sleep-waking states. The neurons were categorized according to their maximum firing rates (slow (S) 10 Hz; fast (F) - 10-55 Hz; and very fast (FF) cells - >55 Hz) and their relationship to the hippocampal theta rhythm (maximum coherence between hippocampal EEG and DR neuron discharge at theta frequency was >0.5, 0.2-0.5, and <0.1 in three groups). The activity of 17 of 30 DR neurons was correlated with the theta rhythm in the hippocampus. As shown in the table, these included</p> cells with a range of firing rates and various firing dynamics.

FF-cells F-cells S-cells total

theta-rhythmic 2 theta-modulated 10 no coherence total 11 12 30

The origin and physiological significance of theta rhythmicity in DR neurons is yet to be determined. The medial septal nucleus (MS) (site of the pacemaking cells that directly drive the hippocampal theta rhythm) has been shown to send pronounced descending projections to the DR nucleus. Through these projections the MS may synchronously drive cells of the DR as it does those of the hippocampus and entorhinal cortex. The present findings suggest DR cells discharging synchronously with the theta rhythm may serve to coordinate the activity of several forebrain structures during theta associated states or behaviors. Supported by NIMH Grant MH45075 to RPV.

#### 7.7

MATERNAL INFLUENCES ON SWIM TEST BEHAVIOR IN A NEWLY DEVELOPED ANIMAL MODEL OF DEPRESSION. M.A. Cierpial\*, C. Lorenz, J.V. Morgan, H. Amir & J.M. Weiss. Department of Psychiatry, Duke University Medical Center, Durham, NC 27710.

Low motor activity in a swim test is used as a measure of "depression-like" behavior in the rat, both in behavioral screens for antidepressant drugs and in a widely used animal model of depression. We have selectively bred Sprague-Dawley rats for high or low motor activity in the swim test. Swim high active (SwHi) rats struggle vigorously in the swim test and float very little, whereas swim low active (SwLo) rats struggle very little and are immobile for much of the test period. SwLo rats may represent a new animal model of depression in that they respond to chronic, but not acute, antidepressant drug treatment with increases in swim test activity.

To assess the role of the preweanling maternal environment on adult swim test behavior in SwHi and SwLo rats, we conducted a cross-fostering study in which SwHi and SwLo litters were either reared by their natural mothers (control litters), foster dams of the same line (in-fostered litters), or foster dams of the opposite line (x-fostered litters). Swim tests were conducted on male and female rats from the 6 groups (2 lines x 3 rearing conditions) at 90 days of age. The results indicated that adult swim test behavior in these lines is dependent on early rearing experience as opposed to genetic factors. Adult SwHi rats reared by SwLo dams displayed low motor activity (not significantly different from SwLo Control or In-Fostered rats) in the swim test, whereas adult SwLo rats reared by SwHi dams displayed high activity (not significantly different from SwHi Controls or In-Fostered rats). These data indicate that an adult phenotypic behavior thought to represent depression-like behavior in the rat is modifiable based on early environmental experience.

ROLE OF THE LOCUS COERULEUS-NORADRENERGIC (LC-NE) SYSTEM IN ANXIOUS BEHAVIOR IN RATS: DECREASED LC ACTIVITY PRODUCES ANXIOGENIC, WHILE INCREASED LC ACTIVITY PRODUCES ANXIOLYTIC EFFECTS. J.C. Stout\*. M.A. Cierpial. K.M. Boericke. & J.M. Weiss. Depts. of Psychology and Psychiatry, Duke Univ., Durham, NC 27710.

The role of LC-NE activity in anxious behavior in rats in normal fear (NF) and shock-enhanced fear (SEF) conditions was investigated by

manipulating the LC-NE system pharmacologically, and then assessing plasma corticosteroids, and anxious behavior in the "drink test" (Stout & Weiss plasma conticosteroids, and anxious behavior in the "drink test" (Stout & Weiss [1989], <u>Soc. for Neurosci. Abstracts</u>, <u>15</u>: 632). Effects of these manipulations of the LC-NE system were verified by assessing noradrenergic turnover in the LC and dorsal hippocampus (DH) by measuring levels of NE and 3-methoxy-4-hydroxyphenylglycol (MHPG) using high pressure liquid chromatography (HPLC). Results indicated that anxious behavior of NF rats was not significantly aftered by pharmacologically-induced increases or decreases in LC-NE activity. However, in the SEF condition, reduced LC-NE activity produced by microinfusions of designamine directly into the LC was associated with increased anxious behavior, while increased LC-NE activity produced by either, (a) a combination of idazoxan and substance P produced by effect, (a) a combination of indexixant and substance r microinfused directly into the LC, (b) idazoxan infused into the lateral ventricle, or (c) chronic administration of idazoxan via an indwelling osmotic mini-pump, was associated with a reduction in anxious behavior. Alteration of LC-NE activity did not significantly affect plasma conticosterone. Analysis of noradrenergic turnover verified that the pharmacological manipulations were effective in producing the predicted alterations of LC-NE activity.

These experiments suggest that the relationship between the LC-NE system and anxious behavior is opposite to that which was postulated by

Redmond et al. in 1976 (Brain Res., 116: 502-510) in that decreased LC activity appears to have anxiogenic effects, while increased LC activity appears to have anxiolytic effects.

#### 7.8

MATERNAL INFLUENCES ON CENTRAL CATECHOLAMINE RESPONSES TO STRESS IN SwHi AND SwLo RATS. J.M. Weiss, M.A. Clerpial, & K.M. Boericke. Department of Psychiatry, Duke University Medical Center, Durham,

SwHi and SwLo rats have been selectively bred to display differential motor activity in a swim test and SwLo rats may be useful as a new animal model of depression. We have demonstrated that adult swim test behavior in these rat lines is dependent on early rearing experience rather than genetic factors (see accompanying abstract). Studies were conducted to determine whether alteration of the preweanling environment (by cross-fostering of litters) would impact on the functioning of brain catecholamine systems in adulthood. Adult male rats from 6 groups (2 lines [SwHi/SwLo] x 3 rearing conditions [Control/In-Fostered/Cross-Fostered]) were either sacrificed out of their home cage (HC) or exposed to mild electric tailshock (30 min. session of 1.5 mA, 3 sec, VI300 sec) and then sacrificed (SHK). Trunk blood was collected for assay of plasma corticosterone (CORT) and various brain areas were dissected out for assay of NE, MHPG, DHPG, DA, and DOPAC.

Of particular interest was that in HC rats, striatal DA concentration was higher in SwHi control and SwLo X-Fostered animals compared to SwLo control and SwHi X-Fostered rats. Mild tailshock caused a significant increase in striatal DOPAC in SwHi vs SwLo rats. SwHi X-Fostered rats had DOPAC values which were equivalent to SwLo controls, while SwLo X-Fostered rats had DOPAC values which were equivalent to SwHi controls. The data indicate that functioning of the striatal dopamine system in adulthood can be modified based on early rearing experience and may have implications with regard to animal models of depression and/or schizophrenia

### GABA RECEPTORS: STRUCTURE AND FUNCTION

MODULATION OF NUCLEUS ACCUMBENS NEURONS BY THEIR LOCAL AXON COLLATERALS. W.-X. Shi\* and S. Rayport. Dept. of Psychiatry, Center for Neurobiology & Behavior, Columbia University; Dept. of Neuropathology, NYS Psychiatric Institute, NY 10032.

The axons of GABAergic medium spiny neurons not only form the principal projections from the nucleus accumbens (NA), but also branch locally to form a dense network overlapping their own dendrites. To examine the synapses formed by these local axon collaterals, we made whole cell recordings in postnatal rat NA cultures. We found that 95% of medium-sized neurons formed GABA autapses (synapses between axon collaterals and their cell of origin). Their reliable presence in culture not only suggests the possibility that such autapses exist in the intact NA, but also provides a way to study individual intrinsic NA GABA synapses. We found that, although cells expressed both GABA<sub>A</sub> and GABA<sub>B</sub> receptors, autaptic potentials were blocked only by the GABA<sub>A</sub> natagonist bicuculline and not by the GABA<sub>B</sub> antagonist saclofen, suggesting that local axons collaterals selectively interact with GABA<sub>A</sub> receptors. Autapses may contribute to dynamic signal processing in the NA in several ways: (1) They selectively inhibit responses to suprathreshold but not subthreshold stimulation. (2) They act as low-pass filters suppressing the responses to high frequency input. (3) They may serve as sites of actions for transmitters or drugs producing a modulation more complicated than simple excitation or inhibition. For example, while baclofen increased spike threshold by hyperpolarizing the cell, it enhanced the suprathreshold stimulation-induced response by blocking autaptic release, thus improving the signal-to-noise ratio. Several other GABA-active drugs including bicuculline, flurazepam and nipecotic acid each modulated NA cell responses in a different way. Since GABA synapses between neighboring NA cells that receive similar inputs should be functionally equivalent to autapses, our data suggest w

THE INFLUENCE OF GABA-UPTAKE ON THE STRENGTH OF FAST AND SLOW INHIBITORY SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS. J. S. Isaacson\*, J. M. Solis, and R. A. Nicoll. Depts. of Physiology and

Pharmacology, University of California, San Francisco, CA 94143.

GABA-uptake inhibitors have been found to prolong the time course of inhibitory synaptic potentials in the hippocampus (Dingledine, R. & Korn S. J. Physiol. 366:387, 1985). However, the specific influence of transmitter uptake on fast 366:387. 1985). However, the specific influence of transmitter uptake on fast (GABAA receptor-mediated) and slow (GABAB receptor-mediated) inhibitory synaptic transmission is unclear. In this study, we have examined the effects of SKF 89976A, a potent GABA-uptake blocker, on monosynaptic GABAA and GABAB receptor-mediated synaptic currents in the hippocampal slice.

Synaptic currents were studied from CA1 pyramidal neurons using "blind" patch clamp recording techniques in thick (500 µm) slices of adult guinea pig hippocampus. Monosynaptic inhibitory post-synaptic currents (IPSCs) were evoked in the presence of the glutamate receptor antagonists APV and DNQX. Pure fast and slow IPSCs were received in the presence of CABABA secretary lessions.

of the glutamate receptor antagonists APV and DNQA. Pure last and stow in Sex were isolated in the presence of GABAB or GABAA receptor antagonists, respectively. SKF 89976A increased the amplitude and prolonged the time course of GABAB receptor-mediated synaptic currents. In contrast, SKF 89976A had no effect on the amplitude of GABAA receptor-mediated IPSCS evoked with a stong stimulus, but greatly augmented the late decay of the synaptic current. This effect was not found for GABAA receptor-mediated IPSCs evoked by a weak stimulus (activating fewer synapses) or for spontaneous unitary IPSCs.

These experiments indicate that GABA-uptake limits the strength of slow, GABAB

rices experiments indicate that GABA-uptake limits the strength of slow, GABA-a receptor-mediated inhibition in the hippocampus. The lack of effect of SKF 89976A on weakly evoked and spontaneous GABAA receptor-mediated IPSCs suggests that uptake does not determine the time course of fast synaptic inhibition at individual synapses. However, its effects on GABAA receptor-mediated IPSCs evoked with a strong stimulus indicate that uptake is important in preventing the accumulation of constitute from paid-but in the properties. transmitter from neighboring, co-activated synapses. Together, these results suggest that transmitter uptake can influence the strength of both GABAA and GABAB receptor-mediated inhibitory synaptic transmission in the hippocampus

ARE RECEPTORS "FULL-FILLED" BY QUANTAL RELEASE? D.S. Faber\*, W.S. Young and H. Korn. SUNY, Buffalo, NY 14214 and Institut Pasteur, Paris, France.

It has been proposed that in the CNS, quantization of synaptic signals is determined by saturation of postsynaptic receptors (Jack et al., 1981; Edwards et al., 1990), as illustrated by modeling with differential equations (Busch and Sakmann, 1990). We used Monte Carlo simulations of glycinergic quanta having large (-1,000) and small (-20-40) numbers of channels and compared the predictions with data from the Mauthner cell. Transition probabilities were calculated for diffusion, and glycine (A) binding to receptors (Rs) according to  $2A + R \leftrightarrow A + AR \leftrightarrow A_2R$  (closed)  $\leftrightarrow A_2R^*$ (opened). Vesicles contained 5 to  $20 \times 10^3$  molecules of glycine, which diffused rapidly in the cleft (D from 0.5 to  $1.0 \times 10^{-5}$  cm<sup>2</sup> sec<sup>-1</sup>). A range of rate constants yielded "quanta" similar to recorded ones. Simulations with fixed parameters predicted a 2-5% CV for peak amplitude and increased variance during the decay phase. While binding was 100% within 50-100 µsec after release, the delayed peak response (at 0.3-0.5 msec) was only 70-80% maximal. Off-center exocytosis and up to 20% differences in the number of molecules per vesicle each added about 2-3% variation. Miniatures recorded in different preparations and having similar numbers of activated channels had comparable variance waveforms. These results are explained by the stochastic behavior of single channels which open and close repetitively during the quantal response, so that saturated binding, if any, does not necessarily imply a fixed postsynaptic response.

#### 8.5

IN VIVO SPECT MEASUREMENT OF BENZODIAZEPINE RECEPTOR NUMBER AND AFFINITY IN BABOONS: A CONSTANT INFUSION PARADIGM. M. Laruelle\*. A. Abi-Dargham, M.S. Al-Tikriti, S.S. Zoghbi, Y. Zea-Ponce, Z. Rattner, E. H. Sybirska, E.O. Smith, D.S. Charney, P.B. Hoffer, R.M. Baldwin, R.B. Innis, Yale Univ./VA Med. Ctr., West Haven, CT 06516

Standard PET methods for quantification of neuroreceptors after bolus injection of a radiotracer can be roughly divided into compartmental kinetic and transient equilibrium methods. We took advantage of the long half-life of 123I to develop a sustained equilibrium method based on radiotracer constant i.v. infusion. This paradigm was used to quantify [123] jiomazenil binding to occipital benzodiazepine receptors in baboons. A bolus injection of 3 mCi (high specific activity, 180000 Ci/mmol) was followed by constant infusion at a rate of 0.5 mCi/hr for Cymmol) was followed by constant infusion at a rate of 0.5 mCyhr for 420 min (n=3). Parent compound reached plasma steady state at 120 min. Occipital activity reached stable levels around 180 min. Experiments were ended by injection of receptor-saturating dose of flumazenil (0.2 mg/kg) to define nondisplaceable activity. Occipital binding potential (BP = Bmax/Kd) measured as bound/free at equilibrium (251±20) was similar to BP calculated as K1\*k3/k2\*k4\*fl with a classical 3 compartment model (266±19). Experiments performed at low specific activity (30-15 Ci/mmol, n=3) provided data for a Scatchard plot (Kd = 0.57 nM, Bmax = 145 nM). This sustained equilibrium method gives results consistent with the kinetic approach and may be easier to implement in humans as, under plasma steady state conditions, arterial and venous radiotracer concentrations equilibrate and no arterial sampling would be needed.

#### 8.7

EXPRESSION OF MITOCHONDRIAL BENZODIAZEPINE RECEPTOR AND ITS PUTATIVE ENDOGENOUS LIGAND DIAZEPAM BINDING INHIBITOR (DBI) IN HUMAN BRAIN TUMORS AND C-6 GLIOMAS. H. Alho, V. Varga, I. Podkletnova and P. Helen\*. Dept. of Biomed. Sci., Univ. of Tampere, PL 607, 33101 Tampere, Finland.

A regocnition site for benzodiazepines structurally different from that linked to the GABA, receptor and the "central type" benzodiazepine receptor is located in the outer membranes of mitochondria and have desingnated as mitochondrial benzodiazepine receptor (MBR). A putative endogenous ligand for MBR is the peptide diazepam binding inhibitor (DBI) that inhibits mitochondrial benzodiazepine (BZ) ligand binding on mitochondrial membranes. The cellular location of DBI- and MBR-LI was studied in human brain tumors and C-6 glioma cell lines by light and electron microscopic immunohistochemistry.

In many brain tumors DBI- and MBR-LI was identified in astrocyte-like cells. In brain glioblastomas the number of DBI and MBR immunoreactive cells was high.In particular, large multinuclear anaplastic cells showed intense immunoreactivity. A co-localization of DBI and MBR-LI was demonstrated in many tumors and C-6 cells. The role of MBR and DBI in glial cells and gliomas is unknown. They may modulate cellular growth via central BD- or mitochondrial BD-receptors, either by acting directly via these receptors or indirectly via neurosteroids regulated by the MBR's.

A SINGLE-NUCLEOTIDE MUTATION EXPLAINS THE ENHANCED ASINGLE-NOCLEOTIDE MOTATION EXPLAINS THE ENHANCED BENZODIAZEPINE SENSITIVITY OF A CEREBELLAR GRANULAR LAYER GABA, RECEPTOR IN AN ALCOHOL-SENSITIVE RAT LINE. E.R. Korpi\*, M. Köhler, P. Werner and P.H. Seeburg. Lab. of Molecular Neuroendocrinology, Zentrum für Molekulare Biologie, Univ. Heidelberg, 6900 Heidelberg, Germany, and Biomedical Research Center, Alko Ltd, Helsinki, Finland.

Alcohol-sensitive ANT (Alcohol Non-Tolerant) rats, produced by selective breeding for high sensitivity to the effects of a moderate dose of ethanol (2 g/kg), are also highly sensitive to motor-impairing effects of lorazepam, a benzodiazepine agonist. The only qualitative difference in the iorazepam, a benzodiazepine agonist. In e only qualitative difference in the central GABA, receptors of the ANT rats is the enhanced benzodiazepine agonist sensitivity of the cerebellar granule cell-specific "diazepaminsensitive" binding sites for [<sup>4</sup>H]Ro 15-4513, which are due to the presence of α6 subunit of the GABA, receptor. Poly A\* RNA was isolated from the cerebella of the ANT rats, cDNA prepared, and two fragments, corresponding to the extracellular and transmembrane domains of the α6 subunit coding region, were amplified by PCR, and sequenced. In the ANT rats, a single-nucleotide mutation (G to A) was found, which caused AN1 rats, a single-nucleotide mutation (G to A) was found, which caused an amino acid change in the extracellular domain of the subunit protein sequence. When this mutation was expressed using wildtype  $\alpha \delta$  backbone plasmid together with  $\beta 2$  and  $\gamma 2$  subunit coding plasmids in 293 cells, the resulting binding sites of  $f^3H$ IRo 15-4513 became sensitive to diazepam. The study was supported by Alexander von Humboldt Foundation, The Finnish Academy of Sciences, and the Deutsche Forschungsgemeinschaft (SFB 317/B9).

CLONING OF THE GENE ENCODING THE DIAZEPAM BINDING INHIBITOR. M. Kolmer and H. Alho\*, Dept. Biomed. Sci., Univ. of Tampere, P.O. Box 607, 33101 Tampere, Finland.

Diazepam binding inhibitor (DBI), an 9-kD polypeptide that is found in nearly all tissues, has been shown to be involved in the regulation of several important cellular functions: mitochondrial steroidogenesis, synthesis of fatty acids, insulin secretion, etc. DBI expression is resticted to certain, usually higly specialized cell types. However, the molecular mechanisms that regulate the cell-specific expression of DBI are poorly understood. Human rat, mouse and bovine DBI cDNAs have previously been cloned. The gemonic structure of DBI is not known.

To study the mechanisms regulating DBI expression, rat DBI genomic gene was cloned by screening the rat genomic library with DBI cDNA (Mocchetti, et al. 1986) as a probe. As revealed by nucleotide sequencing studies, rat DBI is encoded at least by three exons, the complete structure of genomic loci encoding for rat DBI will be presented. Promoter function experiments using luciferase gene as a reporter will be discussed.

#### 8.8

2-ARYL-3-INDOLEACETAMIDES (FGIN-1): LIGANDS FOR THE MITOCHON-DRIAL DBI RECEPTORS (MDR) THAT ACT AS INDIRECT ALLOSTERIC MODULATORS OF GABA, RECEPTORS. E. Romeo", A. Kozikowski<sup>1</sup>, A. Korneyev, G. Puia, J. Auta, E. Costa and A. Guidotti. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Med. School, Washington, DC 20007; <sup>1</sup> Mayo Clinic, Jacksonville, FL 32224

The 2-aryl-3-indoleacetamides (FGIN-1) are a new potent and specific class of ligands for the glial MDR that, by regulating intramitochondrial cholesterol transfer, increase pregnenolone formation. FGIN-1-27[N,N-di-n-hexyl2-(4-fluorophenyl)indole-3-acetamide] (115 to 230  $\mu$ mol/kg, p.o.) and its prodrug FGIN-1-44 (40 to  $80\mu$ mol/kg p.o.) reduce fear of novelty (neophobia) in rats exposed to an elevated plus maze test. The antineophobic effect of FGIN-1-27 or FGIN-1-44 was blocked by PK11195 isoquinoline carboxamide - a partial agonist at MDR, but not by flumazenil, a specific blocker of the antineophobic action of benzodiazepines. Because FGIN-1-27 does not have any direct action on GABA, receptors and does not block bicuculline-induced seizures, but antagonizes the convulsant action of isoniazid, it was thought that FGIN-1-27, acting at MDR, modulate GABA, receptor function indirectly by increasing neurosteroid biosynthesis

Indeed, the neurosteroids 3α-OH-DHP (3-15μmol/kg) and THDOC (3-15μmol/kg) elicit a dose related antineophobic action which is insensitive to the administration of PK 11195, flumazenil, and bicuculline. A stereoisomer of 3β-5α-OH-DHP - a steroid that acts as a partial agonist on GABA activated CI currents and antagonizes the positive modulation by  $3\alpha$ -OH-DHP of GABA, receptor - reduces the antineophobic action of FGIN-1-44 (40 \( \mu\text{mol/kg} \). Moreover, FGIN-1-27 administered to adrenalectomized and castrated rats treated with trilostane, an inhibitor of pregnenolone metabolism, increases in a dose related manner (from 50 to 230µmol/kg po), the brain content of pregnenolone (Korneyev, Neurosci Abs, 1992). These data suggest that FGIN-1-27 and FGIN-1-44, by binding to the MDR located in glial cells or neurons indirectly act on GABA, receptors, presumably by stimulating brain's neurosteroid production

ENDOGENOUS POSITIVE ALLOSTERIC MODULATORS FOR GABA, RECEPTORS (ENDOZEPINES): A CAUSE OF STUPOR AND COMA?

JD Rothstein\*, W Garland, G Puia, P Montagna, P Tinuper, P Cortelli, P Avoni, G Plazzi, E Sforza, E Lugaresi, A Guidotti, Dept of Neurology, Johns Hopkins Univ, Baltimore, MD 21205; Hoffman-La Roche, Nutley, NJ; Fidia-Georgetown Univ, Washington DC; Inst of Clinical Neurology, Univ of Bologna, Italy

Idiopathic Recurring Stupor (IRS) is a recently described syndrome of repeated stuporous episodes with no known metabolic or structural causes, and which can be rapidly reversed with the benzodiazepine antagonist flumazenil (Ann Neurol, 1992 in press). This suggested that the syndrome could be due to excess endogenous agonists acting at the allosteric regulatory extraneuronal domain of GABA, receptors. Using chloroform extractions, silica HPLC and reverse-phase HPLC, we have purified 2 endozepines (endozepine-2 and endozepine-4) from brain (bovine, rat, and human) and cerebrospinal fluid. These are endogenous substances that act as positive allosteric modulators of GABA, receptors (J Neurochem, 1992 in press). Mass spectrometry and NMR analysis of purified endozepine-4 revealed that it has a small molecular weight with a quinoline core structure. It has an apparent high affinity for benzodiazepine binding sites on cerebellar granule cells (~20 nM) and it can displace [3H]PK 11195 binding to rat brain mitochondria. Endozepine-4 potentiates GABA evoked chloride influx on patch clamped kidney 293 cells transfected with cDNA for  $\alpha_1~\beta_1~\gamma_2$  GABA subunits. Intraventricular administration of 1-2 nmoles endozepinesignificantly delayed bicuculline seizures. Serum or CSF from stuporous patients with IRS contained an enormous concentration of these endozepines, with levels as high as 400 nM, compared to 5-10 nM in control serum or CSF. Serum or CSF in IRS patients during normal periods contained endozepine levels similar, but greater than, control CSF and serum. These results suggest that IRS may be due to excess endozepines and provide further proof for the existence and functional role of endozepine acting as an allosteric modulator of GABA, receptors. The cause for increased endozepine is

#### 8.11

A NEW CLASS OF POTENTIAL LIGANDS FOR THE STEROID BINDING SITE ON GABA, RECEPTORS N.T. Rodgers-Neame\*, Y. Hu, D.F. Covey, K.E. Isenberg, & C.F. Zorumski, Depts. of Psychiatry and Mol. Bio. & Pharm., Washington Univ. Medical Sch., St. Louis MO 63110

Anesthetic steroids are potent modulators of GABA-gated Cl<sup>-</sup> channels, acting at a site which appears to differ from the GABA, benzodiazepine, barbiturate and picrotoxin sites. To understand structure-activity relationships at this steroid site we have synthesized and evaluated a series of substituted benz[e]indenes (Bls). The Bls are tricyclic structures lacking an analogous steroid A-ring.

In voltage clamped postnatal rat hippocampal neurons, BIs potentiate GABA-gated CI currents with ECs0 values between 0.1-1.0  $\mu$ M and maximal effects at about  $10 \mu$ M. The best of these agents, BI-1 ( $10 \mu$ M), produces 467  $\pm$  38% (N=15) increase in the peak response to  $1 \mu$ M GABA. By comparison the neurosteroid,  $5 \alpha$ -pregnan- $3 \alpha$ -ol-20-one ( $3 \alpha$ -OH-DHP) enhances GABA currents by  $478 \pm 20\%$  (N=5) at  $10 \mu$ M. BI-1 produces a leftward shift in the GABA dose-response curve with a smaller degree of potentiation at saturating GABA concentrations. BI-1 does not after the shape of the GABA current-voltage (IV) relationship and does not affect the GABA reversal potential. A major difference between BIs and steroids is that the BIs do not directly gate GABA currents at concentrations up to  $10 \mu$ M whereas CI currents are activated by  $3 \alpha$ -OH-DHP at  $> 1 \mu$ M.

These observations indicate that removal of the steroid A-ring produces compounds which potentiate GABA currents but which are significantly less effective in directly gating Cl channels.

#### 8.10

RAT BRAIN MINCES: A MODEL TO STUDY NEUROSTEROIDOGENESIS. M.L. Barbaccia\*, G. Roscetti, M. Trabucchi, C. Ambrosio(a) and M. Massotti(a). Dept. Exp. Medicine and Bioch. Sci., Univ. of Roma "Tor Vergata", 00173, Roma, Italy, and (a) Lab. of Pharmacology, Istituto Superiore di Sanita, 00161, Roma, Italy.

Steroids have been recently indicated as endogenous modulators of GABA-A receptor function. Moreover, several lines of evidence indicate that in brain selected populations of glial cells may be endowed with the capability of synthesizing steroids (neurosteroids) (Hu et al, PNAS, 84:8215, 1987;Guarneri et al, PNAS, 89, 1992 in press).

We used brain cortical minces (300x300 um) prepared from adult intact male rats. In minces, allowed to stabilize for 1 hr at 37°C, the content (ng/g of protein) of progesterone, dehydroepiandrosterone, pregnenolone and deoxycorticosterone, determined by specific radioimmunoassay after HPLC purification, were 18.3, 1.7, 59.7 and 6.1, respectively. These values are in the same order of magnitude of those we found in brain cortex of three-day adrenalectomized/orchiectomized rats.

The exposure of cortical minces to dibutyryl-cyclic AMP (1 mM) or forskolin (10 uM) for 30 minutes increases the content of pregnenolone (the precursor of all steroids) up to 60% and 180%, respectively, over the basal values. This confirms that also in brain cyclic AMP can stimulate steroidogenesis as previously reported in adrenal cortex, ovary and testes.

These data suggest that rat brain minces are a suitable experimental model to study the physiology and pharmacology of brain steroidogenesis, excluding interference by blood-borne steroids.

#### CATECHOLAMINE RECEPTORS: DOPAMINE I

#### 9.1

THE HUMAN DOPAMINE D1 RECEPTOR EXPRESSED IN A BACULOVIRUS-INSECT CELL SYSTEM IS FUNCTIONALLY IDENTICAL TO THE NATIVE NEURONAL RECEPTOR. S.R.George, G.Ng, B.Mouillac, M.Caron, Y.Israel\*, M.Dennis, M.Bouvier, B.F.O'Dowd. Univ.de Montreal and Biosignal Inc., Que and Univ.of Toronto, Ont, CANADA MSS 148

The cDNA encoding the human dopamine D1 gene (DRD1) and a cDNA encoding a c-myc protein epitope in the aminoterminus of the dopamine D1 receptor (mDRD1) were subcloned into the cloning site of the baculovirus expression vector. These viral constructs were used to infect Spodoptera frugiperda cells (Sf9), which were harvested after periods of 24 and 48 hours. Membrane preparations from cells at these time points bound [3H]SCH23390 with densities of 5 pmol/mg and 40 pmol/mg respectively, with an affinity constant of 624 pM. Membranes from Sf9 cells infected with wild-type baculovirus did not exhibit specific D1 binding. The [3H]SCH23390 labelled DRD1 and mDRD1 receptor proteins displayed a rank order of agonist and antagonist inhibition potencies similar to the native brain DRD1: SKF 38393=dopamine>(-) noradrenalin>serotonin>isoproterenol, and SCH23390>(+)butaclamol >haloperidol. Dopamine displacement of SCH23390 labelled receptor protein was biphasic, with 50% detected in the high-affinity form with Kd 12.4 nM and 50% in the low-affinity form with Kd 490 nM. The high-affinity state of the receptor was converted to low by Gpp(NH)p. The receptors were coupled to adenylate cyclase as evidenced by dopamine stimulation of enzyme activity and inhibition by SCH23390. Photoaffinity labelling of the D1 receptor and the mDRD1 receptor revealed molecular weights similar to the neuronal receptor. These data confirm that, in the Sf9 cells, the DRD1 is fully functional, and pharmacologically and biochemically similar to the native brain human DRD1.

#### 9.5

DOPAMINE REGULATES THE CELLULAR REDISTRIBUTION OF THE HUMAN D1 DOPAMINE RECEPTOR. B.Mouillac, G.Ng, M.Caron, M.Dennis, B.F.O'Dowd, M.Bouvier, and S.R.George\*, Univ.de Montreal and Biosignal Inc., Que and University of Toronto, Ort, CANADA M5S 1A8 The human dopamine receptor D1 (DRD1) and a c-myc-epitope tagged

human dopamine receptor D1 (mDRD1), functionally expressed in Sf9 cells were phosphorylated, palmitoylated and stimulated adenyl cyclase in an agonist-dependent manner. To further evaluate DRD1 desensitization and to determine whether redistribution of surface receptors contribute to the mechanisms regulating DRD1 activity, the specific monoclonal antibody 9E10 recognizing the c-myc epitope in the extracellular aminoterminus of DRD1 was used for immunofluorescent localization of receptors in Sf9 cells following exposure to 10 uM dopamine for 5 min and 15 min. To assess relative receptor numbers and localization, cells were permeabilized to define total receptor number or left unpermeabilized to define surface receptor number. In nonpermeabilized cells in the basal state, the surface receptor labelling pattern was diffuse. Upon exposure to dopamine, the fluorescence coalesced into large aggregates, in a time-dependent manner. Permeabilization of cells desensitized at 5 and 15 minutes revealed intense cytoplasmic fluorescence. redistribution of surface receptors could be blocked by SCH23390. Cells exposed to agonist for 15 minutes and washed to remove the agonist 3 hours before fixation showed a reversal to pattern of surface labelling similar to that observed in basal cells and suggests DRD1 recycling. These results show for the first time that the number of surface DRD1 is regulated following agonist activation.

DESENSITIZATION, PHOSPHORYLATION AND PALMITOYLATION OF THE HUMAN D1 DOPAMINE RECEPTOR. G.Ng. B.Mouillac, M.Caron, D.A.Haas\*, S.R. George, M.Dennis, B.F.O'Dowd and M.Bouvier. Univ. of Toronto, Ont and Univ.de Montreal and Biosignal Inc., Que, CANADA MSS

Phosphorylation and more recently palmitoylation of the B2-adrenergic receptor (B2AR) have been shown to play important roles in the ability of the receptor to interact with the stimulatory guanine nucleotide binding protein (Gs), and to activate adenylyl cyclase. In fact, it has been proposed that these post-translational modifications are involved in the process of agonist-induced desensitization. Consensus sequences for phosphorylation by protein kinase A (PKA) are conserved in the dopamine receptor D1 (DRD1), and a cysteine residue present in the carboxyl tail of the DRD1 occupies a position equivalent to that which is palmitoylated in the B2AR. To evaluate whether these covalent modifications take place the BZAH. To evaluate whether these covalent modifications take place in the DRD1 and play a role in agonist promoted desensitization, the human DRD1 was expressed in Sf9 cells using the recombinant baculovirus system. The expressed receptor exhibited the appropriate pharmacology and promoted dopamine-dependent activation of the adenylyl cyclase. Preincubation of the cells with 10 uM dopamine for 15 minutes induced a desensitization of the receptor which resulted in a 40% decrease in the maximal agonist-stimulated adenylyl cyclase activity. This desensitization was accompanied by an increase in the level of phosphorylation of the DRD1, as shown by immunoprecipitation of the receptor. Also accompanying the desensitization was an increase in the incorporation of tritiated palmitate in the DRD1. Thus, these results show that the DRD1 undergoes rapid agonist-promoted desensitization and that this phenomenon is accompanied by an increase in the phosphorylation level and in the palmitoylation turnover of the receptor in Sf9 cells.

CHARACTERIZATION OF D2, D3 AND D4 DOPAMINE RECEPTORS EXPRESSED IN THE SAME CELL BACKGROUND L. Tang\*, J. Hickok+, S. Harmon, R.D. Todd+ and K.L. O'Malley. Dept. Anatomy & Neurobiology, +Genetics & Psychiatry Washington Univ. Med. Sch., St. Louis, MO 63110

Dept. Anatomy & Neurobiology, +Genetics & Psychiatry. Washington Univ. Med. Sch., St. Louis, MO 63110

The rat D2(444) cDNA, a human D3 cDNA and the rat D4 gene were subcloned into the expression vector pcDNA/neo and transfected into mouse tk fibroblast cells. Cell lines were purified by limiting dilution. As determined by radioligand binding assays, the expressed levels of D2, D3 and D4 subtypes were 2.0, 0.5 and 0.11 pmole receptor/mg membrane protein, respectively. The pharmacological characteristics of these D2 receptor subtypes were examined by competition binding experiments. The rank order potencies for antagonists are (+)-butaclamol, D2>D3>D4; clozapine, D4>D2>D3 and (-)-sulpiride, D2>D3-D4; and for agonists dopamine, D3-D4>D2 and quinpirole, D3>D4>D2. The D3 receptor exhibits a twelve fold higher potency for the agonist 7-(OH)-DPAT than does the D2 receptor in these cells. Functional studies demonstrated that D2 inhibits forskolin-stimulated adenylate cyclase activity, but increases inositol phosphate levels in transfected cells, while D3 shows a negative response in both assays. The D4 receptor also does not couple to adenylate cyclase. These data suggest that different D2 receptors may couple to different intracellular second messengers and thus have different signal transduction properties.

#### 9.7

ALLELIC VARIATION OF THE HUMAN D4 RECEPTOR. H.H.M. Van Tol\*, C.M. Wu, H.-C. Guan, K. Ohara, J.R. Bunzow, O. Civelli, J. Kennedy, P. Seeman, H.B. Niznik and V. Jovanovic. Clarke Institute of Psychiatry, Toronto, Ontario, Canada M5T 1R8, Vollum Institute, Oregon Health Sciences University, Portland, Oregon 97201, USA.

The dopamine D4 receptor belongs to the group of receptors that acts through G proteins. Structurally and pharmacologically, the D4 receptor resembles most the dopamine D2 and D3 receptors. The antipsychotic clozapine, which is devoid of drug-induced tardive dyskinesia, has a ten-fold higher affinity for the D4 than the D2 and D3 receptors. This may explain clozapine's atypical properties. Screening of various human and genomic libraries resulted in the isolation and identification of various allelic forms of the D4 receptor. These receptors vary in the frequency of a 48-bp directrepeat present in the putative third cytoplasmic loop. Expression of the cDNA of these allelic variants in COS-7 cells indicated differences in pharmacological properties with respect to spiperone and clozapine binding. This is the first example of allelic variations for catecholamine receptors. Such repeat polymorphisms are the basis for X-linked spinal and bulbar atrophy, fragile X-syndrome and myotonic dystrophy. The D4 receptor is located in a region of the genome (11-pter) that has been implicated in bipolar affective disorder and long QT syndrome. This polymorphism could have important implications in predisposition to psychiatric disorders and drug treatment.

#### 9.4

GT<sub>1</sub> GnRH CELL LINES: A MODEL FOR D<sub>1</sub>-DOPAMINE RECEPTORS IN THE CENTRAL NERVOUS SYSTEM. G. Martínez de la Escalera, F. Gallo, A. L. H. Choi, C. Clapp\* and R. I. Weiner, Reproductive Endocrinology Center, University of California San Francisco, CA 94143, USA, and Instituto de Investigaciones Biomédicas, National University of México, México City 04510, México.

Preliminary findings suggested that GnRH release from GT<sub>1</sub> GnRH cell lines was regulated by dopamine (DA). We report that these cells regulate GnRH release via D<sub>1</sub> DA receptors and express associated molecules involved in signalling in CNS neurons. Superfusion of GT<sub>1-1</sub> cells with DA for 100 min increased the amplitude of spontaneous GnRH pulses (assessed by "cluster analysis"). DA also stimulated GnRH release and increased intracellular cyclic AMP in GT<sub>1-7</sub> cells in static culture. These effects were mimicked by the selective D<sub>1</sub> agonist (±)SKF 38390 and blocked by the D<sub>1</sub> antagonist R(+)SCH 23390. However, the D<sub>2</sub> agonist bromocryptine or antagonist spiroperidol had no effect on GnRH release or intracellular cyclic AMP levels. Northern analysis of total RNA from GT<sub>1-1</sub>, GT<sub>1-3</sub> and GT<sub>1-7</sub> cells showed the expression of DARPP-32 (DA and cyclic AMP regulated phosphoprotein, Mr 32,000), a specific substrate for protein kinase A, generally coexpressed with D<sub>1</sub> receptors. These findings demonstrate that GT<sub>1</sub> cell lines express D<sub>1</sub> DA receptors coupled to adenylate cyclase. Further experiments will determine the role of DARPP-32 in signalling in GT<sub>1-1</sub> cells, including its role in dopaminergic regulation of GnRH secretion. (Work supported by NIH Grant HD 08924 and The Rockefeller Foundation).

#### 9.6

PHARMACOLOGICAL CHARACTERISATION OF THE HUMAN D<sub>3</sub> DOPAMINE RECEPTOR. S.B. Freedman, S. Patel, R. Marwood, F. Emms, M. Knowles, A. Fletcher, G. Seabrook and G. McAllister. Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex, CM20 2QR, Great Britain.

Human D<sub>2</sub> and D<sub>3</sub> binding was characterised in CHO cells using [<sup>125</sup>I]-iodosulpiride. No binding selectivity was observed for the antagonists S-sulpiride, clozapine or haloperidol or the agonists apomorphine or bromocryptine. In contrast, dopamine, quinpirole and the efficacious agonists PHNO and 6,7 ADTN showed marked apparent hD<sub>2</sub> selectivity.

apparent hD<sub>3</sub> selectivity.

Functional coupling was investigated in a number of cell lines in which the hD<sub>3</sub> receptor was transiently or stably transfected. Both biochemical and electrophysiological studies were used to test for functional coupling in CHO, HEK-293, NG108-15, LTK and GH4 C1 cells. No evidence of functional coupling was found in any of these cell lines

These results may be explained by a number of reasons. The hD<sub>3</sub> receptor may be locked in a high affinity state, these cells may not have appropriate G-proteins, or alternatively this receptor may couple by a mechanism, as yet, not determined.

#### 9.8

STIMULATION OF DOPAMINE D-2 RECEPTOR IN CHO TRANSFECTED CELLS INHIBITS ADENYLATE CYCLASE ACTIVITY VIA GUANINE NUCLEOTIDE BINDING PROTEIN DISTINCT FROM THOSE EXPRESSED BY RAT PITUITARY CELLS A. VALERIO. C. TINTI. M. RIBOLA, P.F. SPANO and M. MEMO\*, Division Pharmacology, Dept. Biomedical Sciences, University of Brescia, Italy.

Transcription of the gene encoding the dopamine D-2 receptor may result in two distinct splicing variants, named D-2s and D-21. In the present study we investigate the involvement of different G-proteins in the signal transduction pathway activated by the stimulation of the two different dopamine receptor isoforms. Chinese Hamster Ovary (CHO) cells, which normally lack dopamine D-2 receptor binding sites, were stably transfected with either the D-2s or the D-21 receptor isoform cDNA. Both CHO-D2s and CHO-D21 displayed a dose-dependent inhibition of adenylate cyclase activity when exposed to dopamine. Polymerase chain reaction (PCR) was used to analyzed the pattern of expression of the mRNA encoding the different G protein a subunits in CHO and pituitary cells. We found that pituitary cells contain transcripts for Gs long, Gs short, Gi2, Gi3, Gz and Go  $\alpha$  subunits. CHO cells contain transcripts only for Gs long, Gs short and very low levels of Go a subunit. Our results demonstrate that Gi1, Gi2, Gi3 and Giz  $\alpha$  subunits possibly expressed by CHO cells, are encoded by mRNAs structurally different from those present in rat pituitary.

VISUALIZATION OF ANTIPSYCHOTIC INTERACTIONS WITH LIVING MESOLIMBIC NEURONS REVEALS SPECIFIC D2 BINDING AND ACIDOTROPIC UPTAKE. S. Rayport\*, M. Rappaport and D. Sulzer. Depts. Psychiatry, Anatomy & Cell Biology, Ctr. Neurobiology & Behavior, Columbia University; Dept. Neuropathology, NYS Psychiatric Institute, NY 10032.

We used fluorescent derivatives of spiperone (Ariano et al., Brain Res 547: 208-222, 1991) to examine the distribution of D2-type dopamine (DA) receptors on postnatal rat mesolimbic cells in culture. 10 nM rhodamine-N-(p-aminophenethyl)spiperone (rhodamine-NAPS, Molecular Probes) produced continuous staining of the exposed somatic membrane of subsets of cells; glial background obscured possible neurite staining. Specific membrane staining was blocked by 10  $\mu$ M (+)-butaclamol but not (-)-butaclamol. In ventral tegmental area cultures, where about 25% of neurons are DAergic, about the same fraction stained; histochemistry showed these neurons were mainly DAergic. In nucleus accumbens cultures, over 50% of the medium-sized (putatively GABAergic) neurons stained, while larger neurons (putatively cholinergic) did so rarely. In contrast, 10 nM bodipy-NAPS principally stained intracellular sites in a punctate pattern that was blocked by prior fixation or 10 mM NH<sub>4</sub>Cl, suggesting that it reflected energy-dependent acidotropic uptake. To visualize acidotropic uptake of non-derivatized antipsychotics, we stained acidic sites with the weak base vital dye acridine orange; spiperone and haloperidol abolished acidic staining at low micromolar concentrations, clozapine and raclopride were less effective, while sulpiride was ineffectual at millimolar levels. For the first time, we have visualized DA receptors on living neurons, which should prove useful in identifying neurons expressing DA receptors and in examining changes in receptor distribution. Acidotropic uptake of antipsychotics may impact on their therapeutic action, side effects, and use in positron emission tomography to evaluate D2-type receptor numbers.

#### 9.11

NICOTINE REGULATES DOPAMINE D1 AND D2 RECEPTOR GENE EXPRESSION IN RAT BRAIN. <u>J. Tsatsos, T. Hattori\* and S.R. George,</u> Dept of Pharmacology, University of Toronto, Ont, CANADA M5S 1A8

The central nervous system effects of nicotine are mediated, at least in part, by the activation of dopaminergic systems in brain, notably in the striatum and mesolimbic regions. In the present study, the effects of nicotine administration on dopamine D1 and D2 receptor gene expression were examined. Male Sprague-Dawley rats were housed in environmental rooms and injected s.c. with nicotine 1 mg/kg/day or saline vehicle for 3 days. Animals were sacrificed and the brain regions were dissected and quickly frozen and stored at -70°C. D1 and D2 receptor mRNA was detected by Northern blot analysis with hybridization of specific 32P-labelled rat cDNA or oligonucleotide probes. Specific dopamine D1 receptor binding was quantified by [3H]SCH23390 in the presence of 1 uM (+)butaclamol, and specific D2 receptor binding by [3H]spiperone in the presence of 10 uM (-)sulpiride. There was a significant decrease in D1 receptor mRNA in the striatum and olfactory tubercle of nicotine treated rats that was accompanied by a decrease in the density of D1 dopamine receptors in striatum. There also was a significant decrease in D2 receptor mRNA in the striatum of nicotine treated rats accompanied by a reducton of D2 dopamine receptor density. D2 receptor mRNA was also decreased in neurointermediate pituitary after nicotine treatment, but was unaffected in anterior pituitary. These results suggest that nicotine alters dopamine D1 and D2 receptor gene transcription with a consequent change in expression of the receptor protein.

#### 9.10

AUTORADIOGRAPHIC LOCALIZATION OF [3H]QUINPIROLE BINDING TO PUTATIVE D<sub>2</sub> AND D<sub>3</sub> DOPAMINE RECEPTORS IN RAT BRAIN. <u>B. Levant</u>, <u>D.E. Grigoriadis, E.B. DeSouza</u>. Central Nervous System Diseases Research, The DuPont Merck Pharmaceutical Co., Wilmington, DE 19880-0400.

The putative D₂ dopamine receptor agonist quinpirole (LY 171,555) has been extensively used in a variety of in vivo and in vitro studies of D₂ receptor mediated effects and may have even higher affinity for the recently described D₃ dopamine receptor (Sokoloff et al., Nature, 347:146-151, 1990). In the present study, conditions for autoradiographic visualization of [³H]quinpirole-labeled D₂-like dopamine receptors were optimized and binding to slide-mounted sections was characterized with respect to pharmacological profile of [³H]quinpirole binding in slidemounted brain sections was: (±)6,7-ADTN ≥ quinpirole > dopamine for putative dopamine agonists; spiperone > (+)butaclamol > (-)sulpiride > SCH 23390 >> cinanserin > (-)butaclamol for antagonists. [³H]Quinpirole binding was decreased in the presence of guanine nucleotides in most brain regions except in the islands of Calleja and the molecular layer of cerebellar lobules 9 and 10. The regional distribution of [³H]quinpirole binding sites roughly paralleled the distribution of [³H](-)sulpiride binding sites, with greatest densities present in the olfactory bulb glomerular layer, islands of Calleja, pituitary intermediate lobe, caudate/putamen, olfactory tubercles, and nucleus accumbens However, significantly greater densities of [³H]quinpirole binding than [³H](-)sulpiride binding were observed in the islands of Calleja, olfactory bulb glomerular layer, and the molecular layer of cerebellar lobules 9 and 10, and somewhat more [³H]quinpirole binding in the olfactory tubercles, in concordance with the high levels of expression of D₂ receptor mRNA recently reported in these brain regions (Bouthenet et al., Brain Res., 564:203-219, 1991). Higher concentrations of [³H]quinpirole binding were also observed in the dorsomedial caudate and pituitary intermediate lobe. These data indicate the utility of [³H]quinpirole in autoradiography to label D₃ as well as D₂ dopamine receptors.

EXPRESSION OF mRNAs ENCODING ARPP-16/19, ARPP-21 AND DARPP-32 IN HUMAN BRAIN TISSUE S. BRENÉ\*, N. LINDEFORS, I, KOPP, H. HALL, M. EHRLICH; G. SEDVALL, P. GREENGARD and H.PERSSON Departments of Medical Chemistry, Pharmacology and Psychiatry

Departments of Medical Chemistry, Pharmacology and Psychiatry and Psychology, Karolinska Institutet, Stockholm, Sweden, Laboratory of Molecular and Cellular Neuroscience, Rockefeller University, New York, NY, USA In situ hybridization with cDNA probes was used to study the

In situ hybridization with cDNA probes was used to study the expression of mRNAs encoding the phosphoproteins ARPP-16/19, ARPP-21 or DARPP-32 in human post mortem brain tissues, using horizontal whole hemisphere sections. Eight representative levels of the brain ranging from 25 mm to 105 mm ventral to vertex were examined. All three probes showed distinct hybridization patterns in the caudate nucleus, putamen, nucleus accumbens and the amygdaloid complex. For ARPP-16/19 mRNA a hybridization signal comparable to the signal in caudate nucleus, putamen and nucleus accumbens was also detected in the neocortex. ARPP-21 and DARPP-32 mRNA, on the other hand, were present in much lower relative levels in neocortical regions. DARPP-32 mRNA was abundant in the deep layer of the cerebellar cortex at the level of the Purkinje cell layer. High levels of ARPP-16/19 and ARPP-21 mRNA were also found in the cerebellar cortex where they were confined to superficial layers. The present results demonstrate high expression of mRNAs for the three phosphoproteins in several areas of the human brain where abundant dopamine D1 receptor binding sites have previously been localized. In situ hybridization in human postmortem tissue should be useful for future detailed studies on mRNA expression for phosphoproteins as well as other proteins in neurological disorders.

### CALCIUM CHANNEL TOXINS I

#### 10.

PROBING NEURONAL CALCIUM CHANNELS WITH BIOTINYLATED DERIVATIVES OF OMEGA-CONOTOXINS. J. A. Haack\*, P. Kinser, D. Yoshikami, B. M. Olivera. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112.

Omega-Conotoxins are a class of homologous peptides, isolated from predatory cone snails, that are potent inhibitors of neuronal subtypes of voltage-sensitive calcium channels (VSCC). Purified and structurally characterized, biotinylated derivatives of two homologous omega-conotoxins, omega-GVIA (Conus geographus) and the recently characterized omega-MVIID (Conus magus) were used to probe the structure/function relationships of interactions between omega-conotoxins and neuronal VSCC. The apparent affinities of biotinylated omega-GVIA derivatives, in receptor binding assays, decreased by an order of magnitude per biotin attached to the peptide. This decrease was independent of the position of the amino acid biotinylated. Preformed complexes between streptavidin and biotinylated derivatives of omega-GVIA also retain their activity in receptor binding assays, suggesting that the receptor binding site is tolerant of large structural additions in the biotinylated regions of the peptide.

In contrast, the apparent affinities of mono-biotinylated derivatives of omega-MVIID vary depending on the position of the amino acid biotinylated. Results from receptor binding assays showed that like omega-GVIA, biotinylation of the N-terminus resulted in a one order of magnitude decrease in apparent affinity. However, biotinylation of the lysine at amino acid #10 of omega-MVIID resulted in an approximately 3 orders of magnitude decrease in apparent affinity. A comparison of the receptor binding characteristics of this collection of biotinylated derivatives allows us to map out regions of the omega-conotoxins which are important for peptide interactions with neuronal VSCC.

#### 10.5

EFFECTS OF ω-CONOTOXIN GVIA AND ω-AGATOXIN IA ON  $Ca^{2+}$  CURRENTS IN RAT SYMPATHETIC NEURONS. V.P. Bindokas\*, S. Foucart, M.E. Adams\* and R.J. Miller. Dept. Pharmacol. and Physiol. Sci., Univ. of Chicago, Chicago IL, 60637; \*Dept. Entomol., Univ. of California, Riverside CA, 92521.

In this study,  $\omega$ -conotoxin GVIA (CgTX) and  $\omega$ -agatoxin IA (AgaTX) were used to characterize the subtypes of calcium channels in acutely isolated sympathetic neurons. Neurons from adult rat superior cervical ganglia were dissociated enzymatically, plated on poly-l-lysine coated coverslips and used within 8 hrs. The whole-cell patch-clamp method was used to record transmembrane Ca²+ currents (Ic\_a). Cells were placed in a perfusion chamber and the Ic\_a was isolated by using the following medium (in mM):CaCl\_2 2, TEACI 138, MgCl\_2 2, HEPES 10, glucose 10, pH 7.4. The internal solution was (mM): CsCl 124, MgCl\_2 1, HEPES 10, BAPTA 10, MgATP 3.6, tris\_creatine phosphate, CPK (50 U/ml), trisGTP 1, pH 7.4. Pressure application of CgTX (5  $\mu$ M) resulted in a 53  $\pm$  6.1% inhibition of the peak Ic\_a (n = 9). The remaining Ic\_a was unaffected by noradrenaline (NA, 10  $\mu$ M; n = 4) or neuropeptide Y (NPY, 300 nM; n = 3) whereas prior to the toxin treatment, NA and NPY inhibited the Ic\_a by 37% and 13% respectively. Application of AgaTX (500 nM) resulted in sla  $\pm$  3% inhibition of Ic\_a (n = 5). This effect did not prevent the inhibitory action of NA on Ic\_a 4 of 4 neurons were further inhibited 41  $\pm$  14% after AgaTX treatment. In a few cases, there was slow, partial recovery of Ic\_a following AgaTX washout. It is known that CgTX blocks N-type Ca²+ channels. Therefore, the results observed with CgTX suggest that NA and NPY inhibit Ic\_a via action affecting an N-type channel. The results observed with CgTX soughts that the traditional N-type Ca²+ channel distinct from the traditional N-type Ca²+ channel distinct from the traditional N-type Ga²+ channel

NOVEL SNAKE TOXIN BLOCKS SELECTIVELY THE L-TYPE CALCIUM CURRENT IN RAT DENTATE GRANULE NEURONS. C.E. Niesen, O.T. Jones\*, P.L. Carlen, Playfair Neuroscience Unit, Toronto Western Hospital, Toronto, Ontario, CANADA M5T 258

Polypeptide toxins have revolutionized the study of ion channels in neurobiology. In an effort to develop ligands for the labelling and characterization of neuronal voltage-gated calcium channels, we have isolated a polypeptide from the venom of the black mamba snake, *Dendroaspis polylepis polylepis*. The toxin was purified by a combination of ion-exchange and reverse-phase (HPLC) chromatographic steps. Whole cell voltage-gated calcium currents (4 mM external Ca<sup>2+</sup>) were recorded in dentate granule neurons from rat hippocampal slices from 2-4 week old animals. Leupeptin and an ATP-regenerating solution in the patch electrode produced stable currents for > 40 min of recording.

> 40 min of recording.

Bath perfusion of 1-2 µM of the mamba toxin reduced the L-type current by 70-80% with little to no effect on the T- or N-type calcium currents. Completion of the block required 6 min of toxin perfusion and appeared to be voltage-dependent. Concentrations in the range of 100-200 nM produced half-maximal reduction of the L-type current. Washout of the toxin for 20 min in control solution did not reverse its effect. Nimodipine at 2 µM produced a 50-70% block of the L-type current, indicating that at near saturating concentrations, the mamba toxin appears to be more potent. A combination of nimodipine and mamba toxin decreased the L-type current to near zero levels, regardless of their order of application.

The mamba toxin is being characterized to elucidate its 1° and 2° structure and confirm its possible identity to a toxin described by de Weille et al. (PNAS 88:2437, 1991) termed calciseptine. To our knowledge, this represents the most potent polypeptide toxin of the L-type calcium current and should prove invaluable in dissecting this channel's pharmacology and cell biology.

Supported by an MRC Fellowship.

### 10.5

USE OF SPIDER TOXINS TO DISCRIMINATE BETWEEN NEURONAL CALCIUM CHANNELS. I.M. Mintz\*, M.E. Adams, and B.P. Bean, Dept. of Neurobiology, Harvard Med. School, Boston MA 02115 and Dept. of Entomology, University of California, Riverside CA 92521.

Venom from the spider Agelenopsis aperta is rich in Ca channel antagonists. The 48 amino-acid peptide  $\omega$ -Aga-IVA potently blocked P-type Ca channels (Kd ~2 nM) but had no effect on T-type, L-type, or N-type channels. Identifed by  $\omega$ -Aga-IVA sensitivity, P-type current contributed 90% of the high-threshold current in cerebellar Purkinje cells and variable smaller fractions in spinal cord interneurons (45%), visual cortical neurons (30%), hippocampal CA1 pyramidal cells (25%), and DRG neurons (25%). Most CA3 hippocampal neurons had little P-type current. In cells with multiple channel types, P-type current identified by  $\omega$ -Aga-IVA showed no overlap with nimodipine-sensitive L-type current or  $\omega$ -conotoxin-sensitive N-type current. Except for Purkinje neurons, almost all CNS neurons also possessed a fraction of high-threshold current that remained unblocked with combined application of  $\omega$ -Aga-IVA,  $\omega$ -conotoxin, and nimodipine.

The 76 amino-acid peptide ω-Aga-IIIA targets most or all high-threshold Ca channels. ω-Aga-IIIA blocked L-type channels potently and completely (Kd~1 nM) and N-type channels potently (Kd~1 nM) but only partially (~70%). Applied to Purkinje neurons, 200 nM ω-Aga-IIIA was saturating but blocked only ~40% of P-type current elicited at -20 mV in 5 mM Ba. The partial block of P-type Ca channels was voltage-dependent, being almost absent at potentials above -10 mV. Noise analysis suggested that ω-Aga-IIIA reduces single P-channel current in a voltage-dependent manner.

## 10.7

THE SPIDER TOXIN ω-Aga-IVA INHIBITS AMINO ACID NEUROTRANS-MITTER RELEASE FROM HIPPOCAMPAL TISSUE IN VITRO. <u>S.P. Burke\*</u>, <u>C.P. Taylor and M.E. Adams</u>. Parke-Davis Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105 and Depts. Entomology and Neuroscience, Univ. Calif. Riverside. CA 92521.

The exocytotic release of transmitter is dependent on the opening of voltage-sensitive calcium channels (VSCC) on synaptic terminals. However, the involvement of specific subtypes of VSCC is not clear. We examined the overflow of amino acids from transverse slices of rat hippocampal CA1 area by brief application of 50 mM KCl, evoking glutamate release that is greater than 95% dependent upon external Ca<sup>2+</sup>.

ω-Aga-IVA is a peptide present in the venom of the funnel-web spider Agelenopsis aperta. This toxin blocks Ca²+ entry in several preparations (Mintz et al. Nature 355:827(1992)). We tested the effect of ω-Aga-IVA upon depolarization-induced glutamate release in a double-pulse protocol. Twenty-five min after a 1-min bolus of 50 mM KCI medium (S1), normal superfusion (1 ml/min) was hafted for 15 min while the tissue slices were submerged in 200 nM ω-Aga-IVA or control medium. Superfusion was then resumed with a second 1-min bolus (S2) of 50 mM KCI. HPLC analysis of amino acids in collected fractions gave an S2/S1 ratio for glutamate release of 0.37 (±0.05 SEM) for ω-Aga-IVA compared to 0.95 (±0.05 SEM) for control medium. S2/S1 Ratios for GABA and aspartate with 200 nM ω-Aga-IVA were 0.5-0.6. Preliminary data suggest that the effect of ω-Aga-IVA is largely reversible with 15 min of washing in control medium. Others have shown that VSCCs sensitive to the marine snail toxin ω-conotoxin-GVIA contribute to the release of monoamine transmitters. Our results suggest that VSCCs sensitive to ω-Aga-VIA contribute to release of amino acid

### 10

Evidence for allosterically coupled toxin binding sites for ω-conotoxin GVIA and ω-agatoxinIIIA on the purified ω-conotoxin receptor. M.W. McEnery\*, A.M. Snowman, A.H. Sharp, M.E. Adams\*, and S.H. Snyder. The Johns Hopkins Univ. Sch. of Medicine, Dept. of Neuroscience, and \*Univ. of California, Riverside, Dept. of Entomol. and Tox.

The N-type calcium channel is the inhibitory site of action of ω-conotoxin GVIA (CTX) and can be distinguished from the neuronal DHP receptor/L-type calcium channel. N-hydroxy-succinimidyl-4-azido-benzoate-125I-CTX labels with high affinity a discrete 230 kDa band in brain membranes which represents the recognition site for CTX in the purified CTX receptor. As with the L-type channel, the ligand binding subunit comprises only a portion of the holo-receptor. We have reported the purification of the CTX receptor with the isolated receptor protein retaining reversible ligand binding (Mc Enery, et al. (1991) PNAS 88, 11095). The purified rat brain CTX receptor comprises five subunits with substantial similarity to the subunit composition of the L-type calcium channel. We have examined the affinity of the purified CTX receptor for peptide toxins considered diagnostic for the intact receptor: CTX, ω-conotoxin MVIIA, and ω-AgaIIIA, a competitive inhibitor of [125]/CTX binding. We demonstrate the high affinity recognition site for ω-AgaIIIA to be dependent upon the presence of exogenous phospholipids, while CTX and MVIIA is not (McEnery (1992) Meth. in Pharm. vol 7, in press). These results suggest 1) the ω-AgaIIIA binding site can be uncoupled from the CTX binding site, a novel finding for VDCC antagonists, 2) phospholipids induce a change in the CTX receptor which selectively effects ω-AgaIIIA potency, 3) the ω-AgaIIIA binding site is in close proximity to the surface of the membrane, while CTX and MVIIA target a more hydrophilic region of the receptor.

### 10.6

TOXITYPING CALCIUM CHANNELS IN THE MAMMALIAN BRAIN WITH RADIOLABELLED  $\omega$ -AGATOXINS AND  $\omega$ -CONOTOXINS. M. E. Adams 1\*, R. A. Myers 2, J. Imperial 2, and B.M. Qlivera 2. Tepts. of Entomology and Neuroscience, Univ. of California, Riverside, CA 92521 and 1Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112.

The spider toxins ω-Aga-IIIA and ω-Aga-IVA have been radioiodinated and used in combination with other ω-agatoxins and ω-conotoxin GVIA to clucidate subtypes of calcium channels in the rat brain. Using Bolton-Hunter derivitization methods for preparation of [125] ω-Aga-IIIA, specific, high affinity binding to rat brain membranes was observed. Unlabelled toxin displaced the radioligand with an IC50 of about 1 nM. No significant inhibition of [125] ω-Aga-IIIA binding was observed by preincubation of membranes with other ω-agatoxins, except at much higher concentrations; IC50 values were approximately 100 nM for ω-Aga-IVA. In reciprocal binding experiments between ω-Aga-IIIA and ω-conotoxin GVIA, a marked asymmetry was observed. Preincubation of membranes with ω-Aga-IIIA blocked all specific binding of [125] ω-conotoxin GVIA, but pre-exposure to ω-conotoxin GVIA inhibited a maximum of 20% of [125] ω-Aga-IIIA binding. This suggests that ω-Aga-IIIA and ω-conotoxin GVIA overlap in their selectivities, but that ω-Aga-IIIA recognizes a larger population of Ca channels (see also Mintz et al., and McIntosh et al., this mectine).

overlap in their selectivities, but that ω-Aga-IIIA recognizes a larger population of Ca channels (see also Mintz et al. and McIntosh et al., this meeting). Inhibition of [125][ω-Aga-IVA binding to solubilized rat brain membranes by unlabelled ω-Aga-IVA yielded an IC50 of approximately 30 nM, which is close to the concentration that inhibits 50% of potassium-induced <sup>45</sup>Ca flux into rat brain synaptosomes. [125][ω-Aga-IVA binding was not significantly inhibited by ω-conotoxin GVIA, ω-Aga-IA, or ω-Aga-IIIA. These data, in combination with electrophysiological results (Mintz et al., this meeting), are consistent with selectivity of ω-Aga-IVA for a unique class of P-type Ca channels in the brain. Supported by NIH grant NS24472 and GM22737

## 10.

PROPERTIES OF TOXIN BLOCK OF PRESYNAPTIC AND SOMATIC CALCIUM CHANNELS IN CULTURED HIPPOCAMPAL PYRAMIDAL NEURONS K.P. Scholz\* M.E. Adams, R.J. Miller, Dept. of Pharm, and Physiol. Univ. of Chicago, Chicago, IL; Depts of Entomology and Neuroscience, Univ. of Cal. Riverside.

Whole-cell voltage clamp recordings of somatic Ca2+ currents (ICa) and of evoked excitatory synaptic currents (EPSCs) were performed in cultured rat hippocampal pyramidal neurons to characterize the sensitivity of presynaptic Ca2+ channels to various Ca2+ channel toxins. Four Ca2+-channel specific toxins were compared. ω-conotoxin GVIA (5 μM) was previously shown to block about 25% of the somatic Ca. SNX-111 (synthetic ω-conotoxin MVIIA) inhibited 15-25% of ICa (n=2) and appeared to have similar specificity as ω-conotoxin GVIA. SNX-183 (synthetic ω-conotoxin SVIB; Miljanich et al., 1991) inhibited 25.7 + 2.3% of ICa (n=4). All three of the above toxins (at concentrations of 5 μM) inhibited evoked EPSCs completely. ω-Aga-IIIA inhibited 58.0 + 4.5% of ICa (n=9) and inhibited EPSCs by about 90%.

It has been observed that many G-protein linked receptors inhibit ICa in a voltage-dependent manner, whereby a depolarizing pre-pulse relieves the inhibition. A component of ICa in pyramidal neurons was inhibited in this manner following activation of adenosine receptors. We have found that \(\phi\)-conotoxin GVIA blocked this component of current. \(\phi\)-Aga-IIIA partially blocked this same component of current and, in contrast to adenosine, the block by \(\phi\)-Aga-IIIA was not relieved by a depolarizing prepulse. This difference in the inhibition of ICa between adenosine and \(\phi\)-Aga-IIIA was used to test the hypothesis that the voltage-dependent relief of inhibition of ICa is involved in increasing paired-pulse facilitation of transmitter release during G-protein linked inhibition of ICa is not a major factor involved in increasing paired-pulse facilitation of ICa is not a major factor involved in increasing paired-pulse facilitation of transmitter release. The authors thank Neurex Corp. for the gift of SNX-111 and SNX-183.

A NOVEL POLYAMINE CALCIUM CHANNEL ANTAGONIST ISOLATED FROM VENOM OF THE SPIDER, DOLOMEDES OKEFENOKIENSIS. K. Kobayashi, J.B. Fischer, A.G. Knapp, L. Margolin, D. Daly, N.L. Reddy, B. Roach, K. McCormick, J. Meinwald, and S.M. Goldin, Cambridge NeuroScience, Cambridge MA; "Chem. Dept., Cornell Univ., Ithaca NY; "Cambridge NeuroScience and Dept. of Biol. Chem., Harvard Medical Sch., Boston MA.

A major pathway of Ca entry into depolarized nerve cells is through voltage-activated, high-threshold Ca channels. A substantial fraction of this Ca entry is mediated through "non-N, non-L"-type Ca channels resistant to blockade by dihydropyridine Ca antagonists such as nimodipine (Regan et al. [1991] Neuron 6, 269). CNS 2103 is a polyamine Ca antagonist present in minute quantities in the venom of the domestic hunting spider *Dolomedes okefenokiensis*. It was discovered using high-throughput radioisotopic "Ca uptake assays of L-type Ca current was confirmed using whole cell patch recordings of GH4C1 cells. CNS 2103 has been purified, its structure elucidated, and was synthesized in gram-scale quantities. Whole-cell recordings of N1E-115 neuroblastoma cells demonstrated that CNS 2103 (60 M) reversibly blocks both L-type and dihydropyridine resistant ("R-type") high threshold channels, with no effect on T-type Ca current or voltage-activated Na or K channels. In whole cell recordings of primary cultures of rat brain cortical neurons, no effect of CNS 2103 was observed against membrane current generated through NMDA- and non-NMDA glutamate receptor subclasses.

non-NMDA glutamate receptor subclasses.

We hypothesize that CNS 2103 may act at a site common to L- and "R"-type Ca channels. The broad spectrum of action of CNS 2103 compared with dihydropyridines, and its selectivity for calcium channels over other classes of ion channels, suggest that CNS 2103 may be an interesting lead towards development of drugs to treat ischemic brain injury and other CNS disorders.

CONTRASTS BETWEEN CLONED BI AND CARDIAC L-TYPE Ca<sup>2+</sup> CHANNELS EXPRESSED IN XENOPUS OOCYTES. W.A. Sather, T. Tanabe, Y. Mori, M.E. Adams, G. Miljanich, S. Numa & R.W. Tsien. Dept. Mol. Cell. Physiol., Stanford Univ., Dept. Medical Chem., Kyoto Univ., Dept. Entomology, U.C. Riverside. Neurex Corp., Menlo Park CA 940

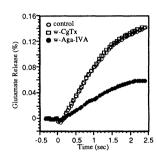

Entomology, U.C. Riverside, Neurex Corp., Menlo Park CA 94025. BI and cardiac L-type Ca<sup>2+</sup> channels differ in their macroscopic current kinetics. In contrast to cardiac L-type channels, BI currents activate more quickly and show a more pronounced inactivation in whole cell recordings (2-40 mM Ba2+). In cell-attached patches, the time course of inactivation of BI is much the same with either Ca<sup>2+</sup> or Ba<sup>2+</sup> as the charge carrier. BI channels displayed a slope conductance ( $\gamma$ ) of ~15 pS and a unitary amplitude (i)~0.8 pA at 0 mV (110 mM Ba<sup>2+</sup>). For L-type channels, $\gamma$ ~22 pS and i = 1.2 pA. The pharmacology of BI and L-type channels is also markedly different. BI channels are not enhanced by the Ca2+ channel agonists Bay K 8644 or FPL 64176, or inhibited by nimodipine, unlike L-type channels. However, BI Ca2+ channels can be blocked by the Neurex conopeptides SNX-230 (MVIIC)(~50% block at 0.5 μM) and SNX-260 (near complete block at 0.5 μM), whereas Ltype  $Ca^{2+}$  channels are unresponsive to SNX-260. We also examined effects of  $\omega$ -Aga-IVA, a peptide toxin that potently blocks P-type channels in cerebellar Purkinje cells (IC50 = 5 nM in 5 mM Ba<sup>2+</sup>, Mintz et al.,1992). BI channels in oocvtes were only , Mintz et al., 1992). BI channels in oocytes were only partly blocked by 200 nM ω-Aga-IVA (2 mM Ba<sup>2+</sup>).

Presynaptic Calcium Channels Coupled to Glutamate Release in Rat Synaptosomes Are Blocked by ω-Aga-IVA. <u>T.J. Turner\*, M.E. Adams¹, and K. Dunlap.</u>¹Dept. of Entomology and Neuroscience, University of California, Riverside, and Dept. of Physiology, Tufts University School of Medicine, Boston, MA 02111.

University School of Medicine, Boston, MA 02111.

ω-Aga-IVA, a peptide toxin of the funnel web spider Agelenopsis aperta, selectively blocks "P-type" calcium currents in Purkinje neurons, as well as <sup>45</sup>Ca<sup>2+</sup> uptake into rat synaptosomes, processes resistant to ω-CgTx and dihydropyridines (Mintz, et al., Nature 355, 827). Since synaptosomal <sup>3</sup>H-glutamate release is also ω-CgTx resistant, we studied the effect of ω-Aga-IVA on this process using a superfusion system with a subsecond temporal resolution. ω-Aga-IVA produced a potent (ICS0=30 nM) but partial block of

calcium-dependent glutamate release. The toxin was more efficacious at low levels of depolarization; little effect was observed with [KC1] > 30 mM. When synaptosomes were depolarized for 1 s with 15 mM KC1, 200 nM @-Aga-IVA blocked 56% of calcium-dependent release: @-CgTx (10 µM) had no effect. The results indicate the @-Aga-IVA sensitive, @-CgTx and DHP resistant, presynaptic calcium channel coupled to glutamate release in rat brain is a "P-type" channel.

### 10.12

A potent peptide calcium channel blocker from *Plectreurys* spider venom contains a C terminal lipid. <u>W. D. Branton, M. S. Rudnick\*, and Yi Zhou.</u> Department of Physiology, University of Minnesota, Minneapolis MN 55455.

We have determined the complete primary structure of PLTX-II; a potent insect calcium channel blocker found in Plectreurys venom. Edmar microsequencing of covalently immobilized, carboxymethylated toxin yielded assignments for a stretch of 42 amino acids ending in Cys. The sequence of the first 41 residues was also confirmed by sequencing and mass spectrometry (MS) of proteolytic fragments. In addition, proteolytic digests yielded a small, but very hydrophobic fragment with a mass that accounts for the total mass of the toxin when combined with residues 1-41. This C terminal fragment contained one Cys. one Asx and one Thr residue. Microsequencing of the fragment yielded the sequence CysAsp. MS of the Pyridinethylated (PE) fragment gave a mass of 680, indicating the presence of 238 mass units of unexplained structure. Collision induced fragmentation of the ion at mass 680 was consistent with the sequence PECysAspThr-amide, with the additional 238 mass units associated with the Cterminal Threonine. Several lines of evidence are consistent with the possibility that the remaining mass is a palmitic acid ester of the C terminal Threonine Attempted synthesis of PECys-Asp-PalmitoylThreonine-amide yielded two products with a mass of 680, and unique HPLC retention like that of the native C terminal fragment. The collision induced fragmentation pattern of one of these products was identical to the natural C-terminal peptide. The putative C terminal structure is novel, but it is closely related to recently described modifications of a number of membrane associated regulatory proteins. It is very likely that it is one of a class of novel, structurally related neurotoxins present in Plectreurvs venom. (Supported by NIH R01 GM42829.)

## VISUAL CORTEX: FUNCTIONAL CIRCUITS AND OSCILLATIONS I

## 11.1

SPATIOTEMPORAL RECEPTIVE FIELD STRUCTURE AND PHASE RELATIONSHIPS BETWEEN ADJACENT SIMPLE CELLS IN THE CAT'S STRIATE CORTEX. G.C. DeAngelis, G.M. Ghose. L. Ohzawa. and R.D. Freeman\*, School of Optometry, Univ. of California, Berkeley, California 94720.

Nearby simple cells in the visual cortex are reported to have overlapping receptive fields which differ in spatial phase by approximately 90° (quadrature phase; Pollen & Ronner 1981) or 180° (anti-phase; Foster et al. 1983). Quadrature phase pairs are of theoretical interest because they may provide a basis set (Gabor 1946) for economical encoding of the visual image. Moreover, anti-phase pairs may be necessary to construct the antagonistic ON and OFF subregions of simple cells (eg. Ferster 1988).

We have studied phase relationships between the receptive fields of pairs of simple cells recorded from a single microelectrode positioned in the striate cortex. Responses are initially characterized using drifting sinusoidal luminance gratings. Subsequently, a reverse correlation technique (Jones & Palmer 1987) is used to obtain spatiotemporal receptive field profiles for each pair of cells. This technique allows a direct assessment of the relative spatial phase between members of a simultaneously recorded pair of neurons. In addition, the relative phase of pairs of receptive fields can be measured as a function of time over the duration of the responses (–200 ms).

Spatiotemporal receptive field profiles have been recorded for 40 pairs of nearby simple cells. Members of a pair typically have similar preferences for orientation, spatial frequency, and direction; in addition, their receptive fields are usually centered at the same spatial location. We have encountered pairs of cells that exhibit relative phase differences of approximately 90' or 180'. Other simple cell pairs have relative phases near 0' or values which are intermediate between 0' and 180'. In many cases, the relative phase between members of a pair remains constant over time. In other cases, relative phase changes dramatically with time (ie. at least one of the receptive fields is not space-time separable). These latter pairs of cells cannot be assigned to any constant-phase group. In some cases, the two members of a pair have different optimal spatial frequencies or different receptive field positions; this complicates interpretation of the phase relationship. Overall, our findings suggest that the phase relationships between adjacent simple cells are not limited to quadrature and anti-phase. (EY01175)

## 11.2

ANTI-HIERARCHICAL CIRCUITRY IN VISUAL CORTEX OF THE CAT AND KITTEN.G.M. Ghose, I. Ohzawa\*, R.D. Freeman, Groups in Biophysics and Neurobiology, School of Optometry, Univ. of California, Berkeley, CA 94720.

Hierarchical processing of visual information specifies that receptive field properties at any stage can be accounted for by combining signals from neurons of the preceding stage. In the case of the visual cortex, it has been proposed that complex cell properties arise from the inputs of multiple simple cells (Hubel and Weisel, 1962). In order to directly investigate such hierarchical organization we have analyzed the simultaneous discharge from adjacent neurons in the cat's striate cortex. We have studied kittens at 4 weeks postnatal and adult cats to determine if this organization changes during postnatal development.

changes during postnatal development.

Receptive field classification of pairs of neurons was done according to the degree of response modulation to drifting sinusoidal gratings. Cross correlation analysis was performed on the responses to optimal gratings. Features in the crosscorrelograms, such as peaks or troughs, were used to group neuronal interactions into three categories: monosynaptic excitation, polysynaptic excitation, and monosynaptic inhibition.

Monosynaptic excitation of complex cells by simple cells was observed in the kitten, but not the adult cat. However, in both the kitten and the cat, excitation in the opposite direction (from complex to simple cells) was observed. Polysynaptic excitation in the kitten was predominantly between cells of similar cell types, whereas no such preference is apparent in the adult. Postnatal expansion of common input to nearby cortical cells can potentially explain the changes in polysynaptic excitation. Such an expansion could also create synchronous discharge which obscures the visibility of monosynaptic interactions. The existence of excitatory input to simple cells from complex cells, however, is difficult to reconcile with a strictly hierarchical model. These results suggest that the interactions between cells of different receptive field types are not completely hierarchical and change with postnatal development. (EY01175)

RESPONSE OF SIMPLE AND COMPLEX CELLS OF AREA 18 TO ORIEN-TATION DURING REVERSIBLE INACTIVATION OF AREA 17 IN CATS. Y. Michaud, S. Molotchnikoff and C. Casanova. Université de Montréal, Dépt de biologie, C.P. 6128, succ. A, Montréal (Québec) CANADA H3C 3J7.

It has been hypothetized that horizontal connections within one visual cortical area link neurons (column) with similar response properties such as the prefered orientation. However the functional connections between cortical visual areas are still unclear. Thus the aim of the present investigation is to study the influence of area 17 upon the orientation tuning properties of cells in area 17 upon the orientation tuning properties of cells in area 18. Anesthetized cats are conventionally prepared for single cell recording, Prior to injection of 300 nl of GABA in superficial layers of area 17 the dominant orien-tation of injected cells in determined and this orientation is correlated with the orientation of the studied unit in area 18. For simple cells (80%) the main effects during the inactivation of area 17 is a decline of the discharge to optimal orientation which results in a substantial loss of orientation selectivity. For complex cells the broadening of the orientation tuning curve is due to enhancement of responses to non-optimal orientation. Most interestingly simple cells are more frequently affected when orientation of injecting and recording sites is similar whereas complex cells are mostly affected when the two orientations are orthogonal. Thus, within the orientational domain one must consider cell types and axis of orientation.

## 11.5

CORTICAL REORGANIZATION FOLLOWING BINOCULAR FOCAL

CORTICAL REORGANIZATION FOLLOWING BINOCULAR FOCAL RETINAL LESIONS IN THE ADULT CAT AND MONKEY. C. Darian-Smith\* C. D. Gilbert, and T. N. Wiesel Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

The adult neocortex is capable of significant topographic reorganization following perturbation of input. We made focal binocular retinal lesions at homologous sites to render a portion of the lateral geniculate nucleus and striate cortex (cortical 'scotoma') inactive to visual stimuli. Within two months, much of the original cortical scotoma was again physiologically responsive, and was effectively 'filled in' by surrounding retinotopic fields. Retinal lesions as large as 89 in the cat and 59 in the monkey induced cortical scotomas of up to 6 and 10mm diameter, respectively. Cortical receptive field maps made 2 to 12 months after the lesions indicate that reorganization can 'fill-in' a cortical area 6 to 7 mm in diameter in both cat and monkey. Topographic maps of the lateral geniculate nucleus (LGN) made 4 and 12 months after the retinal lesions indicated little, if any, 'recovery'. To determine the connections responsible for cortical reorganization, 4 retrograde fluorescent dyes were injected into normal cortex, the border of the original cortical scotoma, and at different positions within the LGN, cell populations projecting to dye injections located within and close to the border of the original scotoma did not overlap spatially. These results indicate that the lateral spread of LGN afferents within the cortex (or the sprouting of these) is insufficient to account for the extent of reorganization observed. Within the cortex, labeled neurons were distributed concentrically around injection sites for a radial distance of 3-4mm. This distance is compatible with the extent of 'fill in' observed in reorganized cortex, and suggests either the strengthening of existing horizontal connections or their collateral sprouting. ## 11.7

SYNCHRONIZATION OF NEURONAL FIRING IN AREAS VI AND V2 OF THE MONKEY.

J. Bullier\*, M.H.J. Munk and L.G. Nowak. Groupe Cerveau et Vision INSERM 94 69500 Lyon/Bron France.

Synchronization of firing between neurons located in different visual cortical areas is supposed to play a role in the binding of neuronal cortical areas is supposed to play a role in the binding of neuronal populations activated by the same stimulus. So far, such inter-area synchronization has only been demonstrated in the cat in which visual cortical areas receive information through many cortical and subcortical pathways. In contrast, areas V1 and V2 of the macaque monkey are thought to be organized in a serial fashion. One would expect therefore that the spikes in area V2 neurons would be displaced temporally with respect to those of neurons in V1. We have tested this possibility by computing cross-correlograms between single neurons isolated in both areas of anaesthetized and paralyzed macaque monkeys.

Several kinds of peaks could be distinguished in the cross-correlograms: broad peaks (mode 800ms), medium-sized peaks (mode 100ms) and narrow peaks (mode 30 ms). Narrow and medium-size coupling was observed between neurons with receptive field separations up to 4.5 degrees but not beyond; broad peaks were observed up to 7 degrees separation but were very rare beyond. The peaks of the cross-correlograms almost always included the origin of time and the latency most often observed was zero. In other words, many neurons in areas V1 and V2 tend to synchronize their responses to a single visual stimulus.

These results demonstrate that synchronization of firing between neurons located in different cortical areas is universal and does not depend on whether the areas are organized in parallel or serially.

FUNCTIONAL CONNECTIVITY BETWEEN V1 AND V2 IN THE PRIMATE. A.W. Roe\* and D.Y. Ts'o. Laboratory of Neurobiology, University, New York, NY 10021.

To better understand the role of corticocortical interactions in sensory processing, we have begun to investigate the rules of functional connectivity between V1 and V2. Guided by in vivo optical imaging maps of the functional compartments of V1 (the blobs and interblobs) and V2 (the stripes), we targeted particular sites in V1 and V2 with a pair of electrodes. Cross correlation analysis was then used to assess the interactions and connectivity between single cells in specific V1 and V2 compartments, as well as particular rules underlying the generation of specific receptive field properties in V2.

In general, the cross-correlograms between V1 and V2 most frequently exhibited common input interactions. Often the correlogram peaks were shifted such that the firing of the V2 cell lagged the V1 cell by 5-20 ms. Peaks were usually broad (widths of 10-100ms), which may indicate a high degree of convergence of inputs from V1. Of particular interest are the interactions between color cells of the V1 blobs and the V2 color stripes. Positive (excitatory) correlations occur most often between non-oriented color cells located in V1 blobs and cells in V2 with similar color specificities, as well as between V1-V2 cell pairs that were broadband. Cells with dissimilar properties most often exhibited flat correlograms. Our results underscore the functional parcellation of corticocortical connectivity in visual cortical processing.

## 11.6

FUNCTIONAL INTERACTIONS BETWEEN MEMBERS OF ADJACENT CELL PAIRS IN THE MONKEY'S VISUAL CORTEX Zheng Liu<sup>1</sup>, James P. Gaska<sup>2</sup>, Lowell D. Jacobson<sup>2</sup> and Daniel A. Pollen<sup>4</sup> <sup>1</sup> Division of Applied Sciences, Graduate School of Sciences and Arts, Harvard University, Cambridge, MA 02138. <sup>2</sup>Dept. of Neurology, Univ. of Massachusetts Medical School, Worcester, MA 01655.

Many neural network models of visual cortical function have postulated local interactions between nearby cells; however, assessment of the validity of these models has been difficult because of the paucity of supporting electrophysiological data with respect to cell connectivity. Here, we report on the connections between physically adjacent cells that were recorded simultaneously by a single electrode. Recordings were made in V1 of the anesthetized Macaque, and a Discovery work-station (BrainWave Systems, Inc.) was employed to discriminate spikes. Con-straints on intercell connectivity were inferred by using cross-correlation analysis.

A total of 56 cell pairs recorded from 21 different electrode placements are reported here. Cell types include 11 simple cells, 44 complex cells and 3 cells with intermediate properties. The cell-cell combinations are 55.4% complex-complex, 25.0% simple-complex, 7.1% simple-simple, and 12.5% of pairs contain at least one cell with intermediate characteristics. For the interactions between members of complex-complex cell pairs (31), 48.4% (15) show common excitatory input, 6.4% (2) exhibit common inhibitory input, 12.9% (4) show monosynaptic excitation, and 32.2% (10) have no interaction at all. For simple-complex cell pairs (14), 21.4% (3) show common excitatory input, 42.8% (6) show no interaction, and 35.7% (5) exhibit monosynaptic excitation. Monosynaptic excitation was always directed from simple cell to complex cell. In terms of simple-simple cell pair and pairs which contain at least one "intermediate" cell, the interactions between members could be of either type. Finally, the cell's orientation and spatial frequency selectivity can be related to the interaction between cells.

## 11.8

SYNCHRONIZATION BETWEEN CORTICAL NEURONS
DEPENDS ON ACTIVITY IN REMOTE AREAS. J. Nelson\*,
L.G. Nowak, G. Chouvet, M.H.J. Munk & J. Bullier, Groupe
Cerveau et Vision, INSERM 94, 69500 Lyon/Bron, FRANCE
Synchronized neuronal firing within and between areas is mediated by
cortice-cortical connections (10V8 1992,33:1020). The connections are
thought to unite cell assemblies distributed between the two recording sites
(Nelson et al., Visual Neurosci. 1992). Synchronized neurons in two areas are
connected not only by the reciprocal projections between those areas, but also
by reciprocal projections to many other areas. Do these remote areas contribute cells to the distributed assembly which synchronizes the neurons?
INTERHEMISPHERIC cross-correlograms were computed for spike trains
from electrodes at the A17/18 border in each cortical hemisphere of the cat.
LOCAL correlograms were also computed for neighboring neurons using spikes
isolated from the same electrode. Coupling appeared with 3 different classes
of correlogram peak widths: T- (1-14ms), C- (20-65ms) and H-type coupling
(100-1200ms). If neurons were coupled, we reversibly inactivated PMLS in the
retinotopically corresponding region with micronijections of GABA, controlled to
silence the neurons around the pipette. In 9 of 15 cases, interhemispheric Htype coupling was reduced on average to 35% (3% - 69%) of original strength,
typically recovering well 15 to 30 minutes later. The same effect was observed
on LOCAL H-type coupling. We also blocked one A17/18 border region and
saw similar decrements in local coupling around the electrode in the other
hemisphere.

We conclude that temporally loose synchronization (H-coupling) of

saw similar decrements in local coupling around the electrode in the other hemisphere.

We conclude that temporally loose synchronization (H-coupling) of neurons within and between cortical areas depends on activity in remote areas. Since the activity from remote areas arrives over two different reciprocal projection systems (A17/18 borders interhemispherically and PMLS to A17/18 border, above) we assume all reciprocal systems participate. These projection systems radiate like a star to many areas, often skipping levels in the cortical hierarchy. We suggest that information transmission and processing in ONE area is modulated by many areas in the star-like reciprocal projection scheme tied to that area. We call this form of functional organization for information exchange in cortex "STAR TOPOLOGY."

GAMMA-OSCILLATIONS AS A VEHICLE FOR SYNCHRONIZATION. P.König\*, A.K.Engel and W.Singer, Max-Planck-Institut für Hirnforschung, Deutschordenstr. 46, 6000 Frankfurt 71, F.R.G.

Increasing evidence supports the idea that cortical representations may be established by a temporal code. Based on studies of the cat visual system, we have argued that synchronization of oscillatory firing patterns may be the relevant code for the binding of distributed neurons into assemblies esthablishing cortical representations. However, these firing patterns, which can be described as recurrent bursting of neuronal groups at frequencies in the γ-band, do not seem to carry information about particular features of the visual input. Hence, their relevance for information processing has remained controversial. In this presentation, we will discuss several potential advantages of these firing patterns: (1) The observed  $\gamma$ -oscillations represent a population phenomenon which allows to establish local groups as intermediate building blocks of cortical representations. (2) Cells engaged in such recurrent firing patterns can be synchronized with zero phase lag despite long conduction delays. (3) Synchronization of oscillators which are not directly linked can be achieved via intermediates, even if the conduction delays show a broad distribution. (4) The broad frequency spectrum of these oscillations makes it easier to desynchronize cell groups and, thus, to segregate several coexisting representations in the temporal domain. (5) Fast oscillations are required for the segregation of several coexisting assemblies, for which a sufficient number of bursts must be accommodated within about 200 ms, the time span required for object recognition. For this purpose, oscillations in the  $\alpha$ - and  $\beta$ -range would presumably be too slow. Altogether, these considerations suggest that oscillations in the  $\gamma$ -range be well adapted as a carrier signal, or vehicle, for response synchronization and ,hence, may offer distinct advantages for the establishment of cortical cell assemblies .

STIMULUS DEPENDENT SYNCHRONIZATION IN THE CAUDAL SUPERIOR TEMPORAL SULCUS OF MACAQUE MONKEYS. A.K. Kreiter\*, A.K. Engel and W. Singer, Max-Planck-Institut für Hirnforschung, Frankfurt, F.R.G.

It has been inferred from experiments in cat visual cortex that synchronization of neuronal responses depends on global aspects of stimulus configuration and could serve as a mechanism to bind features of individual visual objects. To investigate whether synchronization occurs also in monkey visual cortex, we recorded with two closely spaced electrodes in the caudal STS of anaesthetized macaques. When spatially segregated cell groups with overlapping receptive fields but different preferred directions of motion were activated with a single light bar, moving in a direction intermediate between the respective preferences, the cells synchronized their responses (Fig. A). However, if two bars were moved simultaneously in the respective preferred directions, synchronization was much weaker or disappeared (Fig. B). The responding cells typically exhibited oscillatory firing patterns with frequencies in the gamma-band. Over short epochs these oscillations could have sufficiently constant frequencies to yield oscillatory cross-correlograms with multiple peaks and troughs (Fig. C, cross-correlogram of a 400ms response epoch, taken from a single trial). These results demonstrate that neurons can synchronize their activity if they are activated by a single object, whereas they desynchronize if they respond to different objects. Thus, synchronous activity might define the set of neurons whose responses represent features of the same visual object.

### 11.10

OSCILLATORY RESPONSES IN THE SUPERIOR TEMPORAL SULCUS OF ANAESTHETIZED MACAQUE MONKEYS. A.K. Engel\*, A.K. Kreiter and W. Singer. Max-Planck-Institut für Hirnforschung, Frankfurt, F.R.G.

Previously, Kreiter and Singer have demonstrated oscillatory responses and their synchronization between different recording sites in the STS of an awake behaving macaque. We have now performed multi-unit recordings in the caudal STS of two anaesthetized macaque monkeys. Contrary to the results of Young et al. (Soc.Neurosci.Abstr.17,176) we have observed oscillatory responses with frequencies in the gamma range. At the majority of 70 recording sites studied quantitatively we have found that local groups of cells engaged in synchronous recurrent bursting. As in the awake monkey, the intervals between successive bursts were variable within and between trials and ranged from 15 to 35 ms. In addition, we have observed a response synchronization between spatially separate cell groups. These results corroborate the hypothesis that a temporal code may be used for assembly formation in the monkey visual system

Figure: Autocorrelograms of STS responses, computed for 500ms data epochs (average over 10 trials). We frequently observed correlograms with a broad center peak flanked by troughs (left), indicating a broad band oscillation with highly variable interburst intervals. At the majority of recording sites, we also found epochs where the correlograms exhibited clear satellite peaks (middle, right), showing that the burst-andpause sequences, which we term oscillations, had a comparatively narrow frequency band. Due to the high variability within and between trials, the correlogram modulation is often blurred if extensive averaging is performed.

### 11.12

POWER SPECTRUM ANALYSIS OF MT NEURONS FROM AWAKE MONKEY W. Bair, C. Koch, W. Newsome<sup>1</sup>, K. Britten<sup>1</sup>, E. Niebur\*. Computation and Neural Systems, Caltech, Pasadena, CA 91125; Dept. of Neurobio., 1Stanford Univ. Sch. of Med., Stanford, CA 94305.

The widely held notion that nerve cells only encode information using mean firing rate has recently been questioned, in particular due to stimulus-related 30-70 Hz oscillations observed in cat V1. We investigated temporal fine structure of single cell spike trains in area MT during a demanding direction discrimination task (Newsome, Britten and Movshon, 1989) and related this to simultaneous behavioral measurements. Two characteristic power spectra are shown below. About half of 200 cells have a flat spectrum with a dip at low temporal frequencies (characteristic of a Poisson process with refractory period) while the others have a peak in the 25-50 Hz band. The peak is correlated to bursting and is explained by a cell that fires Poisson distributed bursts with a burst-related refractory period without assuming explicit oscillatory firing patterns. We find no statistically significant correlation between spectral peak and behavior.

## NERVE GROWTH FACTOR I

VISUAL INPUT REGULATES THE EXPRESSION OF BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) mRNA IN RAT VISUAL CORTEX.

REGOTROPHIC FACTOR (BDNF) mRNA IN RAT VISUAL CORTEA.

EFOR Castrie<sup>4</sup>. Hans Thoenen and Dan Lindholm. Department of Neurochemistry, Max Planck Institute for Psychiatry, Am Klopferspitz 18A, 8033 Martinsried, Germany Neuronal activity regulates BDNF and nerve growth factor (NGF) mRNA in hippocampal neurons. We have now investigated whether physiologically relevant neuronal activity regulates the expression of these neurotrophins by studying the BDNF and NGE mBNA accession in the visual context when the invite a context of the and NGF mRNA expression in the visual cortex, where the input can readily be manipulated. In rats that were kept in total darkness for a week, BDNF but not NGF mRNA in the visual cortex was reduced to about about 50% of that of control rats kept in normal animal house illumination with a 12-hour light-dark cycle. The exposure to normal animal house illumination after a period of total darkness for 7 days restored the BDNF mRNA to the control levels within 1 h. Darkness or light exposure had no effect on the NGF mRNA in the visual cortex. To study whether the neuronal activity of the retino-corrical pathway was responsible for the increase in BDNF mRNA, we injected tetrodotoxin (TTX) into the right eye and measured BDNF mRNA in ipsi- and contralateral visual cortex. Already six hours after the injection, the BDNF mRNA had decreased significantly in the left visual cortex compared to the right side. Intravitreal injection of saline had no effect on the BDNF mRNA in the visual cortex.

In situ hybridization showed that BDNF mRNA is expressed in individual cells in the

In sim hybridization showed that BDNF mRNA is expressed in individual cells in the layers II-III and VI in adult rat visual cortex. Keepting rats in darkness markedly reduced the number of BDNF mRNA positive neurons in both superficial and deep cortical layers. The neurons in layers II-III are predominantly cortico-cortical assosiation neurons, which receive input directly from the primary targets of the LGN afferents in the layer IV. Recent experiments suggest that adult sensory cortex may have more plasticity than was previously believed. Neurons, whose receptive fields have been destroyed, can aquire new receptive fields over a considerable distance and at least in visual cortex, this effect is remarkably rapid. Cortico-cortical association connections have been implicated in this process. The expression and the regulation of BDNF mRNA in the layers, where these association neurons are situated suggests that neurotrophic factors may play a role in the plasticity of adult visual cortex. neurotrophic factors may play a role in the plasticity of adult visual cortex.

REGULATION OF NEUROTROPHIN GENE EXPRESSION IN THE RAT CNS. D. Lindholm\*, E. Castren, M. Berzaghi, A. Leingärtner, F. Zafra and H. Thoenen. Dept. of Neurochemistry, Max-Planck-Institute for Psychiatry, Am Klopferspitz 18A, 8033 Planegg-Martinsried, FRG

In the CNS, nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF) are predominantly expressed by neurons and regulated by neuronal activity. Limbic seizures and injection of kainic acid, a glutamate receptor agonist, increased mRNA levels of these factors in the hippocampus. The Increase in NGF mRNA was confined to the dentate gyrus whereas BDNF mRNA increased in the hippocampal pyramidal neurons as well as in dentate granule cells. The GABA-A receptor agonist, muscimol and the NMDA receptor antagonist, MK-801 both reduced NGF and BDNF mRNA levels in the hippocampus in vivo. Moreover, NGF protein levels decreased in hippocampus and in the septum after muscimol and MK-801 treatments. The results demonstrate that there is a balance expression of NGF and BDNF in vivo in adult rats. In neonatal rats, however, hippocampal BDNF mRNA levels were not increased by kainic acid but by pilocarpine, acting on muscarinic receptors. Moreover, the relative contribution of glutamate and the cholinergic system to the upregulation of neurotrophic gene expression seem to change with age. In contrast to NGF and BDNF, neurotrophin-3 (NT-3) is not regulated by neuronal activity. However, NT-3 mRNA levels seem to be regulated by hormones as shown in rat cerebellum during development

NEUROTROPHIN RESPONSIVENESS OF RAT BRAIN NEURONS. B. Knüsel, D.R. Kaplan, H.R. Widmer, K. Nikolics\* and F. Hefti. Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90089; NCI-Cancer Research and Development Center, Frederick, MD 21701; Genentech Inc., South San Francisco, CA 94080.

Expression of brain-derived neurotrophic factor (BNDF) and neurotrophin-3 (NT-3) in rat brain are regionally specific and developmentally regulated. Little is known about responsive cell populations. We show phosphorylation of trk type proteins after short-term (4 min) stimulation of primary cultures of different areas of embryonic rat brain with BDNF, NT-3 and NGF. Assay was by immunoprecipitation and Western blotting. NGF phosphorylation signal was detected in basal forebrain cultures only, and was much weaker than the phosphorylation signal after BDNF or NT-3 stimulation. BDNF and NT-3 evoked similar signals in cultures of basal forebrain, ventral mesencephalon, striatum and cortex and the two factors were not clearly additive when added in combination. Pretreatment of the cultures for 5 min resulted in reduced effect at later stimulation with the same factor, the reduction being proportional to the delay between pretreatment and final treatment. The relative refractory period lasted up to one day. Prolonged, 3-day pretreatment of cortical cultures with BDNF or NT-3 completely abolished any response to subsequent stimulation with the same factor, while a minor proportion of the response to the other neurotrophin remained. Our results show that neurons from different areas of embryonic rat brain are responsive to BDNF and NT-3. A major part of the response measured at the level of trk type proteins does not distinguish between these two related proteins. It remains to be seen whether the part of the phosphorylation signal which is selective for either factor reflects a functional response specific for each neurotrophin.

INTERLEUKIN-1 BETA AND SCIATIC NERVE EFFECTS ON NEURONAL DIFFERENTIATION OF CULTURED PC-12 CELLS, E.S. Lo', K.B. Kim', L.R. Ptak, J.H. Kordower, and P.M. Carvey. Dept. Neurological Sciences, Rush-Presbyterian St. Luke's Med Ctr and 'University of Illinois School of Medicine, Chicago, II. 50612.
Previous studies have shown that Interleukin-1 Beta (IL-1) stimulates schwann cells to release nerve growth factor (NGF). NGF is known to induce the neuronal differentiation of PC-12 cells. We examined the ability of IL-1 to potentiate NGF-mediated differentiation of PC-12 cells by sciatic nerve explants. Sciatic nerve was removed from adult rats and cut into 0.5 mm segments. Between 1 to 4 sciatic nerve segments were cultured in complete media on collagen-coated plates for one week in the presence or absence of 1 to 8 pellets each containing 0.18 µg of IL-1. After 1 week, 100 µL of this "conditioned" media was collected and transferred to freshly plated, low cell density (1,750 cells/well) PC-12 cell cultures growing in PC-12 media (100 µL). After 4 days in culture, the number of cells with processes greater than 1 cell diameter was counted. Conditioned media from sciatic nerve explant cultures stimulated the differentiation of PC-12 cells into a neuronal morphology. This effect was dependent upon the number of explants in culture (r = 0.984). IL-1 alone also induced PC-12 differentiation in a dose-dependent fashion (r = 0.974). Conditioned media from cultures containing both sciatic nerve explants and IL-1 had an additive effect on PC-12 differentiation which was also dose-dependent. These results suggest that IL-1 has a direct effect on PC-12 cell differentiation and enhances NGF-mediated differentiation. Supported by NS29585 (JHK).

## 12.7

REGULATION OF TRK PROTO-ONCOGENE EXPRESSION IN HUMAN MONOCYTES. P. Ehrhard, U. Ganter, J. Bauer, A. Stalder and U. H. Otten\*. Dept. of Physiology, Univ. of Basel, CH-4051 Basel,

Increasing evidence indicates that neurotrophins, including nerve growth factor (NGF), exert specific effects on cells of the immune system in addition to their neurotrophic actions. Recent studies have established that addition to the hemotophic actions. Recent studies have established that the proto-oncogene, a member of the family of receptor tyrosine protein kinases, is necessary for NGF signal transduction. Using reverse transcription in combination with polymerase chain reaction the regulation of the proto-oncogene expression in human monocytes was investigated. We trk proto-oncogene expression in human monocytes was investigated. We found that a highly purified population of human blood monocytes expresses significant levels of trk proto-oncogene mRNA. During in vitro differentiation of human blood monocytes to macrophages, trk expression decreased suggesting maturation-dependent trk regulation. Treatment of monocytes with 1 mM dibutyryl cyclic AMP (dbcAMP) stimulated trk synthesis in a time-dependent manner. To analyse cell type-specific trk expression further we used the promonocytic cell line U 937. We found that the AMP (1 miles) stimulated triangulation to the state of the sta that dbcAMP (1 mM) elicited a time-dependent trk induction in phorbol-ester-differentiated U 937 cells. In contrast, no effect of dbcAMP was ob-served in undifferentiated cells. Our finding that treatment of human mo-nocytes with NGF resulted in a significant increase in oxidative burst suggests that trk stimulation has functional importance. Since both NGF protein and monocytes accumulate at sites of lesion and inflammation it is attractive to postulate that NGF-trk interactions modulate nerve regeneration and immune responses

IS K-252a A NON-COMPETITIVE PARTIAL AGONIST OF HIGH AFFINITY NGF RECEPTORS? M.E. Lewis, K.V. Callison and N. Neff\*. Cephalon, Inc., West Chester, PA 19380.

The protein kinase inhibitor, K-252a has been reported to inhibit a wide variety of NGF-stimulated responses in PC-12 cells, such as neurite outgrowth, ornithine decarboxylase (ODC) induction, and increased c-fos transcription. Following the identification of trk as the high-affinity NGF receptor, K-252a was reported to block the NGF-induced autophosphorylation of trk. Thus, K-252a has been suggested to act as an NGF antagonist at the level of signal transduction. Paradoxically, though, several investigators have reported that K-252a ratadoxically, inough, several investigators have reported that K-252a or related compounds, such as staurosporin, exhibit some NGF-like pharmacological actions. To begin to explore this paradox, we studied the effects of a wide range of concentrations of K-252a and staurosporin, in the presence or absence of NGF, on ODC activity in PC-12 cells. At low concentrations, both K-252a and staurosporin stimulated ODC activity and potentiated the ability of NGF to induce this enzyme. At higher concentrations, however, both compounds inhibited enzyme. At higher concentrations, however, both compounds inhibited the ability of NGF to induce ODC activity, as reported before. One model to explain these findings is that the compounds act like agonists/potentiators via a high-affinity allosteric site on trk, and like antagonists via a dominant, lower affinity site on trk. In this model, therefore, K-252a could be functionally defined as a noncompetitive partial agonist at the high-affinity NGF receptor. This model generates testable predictions which are now under experimental evaluation.

### 12.6

BRIEF DEPOLARIZING STIMULI FLICIT INCREASES IN CULTURED HIPPOCAMPAL NEURON NGF GENE EXPRESSION. R.C. Elliott\*, C.F. Dreyfus, and I.B. Black, UMDNJ/Robert Wood Johnson Med. Sch. Piscataway, NJ 08854.

Prevolus studies in our laboratory and others have shown that addition of depolarizing concentrations of KCI or the sodium channel agonist veratridine to cultures of embryonic day 18 (E18) rat hippocampal cultures can elicit increases in NGF mRNA. To more fully define the temporal relationship between depolarization and message expression we have pursued investigations into the kinetics of this increase, starting with a more detailed time-course study of message levels over two days of exposure to

Virtually pure dissociated neuronal cultures of rat E18 hippocampi were grown in fully-defined, serum-free medium for five to six days prior to treatment with depolarizing concentrations of KCI (50 mM). Cultures were treated for 6, 24, or 48 hours, after which RNA was immediately harvested. To measure subtle changes in NGF mRNA expression, a highly sensitive and efficient solution hybridization technique (Elliott et al., Society for Neuroscience Abstracts, 1991), was utilized to quantitate message levels.

Compared to mock-treated controls, increases in NGF mRNA levels were evident as early as 6 hours after treatment began. The magnitude of the depolarization-elicited increase rose gradually as the duration of depolarization continued. After 48 hours of treatment with depolarizing agents, NGF message levels had risen by 40% over that of control groups. Our results suggest that relatively brief exposure to depolarizing stimuli increases NGF gene expression. Further experiments will determine the degree of persistence of these depolarization-induced increases in NGF mRNA levels.

## 12.8

IRANSCRIPTS FOR THE NGF RECEPTORS gp140<sup>th</sup> AND gp80<sup>LNGFR</sup> ARE DECREASED IN DRG FOLLOWING AXOTOMY

C.A.Krekoski, S. Lee, I.M. Parhad, A.W. Clark\*. Depts of Pathology and Clinical Neuroscience, Univ. of Calgary, Alberta, Canada.

NGF receptor (NGFR) consists of two proteins, gp80<sup>LNOFR</sup> and gp140<sup>th</sup> which contribute to its function. NGF induces expression of gp80<sup>LNOFR</sup>, but its effect on gp140<sup>th</sup> has not been defined. Axotomy interrupts the retrograde transport of target-derived NGF, which is severely decreased by 1 day and begins to recover by 21 days. Our hypothesis is that the decrease in supply of NGF or other target derived factors after axotomy leads to decreased expression of gp80<sup>LNGFR</sup> and gp140<sup>tst</sup>. We evaluated the mRNA levels for these proteins in the DRG after axotomy. In adult rats the sciatic nerve was crushed in midthigh, or transected and ligated to prevent regeneration; the L5-L6 DRG were dissected (4, 7, 14, 30 & 60 days; 5 rats/ time point), and quantitative Northern analysis performed. Gp80<sup>LNGFR</sup> and gp140<sup>uk</sup> mRNAs were both decreased to 60% of controls at 4-14 days pg140<sup>th</sup> mRNAs were both decreased to 60% of controls at 4-14 days post axotomy (U test, p<0.02) and returned to slightly above normal at 60 days, a time that coincides with reinnervation. When regeneration was blocked, gp80<sup>LNGFR</sup> and gp140<sup>th</sup> mRNA levels were only slightly decreased (15%, 6% respectively; p>0.1)at 60 days. Thus gp80<sup>LNGFR</sup> and gp140<sup>th</sup> expression decline coordinately early after axotomy, and later recover irrespective of reinnervation. These results suggest that target daying factors are required for the maintenance of suggest that target derived factors are required for the maintenance of NGFR proteins early following axotomy, but that non-target derived factors can appropriate this function at later times.

REVERSAL OF AXONAL INJURY-INDUCED ABERRANT NEUROFILAMENT PHOSPHORYLATION IN SENSORY NEURONAL CELL BODIES BY NGF. B.G. Gold\*1\*. D.R. Austin†. W.C. Mobley# and T. Storm-Dickersont+CROET, ^Dept. Cell Biol. & Anat., Oregon Hith Sci. Univ., Portland, OF 7201 and #Depts. Neurol. Pediat., UCSF, San Francisco, CA 94143. We have previously proposed (Gold et al., J. Neurosci. 11:943, 1991) that the neuronal cell body response to injury (axon reaction)

We have previously proposed (Gold et al., J. Neurosci. 11:943, 1991) that the neuronal cell body response to injury (axon reaction) is initiated by an interruption of target-derived supply of NGF. In the present study, we examined the regulation by NGF on aberrant expression of phosphorylated neurofilament (pNF) epitopes (another component of the axon reaction) in dorsal root ganglion (DRG) cell bodies. Rats underwent a sciatic nerve crush or were given  $\beta,\beta$ -iminodipropionitrile (IDPN) or 3,4-dimethyl 2,5-hexanedione (DMHD) which have been previously found to induce pNF expression in 45-50% of DRG neurons. NGF (125 ng/hr) was continuously infused into the subarachnoid space of the lumbar spinal cord via a osmotic minipump (Alzet); controls received cytochrome C. The number of immunoreactive DRG cell bodies to antibody 06-17 (directed against pNF epitopes) was reduced in animals given NGF for 14 days (to 21%, 25% and 31% in axotomized, IDPN- and DMHD treated rats, respectively). The number of immunostained cells was not as decreased at 7 days, indicating that NGF reverses (as opposed to prevents) pNF expression. Reduction in immunostaining to the low-affinity NGF receptor (antibody 192) by these protocols was restored by NGF infusion. Since axotomy decreases high-affinity binding it is unclear how reversal of pNF expression by NGF is mediated, although loss of the low-affinity receptor (Verge et al., Soc. Neurosci. Abst. 17:1498,1991) implicates trkA. Supported by NS19611 and NS26265.

## 12.11

DIFFERENTIAL REGULATION OF ASTROGLIAL NERVE GROWTH FACTOR mRNA CONTENT BY INTERLEUKIN-1, TPA AND STEROIDS. S.P. Pshenichkin, A.M. Szekely and B.C. Wise. Fidia-Georgetown Institute for the Neurosciences, Georgetown University, Washington, D.C. 20007.

Nerve growth factor (NGF) expression in astroglial cells is regulated by neurotransmitters, growth factors and cytokines. Our previous studies showed that interleukin-1 (IL-1) increases NGF mRNA content and NGF secretion in primary cultures of rat cortical astrocytes. Because protein kinase C activation mediates many of the cellular effects of cytokines and because steroids are physiological antagonists of cytokine action, we studied their role in astrocyte NGF regulation by IL-1. TPA, a protein kinase C activator, increases (EC so = 10 nM) by 6-10 fold NGF mRNA content followed in time by increases in cell content and secretion of NGF. The induction of NGF mRNA content by TPA is transient; the maximal increase is at 3 hrs and by 18 hrs the mRNA content has returned to basal levels. IL-1 treatment (10 U/ml), on the other hand, induces a prolonged increase in NGF mRNA content. The stimulatory action of TPA on NGF expression is additive with maximal amounts of IL-1, indicating different mechanisms of action by these two agents. In contrast to the IL-1 induced stabilization of NGF mRNA, TPA fails to change NGF mRNA half-life (control,  $t_{1/2}$ =35 ± 5 min; TPA treated,  $t_{1/2}$ =45 ± 4 min). As assessed by nuclear run-on assays, TPA and IL-1 differentially affect the transcriptional rate of NGF and c-fos genes, the latter being implicated in the transcriptional regulation of NGF expression. The positive modulation of NGF expression by IL-1 or TPA is inhibited by dexamethasone (IC<sub>50</sub>=3 nM) with maximal inhibition apparent by 2 hrs of treatment. The rank order of potency of active steroids are dexamethasone>hydrocortisone>corticosterone>aldosterone. Other ligands of the steroid/thyroid receptor superfamily fail to alter astroglial cell NGF production. Thus, there are distinct regulatory mechanisms, sensitive to steroid repression, mediating IL-1 and TPA facilitation of astroglial cell NGF expression.

## 12.13

RAS p21: A SECOND MESSENGER FOR NEUROTROPHIC FACTORS. G.D. Borasio\*1, A. Markus², A. Wittinghofer³, Y.-A. Barde⁴ and R. Heumann². ÎNeurologische Univ.-Klinik, Klinikum Großhadern, D-8000 München 70; ²Lehrstuhl f. Neurobiochemie, Ruhr-Univ., D-4630 Bochum 1; ³Abt. Biophysik, Max-Planck-Inst. f. med. Forschung, D-6900 Heidelberg; ⁴Abt. Neurobiochemie, Max-Planck-Inst. f. Psychiatrie, D-8033 Martinsried, Germany

We have previously shown that cytoplasmic introduction of the oncogene product ras p21 into different types of cultured chick embryonic neurons promotes their survival and fiber outgrowth, mimicking the effects of nerve growth factor (NGF), brain derived neurotrophic factor (BDNF) and ciliary neurotrophic factor (CNTF), respectively. To assess the potential signal-transducing role of the endogenous ras p21 we microinjected function-blocking anti-ras antibodies and their biologically active, affinity-purified Fab fragments into cultured chick embryonic neurons. The antibodies blocked BDNF-induced neurite outgrowth in E12 nodose ganglion neurons to below control levels, while the Fab fragments inhibited in a dose-dependent fashion the NGF-induced survival of E9 dorsal root ganglion (DRG) neurons. Both effects could be reversed by saturating the epitope-binding sites with biologically inactive ras p21 prior to microinjection. We have previously shown a strong survival-promoting activity of the protein kinase inhibitor K-252a in chick DRG neurons. This survival effect was not affected by the Fab fragments. Surprisingly, ras p21 showed no survival activity on NGF-dependent E12 chick sympathetic neurons, and the NGF-induced survival in these cells was not inhibited by the Fab-fragments. These results support the concept of an involvement of ras p21 in the intracellular signal transduction of neurotrophic factors, and raise the possibility of the existence of multiple signal transduction pathways for NGF in different neuronal populations of the chick embryo.

### 12.1

REGULATION OF NGF RECEPTOR mRNAs DURING LESION-INDUCED COLLATERAL SPROUTING IN NEURONAL POPULATIONS IDENTIFIED BY TRANSYNAPTIC NEURONAL LABELING. G.A. Kuchel 1-2.3 and M. Blum 1, Fishberg Res. Ctr. in Neurobiology 1 and Dept. Geriatrics 2, Mt. Sinai School of Medicine, New York, NY 10029; Mtl.Gen.Hospital Res. Inst., Montreal, Canada 3.

The rat pineal gland receives bilateral innervation from the two sympathetic superior cervical ganglia (SCG) through internal carotid nerves (ICN). We have demonstrated that levels of low-affinity NGF receptor (p75NGFR) mRNA undergo a specific 25% increase in the SCG from which collateral neuronal sprouting takes place following a contralateral ICN cut lesion (Exp. Neurol., 117:3, 1992).

Injection of right SCG with WGA-rhodamine resulted in labeling of some SCG neurons in the left SCG. Control experiments suggest that these cells represent a subpopulation of SCG neurons providing innervation to those target tissues which are also innervated from the opposite SCG. WGA appears to be transported anterogradely to these targets, across nerve terminals and then retrogradely to the opposite SCG. Fast Blue was injected into the left eye or left peri-aural skin and this was followed 2-3 days later by a right ICN cut or sham operation. In-situ hybridization using <sup>35</sup>S-riboprobes complementary for p75<sup>NGFR</sup> mRNA revealed significant (2-3x fold) increases in levels of this mRNA in WGA-rhodamine labeled cells, but not in cells labeled with Fast Blue, as soon as 1 day after this lesion. Preliminary studies demonstrate a similar pattern for the p140prototrk gene which contributes to the high-affinity NGF receptor. These changes take place before we can detect collateral sprouting and are consistent with the hypothesis that regulation of the NGF receptor genes may play a role in the sequence of events resulting in the collateral sprouting response.

## 12.12

RECEPTOR-MEDIATED CYTOSOLIC CA<sup>++</sup> TRANSIENT IS INDEPENDENT OF RECEPTOR MEDIATED STIMULATION OF NGF SECRETION. J.B. Tuttle\*, D. Layton and D.J. Creedon, Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908

Smooth muscle cells (SMC) synthesize and secrete NGF that supports innervating neurons. Cultured SMC's increase NGF synthesis and secretion during mitotic growth, with fresh culture medium, contractile agonists (vasopressin, a-adrenergic) and muscle stretch. NGF secretion is inhibited by ß-adrenergic and adenosine (ADO) receptor activation. However, when angiotensin II (AnglI) is present, AnglI and ADO together increase NGF mRNA and secretion. Angll alone has no effect on NGF output. The relationship between receptor-mediated transient increases in cytosolic [Ca++], and regulation of NGF output was examined by testing for interactions between ADO and AnglI during indo-1-based measurement of  $[Ca^{++}]_i$ . AnglI  $(1\mu M)$  transiently elevates  $[Ca^{++}]_i$ , independent of the presence of ADO or the ADO receptor agonist NECA. With endogenous ADO eliminated by ADO-Desaminase (2.5U/ml), the ADO agonist NECA alone caused no change or a slight reduction in [Ca<sup>++</sup>]. Thus, a negative [Ca<sup>++</sup>] transient is not required for ADO inhibition of NGF output and AnglI causes a positive transient even when not activating NGF output. The data suggest changes in cytosolic Ca<sup>++</sup> are not necessary and sufficient to regulate NGF synthesis and secretion in SMC's.

GABA-INDUCED INTRACELLULAR Ca2+ RESPONSES OF THE B PHOTORECEPTORS OF HERMISSENDA. K.Oka', E. Ito' C. Collin', T. Yoshioka<sup>2</sup> and D.L. Alkon<sup>1</sup>. <sup>1</sup>Neural Systems Section, NINDS, NIH, Bethe MD, 20892, <sup>2</sup> Dept. Molecular Neurobiology., Sch. Human Sci., Waseda University., Tokorozawa 359, Japan.

Previous findings implicate GABA as an inhibitory neurotransmitter released by pre-synaptic hair cells onto post-synaptic B photoreceptors in the snail Hermissenda. This synaptic inhibition can also be transformed into excitation after pairings of GABA stimulation and post-synaptic depolarization. Under voltage-clamp the synaptic transformation of the B cell has been shown to be caused by the modulation of GABA<sub>A</sub> and GABA<sub>B</sub> coupled  $I_{Cr}$  and a  $I_{Ca}2+_{K}+$ . Because a GABA-induced Ica2+ was ruled out, here we studied the intracellular Ca2+ responses to a 15 sec, 10 μM GABA pulse onto the B cell's terminals, or the Ca2+ responses to membrane depolarization, and their role in the synaptic transformation. We used digital ratio imaging (F340/F380) of a single fura-2 stained B cell (while it was impaled with a microelectrode). Samples were taken every .2 or 2 sec, while UV stimulation was restricted to the axon were taken every 2.0 if 2 set, while ovisilihidation was restricted to the axion to avoid light-induced responses. 15 to 20 sec after GABA stimulation, persistent (60 sec) intracellular Ca<sup>2+</sup> elevation was observed at the terminals, outlasting the GABA-post-synaptic potentials (psp). After light-GABA pairings, GABA-induced Ca<sup>2+</sup> signals were prolonged by an additional 20 sec. Co<sup>2+</sup> (.2mM) blocked GABA psp's, but not its Ca<sup>2+</sup> signal. Membrane depolarization (with high external K\*) also induced intracellular Ca²\* elevation that had a much faster onset than the GABA-induced Ca²\* signals, that followed membrane potential, and that were blocked by Co²\*. These data suggest that GABA-induced Ca<sup>2+</sup> elevation and synaptic transformation can play a crucial role in producing previously observed long-lasting biophysical and molecular changes following classical conditioning of the snail Hermissenda.

## SYNAPTIC INTERACTIONS BETWEEN PAIRS OF IDENTIFIED TYPE A & B PHOTORECEPTORS IN CONDITIONED HERMISSENDA. R.J. Frysztak

T. Crow. Dept Neurobiology & Anatomy, Univ Texas Med Sch, Houston, TX 77030 assical conditioning results in intrinsic modification of the excitability of type A & B photoreceptors in Hermissenda. The mutually inhibitory synaptic connections between A and B photoreceptors have been well documented, however changes in the strength of connections between identified pairs of A and B photoreceptors in conditioned animals has not been previously examined. We recently reported that the lateral A photoreceptor exhibits a significant increase in the light-elicited spike discharge rate and enhanced excitability expressed by increased spike frequency to extrinsic current (Frysztak & Crow, 1991). As a first step in the analysis of the potential contribution of altered synaptic inhibition to the enhanced excitability observed in conditioned animals, we examined changes in spike elicited exchaoniny observed in conditioned animals, we examined changes in spike elicited unitary IPSPs in type A photoreceptors. Here we report that conditioning does not significantly effect the amplitude of unitary IPSPs recorded in lateral type A photoreceptors, that are elicited by single action potentials in lateral type B photoreceptors (conditioned; X=0.72mV, n=6; pseudorandom controls: X=0.57mV, n=5; NS). A second assessment of synaptic inhibition consisted of an analysis of decreased spike activity in A photoreceptors produced by a current step in the lateral B photoreceptor. Consistent with the analysis of unitary IPSPs, activation of the lateral B did not significantly after the spike frequency elicited by extrinsic current in the lateral A photoreceptor of conditioned animals (\$\infty\$\_0.01, n=5) accompared to controls (\$\infty\$\_0.08, n=5; NS). In contrast to the analysis of the pairs of lateral A and B photoreceptors, preliminary evidence suggests that unitary IPSPs photoreceptor, are enhanced by conditioning. These results indicate that enhanced synaptic inhibition does not provide an important functional contribution to correlates of conditioning detected in intact lateral A photoreceptors, but potentially could contribute to altered activity in other postsynaptic targets.

CONDITIONED AND UNCONDITIONED RESPONSES TO ALTERED SEAWATERS IN APLYSIA ARE QUALITATIVELY DIFFERENT. M. Levy &

A...J. Susswein\*. Dept Life Sci, Bar Ilan Univ. Ramat Gan, Israel 52 900
In Aplysia fasciata, shocks delivered in the presence of 85%, 120% or pH
7.0 seawater leads to paining-specific increases in the respiratory pump rate when animals are re-exposed to the same altered seawaters an hour later. Respiratory pumping is also elicited by 75%, 140% or pH 6.0 seawater, independent of previous pairing with shock. We tested the hypothesis that the learning occurs by amplifying the response to sub-threshold stimuli, so that after pairing these stimuli elicit responses similar to those elicited by suprathreshold stimuli. Both conditioned and unconditioned responses to decreased pH were affected by treatment with the neurotoxin 5,7-DHT, and by lesioning the cerebral-pleural connectives. These treatments did not affect either conditioned or unconditioned responses to changes in seawater concentration. However, significant differences were seen between conditioned and unconditioned responses with to altered seawaters. Part of the unconditioned response to altered seawaters is an increase in defensive responses, such as escape swimming and inking. Also, exposure to 75%, 140% and pH 6.0 seawaters produces sensitization of respiratory pumping upon re-expo-sure to these stimuli. No increase in inking was seen as part of the conditioned responses, while an increase in swimming seen after training could be attributed to sensitization as a result of shock. In addition, patterns of specificity or generalization of sensitization were different from those seen as a result of associative learning. These data indicate that associative learning does not arise from by a simple amplification of subthreshold responses, as has been suggested for classical conditioning of the gill withdrawal reflex, but rather learning leads to qualitatively different responses than those elicited by supra-threshold stimuli independent of pairing.

ASSOCIATIVE LEARNING PROLONGS GABA-MEDIATED Ca2+ RESPONSES OF THE B PHOTORECEPTORS OF HERMISSENDA E.Ito, K.Oka, B.G. Schreurs, C.Collin and D.L.Alkon'. Neural Systems Section, NINDS, NIH, Bethesda MD 20892

We studied GABA-induced intracellular Ca2+ responses of the post-synaptic B cells, after associative learning in Hermissenda, using digitized imaging (F340/F380) of fura-2 injected B cells. Associative learning resulted from 3 days of paired presentations of light and orbital rotation and not from unpaired presentations or in naive controls. While the B cell was impaled with a microelectrode, voltage-dependent Ca<sup>2+</sup> signals at the terminal branches were elicited by 2sec depolarizing current pulses, followed later by a 15sec GABA perfusion (10 $\mu$ M) that elicited Ca²+ signals at the branches. The same stimulation was repeated after a series of 3 pairings of a 3sec flash of light with GABA. The sustained phase of the Ca<sup>2+</sup> signal with the first GABA stimulation persisted for more than 3min in conditioned cells (N=7; F340/F380=0.82±0.07 (mean±SD(N-1)) at 60sec after the GABA stimulation) but control cells had only 60sec responses (N=4;  $F340/F380=0.60\pm0.06$  at 60sec; p<0.01). No conditioning-specific differences were observed in the latency times or peak values of these Ca2+ responses. After 3 light-GABA pairings, control cells also showed 90sec Ca2+ responses induced by the second GABA stimulation, which was 20-30sec longer than that of the first GABA stimulation (N=4; F340/F380=0.77 $\pm$ 0.03 at 90sec). Conditioned cells, however, showed higher resting Ca2+ levels and they did not become more prolonged after further GABA stimulation at all in the terminals (N=4). No significant differences were observed among groups with depolarizing-induced  $Ca^{2+}$  signals.

These data suggest that associative learning causes a GABA-induced Ca2+ accumulation at the terminal branches of the B cell, which plays an important role in long-term transduction of associative memory signals.

## 13.4

CALCIUM TRANSIENTS, NOT ACCUMULATION, INDUCE BIOPHYSICAL CORRELATES OF LEARNING IN HERMISSENDA. L.D. Matzel, R.F. Rogers, and D.M. Fass

Department of Psychology, Rutgers University, New Brunswick, NJ 08903

During in vivo and in vitro pairings of light and rotation, the B photoreceptors in the Hermissenda's eye undergo an accumulating depolarization. This "cumulative depolarization" has been cited as a principal contributor to the initiation of Ca<sup>2+</sup>-dependent processes which result in the phosphorylation of membrane proteins and a reduction of neuronal K\* conductance indicative of memory formation. Using an *in vitro* preparation in which a 5 sec light was paired with mechanical stimulation of the vestibular organ, the statocyst, it was determined that 1, 2, or 9 pairings resulted in a progressive reduction of K\* conductance and an increase in resistance across the soma membrane of the B photoreceptors, although a progressive depolarization was not observed following 1 pairing. The biophysical modifications were not observed when the stimulus palring(s) was preceeded by an iontophoretic injection of the Ca<sup>2+</sup> chelator EGTA into the B photoreceptor. In a subsequent experiment, the B photoreceptor was held at -60 mV (via current injection) both before and after each of 9 pairings of light and statocyst stimulation, thus eliminating any accumulation of depolarization. An increase in resistance in the B photoreceptor accumulation of depolarization. An increase in resistance in the B photoreceptor was observed relative to unpaired controls. Moreover, this increase was greater than that seen following pairings in which the B photoreceptor was allowed to cumulatively depolarize following each pairing. This diminution of learning by cumulative depolarization arose from a post-pairing inactivation of the voltage-dependent Ca<sup>2+</sup> current, thus attenuating Ca<sup>2+</sup> influx on subsequent pairings. In total, these results indicate that cumulative depolarization is neither necessary or sufficient for the induction of learning in this system. Rather, it appears that presynaptic activity, paired with a transient postsynaptic Ca<sup>2+</sup> rise is the critical determinant of memory induction.

is the critical determinant of memory induction.

## 13.6

THE MEMORY FOR HABITUATION OF SWIMMING IN TRITONIA IS REGIONALIZED. G. D. Brown, P. A. Getting, and A. O. D. Willows. Friday Harbor Laboratories, Friday Harbor, WA 98250.

Habituation is a reduced responsiveness to repetitive stimuli. When the escape swim response of the sea slug *Tritonia* is repeatedly elicited, multiple behavioral changes occur. The duration of the swim decreases (Abraham and Willows, 1971), and the strength of the swim flexion movements gets weaker (Brown et al. 1998). When the nervous system is isolated and nerve root stimulation is used to repeatedly initiate the neural program for swimming, neuronal analogs for the behavioral changes seen during habituation can be found in the flexion neurons which control the muscles used for swimming (Brown et al, 1988).

During habituation in *Triotonia*, it is likely that multiple neuronal

modifications occur in the animal's nervous system. Synaptic connections made by afferents which trigger swimming decrement when repeatedly activated (Getting, 1976). The excitatory parts of swim interneuron C2 synapses also get weaker with repeated use (Snow, 1978).

It is possible to differentially stimulate parts of the swim neural circuit to determine whether the memory for habituation of specific parts of the swim behavior is distributed or regionalized. Afferents were repetitively stimulated while short circuiting the swim circuit by hyperpolarizing C2's. This produced progressively weaker bursts of action potentials in the flexion neurons without significantly changing the overall number of bursts. However, when the swim neural program for swimming was jump started by stimulation of C2's, the number of bursts decreased without a concomitant change in burst strength. These results indicate that the memory for habituation of multiple components of the swim response in Tritonia is regionalized.

## DOES THE GIANT FIBER PATHWAY MEDIATE THE VISUALLY EVOKED ESCAPE RESPONSE OF THE FLY?

M. H. Holmqvist \*. Centre for Visual Sciences, Research School of Biological Sciences, Australian National University, Canberra ACT 2601, Australia.

Visual information is probably the most reliable sensory cue used by a fly to detect an approaching predator. We have recently shown that flies escape only when the visual stimulus provides darkening as well as motion (Holmqvist & Srinivasan, J Comp Physiol, 169:451-59, 1991). I then wished to know whether the visually evoked escape response is mediated by the giant fiber pathway, which has bee implicated in the initiation of flight of flies.

implicated in the influence of right of these. I recorded simultaneously from the tergotrochanter muscle (TTM), which provides the main thrust of the jump, and intracellularly from several descending axons in the nerve cord of houseflies. Visual stimulation to the dorsal part of the compound eyes was provided by displaying expanding or contracting bright or dark disks on a CRT-

Unrestrained flies escaped and tethered flies occasionally showed TTM potentials Unrestrained titles escaped and tethered lites occasionally showed 11M potentials in response to an expanding dark disk, but not to a bright expanding disk or a contracting disk (bright or dark). During electrical stimulation of the brain, by means of stimulating electrodes inserted into the ventral part of each compound eye, a single spike in the giant descending neuron (GDN) drives the TTM. However, when the TTM responded to visual stimulation, the GDN showed no activity. Many other descending neurons chought their bishest first between the contract with Many other descending neurons showed their highest firing rate when presented with a dark expanding disk, but so far none individually has been shown to drive the

Thus, although the visually evoked escape response is likely to be started by the TTM, it is not mediated by the GDN. This finding suggests that during the escape response several pathways may act in parallel and neural integration may occur at the motorneuron level.

## 13.9

CAMP MODULATION OF MULTIPLE K+ CURRENTS CONTRIBUTES TO BOTH ACTION POTENTIAL BROADENING AND INCREASED EXCITABILITY IN APLYSIA SENSORY NEURONS. T.W. Abrams\* and B.A. Goldsmith Dept. of Biology & Institute of Neurological Sciences, Univ. of Pennsylvania, Phila., PA 19104.

Low concentrations of cAMP analogs increase excitability and reduce IK-S in Aplysia sensory neurons without causing spike broadening or modulation of the highly voltage sensitive, rapidly activating K+ current (I<sub>K-V,early</sub>) described by Baxter and Byrne (1989,1990). However, Goldsmith and Abrams (preceding abstract) found that more powerful activation of cAMP-dependent phosphorylation effectively broadens the sensory neuron action potential. This suggested that a low level of activation of PKA reduces IK-S, while a high level of activation of the same kinase is required to modulate  $I_{K-V,early}$ . We compared modulation of these two currents by 50 uM and 500 uM chlorophenylthiocAMP (CPT-cAMP), added with 0.5 mM RO 20-1724.  $I_{K-S}$  was measured at the end of a 300 ms step to -20 mV, while  $I_{K-V,early}$  was measured at its peak during a step to +40 mV; V<sub>hold</sub> = -70 mV. Exposure to 50 uM CPTcAMP reduced I<sub>K-S</sub> substantially with little or no effect on I<sub>K-V,early</sub>. 500 uM CPT-cAMP produced a further reduction in I<sub>K-S</sub> and reduced IK-V.early. 500 uM CPT-cAMP also produced a slowing of the rate of activation and inactivation of IK-V, early, similar to that observed with 5-HT. Thus, it appears that a single second messenger system may modulate multiple K+ currents at different levels of kinase activation.

## 13.11

SEROTONIN-INDUCED INCREASES IN EXCITABILITY AND ACTION POTENTIAL DURATION IN MECHANOSENSORY NEURONS: SIMILARITY ACROSS GANGLIA AND BETWEEN SPECIES. W. G. Wright and D. Kirschman. Dept. Biology, Colo. St. Univ., Ft. Collins, CO 80523.

<u>Kirschman.</u> Dept. Biology, Colo. St. Univ., Ft. Collins, CO 80523.

Two robust effects of the neuromodulatory transmitter serotonin (5HT) on the firing properties of mechanosensory neurons (5Ns) in *Aplysia* are increases in excitability and action potential (AP) duration. In order to begin an evolutionary analysis of these two effects we have (a) established the baseline effects of 5HT on SNs of different ganglia (tested under identical conditions), and (b) compared this baseline to the effects of 5HT on putative SN homologues in the related species *Bursatella leachii pleii*. Standard intracellular recording techniques were

species Bursatella leachi peri. Standard miradellular recording lech iniques were used. SHT (10 µM) was bath applied through a constant drip perfusion system. Aplysia. 5HT produced similar effects on the firing properties of tail SNs in the pleural ganglion. Increases in AP duration were indistinguishable (mean % increase ± s.e.m.: Tail SNs, 64.1±21.5, t=2.98, p≤0.05, n=10; siphon SNs, 41.5 ± 5.8, t=7.18, p≤0.001, n=8). Increases in excitability (1 to 12.6 APs in tail SNs, p≤0.001; 1 to 10.2 APs in siphon SNs, p<0.001; 1 to 10.2 APs in tail SNs, p≤0.001 to 10.3 APs in tail SNs, p≤0.001; 1 to 10.2 siphon SNs, p≤0.001) were similar, although significantly greater in tail SNs (Mann-Whitney U-test, p≤0.05).

Bursatella. Recordings were made from cells in the left pleural ganglion whose location, relative size, and physiological properties suggested that they are evolutionarily homologous to the tail SNs of Aplysia. As in Aplysia, SHT produced an increase in AP duration (mean % increase 45.5 ± 15.5, 1=2.95, p≤0.05, n=9) and excitability (mean number of action potentials increased from 1 to 5.2 APs, t-lest, p<0.01, n=9). Although the increase in AP duration was indistinguishable from that in *Aplysia*, the increase in excitability was significantly smaller than the increase observed in *Aplysia* (t-6.2, p<0.001).

We conclude from these data that under identical conditions, 5HT produces

(a) very similar physiological effects on siphon versus tail sensory neurons in Apiysia and (b) qualitatively similar effects on tail SN homologues in the closely related genus Bursatella.

CAMP MEDIATES ACTION POTENTIAL BROADENING, AS WELL AS INCREASED EXCITABILITY, PRODUCED BY 5HT IN APLYSIA SENSORY NEURONS <u>B.A. Goldsmith\* and T.W. Abrams</u> Dept. of Biology & Institute of Neurological Sciences, Univ. of Pennsylvania, PA 19104.

Action potential (AP) broadening in Aplysia sensory neurons contributes to the enhancement of transmitter release produced by the facilitatory transmitter serotonin (5HT). Recent experiments have found that cell-permeable cAMP analogs are effective in mimicking the decrease in accommodation produced by 5HT, while producing only minimal AP broadening (Baxter and Byrne, 1990), suggesting that broadening is cAMP-independent. However, we have found that injection of the PKA peptide inhibitor, Walsh-PKI (5-24), blocked 76% of the AP broadening produced by a 2 min exposure to 5HT broadening = 28±5.8% in controls vs. 7±1.5% with Walsh-PKI (5-24), p<.01). Injection of Walsh-PKI (5-24) also blocked 91±5.7% of the anti-accommodation effect produced by 5HT. Control injections of the autoinhibitory domain of PKC (19-36) did not significantly reduce the broadening or anti-accommodation produced by 5HT. In addition, the forskolin analog L-85 8051 applied with the phosphodiesterase inhibitor RO 20-1724 produced significant AP broadening (26±5.8%, p<.01). 1 mM chlorophenylthio-cAMP also increased the AP duration significantly (28±3.0%, p<.01). Thus, a cAMP-dependent mechanism appears to mediate AP broadening at early time points, but may require higher levels of cAMP than anti-accommodation. In contrast, at late time points, Sugita et al (1992) found that PKC may mediate AP broadening.

### 13.10

DIFFER ENTIAL. CYCLIC DEPENDENCE AMP SEROTONIN-INDUCED FACILITATION AT DEPRESSED AND RESTED APLYSIA SYNAPSES. M. Klein\*, Montréal, Montréal, Québec H2W 1R7, Canada. M. Klein\*, IRCM & Univ. de

Enhancement of synaptic transmission by serotonin (5HT) at sensory neuron synapses of Aplysia contributes to sensitization and dishabituation of defensive withdrawal reflexes. Earlier work implicated elevation of cyclic AMP (cAMP) in the sensory neurons in this facilitation. More recently, it was found that facilitation at synapses depressed by repeated activation, as occurs in dishabituation, involves different processes from facilitation at rested synapses, a mechanism underlying sensitization. The present study was designed to determine whether the two forms of facilitation differ in their utilization of cAMP.

Radioimmunoassay confirmed earlier findings that 5HT increases cAMP in sensory neurons. Forskolin also increased cAMP. Moreover, forskolin potentiated the effect of 5HT by 2 to > 10-fold. Effects of forskolin on postsynaptic currents (PSCs) were then examined at rested and depressed sensory-motor synapses in culture. Forskolin doubled the PSC at rested synapses, while it had no effect at depressed synapses. Furthermore, facilitation by 5HT at depressed synapses was unchanged with addition of forskolin.

These results imply that facilitation by 5HT at depressed synapses of Aplysia depends on factors other than cAMP, while facilitation at rested synapses may utilize cAMP. Extension of these findings to the behavioral level suggests that different biochemical mechanisms underlie the reflex enhancement in sensitization and in dishabituation.

## 13.12

EGG LAYING HORMONE. S. M. Bernheim, S. Hestrin\* and E. Mayeri. Department of Physiology, University of California, San Francisco, CA 94143-0444. INDUCTION OF EGG LAYING BEHAVIOR IN APLYSIA BY

The marine mollusc Aplysia displays a regular pattern of behavior during egg laying. Egg laying and this accompanying behavior are initiated by an all-or-nothing synchronous burst of impulse activity in the neuroendocrine bag cells of the abdominal ganglion. In previous behavioral experiments, egg laying was elicited by electrical stimulation of the bag cells or by injections of bag cell extract. To identify the particular factor responsible for inducing the overt aspects of the behaviorary injected extracts. of the behavior we injected animals with egg laying hormone (ELH), one of the neuropeptides secreted by the bag cells. We found that ELH causes a behavior pattern similar to that found in previous experiments. This behavior includes inhibition of locomotion and a pattern of head movements consisting of waves and undulations followed at the beginning of egg deposition by weaves and tamps. A similar pattern occurred in a second group of animals injected with stiminar pattern occurred in a second group of animals injected with a trial gland homogenate, which is presumed to cause a bag cell discharge and thus elicit normal egg laying behavior. The pattern did not occur in control animals injected with artificial sea water. These results further implicate ELH in regulation of egg laying behavior. We propose three possible regulatory mechanisms mediated by ELH: hormonal action of ELH released from the bag cells on neuronal circuits in the head ganglia, parasynaptic action of ELH released locally by ELH cells in the head ganglia, or reflex action in response to ELH-induced egg release from the ovotestis.

LINEAGE ANALYSIS REVEALS HETEROGENEITY IN CELL FATE OF NEURAL PLATE PRECURSOR CELLS. P. Cochard, C. Soula

J. Smith\* and A.-M. Duprat. Ctre Biol. Developm., CNRS UMR 9925, Univ. Paul Sabatier, 31062 Toulouse Cedex, France.

We have studied the lineage relationships of neurons and astroglial cells at the onset of central nervous system (CNS) ontogeny, i.e. immediately after neural induction, in an amphibian embryo, Pleurodeles waltl. The fluorescent dyc lysinated-rhodamine-dextran (LRD) was iontophoretically injected into individual cells in various areas of the neural plate of stage-13 embryos. The phenotype of LRD-labeled, clonally-related cells was documented at larval stages, 12 days later. Neurons were identified by morphological criteria and astroglial cells were recognized using antibodies directed against

astrogual cells were recognized using antibodies directed against glial fibrillary acidic protein, expressed early by cells of the astroglial lineage in this species.

Among the 40 clones analyzed in the rhombencephalon and spinal cord, 33 were composed of both neurons and astroglial cells, while 7 contained only neurons. These purely neuronal clones were not assigned to a specific CNS region. Interestingly, however, they always derived from cells located in the lateral area of the neural plate, thus suggesting an early regionalization. Most cells in each clone remained grouped, except for some neurons which frequently underwent tangential migrations away from the clonal cohort. Purely astroglial clones were never observed.

These results suggest that precursor cells in the neural plate do not form a homogeneous population. Some of these cells may be restricted early to a specifically neuronal fate.

CLONAL ANALYSIS OF GRANULE CELL MIGRATION PATTERNS DURING DEVELOPMENT OF THE CHICK CEREBELLUM. E.F. Ryder\* and C.L. Cepko. Department of Genetics, Harvard Medical School, Boston, MA 02115.

During the development of the cerebellum, granule cells and their progenitors undergo complex migrations to achieve their appropriate locations. Granule cell progenitors migrate from the inner proliferative zone (VZ) onto the cerebellar surface, where they form another proliferative zone, the external granule layer (EGL). As the granule cells are generated within the EGL, they extend axons, and their cell bodies descend deeper into the cerebellum. Using a replication incompetent retrovirus vector to label dividing granule cell progenitors and their descendents in a clonal fashion, we have traced the paths followed by clones of cells during the initial part of this migration. This study confirmed that migration begins in the most caudal portion of the cerebellar VZ, and that initially, progenitor cells move directly rostrally onto the cerebellar surface. This rostral migration is followed by extensive medial and lateral migration which has not been previously described. Clones can cross the cerebellar midline, and often cover large expanses of the cerebellum. The simplest model consistent with the data is that cells which were thought simply to extend their processes in the deeper part of the EGL are actually migrating long distances medially and laterally within this layer. This extensive and stereotypic migration may be important in positioning cells appropriately, or in establishing proper connectivity within the cerebellum.

IDENTIFICATION OF A TRANSIENT STAGE OF GRANULE NEURON DIFFERENTIATION. L. Feng1\*, S.G. Kuhar1, C.A. Mason2, M.E. Hatten2, N. Heintz1. ¹Rockefeller Univ., New York, NY 10021, ²Columbia

M.E. Hatten<sup>2</sup>, N. Heintz<sup>1</sup>. Thockefeller Univ., New York, NY 10021, <sup>2</sup>Columbia Univ., New York, NY 10032

To elucidate the epigenetic mechanisms of cerebellar development, we have isolated cDNA clones expressed at different stages of granule neuron differentiation using an antibody subtraction strategy (Kuhar et al, Soc. Neurosci. Abs., 524.10, 1991). The transient expression of two genes in small cells in the Purkinje cell layer during first two postnatal weeks implies the existence of a previously unidentified stage of granule neuron differentiation. Using digoxigenin labeled riboprobes we have been able to obtain clear cellular localization of their messages. The distinction of their *in situ* expression patterns from those of calbindin and GFAP strongly suggests that these two genes are expressed in granule neurons at the end of their radial migration and before their terminal differentiation. In P8 mouse cerebellum, these cells occupy a zone of several cell thicknesses in the outermost IGL and do not express mature granule neuron markers such as GABA receptor. One of the two genes is brain specific, and shares 70% homology to heart fatty acid binding protein, and thus is named brain fatty acid binding protein (BFABP). The other has restricted tissue distribution and is the 10-formyl tetrahydrofolate dehydrogenase. Antibody raised against BFABP stains small cells just below PCL, extracellular matrices in ML and distal Bergmann glia fibers in P8 mouse cerebellum. Since BFABP also has significant homology to cells just below PCL, extracellular matrices in ML and distal Bergmann glia fibers in P8 mouse cerebellum. Since BFABP also has significant homology to retinoic acid binding protein, this staining pattern raises the possibility that BFABP is released by granule neurons to regulate the function of some signalling molecules. During early embryonic development, these two genes are expressed in postmitotic cells in the ventricular zone and some cells migrating away from there. The study of the regulation and functions of these two genes will shed light on the mechanisms of neuronal differentiation.

CELL LINEAGE ANALYSIS IN CHICK DIENCEPHALON. S. A. Arnold-Aldea\*, C. Cepko. Dept. of Genetics, Harvard Med. Sch., Boston, MA 02115 Our laboratory has been interested in lineage analysis in the central nervous system, and has carried out such work using retroviruses to mark progenitor cells and their progeny. This study focused on a detailed analysis of lineage in the diencephalon to establish whether hypothalamic versus thalamic identity and the more restricted hypothalamic nuclear identity is lineage dependent. To establish lineage relationships with a high degree of certainty, a new marking technique was utilized that can allow establishment of clonal relationships even when sibling cells migrate a long distance or if multiple clones are close together in a small area of the brain. A retroviral library was constructed by inserting DNA fragments of different lengths and with different restriction sites into viral vectors that already contained a histochemical reporter gene. Two such retroviral libraries were constructed, one encoding the lacZ gene and the other encoding the gene for human placental alkaline phosphatase. Over one hundred different DNA fragments were used. Initially, infected cells are identified with histochemical techniques and then, such cells are analyzed using the polymerase chain reaction to amplify the DNA tag and determine its length and restriction pattern. Clonal relationship can then be determined using these genetic tags as cells derived from the same progenitor share the same tag regardless of their pattern of migration. Retroviral libraries were injected into embryonic chicks and the animals were harvested and analyzed at two time points: days 8-10 and days 19-21. These studies have revealed several interesting patterns of cell lineage relationships amongst hypothalamic and thalamic

EXPRESSION OF MN20, A NOTCH-RELATED MOUSE GENE, IS CONFINED TO MITOTICALLY ACTIVE PRECURSOR CELLS OF THE EARLY POSTNATAL CEREBELLUM. ME Ross\*and M Risken Univ of Minnesota, Mpls, MN, 55455

In Drosophila, the neurogenic locus Notch (N) plays a pivotal role in the differentiation of neuroectodermal cells as they adopt a neuronal or epidermal fate. Its encoded protein is thought to act through cysteine rich repeated units in the extracellular domain which are homologous to epidermal growth factor (EGF) and to EGF-like repeats in the cell lineage control gene, lin-12 of C. elegans. Several other neurodevelopmental genes in Drosophila possess EGF-like repeats, suggesting that proteins containing EGF-like regions represent a class of developmentally important genes, many working via cell-cell interactions. To identify mammalian members of this gene family and determine their role in CNS development, we have used probes encompassing the EGF-like repeats of N to screen a mouse cDNA library made from postnatal day (P) 3 to 5 cerebellar granule neurons (Ross and Heintz, Soc. Neurosci. Abs., 17:707, '91). Among these clones, MN20 expression appears to be cerebellar specific and strongly developmentally regulated. Northern analysis indicates that at postnatal day (P) 6, MN20 is heavily expressed in cerebellum but is not found in forebrain. Moreover, MN20 message is down regulated nearly 10 fold between P5 and P11 and p17 in cerebellum, in parallel with proliferation of cells in the external germinal layer (EGL). In situ hybridization of P6 mouse brain reveals MN20 message is confined in cerebellum to the superficial, proliferative zone of the EGL. A further developmental time Course is being pursued. Upon differentiation of the embryonal carcinoma cell line P19 by In Drosophila, the neurogenic locus Notch (N) plays a pivotal role in the superficial, proincardive zone of the EDL. A further overlopmental time course is being pursued. Upon differentiation of the embryonal carcinoma cell line P19 by retinoic acid into a mixed population of neuronal, glial and fibroblast cells, no MN20 expression was detected either by northern analysis or RT-PCR. These data suggest that MN20 expression is not a general feature of differentiating neuroectoderm but rather may have a more specific role in granule neuron development.

## 14.6

DEVELOPMENTAL POTENTIAL OF NEURAL CREST CELLS IN THE MOUSE. George N. Serbedzija, Marianne Bronner-Fraser and Scott E. Fraser. Division of Biology, Caltech, Pasadena, CA 91125 and Dev. Biol. Center, U. C. Irvine, CA 92717.

The neural crest, as a population, gives rise to a wide variety of cell types including both neuronal and non-neuronal cells of the peripheral nervous system. To determine the developmental potential of individual neural crest cells in the mouse an in situ cell lineage analysis was performed. Single neural crest precursor cells were labelled by inotopheretic injection of Lysinated Rhodamine Dextran (LRD) into neural tube cells of embryos in culture. The embryos were allowed to develop for 1 to 1.5 days before being analyzed. Injections into dorsal neural tube cells resulted in LRD labelled cells in the neural tube, the dorsal root ganglia, the sympathetic ganglia and between the dermamyotome and the ectoderm. While individual embryos contained labelled cells in a subset these locations, most of the embryos contained labelled cells both in the neural tube and at least one neural crest cell derivative. Injection into a lateral neural tube cell resulted in labelled cells in injection into a lateral neural tube cell resulted in labelled cells in the neural tube and in the limb bud (which have the morphological characteristics of Schwann cells). These experiments suggest that in the mouse embryo, as in the chicken embryo, there is: 1) a common precursor for neural crest cells and neural tube cells; and 2) a neural crest precursor that is capable of giving rise to multiple neural crest cell derivatives.

REGULATIVE CAPACITY OF THE CRANIAL NEURAL CREST AND NEURAL TUBE. Talma Scherson, G. Serbedzija, S. Fraser\* and M. Bronner-Fraser, Developmental Biology Center, Univ., of

Calif., Irvine, Ca. 92717
Cranial neural crest cells are thought to arise from the neural folds. However, cell lineage experiments suggest a common origin for some neural tube and neural crest-derived cells. To examine for some neural tube and neural crest-derived ceils. To examine this lineage relationship, we have ablated the neural crest and/or portions of the neural tube in the midbrain and hindbrain region and examined the subsequent regulative capacity of the residual neural tube. To determine the fate of the remaining cells, neural tissue bordering the ablated region was marked by a single focal injection of the vital dye, Dil, either ventral, rostral or caudal to the extended action. Abbations were performed on A. Comition. extirpated region. Ablations were performed on 4 - 6 somite embryos, which subsequently were examined by confocal microscopy 24 hours later. Removal of the neural folds results in Dil-labelled cells in normal neural crest locations. Similarly, removal of nearly half of the neural tube results in reformation of neural tube and neural crest structures from the remaining half neural tube. The neural tube ventral to the ablated region, but not the flanking neural crest, regulated to form the missing neural crest/neural tube cells. In embryos sectioned 9 hours after ablation, the neural tube appeared to have completely reformed and some DiI-labelled cells were observed emigrating from its dorsal margin. These results suggest a remarkable regulative capacity of neural crest/neural tube in the chick. This plasticity appears to be age limited, since ablations at the 12 somite stage no longer yield neural crest cells. (Supported by USPHS HD-25138)

SPECIFICATION OF SEROTONERGIC PHENOTYPE IN NEURONS OF C. ELEGANS C. M. Loef and C. J. Kenyon. Dept. of Biochemistry & Biophysics, Box 0554, University of California, San Francisco, CA 943143. Box 0554, University of California, San Francisco, CA 943143.

We are seeking to identify genes required for specification of neurotransmitter phenotype in the nematode C. elegans by two approaches. The first approach is genetic: by isolating and characterizing mutations that eliminate the expression of serotonin. Mutations reducing serotonin may alter genes required for serotonin synthesis and handling or genes that coordinately regulate their expression. As a first step, we have characterized a male mating behavior that requires specific serotonergic neurons and shown that the known serotonin-deficient mutants cat-1, cat-4, and ad446 are defective in this behavior. We should be able to isolate additional serotonin-deficient mutants by screening for animals displaying these male-specific behavioral defects. Our second approach is molecular: we are isolating by homology genes required for serotonin synthesis to serve as markers of the serotonergic phenotype. These are the genes acted upon by regulators of serotonin expression. We have cloned and sequenced an aromatic amino acid hydroxylase gene (AAH-1) encoding a candidate serotonin synthetic enzyme. In situ hybridization and a reporter gene fusion suggest that AAH-1 is expressed in hypodermal cells of the worm; therefore, this gene may not encode a serotonin synthetic enzyme. It does suggest, however, that biogenic amines in the worm may be used not only as neurotransmitters, but also as cuticle cross-linking agents as they are in insects. Supporting this hypothesis, we have found that serotoninbe used not only as neurotransmitters, but also as cuticle cross-linking agents as they are in insects. Supporting this hypothesis, we have found that serotonin-deficient cat-4 mutants are more sensitive to a variety of drugs, consistent with their having a more permeable cuticle. We are also analyzing the expression pattern of a candidate serotonin synthetic decarboxylase gene kindly provided by M. Marra and D. Baillie. Analysis of the expression of serotonergic markers in serotonin-deficient mutants should help us to understand how the serotonergic phenotype is regulated.

NEX: A NEURONAL HELIX-LOOP-HELIX PROTEIN OF THE DEVELOPING AND ADULT CENTRAL NERVOUS SYSTEM K.-A. Nave\* and A. Bartholomä. Center for Molecular Biology (ZMBH), University of Heidelberg, D-6900 Heidelberg, Germany.

The molecular mechanisms underlying cell lineage decisions and subsequent differentiation in the mammalian nervous system are largely unknown. In invertebrates and in the mammalian myogenic lineage, cell determination has been linked to the expression of transcription factors of the helix-loop-helix (HLH) superfamily of proteins. We have used highly degenerate oligonucleotides against HLH consensus sequences, in order to PCR amplify homologous sequences from mammalian neuronal and glial cells. Using this strategy, we have identified and cloned a novel HLH protein, termed NEX (for neural helix-loop-helix), that is specifically expressed in the mammalian central nervous system. The predicted structure of NEX includes a basic DNA binding domain and a leucin-zipper flanking the HLH domain. Outside this homology region, NEX has no similarity with other HLH family members. By Northern blot analysis, NEX mRNA is remarkably abundant in the adult rat brain but undetectable in any other organ tested. NEX expression begins in the third week of gestation, coinciding with the generation of postmitotic neurons and the onset of neuronal differentiation and synaptogenesis. By in-situ hybridization, NEX is expressed throughout the embryonic brain and spinal cord. In the adult rat brain, hybridization remains most prominent in the neocortex and in pyramidal neurons of the hippocampus, two regions that have been implicated in neuronal plasticity. (Supported by a grant from the Bundesministerium für Forschung und Technologie to K.A.N.)

SPATIOTEMPORAL RESTRICTION OF TRUNK NEURAL CREST CELL LINEAGE IN THE EMBRYONIC ZEBRAFISH. D.W. Raible\* and J.S. Eisen, Institute of Neuroscience, University of Oregon, Eugene, OR, 97403

We developed a fate map of the premigratory trunk neural crest of the embryonic zebrafish by labeling individual cells intracellularly with rhodamine-dextran. Cells that migrated laterally between somite and ectoderm gave rise only to pigment cells. Cells that migrated medially between somite and neural tube generated different cell types depending upon the time at which they began to migrate. Cells of the sensory and sympathetic ganglia were only derived from neural crest cells that began to migrate early. Schwann cells and pigment cells were derived from neural crest cells that began to migrate at any time. The first cells to migrate medially gave rise to clones of progeny with several phenotypes. Later, migrating cells gave rise to clones of progeny restricted to a single phenotype. We can now test whether there are temporal changes in the ability of individual premigratory neural crest cells to produce specific types of progeny. NIH HD22486; MDA.

OLIGODENDROGLIAL TROPHIC FACTOR IS A NEURONAL PROTEIN

OligoDENDROGIAL TROPHIC FACTOR IS A NEURONAL PROTEIN

B.M. Ances and B.Q. Kreider\*, Neurology Research, Children's Hospital
of Philadelphia, Philadelphia, PA 19104
Oligodendroglia trophic factor (OTF), isolated from salt-extracted
brain membranes of 3 day old rats, is a mitogen for cells of the
oligodendroglial lineage. In addition to increasing the rate of
proliferation of oligodendroglial precursor cells and galactocerebrosidepositive oligodendroglia in rat cerebral white matter cultures, OTF positive oligodendrogila in rat cerebral white matter cultures, OTF inhibits myelin basic protein gene expression by cultured oligodendrogila. OTF activity can be eluted from an SDS-PAGE gel in the region corresponding to a molecular weight of approximately 65 kD. Monoclonal antibodies (mAb) against this protein band were generated, and two of these mAbs at a 1:100 dilution of hybridoma supernatant blocked 90% of the OTF mitogenic activity when incubated for three days with OTF in cerebral white matter cultures. These blocking antibodies were used to determine the cellular localization of the antibodies were used to determine the cellular localization of the mitogen. Peroxidase anti-peroxidase staining demonstrated the presence of OTF in the cell bodies of a majority of the large and small neurons in aceton-fixed dorsal root ganglion cultures from P15 rats, but not in the satellite or Schwann cells. There was no detectable binding of the blocking antibodies in rat sciatic nerve cultures (containing Schwann cells and fibroblasts) or rat cerebral white matter cultures (containing oligodendroglia, astrocytes, O2A cells and microglia). These data strongly suggest that the cell of origin of OTF is neuronal

## 14.12

THE IDENTIFICATION OF NOVEL, NEURONAL PROTEIN

THE IDENTIFICATION OF NOVEL, NEURONAL PROTEIN TYROSINE PHOSPHATASES. K. M. Walton\*, K. J. Martell and J. E. Dixon, Dept. of Biol. Chem., Univ. of Mich., Ann Arbor, MI 48109-0606.

The role of tyrosine phosphorylation in the control of cellular function, proliferation and development has been well documented. The receptor for nerve growth factor, for example, is a tyrosine kinase. This family of tyrosine kinase receptors regulates its own activity via autophosphorylation, followed by the phosphorylation of other protein substrates. To control these by the phosphorylation of other protein substrates. To control these receptors efficiently and specifically, counteracting protein tyrosine phosphatases (PTPs) are directed at both the autophosphorylation site and

brosphalases (FTP) are directed at both the autophosphorylation site and the cellular substrates. Many tyrosine kinases have been cloned over the past decade. Recently, attention has turned to the investigation of PTPs. Since the isolation of the first identified PTP in 1988 from human placenta, over thirty PTPs have been cloned from various tissues. Because many tyrosine kinases have specific functions and highly restricted tissue localization, it is believed that PTPs will ultimately show an analogous pattern. However, only a few of the cloned PTPs appear to be expressed in a restrictive fashion. Similarly, the role of only a few PTPs have been established.

We are attempting to isolate PTPs specific to neuronal tissue. We are using PCR directed at two conserved regions of previously cloned PTPs to isolate novel phosphatases from adrenal medulla. The adrenal medulla, derived from the neural crest, is the source of virtually the entire peripheral nervous system. We have identified six novel PTPs using this technique, and have assessed their tissue specificity by RNase protection. Two of the clones have a broad tissue distribution, while another is abundant only in lung and spleen. Three of the isolated clones are strongly expressed in brain; one of these is abundant in adrenal medulla but not adrenal cortex. By identifying PTPs specific to neuronal tissue, we have taken the first step towards determining the role they play in neuronal development and differentiation. determining the role they play in neuronal development and differentiation. Supported in part by grants from the NIH.

ENDOCYTIC TRAFFICKING OF CELL SURFACE ALZHEIMER'S PRECURSOR PROTEIN. L.M. Refolo, K. Sambamurti\* and N.K. Robakis. Dept. of Psychiatry and Fishberg Center for Neurobiology, Mount Sinai Medical Center, New York, NY 10029.

Normal metabolic processing of the Alzheimer's Amyloid Precursor (APP) involves cleavage within the B/A4 peptide region and secretion of the truncated form. At least two potential subcellular locations have been proposed as the site for this processing event: an intracellular post-Golgi compartment or the plasma membrane. To distinguish between these two sites we have investigated the processing of cell surface APP in the C6 glioma cell line. We have found that, radiolabeled, cell surface APP is cleaved and secreted as a 120 kD truncated form. After a 5 min chase low levels of the truncated form was detected in the media and reached the maximum level at 10 min. Secretion of cell surface APP was reduced by several treatments known to inhibit endocytosis including: methylamine, colchicine and a 18°C temperature block. These data suggest that endocytosis of cell surface APP is a prerequisite for its cleavage at an intracellular location . In addition, treatment of cells with the lysosomotrophic amine chloraquine resulted in an increase in the levels of cell surface APP and a concomitant increase in the levels of cell surface derived-secreted form . From these studies, we propose that cell surface APP is processed either by the secretase or by a lysosomal pathway after endocytosis.

### 15.3

THE ROLE OF LYSOSOMAL PROCESSING IN METABOLISM OF THE AMYLOID PRECURSOR PROTEIN. D.H. Gabuzda\*, J. Busciglio, L.B. Chen and B.A. Yankner. Harvard Medical School, The Children's Hospital and Dana Farber Cancer Institute, Boston, MA 02115.

The cellular localization and route of processing of the amyloid precursor protein (APP) was examined in COS cells transfected with eukaryotic expressor plasmids encoding the 695 and 751 amino acid isoforms of APP. Immunoprecipitation was performed with antibodies which recognize the APP C-terminal, N-terminal and amyloid β protein domains. In cell lysates, the C-terminal antibody identified the intact differentially glycosylated forms of APP and a 9 kd fragment that previous work has shown represents the normal secretase cleavage product. There was no significant production of APP C-terminal fragments containing full-length β amyloid under normal conditions. Treatment with the lysosomal inhibitors chloroquine, leupeptin or low dose ammonium chloride did not change cellular level of intact APP suggesting that most of the intact APP is not initially processed in lysosomes. However, the lysosomal inhibitors prevented the degradation of the 9 kd C-terminal fragment. Indirect immunofluorescence of transfected cells showed C-terminal APP immunoreactivity in lysosomes but little lysosomal immunoreactivity for aminoterminal APP epitopes. These results suggest that most APP is initially processed in a non-lysosomal cellular compartment and that the C-terminal fragments are subsequently translocated to lysosomes and degraded. The demonstration that familial mutations in APP alter the degradation of C-terminal fragments in lysosomes suggests that lysosomal processing of APP fragments may be important in the pathogenesis of Alzheimer's disease.

## 15.5

An Alternative Secretase Cleavage Produces Soluble Alzheimer Amyloid Precursor Protein Containing a Potentially Amyloidogenic Sequence

N.K. Robakis\*, J.P. Anderson, Y. Chen, K.S. Kim, Department of Psychiatry and Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, NY 10029

Cell culture studies have shown that the Alzheimer amyloid precursor protein (APP) is secreted after full length APP is cleaved by a putative secretase at the Lys16-Leu17 bond ecretase cleavage I) of the amyloid peptide sequence. Since this cleavage event is incompatible with amyloid production it has been assumed that secreted APP cannot serve as a precursor of the amyloid depositions observed in Alzheimer's disease. Here we show that in neuronal PC12 cell cultures a portion of the secreted extracytoplasmic APP reacted specifically with both a monoclonal antibody recognizing amyloid protein residues Leu17 to Val24 and a polyclonal antiserum directed against amyloid protein residues Ala21 to Lys28. Furthermore, this APP failed to react with antisera recognizing the cytoplasmic domain of the full length protein. Similar results were obtained in human embryonic kidney 293 cell cultures. These data indicate that in mamalilan cells exists an alternative APP secretase cleavage site (secretase cleavage II), Cterminal to the predominant secretase cleavage I. Depending on the exact location of cleavage site II, potentially amyloidogenic secreted APP species may be produced.

PROCESSING OF THE B-AMYLOID PRECURSOR PROTEIN: A COMPARISON OF THE REINTERNALIZATION AND SECRETORY PATHWAYS. C. Haass, E.H. Koo, A. Mellon, A.Y. Hung and D.J. Selkoe\*. Center for Neurologic Diseases, Harvard Med. School, Brigham and Women's Hospital, Boston, MA 02115.

Progressive cerebral deposition of the  $\mathfrak B$  amyloid peptide is an early and invariant feature of Alzheimer's disease. Because secretory cleavage of BAPP inhibits amyloid formation, we searched for an additional pathway which might use the NPXY consensus sequence for coated pit mediated internalization found in the C-terminus of BAPP. Upon addition of the lysosomal protease inhibitor, leupeptin, to human endothelial cells, we observed a perinuclear lysosomal/late endosomal staining pattern with antibodies against various regions of BAPP. Incubation of living cells with an antibody against the extramembranous part of BAPP leads to its binding to cell surface BAPP and targeting to lysosomes. After cell surface biotinylation, we recover biotinylated full length BAPP within cell extracts. Furthermore, purification of length BAPP within cell extracts. Furthermore, purification of lysosomes from leupeptin-treated cells shows that they contain full length BAPP, the 10 kDa fragment and an array of C-terminal fragments bearing the intact \(\beta\)-peptide. Deletion of the NPTY motif or the complete C-terminus results in a two fold increase in secretion of soluble \(\beta\)-APP, indicating that this alternative pathway could account for about 50% of \(\beta\)-P2 turnover in the analyzed cell types. We present a model proposing that the mutations found within the \(\beta\)-P2 gene in familial AD might either cause a stabilization of lysosomally derived fragments or might change the degree of reintermalization and lysosomal fragments or might change the degree of reinternalization and lysosomal targeting of BAPP.

LYSOSOMAL DEGRADATION OF AMYLOID B/A4-PRECURSOR (APP). G.M. Cole\*, L. Bell, T. Saitoh, and A.L. Miller, Univ. California, San Diego, Dept. of Neurosciences, La Jolla, CA 92093-0624.

We have previously shown that N-terminal and C-terminal APP domains are elevated in cultured human neuroblastoma and PC12 cells by longterm treatment with lysosomal protease inhibitors (Cole et al.,Neurochem.Res.14:933-939,1989). Primary amines such as chloroquine and ammonium chloride are effective in inhibiting degradation of mature APP and fragments in pulse-chase immunoprecipitation studies with C-terminal antisera. Because these drugs have many non-lysosomal targets, we have conducted similar studies, comparing APP degradation in normal and chloroquine treated fibroblasts with cells from I-cell patients with defective lysosomal hydrolase targeting. Both the I-cells and the chloroquine treated normal fibroblasts showed delayed degradation of both mature APP and a set of small C-terminal fragments. We also confirmed the lysosomal degradative pathway in transfected B103 rat CNS neuroblastoma cells overexpressing APP695 or APP751. Having established a lysosomal degradative pathway for APP including the beta protein domain , we have sought to determine both intrinsic and extrinsic factors which may modulate the capacity for degradation of potentially amyloidogenic fragments in vitro and whether or not the lysosomal pathway is active in the normal and AD brain. We found endogenous metabolites could inhibit lysosomal degradation in vitro and confirmed that potentially amyloidogenic C-terminal fragments can be detected in both the normal and AD brain.

## 15.6

EXPRESSION OF AMYLOID PRECURSOR PROTEIN AND ITS ALTERED DERIVATIVES IN CULTURED CELLS SUGGESTS A BROAD SPECIFICITY FOR SECRETASE CLEAVAGE. S.R. Sahasrabudhe. M.A. Spruyt. H.A. Muenkel, A.J. Blume, M.P. Vitek and J.S. Jacobsen\* Department of Molecular Pharmacology, Lederle Laboratories, American Cyanamid Company, Pearl River, NY, 10965.

The mechanism of abnormal proteolytic processing of amyloid precursor protein (APP) leading to the extraction and deposition of beta amyloid peptide (BAP) is thought to be central to the development of Alzheimer's Disease. The putative "secretase" activity normally cuts APP at residues within BAP leading to the release and secretion of an amino-terminal APP fragment, thereby precluding BAP formation and amyloidogenesis.

precluding BAP formation and amyloidogenesis.

In order to better understand the features which make the APP molecule secretase cleavable, we have expressed a cDNA reporter construct representing the 751 amino acid isoform of APP (APP-REP) and its altered derivatives in cultured cells (see figure below).

Here, we show that (a) APP-REP is predominantly associated with the plasma membrane, (b) secretase cleavage of APP-REP, and its intracellular turnover is similar to that reported for intact APP molecule, (c) secretion appears unaltered by introduction of the glutamate to glutamine mutation found in the APP gene of patients suffering from HCHWA-D disease, (d) deletion of 19 juxtamembranous amino acids encompassing the secretase site also allows secretion. (e) the rate of accumulation of fragments secreted from also allows secretion, (e) the rate of accumulation of fragments secreted from altered derivatives, and their intracellular turnover is similar to that of APP-REP, (f) modulators of secretion have a similar effect on the APP-REP constructs tested. Our results indicate an unexpected broad substrate specificity for the secretase activity.

IMMUNOCYTOCHEMICAL ANALYSIS OF MUTANT AMYLOID PROTEIN PRECURSORS (APP) IN TRANSFECTED CELLS. M. Tabaton. T.E. Golde. Gambetti, and S. G. Younkin\* Case Western Reserve University, Cleveland, OH 44106

Recent studies of several familial AD (FAD) kindreds have identified Recent studies of several familial AD (FAD) kindreds have identified mutations in the membrane-spanning domain of the APP that cosegregate with the AD phenotype. In the three point mutations that have been identified, a valine in the middle of the membrane-spanning domain is converted to isoleucine, phenylalanine, or glycine respectively. Using 293 (human embryonic kidney), K562 (mononuclear leukemic), and M-17 (human neuroblastoma) cells, we have prepared stable cell lines transfected with normal APP695, 751, and 770, as well as the mutated forms of these proteins that have been identified in the various FAD kindreds. As part of effort to determine whether there is differential processing of the mutated and normal APPs expressed in these transfected cell lines, we are analyzing the APP in these cell lines immunocytochemically paying particular attention and normal APPs expressed in these transfected cell lines, we are analyzing the APP in these cell lines immunocytochemically paying particular attention to the localization of fragments containing (i) the 20 residues at the carboxyl terminus of the APP or (ii) the BAP region. In general all of the transfected cells showed a moderate increase in immunoreactivity to a variety of APP epitopes when compared to cells transfected with vector alone. However, a small percentage of the K562 and M17 cells transfected with the FAD mutations also showed an extremely strong diffuse cytoplasmic immunoreactivity to anti-8AP and anti-carboxyl-terminal antibodies. These initial results indicate that the mutations cause marked accumulations of BAP initial results indicate that the mutations cause marked accumulations of BAP and carboxyl-terminal epitopes in a small percentage of the cells. Work is in progress to localize these epitopes ultrastructurally, to correlate the immuncytochemical data with biochemical studies of these cells (see Golde et al. these meetings), and to determine why a small percentage of the cells show a marked accumulation of BAP and carboxyl-terminal epitopes in their cytoplasm.

ALTERED PROCESSING OF MUTANT AMYLOID PROTEIN PRECURSORS IN TRANSFECTED CELLS. T. E. Golde\*, M. Usiak, L. H. Younkin, and S.

IN TRANSFECTED CELLS. <u>T. F. Golde\*. M. Usiak. L. H. Younkin. and S. G. Younkin</u> Case Western Reserve University, Cleveland, OH 44106
Our previous data (Golde et al., Science 255:728-730) indicate that normal endosomal/lysosomal processing of the amyloid protein precursor (APP) generates a complex set of carboxyl-terminal derivatives including potentially amyloidogenic derivatives containing the entire amyloid ß protein (BAP). To further examine APP processing we have stably transfected 293 human embryonic kidney cells, K562 leukemic cells, and a human neuroblastoma line with expression constructs encoding wild type APP695, 751, 770 cDNAs and APP695, 751, and 770 cDNAs that encode the mutations associated with familial AD (FAD) and the Dutch form of hereditary cerebral hemorrhage with amyloidosis (HCHWA-D). When transfected with wild type APPs, each of the cell lines produce a qualitatively similar set of augmented 8-12 kDa carboxyl-terminal derivatives; however, the neuroblastoma lines have a higher level of the BAP bearing derivatives than neuroblastoma lines have a higher level of the BAP bearing derivatives than the peripheral lines. In addition we have also identified larger (15-50 kDa) carboxyl-terminal derivatives that are augmented in these transfected cell lines and appear to be generated by endosomal/lysosomal processing. In K562 cells, stable transfection of the mutant APPs associated with FAD and HCHWA-D resulted in increased accumulation of carboxyl-terminal derivatives that resemble the derivatives generated by normal endosomal/lysosomal processing. These results indicate that one of the effects of these mutations is to cause an increase in the steady state level of carboxyl-terminal derivatives of the APP. Significantly many of these derivatives contain the entire 8AP and therefore are potentially amyloidogenic. We are currently employing a variety of experimental strategies to determine how the mutations after the dynamics of APP processing and to determine whether the accumulation of these derivatives is due to altered processing of the mutant APPs in the lysosomal system.

ABNORMAL PROCESSING OF AMYLOID PRECURSOR PROTEIN IN OLFACTORY NEUROBLASTS FROM ALZHEIMER DONORS: B. L. Wolozin\*, C. Chen, D. Jablonska, L. Zhang, J. Basaric-Keys, J. Resau, R. S. Lebovics and T. Sunderland. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892

We have been studying the expression of amyloid precursor protein (APP) in olfactory neuroblasts (ON) grown from Alzheimer (AD) and age matched neuropsychiatrically tested normal donors. Immunoblots of homogenates from the ON grown under basal conditions reveal that the 11.5 kDa C terminal derivative (CTD) of APP is more readily detectable in the AD cell lines than in the normal cell lines. Blockade of lysosomal metabolism by incubation of the ON with the lysosomal inhibitor chloroquine results in a 6.4 fold higher level of CTD's in Alzheimer ON (N=8) than in the ON from age matched normal donors (N=6). In contrast, lymphoblasts from AD and normal donors grown under similar conditions of lysosomal blockade do not show changes in CTD levels. The elevated levels of CTD's seen in ON from AD donors are associated with elevated levels of amyloidogenic CTD's. have also found that the levels of CTD's can be decreased by activating protein kinase A or, to a lesser extent, by inhibiting protein kinase C. Thus, inadequate catabolism of APP within a nonlysosomal or chloroquine insensitive pathway leads to elevated levels of CTD's and may contribute to the formation of  $\beta$ -amyloid in centrally derived ON cells but not in peripherally derived lymphoblasts of AD

SECRETORY PROCESSING OF THE ALZHEIMER AMYLOID B-PROTEIN PRECURSOR (APP) IS INCREASED BY PROTEIN PHOSPHORYLATION. S. L. Gillespie, T. E. Golde, L. H. Younkin\*, and S. G. Younkin Case Western Reserve University, Cleveland, OH 44106

Phorbol ester activation of protein kinase C increases the production of secreted forms of several membrane-bound proteins including the secreted forms of several membrane-bound proteins including in-neutrophil MEL-14 adhesion protein, colony stimulating factor-1 receptor, the precursor of transforming growth factor a, and tumor necrosis factor receptor. Thus increased production of secreted APP derivatives could account, at least in part, for the decreased mature APP and the increase in a account, at least in part, for the decreased mature APP and the increase in a small COOH-terminal derivative that have been observed following treatment with phorbol esters (Buxbaum, et al., PNAS 87, 6003, 1990). To evaluate this possibility, we examined human embryonic kidney (293) cells transfected with a APP<sub>695</sub> expression construct. Cells were labeled with <sup>35</sup>S-methionian and cysteine for 20 minutes. Treatment during the chase with 1.0 μM PDBu had a marked effect on APP metabolism. The most striking change was a marked increase in the level of the ~105 kD secreted derivative that began at 15 min and continued for every time point threatter. Accompanying this 15 min and continued for every time point thereafter Accompanying this, there was a decrease in the mature holoprotein similar to that described by Buxbaum et al. We have observed this PDBu-induced increase in secretion of APP and the accompanying decrease in mature holoprotein in each of 15 additional experiments that we have performed on 293 and K562 cells, and this effect has been observed in cells transfected to express APP<sub>751</sub> and APP770 or APP695. Thus it appears that PKC activation may diminish the likelihood of amyloid deposition by increasing processing of APP in the secretory pathway. Before this concept can be accepted, however, it will, be important to more thoroughly evaluate the effect of PKC activation on the holoprotein that escapes cleavage by APP secretase and to evaluate in particular the effect of PKC on the BAP-bearing carboxyl-terminal derivatives produced in the endosomal/lysosomal pathway.

ALTERED PROCESSING OF DISEASE RELATED MUTANT AMYLOID & PROTEIN PRECURSORS. R.Bhasin\*, I.A.Morozov, E.A.Barnes and D.Goldgaber. Dept. of Psychiatry, SUNY, Stonybrook, NY 11794

Amyloid β protein (AβP) is formed from a larger transmembrane glycoprotein called the amyloid β protein precursor (APP). Normally, formation of AßP is prevented due to a proteolytic cleavage within the ABP region of APP. The larger N-terminal part of the cleaved molecule is secreted. Using the baculovirus expression system, we have expressed APPs with mutations found in Alzheimer's disease (AD) (Val<sup>717</sup> to Ile) and hereditary cerebral hemorrhage with amyloidosis-Dutch type (HCHWA-D) (Glu693 to Gln) . We found that some APP molecules were secreted without proteolytic cleavage of the C-terminal part. The amount of these molecules increased in media of cells expressing mutated APPs. Thus, mutations found in AD and HCHWA-D increase the amount of rinus, indications found in AD and richward increase the amount of secreted C-terminus containing APP. In addition, we analyzed media from fibroblasts of patients with the AD mutation (Val<sup>77</sup> to Ile) and detected secreted APP molecules with the C-terminus intact. The secreted C-terminus containing APPs have both the N- and C-terminus ends of the ABP region accesible for proteolysis and could serve as substrates for extracellular amyloid formation. Based on the above data we hypothesize that the critical step that determines the fate of APP molecules might occur during translocation of newly synthesized APP molecules across the endoplasmic reticulum (ER) membrane. Mutations found in AD and HCHWA-D interfere with efficient retention of APP molecules in the ER membrane.

## 15.12

THE ALZHEIMER AMYLOID PRECURSOR PROTEIN IS A SERINE ESTERASE ENZYME CAPABLE OF CLEAVING ACETYLCHOLINE. U.S. Kayvali. <sup>©</sup>B.D. Greenberg. <sup>©</sup>M.B. Fairbanks\*, and H. Potter. Dept. Neurobiology, Harvard Medical School, Boston MA 02115; <sup>©</sup> Upjohn Co., Kalamazoo, MI 49001.

Kalamazoo, MI 49001.

The precursor of the Alzheimer amyloid β/A4 protein, β-APP, is generated in at least three forms by alternative mRNA splicing. Two of the forms contain an extra domain with a Kunitz-type protease inhibitor (KPI) function. The secreted isoforms of the APP molecules that contain the KPI domain have been shown to be identical to the known protease inhibitor, protease nexin 2, and are therefore presumed to have as their function the inhibition of trypsin- and chymotrypsin-like proteases released during inflammation. However, no function for the APP695 protein, lacking the KPI domain, has been found. Here we report that the 695 amino acid isoform of β-APP has an esterase enzyme activity that is capable of cleaving acetylcholine and other ester substrates such as p-nitrophenylacetate. The fact that APP695 can be labeled with radioactive diisopropylphosphofluoridate (DFP) in a reaction inhibitable by excess substrate and then separated on SDS-PAGE indicates that the enzyme is an esterase/protease with a serine-based active reaction inhibitable by excess substrate and then separated on SDS-PAGE indicates that the enzyme is an esterase/protease with a serine-based active site and that the esterase activity is not due to a contaminant in the preparation. The larger APP isoforms can also be shown to have an esterase activity that is normally inhibited by their KPI domain. Thus together, the various isoforms of  $\beta$ -APP constitute a family of serine esterases and inhibitors whose normal function may be to control an esterases and inhibitors whose normal function may be to control an important physiological process in much the same way that antithrombin III controls the blood clotting cascade. The increase in acetylcholinesterase activity due to over-expression or aberrant processing of  $\beta$ -APP695 may also be significant to the pathology of Alzheimer's disease by reducing the level of the key neurotransmitter, acetylcholine.

PROCESSING OF ALZHEIMER AMYLOID PRECURSOR PROTEIN IS REGULATED BY MUSCARINIC ACETYLCHOLINE RECEPTOR ACTIVATION. Roger M. Nitsch\*, Barbara E. Slack, Richard J. Wurtman and John H, Growdon. Dept. of Neurology, Massachusetts General Hospital, ACC 830, Boston, MA 02114 and Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Abnormal processing of the amyloid precursor protein (APP) is a central event in the formation of amyloid deposits in Alzheimer's disease brain. APP can be processed by a secretory and an alternate internal pathway, the regulatory mechanisms of which, however, are unclear. We investigated the possibility that APP processing is regulated by activation of cell-surface neurotransmitter receptors by stimulating human 293 cells transfected with the genes for human acetylcholine receptors with the cholinergic agonist carbachol, and measured the APP release from these cells using Western blot analysis and densitometric quantitation. 293 cells transfected with the muscarinic m1 and m3 receptor subtypes responded to receptor activation with a rapid 3-5 fold increase of APP release within a time-frame of minutes, indicating that preexisting APP is processed and released as a response to receptor stimulation. Receptor-coupled APP release from the m1 and m3 transfected cells was blocked by inhibition of PKC with staurosporine. Receptor-coupled activation of APP processing was subtype-specific as indicated by the failure of muscarinic m2 and m4 receptor subtypes (linked to adenylyl cyclase) to alter release of APP. These results show for the first time the APP processing can be regulated by cell-surface neurotransmitter receptors, presumably via receptor-coupled activation of PKC. Furthermore, the results reported here may provide an initial basis to tie together the abnormal APP processing and the cholinergic deficit in Alzheimer's disease brain. Supported by NIMH, NIA and the CBSM.

### OPIOID AND SIGMA RECEPTORS

## 16.1

CLONING OF A cDNA ENCODING DELTA OPIOID RECEPTOR CHARACTERISTICS. C.J. Evans\*, D. Keith Jr., H.M. Morrison#, and R.H. Edwards.# Brain Research Institute and Departments of Psychiatry and Neurology#, UCLA School of Medicine, Los Angeles, CA. 90024.

The endogenous opioid system has evolved a complex family of ligands and receptors. The known opioid precursors, POMC, proenkephalin and prodynorphin, in a processing dependent manner give rise to a wide spectrum of opioid peptides with very different properties, including differential affinity for the  $\mu,\!\partial$  and  $\kappa$  receptor types. Based upon their physiological and pharmacological characteristics, all the opioid receptors belong to the G-protein coupled receptor family. The NG108-15 cell line is a rich source of delta opioid receptors. A size selected cDNA expression library (constructed in CDM8) was transfected into COS cells. Cells binding a radiolabelled delta peptide agonist (DADLE) were selected, the plasmids isolated and expanded in bacteria and re-transfected into COS cells. Following three such plasmid enrichments a clone of 1.8KB was obtained which upon transient transfection into COS cells exhibited DADLE binding to the intact cells. The DADLE binding showed stereospecific alkaloid displacement (dextrophan verses levorphanol), displacement by morphine, etorphine, diprenorphine, DISLET, DADLE and DPDPE but not with DAGO. The DNA sequence of this clone shows homology with other G-protein receptors

Supported by grants from NIDA and the Keck Foundation.

## 16.3

BINDING OF [4<sup>-125</sup>1-PHE<sup>3</sup>, Glu<sup>4</sup>]DELTORPHIN TO δ OPIOID RECEPTORS OF RAT BRAIN, R.J. Knapp<sup>\*</sup>L. Fang, T. Matsunaga, S. Weber, T. Davis, V.J. Hruby, and H.I. Yamamura Univ. Arizona Pharmacol. & Chemistry Dept.s, Tucson, AZ 85774

Tyr-D-Ala-Phe-Glu-Val-Val-Gly-NH<sub>2</sub> ((Glu<sup>4</sup>)deltorphin) is one of 3 amphibian peptides that contain a naturally occurring D-amino acid substitution in the 2 position and are highly selective for δ opioid receptors. Binding inhibition studies using [<sup>3</sup>H]<sub>D</sub>-Cl-DPDPE (δ) and [<sup>3</sup>H]CTOP (μ) give IC<sub>50</sub> values of 0.7 and 17,000 nM at δ and μ opioid receptors. Presentively.

[PH]P-CI-DPDPE (0) and [PH]-TOP (μ) give IC 50 values of 0.7 and 17 400 find at 0 and μ opioid receptors, respectively.

Iodination of the 4' position of the Phe<sup>3</sup> aromatic ring reduces δ receptor binding affinity to 5.0 nM and increases that at μ receptors to 12,000. [4-1251-Phe<sup>3</sup>, Glu<sup>4</sup>]deltorphin was prepared from [4-NH<sub>2</sub>-Phe<sup>3</sup>, Glu<sup>4</sup>]deltorphin via a diazonium reaction to produce radioiodinated [Glu<sup>4</sup>]deltorphin having a specific activity of 2,200 C/mmol. The site labeled in rat brain by 1251-deltorphin was characterized by binding inhibition studies giving the following IC 50 values:

| Inhibitor                     | IC <sub>50</sub> (nM ± SEM) | Hill Slope      |  |
|-------------------------------|-----------------------------|-----------------|--|
| δ Selective                   |                             |                 |  |
| naltrindole                   | $0.085 \pm 0.012$           | 1.12 ± 0.14     |  |
| [Glu <sup>4</sup> ]deltorphin | $0.558 \pm 0.137$           | 1.39 ± 0.22     |  |
| pCI-DPDPE                     | $0.423 \pm 0.096$           | 1.19 ± 0.25     |  |
| DPDPE                         | $3.61 \pm 0.85$             | 1.01 ± 0.11     |  |
| DSLET                         | $1.01 \pm 0.08$             | $1.00 \pm 0.04$ |  |
| μ Selective                   |                             |                 |  |
| PL-017                        | 30200 ± 14400               | 1.20 ± 0.19     |  |
| k Selective                   |                             |                 |  |
| U-69593                       | 7000 ± 4300                 | 1.72 ± 0.03     |  |

The major advantages of  $^{125}$ I-deltorphin are high  $\delta$  receptor affinity and selectivity, and high specific activity. Supported in part by NIDA grants.

## 16.2

EFFECT OF ICV  $\beta$ -FUNALTREXAMINE ( $\beta$ -FNA) ON  $\mu$  AND  $\delta$  OPIOID RECEPTORS IN THE RAT BRAIN: CONSIDERATION OF BINDING CONDITION. <u>H.-H. Yang, J.U. Adams, & L.-Y. Liu-Chen^+</u>, Dept. of Pharmacology, Temple Univ. Sch. of Med., Philadelphia, PA 19140.

We demonstrated previously that icv β-FNA (10 μg, ~20 nmole), while profoundly diminishing the antinociceptive effect of icv morphine, had a relatively minor effect on μ opioid receptor binding. In this study, we re-examined the effect of 24 h pretreatment with icv β-FNA in rats on brain μ and δ opioid receptor binding under three different binding conditions (all at 25°C): (i) pretreatment of membranes with GDP and NaCl and binding in the presence of Mg++ in 50 mM Tris-HCl containing EGTA and leupeptin for 34 h; (ii) binding in 50 mM Tris-HCl containing EGTA and leupeptin for 45 min. For μ receptor, comparison of three binding conditions revealed that control [34]DAMGO (1 nM) binding was much higher with i than with ii or iii and that there was no significant difference between ii and iii, β-FNA (2, 6 or 20 nmole) significantly reduced [34]DAMGO binding with i but not with ii or iii. Saturation experiments with i showed that the reduction in [34]DAMGO binding following 20 nmole β-FNA was due to a decrease in B<sub>max</sub> (by 50%) with no change in Kd. For δ receptor, [34]DPDPE (2 nM) binding was much higher with i than with ii or iii. There was no significant change in [34]DPDPE binding with i after 2, 6, or 20 nmole β-FNA. Opioid receptors are known to exist in multiple affinity states. Divalent cations such as Mg++ increase the number of high affinity sites for agonists when membranes are pretreated with GDP or GTP. β-FNA binds irreversibly to μ opioid receptors only in the presence of Na+, which induces the low affinity state. When binding is performed without Mg++ and pertreatment with a guanine nucleotide, changes in the receptors at the low affinity state can not be detected (ii, iii). It is only when the receptors at the low affinity state can not be detected (ii, iii). It is only when the receptors at the low affinity state can not be detected (ii, iii).

## 16.4

CYCLIC AMP PROMOTES DESENSITIZATION OF THE OPIOID RESPONSE IN LOCUS COERULEUS (LC) NEURONS - EVIDENCE FOR HETEROLOGOUS DESENSITIZATION G.K. Aghajanian\* and M. Alreja. Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Membrane-permeant analogs of cAMP reverse morphine and clonidine-induced hyperpolarizations in LC neurons (Andrade and Aghajanian, 1985). This reversal may be due to heterologous desensitization since phosphorylation of the opiate receptor by protein kinase A decreases agonist-induced G-protein activation (Harada et al, 1990). Therefore, we investigated the role of cAMP and other phosphorylation pathways in acute desensitization of the opioid response in LC neurons.

Intracellular recordings were made from rat LC neurons in 500  $\mu m$  thick slices. The effect of prolonged bath applications of 8-Br-cAMP, 8-Br-cGMP, or phorbol 12,13-diacetate (PDA) on the met-enkephalin-induced outward currents were studied in LC neurons voltage-clamped at-60 mV. In accord with a previous report (Harris and Williams, 1991), a maximal dose of metenkephalin (200  $\mu$ M) produced an outward current which partially desensitized during a 5 min. application period. Following bath application of 8-Br-cAMP (2 mM, 12-15 mins.) but not 8-Br-cGMP (2 mM) or PDA (100  $\mu$ M), the opiate response showed a more rapid and pronounced desensitization.

We conclude that cAMP promotes desensitization of the opioid response in LC neurons possibly via receptor phosphorylation. Since the cAMP pathway is upregulated by chronic morphine, the resulting cAMP-induced heterologous desensitization of the opiate receptor may contribute to opiate tolerance.

ANATOMICAL AND SUBCELLULAR DISTRIBUTION OF "Sigma-1" AND "Sigma-2" SITES PRESENT IN RAT BRAIN.
D. J. McCann\*, A. D. Weissman, and T.-P. Su. NIDA Addiction

Research Center, P. O. Box 5180, Baltimore, MD 21224.
Conditions were established for the selective labeling of two *sigma* ligand binding sites present in rat brain. At sigma-1 sites, labeled with 5 nM (+)[3H]SKF-10,047 in the presence of 300 nM MK-801, rank-order affinities were as follows: (+)pentazocine > (-)pentazocine > DTG > (+)SKF-10,047 > (-)butaclamol > (-)SKF-10,047 > (+)butaclamol. At sigma-2 sites, labeled with 5 nM [3H]DTG in the (+)butaclamol. At sigma-2 sites, labeled with 5 mm [Ph]DTG in the presence of 1 μM (+)SKF-10,047, rank-order affinities were as follows: DTG > (-)pentazocine > (-)SKF-10,047 > (-)butaclamol. (+)SKF-10,047 > (-)butaclamol. Rat brains were dissected into nine regions, and their corresponding that brains were dissected into nine regions, and their corresponding

homogenates were assayed using the selective conditions described above. Sigma-1 binding was enriched (> binding per mg protein than whole brain) in the hypothalamus, cerebellum, and pons-medulla. Sigma-2 binding also was enriched in the hypothalamus and cerebellum, but the pons-medulla yielded a level of sigma-2 binding which was among the lowest measured. Enrichment of sigma-2 without enrichment of sigma-1 binding was observed in both the frontal and posterior cortex, as well as the hippocampus. These findings strongly suggest that sigma-1 and sigma-2 sites are distinct entities which do

not exist on the same receptor protein.

Experiments comparing the relative enrichment of sigma-1 and sigma-2 sites in subcellular fractions of rat brain homogenates are now underway.

## 16.7

A NOVEL SIGMA BINDING SITE THAT MAY NEGATIVELY MODULATE EXCITATORY AMINO ACID NEUROTRANSMISSION. R. R. Matsumoto, W.D.

EXCITATORY AMINO ACID NEUROTRANSMISSION. R. R. Matsumoto, W.D. Bowen, B.R. de Costa and J.C. Houk. Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL 60611 and Lab. of Med. Chem., NIDDK, Bethesda, MD 20892. Bath application of sigma ligands affected the burst duration of red nucleus (RN) neurons in the *in vitro* turtle brain in a dose-dependent manner. Some sigma ligands [DTG, haloperidol, BD1031, BD1052, BD1069] increased burst duration while others [DTG, haloperidol, BD1031, BD1052, BD1069] increased burst duration while others (dextrallorphan, (+)-pentazocine, (-)-pentazocine, BD1047, BD1063] decreased burst duration. The opposite effects appear to be mediated through different populations of sigma sites. Scatchard analysis showed that the turtle brain contains sigma sites that can be labelled with [3H]DTG and [3H](+)-pentazocine. The two radioligands appear to label different populations of sites because 1) competition studies show no correlation between the ICSO values of a number of cold ligands against the two radioligands, and 2) preliminary autoradiorgands: studies in the turtle brain suggest different patterns of labelling for the two radioligands. Competition studies under regular and masking conditions suggest that [3H]-DTG predominantly labels sigma-2 sites in the turtle brain. Furthermore, the rank order of IC50 values from [3H]DTG binding correlates with the rank order of EDS0s for compounds that increase the burst response in the electrophysiological experiments. The sigma compounds that increase the burst response in the electrophysiological experiments also represent the subset of sigma ligands that produce dystonia when microinjected into the RN of rats and this behavior is also thought to be mediated through sigma-2 receptors. In contrast, [3H](+)-pentazocine appears to label a novel (non-sigma-1 or sigma-2) site in the turtle brain as suggested by its greater Bmax value (3X that of [3H]DTG) in Scatchard experiments and different drug selectivity pattern than would be expected from the typical sigma-1 binding. The rank order of ICSO values from [3H](+)-pentazocine binding correlates with the rank order of ED50s for compounds that decrease the burst response in the electrophysiological experiments. Since the burst response in turtle RN neurons is mediated through excitatory amino acid (EAA) neurotransmission, this novel site may be involved in the negative modulation of EAA neurotransmission.

## 16.9

BIPHASIC EFFECTS ON NMDA RESPONSE OF TWO ANTIDEPRESSANTS WITH HIGH AFFINITY FOR SIGMA SITES. R. Bergeron\*, G. Debonnel and de Montigny, Neurobiological Psychiatry Unit, Department of Psychiatry, McGill University, Montréal, Québec, Canada.

We have previously shown, using in vivo extracellular unitary recordings, a selective potentiation of the NMDA-induced activation of rat  $CA_3$  dorsal hippocampus pyramidal neurons by low doses of sigma (o) agonists and the suppression of this effect by σ antagonists such as haloperidol and BMY-14 802 (Monnet et al., JPET, 261:123-130, 1992). The present studies were undertaken to compare the effects of two antidepressants with high affinity for  $\sigma$  sites sertraline and clorgyline, to those of paroxetine and tranylcypromine, two antidepressants devoid of affinity for  $\sigma$  sites.

Male Sprague-Dawley rats were anesthetized with urethane. Five-barrelled micropipettes were used for extracellular recording of CA<sub>3</sub> dorsal hippocampus pyramidal neurons and microiontophoresis of NMDA, QUIS and ACh. All other drugs were administered intravenously.

Sertraline and clorgyline, but not paroxetine nor tranylcypromine, potentiated selectively and dose-dependently, with a bell-shaped curve, the excitatory effect of NMDA. A maximal potentiation, with both  $\sigma$  ligands, was obtained at a dose of 250 µg/kg i.v. At higher doses, the potentiation progressively decreased and completely disappeared at 500 µg/kg. The potentiation was reversed by haloperidol (10  $\mu$ g/kg), suggesting that it is mediated via  $\sigma$ receptors. To determine if this biphasic effect was specific for sertraline and clorgyline, the  $\sigma$  ligands DTG, JO-1784, (+)pentazocine, BD-737, L-687-384 were tested at the same doses. All  $\sigma$  ligands presented a similar bell-shaped dose-response curve. These data suggest that, at high doses, the  $\boldsymbol{\sigma}$  agonists might act on a different site, for which they would have a lower affinity, the activation of which would neutralize the potentiating effects obtained with the low doses. The basis for this phenomenon remains to be elucidated

THE EFFECTS OF SIGMA COMPOUNDS ON BOTH NMDA- AND NON NMDA-MEDIATED NEURONAL ACTIVITY IN RAT HIPPOCAMPUS.

W.J.Martin\*, J.S. Both and J.M. Walker. Schrier Research Laboratory, Dept. of Psychology, Brown University, Providence, BL02912

The purpose of this study was: (1) to confirm the existence of a putative sigma/ NMDA interaction by examining the effects of sigma ligands on NMDA-induced neuronal activity of CA<sub>3</sub> pyramidal neurons and (2) to examine the effect of sigma compounds on low frequency stimulus-evoked population potentials. In vivo extracellular recordings of dorsal hippocampus CA<sub>2</sub> pyramidal neurons in rat hippocampus were carried out in urethane-anesthetized rats. NMDA was microiontophorically-applied to elicit baseline levels of excitation. Low doses of DTG (1-3 µg/kg i.v.) and haloperidol (10 µg/kg i.v.) were administered, and their effect on NMDA-induced activity was determined. This study also examined the effect of DTG (6µg/kg i.v.) on CA<sub>3</sub> population potentials. DTG potentiated NMDA-induced responses (5.50 ± .77 vs. 2.62 ± .24 spikes/ nC: p < .02; n = 6), but had no effect on the amplitude of non NMDA-mediated CA<sub>3</sub> population potentials. These results indicate that the potentiating effect of DTG is specific to NMDA activity, and not reflective of a generalized enhancement of neuronal activity. The present study confirms the results reported by Monnet et al. (Eur. J. Pharmacol., 179: 441–445, 1990) and suggests an important role of sigma receptors in hippocampal physiology.

Supported by NSF Grad. Fellowship to WJM and PHS grants DA04988, MH48869 to JMW.

### 16.8

CHARACTERIZATION OF A NOVEL SIGMA-LIKE BINDING SITE FOR [3H](+)-PENTAZOCINE IN CLONAL CELL LINES. B.J. Vilner\*, B.R. de Costa, and W.D. Bowen. Unit on Receptor Biochemistry and Pharmacology, Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

We have previously reported that NB41A3 and N1E-115 neuroblastomas, C6 glioma, and NG108-15 hybrid cells contain sigma-2 sites as determined by binding of [3H]DTG (Soc. Neurosci. Abstr. 17: 593, #236.15, 1991; in: Multiple Sigma and PCP Receptor Ligands: Mechanisms for Neuromodulation and Protection?, J.-M. Kamenka and E.F. Domino, eds., 1992, in press). However, the presence of sigma-1 sites was difficult to detect, as binding of the sigma-1-selective ligand, [3H](+)-pentazocine was anomalous. Here we characterize [3H](+)-pentazocine binding in these cells and demonstrate a novel sigma-like site which is distinct from sigma-1. Ligands were incubated with membranes (100 ug protein) in 250 ul of 50 mM Tris-HCl, pH 8.0 at 250C for 120 min. Non-specific binding was determined with 10 uM (+)-pentazocine. Saturation analysis revealed the presence of two sites (range of values in the four cell types): Kd1 = 3.0 - 7.0 nM. Bmax1 = 31.4 - 94.8 fmol/mg protein. Kd2 = 247 - 360 nM, Bmax2 = 946 - 5,431 fmol/mg protein. The high affinity site may represent sigma-1, while the low affinity, high capacity site is novel. Competition studies using 10 nM [3H](+)-pentazocine revealed the following rank order of potency: haloperidol > (+)-pentazocine edextrallorphan > (+)-3-PPP > DTG > (-)-pentazocine > fluphenazine = (+)-SKF 10,047 > (-)-SKF 10,047 >> MK-801, naloxone, naltrexone. Although this site shows some of the characteristics of sigma-1 sites (enantioselectivity for lowever, the presence of sigma-1 sites was difficult to detect, as binding of site shows some of the characteristics of sigma-1 sites (enantioselectivity for (+)-benzomorphans) and sigma-2 sites (haloperidol Ki = 29 - 65 nM; (+)-3-PPP (Ki = 132 - 436 nM), the affinity for (+)-pentazocine (Ki = 98 - 376 nM) and DTG (Ki = 434 - 1,028 nM) clearly distinguish this site from either sigma-1 or sigma-2. Preliminary data suggests that human SK-N-SH cells, human placenta, and turtle brain (see Matsumoto et al., this meeting) also contain this putative sigma subtype

## 16.10

ELECTROPHYSIOLOGICAL EVIDENCE FOR THE EXISTENCE OF SUBTYPES OF SIGMA RECEPTORS IN THE RAT DORSAL HIPPOCAMPUS: I. ANTAGONISTIC EFFECTS OF HIGH DOSES OF SERTRALINE, CLOR-GYLINE AND L-687-384. G. Debonnel\*, R. Bergeron and C. de Montigny. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada. We have shown (*Bergeron et al.*, *Neurosci. Abst. 1992*), using *in vivo* 

extracellular unitary recording of rat CA<sub>3</sub> dorsal hippocampus pyramidal neurons, that the high affinity sigma ( $\sigma$ ) ligands sertraline, clorgyline and L-687-384 potentiate at low doses the neuronal response to NMDA and that this potentiation disappears when high doses are administered. The present study was undertaken to determine if high doses of these sigma ligands would antagonize the potentiation of the NMDA response by low doses of the three prototypical σ agonists DTG, (+)pentazocine and JO-1784. All drugs were

Sertraline (1 mg/kg) prevented and reversed the potentiating effects of DTG (1 µg/kg) and (+)pentazocine (10 µg/kg), but not that of JO-1784 (4 µg/kg). Clorgyline (1 mg/kg) prevented and reversed the potentiating effect of JO-1784 and (+)pentazocine, but not that of DTG. Finally, L-687-384 (100  $\mu$ g/kg) prevented and reversed the potentiating effect of DTG, but not those of JO-1784 and (+)pentazocine. Haloperidol (10  $\mu$ g/kg) antagonized the potentiating effects of all three agonists.

The different antagonistic profiles of sertraline, clorgyline and L-687-384 suggest that at least three subtypes of  $\sigma$  receptors are involved in mediating the potentiation of the NMDA response by low doses of  $\sigma$  agonists in the rat CA<sub>3</sub> dorsal hippocampus. These data provide the first electrophysiolgical evidence for multiple  $\sigma$  receptors, the existence of which had been postulated from radioligand binding studies (*Quirion et al., TIPS, 13: 85-86, 1992*).

ELECTROPHYSIOLOGICAL EVIDENCE FOR THE EXISTENCE OF SUBTYPES OF SIGMA RECEPTORS IN THE RAT DORSAL HIPPOCAMPUS:
II. EFFECT OF LESIONING THE MOSSY FIBER SYSTEM. F.P. Monnet\*, G.
Debonnel and C. de Montigny. Neurobiological Psychiatry Unit, McGill University Montréal, Ouébec, Canada and Institut de Recherche Jouveinal, France.

sity, Montréal, Québec, Canada and Institut de Recherche Jouveinal, France. The existence of different subtypes of sigma (σ) receptors is now accepted (*Quirion et al., TIPS, 13:85-86, 1992*). However, there is little functional evidence for the existence of these subtypes. We have previously shown that, *in vivo*, high affinity or agonists selectively potentiate NMDA-induced activation of pyramidal neurons in the rat CA<sub>3</sub> dorsal hippocampus, and that these effects are reversed by the σ antagonist haloperidol (*Monnet et al., JPET. 261:123-130, 1992*). The present studies were undertaken to evaluate, in this model, the involvement of the mossy fiber system, the major input to CA<sub>3</sub> pyramidal neurons, using extracellular unitary recording, following a unilateral destruction of the dentate gyrus by a local injection of colchicine (10 μg in 2 μl). (+)Pentazocine (5 μg/kg, i.v.) did not affect the NMDA response in the lesioned side, while it produced a robust potentiation in the contralateral side. JO-1784 (5 μg/kg, i.v.) reduced in the injected side and potentiated in the contralateral side the NMDA response. The effects of both JO-1784 and DTG were reversed by the subsequent injection of haloperidol (10 μg/kg, i.v.). Applied iontophoretically in lesioned rats, JO-1784 and DTG induced effects similar to those obtained when administered intravenously. These results support the existence of several types of σ receptors. The σ receptor responsible for the potentiating effects of (+)pentazocine and DTG is likely located on the mossy fiber terminals, whereas the potentiating effect of JO-1784 and the inhibitory effect of DTG are mediated by different subtypes of σ receptors not located on mossy fibers.

### 16.12

NOVEL PHENYLAMINOTETRALINS AS POSSIBLE AGONISTS AT SIGMA-TYPE NEUROMODULATORY RECEPTORS. <u>R.G. Booth\*</u>, N.S. Kula, A.M. Myers, S.D. Wyrick, & R.J. Baldessarini, Medicinal Chemistry Division, Sch. of Pharmacy, Univ. of North Carolina, Chapel Hill, NC 27599; Harvard Med Sch. & Mailman Res. Ctr, McLean Hosp., Belmont, MA 02178

Effects of the phenylaminotetralin (±) trans-1-phenyl-3-dimethylamino-6-CI-7-OH-tetrahydro-naphthalene (PAT-6) and its analogs on tyrosine hydroxylase (TH) activity were assessed in rat striatal minces. Also, the binding profile of  ${}^{3}\text{H-PAT-6}$  was evaluated under  $\sigma$  assay conditions with membranes from guinea pig brain. PAT-6 stimulated striatal TH activity by 28% at 100 nM; this effect was blocked selectively by the putative  $\sigma$ antagonist BMY-14802. Similar results were obtained with other PAT analogs. Activation of TH by PAT-6 was not additive with a greater increase (95%) of TH activity produced by 1  $\mu M$  forskolin. <sup>3</sup>H-PAT-6 showed very high affinity for cerebral membranes ( $K_d = 50 \text{ pM}$ ). The pharmacology of this binding was not consistent with dopamine, serotonin, adrenergic, or opioid receptors, nor with P-450 or MAO enzymes. BMY-14802 had moderate affinity (Ki = 64 nM) for the <sup>3</sup>H-PAT-6 site, but other  $\boldsymbol{\sigma}$  ligands showed little affinity. Theses results suggest that PAT analogs may act as agonists at a novel neuromodulatory  $\sigma$  receptor subtype that mediates stimulation of brain catecholamine synthesis, perhaps via stimulation of adenylate cyclase and TH phosphorylation. [Support: UNC-CH 5-44339, 6-69410; NIMH 34006, 47370; Anderson Foundation]

## CATECHOLAMINES

### 17.1

NEURAL CONTROL OF PHENYLETHANOLAMINE N-METHYLTRANS-FERASE AND DOPAMINE β-HYDROXYLASE. D.L. WONG'. B. SIDDALL. W. WANG AND A. LESAGE. Dept. Psychiatry & Beh. Sci., Nancy Pritzker Laboratory, Stanford Univ. Sch. Med., Stanford, CA 94305

Laboratory, Stanford Univ. Sch. Med., Stanford, CA 94305
 Activation of the splanchnic nerve to the adrenal gland increases the synthesis of the catecholamine biosynthetic enzymes, phenylethanolamine N-methyltransferase (PNMT) and dopamine β-hydroxylase (DBH). To examine whether this response involves gene transcription, temporal changes in PNMT and DBH mRNA, activity and protein have been followed after acute (1 injection, 10 mg/kg i,p.) or chronic (4 injections on alternate days) resempine treatment. PNMT and DBH mRNA were measured by solution hybridization, activity by radioenzymatic assay and protein by immunotitration. PNMT mRNA increases very rapidly, peaking at 7.5-fold control 6 hr after a single injection. With additional resempine treatment, a second, slower rise occurs (2.8-fold control after 3 injections). Protein and activity changes lag behind and are of lesser magnitude. Activity rises 2.0-fold 12 hr after acute treatment and after 4 injections as well; protein increases 1.2-fold and 1.4-fold simultaneously. In contrast, an acute dose of resempine does not change either DBH mRNA or activity. However, chronic treatment increases both indices in parallel with a plateau at 2-fold basal values. Interestingly, adrenal corticosterone (CORT) also responds to resempine, peaking at 4-fold normal 3 hr after a single dose, declining slightly at 12 hr and then, resting at 4-fold normal thereafter. Changes in PNMT and DBH mRNA and activity/protein appear consistent with gene activation, although in the case of PNMT, magnitudinal differences in activity and protein suggest that other posttranscriptional controls may exist. Furthermore, although hormonal and neural stimuli have been shown to control PNMT and DBH degradation and synthesis respectively, the concommitment rise in CORT suggests an interplay between these regulators.

NOREPINEPHRINE AND ANXIETY-LIKE BEHAVIOR: ELECTROPHYS-IOLOGY STUDIES IN MAUDSLEY RATS.

Commissaris, H.J. Altman and D.K. Pitts. Dept. Pharmaceut.
Sci & Psychiatry, Wayne St. Univ., Detroit, MI 48202.

The Maudsley rat strains are purported to be a genetically-inbred animal model for anxiety. Consistent with this, Maudsley Reactive (MR) rats exhibit greater anxiety-like behavior than do their Non-Reactive (MNRA) counterparts in many behavioral tests. Norepinephrine (NE) neuronal transmission, particularly that eminating from the nucleus locus ceruleus (LC), has been proposed to be involved in the expression of anxiety-related behavior. In the present study, extracellular single-unit recording and behavioral conflict testing were conducted in the same subjects to determine the relationship between LC neuronal discharge and anxiety-like behavior in MR and MNRA rats. Consistent with their presumably lower level of anxiety, MNRA rats accepted significantly more shocks than did MR rats in the conflict task. The characteristics of LC neuron electrophysiology in conflict-experienced rats were found to be strikingly similar to those observed in naive MR and MNRA rats. That is, LC neuron basal discharge rates were lower in MR compared to MNRA rats. In addition, LC cells from MNRA rats were less sensitive to the rate decreasing effects of IV clonddine. Preliminary data suggests that there is no significant correlation between LC firing rates and conflict behavior in either MR or MNRA rats. Supported by MH47181 (RLC) and MH47857 (DKP).

THE EFFECT OF THE DURATION OF STREPTOZOTOCIN-INDUCED DIABETES ON TURNOVER OF CENTRAL BIOGENIC AMINES IN MICE. C.C. Chen, J.C. Yang and C.Y. Wen\* Dept. of Pharmacology and Anatomy, College of Medicine, National Taiwan University, Taipei, Taiwan 10018, R.O.C.

The relationship between central catecholaminergic and

The relationship between central catecholaminergic and serotonergic neurons and the development of streptozotocin (STZ)-induced diabetic mice was examined over a periods of 3,14,50 to 100 days. The accumulation of 3,4-dihydroxyphenylalanine (DOPA) and 5-hydroxytryptophan (5-HTP) were measured after central decarboxylase activity was inhibited by m-hydroxybenzylhydrazine (MSD-1015). Results indicated that DOPA accumulation in the hypothalamus was not altered during the entire time course of the experiment studied. On the other hand, DOPA accumulation in the striatum was decreased in 50 and 100 day diabetic mice. The DOPA levels in pons-medulla were not increased until 100 day diabetics. The accumulation of 5-HTP was decreased in the hypothalamus of 14 day diabetic mice and was also present at 50 and 100 days, that in the striatum and pons-medulla was not decreased until 50 day diabetics and persisted to 100 days in the the striatum. These data showed that both DOPA and 5-HTP accumulation in the striatum and pons-medulla were changed only in the long term diabetic mice, and suggested that changes in catecholamine and serotonin turnover rates are not generalized, but restricted only to some particular brain regions and time courses.

## 17.4

FLUORINE-18 LABELED BIOGENIC AMINES: POTENTIAL RADIOTRACERS FOR ADRENERGIC NEURONAL MAPPING BY PET. M.E. Van Dort. Y-W Jung. M.R. Kilbourn. P.S. Sherman. T.L. Pisani, D.M. Wieland\*. Div. of Nucl. Med., Univ. of Michigan, Ann Arbor, MI 48109.

The overall goal in this work is to develop fluorine-18 labeled analogs of biogenic amines for mapping cardiac adrenergic neurons by Positron Emission Tomography (PET). The purpose of this study was to 1) evaluate the synthetic feasibility of replacing the benzylic hydroxyl group in biogenic amines with fluorine-18, and 2) determine the in vivo disposition and stability of these fluorine-18 labeled biogenic amines, Accordingly the \( \mathbb{B}-hydroxyl functionality of two model biogenic amines, (1R,2S)(-) ephedrine and (1S,2S)(+) pseudoephedrine was stereospecifically replaced with fluorine-18 by a novel cyclic sulfamate route to yield 1-[18Ffluoro-1-deoxy-pseudoephedrine and [18Ffluoro-1-deoxy- ephedrine, respectively, in high radiochemical yields. Preliminary biodistribution studies in mice indicated excellent in vivo stability towards defluorination and high blood-brain barrier permeability. These radiofluorinated analogs displayed time-radioactivity curves in mouse brain similar to that observed with carbon-11 labeled methamphetamine. Extension of this work towards the synthesis of a fluorine-18 labeled analog of the adrenergic neuronal mapping agent meta-hydroxyephedrine is currently in progress.

PHARMACOLOGICAL ACTIVATION OF QUINPIROLEMEDIATED PATHWAYS IN BABOON BRAIN STUDIED WITH PET. J.S. Perlmutter\* & L.L. Lich Washington Univ. School of Medicine, St. Louis, MO 63110.

Previously, we measured regional cerebral blood flow responses to dopamine agonists in sedated baboons. Acute quinpirole produced a dose responsive reduction of pallidal flow. We now demonstrate the specificity of this response and evaluate the effects of sedation. We surgically implanted a customized skull cap that fits into a headholder to permit precise fixation and correlation between PET and MR images. Flow was measured with 40sec PET scans after bolus [O-15] water before & after quinpirole (.2mg/kg i.v.). Regional changes in flow were identified by subtraction image analysis. In sedated baboons (ketamine for induction, atropine to decrease secretions. nitrous oxide for sedation & gallamine to permit careful control of pCO2), pallidal flow decreased an average of 16%. Pretreatment with the selective D2 antagonist eticlopride (4mg/kg) eliminated the quinpirole-induced response. We also trained a monkey (operant conditioning using positive reinforcement, only) to lie awake in the PET. The qualitative decrease in pallidal flow (15.5%) after quinpirole was not significantly different from sedated baboons. These data demonstrate the specificity of the local flow response to quinpirole and validate the use of the sedated baboon. Pharmacologic activation using PET permits repeated evaluation of the function of receptor mediated pathways.

### 17.7

effects of the 5-Ht $_{1A}$  agonist 8-ob-dpat on brain catecholaminergic neurotransmission in the rat. S. Ahlenius $^{1*}$ , V. Billegaart $^{1}$  and A. Wijkström<sup>2</sup>. Departments of Behavioral Pharmacology and Bioanalysis<sup>2</sup>, Astra Arcus AB, S-151 85 Södertälie, Sveden.

The activity of 8-OH-DPAT at brain DA and NA receptors was studied by measuring compensatory changes in catecholamine synthesis, as estimated by DOPA accumulation in NSD-1015 (100  $\,$  mg  $\,$  kg  $^{-1}$  IP) treated rats. Corresponding measurements of 5-HTP accumulation were made in parallel. In normal rats, there were no effects on the DOPA accumulation in the ventral or in the dorsal region of the neostriatum after the administration of 8-OH-DPAT (2.4 umol kg<sup>-1</sup> SC), whereas a significant increase was found in the frontal neocortex. Since NA is the predominant catecholamine in this latter area, the results suggest  $\alpha_2$ -receptor blocking properties of 8-OH-DPAT. The two 5-HT<sub>1A</sub> agonists 8-OH-DPAT and flesinoxan both produced a marked decrease in forebrain 5-HTP accumulation. Since an increased neocortical DOPA accumulation was only obtained by 8-OH-DPAT, and not by flesinoxan (0.6-10.0  $\mu mol\,kg^{-1}$  SC), administration, it appears that 8-OH-DPAT may have a direct action as an  $\alpha_2$ -receptor antagonist in the rat brain. In reserpine treated rats, 8-OH-DPAT produced a decreased DOPA accumulation in the ventral, but not the dorsal, neostriatum, indicating a selective stimulation of DA receptors in this limbic forebrain area. Taken together, these observations suggest that in addition to its demonstrated ability to stimulate brain 5-HT<sub>1A</sub> receptors, 8-OH-DPAT possesses  $\alpha_{j}$ -receptor blocking properties and also produces a regionselective stimulation of brain DA receptors.

EXTRACELLULAR LEVELS OF MONOAMINES IN STRIATUM OF BABOON AND RAT FOLLOWING ORAL PHENYLALANINE.

B.Arvin, A.G Chapman & B.S.Meldrum. Spon: Brain Res. Assoc. Inst Psychiatry London SE5 8AF U.K.

L-phenylalanine (PHE) has been suggested to reduce seizure thresholds in some models of epilepsy by modulating brain dopamine (DA) meta-bolism. In this study we compared the effects of oral PHE on extracellular levels of DA and metabolites in baboon striatum with that of metabolites in baboon striatum with that of 1.V amphetamine (amph 0.5mg/kg) in 8 conscious adult baboons (<u>Papio papio</u>) bilaterally implanted with guide cannula. Microdialysis samples (20µl/20min) were collected over 3 periods, basal (0-60min), 0-140min post PHE and 0-60min post amph. Mean plasma PHE levels were 49nmol/ml (control) and 930nmol/ml 100min after PHE 450mg/kg. In a parallel study transverse dialysis was (control) and 930nmol/ml 100min after PHE 450mg/kg. In a parallel study transverse dialysis was done in the striatum of 10 Wistar rats using a similar protocol as above. There was an apparent (1.5 in baboon and 3 fold in rat) but nonsignificant increase in DA 100min post PHE (450 but not 100mg/kg). No change was seen in other metabolites after either dose of PHE. Amph caused a large increase in DA (5-30 fold) in both studies. In summary, oral PHE did not significantly change extracellular levels of DA and metabolites in baboon or rat striatum.

DOPAMINE SYNAPTIC ORGANIZATION IN MONKEY PREFRONTAL CORTEX J.F. Smiley\* and P.S. Goldman-Rakic, Section of Neurobiology, Yale Sch. Med., New Haven, CT

The ultrastructural features and synaptic organization of dopamine axons were analyzed in individual layers of monkey prefrontal cortex. Dopamine immunoreactivity was visualized with a silver precipitation technique, recently developed in our lab, which allowed clear resolution of internal structures and cell membranes of labeled axons. Dopamine varicosities contained numerous clear vesicles, and always contained dense core vesicles This description contrasts to our finding in the anterior caudate of monkey, where dopamine axons lacked dense core vesicles, and suggests the presence of colocalized neuropeptides in the cortex Complete serial sectioning through labeled varicosities showed that 40% of all varicosites formed synapses. However, dopamine synapses were small and symmetric, typically seen in only one or two serial sections. We therefore conclude that these are sometimes not visualized, and it is possible that all dopamine varicosities form synapses. In all layers dopamine synapses were onto spines and small dendritic shafts, some of which were seen to form spines. conclude that the majority of dopamine synapses are onto distal dendrites of pyramidal cells. The homogeneous appearance of dopamine axons and their postsynaptic targets suggests that they arise from a single population of cells in the midbrain. Supported by MH44866.

EFFECT OF DAU 6215, A NOVEL 5HT3 ANTAGONIST, ON (+)- SKF 10,047-INDUCED DOPAMINE RELEASE IN STRIATUM NUCLEUS ACCUMBENS. A COMPARATIVE STUDY HALOPERIDOL AND CLOZAPINE. M. Volonte. A. Ceci, E. Esposito and Franço Borsini. Boehringer Ingelheim Italia S.p.A. Milan, Italy.

The potential antagonist effects of haloperidol and clozapine and of a new selective 5HT3 antagonist, DAU 6215 (3-alfa-tropanyl 1Hbenzimidazolone-3-carboxamide) (Turconi et al. 1991), were evaluated on dopamine release stimulated by the sigma agonist (+)- SKF 10,047 (N-allylnormetazocine). Dopamine release was estimated in the striatum and nucleus accumbens of the same animal by transcerebral dialysis of freely moving rats. (+)- SKF 10,047 (2.5, 5 and 10 mg/kg s.c.) increased in dose-related manner the release of dopamine, with preferentially effect in nucleus accumbens versus striatum. Saline or (+)- SKF 10,047 (5 mg/kg s.c.) was administered 45 min after vehicle, DAU 6215 (10  $\mu g/kg$ ), haloperidol (50  $\mu g/kg$ ) and clozapine (10 mg/kg). All compounds were given s.c. at the volume of 1 ml/kg. Clozapine and DAU 6215, which per se did not modify dopamine release in both areas, antagonized (+)- SKF 10,047induced dopamine release in nucleus accumbens but not in striatum. Haloperidol, which per se increased dopamine release in both areas. induced addictive effects with (+)- SKF 10,047 (5 mg/kg). Our results suggest that DAU 6215, similarly to clozapine, may have potential antipsychotic activity with low incidence of extrapyramidal side-effects

IS HUMAN TRICEPS SURAE ELECTROMYOGRAM A VESTIBULOSPINAL REFLEX RESPONSE? I. S. Storper and V. Honrubia\*, Victor Goodhill Ear Center, UCLA School of Medicine, Los Angeles, 90024

Interest in understanding the human vestibulospinal reflex has increased enormously over the past three decades, as this reflex is the primary effector of maintenance of posture and balance. On a posture platform, forces exerted by the triceps surae (TS) and tibialis anterior (TA) muscles are measured to calculate center of mass (COM) sway. We wished to determine whether the TS response is a direct component of the vestibulospinal reflex.

Ten healthy human beings were stimulated with sinusoidal galvanic currents delivered over their mastoid processes. Sway response on a posture platform and TS electromyogram (EMG) were recorded for the following conditions: (1) standing unrestrained; (2) standing completely restrained above the leg; and (3) sitting unrestrained.

Results were similar for all subjects. Computer-aided analysis for case (1) reveals that TS EMG and horizontal body sway responses are case (1) reveals that 15 EMG and nonzonial body sway responses are generated at the same frequency as the stimulating current, with a phase lag of 90 degrees. For case (2), body sway response and any component of the TS EMG over the unstimulated condition were absent in all subjects. For case (3), body sway persisted but no TS EMG above the unstimulated condition was recorded.

As the TS EMG disappears when the standing subject is restrained from swaying or in the unrestrained subject, we conclude that the TS EMG response is compensatory to motion of more superior portions of the musculoskeletal system; it is not part of the vestibulospinal reflex.

EFFECTS OF NORMAL AND MAGNIFIED VISION ON HEAD OSCILLATIONS. J. Goldberg\* and L. Weider. Clayton Lab., Dept. of Otolaryngology, Baylor College of Medicine, Houston, TX 77030.

Involuntary oscillations of the head on the trunk contain frequency components up to 15 Hz, beyond the limitations of visuo-motor reflexes. Thus, visual feedback can be expected to increase oscillation intensity. To test this hypothesis in 3 dimensions, we recorded angular head

velocity in roll, pitch, and yaw axes in 16 seated volunteers. They wore a headband carrying velocity sensors and a light source for projecting an arrow onto a screen 4m away. Root mean square (RMS) velocity was computed over 30 seconds and served as an index of oscillation intensity for each axis. Each subject was instructed to hold his/her head still and "look" at a horizontal or vertical line on the screen under four conditions

"look" at a horizontal or vertical line on the screen under four conditions presented in random order. These included: (i) normal 1x vision with arrow off (1xV), (ii) normal vision pointing (1xP) - keeping the arrow on the target line, (iii) 4x magnified vision pointing (4xP) - keeping the arrow on the line viewed through 4x magnifying spectacles, and (iv) baseline - vision occluded by opaque goggles, eyes open (0xV). Analysis of variance on repeated measures indicated that visual feedback affected RMS velocity in the pitch and yaw axis during horizontal line viewing (p<0.01) and in yaw, pitch and roll axis during vertical line viewing (p<0.05). For the horiz. line, the largest increase relative to baseline 0xV was observed in pitch RMS, condition 4xP (p<0.005). For both line targets, RMS increased significantly with vision (1xV vs 0xV) in yaw (p<0.005) but not pitch. These preliminary results show that visual feedback causes an increase in head oscillations, which appears to depend on feedback gain.

CHARACTERISTICS OF GAIT INITIATION IN NORMAL AND ABNORMAL OLDER PEOPLE. R.J. Elble\* and C. Moody. Southern
Illinois Univ. Sch. of Med., Springfield, IL 62794-9230.
Electromyograms of the thigh and leg muscles, footfloor reaction forces and motion of the body were re-

corded from 16 normal adults, ages 18 to 83, during initi-ation of a rapid forward step in response to a visual cue. These measures were compared with those from elderly patients with Binswanger disease (2), Alzheimer disease (2). Parkinson disease (3), sensorimotor neuropathy (1) and communicating hydrocephalus (1). During normal gait initiation the body rotates about the ankles like an inverted pendulum. The ventral muscles of the lower extremities pendulum. The ventral muscles of the lower extremities fire synergistically in the initiation of gait to create a forward moment about the ankles, propelling the body into forward motion. The dorsal muscles fire subsequently as the center of mass is displaced laterally over the stance foot, in preparation for toe-off. This smooth, stereotypic sequence of postural shifts was exhibited by all of our healthy volunteers. The Alzheimer patients exhibited normal patterns of gait initiation but their exhibited normal patterns of gait initiation, but their reaction times were approximately twice normal. Start hesitation in the remaining patients resulted from disordered patterns of muscle activation, which produced highly erratic, ineffectual postural shifts. Specific disturbances in the control of posture and movement, not a delayed formulation of the motor plan, probably underlie start hesitation in such patients. (Supported by NIA P30 AG08014)

POSTURAL FORCE FIELDS OF THE HUMAN ARM. R Shadmehr\*, FA Mussa—Ivaldi and E Bizzi. Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

When a perturbation displaces the hand from equilibrium, arm muscles respond by producing restoring forces. Displacements given at various directions from the same equilibrium position result in restoring forces which describe a postural force field. We ask whether these forces are related to forces generated when a reaching movement is executed: if a movement is a consequence of a shift when a reaching movement is executed: If a movement is a consequence of a shift of the equilibrium position of the hand toward the target, then, from the postural force field, predictions can be made regarding the elastic forces generated during a movement. We have measured the postural force field over relatively large distances and compared these forces with the static forces generated at the hand during a reaching movement.

A robot was used to displace the hand at various directions from an equilib-A robot was used to displace the hand at various directions from an equilibrium position. The measured restoring forces were fitted to a non-linear model to define a postural force field for that equilibrium position. This field was used to predict elastic forces generated when the subject attempted to move the manipulandum from a point on the circumference of a circle to a target at its center—the center corresponded to the equilibrium position where the postural field was measured at. In some of the movement trials, the manipulandum was locked during approximately the first 120 msec of the program for motion and the resulting static evoked forces measured. We found that: (1) the motion and the resulting static evoked forces measured. We found that: (1) the evoked forces did not point to the target, but were a function of the configuration of the arm and rotated with the shoulder joint, and (2) the magnitude of the evoked forces varied systematically, even though the movements were of the same magnitude. These patterns were remarkably similar to those observed in the postural forces. Our results provide experimental evidence linking maintenance of posture to the generation of movement in a multi-joint system. The nance of posture to the generation of movement in a muti-joint system. In evidence is consistent with the hypothesis that the CNS programs a reaching movement by shifting the equilibrium position of the hand toward the target.

## 18.4

ASYNCHRONY BETWEEN 2-D BIMANUAL HAND MOVEMENTS AS A FUNCTION OF CEREBRAL DOMINANCE. P. Viviani, N. Stucchi, and J.Requin\* Dept. of Psychobiology, Faculty of Psychology, University of Geneva, 1211, Geneva, Switzerland and Dept. of Psychobiology, CNRS, Marseille, France.

Reaction times for bimanual movements aimed simultaneously at visual targets are poor discriminators of cerebral dominance (Bartlett & White, 1965). By are poor discriminators of cerebral dominance (Bartiett & White, 1903). By contrast, we found that temporal phase during periodic movements of the two hands depends on subject's handedness. Right- and left-handers were asked to trace continuously with both hands simple, closed, geometrical patterns (ellipses). Movements were performed in the frontal plane. Four types of motor tasks were considered which resulted from combining the two possible directions of rotation in each hand. Each type was executed at six different tempos (40 to 90 cycles/min). The trajectories of the outstretched index fingers were recorded with the ELITE system (spatial accuracy: ≤ 1 mm; sampling frequency: 100 Hz). By measuring the passage times at homologous points of the trajectories, we measured the instantaneous asynchrony between the two hands throughout several cycles of movement. It was found that, although motor performances in both hands are comparable for all subjects, the dominant hand leads the non-dominant one by about 30 msec. This temporal delay is affected neither by the type of movement nor by its rhythm. Thus, it cannot be construed as the result of a strategy in which the non-dominating hands tracks the other one. The variability of the delay across cycles depends on the location within the trajectory. The variability profile has well-defined maxima and minima. The profiles for movements engaging homologous muscles differ markedly from those engaging non-homologous muscles. We argue that the results are compatible with the hypothesis that bimanual periodic movements are timed by a functional module residing in the dominant hemisphere, and that the observed asynchrony is due to the necessity of transmitting time-keeping information to the other hemisphere, possibly through callosal pathways (Filbey & Cazzaniga, 1969).

MODULATION OF RISE IN PREMOVEMENT CORTICAL EXCITABILITY IN A CHOICE REACTION TIME PARADIGM. A. Pascual-Leone \* and M. Hallett Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892

In a simple reaction time (RT) paradigm, the excitability of the motor structures targetting agonist and antagonist muscles for the requested response movement increases progressively leading up to movement onset. Here we studied this premovement facilitation in a choice RT paradigm.

We studied 7 right-handed normal volunteers (5 men and 2 women, aged 23 to 50

We studied 7 right-handed normal volunteers (5 men and 2 women, aged 23 to 50 years). A monitor displayed a yellow dot (warning signal) for 500 ms followed randomly, after a variable foreperiod (1-3 s), either by a red or a green dot (go-signal). In different sets of 200 trials, the subjects had to respond as fast as possible with right thumb abduction (sRT1) or with right ankle extension (sRT2) regardless of the color of the go-signal, or with right thumb abduction to the green and right ankle extension to the red go-signal (cRT). Surface EMG was recorded simultaneously from right abductor pollicis brevis (APB) and right anterior tibialis (AT). Transcranial magnetic stimulation was applied at different times following the go-signal at an intensity subthreshold for evoking motor potentials (MEPs) at rest.

In sRT1 and 2, the probability of evoking MEPs and their amplitude began to increase 110 ms before voluntary EMG onset and raised steadily thereafter but only for the muscle involved in the requested response (APB in sRT1 and AT in sRT2). In cRT, the probability of evoking MEPs and their amplitude began to increase 120 ms before voluntary EMG onset and raised steadily thereafter but only for the muscle involved in the requested response (APB in sRT1 and AT in sRT2). In cRT, the probability of evoking MEPs and their amplitude began to increase 120 ms before voluntary EMG onset and raised steadily thereafter in parallel for APB and AT regardless of the eventual response. This pre-movement facilitation diverged only 20-

regardless of the eventual response. This pre-movement facilitation diverged only 20-30 ms before voluntary EMG onset when MEPs in the muscle involved in the eventual response became further facilitated while those in the other muscle ceased to grow or even decreased in amplitude.

The results suggest that in a two-choice RT paradigm, the motor structures targetting muscles involved in both responses are activated in parallel and only very shortly before execution of the response do the incorrect response structures get inhibited in favor of the correct ones.

H-REFLEX MODULATIONS DURING VOLUNTARY MOVEMENTS FOLLOWING PERINATAL BRAIN DAMAGE. <u>C. T. Leonard\*</u>, Motor Control Research Laboratory, The Univ. of Montana, Missoula, MT 59812

Laboratory, The Univ. of Montana, Missoula, MT 59812
An adaptation of H-reflex testing procedures has been developed that allows the continuous monitoring of human alpha motoneuron activity during movement. The technique differs from previously used H-reflex testing techniques in that it utilizes a 5 Hz stimulation to elicit the H-reflex. This allows for continuous and concomitant H and M wave recordings during a movement. This is an improvement over single stimulus techniques in that more data points are collected in less time, and subject anticipatory reactions are less of a factor. The procedure has proven particularly useful for the testing of neurologically impaired patient populations.

The technique has been used to assess agonist muscle alpha motoneuron activation and reciprocal inhibition of antagonist musculature during various voluntary movements of non-disabled individuals and of individuals with spastic-type cerebral palsy (CP). During voluntary dorsiflexions of the ankle, non-disabled individuals show an inhibition of the antagonist soleus alpha motoneurons prior to activation of the tibialis anterior (TA) muscle. The inhibition increases and remains during the time the tibialis anterior is actively contracted. Individuals with CP do not show inhibition of the antagonist soleus either prior to or during activation of the TA. These results suggest that the supraspinal component to reciprocal inhibition is absent in individuals with CP and explains, in part, the abnormal muscular co-contraction present during voluntary movement in individuals with CP.

## 18.9

MAINTAINING LATERAL EQUILIBRIUM DURING STANDING. W.A.Lee\*, A.M. Wing J.R. Jenner. Physical Therapy, Northwestern Univ., Chicago IL USA 60611; MRC-APU, Cambridge Univ.; Addenbrooke's Hospital, Cambridge UK How subjects maintain standing equlibrium against

How subjects maintain standing equlibrium against external perturbations has been less investigated in the frontal than the sagittal plane. We studied the properties of normal adult responses to abrupt step changes in force applied laterally to the hips.

A servo-controlled actuator coupled to a semi-rigid belt around the hips delivered forces of up to 15% body weight and measured hip displacement. Subjects were told to stand straight and resist force steps of increasing magnitude (maximum force = load sustained without stepping). Push and release trials (i.e., force increased from or decreased to zero) were alternated; force direction (right, left) was blocked. Trials were 5.0 s; the load was applied at 0.5s. Natural visual surround but not hip motion information was available to the subjects.

Hip displacement increased rapidly in the direction of the force to a final steady posture, measured during the last 0.5s of the trial. The initial peak and final displacements increased linearly with force, until subjects had to step. The form of the hip-force functions was consistent with a second-order system, implying that control of lateral hip displacement in this task can be modelled as an inverted pendulum with constant stiffness springs. (Partial support of W.L.by NSF BNS-9021486)

## 18.11

FREQUENCY ANALYSIS OF THE POSTURAL SWAY OF NORMAL AND VISUALLY IMPAIRED CHILDREN. <u>C.V. Portfors-Yeomans and C.L. Riach\*</u>. Department of Physical Education, McMaster University, Hamilton, Ont., Canada L8S 4K1

Thirty-six normal (N) children aged 4-12 and 12 congenital visually impaired (VI) children aged 5-12 stood quietly on a force plate (AMTI) under 4 conditions: normal surface, eyes open (NEO); normal surface, eyes closed (NEC); foam surface, eyes open (FEO); foam surface, eyes closed (FEC). Centre of pressure excursions (LAT and A-P) were sampled at 10 Hz and then analyzed using fast fourier transformation. frequency data was analyzed between 0-4 Hz. Total power was calculated for each trial by integrating the frequency function. The frequency data was logarithmically transformed before linear regression analysis. The slope of the regression line was used to compare the relative amounts of low and high frequency sway. The N children were grouped by age (4-5,6-7,8-9,10-12) for ANOVA. The Mann-Whitney test was used to compare N and VI children. Young N children had higher power and relatively more high frequency sway in EO and EC. Total power and relative sway at high frequencies decreased with age with significant decreases after 7 years in the A-P direction. Young children may use a preprogrammed ballistic strategy of control as seen by increased high frequency sway while older children may integrate multi-sensory feedback control to produce slower but more accurate corrections. No observable changes were seen with age in VI. VI children had significantly greater total power and relatively more low frequency sway than N children. The postural control system of VI children may adapt at a young age to rely more on vestibular and somatosensory inputs to stabilize sway

LOCOMOTOR-LIKE ROTATION OF EITHER KNEE OR HIP STRONGLY INHIBITS SOLEUS H REFLEXES. J.E.

Misiaszek', J.D. Brooke and J. Cheng. Human Neurophysiol. Lab., School of Human Biology, University of Guelph, Ontario, Canada, NIG 2W1. Human soleus H reflexes are depressed during

Human soleus H reflexes are depressed during active and passive pedalling of the ipsilateral leg, compared to control reflexes when sitting. We investigated whether this inhibition arises from peripheral events associated with rotation of either the knee or hip. H reflexes were recorded from four subjects during 1. passive pedalling rotation of the ipsilateral leg at 60 rpm, 2. rhythmic rotation about the ipsilateral knee, with maximum velocity and range as in pedalling (p>0.05), 3. similar movement of the hip and 4. stationary sitting. Rotation of either knee or hip significantly reduced (p<0.05) the magnitude of mean H reflexes compared to sitting control, arriving at values close to those when the whole limb was moved. [mean H reflexes: sitting 71.09%, whole leg 9.92%, knee only 13.19%, hip only 13.58%, as % Mmax from each subject]. Thus, somatosensory receptor discharge, from movement of the knee and also the hip, appears to be a foundation for leg movement induced inhibition of H reflexes in humans. TRIGEMINAL STIMULATION AND ACTIVITY IN NECK MOTONEURONS. V.C. Abrahams\*, F.J.R. Richmond, P.K. Rose, A.A. Kori and G.E. Loeh, MRC Group in Sensory-Motor Physiology, Department of Physiology, Queen's University, Kingston, Ontario K7L 3N6.

Most work on the control of head movement has been concerned with gaze, in which head movement is largely subordinated to the requirements of vision There are, however, many head movements in which the requirements of vision are not pre-eminent. In the cat these include movements of grooming, tactile and olfactory exploration and reflex movements such as inertial feeding and head aversion. The neck muscle activity underlying head aversion following tactile stimulation of the face was examined in videotaped unrestrained cats instrumented with EMG electrodes. Typically a light tactile stimulus results in an upward and backward movement associated with simultaneous contraction of deep and superficial dorsal neck muscles. Studies in the ketamine/chloralose anaesthetized cat have shown that a similar pattern of muscle activation can be produced by applying a mechanical stimulus to the face. Light touch of receptor-rich glabrous skin around the nostrils is particularly effective. Brief stimulus trains delivered to the infraorbital nerves at or near threshold causes a compound action potential in dorsal neck muscle nerves at a latency similar to that of muscle contraction in the conscious cat and raises the possibility that this trigemino-neck reflex (TNR) arises from the same neural substrate as head aversion. Intracellular recording from neck motoneurons showed small EPSPs at a minimum latency of 2.5 msec following weak stimulation of the infraorbital nerve. However, the first action potentials arose from a large, later EPSP at a latency consistent with the observations made in the conscious animal and observation of the TNR. The TNR has been shown to be abolished by a low section of the descending tract of V, suggesting that an interneuronal system responsible for the TNR and perhaps head aversion may be located intraspinally.

SYNERGISTIC MUSCLE COMPENSATION DURING FATIGUE.

J. Mao, R.B. Stein\* and J.W. Osborn. Faculties of Dentistry and
Medicine, Univ. of Alberta, Edmonton, AB, CANADA T6G 2N8.

We have previously shown that when jaw closing muscles sustain a maximum incisal bite force (isometric) for as long as possible, the direction of the bite force changes. The goal of this study was to test possible associated changes in the tensions generated by these muscles. Three healthy human subjects sustained maximum voluntary bite forces on a custom developed 3-D force transducer placed horizontally between upper and lower central incisors. The magnitude of the bite force was displayed on a computer screen. Subjects could therefore verify that they were maintaining constant, maximum bite forces. Surface EMG of bilateral superficial masseter and anterior temporal muscles was measured. EMG of each muscle was plotted against time. The results showed that the masseter EMG steadily decreased during the test while the temporalis EMG was roughly maintained or slightly increased. These results seem to account for the change in bite force direction from anterior to nearly vertical in the previous study. The changes in tensions of these muscles may be attributed to (1) subjects learning to use combinations of muscles more effectively and (2) one muscle (and probably others) increasing its activity to compensate for a loss in the tension of a fatiguing synergistic partner.

H-REFLEX MODULATION BY BALANCE PERTURBATION. M. Sabbahi,\* H. Qureshy, F. Lin, and A. Overby. University, School of Physical Therapy, Houston, Texas Woman's TX 77030

Postural and balance control are often set by volitional and reflex components of movement. The gain of the stretch reflex has been found to be modulated during locomotion and balance (Brooke & Collins, 1991). This study evaluates the

balance (Brooke & Collins, 1991). This study evaluates the excitability of the H-reflex in response to perturbation.

Twenty young adult subjects stood comfortably on the footplates positioned on the platform of the Balance System with eyes open and eyes closed while forward-backward linear perturbations (LP) were elicited for 1.5 inches at a speed 0.8 inches/sec. The platform was then moved into angular dorsiflexion (ADP) or plantarflexion (APP) for 80 excursion at a speed of 0.50/sec. Soleus H-reflexes were recorded using a speed of 0.5°/sec. Soleus H-reflexes were recorded using surface electrodes after tibial nerve stimulation (0.5 ms., 0.2 pps at 70% of maximum reflex). Reflex was recorded halfway into the perturbation and was monitored by the M-response. Responses were amplified 1000x using 10Hz - 10KHZ bandpass and four sweeps were averaged. A MANOVA was employed to compare the H-reflexes during different testing conditions. Results showed significant H-reflex inhibition during ADP with eyes open and closed; and H-reflex facilitation during APP with eyes open and closed. No measurable changes were recorded during LP. Results indicate that reflex modulation may occur during angular and not slow linear perturbation of may occur during angular and not slow linear perturbation of Visual feedback appears to have minimal effect on Hreflex modulation and motoneuron excitability.

EYE POSITION AND VELOCITY INTEGRATORS ARE IN SEPARATE COMPARTMENTS OF THE GOLDFISH HINDBRAIN. A. M. Pastor. R. R. de la Cruz. and R. Baker\*. Dept. of Physiology and Biophysics, NYU Medical Center, New York, NY 10016.

Two neural integrators are required for generating horizontal eye position and extending the time span for oculomotor compensation of self or visual world motion. The location of these integrators was established in goldfish by single-unit recordings and lidocaine inactivation of brainstem areas while monitoring eye movements. Four regions, called Areas I-IV, were identified in the region extending from the obex to the caudal pole of the vestibular nuclei. Areas I and III processed signals related to eye position while Areas I and IV were related to eye velocity. Neuronal responses in Areas I and II were strongly correlated with eye position and velocity. Bilateral, 1nl injections of lidocaine into Area I produced, after spontaneous saccades, a centripetal exponential drift in eye position with a time constant of 240ms. Unilateral Area I inactivation resulted in time constants of about 1s. Unilateral Area II inactivation produced a nystagmus with constant velocity 20°/s slow phases directed towards the contralateral side. Bilateral Area II inactivation caused no velocity bias, but reduced the time constant of the per-rotatory responses to head velocity steps from a control value of 10s to a minimum of 270ms. Up to 10nl of lidocaine in Areas III and IV produced only small changes in eye movement that were likely due to spread into adjacent areas. Given the specificity and extent of horizontal eye movement deficits, we conclude that Areas I and II represent the 'velocity to position' and 'velocity storage' integrators, respectively. The uniformity of neuronal activity within each compartment suggests that integration is a local, one-step process that could be the consequence of the intrinsic membrane properties of individual neurons.

EYE-POSITION SIGNAL OF THE ABDUCENS MOTONEURONS DURING GAZE HOLDING AND VESTIBULOOCULAR REFLEX IN THE ALERT CAT. E. Godaux and G. Cheron (SPON: European Neuroscience Association). Lab. of Neurophysiology, University of Mons, 7000 Mons, Belgium.

Eye movements are triggered by velocity signals that must be converted into position signals by a brainstem network, the oculomotor neural integrator (NI). Theoretical and indirect experimental evidences suggest that the integration of all the eye-movement commands is made by a common network (Robinson, 1975). In a first step of our attempt to test this hypothesis by a direct way, we studied the output signal of the horizontal NI at the level of the abducens motoneurons.

The discharge of 32 antidromically identified abducens motoneurons were recorded in the alert cat during spontaneous saccades made in the light and during vestibuloocular reflex (v.o.r.) elicited in complete darkness by sinusoidal stimuli During intersaccadic fixation, the firing rate of the motoneurons changed only with eye position (as eye velocity was null throughout). As a result, eye position sensitivity was obtained by establishing the firing rate - eye position relationship and by measuring the corresponding slope. During the slow phases of the v.o.r., the firing rate of the motoneurons consisted of two portions : one was related to eye velocity, the other to eye position. The problem was to take them apart. For this purpose, each time the eye passed through a chosen position during a slow phase, the firing rate was measured. Then, for that chosen eye position, the firing rate – eye velocity relationship was established. From this linear relationship, the firing rate of the neuron at null velocity was interpolated. Such a procedure was applied for a set of chosen eye positions. Finally, the sensitivity to eye position was obtained from the relationship between the interpolated firing rate and eye position.

If the NI was really common, each individual abducens motoneuron should have the same sensitivity to eye position in both studied movements. We found it to be the case.

### 19.2

OF OMNIPAUSE NEURONS IN SACCADE-VERGENCE INTERACTIONS. L.E. Mays\* and P.D.R. Gamlin. Dept. of Physiological Optics, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Saccades are high velocity movements in which the two eyes move as if voked. Looking between targets at different distances requires ocular vergence, in which the two eyes move slowly in opposite directions. Most gaze shifts between targets at different distances also require changes in direction mediated by saccades. When a saccade occurs during a vergence movement, the amplitudes of the saccades in the two eyes may be markedly unequal. This observation has led to speculation that primates retain circuitry which allows relatively independent control of the movements of two eyes. Instead, Fitzgibbon et al. (ARVO 1992) have proposed that the accelerated vergence movements might be the result of the release of omnipause neuron (OPN) inhibition of vergence burst cells during saccades. We report an experiment that is a critical test of this hypothesis

Two rhesus monkeys were trained to track visual targets that could elicit symmetrical vergence, saccades, or mixed saccade-vergence movements. movements were measured with search coils. Microelectrodes were localized in the pontine OPN region by recording the characteristic activity of these cells and by noting that electrical microstimulation halted all saccades. If OPNs partially inhibit vergence burst cells, then increasing the activity level of the OPNs should further depress the activity of vergence burst cells, resulting in a reduction of vergence velocity. We found that 1 sec stimulation trains in the OPN region during symmetrical vergence reduced the velocity of these movements by about 50%. Brief stimulus trains produced transient decreases in both convergent and divergent velocity with a mean latency of 24 msec. These findings strongly support the hypothesis that the acceleration of vergence during saccades is due to the cessation of the OPN inhibition. (Supported by NEI EY03463, EY07558, and P30 EY03039).

VERTICAL EYE MOVEMENT-RELATED NEURONS IN THE INTERSTITIAL NUCLEUS OF CAJAL PROJECT TO THE VESTIBULAR NUCLEUS. Y. Iwamoto\*, S. Chimoto, K. Yoshida Dpt. Physiology, Inst. Basic Med. Sci., Univ. of Tsukuba, Tsukuba, Ibaraki, 305 Japan

Both the vestibular nucleus (VN) and interstitial nucleus of Caial (INC) contain neurons with activity related to vertical eye movement. To examine a possible interaction between these two structures, projection of INC neurons to VN was studied in the alert cat.

Sixty-two INC neurons with activity related to vertical eye position were tested for the response to stimulation of the ipsilateral VN. Fortyone had a downward and 21 an upward on-direction. Thirteen of 41 downward neurons were antidromically activated following stimulation of VN with thresholds 36 to 220  $\mu$ A. In some neurons, the latency jumped to a shorter value as the stimulus increased, suggesting branching in VN. None of 21 upward neurons showed antidromic responses. The stimulation sites were in the ventral part of VN at the level of the caudal edge of the abducens nucleus.

About half of INC neurons examined (9/13 upward, 13/23 downward) responded orthodromically to stimulation of the contralateral vestibular nerve. In particular, all the downward INC neurons antidromically activated from VN were excited at disynaptic latencies (1.3 to 2.0 msec). Thus, they not only projected to VN but also received excitatory connections from VN, most likely from secondary neurons carrying vertical eye position signals, which we have recently shown to project to INC. Such interconnections between VN and INC may form an important part of the neural circuitry responsible for the generation of vertical eye position signals.

EFFECTS OF ORBITAL POSITION OF THE EYE ON SACCADES ELICITED BY ELECTRICAL STIMULATION OF SINGLE AND PAIRED FRONTAL EYE FIELD SITES. E. C. Dias\* G. S. Russo and C. J. Bruce. Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The direction and amplitude of saccades elicited by electrical stimulation of the

The direction and amplitude of saccades elicited by electrical stimulation of the frontal eye field (FEF) can be systematically influenced by the position of the eye in the orbit during stimulation, with the magnitude of this orbital perturbation effect varying across FEF sites. Here we analyze the effect of simultaneous electrical stimulation of two different FEF sites on the orbital perturbation of elicited saccades. Electrical stimulation consisted of 70 ms trains of 350 Hz biphasic pulses given through glass-coated elgiloy electrodes with exposed tips of 20-40 µm. Stimulation was delivered through one, the other, or both electrodes while the monkey fixated a spot of light on one of a matrix of 15 locations on a tangent screen. All 45 stimulation conditions were tested 5-10 times in pseudo random order.

We tested 17 different pairs of FEF sites of one macagine monkey. All sites had low

stimulation conditions were tested 5-10 times in pseudo random order. We tested 17 different pairs of FEF sites of one macaque monkey. All sites had low thresholds (<50µA) for eliciting saccades, and all site pairs were separated by at least 2 mm. The orbital perturbation of elicited saccades was quantified by linear regressions of fixation position on the direction and the amplitude of elicited saccades. In most cases orbital perturbations for paired stimulation was larger than the mean of the perturbations for stimulation of each site separately. This supports our hypothesis that large orbital perturbations of electrically elicited saccades could reflect multiple saccade representations being activated simultaneously through one electrode.

Paired stimulation usually elicited saccades at a higher probability and shorter latency than stimulation of either constituent site. Saccade dimensions from paired stimulation were often the weighted average of the saccade vectors from each stimulation site, with the shorter latency site having a larger weight. Saccade latency and probability also varied systematically with fixation position, with centripetal saccades having shorter latencies and higher probabilities, and centrifugal saccades having longer latencies and lower probabilities. Saccade latency and probability may reflect the orbitally-dependent weighting underlying the above hypothesis.

SPATIAL ORGANIZATION AND NEUROTRANSMITTER UTILIZATION OF PREMOTOR NEURONES RELATED TO VERTICAL SACCADIC EYE MOVEMENTS IN THE CAT. <u>S-F. Wang and R. F. Spencer</u>\*, Department of Anatomy, Medical College of Virginia, Richmond, VA 23298.

The rostral interstitial nucleus of the medial longitudinal fasciculus (riMLF) is the location of premotor neurones that control vertical saccadic eye movem Toward the goal of delineating an intrinsic organization of neurones in the riMLF in relation to upward and downward eye movements, microinjections of HRP and biocytin have been made in different regions of the oculomotor nucleus and the riMLF, respectively. The results of these complimentary retrograde and anterograde labelling experiments demonstrate a caudal-upward and rostraldownward relation of neurones in the riMLF to the vertical motoneurones targeted in the ipsilateral oculomotor and trochlear nuclei. Two populations of biocytinlabelled riMLF synaptic endings are observed in the ipsilateral oculomotor and trochlear nuclei: (a.) presumed inhibitory synaptic endings that contain pleiomorphic synaptic vesicles, establish symmetrical synaptic contacts, and are GABA-immunoreactive, and (b.) presumed excitatory synaptic endings that contain spheroidal synaptic vesicles, establish asymmetric synaptic contacts, and are immunoreactive toward glutamate or possibly aspartate. Both populations of synaptic endings overlap in the same motoneurone subgroups, and retrograde HRP-labelled neurones that are immunoreactive toward GABA or glutamate/aspartate coexist within the riMLF. This ipsilateral inhibitory and excitatory organization of riMLF projections to vertical motoneurones differs from the reciprocal inhibitory and excitatory synaptic connections that characterize the vertical vestibulo-ocular and horizontal eye movement systems

SYNAPTIC INPUT TO OCULOMOTOR NEURONS OF THE FROG. S.L. Cochran\*. University of Texas Medical Branch, Department of Otolaryngology, Rt. J63, Galveston, TX 77555-1063.

This study was undertaken to investigate the physiology and pharmacology of afferent synaptic transmission to the frog oculomotor nucleus. Intracellular recordings were obtained from these cells in the isolated brain bathed with Mg+2-free saline. The neurons were identified by their location medial to the exit of the nerve 250-450  $\mu$ m from the ventral brain surface. Some could be activated antidromically from either the ipsi- or contralateral nerve stump. Electrical stimulation of the VIIIth cranial nerves, the optic chiasm, vestibular nuclear complexes medial longitudinal fasciculi, and optic tecti, evoked complex patterns of EPSPs and IPSPs in these cells. Two populations of cells appear to exist. One exhibits disynaptic EPSPs from stimulation of each VIIIth nerve. A second shows EPSPs from the contralateral and disynaptic IPSPs from the ipsilateral VIIIth nerve. Bath application of 3 mM kynurenic acid nearly abolished all evoked EPSPs (N=22), IPSPs that were other than monosynaptic, and spontaneous or bicuculline-induced rhythmic oscillations in the cells' resting potentials. Bath application of  $5 \mu M$  bicuculline (but not  $50 \mu M$  strychnine) abolished the IPSPs (N=4). These findings implicate glutamate and related compounds as the major excitatory transmitters employed by afferents to this nucleus, while GABA would seem to be the principal inhibitory transmitter.

### 19.6

NEUROETHOLOGY OF SACCADIC EYE MOVEMENTS IN CHICKENS. <u>I-C. Letelier and I. Wallman\*</u>. Biology Department, City College, City Univ. of NY, New York, N.Y. 10031.

The saccadic behavior of birds is peculiar in that the eye proceeds toward the target not in a straight line, but in a slow (180 msec) trajectory containing extravagant (10-12 deg, 28 Hz, 600 deg/sec) oscillations mostly in the torsional plane. These oscillations are conjugate even during non-conjugate saccades.

Extracellular recording shows two classes of motoneurons in the trochlear nucleus. One type is like mammalian extraocular motoneurons in that the neurons fire during fixations with a rate dependent on position, but unlike mammalian motoneurons in that they pause for about 35 msec at the start of all saccades. The other type is silent between saccades, but active during saccades in all directions, firing bursts time-locked to each intorsional phase of the saccadic oscillation.

This separation into two classes of units, one with responses related to eye position and the other related to the saccadic oscillations, was also found in the afferents to the trochlear nucleus in the medial longitudinal fasciculus, using intracellular recording and labeling with HRP. Motoneurons with the pulse-step responses characteristic of mammals were never encountered. The functional segregation seen in avian motoneurons is an exception to the uniform activation found in most vertebrate motor pools and suggests that different vertebrates may employ different oculomotor strategies. ## 19.8

A MODEL OF HUMAN OCULAR PURSUIT: INTEGRATION OF SMOOTH PURSUIT AND SACCADES. Ph.W. Koken and C.J. Erkelens (SPON: European Neuroscience Association)\*. Utrecht Biophysics Research Institute, Dept. of Medical and Physiological Physics, University of Utrecht, 3584 CC Utrecht, the Netherlands.

We studied human ocular pursuit while a target was tracked either by the hand and the eyes together or by the eyes alone. Eye movements were measured by using the magnetic-field induction-coil technique. Hand movements were measured by recording the position of a hand held stick. The target was externally generated and moved horizontally in the fronto-parallel plane.

Ocular pursuit was smoother during simultaneous tracking with the hand of predictable target movements than during tracking by the eyes alone. However, gain and delay of ocular pursuit (smooth pursuit plus saccades) were not affected by simultaneous tracking with the hand. Tracking with the hand did not affect ocular pursuit when the target motion was unpredictable (Koken and Erkelens 1990, 1992a). Although the vergence system can track predictable target movements with a short delay comparable to the delay of smooth pursuit system (Koken and Erkelens 1992b), simultaneous tracking with the hand did not affect vergence pursuit.

From the obtained results we conclude that the ratio of smooth and saccadic

From the obtained results we conclude that the ratio of smooth and saccadic components of ocular pursuit is task-dependent when a predictable target motion is tracked. We propose a model of ocular pursuit in which the predicted target motion results in input signals which are distributed (depending on the tracking condition) over the smooth pursuit and the saccade control systems.

## 19.10

Predictive Components of Smooth-Pursuit Responses on Neurons in the Dorsomedial Frontal Cortex. <u>S.J. Heinen</u>\* Smith-Kettlewell Eye Res. Inst., San Francisco CA.

The dorsomedial frontal cortex (DMFC) has been shown to be involved in saccadic eye movement generation (Schlag and Schlag-Rey, 1987). This area receives input from MST, an area which has neurons activated during smooth pursuit and for visual motion (Komatsu and Wurtz, 1988). Similar responses have been found on neurons in the DMFC, although these responses are weaker in terms of strength and tuning (Heinen, 1992). These cells were also sometimes modulated before tracking targets began to move, and often showed an increased discharge before the end of the trial, suggesting a more complicated role of these neurons than what would be expected from a cell conveying a simple motor signal. Single-units were recorded from neurons in the DMFC of two *Macaca fascicularis* monkeys. Eye position was recorded using the search coil. The monkeys task was to pursue sinusoidal and triangle-wave stimuli with amplitudes of either 10, 20 or 30 deg, and with frequencies of .3 or .5 Hz. It has been demonstrated that monkeys can predict periodic stimuli such as these, thereby producing a much smaller phase lag between the eye and the target than would be expected from the physiological latency (Deno et al. 1990). Seven of 14 cells tested with these stimuli showed peaks of activity that occurred an average of 104 ms before target turnaround. These results suggest that neurons in the DMFC carry a signal that could be used by the oculomotor system to predict target turnaround and reduce phase lag in periodic tracking tasks.

POSSIBILITIES FOR CONVERGENCE OF FRONTAL EYE FIELD AND CEREBELLAR FASTIGIAL EFFERENT PROJECTIONS WITHIN BRAINSTEM PREOCULOMOTOR NUCLEI IN THE MONKEY, G.R. Leichnetz\*, A. Gonzalo-Ruiz, R.F. Spencer, and D.J. Smith. Department of Anatomy, Medical College of Virginia, Virginia Commonwealth University, Richmond VA 23298

The frontal eye field (FEF) and fastigial nucleus (FN) of the cerebellum are both thought to play a role in the ocular motility. We have been interested in identifying: (1) areas of potential convergence between FEF and FN efferents within brainstem pre-oculomotor nuclei, and (2) areas where FEF efferents terminate in relation to sources of FN afferents. The research is based upon studies of anterograde and retrograde horseradish peroxidase (HRP) labeling following fluid injections or solid polyacrylamide HRP gel implants into the FEF, FN, or oculomotor-related brainstem nuclei in capuchin (Cebus) monkeys. It was found that the FEF and FN efferent projections probably converge in the supraoculomotor periaqueductal gray matter above the oculomotor complex, paramedian pontine reticular formation (PPRF) and nucleus raphe interpositus, and the nucleus prepositus hypoglossi. FEF efferents project to the nucleus reticularis tegmenti pontis, and dorsomedial and dorsolateral basilar pontine nuclei which are sources of FN afferents. The functional predisposition of the brainstem nuclei involved and their connections seem to support the interaction of FEF and FN in the control of both saccadic and smooth pursuit eye movements. The lack of a significant fastigiotectal projection suggests that convergence of FEF and FN efferents does not occur in the superior colliculus.

CONTACT WITH SELECTED CELL TYPES CAN STIMULATE DIVISION OF E14 RAT CORTICAL PROGENITOR CELLS. S. Temple\* and A.A. Davis Dept. of Pharmacology and Toxicology and Div. of Neurosurgery, Albany Medical College, Albany NY 12208.

We have investigated how cell-cell contact affects the proliferation of rat cortical progenitor cells. At E14 most cortical cells are in division, but when they are dissociated and plated as single, isolated cells in vitro, division largely ceases and the cells differentiate. In contrast, when E14 cortical cells remain in contact with each other as small clusters of cells, division can continue and differentiation yields both neurons and glial cells. The incidence of progenitor cell division increases with cluster size. BrdU uptake over the first 24 hours of culture reveals that only 11% +/-3{SD} of cells in clusters of 2-3 cells are dividing compared to 93% +/-3{SD} of cells in clusters of 8-15 cells.

Cell-surface contact appears important for the continuation of proliferation. Single, dil-labelled, E14 cortical cells placed close to, but not in contact with, an unlabelled cluster of E14 cortical progenitor cells cease division, whereas if they are placed on top of such clusters they are stimulated to divide. The cell-contact effect appears to be cell-type specific: while single, dil-labelled, E14 cortical cells can also be maintained in division by neonatal cortical astrocytes, contact with meningeal fibroblasts reduces the chance of division even more than contact with poly-l-lysine coated plastic. These data suggest that close apposition between ventricular zone cells may be key to maintaining cell proliferation in the embryonic cortex, and that changing cell contacts may play a role in the differentiation of cortical cells. (Aided by the Klingenstein Fellowship Award in the Neurosciences, and by the Basil O'Connor Starter Scholar Research Award No. 5-FY91-0636 from the March of Dimes Birth Defects Foundation).

## 20.3

DEVELOPMENTAL FATES AND MIGRATION PATTERNS OF JUVENILE RAT SUBVENTRICULAR ZONE CELLS.

C. Chuang, S.W. Levison, and J. F. Goldman\*, Dept. Pathology, Columbia University College of P&S, New York, NY 10032.

The subventricular zone (SVZ) is a germinal center of the mammalian forebrain that develops late in gestation. Using a murine retrovirus containing the E.Coli LacZ gene we have shown that immature cells infected in the P2 rat SVZ migrate dorsally and laterally into hemispheric gray and white matter (WM) and become both oligodendrocytes and astrocytes. determine if SVZ cell fate changes with time, we injected the vector stereotactically into the forebrain SVZ of P14 rats. Infected cells were visualized histochemically after various intervals and their morphologies characterized. Two days post-injection their morphologies characterized. (2dpi), most of the labeled cells were within the SVZ and displayed the same apolar or unipolar appearance as earlier SVZ cells. The remainder were located in WM and consisted of immature oligodendrocytes. At 21 dpi, only 8% were in the SVZ; the rest had developed into oligodendrocytes in WM. In contrast to SVZ cells labeled at P2, these had largely migrated medially towards the callosum, occasionally appearing in the WM on the contralateral side. Cells rarely migrated into gray matter and only few developed into astrocytes. Thus, both the migratory patterns and the developmental fates of SVZ cells change during the first 2 weeks of postnatal life. Supported by NS 17125 and MH 15174.

### 20.2

CHANGES IN STRUCTURAL AND FUNCTIONAL PROPERTIES OF RAT TELENCEPHALIC CELLS DURING EMBRYONIC DEVELOPMENT. J.-M. Mienville and J.L. Barker. Lab of Neurophysiology, NINDS, NIH,

We have recorded whole-cell from embryonic (E12-E21) rat telencephalon and cerebral cortex with "in-situ patch-clamp" techniques (Edwards et al. Pflügers Arch. 414, 1989), using a standard NaHCO3 buffer bubbled with carbogen at room temperature, and a K-free intracellular solution. As revealed by Lucifer Yellow spread from recorded cells and by low input resistances (down to  $\sim$  50 M $\Omega$ ), younger cells were consistently coupled in clusters whose size (up to  $\sim$  100 cells) and occurrence decreased with development (Lo Turco and Kriegstein, Science 252, 1991). Furthermore, specific differences were noted when recording from ventricular vs. pial sides. In the absence of extracellular Ca, cells sealed to the electrode tip could be pulled away from the cluster, displaying sharp increases in resistance toward single cell values. Hence, there was close correspondence between apparent resistance and extent of coupling. resistance of the majority of coupled cells was increased at low intracellular pH or in mM heptanol and octanol. Although they were only partially reversible, these effects suggest involvement of gap junctions in coupling.

Recordings from spontaneously uncoupled cells revealed immature, TTXsensitive (0.5  $\mu M$ ) action potentials, consistent with a low density of Na currents ( $I_{Na}$ ). Density and occurrence of  $I_{Na}$  increased during development but, even at E21, the former remained much below adult values. Thus, telencephalic embryogenesis is characterized by a progressive decrease in junctional coupling and an increase in electrical excitability, the latter being present in the earliest period of post-mitotic differentiation.

PCNA EXPRESSION IN CEREBRAL CYTOGENESIS. <u>V.S.Caviness, ir\*.</u> and <u>T.Takahashi</u>, Dept. of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, 02114

Expression of proliferating cell nuclear antigen (PCNA, auxiliary protein of DNA polymerase-ð) fluctuates and is highly regulated during the cell cycle in normal as well as in tumor cells. The spatial distribution of cells expressing PCNA in the developing mouse cerebral wall has been determined for the first time. The alcohol fixed tissue from E14 mouse was stained immuno-cytochemically using an antiserum against PCNA. Only nuclei where PCNA was bound within the nucleus were stained.

Neocritical cytogenesis occurs within the venticular zone (VZ).

nuclei where PCNA was bound within the nucleus were stained.

Neocortical cytogenesis occurs within the ventricular zone (VZ). Progenitor cells within this proliferative zone undergo DNA synthetic (or S-) phase in the outer half of the VZ (S-phase zone). PCNA positive nuclei are concentrated at the outer margin of the VZ. A tritiated thymidine (PH) PCNA double labeling experiment (animals were sacrificed 1hr after <sup>3</sup>H injection) partitioned the total PCNA+ population into two subpopulations (i.e., PCNA+/<sup>3</sup>H- and PCNA+/<sup>3</sup>H-). PCNA+/<sup>3</sup>H- (26% of total PCNA+ cells) should be in late G1-phase while PCNA+/<sup>3</sup>H+ (74%) should be in early S-phase (within the S-phase population, PCNA+ represents only 30% of the total). Both PCNA+/<sup>3</sup>H- and PCNA+/<sup>3</sup>H+ cells have their peak distributions at the outer margin of the S-phase zone. have their peak distributions at the outer <u>margin</u> of the S-phase zone, evidence that the transition from late G1 (PCNA+/<sup>3</sup>H-) to early S-phase

evidence that the transition from late G1 (PCNA+/³H-) to early S-phase (PCNA+/³H+) occurs at the outer margin of the VZ.

These observations suggest that the G1/S transition of the progenitor cells of the cerebral cortex occurs at the interface between the proliferative zone (i.e., VZ) and the zone of the postmitotic migrating cells and ingrowing axons (i.e., intermediate zone). PCNA evidently participates in this transition and its pattern of expression may be sensitive to mechanisms which govern neocortical cytogenesis. Supported by NIH grant NS12005.

CELL CYCLE KINETICS OF THE VENTRICULAR ZONE IN THE FETAL MONKEY TELENCEPHALON. <u>D.R. Kornack\* and P. Rakic</u>. Section of Neurobiology, Yale School of Medicine, New Haven, CT 06510.

Neutrobiology, Tale School of Neutrine, New Haven, C1 (0010).

Cell cycle kinetics in cerebral germinal zones may potentially influence the development of the unique size and configuration of primate neocortex, and may also play a role in the pathogenesis of particular genetic and acquired cortical abnormalities. However, the duration of the cell cycle and its phases has not been examined in the nervous system of any primate species.

authorisatives. The newest, the fundation of the terrelyce and its phases has not examined in the nervous system of any primate species.

We have begun to examine cytokinetic parameters in the cerebral ventricular zone (VZ) of the macaque monkey fetus using a cumulative S-phase labeling protocol that employs bromodeoxyuridine (BrdU) immunohistochemistry (Nowakowski et al., '89, J. Neurocytol., 18:311: Takahashi et al., '92, J. Neurocytol., 21:185). BrdU, a thymidine analog, is injected into the pregnant animal and incorporated into DNA of proliferative cells during the S-phase. This procedure allows the determination of (1) the duration of the cell cycle (Tc), (2) the length of the DNA-synthetic phase (TS), and (3) the proportion of cells that comprise the proliferating population. Three pairs of animals were injected at embryonic days (E) 40, 60, and 80, corresponding to the beginning, middle, and end of the period of corticogenesis.

Our preliminary results indicate that at the onset of corticogenesis (E40), VZ cells in dorsomedial telencephalon have a Ts of 6.3 hrs; this duration is identical to that reported in a BrdU study of mouse VZ at a comparable developmental stage (E13)(Caviness et al., '91, Soc. Neurosci. Abstr., 17:29). By contrast, Tc in monkey lasted 24.1 hrs, substantially longer than the 14.7 hrs reported for mouse. Consequently, Ts may be conserved in mammalian VZ at early stages of corticogenesis, whereas the duration of at least one other phase of the cell cycle may vary across species. Experiments in progress focus on analyzing Tc and Ts in other cerebral areas at the middle and end of corticogenesis to determine whether cell cycle kinetics in primate VZ vary regionally and temporally. A COMMON PROGENITOR FOR TYPE 1 AND TYPE 2 ASTROCYTES EXISTS IN NEWBORN RAT SUBVENTRICULAR ZONE. S.W. Levison\*, B.J. Abramson, and J.E. Goldman. Dept. of Pathology and Center for Neurobiology and Behavior, Columbia University College of P & S, New York, NY 10032.

We recently demonstrated that both oligodendrocytes and protoplasmic astrocytes are generated in vivo from immature cells of the subventricular zone (SVZ). To determine the developmental potential of these glial progenitors in vitro, SVZ cells of P2 rats were labeled by stereotactic injection of recombinant retroviral vectors. Two days later, forebrains were dissociated and cultured in MEM with 5% FBS. Labeled cells were visualized with X-gal and phenotyped using triple label immunocytochemistry with a panel of antibodies. After 1 div most of the labeled cells were apolar or unipolar. Sixty percent were ganglioside GD3+, 50% were nestin+, and 30% were vimentin+, with overlapping expression. Less than 5% expressed GFAP. When examined from 4-21 div, several types of clones were observed: 1, GD3-, GFAP+,Vim+, flat, "Type 1" astrocytes; 2, GD3+,GFAP+,Vim+, process-bearing, "Type 2" astrocytes; and 3, clones of cells with mixed morphologies and antigenic phenotypes, often containing both "Type 1 and 2" astrocytes. Large, flat, GD3+ astrocytes were not observed in any clones. Thus postnatal germinal matrix cells in the SVZ can produce both "Type 1" astrocytes and O-2A lineage cells. Supported by NS 17125 and AG 00189.

## 20.9

INTERKINETIC MOVEMENT OF NUCLEI IN THE PROLIFERATIVE VENTRICULAR EPITHELIUM OF THE DEVELOPING MOUSE HIPPOCAMPAL FORMATION. R.S. Nowakowski\*, N.L. Hayes and W.A. Gregory. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

The developing archicortical structures of the hippocampal formation are produced in a single proliferative zone, the proliferative ventricular epithelium (PVE), that corresponds approximately to the cytoarchitectonically defined ventricular zone (VZ). In contrast, in the developing periarchicortex and neocortex there are two proliferative zones, the PVE and an adjacent secondary proliferative population (SPP). We have used cumulative labeling with the S-phase label bromodeoxyuridine (BUdR) to study the changes in the distribution of nuclei as they progress through the cell cycle. For this study, the hippocampal formation of the mouse on embryonic day 16 was divided into four 100-150  $\mu m$  wide sectors and the PVE was divided into 10  $\mu$ m deep bins. The number of labeled and unlabeled cells was counted in each bin and sector, and the proportion of labeled cells per bin (i.e., the labeling index) was computed. The results demonstrate that the PVE cells of the hippocampus enter the S-phase at the outer-most border of the VZ and move inward toward the ventricular surface as they progress through S, G2 and M, and that the entire outward movement of the nuclei takes place in G1. Thus, despite the fact that the hippocampal PVE is only half the thickness of the neocortical PVE, the behavior of the constituent cells of the two PVE's is similar.

CYTOGENESIS IN THE SECONDARY PROLIFERATIVE POPULATION OF THE MURINE CEREBRAL WALL. T. Takahashi\*, R.S.Nowakowski\* and Verne S. Caviness, jr.¹,¹Dept. Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA 02114, ¹Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

The secondary proliferative population of the developing cerebral wall (SPP) is generally thought to be the source of most cortical glial cells. The present analysis, based upon sequential S-phase labeling (H-T-TAR, Ihr; BUdR, 30 minutes; sacrifice), on embryonic days 14-17 (E14-E17) is concerned with the magnitude, distribution and rate of cell production within this population. The cells of the SPP are distributed from the ventricular zone (where they overlap with the proliferating pseudostratified ventricular zone and across the intermediate zone to the level of the external sagittal stratum, a fiber plane marking the inferior limit of the future cortex. Assuming that the length of the cell cycle is the same in PVE and SPP we calculated that: (1) The absolute size of the SPP increases by almost 500% by E16 but then declines approximately 25% between E16 and E17. (2) The relative size of the SPP as a proportion of the total proliferative population advances from 11 to 46% between E14 - E17 and then to 100% of the proliferative population on E18 after exhaustion of the PVE. From estimates of the rate of daughter cell production within this population, and with corrections for growth-caused tangential expansion of the proliferative zone, the proportion of SPP cells re-entering S-phase of the next cell cycle is estimated to be nearly 100% from E14 through E16. Over the next 24 hr, this proportion drops sharply to less than 30%. The waxing and waning of the SPP observed here precedes the seeding with glial cells of the outer cerebral wall and neocortex in the perinatal period. Supported by NIH grants NS12005 and NS28061 and NSF grant BNS8921020.

### 20.8

VARIATIONS IN CELL PROLIFERATION IN SUBDIVISIONS OF DEVELOPING MOUSE HIPPOCAMPAL FORMATION. W.A. Gregory\*, N.L. Hayes, and R.S. Nowakowski. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

We have used cumulative S-phase labeling with bromodeoxyuridine (BUdR) to measure the cell cycle in different subdivisions of the proliferative ventricular epithelium (PVE) of the developing mouse hippocampal formation. Cell proliferation was assessed at embryonic day 16 by injecting BUdR at two hr intervals over a period of 12 hr. Sections midway through the hippocampus were drawn for each time point using a drawing tube, and sectors 100-150 µm in length were defined along the ventricular surface. Counts of labeled and unlabeled cells in each sector were used to calculate the labeling index, from which the lengths of the cell cycle (Tc) and the S-phase (Ts) were determined. For the entire proliferative population, the average length of the cell cycle (T<sub>c</sub>) was 13.8 hr, and the average length of the S-phase (Ts) was 5.2 hr. However, these parameters were not uniform in all hippocampal subdivisions. The cell cycle was longest in the portion of the PVE giving rise to the dentate gyrus  $(T_c=17.4 \text{ hr}; T_s=6.5 \text{ hr})$  and shortest in the middle of three sectors along the length of the PVE of the hippocampus ( $T_c=9.9 \text{ hr}$ ;  $T_s=2.9 \text{ hr}$ ). These significant variations in the lengths of the cell cycle and the S-phase could contribute to known differences in the development of the hippocampal subdivisions

Supported by NIF grant NS28061.

## 20.10

CLUSTERING OF NUCLEI AND SYNCHRONY OF CELL PROLIFERATION IN THE PROLIFERATIVE VENTRICULAR EPITHELIUM OF THE DEVELOPING MOUSE HIPPOCAMPAL FORMATION. N.L. Hayes', W.A. Gregory, and R.S. Nowakowski. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

During the cell cycle the nuclei of the cells of the proliferative ventricular epithelium (PVE) enter the S-phase at the outer-most border of the cytoarchitectonically defined ventricular zone and move inward toward the ventricular surface as they progress through S, G2 and M. The nuclei retrace their path during G1 during which the entire outward movement of the nuclei takes place. We have used bromodeoxyuridine (BUdR) immunohistochemistry and basic fuchsin staining to examine the distribution of cells in S-phase and of mitotic figures in the mouse hippocampal formation at embyronic day 13. It was noted that cells with BUdR label confined to small clumps of chromatin were located preferentially in small clusters at two levels in the outer two-thirds of the PVE. This position of cells along the radial dimension of the PVE and this pattern of labeling are consistent with the cells having either entered the S-phase just prior to sacrifice or having left the S-phase shortly after exposure to BUdR. Reconstructions from serial sections of the distribution of mitotic figures demonstrated that they also are located in clusters at the ventricular surface. These findings indicate that 1) cells in similar phases of the cell cycle tend to be located adjacent to one another and 2) small clones of PVE cells remain in approximate synchrony as they progress through the cell cycle.

BIRTHDATES OF DEFINED AND MUTUALLY EXCLUSIVE SUBSETS OF TRIGEMINAL GANGLION CELLS. F.A. White and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Many trigeminal (V) ganglion cells respond to neonatal transection of their peripheral axons by dying and previous results from this laboratory (e.g. White et al., <u>I. Comp. Neurol.</u>, 300:249-262, 1990) suggested that V ganglion cells that contained substance P- or calcitonin gene-related peptide- (CGRP) like immunoreactivity were less likely to be lost after neonatal infraorbital nerve lesion than a distinct subpopulation of cells that bound the lectin Bandierea simplicifolia-I (BS-I). To determine whether this differential effect of nerve damage might be related to the times at which BS-I- and CGRP-positive ganglion cells were born, we combined immunocytochemistry and histochemistry with [3H]-thymidine labelling. We also determined the birthdates of the V ganglion cells expressing neurofilament protein (NFP). The distributions of birthdates for the three subpopulations were significantly different. Nearly all V ganglion cells are born between embryonic days (E-) 10.5 and 14.5. Cells containing NFP constituted 22.2% of all cells born on E-10.5, 10% of the cells born on E-11.5, 15.8% of those born on E-12.5, 4.4% of those born on E-13.5, and 1.8% of the cells born on E-14.5. The values for CGRP-containing cells were E-10.5: 0.1%, E-11.5: 0.5%, E-12.5: 1.0%, E-13.5: 14.9%, E-14.5: 14.4%. Those for BS-I-positive cells were E-10.5: 6.0%, E-11.5: 5.9%, E-12.5: 3.8%, E-13.5: 28.7%, E-14.5: 13.7%. These data show that a substantial fraction of the BS-I- and NFP- populations are born prior to CGRP-positive cells. These results are consistent with the conclusion that the latest born of these three subpopulations of V ganglion cells is the most likely to survive neonatal axotomy. NS 28888, DE 07734

MAPPING OF CELL PROLIFERATION PATTERNS IN EARLY EMBRYONIC RHOMBENCEPHALON USING A DOUBLE PULSE-CHASE PARADIGM WITH IODO- AND BROMO-DEOXYURIDINE. I. Maric\*, D. Maric, W. Ma and J.L. Barker, Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

We investigated the spatio-temporal proliferation patterns of cells in E11-E14 rhombencephalon using two thymidine analogues, bromodeoxyuridine (BrdU) and iododeoxyuridine (IrdU). Within a period of 60 minutes timed pregnant E11 Sprague-Dawley rats received multiple intraperitoneal (i.p.) injections of IrdU (50) mg/kg b.w.) in order to achieve maximum labelling of the embryonic proliferative cells. The animals were divided into four groups and sacrificed 2, 24, 48 and 72 hours later. Thirty minutes before sacrifice each rat was given a single i.p. BrdU (50mg/kg b.w.) injection. The E11-E14 embryos were removed from their mothers and the developing rhombencephalic regions either processed for immuno-histochemistry or acutely dissociated into single cell suspensions and further fractionated into germinal zone and mantle zone cells using discontinuous Percoll gradients. Both the cells and corresponding 12um thick coronal tissue sections of rhombencephalon were stained with FITC-conjugated mouse anti-Br-3 and IU-4 MAbs, specific for BrdU and BrdU/IrdU, respectively. In addition, the dissociated cells were counterstained for total DNA content with propidium iodide and their cell cycle profile quantified with a flow cytometer. The results show that at E11 92.8% of rhombencephalic cells proliferate and are located exclusively in the germinal zone. During the period of E12-E13 there is a progressive migration of IrdU labelled cells from the germinal to the mantle zone. The great majority of these IrdU+cells generally do not incorporate BrdU, indicating a terminally divided cell population. However, by E14 there is a dramatic 89.8% depletion of IrdU-labelled cells in the mantle zone suggesting excessive pre-programmed cell death in this region. At this embryonic age there were equal numbers of IrdU-labelled and BrdU-labelled cells in the germinal zone of the developing rhombencephalon.

## CELL SHAPE AND DIFFERENTIATION I

DIFFERENTIATION THERAPY POTENTIATES CHEMOTHERAPY AND HY-PERTHERMIA CYTOXICITY IN HUMAN AND CANINE GLIOMA CELLS IN VITRO. P.S. Ebert & M. Salcman\*. University of Maryland School of Medicine, Baltimore, MD 21201.

Human glioblastoma (U-87MG) and canine glioma (CBT)

cell lines were tested in vitro for their sensitivity to sequential treatment with differentiating agents and chemotherapy or hyperthermia. Both cell lines responded to the inducer combination 1 mM dibutryl cyclic adenosine mo nophosphate/l mM Na butyrate, by the formation of cytoplasmic processes attaining approximately 90% morphological differentiation within 2 days of exposure. Clonogenic viability was assessed by the formation of macroscopic colonies originating from single cell suspensions plated after cultures were exposed to various regimens. The clonogenicity of both lines gradually decreased with lengthening exposure (up to 7 days) to the inducers, but differentiation alone did not eliminate clonogenicity. BCNU at 5 µM for 1 hr administered to both lines before or after 3 days of treatment with inducers potentiated their antiproliferative effects. Sequential treatment of CBT cells at 44°C for 30 min followed by inducers produced an additive potentiation of cell killing, while the reverse sequence did not. This study demonstrates that differentiation therapy can potentiate the therapeutic effects of hyperthermia and chemotherapy in glial tumors and can thereby reduce the concentration of cytotoxic drugs required to achieve effective cell killing.

PROCESS OUTGROWTH OCCURS MORE RAPIDLY IN N1E-115 CELLS AS PASSAGE NUMBER INCREASES. M.Heil & P.Cobbett Dept.Pharmacol./Toxicol.& Neuroscience Prog., Michigan State Univ., East Lansing, MI 48824.

Cells of lines which are derived from the murine sympathetic neuroblastoma designated C1300 have been used as models to study neurite outgrowth. These cells proliferate when cultured in serum containing medium (SCM) but differentiate morphologically (i.e., become process bearing) when transferred to serum free medium (SFM). The maximal proportion (\$60%) of differentiated C1300 derived Nb2A clonal cells was attained within 3hrs of being placed in SFM (Gurwitz & Cunningham, 1988). Similarly, cells of the related C1 clone are 90% differentiated within 24hrs (Schubert et al., 1971). In contrast Cosgrove & Cobbett (1991) reported that differentiation of N1E-115 cells in SFM started within 2 days but was incomplete even after 8 days. We have now examined whether N1E-115 cells of different passage age differentiate at different rates. Cells of passages 12, 17 and 23 were plated at the same density in SCM which after 24hrs was replaced by SFM. Photographs of the cells were taken after 0.5, 1, 3 and 6 days in SFM. The fraction of cells that were process bearing and the mean process length were then determined. We found that the fraction of cells which were process bearing and the mean process length were smaller for cells of passage age 12 compared to cells of passages 17 and 23 after 1 day in SFM. This pattern continued through days 3 and 6. The data suggest that passage age is an important determinant in differentiation of N1E-115 cells and perhaps of other model neuronal cells.

PC12 CELLS GROWN IN SPINNER CULTURES RETAIN CHARACTERISTIC CYTOLOGICAL MARKERS AND MORPHOLOGICAL RESPONSES TO

CYTOLOGICAL MARKERS AND MORPHOLOGICAL RESPONSES TO NERVE GROWTH FACTOR. M. Palmatier\*, B. Frydel, C. Barcus, J. Embree. T. Wright, F. Kaplan, CytoTherapeutics, Inc. Providence, RI 02906

The PC12 cell line is derived from a rat pheochromacytoma, a tumor of the adrenal chromaffin cells. Under attached growth conditions, PC12 cells express cytological markers, thy 1.1, tyrosine hydroxylase and chromogranin, consistent with the species and cell type of origin. They also are morphologically responsive to NGF and subsequently stain for neurofilament, indicative of the development of the chromaffin cell from the neural crest.

We grew PC12 cells in suspension to determine if the cells retained the

We grew PC12 cells in suspension to determine if the cells retained the expression of cytological markers and morphological responses to NGF of attached PC12 cells. PC12 cells were grown in spinner cultures at 30-100 rpm, 37°C, and 5-7% CO2. The cultures were seeded at 1-5 X  $10^4$  cells/ml

rpm, 37°C, and 5-7% CO2. The cultures were seeded at 1-5 X 10<sup>4</sup> cells/ml and grown to 0.5-1 X 10<sup>6</sup> cells/ml in PC12 medium (RPMI-1640 with 2 mM glutamine, 5% fetal bovine serum, and 10% donor horse serum).

For cytological staining, PC12 cells from spinner cultures were fixed immediately or plated onto collagen-coated slides in PC12 medium and allowed to attach for 12 to 72 hours. The cells were fixed in 4% paraformaldehyde and stained for thy 1.1, tyrosine hydroxylase, or chromogranin. For NGF responsiveness, PC12 cells from spinner cultures were plated onto collagen-coated slides in PC12 medium supplemented with 0, 10, 50, or 100 ng/ml mouse NGF. The medium was changed every 4 days. At the end of 2 weeks, the cells were scored for neurite outgrowth, fixed in 4% paraformaldehyde, and stained for thy 1.1, neurofilament, or chromogranin.

At the end of 2 weeks, the cells were scored for heurite outgrown, taken in 4% paraformaldehyde, and stained for thy 1.1, neurofilament, or chromogranin. PC12 cells grown in spinner cultures stained for thy 1.1, tyrosine hydroxylase, and chromogranin. Greater than 80% of the spinner PC12 cells responded to NGF and stained for neurofilament. PC12 cells retain characteristic cytological markers and morphological responses when grown in spinore returns. spinner cultures

BIOCHEMICAL, IMMUNOLOGICAL, AND MOLECULAR CHARACTERIZATION OF HCN-1A CELLS. M. Charlton M. Connelly, J. Lancaster, A. Snowman, L. Williams and P. Sweetnam. Dept. of Biology, Georetown University, Washington DC 20057; NINCDS, Bethesda, MD 20892; NovaScreen. Baltimore, MD 21224.

Ronnett, et al., (Science, 1990) recently described the establishment of a human cerebral cortical neuronal cell lines (HCN-1A) using tissue obtained from patient with unilateral megalencephaly. These cells were shown to differentiate in response to a mixture of NGF, IBMX, and dibutryl cAMP. Several other agents have now been examined (EGF, bFGF, PDGF, and ILGF-1) and none appear to induce differentiation. Following differentiation, HCN-1A cells exhibit a neuronal morphology and neurofilament, tetanus, and synaptophysin-like immunoreactivity, but not R-mAB, O1, or GFAP-like immunoreactivity. The cells express a variety of neurotransmitters and neurotransmitter receptors. They stain positively for GABA and GAD but do not express the GABA uptake site as determined by [3H]GABA labeling. PCR analysis has revealed that these cells express several  $\mathsf{GABA}_\lambda$  receptor subunits but not the  $\mathsf{GABA}$  uptake site. In addition, the +MK801 binding site, and the endothelin (ET<sub>B</sub>) receptor have been identified by radioligand receptor binding. These studies confirm that the HCN-1A cells express numerous neuronal elements following differentiation.

DESTABILIZATION OF THYMOSIN BETA-10 mRNA WITH AN ANTISENSE DEOXYOLIGONUCLEOTIDE INHIBITS GROWTH

DESTABILIZATION OF THYMOSIN BETA-10 mRNA WITH AN ANTISENSE DEOXYOLIGONUCLEOTIDE INHIBITS GROWTH OF NEUROBLASTOMA CELLS. A.K.Hall.,T Lysz\*., J.J.Seebode and R.J.Irwin Jr., Dept of Surgery, UMDNJ-NJ Medical School, Newark, NJ 07103, U.S.A. Thymosin beta-10, a 5Kda, retinoid-responsive, putative G-actin sequestering protein, is known to be expressed at high levels in the embryonic CNS and proliferating neuroblastoma cells [see J.Mol.Neurosci 2:229-237,1991]. It was thus reasoned that as retinoic acid-induced regulation of this gene precedes differentiation, the thymosin beta-10 protein may function as an independent oncogenic factor per se. As a first pass at studies designed to focus on this possibility, we made use of synthetic antisense deoxyoligonucleotides to neutralize expression of the endogenous beta-10 gene in neuroblastoma cells. An antisense deoxyoligonucleotide (made complementary to the first 20 bases starting at or the endogenous beta-10 gene in neuroblastoma cells. An antisense deoxyoligonucleotide [made complementary to the first 20 bases starting at the AUG initiation codon of the beta-10 mRNA] at a concentration of 30uM induced a >40% reduction of steady-state beta-10 mRNA levels; this effect was dependent upon medium serum concentration. Partial neutralization of beta-10 gene expression significantly inhibited neuroblastoma cell proliferation. These findings, together with previous observations suggest that thymosin beta-10 (and perhaps other related proteins) may function as a novel class of oncogenes.

## 21.7

"DIFFERENTIATION INDUCTION" IN NEUROBLASTOMA CELLS. N. F.

Schor\*. University of Pittsburgh, Pittsburgh, PA 15213
Neocarzinostatin (NCZ) is a chemotherapeutic agent which induces morphological maturation in human and murine neuroblastoma (nb) cells. In murine cells, this is associated with an increase in cell surface neural cell adhesion molecules (N-CAM's), and cell death within 14 days. Unlike maturation, however, there is no change in expression of GAP-43 or MAP-1, and no detectible message for or morphological evidence of neurofilament proteins in these cells. Nerve growth factor (NGF) does not after the effects of NCZ upon murine cell growth rate, morphology, or longevity. Treatment of murine nb cells with NCZ results in loss of their tumorigenicity. Treatment of low passage number SK-N-SH human nb cells with NCZ results in marked elongation and enlargement of these spindle-shaped cells, with bipolar others of these spindle-shaped cells, with bipolar elongation and enlargement of these spindle-shaped cells, with bipotar extension of processes. The percentage of the cells which undergo this morphological change is dose-dependent, as is the decrement in the rate of cell culture growth. Unlike murine cells, low passage number human cells maintained in the presence of NGF (100-1000 ng/ml) are "protected" from the cytostatic and morphologic effects of NCZ. Furthermore, in contrast to low passage number human cells, higher passage number cells (no exposure to NCZ) die within 24 hours after exposure to NCZ without undergoing morphological change. This change in response to NCZ is not a function of altered sensitivity to the drug. Concomitant with this change in response to NCZ with increasing passage number, human cells lose their avid binding to tissue culture plastic. Western blot assay for N-CAM using a polyclonal antibody revealed that low passage number cells contain large amounts of two reactive proteins centered at 80 kD molecular weight, and smaller amounts of a 120 kD molecular weight reactive protein. In contrast, homogenates of up to ten times as many high passage number cells contained no detectible anti-Nten times as many high passage number cells contained no detectible anti-N-CAM antibody-reactive proteins. These studies indicate that the effects of NCZ on no cells are highly cell line and passage number dependent, and differ significantly from the normal induction of neuronal differentiation.

CELLS CULTURED FROM ADULT RAT BRAIN CAN DIFFERENTIATE INTO NEURONS OR OLIGODENDROCYTES L.A. DeGiorgio and J.P. Blass\*, Cornell Univ. Med. Coll. at Burke Med. Res. Inst., White Plains, NY 10605

Cells derived from adult rat cerebral cortex proliferated in vitro when supported by a modified N2 medium including nerve growth factor (NGF), basic fibroblast growth factor (bFGF) and 20% FCS. Initial antigenic characterization revealed the coexpression of neuronal markers (200 kDa and 160 kDa MW neurofilament proteins) with glial markers (\$100 protein and the oligodendrocyte marker MBP. Vimentin was also strongly visualized. The RB3A cells also demonstrated positive reactivity to antibodies directed against the neurotransmitter synthetic enzymes tyrosine hydroxylase (IH) and glutamate decarboxylase (GAD) was visualized. Serotonergic and cholinergic markers were not found. When exposed to N2 medium lacking growth factors and serum, approximately 50% of the RB3A cell population formed MBP+/GC+/NF-Single putative oligodendrocytes were less frequently observed (3-4%). The remaining cells were morphologically and antigenically disparate. Attempts to induce astrocyte differentiation by culturing cells in DMEM/10%FCS were unsuccessful. However, these cultures retained the RB3A parental antigenic profile. It was found that 90% of cells maintained solely in DMEM/10%FCS and then transferred to N2 medium containing NGF, bFGF and dibutyryl cAMP underwent neuronal differentiation. Such cells possessed phase-bright rounded somas that extended neurites strongly reactive to antibodies directed against the NF triplet and unresponsive to both anti-vimentin and anti-MBP. TH-immunoreactivity was intensified while anti-GAD reactivity was diminished. This study suggests that a reservoir of cells persists in adult rat brain retaining the capacity to differentially generate neurons or oligodendrocytes

### 21.6

TERMINAL DIFFERENTIATION OF A HUMAN NEUROBLASTOMA CELL LINE. A.H. Ross\*, W. Poluha and D. Poluha. Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, MA 01545.

Human neuroblastoma cell line SHSY5Y expresses both the 75 kDa low-affinity nerve growth factor (NGF) receptor and the trk protooncogene and is responsive to NGF. Treatment of these cells with NGF resulted in neurite extension, but not in cessation of cell growth. SHSY5Y cells were treated with NGF and a pulse of cell cycle blockers aphidicolin, hydroxyurea or thymidine. Most of the cells extended long neurites (>400  $\mu$ m). The response of the neuroblastoma cells was synergistic, i.e., differentiation was much greater for cells treated with NGF and aphidicolin than for cells treated with either drug alone. If maintained in NGF, the differentiated cells were stable for at least a month and were mitotically inactive. The sequence of events leading to differentiation was assessed. After about 1 day of treatment of SHSY5Y cells with NGF and aphidicolin, the protooncogene c-myc is downregulated. The cells cease to proliferate and commit to differentiation after about 3 days treatment. These two events could not be temporally distinguished and may be the same event. In preliminary studies, expression of the c-ret protooncogene and the id-2 gene were upregulated during differentiation. mRNAs for cdc2, cdk2, cyclin A and cyclin B were not downregulated.

## 21.8

MORPHINE AFFECTS THE MORPHOLOGY OF DEVELOPING TYPE 1 ASTROCYTES BY INCREASING INTRACELLULAR CALCIUM. A. Stiene-Martin\*, M.P. Mattson and K.F. Hauser, Depts. of Clin. Sci., Sanders-Brown Ctr. on Aging, and Anat. and Neurobiol., Univ. Kentucky Med. Ctr., Lexington, KY 40536-0080.

Opiate drugs can suppress the rate of proliferation while increasing orphale drugs can suppress the rate of prointeration while increasing morphologic differentiation in developing type 1 astrocytes *in vitro*. To address whether Ca<sup>2+</sup> has a role in opiate-dependent astrocyte growth, astrocyte-enriched cultures derived from newborn ICR mouse cerebra were treated with Ca<sup>2+</sup>-free DMEM media containing Ca<sup>2+</sup> concentrations of 0, 0.3, 1.0, and 3.0 mM. Additional cultures were treated with DMEM containing the Ca<sup>2+</sup>ionophore A23187. The cultures were grown for 5-6 days, fixed, and stained immunocytochemically for glial fibrillary acidic protein (GFAP). Areas of single, GFAP+, type I astrocytes were measured using computer-assisted image-analysis. There was a positive correlation between astrocyte area and  $[Ca^{2+}]$ . Morphine (1 There was a positive correlation between astrocyte area and  $[Ca^{2+}]$ . Morphine (1  $\mu$ M) had an additive effect at calcium concentrations of 0.3 and 1.0 mM. Morphine had no effect on astrocyte area at high  $[Ca^{2+}]_0$ , in the absence of  $Ca^{2+}$  or in the presence of 1  $\mu$ M A23187. Fluorescent microscopic measurements of intracellular  $Ca^{2+}([Ca^{2+}]_i)$  in individual identified cells using Fura-2 indicated that 1  $\mu$ M morphine significantly increased  $[Ca^{2+}]_i$  in type 1 astrocytes within 1 min following exposure and this effect was still apparent at 48 h. Morphine-dependent increases in astrocyte area, and in  $[Ca^{2+}]_i$ , were completely blocked by 3  $\mu$ M naloxone. The data suggest that morphine affects the morphologic differentiation of type 1 astrocytes by increasing  $[Ca^{2+}]_i$ , and that  $Ca^{2+}$  normally mediates cellular differentiation in developing type 1 astrocytes. IDENTIFICATION OF NEURONS AND GLIA IN CULTURE; DIRECT NEURONAL LOCALIZATION WITH NEUROTAG D.S. Grega , Nousck-Goebl and T.J. Cavanagh. R&D Division, Boehringer Mannheim Corp. and Indiana Univ. School of Medicine, Program in Medical Neurobiology, Indianapolis, IN 46250

Neurons and glia can be distinguished based upon their unique cellular epitopes. Tetanus toxin, in addition to being toxic, has been shown to bind to gangliosides in neuronal membranes, which make it a good, if somewhat dangerous neuronal marker. Tetanus toxin C fragment (TTC, papain digestion digestion of the native toxin) retains the binding properties of the tetanus toxin with a reduced hazard. Recombinant TTC functions indistinguishably from the natively derived TTC with no risk of contamination by the native toxin Neurotag<sup>M</sup> is recombinant TTC conjugated to either fluorescein (Green) or rhodamine (Red) which can be used to directly label neurons in culture.

We report labeling data using NGF-treated, mixed spinal cord/dorsal root

ganglia (SC/DRG) cultures derived from fetal rat. Glial fibrillary acidic protein (GFAP) is the principle (and characteristic) component of intermediate filaments of the cytoskeleton within astrocytes. Neurons and astrocytes were localized in these cultures using Neurotag™ and anti-GFAP respectively. Neurotag™ labeled neuronal surfaces, permitting the visualization of soma and processes. Even very fine branches and processes were visible. Anti-GFAP labeled the cytoskeleton of stellate astrocytes, whose morphology and distribution were distinct from the neurons. Good cellular resolution was observed with both markers, permitting excellent discrimination of these two important neural cell types.

ULTRASTRUCTURAL AND IMMUNOCYTOCHEMICAL ANALYSIS OF DIFFERENTIATION IN A HUMAN CORTICAL NEURONAL CELL LINE (HCN-1A). R.L. Moses\* and J.W. Haycock. Depts. Anat. and Biochem. & Molec. Biol., LSUMC, New Orleans, LA 70119

A neuronal cell line (HCN-1A) cloned from the cerebral cortex of a megalencephalic patient undergoes process formation when treated with a combination of cAMP and nerve growth factor (Ronnett et al., Science 248, 603 (1990)). In the present studies, treated and untreated HCN-1A cells were characterized by phase-contrast and immunofluorescence light microscopy (LM) as well as by scanning (SEM) and transmission (TEM) electron microscopy.

After treatment, the normally epithelioid cells became highly branched via a process of cytoplasmic contraction (vs. neurite extension). orders of branching were observed by both LM and SEM. By TEM, processes were heterogeneous in terms of membranous organelles and cytoskeletal elements. Microtubules and intermediate filaments were both present in the majority of processes and were oriented parallel to the long axes of the processes. Larger processes contained a variety of membranous organelles including RER. The very thin processes often contained only cytoskeletal elements and small vesicles. Although varicosities along their lengths contained a wider variety of membranous organelles, no immunocytochemical (e.g., synapsin) or ultrastructural hallmarks of synaptic profiles were discerned. Moreover, although some neurons appeared to progress toward a more stable and polarized phenotype, distinction of axonal vs. dendritic processes was not apparent either immunocytochemically or by TEM.
[Cells were provided through The Johns Hopkins University Office of Technology Licensing.]

STIMULUS EVOKED CHANGES IN CALCIUM LEVELS ARE DEVELOPMENTALLY REGULATED IN CULTURED CEREBELLAR GRANULE NEURONS. J. Holliday\*, and D.L. Gruol. Department of Neuropharmacology, The Scripps Research Inst., La Jolla, CA 92037.

The development of cultured cerebellar granule cells has been well studied and has been found to be dependent upon calcium influx through either voltage or ligand gated channels (see Gallo et al., 1987). In order to determine how calcium levels are controlled during differentiation and subsequently regulate further development, we have studied calcium responses to a variety of stimuli using fura-2 imaging. Neurons were cultured as either purified or mixed cell types or as organotypic slice cultures from 8 day rats. This will allow us to assess the effects of interactions between various cell types on the maturation of granule cell calcium responses.

In mixed cell cultures, virtually all granule neurons responded to KCl depolarization from the first day in culture. The magnitude of the response increases during the first week in culture, from less than 3 to at least 10 times the resting concentration of calcium. The response was inhibited by the voltage-gated calcium channel antagonist, nifedipine. In contrast, the percentage of cells responding to the neurotransmitter, glutamate, increased during the first week in culture and developmental changes in the amplitude of the response were less evident than observed with KCl depolarization. The developmental profile of caffeine responses was similar to that of glutamate suggesting that granule cells become better able to amplify calcium responses through the calcium dependent release of calcium from intracellular stores during the first week in culture. After 12 days in culture, all responses appear to be more robust in the organotypic cultures. Supported by #MH47680.

## 21.15

Serum affects neuronal cell growth and channel expression M. L. Zhang, Q. Y. Liu, Y. Y. Zeng, E. Karpinski, R. Berdan\* & P. K. T. Pang

Dept. of Physiology, University of Alberta, Edmonton, Canada

Neuroblastoma cells (N1E-115 cells), which were derived from undifferentiated murine neuroblastomas, were normally maintained in DMEM (Dulbecco's modified Eagle medium) with 10% FBS (fetal bovine serum) and antibiotics (penicillin, neomycin and strentomycin). Fetal bovine serum usually provides nutritional needs for cell growth. When the neuroblastoma cells were cultured in DMEM with 10% FBS, they grew fast with few neurites. Data from our experiments show that <sup>3</sup>H-thymidine incorporation was serum dependent with maximal response at 1.25% FBS in the media (cell density 5x106/ml). However, when the cells were cultured in DMEM without FBS, the cells grew slowly and neurites appeared from the 2nd day of culture. The percentage of the cells with neurites significantly increased and the density of the cells was markedly reduced. When neuroblastoma cells were cultured normally with 10% FBS, the T type Ca2+ channel current was observed. However, when the cells were cultured without FBS for approximately 1 month, the T channel current disappeared. These cells expressed an inward Ca<sup>2+</sup> channel current which showed slow inactivation. This current was sensitive to Bay K 8644 and completely blocked by 2 mM La<sup>3+</sup>. Therefore, these results suggest that serum-free media may promote neurite growth and alter the channel expression in neuroblastoma cells.

CHARACTERIZATION OF STRIATALLY-DERIVED IMMORTALIZED CELL LINES. M. Giordano\*, H. Takashima. M. Poltorak, H.M. Gellera and W.J. Freed. NIMH Neuroscience Center at St. Elizabeths, Washington DC 20032; <sup>a</sup>Department of Pharmacology, UMDNJ-RWJMS, Piscataway NJ 08854.

From primary cultures of fetal rat (E14) striatal primordium, immortalized cell lines were produced by infection with a retroviral vector containing the temperature-sensitive tsA58 mutant of the SV40 vector containing the temperature-sensitive isA38 mutant of the SV40 large T antigen. Cultures were maintained in chemically-defined medium or DMEM:F12 containing 10% FCS for 5-21 days and then exposed to geneticin (200 ug/ml). Clones were initially screened for expression of SV-40 large T antigen at the permissive temperature (33°C). The 40 clones initially obtained were classified according to cellular morphology at 33°C: (a) small with no processes; (b) multipolar with short processes; (c) elongated or fibroblast-like, usually unipolar or bipolar; or (d) large cytoplasm without processes. Cells with type "b" and "c" morphology differentiated and developed processes when exposed to dibutyryl cAMP, IBMX, and NGF at the non-permissive temperature (39.5°C), while cells of type "a" and "d" did not change. Type "a" cells were positive for vimentin whereas most clones of the "b" and "c" types were vimentin-negative. Four cell lines (one clone, and three subclones derived from a second clone) of the multipolar "b" type were found to be positive for MAP. 2, expressing immunoreactivity on short cytoplasmic extensions and on some, but not all, of their processes. These cells were selected for further characterization.

## 21.14

MORPHOGENESIS AND SURVIVAL OF MOTONEURON SUB-POPULATIONS IN VITRO. C.E. Henderson\*, H. Ansanay-Alex, E. Bloch-Gallego, B. Buisson, W. Carnu, H. El M'Harndi, A. Gouin and C. Mettling. Biochimie CNRS-INSERM, Montpellier, France. Soon after motoneurons (MN) are born, their axons grow out through

the rostral half of each somite while dendrites develop within the spinal cord. From E6 on in the lumbar cord, half the MN die. At brachial levels, cell death begins later and occurs more slowly. We used cultures of purified MN sub-populations to analyse the extrinsic and intrinsic

factors regulating these phases of development.

Explants of rostral and caudal somite from E3 embryos were grown for 3 days until they had formed monolayers; they were still labeled appropriately by markers such as peanut lectin and M7412 antibody (gift appropriately by markets such as peants ectin and MY-12 animoty (gift of H. Tanaka). Astrocyte monolayers were prepared from E6 chicken spinal cord and neonatal rat cortex. Purified MN were seeded on the monolayers. After 3 days, their morphology differed markedly: on astrocytes, they were highly multipolar, on rostral somite they grew well but were pseudo-unipolar, and on caudal somite they failed to grow, suggesting that the signals for MN morphogenesis are to a large extent present at the surface of cells in their environment.

Using a modified metrizamide method that enriches for MN with an acute requirement for trophic support, MN were purified from brachial and lumbar regions of E5 neural tube. Extracts of wing and leg at E6 showed identical survival-promoting activity, whatever the motoneurons used. However, brachial MN died more slowly in the presence of any given extract than did lumbar MN, suggesting that cell death *in ovo* is at

least partly regulated by factors intrinsic to the motoneurons. This work was supported by AFM and IRME.

## 21.16

NEURONAL PROPERTIES OF IMMORTALIZED RAT SEPTAL CELL LINES. J. Kwon<sup>1</sup>, E. M. Eves\*<sup>1</sup>, and B. H. Wainer<sup>1</sup>,<sup>2</sup>. Depts. <sup>1</sup>Pharm. & Phys. Sci., and <sup>2</sup>Path., The University of Chicago, Chicago, IL 60637.

The immortalization of embryonic day 14-15 rat septal neuronal progenitor cells via retroviral transduction and their initial characterization was described previously (Soc. Neurosci. Abs. 17:37, 1991). Agents that act to increase intracellular cyclic AMP levels, such as forskolin and dibutyryl cAMP, induced a morphological change from a flat epithelioid morphology to a highly effective control of the contro refractile neuron-like morphology within a period of 4 hours. Subsequent studies have shown that 20µM norepinephrine and 100µM dopamine produce a similar rapid morphological response while other transmitter agonists such as carbachol, galanin, l-glutamate, histamine, serotonin, substance P, vasopressin, and VIP do not. Basic fibroblast growth factor also induces a similar morphological change but with a time course of 48 hours. Several cell lines express measurable levels of either choline acetyl transferase or GABA. The data indicate that the septal transductant cell lines express characteristics displayed by developing septal neurons. Furthermore, the cell lines may provide a good model for the study of cellular functions that are regulated by the activation of specific receptors for neurotransmitters and growth factors. (Supported by NS 25787, the IDPH Alzheimer's Disease Research Fund, and GM 07151-17.)

DIFFERENTIATION OF PRIMARY BASAL FOREBRAIN NEURONS IN COCULTURE WITH HIPPOCAMPAL AND SEPTAL CELL LINES. M. Downen'. C. Christian, E. Eves, & B. H. Walner, Dept. of Pharm. & Physl. Sciences, U. Chicago, Chicago, IL 60637

A "bilaminar" culture system was used to investigate the survival and differentiation of developing basal forebrain (BF) neurons. Dissociated E16 BF cells on coversilps were inverted above a cell feeder layer. The cultures were treated with an antimitotic agent at 2 days to arrest glial proliferation. The ability of immortalized progenitor cell lines from E17 hippocampus and E15 septum to support the maturation of developing BF neurons was compared to that of primary forebrain glia. The feeder layer consisted of primary glial cells, a hippocampai glial line (H19-5) or neuronal line (H19-7), a septal neuronal line (AS583-6), a neuroblastoma line (N18TG2), a glioma line (C6) or a fibroblast line (NIH 3T3). Survival of BF neurons was assessed using the intravital dye, fluorescelin diacetate. The hippocampai lines were as effective as primary glial in the maintenance of viability of BF neurons, while the septal line was somewhat less effective. N18TG2 cells were only 50% and C6 glioma cells were only 20% as effective as glia in maintaining viability. BF neurons did not survive in the presence of NIH 3T3 cells. Differentiation of the low affinity nerve growth factor receptor (LNGFR). The proportions of LNGFR+ BF neurons were 5.8% over primary glia, 5.6% over H19-5, 9.2% over H19-7, and 2.6% over AS583-6. These data indicate that immortalized cell lines derived from the hippocampus can support survival of BF neurons in blaminar culture appears to be differentially modulated by different feeder layers: it is equivalent in occulture with H19-7 cells, and decreased in coculture with AS583-6. (Supported by NS 25787; IDPH Althelmer's Disease Research Fund)

## 21.19

EFFECTS OF POSTNATAL MOSSY FIBER DEVELOPMENT ON CA3 APICAL DENDRITES IN DIFFERENTIALLY REARED MONKEYS. S.J. Siegel \*1, P.R. Hof 1, 2, G.W. Kraemer 3, W.T. McKinney 3, and J.H. Morrison 1, 2, 1 Fishberg Res. Ctr. for Neurobiology and 2 Dept. of Geriatrics and Adult Development, Mt. Sinai Sch. of Med., New York, NY 10029, 3 Dept. of Psychiatry, Univ. of Wisconsin Sch. of Med. Madison, WI 53792.

The pattern of pyramidal and granule cell development in the primate hippocampal formation has been examined with respect to the effect of

hippocampal formation has been examined with respect to the effect of the mossy fiber system on apical dendrites of CA3 pyramidal cells. Other investigators have previously demonstrated in monkeys that postmitotic pyramidal cells in the CA3 subfield only develop specialized postmitotic pyramidal cells in the CA3 subfield only develop specialized dendritic appendages called thorny excrescences following ingrowth of mossy fibers during the first six postnatal months. Based on our earlier observation of neurofilament changes in the granule cell somata of socially deprived monkeys (Siegel et al. Soc. Neurosci. Abstr. 17, 895 1991), studies of the development of the mossy fiber system and apical dendrites within CA3 have been undertaken. Antibodies to MAP2, which label CA3 pyramidal cells, calbindin, which label axons within the entire stratum lucidum, and phosphorylated neurofilament, which label axons within a portion of stratum lucidum have been used to characterize mossy fiber development within stratum lucidum and the coincident organization of CA3 apical dendrites. We postulate that mossy fiber have an organizing effect on dendritic spacing and bundling of apical baye an organizing effect on dendritic spacing and bundling of apical dendrites within CA3. Additionally, our results suggest that this organizing effect is delayed or disrupted in monkeys which have been raised in social deprivation. Supported by the John D. and Catherine T. MacArthur Foundation and the Brookdale Foundation.

CHARACTERIZATION OF GABA-ERGIC NEURONS IN HIPPOCAMPAL CULTURES. D.L. Benson.\* F.H. Watkins, O. Steward, and G. Banker, Department of Neuroscience, University of Virginia School of Medicine,

Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, Virginia 22908.

Neurons normally develop in a complex environment where genetically determined patterns of development can be influenced or modified by epigenetic factors. When embryonic hippocampal neurons are dissociated and grown in culture, they must develop in comparative isolation, and it remains to be determined how closely they resemble their counterparts in situ. To examine this question, we analyzed the development of a specific subpopulation of hippocampal neurons, identified by their immunoreactivity for GABA. After two weeks in culture, 11-15% of the total number of neurons are GABA-immunoreactive, which is similar to the proportion of GABA cells in the hippocampus in situ. This proportion remains relatively constant between 4 and 35 days in culture. GABA-immunoreactive axons arborize extensively throughout the cultures, contacting both GABA-negative and GABA-positive neurons. Most of the cultured GABA-immunoreactive neurons can be separated into three broad categories based on their morphology: 1) large cells, frequently triangular in shape, with beaded axons and only two or three major dendrites, 2) medium to small cells that are fusiform in shape and 3) medium sized multipolar cells, some of which have large straight spines. These three subclasses correspond in many respects to distinct classes of nness lines successes of many respects to distinct classes or non-pyramidal neurons that have been previously identified in situ. The results of the present study would suggest that the basic form of GABA neurons is endogenously determined. Supported by NIH grant NS23094; DLB was recipient of postdoctoral fellowship. NS07199.

### 21.20

HORPHOLOGIC STUDY OF THE HYPOTHALAMIC NUCLEI IN THE HUDE MICE DURING ITS POSTMATAL DEVELOPMENT, 1. de 18 ROSS A., G. G. OTTZ Forta-Velanco, F. Mantiner-sandoval. Universidad Autónama de Guadalajara, México., Unidad Invest. Biomed. Occte., I.M.S.S. Guadalajara, Jal., Unidad Invest. Biomed. Centro Médico Siglo XXI., I.M.S.S., México, D.F.

Mutant mouse strain ( Bulb/c, An Bom nu/nu) is characterized by the absence of the thymus and some endocrine deficiencies such as alterations in the growth and maturation of some tissues, mainly the CNS, particulary the cerebral and cerebellar cortices, although the remaining SNC structures develop prenatally in rodents. This study reports our comparative morphological observations in some hypothalamic nuclei of 40 male mice: 20(nu/nu) and 20 non-mutant mice (nu/-), at postnatal age 15,30,60 and 90 days (n=5). Frontal sections were used for Hematoxylin and Eosin stain. Identification of the nuclei was based upon the numenclature of Paxinos and Watson. Selected nuclei were the Suprachiasmatic (SCh), Periventricular (Pe), Paraventricular (Pe), Anterior Mypothalamic arca (ANA), Supraeptic (So), and Medial Preoptic Area (MPA). In the non-mutant mouse (nu/-) of all ages ovoid cells with bosophil cytoplasm and central nucleolus were identified in (SCh). (ANA) and (MPA). A monolaver of flattened cells, with a thin thymus and some endocrine deficiencies such as alterations in the growth and identified in (SCh), (AHA), and (MPA). A monolayer of flattened cells, with a thin cytoplasm was seen lining the wall of the III ventricle in the area corresponding to Pe and Pe. Additionally, an abundant and well distributed pockage of cells was seen in all nuclei. In the mutent mouse (nu/nu) of 15 postnatal days, the periependymal zone had a spongy-like appearance in the area corresponding to (Po) periependymal zone had a spongy-like appearance in the area corresponding to (Po) and (Pa) larger, irregular from flottened to cuboidal cells were arranged into two or three layers lining the cavity of the third ventricle. The cells were larger than those observed in the control group and showed a thin acidophilic cytoplasm, hyperchromatic nucleus, 2 or more nucleoil, and cilia-like structures in the apical region of some cells. At 30,60 and 90 postanated days (MPA) showed scattered cells; SCh had cells with hyperchromatic nuclei and pink granules in their cytoplasm. (SO) and (AMA) depicted irregular shaped cells with a thin cytoplasm, hyperchromatic nucleus, and 2 or more nucleoil. These morphologically differences between (nu/-) and (nu/nu) strains suggest the presence of clear signs of delay in cell migration proceedly due to a deficiency in the growth and development of the SNC of this nucle mouse that may be associated with some neuroendocrine alterations previously renorted.

## AXON GUIDANCE MECHANISMS AND PATHWAYS I

SIGNAL TRANSDUCTION BY RETINAL GROWTH CONES NAVIGATING IN VIVO: THE ROLE OF FILOPODIA AND SECOND MESSENGERS. C.-B. Chien D.E. Rosenthal . W.A. Harris, and C.E. Holt. Dept. of Biology, UC San Diego, La Jolla, CA 92093-0322.

During initial development, Xenopus retinal axons navigate along a stereotypical path to their target using cues seen by their growth cones. To study the signal transduction mechanisms involved, we expose the embryonic optic tract by removing the skin, dura, and eye from one side of the head, and then bath-apply various drugs. Effects on pathfinding are assayed by HRP-filling the optic projection, and then correlated with effects on growth-cone dynamics, assayed by high-magnification time-lapse imaging of dil-stained growth cones.

To test this pharmacological strategy, we have first used cytochalasins, which disrupt microfilaments. Experiments in grasshopper limb bud [Bentley and Toroian-Raymond (1986) Nature, 323:712] have shown that cytochalasins disrupt pathfinding, presumably by their removal of growth cone filopodia. Using time-lapse video, we find that  $0.15\,\mu g/ml$  cytochalasin B (CB) removes nearly all filopodia and slows the advance of the growth cone, while leaving lamellipodia intact and active. Both effects are reversed by washing out the drug. After 18-24 h in CB, HRP-filled retinal axons display a characteristic pathfinding error, missing their normal posterior turn towards the tectum and instead continuing dorsally within the diencephalon. Though this could be an indirect effect, the most parsimonious explanation is that intact filopodia are required in order to

make the posterior turn, perhaps playing a sensory role.

We are now screening a variety of drugs (eg cAMP and cGMP analogs) that could perturb signal-transduction pathways involved in pathfinding, and will report on any results.

THE ORGANIZATION OF F-ACTIN AND MICROTUBULES IN GROWTH CONES EXPOSED TO A BRAIN-DERIVED COLLAPSING FACTOR. J.Fan, S.G.Mansfield, T.Redmond, P.R. Gordon-Weeks & J.A.Raper\*, Dept. Neurosci., U. Penn., Phila., PA 19104
Growth cones from dorsal root ganglia grown in culture can be induced to collapse by a brain derived collapsing factor (Raper & Kapfhammer, 1990). We studied the organization of F-actin and microtubules during collapse induced by enriched collapsing factor. Growth cones before or during collapse were analyzed by time-lapse videomicroscopy and stained for F-actin with Rhodamine-Phalloidin and for tyrosinated \( \alpha \)-tubulin with FITC-YL1/2.

Actin: Time-lapse video studies showed that the behavior of

Phalloidin and for tyrosinated  $\alpha$ -tubulin with FITC-YL1/2. Actin: Time-lapse video studies showed that the behavior of growth cones in response to 500x enriched collapsing factor was similar to their behavior in response to 2  $\mu$ M cytochalasin B, suggesting that collapsing factor inhibits actin polymerization. We measured the spatial pattern of F-actin in control and collapsing factor treated growth cones by comparing the distribution of Rhodamine-Phalloidin to a fluorescent marker for all proteins. In control growth cones, the concentration of F-actin in the leading edges is about twice as high as in growth cone centers. In growth cones treated with collapsing factor for 5 min, the concentration of F-actin in the leading edges decreases dramatically, while the concentration in the centers remain unchanged. These results suggest that collapsing factor causes net depolymerization of actin.

Microtubules: Growth cones treated with 10x enriched collapsing factor for 0, 5, 10, or 60 min were stained with F17C-YL1/2, Growth cones were also analyzed using time-lapse videomicroscopy before

cones were also analyzed using time-lapse videomicroscopy before and during collapse, and then stained with FITC-YL1/2. We found no evidence that collapsing factor stimulates polymerization or depolymerization of microtubules.

ROLES OF SECOND MESSENGERS IN CONTROL OF PIONEER NEURITE OUTGROWTH AND PATHFINDING IN THE

GRASSHOPPER LEG. K. L. Lankford\* Dept. of Mole. & Cell Biol, University of California, Berkeley CA 94720

To assess the roles of specific second messengers in growth cone steering and neurite outgrowth, cultured grasshopper embryos or dispersed neurons were exposed to specific second messenger agonists or antagonist at different developmental stages. Transient (3 hour) calcium elevating treatments could inhibit axon initiation almost completely in 28-29% stage embryos or increase axon initiation by an average of 67% in CNS cultures from 35-45% stage embryos. Chronic calcium elevation or lowering also reduced the rate of outgrowth in embryos by an average of 26% and calcium elevation noticeably decreased axon diameter. Calcium manipulations had no significant effects on pathfinding however, suggesting that global calcium levels did not play a critical role in steering. Whole mount TEM micrographs showed losses of actin filaments in growth cones after calcium elevation, suggesting a possible site of calcium action in control of neurite outgrowth. In contrast to calcium manipulations, 1 mM 8-bromo cGMP had no effect on axon initiation or rate of outgrowth, but induced a variety of axonal steering errors and ordigiowin, but induced a variety of axona steering errors and produced curved axons in dispersed culture. Drugs affecting intracellular pH inhibited the rate neurite outgrowth as well as inducing steering errors. Many manipulations, including cAMP and protein kinase C agonists affected the epithelial development without detectable effects on neurons

## 22.5

EXPRESSION OF ENDOGENOUS CELL SURFACE ALKALINE PHOSPHATASE ACTIVITY IN GRASSHOPPER LIMB BUD EPITHELIA DURING OUTGROWTH OF PIONEER AXONS. Wesley S. Chang\* and David Bentley. Department of Molecular &

Cell Biology, University of California, Berkeley, CA 94720.

Alkaline phosphatases (ALPs) are expressed in highly localized patterns during embryogenesis of many different organisms. In grasshopper embryos, endogenous ALP activity is expressed in the epithelia of segmented appendages, as revealed by enzyme histochemistry. In limb buds, ALP activity is present during initial epithelial outpocketing and later becomes restricted to a pattern of circumferential bands of cells. Growth cones of the Ti1 pioneer neurons contact ALP-expressing cells as they pathfind along a highly stereotyped route towards the central nervous system. Double-labeling studies show that the Ti1 axons reorient from proximal to ventral growth immediately proximal to a band of ALP expression that spans the femur-trochanter segment boundary. (Fe-Tr). Thus, the change in Ti1 growth cone orientation occurs at a location in the limb that is specified by the transition from expression to non-expression of ALP activity by substrate cells.

Analysis of the embryonic grasshopper ALP indicates that it is

active at neutral pH, dependent on divalent cations and resistant to inhibition by levamisole or tetramisole. It can be inhibited by millimolar quantities of nucleotide phosphates, such as AMP and IMP. Treatment of embryos in vivo with phosphatidylinositol-specific phospholipase C (PI-PLC) releases the ALP activity, suggesting that it is due to a cell surface enzyme(s) attached to the membrane via a glycosyl-phosphatidylinositol (GPI) anchor.

## 22.7

A MULTI-STEP PROCESS INVOLVING CARBOHYDRATE RECOGNITION MEDIATES THE FORMATION OF PRESYNAPTIC PROJECTIONS OF LEECH SENSORY NEURONS. J. Song and B. Zipser\*. Dept. of Physiology, Neuroscience Program, Michigan State Univ., E Lansing, MI 48824.

We are using leech sensory afferents as a model system to test the hypothesis that the interactions of carbohydrate-binding proteins with their cognate saccharides mediate pathfinding and target recognition. A given sensory afferent expresses two different carbohydrate epitopes on 130 kD peripheral membrane proteins, the mannose-containing Lan3-2 epitope (fullset epitope) and one of several mixed carbohydrate epitopes (subset epitopes) which distinguish subsets of sensory afferents transducing different modalities. Sensory afferents form their presynaptic projections in the CNS neuropile in a multi-step process. First, they defasciculate into the neuropile after having grown through peripheral nerves in tightly bundled tracts. Previously, we presented direct experimental evidence that this axonal defasciculation is mediated by mannose-specific recognition involving the fullset epitope. Second, each axonal subset, identifiable by its subset epitope, forms a unique presynaptic projection. The formation of unique presynaptic projections by the different subsets correlates with the late expression of the subset epitopes. The subset epitopes appear two days after the fullset epitope is expressed. Third, the presynaptic projections of these different neuronal subsets are stabilized. The stabilization of presynaptic projections correlates with the late expression of the fullset epitope on integral membrane It remains to be seen whether the late onset of subset epitopes and of integral membrane proteins during the formation of presynaptic projections are activation-dependent processes as are those found during the multi-step process of lymphocyte homing.

EFFECTS OF TYROSINE KINASE INHIBITION ON GROWING RETINAL GANGLION CELL AXONS. T. L. Worley and C. E. Holt.\* Dept. of Biology, Univ. of Calif., San Diego, La Jolla, CA 92093.

We are investigating the role of tyrosine kinases (TKs) in the growth and guidance of retinal ganglion axons in Xenopus laevis. Immunostaining of wholemount embryonic brains with an anti-phosphotyrosine antibody (PY20) has revealed positive immunoreactivity in the fibers crossing the optic chiasm and in the ventral to midoptic tract. A similar pattern of staining was obtained using a *Xenopus* anti-pp60src antibody (T. Unger and R. Steele), which is specific for the plasma membrane associated TK src. To test the possible role of TKs in vivo we have directly applied TK inhibitors to the developing optic tract using an exposed-brain preparation. Lavendustin A and genistein were bath-applied for 10-14 hours and the optic projections subsequently assayed with HRP. We found that treated projections are delayed, have an altered growth cone morphology and display possible pathfinding defects. Similarly, retinal ganglion axons treated with TK inhibitors in culture show a reduction in neurite length as well as an altered growth cone morphology. These results suggest that TKs are important for the normal growth of retinal ganglion axons in the developing optic tract. (Supported by grants from NIH, the March of Dimes and the Pew Foundation.)

ACTINOMYCIN D BLOCKS CHANGES IN AXON PATHWAY SELECTION IN THE GRASSHOPPER EMBRYO: CHANGES IN THE EXPRESSION OF SURFACE MOLECULES. R. yon Bernhardi\* and M. J. Bastiani, Dept. of Biology, University of Utah, Salt Lake City UT 84112.

Actinomycin D (A-D) administered at early stages of the development of the grasshopper nervous system inhibits the ability of growth cones to switch pathways at pathway choice points (von Bernhardi & Bastiani. Soc. Neurosci. Abst. 17:743). Our findings raise two main questions: Is the expression of molecules that may participate in pathfinding modified by the A-D and, at the low doses of A-D used (0.05-0.1 µg/ml), how much is RNA synthesis affected?

We examined the effects of A-D on the immunolabeling patterns of 6 different antibodies (Ab) that recognize surface molecules expressed during the period of early axon outgrowth. A-D affected the labeling of 4 of them, including the Ab recognizing Fasciclin I and Lachesin (Kalstrom & Bastiani, Soc. Neurosci. 192). In the presence of A-D, Fasciclin dramatically decreased over time, and Lachesin failed to be expressed in the leg sensory neurons Ti1 and CT1. These changes in immunolabeling suggest that the expression of these surface molecules is closely related in time with the synthesis of their messages. It is also evidence that the effect of A-D may depend on its suppression of surface molecules required for pathfinding. To explore the effect of A-D on RNA synthesis, we measured the incorporation of <sup>3</sup>H-Uridine in total RNA. Paradoxically, we found that embryos treated with A-D showed a 30-200% increase in the incorporation of The effect of A-D on the Ab labeling pattern suggests that the synthesis of mRNA and probably rRNA is being blocked. Our hypothesis is that the increased incorporation may be the result of an increased synthesis of tRNA. Assays of <sup>32</sup>P-Uridine incorporation will allow us to identify the RNA species that may be responsible for this increased incorporation. Supported by NIH grant NS25378, the McKnight Foundation and a ASO training fellowship to R.v.B.

## 22.8

CHARACTERIZATION OF TWO LEECH LECTINS: GALACTOSE-BINDING PROTEINS THAT SHARE EPITOPES WITH THE 130 KD GLYCOPROTEIN ON SENSORY NEURONS. R.N. Cole\* and B. Zipser. Dept. of Physiology, Neuroscience Program, Michigan State Univ., East Lansing, MI 48824. Previously we presented evidence that carbohydrate recognition

mediates the projection of sensory neurons in the synaptic neuropile of the developing leech CNS (J. Neurosci, 11: 3471). This event involves the Lan3-2 carbohydrate epitope (identified by mAb Lan3-2) that is present on the 130 kD glycoprotein expressed on sensory neuron surfaces and a putative carbohydrate-binding protein (CBP) that must be present in the CNS. Presently we are characterizing two CBPs isolated from the leech which have apparent MWs of 35 and 67 kD, termed Leech Lectin 35 (LL35) and Leech Lectin 67 (LL67). Approximately 10 µg of LL35 and LL67 can be isolated from one leech by passing Triton X-100 extracts of crude whole leech membranes through an asialofetuin affinity column and eluting the CBPs with lactose. Both lectins specifically bind to galactose derivatives and not to the corresponding glucose and mannose derivatives. Both lectins share common epitopes since polyclonal antibodies generated against the LL35 gel band (anti-LL35) bind to both LL35 and LL67. LL35, however, can be separated from LL67 because LL35 binds to  $\alpha\text{-}$ however, can be separated from LL67 because LL35 binds to  $\alpha$ -methyl-galactose and LL67 does not. In addition, LL35 is more abundant than LL67 in the CNS. Peptide maps of these lectins indicate that LL35 and LL67 are different proteins. Interestingly, both lectins share the anti-LL35 epitopes and Lan3-2 carbohydrate epitope with the 130 kD glycoprotein on sensory neurons. Anti-LL35 recognizes the 130 kD sensory glycoprotein and Lan3-2 binds to both leech lectins. Preliminary data suggests that anti-LL35 stains axons, glia, and muscles in whole mounts of leech CNS.

EFFECT OF GROWTH ASSOCIATED GANGLIOSIDES ON AXONAL OUTGROWTH. R. Mendez-Otero\*, J. Friedman and M. Constantine-Paton. Instituto de Biofisica Carlos Chages Filho, Univ. Federal do Rio de Janeiro, RJ, 21941, Brazil and

Dept. Biology, Yale University, New Haven, Ct. 0651.
Gangliosides constitute a major group of cell surface carbohydrate molecules that have been implicated in numerous cellular functions in the developing and adult mammalian nervous system. We have investigated the role of 9-0-acetylated gangliosides, identified by the Jones monoclonal antibody (Mab)(Constantine-Paton et al., <u>Nature</u>, 324:459,1986), in the migration of growth cones extended by sensory neurons of embryonic rat dorsal root ganglia(DRG) explants grown on laminin substrate. The behavior of individual growth cones was recorded using a time-lapse video-enhanced imaging system before and after the addition of antibodies that recognize especific gangliosides known to be expressed on these growth cones. It was possible to demonstrate that the advance of growth cones on laminin was halted in the presence of Jones Mab. The onset of effects was rapid and signaled by an immediate cessation of elongation, a loss of lamellipodia and a retrieval of axoplasm. This effect was partially reverted by washing the explants for several minutes with culture medium. Mab A2B5 which also recognizes gangliosides expressed on these growth cones does not induce any change on the growth rate. Our findings shown that membrane associated molecules, such as 9-0-acetyl gangliosides, may play an important role on the adhesion of growth cones to different substrates and consequently influence navigation and pathway finding during development

MISEXPRESSION OF FASCICLIN II LEADS TO ALTERED GROWTH CONE GUIDANCE IN THE DROSOPHILA EMBRYO. D. Lin. D. Van Vactor. M. Tiemeyer, and C.S. Goodman, HHMI, MCB, U.C. Berkeley, CA 94720 In principle, there are two key experiments to test the function of a molecule such as fasciclin II in growth cone guidance. First, as reported last riolecule such as fascicin i in growin cone guidance. First, as reported last year, we would like to use genetic analysis to remove the function of the molecule, to determine if identified growth cones stall at specific choice points. Second, we would like to misexpress the molecule on cells that normally don't express it, to determine if identified growth cones can be selectively mis-routed. To this end, we have utilized the GAL4 enhancer trap method (A. Brand and N. Perrimon) to obtain lines expressing GAL4 in specific subsets of neurons and muscle during embryogenesis (GAL4 is a yeast transcription factor that can activate its specific binding site, UASG, in Drosophila). One such transformant line expresses GAL4 in all PNS neurons. In separate transformants, we generated flies that carry a P element containing the fas II cDNA under the control of the UAS<sub>G</sub>. By element containing the fas II cDNA under the control of the UASG. By mating these flies, we generate embryos that specifically misexpress fas II in all PNS neurons. Normally, fas II is expressed by many motoneuron growth cones, including aCC, but by virtually none of the PNS. As a result of ectopic fas II PNS expression, dramatic misrouting of the aCC growth cone is seen. At a specific choice point, the aCC growth cone extends abnormally along the axons of the PNS neurons. In many segments, the aCC growth cone appears to stall at these PNS neurons, while in others it extends abnormally across segment boundaries, sometimes fasciculating with motorneurons from neighboring segments instead of extending towards their targets. These striking phenotypes demonstrate that misexpression of fas II is sufficient to alter growth cone guidance.

To improve our ability to visualize specific axons of interest in these and other experiments, we are testing a variety of different reporter constructs (which in principle will mark either the cell surface or the cytoskeleton) in this type of ectopic expression system in order to visualize specific axons.

THE PATHWAY AND MOLECULAR ENVIRONMENT OF DEVELOPING CALLOSAL AXONS POLLOWING EMBRYONIC CORTICAL LESIONS. K. Morigiwa\*. C. Doller and I. Silver. Dept. of Neurosciences, Case Western Reserve University, Cleveland, OH 44106
In the rat, callosal axons project toward the cerebral midline around embryonic day 18 (E18). They course through the deeper layers of the intermediate zone (IZ) and form a distinct bundle above the subventricular zone (SZ), which appears to be a non-preferred growth region. We are interested in the pathfinding of callosal axons laterally within the hemispheres, particulary after perturbation, and whether they are capable of coursing through a lesioned area and of redirecting themselves toward their correct pathway. We mechanically lesioned the cortical area above the ventricle of embryonic rats from E17 to E21 using an angled dissection needle passed through the uterus. At different survival times, the cytoarchitecture of the lesioned region was examined with 1 µm plastic and EM sections. Dil and/or DiA were applied to the cortical surface medial and/or lateral to the lesioned site in fixed whole brains and in 100 µm vibratomed slices. These sections and 10 µm frozen sections were stained with antibodies to 8-tubulin, vimentin, GFAP, chondroitin-6-sulfate proteoglycans (CSPG), and tenascin/cytotactin (TN). In the lesioned brain, the cortex appears to develop parallel to the lesion rather than to the pial surface. Radial glial cells change their geometric pattern and appear to arch toward the lesion, but with no evident gliosis as seen in adult lesions. The axons can go around but also directly through the lesion in E17-18 brains. The majority of the axons course along the lesion, are allowed into SZ, and form pseudo-glomeruli. In some regions, however, axons also appear to cross through the ventricular zone (VZ) to the other side of the lesion. In superficial lesions, they course around the lesion through SZ and VZ. No dramatic upregulation of CSPG or TN was seen as in adults following lesions

MOLECULAR CHARACTERIZATION OF EMBRYONIC GLIA IN

MOLECULAR CHARACTERIZATION OF EMBRYONIC GLIA IN DROSOPHILA. V.J. Auld' and C.S. Goodman, HHMI, Dept of Molecular and Cell Biology, U. of California, Berkeley, CA 94720
The growth cones that pioneer many of the major CNS axon tracts and nerve roots, and many PNS axon pathways, in the Drosophila embryo extend towards and along specifically positioned glial cells. A large-scale enhancer trap screen was conducted previously (see Auld et al., 1991) to obtain new molecular lineage markers that selectively label different subsets of glia, and to identify new genes expressed in these glia that might function in the formation or maintenance of axon pathways. For example, two lines (AE2 and 1613) are expressed in embryonic PNS glia might function in the formation or maintenance of axon pathways. For example, two lines (AE2 and rS136) are expressed in embryonic PNS glia, and a third line (rQ286) is expressed in the exit glia (just outside the CNS); all three of these genes mutate to lethality. Embryos mutant for AE2 appear uncoordinated and are unable to hatch. Although all three genes are being cloned and further characterized, the most is known about AE2. This gene encodes a new transmembrane protein with a serine esterase-like domain that is related to neurotactin and glutactin, two other Drosophila proteins; in all three cases, the serine esterase-like domain is simply a proteins; in all three cases, the serine esterase-like domain is simply a structural molif and appears to lack esterase enzymatic activity. Glutactin is found in basement membranes throughout development; neurotactin is a transmembrane protein that is expressed in the embryonic and larval nervous system and appears capable of mediating cell aggregation in a heterophilic fashion. We are currently generating antibodies against the AE2 transmembrane protein to localize its expression, sequencing the TS136 and r0286 genes, and characterizing the defects that lead to lethality in mutations in all three of these genes expressed in embryonic PNS or exit glia.

## 22.14

IN VITRO DEMONSTRATION OF TRANSIENTLY EXPRESSED ECM MOLECULES, TENASCIN AND A PROTEOCILYCAN. Monte A. Gates, Andreas Faissner, and Dennis A. Steindler\*, Dept. Anat. & Neurobiol., Univ. of Tennessee, Memphis; Dept. of Neurobiol., Univ. of Heidelberg. Extracellular matrix (ECM) molecules play important roles during pattern formation of the central nervous system. We have made use of culturing

tormation of the central nervous system. We have made use of culturing techniques of embryonic and neonatal explants to examine the expressions of two developmentally regulated ECM molecules, tenascin and a chondroitin sulfate proteoglycan (CSPG). Previous in vivo and in vitro studies of these glycoconjugates have shown that they are concentrated in boundaries which surround developing neural units, and they may play a role in the complex events which bring about growth, migration and organization of functional neuronal aggregates. The tenascin glycoprotein, itself, has been shown to be synthesized and released by women agrecules and may also produce to the surround diverse.

neuronal aggregates. The tenascin glycoprotein, itself, has been shown to be synthesized and released by young astrocytes, and may alone produce diverse effects on cellular attachment and process outgrowth of developing neurons. Here we report that tenascin and a CSPG are expressed in long term cultures of embryonic and neonatal neostriatum. We have defined culturing conditions (e.g. using plasma clot substrates and sera-containing media as previously described by Gähwiler) in roller tubes which maximize the expression of glycoconjugates involved in glia-neuron interactions during development. Mono- and polyclonal antibodies to tenascin and a CSPG (previously, 473 proteoglycan) have been used to observe intense expression development. Mono- and polyclonal antibodies to tenascin and a CSPG (previously, 473 proteoglycan) have been used to observe intense expression of such glycoconjugates in neostriatal explants, on and around astrocytes (labeled with GFAP) with various morphologies. We are attempting antibody perturbations of these glycoconjugates to study their effect on the development of substantia nigra-neostriatal co-explants where we know that the expressions of ECM molecules like tenascin and the 473 proteoglycan are, to some extent, afferent-dependent. Supported by NIH grant NS 20856 and NISE gent-BMS 6901541. NSF grant BNS 8911514.

DISTRIBUTION OF PROTEOGLYCANS IN THE DEVELOPING VISUAL PATHWAY OF CHICK. B.D. McAdams and S.C. McLoon\*. Dept. of Cell Biology & Neuroanatomy, Univ. of Minnesota, Minneapolis, MN 55455.

Previous investigations have suggested that proteoglycans can have an inhibitory effect on neurite extension in vitro and are found in situ in regions of the CNS and PNS that may act as barriers to axon growth. prominent among these presumptive inhibitory proteoglycans are keratan sulfate and chondroitin-6-sulfate. The present study utilized immunohistochemistry to examine the spatial and temporal distribution of keratan sulfate and chondroitin-6-sulfate glycosaminoglycans in the embryonic chick retina, optic nerve, chiasm, tract, and tectum to determine whether their localization might be relevant to the pathfinding of retinal ganglion cell axons through these regions. Keratan sulfate immunoreactivity was first observed in the optic chiasm and on radial cells in the optic tectum at E6, when the first optic axons were just reaching the tectum. By E10, it was expressed by cells in the optic nerve, tract and tectum where optic axons were also observed. Chondroitin-6-sulfate was found in the inner retina at E2. At E3, it was coextensive with retinal axons in the retina and was found in the optic stalk and chiasm. Chondroitin-6-sulfate was expressed in the outer layers of the tectum throughout the period of invasion by optic axons. In the neonate, the entire retinotectal pathway was immunoreactive for this glycosaminoglycan. These results reveal a distribution of keratan sulfate and chondroitin-6-sulfate that is not consistent with a role as a barrier molecule, except possibly in the The functions of these glycosaminoglycans are also being investigated by disrupting their synthesis in vivo and by looking at their effects on growing neurites in vitro.

EXPRESSION OF T-CADHERIN IN THE FLOOR PLATE CORRELATES WITH COMMISSURAL AXON GROWTH ACROSS THE VENTRAL MIDLINE OF THE SPINAL CORD <u>S.S. Kanckar\* and B. Ranschi</u>, La Jolla Cancer Research Foundation, La Jolla, CA 92037.

Commissural (C) neurons in the dorsal and ventrolateral chick spinal cord extend axonal projections ventrally through the motor neuron pool and then medially across the ventral midline through the floor plate (FP). Immediately after crossing the FP, C axons after their trajectory from a transverse to a longitudinal plane. The FP has been implicated in providing both chemotrophic and contact guidance cues for C axons. T-cadherin is a glycosyl phosphatidylinositol-anchored membrane protein that belongs to the cadherin family of cell adhesion molecules and mediates calcium-dependent, homophilic tamity of cell adhesion molecules and mediates calcium-dependent, nomophilic cell-cell adhesion. In the developing chick spinal cord, T-cadherin immunoreactivity is detected at Hamburger/Hamilton stage 15 in dorsal and lateral, but not ventral neuroepithelial cells. Staining in the FP is first distinguished in its dorsal aspect at stage 17, when the first C axons (identified with monoclonal antibody 3A10 from J.Dodd, Columbia Univ.) cross the FP. Plus treas 20. T. autheria immunoractivity is also seen along the ventre. with monoclonal antibody 3A10 from J.Dodd, Columbia Univ.) cross the FP. By stage 20, T-cadherin immunoreactivity is also seen along the ventral boundary of the FP, where the C axons project. Dense staining in the FP is detected between this stage and stage 26, when most of the C axons have crossed over to the contralateral side of the spinal cord. At all of these stages, however, T-cadherin expression is not restricted to the FP, but is also detected at lower intensity in the dorsal and ventral spinal cord, including the motor neuron pool. By stage 27, T-cadherin staining in the FP is diminished, but is dense in the ventromedial funiculus, which defines the longitudinal projections of C neurons. The spatial and temporal distribution of T-cadherin in the FP correlates with C axon prowth through this region and raises the possibility that T-cadherin may axon growth through this region and raises the possibility that T-cadherin may ite to the establishment of the commissural axon trajectory. (Supported by NIH (HD25938), the MOD and the McKnight Foundation)

## 22.19

AXONIN-1 HETEROLOGOUSLY EXPRESSED IN MYELOMA CELLS IS FUNCTIONALLY ACTIVE. C. Rader, E.T. Stoeckli\*, T.H. Hasler, B. Kunz, R.A. Zuellig, K. Karjalainen\* & P. Sonderegger, Institute of Biochemistry, University Zurich, CH-8057 Zurich, Switzerland, and +Basel Institute of Immunology, CH-4058 Basel, Switzerland

The 135-kd chicken axonal glycoprotein axonin-1 is involved neurogenesis. Molecular cloning of axonin-1 revealed its membership in the group of Ig/FNIII-like proteins and its homology to rat TAG-1. Recently, we have shown that axonin-1 does mediate neurite outgrowth-promoting activity by a heterophilic interaction with NgCAM, the putative chicken homologue of by a heterophimic interaction with NgCAM, the putative chicken holinologie of mouse L1. Here we report the heterologous expression of axonin-1 in myeloma cells. A stable expression system designed for the large-scale production of biologically active mammalian proteins has been used (A. Traunecker, F. Oliveri & K. Karjalainen, TIBTECH 9, 109-113, 1991). This system is based on the mouse myeloma cell line J558L and vectors including an  $\lg V_\kappa$  promoter, an  $\lg x$  enhancer, and an  $\lg C_\kappa$  exon which constitutes the 3' an  $\lg V_k$  promoter, an  $\lg x$  enhancer, and an  $\lg C_k$  exon which constitutes the 3' end of the transcript encoding the recombinant protein; it has successfully been applied to the production of soluble lymphocyte-derived cell-surface receptor proteins. We transfected myeloma J558L cells with two different vector constructs. One (pMAX) representing the entire axonin-1 coding sequence, the other (pSAX) containing a termination codon where the putative GPI cleavage site is encoded and therefore representing a truncated, soluble version of axonin-1. Transfection was performed by protoplast fusion or electroporation. Clones were selected in the presence of histidinol and screened by a sandwich dot blot and by immunofluorescence analysis. Both constructs gave rise to high-level expression of a 135-kd protein which screened by a sardwich dot but and by initial outputs each all as to be constructs gave rise to high-level expression of a 135-kd protein which exhibits axonin-1 immunoreactivity. Like axonin-1, the product of pMAX occurs both as a membrane-bound GPI-anchored and as a soluble form. In contrast, the product of pSAX was detected in the supernatant only. Functional analysis revealed that recombinant axonin-1 has biological activity: as native axonin-1, it promotes neurite outgrowth and interacts with NgCAM.

DIFFERENTIAL LOCALIZATION OF EXTRACELLULAR MATRIX MOLECULES AND CELL ADHESION MOLECULES IN THE PATHWAY OF DEVELOPING PRIMARY AFFERENT FIBERS. T.Shigai\*, H.Tanaka\*, M.Grumet\*.

C.M.Edelman\*, R.W. Oppenheim\* and T.Shirai\*. Dept. Anat., Yamagata Univ., Yamagata\*, Dept. Neurosci. & Immunol. Kumamoto Univ., Kumamoto\*, Dept. Pharmacol., New York Univ. Medical Centr., NY\*, Rockefeller Univ., NY\*, Dept. Neurobiol. & Anat., Wake Forest Univ., NC\*.

To investigate the role of extracellular matrix and cell adhesion molecules in the pathway formation of primary afferent fibers (PAFs), we examined immunohistochemically the distribution of laminin, fibronectin, type IV collagen, Ng-CAM, and SC2 (cell surface molecule specific for PAFs) in chick embryos. The pathway formation of PAFs could be divided into three stages. At stage I, PAFs extended through migrating neural crest cells and abundant extracellular space, from dorsal root ganglion (DRG) to spinal cord. At stage II, PAFs ran longitudinally in the dorsal funiculus, forming fascicles. At stage III, PAFs entered the gray matter without fasciculation. Laminin was localized in the pathway of PAFs at stage I, although it was never found within the spinal cord throughout the stages examined. At stage II, Strong immunoreactivity of both Ng-CAM and SC2 was found on the fasciculated PAFs running in the dorsal funiculus. At stage III, Ng-CAM was still expressed on PAFs both in the dorsal funiculus. These results suggest that Ng-CAM and SC2 may be involved in the outgrowth and fasciculation of PAFs, respectively. The disappearance of SC2 may play some role in the entry of PAFs into the dorsal funiculus.

### 22.18

THE DEVELOPMENT OF SENSORY PROJECTIONS IN THE CHICK HINDLIMB IN THE PRESENCE OF ANTIBODIES AGAINST L1. M.G. Honig\* and U. Rutishauser, Dept. of Anatomy and Neurobiology, Univ. of Tennessee Memphis, Memphis TN 38163 and Dept. of Genetics, Case Western Reserve Univ., Cleveland, OH 44106.

We are interested in understanding how sensory neurons in the chick hindlimb choose the correct pathways to grow along and, in particular, how these choices are influenced by interactions between sensory growth cones and the axons they encounter as they grow. To study this, we have injected antibodies that block the function of various cell adhesion molecules (CAMs) into the developing limb. The injections were done at St. 25 since interfering with CAM function at this stage should be too late to alter motoneuron pathway selection, but may still perturb the subsequent growth of sensory axons. The embryos were allowed to develop for 2 additional days and then the pattern of nerve projections was assessed. Here, we have focused on the action of the L1 adhesion molecule because of its known importance in mediating axon-axon interactions. In the presence of aL1, sensory axons projected along muscle nerves and along cutaneous nerves in relatively normal numbers and the segmental pattern of projections was generally appropriate. However, there were significant alterations. In normal embryos, the medial femoral cutaneous nerve contains axons from sensory neurons situated in segments LS1-3; the axons from LS1 have to cross from the anterior part of the crural plexus to a posterior position in order to project along this nerve. In the presence of  $\alpha L1$ , the projection from LS1 was decreased and the projection from more posterior segments (LS2 or LS3) was increased. In other αL1-treated embryos, we found that the sensory projection to the sartorius muscle was dominated in above-normal proportions by neurons from a single segment. These results suggest that L1-mediated interactions may influence the ability of sensory growth cones to navigate through the axon-rich environment of the plexus.

## 22.20

HUMAN AXONIN-1: cDNA-CLONING, STRUCTURAL CHARACTERIZATION, AND EUCARYOTIC EXPRESSION. T.H. Hasler, C. Rader, R.A. Zuellig, H.-C. Bauer\*, and P. Sonderegger. Institute of Biochemistry, University of Zurich, CH-8057 Zurich, Switzerland, and +Institute of Molecular Biology, OAW,

A-5020 Salzburg, Austria.

Axonin-1 of the chick and TAG-1 of the rat are homologous members of the Axonin-1 of the chick and TAG-1 of the rat are homologous members of the immunoglobulin superfamily expressed either as membrane-associated GPI-linked or as soluble forms, and they are believed to play an important role in the axon guidance mechanisms in developing nerve tissues. We have now cloned the human homologue from a fetal brain cDNA library (Stratagene). At the amino acid level, human axonin-1 has a homology of 91% and 75% to rat TAG-1 and chicken axonin-1, respectively. Of the six immunoglobulin C2 and the four fibronectin-type-III domains, the highest degree of conservation is found in the second IgC2 domains 99% identity with TAG-1 and 83% with axonin-1. The least conserved domain is the first IgC2 domain: 81% identity with TAG-1 and 66% with axonin-1. Chicken axonin-1 avonin-1 chicrosa a heterophilic interaction with NgCAM and this interaction is a prerequisite for the process outgrowth on immobilized axonin-1 (Kuhn et al., J. Cell Biol. 115, 113-26, 1991). Recently, human L1, most likely the homologue of chicken 1113-26, 1991). Recently, human L1, most likely the homologue of chicken NgCAM, has been cloned (Hlavin and Lemmon, Neuroscience Abstracts, 1991). The overall homology of human L1 and chicken NgCAM is considerably lower than for human and chicken axonin-1: 40% identity at the amino acid level. We have now been able to transiently express the human axonin-1 in monkey COS 1 cells and to select stable human axonin-1 expressing cell lines with a myeloma-based expression system (Rader et al., Neuroscience Abstracts, 1992). The expressed protein shows a strong immunocrossreactivity with polyclonal anti-chicken axonin-1 antibodies. Considerable amounts of the expressed protein are also released into the cell culture medium. With this tool in hand we should soon be able to investigate a possible heterophilic interaction between human axonin-1 and human L1.

GENOMIC CLONING OF THE AXONALLY SECRETED CELL ADHESION MOLECULE AXONIN-1. R.J. Giger. R.A. Zuellig. and P. Sonderegger\*. Institute of Biochemistry, University of Zurich, CH-8057 Zurich, Switzerland. Axonin-1 is a 135-kd glycoprotein of the chick. It is secreted from the neurites of cultured neurons (Stoeckli et al., Eur. J. Biochem.180, 249-258,

1989) and occurs also as a membrane-bound form (Ruegg et al., J. Cell Biol. 109, 2363-2378, 1989). Axonin-1 of the chick is presumably the species homologue of TAG-1 of the rat. The cDNA of axonin-1 has recently been cloned (Zuellig et al., Eur. J. Biochem. 204, 453-463, 1992). The deduced amino acid sequence contains six immunoglobulin ([9]-like domains and four fibronectin-type-III (FN III )-like domains. In addition, extrapeptides of 23 amino acids and 35 amino acids are located at the N- and C-terminus, respectively. Fragments from a cDNA encoding axonin-1 were used to isolate genomic axonin-1 clones from a lambda EMBL-3 chicken liver library. Sequence analysis of the aligned lambda clones revealed a genomic structure of 23 exons and 22 introns spanning over approximately 20 kb. Each Ig and FN III domain is encoded by two exons. The introns between two domains are exclusively phase I infrons, suggesting that axonin-1 had been generated by exon shuffling. Introns interrupting a domain are either phase I or II. The leader sequence is encoded by two exons, exon 2 and exon 3. The first exon, only 77 bp long, is located several kb upstream from the rest of the axonin-1 gene. // bp long, is located several kb upstream from the rest of the axonin-1 gene. Exon 2 encoding the first part of the signal peptide and exon 3 are separated by an intron of approximately 3.6 kb. The introns separating exon 3 through 23 are relatively short, ranging from 89 to 700 bp. The last exon codes for the C-terminal 35 amino acids which are probably responsible for GPI-anchorage. At least three different transcripts of the axonin-1 gene were detected by Northern blot analysis. It is most likely that they are generated by usage of different polyadenylation signals.

DISRUPTION IN VIVO OF THE DEVELOPING HIPPOCAMPAL MOSSY

DISRUPTION IN VIVO OF THE DEVELOPING HIPPOCAMPAL MOSSY FIBER CIRCUIT BY ANTIBODIES TO THE LIMBIC SYSTEM ASSOCIATED MEMBRANE PROTEIN. M. F. Barbe\* and P. Levitt, Dept. of Physical Therapy, Temple Univ., Phila. PA 19140 and Dept of Anatomy and Neurobiology, Med. Coll. of Penn., Phila., PA 19129.

The limbic system associated areas from the time of inception of the neurons. Results of previous in vitro explant studies, in which the addition of anti-LAMP prevented the de novo formation of the cholinergic septohippocampal circuit, suggested that LAMP may be a target recognition molecule (Keller et al., Neuron 3: 551,1989). In an attempt to demonstrate the role of LAMP in circuit formation in vivo, we examined the effects of antibody treatment on a connection that forms postnatally in the rat, the mossy fiber projections from the dentate granule neurons to the CA3 pyramidal cells. Five µl of either saline or purified Fab fragment of anti-LAMP (2 mg/ml) was injected into the cisterna magna postnatal days (P) 0, 2, 4, and 6. The brains were prepared and stained for zinc using the Timms' method on P8 in order to identify the terminal distribution of the developing mossy fibers. The mean area fraction of the suprapyramidal mossy fibers occupying the CA3 region was measured using a Bioquant imaging System. The mean area fraction of suprapyramidal mossy fibers in the saline injected animals was 0.60±0.09, which was three fold higher than the mean area fraction of mossy fibers appeared to distribute more diffusely throughout the molecular layer. Qualitative examination of cresyl violet stained sections indicates that there is not a noticeable decrease in the number of granule or CA3 pyramidal neurons. These results suggest that LAMP provides chemospecific cues that are necessary for proper axonal pathfinding and synaptogenesis. (Supported by NIMH Grant MH45507).

DEVELOPMENT SPECIFIC CELL-SURFACE ANTIGENS OF THE MAMMALIAN CNS. M.J. Riggott\* and W.D. Matthew Dept. of Neurobiology, Duke University Medical Center, Durham,

Molecules that direct axonal growth in the developing CNS may be in low abundance. In order to generate immunological probes to these molecules, we used a chemical tolerization technique to bias the immune response. Monoclonal antibodies were made from mouse spleens after the mice had been tolerized to a homogenate of adult rat brain, and then immunized with a homogenate of brain from E16, P0 and P7 brains. From this set of fusions, we generated 60 antibodies that bind developing CNS tissues. Of these, 28 label neuronal or glial

The functions of cell-surface antigens were explored using antibodies in bioassays testing neuronal cell aggregation as well as adhesion and neurite outgrowth on cryostat sections of developing brain. We found that seven of these antibodies promoted cell aggregation and one inhibited aggregation. Eight antibodies promoted neuronal cell adhesion to cryostat sections in culture; at least one of these promotes neurite growth. Further studies will determine whether these antibodies affect axonal outgrowth in living slices of brain tissue in culture. Such antibodies may provide probes for molecules that direct axonal growth in the normal developing

HNK1 AND NCAM EXPRESSION IN CULTURES OF DEVELOPING XENOPUS NEURAL TISSUE. R.H.Nordlander\* and P.L.Booth Dept.Oral Biol., Ohio State Univ., Columbus, OH 43210.

The neural cell adhesion molecule (NCAM) is one of many adhesion molecules with subclasses that bind the antibody HNK1. HNK1 recognizes a carbohydrate epitope which has been implicated in cellcell interactions during neurodevelopment. Studies of Xenopus embryonic CNS in wholemounts and sections have revealed coincident immunoreactivity (IR) of neurons with both HNK1 and anti-NCAM, but marking of non-neuronal elements only with anti-NCAM (Nordlander, '89, Dev Br Res 50; Nordlander and Liu, '90 Abst Soc Neurosci 17).

To further define the cellular expression patterns of the HNK1 and NCAM antigens we examined antibody marking patterns in mixed cultures from the developing Xenopus CNS. Cells with distinctly neuronal morphologies were almost always labeled by both antibodies. Double labeling of individual neuron-like cells showed nearly point to point correspondence, but with HNK1 being somewhat more distinct. HNK1 was consistently localized in vesicles of the golgi apparatus and axoplasm, and on the surface membranes of soma, axon and growth cone. HNK1-IR in these cells was especially dense at sites of axon or growth cone contact with other cells. Type I astrocytes were usually NCAM-IR but not HNK1-IR. These observations confirm and expand our earlier findings that the two antibodies mark with overlapping, but differing patterns

ACTIVELY-SCANNED MICROELECTRODE ARRAYS. T. K. Whitehurst. C. W. Storment. C. R. Belczynski\* and G. T. A. Koyacs. Stanford Univ. Dept. of Electrical Engineering, Room 130, Stanford, CA 94305-4070.

Numerous cell culture systems incorporating microelectrodes have been developed in order to study populations of electrically active cells in vitro, by means of multi-site, simultaneous recording and/or stimulation. Since a prime objective of such devices is to allow electrical access to numerous microelectrodes in contact with cells, large numbers of electrical interconnections are necessary. Typically, either large arrays of external amplifiers (and/or current sources and other circuits) are employed, or small numbers of such instruments are used at one or two microelectrodes at a time, defeating the purpose of the multi-site arrays. The goal of this work is to overcome this problem by developing silicon-substrate microelectrode arrays that incorporate on-chip signal processing and multiplexing circuitry. Since multiplexing circuitry is included, the number of connections to external circuits would be greatly reduced (for example, a large array of recording sites could be scanned using only five external connections). The current focus of this project is the implementation and testing of an actively-scanned, two-dimensional array of microelectrodes. This device should provide improved access to the electrical activity of living cells in vitro, allowing simultaneous recordings to be made from a large number of microelectrodes. The basic approach is to fabricate the active microelectronic circuits using a standard BiCMOS process and follow this with additional processes for fabrication of the microelectrodes and application of an insulation (or passivation) layer for protection of the active circuits from biological fluids. We are performing numerous evaluations of the active arrays and other test circuits in saline and cell culture media, to verify that the technology proposed can be used to protect active microcircuits under continuous nersion in biological fluids.

Research funding provided by Department of Veterans Affairs Merit Review Grant No. B003 and a Stanford OTL Research Grant. Todd K. Whitehurst was partially supported by a National Science Foundation Graduate Fellowship.

## 22.26

COVALENT BINDING OF LAMININ FRAGMENTS TO TEFLON-FEP MEMBRANES PROMOTES THE SELECTIVE ATTACHMENT AND DIFFERENTIATION OF NEURAL CELLS. R. Bellamkonda\*, J. P. Ranieri P. A. Tresco, T.G. Vargo<sup>1</sup>, J.A. Gardella<sup>1</sup> and P. Aebischer. ABC Section, Brown University, <sup>1</sup>Dept. of Chem., SUNY at Buffalo.

P.A. Tresco, I.D. Yargo' J.A. Gardella' and P. Aebischer. ABC Section, Brown University, <sup>1</sup>Dept. of Chem, SUNY at Butfalo. Cell adhesion proteins contain minimal peptide sequences which are specifically recognized by cell surface receptors and can be covalently immobilized on synthetic materials. In the present study we tested the possibility of guiding axonal outgrowth on a patterned surface on which fragments of the laminin molecule, such as YIGSR and IKVAV, have been covalently immobilized. Fluorinated Ethylene Propylene (FEP) films were chemically modified in a patterned fashion (300µ stripe modifications by 500µ land spacings) using a radio frequency glow discharge (RFGD) process in a low vacuum chamber containing both hydrogen and methanol gases. This modification allows for the replacement of the surface fluorine atoms with hydroxyl functionalities while maintaining the desirable topographic and surface energy properties of the base FEP material. The laminin fragment YIGSR, was then covalently bound to the FEP surface hydroxyl groups via an ester bond to the carboxylic terminus of the peptide using a nucleophilic substitution reaction (SN2) in an aprotic solvent (DMSO) containing potassium carbonate as an acid acceptor. Covalent binding of the YIGSR peptide was verified with both Time of Flight-Secondary Ion Mass Spectroscopy (TOF-SIMS) and Attenuated Total Reflectance-Fourier Transform Infrared Spectroscopy (ATR-FTIR). Rat E15 septal cells plated onto these patterned membranes in DMEM containing 10% FBS demonstrated selective attachment to the YIGSR regions. The outgrowth of the neurites remained primarily on the YIGSR stripes with few neurites extending onto the unmodified regions. No attachment was observed when IKVAV or hexaglycine was immobilized. These results demonstrate that a non-adherent substrate can be modified with signaling peptides to induce both attachment and differentiation in a controlled manner.

AN IMPROVED METHOD FOR CREATING WELL-DEFINED, PATTERNED SUBSTRATES FOR STUDIES OF NEURONAL ADHESION AND GUIDANCE

ADHESION AND GUIDANCE

B. Lom\*, K.E. Healyt, and P.E. Hockberger, Department of Physiology and the Institute for Neuroscience, †Departments of Biomaterials and Biomedical Engineering, Northwestern University Medical School, Chicago, IL 60611.

We are developing techniques for patterning tissue culture substrates with adhesive molecules to study fundamental issues in neuronal development such as cell adhesion and guidance. Kleinfeld et al. (J. Neurosci. 8:4098, 1988) combined silane chemistry and photolithographic techniques to pattern neurons on quartz and silicon substrates. That strategy eliminated imprecise boundaries and topographical features inherent in previous methods (e.g., evaporation and filtration techniques), but it required 36 hours and utilized expensive facilities and materials. We report here a faster, inexpensive method of patterning culture filtration techniques), but it required 36 hours and utilized expensive facilities and materials. We report here a faster, inexpensive method of patterning culture substrates while maintaining submicron precision and complete control of the surface features. With our approach, well-defined, patterned substrates can be made in 10-12 hours in a conventional biological laboratory. Patterns of amines, peptides, proteins, lipids, and/or carbohydrates can be made on borosilcate glass. We have focused on patterns of amines (e.g., ethylenediamine) and lipids (e.g., hexadecane) for biological studies (see Soekarno et al., these abstracts). Using surface analysis techniques (X-ray photoelectron spectroscopy) we have confirmed that surfaces covalently bound with amines are of monolayer thickness (10-20 Å) and therefore provide no topographical features. We have also used photolithographic techniques to pattern extracellular matrix molecules (fibronectin, laminin, collagen) on glass. These patterning techniques may be useful for studies of cell-substrate interactions, analysis of pathfinding strategies, and formation of neural networks in vitro.

This research was funded by MH-10217 and by a Biomedical Engineering Grant from the Whitaker Foundation.

22.28

DIGITAL IMAGING MICROSCOPY OF CELL GUIDANCE ON WELL-DEFINED PATTERNED SUBSTRATES

A. Sockamo\*, B. Lom & P. E. Hockberger.

Department of Physiology and the Institute for Neuroscience, Northwestern University Medical School, Chicago, IL 60611.

We are studying locomotion of mouse neuroblastoma cells (N1E-115) cultured on photolithographically patterned substrates. Substrates were patterned with monolayers of adhesive amines (ethylenediamine) and non-adhesive alkanes (hexadecane) allowing us to study cell guidance in the absence of topographical cues (cf. B. Lom et al., these abstracts). Cell behavior on aminecoated lines (10 µm in width) was visualized using digital imaging microscopy. The leading edge or nuclei of undifferentiated cells (i.e., those with fibroblastic morphology) migrated along lines at speeds one-half the rate of growth cones or nuclei of differentiated cells. Regardless of the state of differentiation, the rate of locomotion slowed considerably at junctions between lines where cells invariably explored their choices. Undifferentiated cells displayed random behavior when choosing between different directions of movement. Growth cones, on the other hand, displayed a statistical preference for moving straight ahead at junctions. Interference reflection microscopy (IRM) was used to assess differential cell adhesion to the substrates, as well as to visualize the pattern which is not visible using either phase-contrast or Hoffman optics. IRM of neurites and cell bodies revealed primarily "close" contacts (30 nm separation) with the substrate and few "focal" contacts (10-15 nm). Although most cells preferred to grow on amines over alkanes, IRM showed that the preference is not due to differences in the type of adhesion on the two substrates. Fluorescent imaging of rhodamine-phalloidin demonstrated little correspondence between actin filaments and focal contacts beneath cells.

This research was funded by NS-17489 and by a Biomedical Engineering Grant from the Whitaker Foundation.

## FORMATION AND SPECIFICITY OF SYNAPSES I

REGENERATION OF ALLOTRANSPLANTED NEURONS IN THE CRAYFISH. K.Krause\*, B.Wang and S.J.Velez. Department of Biological Sciences, Dartmouth College, Hanover, N. H. 03755.

We are studying the transplantation, between different animals, of the neurons innervating the superficial flexor

muscle system of the crayfish Procambarus clarkii. The isolated ganglion containing the somas of these neurons can be successfully transplanted from one crayfish to another: the neurons survive, grow and form new synaptic another: the heartons survive, grow and form hew synaptic contacts with a denervated muscle target (Krause et. al., Soc. Neurosci. Abstr. 16: 489, 1990). Some initial small-size, long duration junction potentials (jp's) eventually become normal sized, short duration jp's, yet the synapses do not acquire the normal facilitation characteristics of mature synapses (Krause & Velez, Soc. Neurosci. Abstr. 17: 216, 1991). Further experiments using this system have shown that (1) there is regrowth by more than one neuron, (2) there are many "holes" in the connectivity maps, i.e. places where no jp's are detected, and (3) most synapses keep their immature jp's characteristics. It appears that the allotransplanted neurons are not able to regenerate normal connections with the target area. The lack of normal connections with the target area. The lack of synaptic input into the isolated ganglion could be affecting the ability of these cells to regenerate normal connections. We are presently backfilling the transplanted neurons with cobalt blue in order to study the dendritic arborization of these cells to see whether the lack of synaptic input could also generate detectable changes in dendritic morphology.

## 23.3

EXPRESSION OF INSULIN AND INSULIN RECEPTORS AT NEUROMUSCULAR JUNCTIONS OF *DROSOPHILA*. V. Budnik and M. Gorczyca\* Dept. of Zoology, Univ. of Massachusetts,

We have been using the body wall muscle preparation of Drosophila larvae as a model system to study the development of neural connections. Our aim is to take advantage of molecular and genetic techniques in this organism to identify molecules that are essential for the development of specific patterns of innervation. One such molecule whose role in regulating neural development has been suggested is insulin. Both an insulin-like peptide and an insulin receptor-like gene have been characterized in *Drosophila*. In this study immunocytochemistry and receptor binding assays were employed to examine the expression of insulin and the insulin receptor at the body wall neuromuscular junction.

Insulin-like immunoreactivity was expressed at a subset of synaptic boutons in one identified muscle fiber per hemisegment. Insulin receptor-like immunoreactivity, as determined by 2 different monoclonal antibodies directed against the receptor alpha subunit, was present at all neuromuscular junctions and surrounded synaptic boutons near the nerve branch point of each muscle fiber. Similar localization was found using FITC-conjugated bovine insulin in unfixed preparations. Receptor binding assays using a wheat germ anglutinin protein extract from larval membranes showed the presence of a high affinity insulin binding activity. We are now screening for mutants of the insulin receptor gene to determine whether insulin and the insulin receptor can regulate the development of neuromuscular junctions. Supported by NIH grant NS30072 and a Sloan Fellowship

DAY/NIGHT AND CIRCADIAN RHYTHMS AMONG CELLS OF THE LAMINA IN THE HOUSEFLY'S OPTIC LOBE. Elzbieta Pyza and I.A. Meinertzhagen\*. Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1.

In the first visual neuropile (lamina) of the optic lobe of the housefly, Musca domestica, photoreceptor terminals (R1-R6) inervate monopolar interneurons within discrete cartridges. Two large cells in each cartridge, L1 and L2, receive input synapses from R1-R6; L2 in turn feeds back synapses upon R1-R6. The frequencies of both synaptic contacts oscillate under day/night (LD) and constant darkness (DD) conditions.

We have now detected that the axon diameters of L1 and L2 also reveal circadian changes. In flies reared in DD, L1 and L2 are both larger in subjective day than in subjective night, indicating a circadian rhythm. Under LD, L2 is larger during the day than the night, whereas L1 is of similar size in both day and night, indicating that L1's circadian rhythm is offset by the effect of light. The difference in response to light between L1 and L2 is confirmed in flies reared in continous light, when L2 is larger during subjective day but L1 larger during subjective night. The changes in L1 and L2 thus reflect two mechanisms: functional (light exposure) and circadian. To untangle the relative influence of these two, we reverse reared flies from day/night to night/day. Cell size does not change, indicating that circadian influence is stronger than light exposure. On the other hand, flies exposed to light for 1h after rearing from pupae in DD show a 60% increase in cell size, indicating a strong direct action of light. Cell size changes in LD are not induced by others factors like water deprivation. Although both mechanisms, functional and circadian, in L1/L2 size changes are unknown, they correlate in the lamina with day/night changes in serotonin-like immunoreactivity of a wide-field optic lobe cell, LBO5HT. Under LD, the lamina fibres of this cell are large in the day and exhibit more varicosities than during the night. L1/L2 were also smaller in the optic lobes of two flies, on the side ipsilateral to that receiving stab wounds to ventral protocerebrum designed to interrupt the axon of LBO5HT.

Supported by NIH grant EY-03592 and National Centres of Excellence grant.

ULTRASTRUCTURAL CHARACTERIZATION OF NEUROMUS-CULAR JUNCTIONS AT *DROSOPHILA* LARVAL BODY-WALL MUSCLES. X. Jia and V. Budnik\* Department of Zoology, University of Mass, Amherst, MA 01003

The body-wall muscles of *Drosophila* larvae are innervated by 3

morphologically distinct subsets of terminals. Mutations that increase the activity of motorneurons increase the number of synaptic boutons in one of these subsets. To examine the structural basis for this morphological plasticity we have initiated an ultrastructural analysis of nerve terminals. Motor axon terminals were examined with TEM by serial transverse thin sections at identified body-wall muscles in third instar wild-type larva.

Three types of motor axon terminals were found. One type of terminal contained clear synaptic vesicles 30-50 nm in diameter. It was surrounded by a well-developed subsynaptic reticulum -- a complex membrane system formed by invagination of the sarcolemma. Synaptic specializations at these terminals were characterized by electron-dense Tspecializations at these criminals were characterized by electron-tense 1-shaped bodies. The second type of terminal contained 80-120 nm dense-core vesicles and was devoid of clear vesicles and subsynaptic reticulum. Preliminary results showed the presence of septate junction at these terminals. The third type was a "mixed terminal" containing both clear and dense-core synaptic vesicles. As in dense-core vesicle terminals, the subsynaptic reticulum in mixed terminals was not well-developed. Both dense core and mixed terminals usually lied on grooves on the surface of the muscle cell, whereas clear vesicle terminals were more deeply invaginated on the muscle. We are in the process of performing serial reconstructions in order to compare the structure of these terminals to those seen at the light microscopic level and to the structure of terminals in mutants with altered excitability. Supported by NIH grant NS30072.

NERVE/MUSCLE INTERACTIONS DURING DEVELOPMENT OF INSECT ADULT LEG MUSCLES IN VIVO AND IN VITRO. J.L.Witten\*, J.Blair, R.Luedeman & R.B.Levine. Div. Neurobiol., Univ. Arizona, Tucson, AZ 85721

During metamorphosis in the hawkmoth, Manduca sexta, larval leg muscles die and are replaced by new adult muscles, while the same motoneurons persist to innervate the adult leg muscles (Kent and Levine, 1988). We are interested in the role leg motoneurons play in the development of adult leg muscles. Markers for muscles and muscle precursors, including peanut agglutinin, phalloidin, and an antibody to the Drosophila twist protein (courtesy F. Perrin Schmidt), were used to follow the differentiation of adult leg muscles in vivo during metamorphosis. 5-bromo-deoxyuridine (BUdR) incorporation was used to determine the time course of muscle cell proliferation. As reported for other muscles in holometabolous insects, we find that innervation is crucial for the development of adult leg muscles. Formation of adult leg muscles was prevented by cutting the leg nerve prior to the onset of metamorphosis.

Similar results were obtained *in vitro*. Dissociated tissue from developing adult legs included spindle-shaped cells that proliferated, fused, and differentiated into contractile networks only when co-cultured with neurons. Development of putative muscle cells was similar regardless of whether thoracic or abdominal ganglia were the source of the neurons. Supported by NIH NS 28495

## 23.7

TARGET CONTACT REGULATES THE EXPRESSION OF SYNAPTIC MARKERS DURING SYNAPTOGENESIS.

R.T. Doyle\*, M.I. Zoran and P.G. Haydon Department of Zoology and Genetics, Iowa State University, Ames, IA 50011

Identified buccal neurons of the snail <u>Helisoma</u> display differing abilities to become the presynaptic element of a functional chemical synapse. Buccal neuron 5 (B5) rapidly forms synapses after contacting targets and does not require new protein synthesis. In contrast , B19 must contact its specific synaptic target (SLT muscle) and undergo protein synthesis for synaptogenesis (Doyle et.al.,,1990, Soc. Neurosci. Abst.).

We have generated monoclonal antibodies with the goal of identifying presynaptic molecules that are necessary for synaptogenesis. Antibody SIN-1 is directed against a presynaptic marker of Helisoma chemical synapses. Immunoreactivity is present in the neuropil of ganglia and at varicosities on muscle fibers as seen in frozen sections. In cell culture the antigen is localized in varicosities of neuron B5 independent of target contact, while immunoreactivity is lacking in the neurites of neuron B19 when cultured alone. However, following contact between neuron B19 and its synaptic target, SLT muscle, immunoreactivity is seen at neuron-muscle contact sites. These contact sites occur either at terminal varicosities or regions along the neurite of B19. Thus, SIN-1 recognizes a synaptic antigen whose expression is retrogradely regulated by synaptic target contact.

## 23.9

ELECTROPHYSIOLOGY OF DEVELOPING SYNAPSES BETWEEN FILIFORM HAIR SENSORY NEURONS AND GIANT INTERNEURONS. J.M. Blagburn\*. Institute of Neurobiology, Univ. of Puerto Rico Sch. of Med., 201 Blvd. del Valle, San Juan, Puerto Rico 00901.

Each cercus of the newly-hatched cockroach (Periplaneta americana) has two filiform hair sensory neurons, one medial (M) and the other lateral (L). Both axons arborize within the terminal ganglion where the L afferent forms a strong monosynaptic connection onto giant interneuron (GI) 3 but does not synapse with GI2. The M afferent evokes large monosynaptic EPSPs in GI3 and small EPSPs in GI3. To determine the initial specificity of the synapses, I recorded intracellularly from the cell bodies of the filiform hair sensory neurons and GIs 2 and 3 at different stages of embryonic development. Action potentials were first detectable in both sensory neurons at 52% of development, at which stage L spikes evoked small EPSPs (0.5 mV) in 5/13 GI3s. Spikes in M did not produce EPSPs in GI2 until the 56% stage. Small M—GI3 EPSPs were detectable at the 59% stage, by which time both sensory neurons showed some spontaneous activity. At no stage did L spikes elicit EPSPs in GI2, suggesting that synapse formation is specific from the outset. Synaptic strengths increased rapidly up to about the 67% stage, when L—GI3 EPSPs had a mean stabilized amplitude of 8.7 mV, M—GI2 EPSPs 3.3 mV, and M—GI3 EPSPs 0.8 mV. The L—GI3 EPSPs subsequently declined to 4.4 mV at 81%, while the others remained constant. The properties of the synapses remained unchanged from 60% up to the first instar; with repeated stimulation at rates above 0.2 Hz the EPSP amplitude stabilized at half its initial value. At greater than 100 Hz the synapses showed modest facilitation (F values of 0.5–1). Supported by NIH Grant NS07464.

### 23.6

MOLECULAR HETEROGENEITY OF EMBRYONIC DROSOPHILA MOTO-NEURONS AND MUSCLES. E. W. Harkins\*, A. Chiba, and H. Keshishian. Biology Department, Yale University, New Haven, CT 06511.

To test the idea that molecular recognition is a guiding factor in connectivity at embryonic neuromuscular junctions, we asked whether molecular specialization exists among muscle and motoneuron populations. Through an enhancer trap second (Soc. Neurosci. Abstr. 16:135:9), we identified expression patterns which include subsets of motoneurons and/or muscles during the time of synaptogenesis (stage 16). Previously undescribed patterns are presented here.

Five lines label subsets of the RP motoneurons, which have identified targets. These lines distinguish RP2 and RP3 from each other and from RP1 and RP4; however, none distinguish between RP1 and RP4, which coinnervate muscle 13. Four lines distinguish motoneuron aCC from its non-motoneuronal sibling, pCC.

Ten lines have expression in a subset of muscles. None represent an obviously position-dependent pattern, in either the dorsoventral or anteroposterior axis. All are segmentally repeated. Embryonic expression patterns are not necessarily maintained in larvae. Line 3250 labels a subset of embryonic muscle fibers including 7 but not 6. Differential labelling of 7 and 6, which is also seen with *Toll* (Nose & Goodman, Soc. Neurosci. Abstr. 17:297.10; Halfon et al., this volume), is interesting because these muscles are dually innervated by the same motoneurons. Line 1849 labels only one of approximately 6 nuclei in muscle 5. The mechanism for this subcellular localization is not known but is intriguing given that heterogeneity between nuclei within a single muscle fiber has recently been described in vertebrates. These and previous results (Soc. Neurosci. Abstr. 17:91.10) show that there are molecular differences between individual cells of both the motoneuron and muscle populations, and perhaps even between nuclei of a given muscle fiber.

### 23.8

SELECTION OF TRANSMITTER RESPONSES AT SITES OF MEURITE CONTACT DURING SYMAPSE FORMATION. S. Ching, S. Catargi and P. Drapeau, McGill University, Center for Research in Neuroscience, 1650 Cedar Ave., Montreal, P.Q. H3G 1A4.

Pressure sensitive (P) cells of the leech receive an inhibitory Cl-dependent synapse from serotonergic Retzius (R) cells; P cells also have an extrasynaptic, excitatory response to 5-HT that is reduced upon contact with the R cell. By allowing cultured neurons to extend neurites, we have observed that this contact mediated loss of response is highly localized to only those neurites and growth cones of a P cell contacted by similar structures of the R cell. In P cell bodies and uncontacted P cell neurites and growth cones, we resolved a depolarizing response to focal application of 5-HT, as measured by intracellular recording at the soma. The excitatory response was markedly reduced in P cell growth cones contacted by R cell growth cones and neurites but not at uncontacted processes from the same cells. Similarly, single channel patch clamp recording identified a cationic channel activated by 5-HT in uncontacted P cell growth cones whose modulation by 5-HT contrasted with the lack of modulation of cationic channels from contacted growth cones. The nature of this loss of channel modulation is described in the accompanying Abstract. We conclude that neurite contact selectively eliminates extrasynaptic responses at sites of future synapses.

Supported by the MRC, FRSQ and FCAR of Canada and the Italian Ministry of Education.

SYNAPTIC TARGET-INDUCED REGULATION OF NEURONAL CALCIUM HOMEOSTASIS. M. J. Zoran\*, L. R. Funte. S. B. Kater, and P. G. Haydon.

Dept. of Zoology and Genetics, Iowa State Univ., Ames, IA 50011.

Dept. Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523.

Synaptogenesis establishes an orthograde flow of information from the presynaptic

Synaptogenesis establishes an orthograde flow of information from the presynaptic neuron to its postsynaptic target. This cellular communication between synaptic partners usually begins as a neuronal growth cone encounters the target cell. We report a retrograde signaling in which contact with a specific muscle target causes a transformation of calcium homeostasis in the growth cones and neurites of an identified presynaptic neuron during early synaptic; interactions in cell culture.

identified presynaptic neuron during early synaptic interactions in cell culture. Motoneuron B19, isolated from the buccal ganglion of Helisoma and plated into cell culture, is highly restricted in its synaptogenesis. Previous studies of interactions between neuron B19 and its normal synaptic partner, the supralateral radular tensor(SLT) muscle, have shown that contact with SLT muscle induces an enhancement in the responsiveness of neuron B19's secretory machinery to internal calcium levels. Through this retrograde signaling, the neuron acquires the ability to couple action potentials to the release of neurotransmitter, thus becoming a

competent presynaptic partner only following appropriate target contact. Resting calcium levels in presynaptic neuron B19 were monitored during initial interactions with synaptic targets. Within minutes of muscle target contact, rest calcium levels are locally elevated in the presynaptic neuronal growth cone. Following 24h of contact with SLT muscle fibers calcium levels were elevated throughout the entire neuron. Estimated calcium levels in muscle-contacted neurites of neuron B19 were 192±66nM (mean±s.d.; n=21) as compared to resting levels of 107±49nM (n=18) in neurites of non-contacted parallel control neurons. These elevated levels were maintained after severing target contacts. Similar elevations were achieved using extracted SLT muscle membranes. This shift in rest calcium set-point, induced by synaptic target contact, is a sustained and integral change in neuronal physiology associated with the onset of synaptic transmission.

H-7 PREVENTS TARGET INDUCED ENHANCEMENT OF ACTION POTENTIAL-EVOKED CALCIUM ACCUMULATION IN THE PRE-SYNAPTIC NEURON DURING SYNAPTOGENESIS L. R. Funte\*, and P. G. Haydon. Dept. of Zoology and Genetics, Iowa State University, Ames, IA

During synapse formation between neuron 19, B19, and its in vivo target the supralateral radular tensor muscle, action potential - evoked calcium accumulation is enhanced at sites of neuron-muscle contact. We have examined the time course of this enhancement using the calcium-sensitive dye Fura-2 to monitor changes in action potential evoked calcium accumulation. Neurons B19 were plated into culture alone and the action potential - evoked calcium accumulation was found to be 247 ± 86 nM (n = 5). Individual muscle fibers were manipulated into contact with B19's neurites. The action potential - evoked calcium accumulation at sites of contact was monitored over time. After contact, action potential - evoked calcium accumulation increased to 461 ± 55 nM after 10 minutes of contact, and to 849 ± 133 nM after 30 minutes of contact. Contact with non-synaptic novel targets did not cause such an enhancement.

We have begun to investigate the role of protein phosphorylation in the enhancement of action potential-evoked calcium accumulation. The addition of the protein kinase inhibitor H-7 (40 - 100 $\mu$ M) to the culture medium prevented the muscle induced enhancement of calcium accumulation (n = 6). However, the addition of H-7 to the bath following sustained contact with muscle (greater than 14 hours) did not reduce the already enhanced calcium accumulation, (n = 3) These data indicate that protein phosphorylation is involved in the induction of the enhancement of action potential evoked calcium accumulation, but is not necessary for its

### ION CHANNELS: DEVELOPMENT

### 24.1

APPEARANCE OF VOLTAGE-DEPENDENT CURRENTS DURING EMBRYONIC CEREBELLAR DEVELOPMENT. M.A. Holman\*, S. Bakalis, K. Kosik, G.R. Strichartz. Anesthesia Research Labs and Division of Neurology, Brigham & Women's Hospital, Boston, MA 02115

During embryonic brain development, neurons differentiate and migrate considerable distances before they achieve their final location and begin process differentiation. They extend processes, develop polarity and continue growth until they synapse on an appropriate target. The focus of this study was to correlate the development of electrical excitability with the distinctive morphological changes that cerebellar neurons undergo in culture

Embryonic cerebella were taken at day 15 of gestation (E15), dissociated, and plated. The development of ionic current was monitored by standard whole cell voltage clamp techniques. Resting potentials (Em) of newly plated cells (3-7 hr) under our recording conditions were generally between -5 and -15mV, with cells developing an average Em of -21mV by 24-48 hr, and -30mV after 72 hr. From initial plating to 24 hrs, cells had only a voltage dependent K' current (I<sub>K+</sub>) with current density at +50 mV = 12.6 pA/pF. This  $I_{K+}$  was completely abolished by 10mM external TEA or 140mM internal Cs\*. These cells had no detectable inward current. 24hr or more after plating, when morphological polarity was clearly evident, an inward Na\* current had developed with midpoint potentials for activation (E<sub>0.5</sub>) of -18mV and inactivation (E<sub>b</sub>) of -58mV, and a current density of 9.2pA/pF. In addition, the TEA sensitive I<sub>K+</sub> in these cells had a current density of 16.9pA/pF at +50mV.

These data suggest that E15 cerebellar neurons are electrically unexcitable initially, but develop Na<sup>+</sup> based excitability within 48 hours of plating. This induction of ionic current is independent of synapse formation and occurs after the cells develop a discrete axon.

## 24.3

Potassium Channel Novel cDNA Developmentally Regulated and is Expressed in Specific Cell Types in the Mouse Cerebellum. E. Chan. D. Goldman-Wohl, and N. Heintz\*. Rockefeller University, New York, New York 10021.

In a screen to identify genes whose expression is either specific to Purkinje cells or whose expression is dependent upon the presence of intact Purkinje cells, a novel potassium channel cDNA was isolated. This gene (Kv3.3P?) is highly homologous to and may be an alternatively spliced form of the previously identified Shaw-related potassium channel gene Kv3.3 (Ghanshani et al, Genomics, 1992). The Kv3.3P gene is developmentally regulated, with expression beginning at P8-P10 and increasing as the animal matures to adulthood. It is clearly expressed at much higher levels in the cerebellum than in any other tissues examined thus far. In situ hybridization using the colorimetric detection technique demonstrates that Kv3.3P is expressed specifically in Purkinje cells and in deep nuclei in the cerebellum. Because of the developmental expression of this gene and the cell types in which it is expressed the possibility exists that the formal contents of the cerebellum. it is expressed, the possibility exists that this novel potassium channel gene plays a pivotal role in connection formation in the cerebellum.

### 24.2

DEVELOPMENT OF MEMBRANE EXCITABILITY IN THE RAT CORTEX BEGINS AT EMBRYONIC DAY 11. D. Maric\*, I. Maric, S.Y. Smith and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH,

In this study we examined the development and maturation of ion channels and membrane receptors in E11-E22 rat cortical cells. Experiments were carried out on single cell suspensions obtained from embryonic cortex by gentle enzymatic digestion with papain. The cellular responses to a Na<sup>+</sup> channel agonist, veratridine, and to steroids, GABA, kainate, glutamate, NMDA, glycine, β-alanine and taurine were detected using a fluorescence-activated cell sorter and a negatively-charged Using a nucleative-activate cert soft and a legal very-value of the fluorescent indicator dye (oxonol) that partitions into the cells according to their transmembrane potential. At E11-E13 we have observed consistent depolarizing responses to veratridine, GABA and a progesterone metabolite  $5\alpha$ -pregnan- $3\alpha$ -ol-20-one  $(5\alpha, 3\alpha)$ , which were not blocked by the 5  $\alpha$ -pregnan-3 $\alpha$ -0-2 $\alpha$ -one (5 $\alpha$ , 3 $\alpha$ ), which were not blocked by the commonly used antagonists tetrodotoxin, becausing used antagonists tetrodotoxin, respectively. In fact these antagonists at E12 and E13 by themselves acted as depolarizing agents. Furthermore, at this early embryonic period there were detectable hyperpolarizing responses to 5 $\beta$ -pregnan-3 $\beta$ -ol-20-one (5 $\beta$ , 3 $\beta$ ), kainate, glutamate and glycine. Over E14-E19 the depolarizing (5p., 5p., kamate, gutannate and gylorine. Over 11-E15 the depotating responses to most of above agonists progressively increased, although some hyperpolarizing responses, particularly to kainate, glutamate and GABA persisted. However, all responses became sensitive to their respective antagonists at E14. In addition,  $5\beta$ ,  $3\beta$  became a very effective blocker of  $5\alpha$ ,  $3\alpha$ . GABA- and veratridine-induced cell depolarizations. From E19-E22 the depolarizing responses to GABA, taurine and some steroids reducible the production of the contraction ually decreased whereas those to kainate, glutamate, NMDA, β-alanine and glycine were enhanced. The results reveal a complex development of membrane excitability at the level of the cell body during the earliest period of postmitotic differentiation of the cortex.

## 24.4

EXTRINSIC FACTORS INFLUENCE THE EXPRESSION OF K+ CURRENTS IN CHICK CILIARY GANGLION NEURONS. M.M.Dourado\* and S.E.Dryer, Department of Biological

 $\begin{array}{lll} \underline{\textbf{M.M.Dourado}^*} & \text{and} & \underline{\textbf{S.E.Dryer}}, & \text{Department} & \text{of} & \text{Biological Science,} & \text{Program} & \text{in} & \text{Neuroscience,} & \text{Florida} & \text{State University,} & \text{Tallahassee,} & \text{FL} & 22306. \\ & \text{Mature neurons of the chick ciliary ganglion are known to express several calcium-dependent potassium currents <math>(I_{K(CA)})$  and two groups of voltage sensitive potassium currents  $(I_{A}, I_{DR})$ . A study of the normal development of these neurons showed that  $I_A$  and  $I_{K(Ca)}$  are barely detectable at early stages, but increase dramatically between stages 30 and 35 (embryonic days 7 to 9), a period that coincides with synapse formation with target tissues. In order to determine whether extrinsic factors are required for the normal development of ionic currents, cells were removed at stage 35 (embryonic day 9) and maintained in vitro for 4 days. These neurons, when compared with those acutely isolated from stage 39 (embryonic day 13) embryos, expressed very low amounts of  $I_A$  and  $I_{K(Ca)}$ . When the neurons were cultured as ganglion explants, rather than as dissociated cells, they were cultured as ganglion explants, rather than as dissociated cells, they expressed subnormal but detectable levels of I<sub>A</sub>, suggesting that cell-cell interaction with satellite cells plays a minor role in the expression of IA but not  $I_{K(Ca)}$ . In contrast, coculture with striated muscle results in the normal expression of  $I_A$  but not  $I_{K(Ca)}$ . Addition of whole chick embryo extract to the culture medium also supports the expression of  $I_A$ , but not  $I_{K(Ca)}$  suggesting the existence of soluble factors regulating  $I_A$  expression. However CNTF, a target-derived trophic factor that supports the survival of these neurons, has no effect on the expression of these currents *in vitro*. Supported by NIH Grant NS-27013

MECHANISM OF AXOTOMY-INDUCED SPIKE BROADENING IN BULLFROG SYMPATHETIC NEURONES. B.S. Jassar\* and P.A. Smith. Dept. Pharmacol. Univ. Alberta, Edmonton, Canada, T6G 2H7.

Axotomy of peripheral and central neurones produces different changes in the shape of the action potential (a.p.) in different neuronal types (Titmus & Faber, Prog. Neurobiol., 35:1,1991). The question therefore arises as to whether axotomy affects the same ion channels in all neuronal types and that the differential response simply reflects the different ion channels which are involved in a.p. generation in different cell types. To start to address this question, we used the whole-cell patch-clamp technique to compare  $Ca^{2+}$ ,  $Na^+$  and  $K^+$  currents from control bullfrog sympathetic B-neurones with those recorded from neurones 14-15days after in vivo axotomy. Axotomy of these cells results in an increase in the width and height of the a.p. and a decrease in the amplitude and duration of the afterhyperpolarization which follows the a.p. (Gordon et al., J. Physiol., 392:213,1987). We studied whether the increase in spike width resulted from decreases in Ca<sup>2+</sup> current and concomitant reduction of the voltage-dependent decreases in  $Ca^{2+}$  current and concomitant reduction of the voltage-dependent  $G_{K,C_a}$  which repolarizes the a.p.  $(I_C; Adams\ et\ al.,\ 1.$  Physiol., 330:537,1982) or whether it resulted from slowing of  $I_{N_a}$  inactivation. We have already established (Jassar & Smith, Soc. Neurosci Abs., 17:67, 1991) that axotomy causes about a 53% reduction in  $Ca^{2+}$  current. Axotomy produced a 55% decrease in  $I_C$  a marked (about 178%) increase in average  $I_{N_a}$  amplitude (at +10mV), and increased the rate of  $I_{N_a}$  inactivation (P < 0.05, for most voltages). These changes in  $I_{N_a}$  may explain the increased spike height seen after axotomy but cannot explain the increased spike width. The latter effect is attributable to changes in  $I_C$ . It remains to be determined whether this decrease in  $I_C$  simply reflects the decrease in  $I_{Ca}$  or whether axotomy produces additional, direct effects on  $I_C$  channels. Supported by the MRC of Canada.

## 24.7

## PRE-SYNAPTIC CALCIUM CHANNELS SUGGEST DIFFERENCES IN EPILEPTIC MOUSE BRAIN: ω-CONOTOXIN BINDING AND SYNAPTOSOMAL DATA

Mouritsen C.L.\*, Layton G.D., Esplin M.S., Abbott J.A., Litzinger M.J. Depts. of Pediatrics and Physiology. University of Utah. SLC, Utah 84132

With a loss of calcium homeostasis suggested as part of the pathophysiology of epilepsy, the VSCC plays a critical role in action potential propagation and neurotransmitter release.  $\omega$ conotoxin is a 27 amino acid neuropeptide toxin believed to mark pre-synaptic transmitter recontoxin is a 27 amino acto neuroperiore toxin beneved to mark pre-synaptic transmiter re-lease related VSCC. Vesicles derived from pre-synaptic membranes of neurons, called synaptosomes allow the entry of <sup>45</sup>Ca through VSCC when they are depolarized. Esplin et.al., 1991, have described a unique pattern of \(\phi\)-conotoxin binding site development in DBA audiogenic seizure mice. Audiogenic seizure susceptibility in DBA mice is greatest at juvenile ages 16 to 30 days and then gradually dissipates with age, whereas C57 mice are resistant to audiogenic seizures at all ages. Audiogenic seizure mice represent a serviceable model of

generalized epilepsy, particularly for human photosensitive and absence seizures.

Binding was done in synaptosomal membrane preparations from whole brain. The DBA show a slow gradual increase in ω-conotoxin binding from birth to postnatal day 7 when seizure susceptibility onsets and plateaus through day 16 when seizure susceptability peaks. Binding in C57 shows a rapid period of increase of 40 - 50% during postnatal days 10 - 15. This corresponds with critical period in non-epileptic mice as described by Himwich (1962) during which the central nervous system appears to be electrically activated. Synaptosomes were prepared from fresh whole brains taken from adult mice (80 days of age). Data shows at least a two-fold increase in calcium fluxes in the DBA audiogenic seizure mice as compared to the C57 mice. This data suggests pre-synaptic calcium channels in DBA mice are functionally more susthis cata suggests pre-synaptic carcium channes in DA mice are uncontany more suc-ceptible to depolarization and may underlie the pathophysiology of audiogenic sezures in these mice. Developmental synaptosomal studies are currently under way. Pre-synaptic calcium channel mechanisms allowing for neurotransmitter release may underlie receptor and calcium homeostatic changes described in various seizure models. (This work was supported in part by NIH grant # HD00886.) We gratefully acknowledge the late Dr. DM Woodbury's contributions.

## PRIMARY CULTURE FROM DISSOCIATED PUPAL NERVOUS SYSTEM OF DROSOPHILA MELANOGASTER. Yi-an Sun and R. J. Wyman\*. Dep't. Biology, Yale University, New Haven, CT 06511

Here we report the first primary culture from dissociated pupal nervous system. The method was basically similar to that of Wu et al. (J. Neurosci. 3:1888-1899, 1983). Pupae were staged according to Bainbridge et al. (J. Embryol. exp. Morph. 66:57-80, 1981). After plating all neurons were round or oval with no neurite or an unbranched neurite of 5-40 $\mu$ . The diameter of the cell bodies ranged from 3-12 $\mu$ . A few cells were as large as 20-25µ. Just after plating there were almost no bipolar or multipolar neurons. In a typical culture plated from an individual ~50 hr. after pupation and counted 84 hours later, there were 1520 monopolar, 1180 bipolar and 2240 multipolar neurons (total cell count: 4940). After 7 days, the average length of the neurites was ~ $103\mu$ (range 20-323 $\mu$ ). The neurites were well developed and extensively branched; most had 3d or 4th order branches. Growth cones had various morphologies: some had clear c- and p-domains. The filopodia were relatively long (10-30 $\mu$ ) compared to the size of the growth cones. The neurons became intricately networked, but we do not yet know if they form real synapses or are coupled electrically. In addition to neurons, the cultures included at least two different kinds of glial cells and several unidentified cells. Preliminary whole cell clamp recordings show action potentials. Some cells even show repetitive firing during current injection. Voltage clamp shows inward, outward and A-type currents. Identification of channels, synaptic function, and neurotransmitters is now ongoing. Support: NIH NS 07314; NSF BNS 85-10678.

MONDAY AM

ACTIVATION OF VOLTAGE- OR LIGAND-GATED CALCIUM CHANNELS INDUCES NEURITE RETRACTION. Luís E. Politi\*, Evan B. Dreyer, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA.

Our laboratory previously showed that NMDA (100 µM) induced retraction of neurites in rat retinal ganglion cells (RGCs; Offermann et al., Soc. Neurosci. Abstr. 1991;17:927). To investigate further the ionic channels involved in this process, glutamate (GLU; 0.1-1mM) or NMDA (100 µM) in Ms2+-free Hanks' solution was 'puffed' lmM) or NMDA (100 µM) in Mg<sup>2+</sup>-free Hanks' solution was 'puffed' onto rat RGCs or hippocampal neurons (HNs) in culture in the presence or absence of various ion channel antagonists, and the responses were recorded by computer-enhanced video microscopy. Following application of GLU or NMDA, ~75% of RGCs (n = 59) and 100% of HNs (n = 14) retracted their neurites within 10 s to 4 min; when agonist was discontinued, the neurites regrew. In RGCs, NMDA-induced retraction was blocked significantly by the NMDA open-channel blocker MK-801 (12  $\mu$ M) or by intracellular Ca<sup>2+</sup> chelation using BAPTA-AM (50  $\mu$ M), but not by nimodipine (1  $\mu$ M). Compared to GLU or NMDA, depolarization with 55 mM KCl resulted in a slightly smaller percentage of cells retracting their neurites (56% for RGCs; 78% for HNs; n = 25). In RGCs, nimodipine (1  $\mu$ M) but not  $\omega$ -CgTX (10  $\mu$ M) blocked the K+induced retraction of neurites, suggesting that L-type voltage-dependent Ca<sup>2+</sup> channels can also be involved in the retraction process. The concentrations of GLU, NMDA & KCl shown to cause neurite retraction contentiation in GLO, NNDA & Coston with a cause feature reduction all evoked similar increases in  $[Ca^{2+}]$  in the RGC body (mean 495 ± 85 nM, n = 5). Thus,  $Ca^{2+}$  entry via either NMDA-operated channels or L-type  $Ca^{2+}$  channels may be associated with neurite retraction.

CALCIUM CHANNELS IN NEURONS DIFFERENTIATING IN VITRO FROM THE NEURAL CREST ARE PREDOMINATELY DIHYDROPYRIDINE AND \(\text{0}\)CONOTOXIN RESISTANT. Steven G. Matsumoto.\* Dept. Biol. Struct. & Funct. Oregon Health Sciences University, Portland, OR 97201.

The neural crest gives rise to all peripheral autonomic and spinal sensory neurons. These neurons possess high threshold calcium channels that display varying degrees of sensitivity to dihydropyridine (DHP) and \(\text{0}\)-contoxin (\(\text{0}\)-CgTX blockade. Sympathetic neurons display the grestest sensitivity to \(\text{0}\)-CgTX blockade with a small component of DHP-sensitive and DHP/\(\text{0}\)-CgTX resistant calcium current. Dorsal root ganglion cells possess a more equal distribution of DHP/\(\text{0}\)-CgTX sensitivity and a significantly larger proportion of calcium current that is resistant to both agents (Regan et al., 1991. Neuron \(\text{6}\): 269). Studies have also shown that the the pharmacology of calcium channels may change during development (eg. Gray, et al., calcium channels may change during development (eg. Gray, et al. 1992 Neuron 8: 715).

The neurons that differentiate in vitro from mouse neural crest cells possess characteristics, such as neurotransmitter expression, that are a composite of many types of peripheral sensory and autonomic neurons. In the present study we have begun to examine the pharmacology of high threshold calcium currents in these neurons in an attempt to determine their state of differentiation. Virtually all of the neurons determine their state of differentiation. Virtually all of the neurons recorded from under whole cell voltage clamped conditions displayed Cd-sensitive Ba currents that were resistant to both calcium channel antagonists. The addition of NGF and/or CNTF which increases the survival rate of these neurons had no effect on their calcium channel pharmacology. Current studies are designed to examine the potential role of synaptic target interactions on the differentiation of calcium channels. (supported by NIH grant NS25644-06)

REDUCTION OF EARLY NEURONAL DEATH IN THE CERVICAL SPINAL CORD OF THE CHICK EMBRYO. S.E. McKay\*. C.J. Cardwell, and R.W. Oppenheim. Dept. Neurobiology & Anatomy, Wake Forest Univ., Bowman Gray Medical School, Winston-Salem, NC 27157.

We have examined the extent of cell death in a population of neurons in the ventral horn of the cervical spinal cord under conditions which reduce motoneuron death in other regions of the spinal cord in order to determine if survival of the cervical neurons is regulated like that of somatic motoneurons. Embryos were treated <u>in ovo</u> with pharmacological agents that reduce motoneuron cell death at later stages in lumbar and brachial spinal cord. The drugs were injected on embryonic days (E) 3 and 4 of incubation. Chicks were sacrificed on E4.5 (stage 24-25). The tissue was embedded in paraffin, cut into serial sections and stained with Hematoxylin. Degenerating neurons were counted in every fifth section of cervical segments 9 through 12. Preliminary results indicate that cervical neurons were protected from cell death by application of the protein synthesis inhibitor, cycloheximide as well as by curare and protein extracts from skeletal muscle, all agents known to prevent motoneuron death in other regions. Unlike motoneurons, however, the cervical neurons also appear to be sensitive to NGF. Further studies are in progress to confirm the sensitivity of these neurons to NGF as well as to identify other neurotrophic agents to which these neurons are responsive.

DEVELOPMENT OF NUCLEUS AMBIGUUS (NA) AND HYPOGLOSSAL NUCLEUS (XII) IN THE RAT: A HISTOLOGICAL, DII, AND IMMUNO-CYTOCHEMICAL STUDY D.R. Friedland, A.R. Eden\*, I.T. Laitman, Depts of Cell Biol./ Anat. and Otolaryngol., Mt. Sinai Sch. of Med., NY 10029.

Our previous studies have focused on the assessment of motoneuron cell death

Our previous studies have focused on the assessment of motoneuron cell death (MCD) in NA and XII by routine histological methods. Current studies continue this approach, and add examination of nucleus formation and cellular identity using fast-Dil and immunocytochemical methods. Rats at gestational ages 15 days (E15), E16, E17, E19 and postnatal days 1 (P1) and adult were studied. MCD was assessed on paraffin embedded tissue, serially sectioned, and stained with H&E. For fast-Dil and immunocytochemical studies, rats were perfused through the umblical vein with fix. Dil was put on vagus and hypoglossal nerves just distal to the brainstem. Standard immunocytochemical methods against ChAT and GABA were employed.

Histology shows organization of both nuclei by E16 although NÅ is not fully distinct until E17. Cell loss in NA between E17 and adult is approximately 48% (P≤0.01). In XII, MCD occurs between E16 and E19 (34% loss, P≤0.001) with no loss through P1 or adult. Fast-Dil studies indicate nucleus formation earlier than that seen histologically. Traces of E15 vagus nerves reveal a well defined NA with no migrating cells apparent outside the nucleus. Thus, MCD in NA may begin prior to E17 but can not be assessed by routine histological methods. Dil traces of the hypoglossal nerve show little change in XII over this time period. This appears to be due to cells of XII undergoing little, if any, migration after neurogenesis. Immunocytochemical studies show few GABAergic intermeurons among the motoneurons in NA and XII consistent with findings in adult rats by Mugnaini and Oertel, 1985.

NA and XII consistent with findings in adult rats by Mugnaini and Oertel, 1985. Precise characterization of nucleus formation, cellular identity, and MCD in NA and XII will define critical periods in the development of upper respiratory tract control, and lend insight into the myriad of postnatal neuromuscular pathologies in this region.

CHANGES IN DNA BINDING TO TRANSCRIPTION FACTORS DURING PROGRAMMED NEURONAL CELL DEATH. S. Wang\*A, J. DiBenedetto, and R. N. Pittman. Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104

Double stranded oligonucleotides representing consensus sequences for Spl, CRE, Oct, HSVOct, and E2F are being used in mobility gel retardation assays to determine if changes in the binding of transcription factors to these sequences correlate with early events in neuronal cell death. Two neuronal populations undergoing programmed cell death are being used. The first population consists of PC12 cells in which 90-95% of the cells become dependent on NGF for survival and undergo RNA-dependent programmed cell death following removal of NGF (Pittman et al., 1992; Soc. Neurosci. Abstr.). The second population consists of whole rat SCG in suspension culture at 37°C. In the absence of NGF, neurons in the ganglia die within 12 hrs, while addition of NGF or Actinomycin D to the medium rescues a large number of cells during the first 6 hrs. Initial observations indicate that changes in gel shift patterns occur in both neuronal populations and that NGF can delay and/or reverse these changes. This work was supported by the Univ. of PA Research Foundation.

NOTOCHORD DEPENDENT CELL SURVIVAL IN THE VENTRAL HALF OF THE CHICK NEURAL TUBE. S. Homma and R. W. Oppenheim, Dept. of Neurobiol. and Anatomy, Bowman Gray Sch. of Med., Winston-Salem, NC 27103

We previously reported that three pycnotic cell loci are observed in the chick embryo neural tube (NT) at stage 17-19: (1) the dorsal part of NT including the roof plate; (2) the area between prospective lateral motor column and the floor clater and (3) the mid-portion of the floor clate.

including the roof plate; (2) the area between prospective lateral motor column and the floor plate; and (3) the mid-portion of the floor plate.

Recently, we have begun to examine the factor(s) that control the extent and the distribution pattern of pycnotic cells in the NT. One candidate is a signal(s) from the notochord (NC). Apparently, the zone of polarizing activity (ZPA) specifies the pattern and extent of cell death in the chick embryo limb bud as well as the polarity in the anterior-posterior axis (Hinchliffe, '81). The NC is analogous to the ZPA in the chick embryo spinal cord, acting to specify polarity in the dorso-ventral axis (Yamada et al., '91). These data led us to test the hypothesis that the NC might specify the extent and distribution pattern of pycnotic cells in the NT.

We used the method described by Yamada et al. ('91) to remove the NC.

We used the method described by Yamada et al., ('91) to remove the NC. The NT at the operated (NC-less) site (lumber segments, stage 20) was embedded in plastic and serial semi-thin sections were cut and stained with toluidine blue. Our preliminary results indicate that ventral NT structures appear to be absent as described by Yamada et al., ('91). In addition, embryos lacking the NC appear to exhibit considerably more pycnosis in the ventral NT compared to controls. Finally, there was also an apparent rostral-caudal gradient of pycnotic cells in the NC-less NT. In the caudal operated regions, more pycnotic cells were observed along the ventral midline, whereas at the rostral regions increased dying cells were located more dorsally.

### 25.4

EXPRESSION OF CELL CYCLE GENES IN POSTMITOTIC NEURONS DURING PROGRAMMED CELL DEATH. R. S. Freeman\*, P. A. Lampe, and E. M. Johnson, Jr. Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO 63110.

Pharmacology, Washington University School of Medicine, St. Louis, MO 63110.

We are interested in characterizing the molecular mechanisms that cause programmed cell death (PCD) in rat sympathetic neurons upon withdrawal of NGF. The hypothesis we are testing is that cell cycle genes may function as regulators of PCD. In several model systems, PCD is characterized by (1) a requirement for transcription and translation, (2) an initial setting of the cell cycle to a Go/Gp-like phase, (3) ultrastructural changes reminiscent of those that accompany mitosis, (4) and increased expression of specific genes that are similarly induced during the cell cycle. We have used northern blot analysis to characterize cell cycle gene expression in neuronal cultures prepared from rat superior cervical ganglia and maintained in the presence or absence of NGF. Several members of the cyclin gene family (cyclins C, D, and E) are expressed in our cultures with cyclin D expression increasing about 3-5 fold concomitant with PCD. These cyclins are believed to function during the G1-phase of the cell cycle as opposed to cyclins A and B that act during the S- and M-phases. We have not detected expression of the A- and B-type cyclins nor have we observed expression of the cdc2 gene. Three genes encoding extracellular-signal related protein kinases (ERKs or MAP kinases) are abundantly expressed although little or no change in expression accompanies PCD. These results suggest that certain cell cycle genes are expressed and, therefore, may function in postmitotic neurons. We are currently using in situ hybridization to determine exactly which cells are expressing these genes and whether the enhanced expression of cyclin D during PCD is neuron-specific. Supported by the Wash. U. ADRC(AG 5P01-A605681-08) and an NIH training grant (2-T32-NS07071-13).

## 25.6

ISOLATION OF GENES UP- OR DOWN-REGULATED IN CELLS UNDERGOING PROGRAMMED NEURONAL CELL DEATH. A.J. DiBenedetto,\*S. Wang, and R.N. Pittman. Department of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

PC12 cells grown under culture conditions that render them dependent on NGF for survival undergo RNA and protein synthesis-dependent cell death upon NGF deprivation. A differential hybridization screen of a cDNA library made from PC12 cells committed to die upon removal of NGF resulted in the isolation of several clones expressed more highly in cells committed to die, and others expressed strongly in control cells but not detectable in dying

Current studies include sequence analysis of newly isolated genes and homology searches for known functional motifs. The time course of differential expression of these genes following removal of NGF is being determined by Northern blot analysis. The newly isolated genes are also being examined for their expression in neurons before, during and after the period of naturally occurring cell death in embryonic rat tissues. In addition, sets of pre-selected genes are being screened for differential hybridization to cDNAs derived from control and dying cells. This work was supported by the University of PA Research Foundation.

THE APOPTOSIS INHIBITOR, AURINTRICARBOXYLIC ACID PREVENTS EXCITOTOXIN-INDUCED NEURONAL DEATH IN VIVO. J. M. Roberts-Lewis\*, V. R. Marcy, Y. Zhao, T. Fedora, M.E. Lewis, R. Siman and J. L. Vaught, Cephalon, Inc., West Chester, PA 19380

It is well established that a precipitous or sustained elevation in intracellular calcium levels can trigger a sequence of events leading to neuronal death. Such a disruption of calcium homeostasis can be brought about by excessive excitatory amino acid (EAA) receptor stimulation. EAAs have been directly linked to ischemia-induced neuronal degeneration in animal models, and may be involved in a host of other neurodegenerative diseases or injuries as well. The lethal effect of elevated intracellular calcium is likely to be mediated by one or more intracellular calcium-dependent enzymes, such as phospholipases, protein kinases, proteases or endonucleases. Programmed cell death, or apoptosis, is characterized by the internucleosomal cleavage of DNA by a calcium-dependent endonuclease. Previous investigations, using in vitro systems, have demonstrated that apoptotic cell death could be prevented with the endonuclease inhibitor, aurintricarboxylic acid (ATA). To begin to explore whether there might be some commonality between apoptosis and excitotoxin-induced neuronal death in vivo, we administered ATA to NMDA-treated rats in order to evaluate the neuroprotective potential of ATA in this model. ATA treatment virtually abolished NMDA-induced spectrin proteolysis in the hippocampus, indicating a robust neuroprotective action of this compound against excitotoxin-mediated neuronal death in vivo. We are presently examining the neuroprotective activity of ATA in cerebral ischemia. Preliminary results have shown that ATA is also neuroprotective in a transient, global ischemia model.

## 25.9

A DEATH-ASSOCIATED mRNA IN THE OLFACTORY SYSTEM OF THE RAT: AN IN SITU HYBRIDIZATION STUDY. T.J. Mahalik, E. W. Johnson and G.P. Owens. Dept. of Cellular and Structural Biology and Rocky Mountain Taste and Smell Center. U. of Colorado Health Sciences Center. Denver, CO. 80262.

In the vertebrate CNS, programmed neuronal death plays an important role in development, little is known about the mechanisms that underlie and control programmed neuronal death, however. To better understand these processes, we examined the expression of a death-related mRNA RP8 (Owens et al.Mol. and Cell. Biol. 11:4177:91) in the rat olfactory epithelium with in situ hybridization.

RP8-labeled cells were primarily located near the basal layer of the olfactory epithelium. This pattern of labeling corresponded to the labeling pattern observed with a GAP43 probe which labels immature olfactory neurons (Verhaagen et al. J. Neurosci. 9:683:89). Virtually no RP8 labeling was observed in regions of the olfactory epithelium containing mature receptor neurons.

Given that the RP8 message is truly a cell death gene, its expression in the olfactory epithelium suggests that newly formed olfactory receptor cells normally undergo programmed cell death. Supported by Grants NS HHS NS09199 and DC00294.

## 25.11

BCL-2 INHIBITS APOPTOSIS IN MULTIPLE NEURAL CELL TYPES. L.T. Zhong, S.P. Mah, R.H. Edwards and D.E. Bredesen\* CEL, UCLA, Los Angeles, CA 90024-1769.

The proto-oncogene bcl-2 (Tsujimoto et al., Science 1984;226:1097) was recently shown to inhibit apoptosis in B lymphocytes (Hockenbery et al., Nature 1990;348:334). We found that PC12 pheochromocytoma cells do not express endogenous Bcl-2; however, expression of Bcl-2 in PC12 cells via a retroviral expression vector led to a marked inhibition of apoptosis (Mah et al., submitted for publication). This inhibition occurred in both undifferentiated and nerve growth factor-treated PC12 cells.

We now report that the expression of Bcl-2 in two temperaturesensitive immortalized central neural lines also inhibits apoptosis. In a nigral neural line (Durand et al., Soc. Neurosci. Abs. 1990;16:40), apoptosis was inhibited at both the permissive and restrictive temperatures. Furthermore, apoptosis induced by either serum and growth factor withdrawal or by the calcium ionophore A23187 was inhibited by the expression of Bcl-2. In a cerebellar neural line (Greenberg et al., PNAS 1984:969), a more modest inhibition of A23187-induced apoptosis was observed at both permissive and restrictive temperatures; serum withdrawal did not induce apoptosis in this cerebellar neural line.

Analyzing the mechanism(s) by which Bcl-2 expression in central neural cells inhibits apoptosis may advance the understanding of certain forms of neural degeneration.

GENES ASSOCIATED WITH NEURONAL APOPTOSIS APPEAR TO DIFFER FROM THOSE IN OTHER CELLS. S.R. D'Mello\* and C. Galli. Inst. of Neurobiology, CNR, 00137 Rome, Italy.

Programmed cell death (apoptosis) occurs naturally during embryogenesis and can be induced in vitro in a variety of cell types.

Programmed cell death (apoptosis) occurs naturally during embryogenesis and can be induced *in vitro* in a variety of cell types. Similar morphological and biochemical changes including increased transcription of specific genes accompanies apoptosis in different cell types, suggesting a common mechanism for this mode of degeneration. Cultured rat sympathetic neurons deprived of NGF die within 48-72 hours by a process resembling apoptosis. As a first step towards understanding neuronal apoptosis, we examined in sympathetic neurons, the expression of 4 genes whose expression is increased in other biological systems. The levels of mRNA encoding sulfated glycoprotein 2 (SGP-2), RP-8, 14-Kd lectin, and ubiquitin have been reported to be dramatically induced in apoptotic prostate, thymocytes, leukocytes, and hawkmoth intersegmental muscle, respectively. Interestingly, in apoptotic sympathetic neurons SGP-2, RP-8, and ubiquitin mRNA levels are not significantly altered, whereas 14-Kd lectin mRNA is reduced 2 fold within 24 hours.

Like sympathetic neurons, NGF-differentiated PC12 cells undergo apoptosis and die in 4-5 days following NGF deprivation. In these cells, SGP-2, RP-8, and ubiquitin mRNA levels are unchanged for up to 48 hours of deprivation. However, 14-kd lectin mRNA decreases 2-3 fold in 24 hours. Taken together, the lack of induction of these genes in neurons raises the possibility that the molecular mechanisms involved in neuronal apoptosis may differ from those operating in other cell types. We are presently attempting to identify genes, if any, that are induced in neurons during apoptosis.

### 25.10

EXPRESSION OF A DEATH-ASSOCIATED MRNA IN THE CEREBELLAR CORTEX OF WEAVER MICE. G.P. Owens, T.J. Mahalik and W.E. Hahn\*Dept. Cell. & Struct. Biology, U. of Colorado School of Medicine, Denver, CO 80262

Despite the numerous examples of programmed cell death (PCD) in the developing nervous system, little is known about the molecules and mechanisms regulating this process. We have recently isolated a cDNA clone, RP-8, that is expressed in immature thymocytes programmed to die. (Owens et al. Mol. Cell. Biol., 11:4177, 1991). To determine if this gene is expressed in dying cells in the brain, we probed the cerebellar cortex of weaver mice by in situ hybridization. In weavers precursors to granule neurons fail to differentiate and die postnatally.

RP-8 positive cells were scattered throughout the inner region of the external germinal layer (EGL) where death of progenitor cells is usually observed. Expression of RP-8 largely ceased by postnatal day 17 and it was not observed in the EGL of normal (control) cerebellae. RP-8 labeling was also detected in the globus pallidus indicating that this may be another brain region where cell death is elevated in the weaver mutant. The infrequent appearance of labeled cells may reflect the rapidity of death and efficient removal of cellular debris. These data suggest RP-8 functions in PCD or is a marker of the process.

## 25.12

# INDUCED NEURON DEATH IN A THALAMIC NUCLEUS INVOLVED WITH VOCAL LEARNING IN ZEBRA FINCHES.

F. Johnson\* & S.W. Bottjer. USC, Los Angeles, CA 90089

A discrete network of forebrain nuclei underlies vocal learning and production in male zebra finches. This network includes three nuclei that form a neural pathway important for vocal learning in juveniles: Area X (X) in the avian basal ganglia projects to a thalamic nucleus (DLM), which in turn projects to a nucleus in the neostriatum (IMAN). Dramatic morphological changes occur in these nuclei over the course of vocal learning. While X increases in volume and neuron number, DLM decreases in volume but not neuron number, and IMAN decreases in both volume and neuron number. We are interested in determining whether access to afferent inputs and efferent targets is necessary for the normal development of these nuclei.

access to afferent inputs and efferent targets is necessary for the normal development of these nuclei.

In an initial study, IMAN was electrolytically lesioned in male birds at various stages of vocal development (20, 40, 60 days of age and adult) and birds were sacrificed either 2, 4, or 6 days post-lesion. Electrolytic lesions of IMAN remove the efferent target of DLM and axotomize the distal portion of DLM axons. Although DLM does not normally lose neurons during development, IMAN lesions in 20 day-old birds result in the appearance of numerous pyknotic cells in DLM by 4 days post-lesion and the near-complete loss of DLM neurons by 6 days post-lesion. In contrast, identical lesions in adult birds have little or no effect on neuronal survival in DLM. Analysis of 40 and 60 day-old birds shows an age-related decrease in the ability of IMAN lesions to induce neuron death in DLM. These data suggest that the survival of DLM neurons may depend on access to a factor(s) supplied by their efferent target, but only during a restricted period of development that coincides with the acquisition of learned vocal behavior.

NATURALLY OCCURRING CELL DEATH DURING POST-NATAL DEVELOPMENT OF THE SUBSTANTIA NIGRA PARS

NATAL DEVELOPMENT OF THE SUBSTANTIA NIGRA PARS COMPACTA (SNpc). E Janec and RE Burke\*. Dept. of Neurology, Columbia University, NY, NY 10032. We have previously shown in rat that a striatal axon-sparing injury, due either to hypoxia-ischemia or to the excitotoxin quinolinate, during development results in a diminished adult number of SNpc dopaminergic neurons (Neuroscience, 1992). This decrease occurs in the absence of direct injury to the SNpc. We have proposed that this effect may be due to diminished striatal target-derived trophic support for the developing SNpc, leading to an augmented developmental regressive event. If this proposal is correct, then it should be possible to demonstrate proposal is correct, then it should be possible to demonstrate naturally occurring cell death during normal SNpc development. Therefore, we examined the post-natal development of this region using Nissl and silver staining, to identify pyknotic cells. Both stains revealed pyknotic cells in SNpc from post-natal day (PND) 2 to 20. Rare pyknotic cells were observed on PND 28, and none on PND 70. Pyknotic cells were most abundant on PND 2 (mean 9.6+1.2 [SEM] pyknotic cells per section), and rapidly decreased to 1.2+0.2 by PND 12. However, on PND 14 5+0.3 second peak of cell death occurred with a mean of 4.5+0.3 raping decreased to 1.2±0.2 by PND 12. However, on PND 14.5±0.3 pyknotic cells. The number then gradually declined to 0.2±0.1 by PND 28. We conclude that programmed cell death does occur during post-natal development of the SNpc. The second peak of cell death may correspond to a period of synaptogenesis (PND 13-17) in the rat striatum. NS26836, PDF, UCP.

NORMAL MORPHOLOGY AND ELECTRICAL ACTIVITY DEMONSTRATED IN A MOTONEURON SPARED FROM DEVELOPMENTAL CELL DEATH IN THE MOTH, MANDUCA SEXTA. A.W. DeLorme<sup>1</sup>, K.A. Klukas<sup>1</sup>, K.A. Mesce •1.2, S.E. Fahrbach<sup>3</sup>. Department of Entomology<sup>1</sup> and Graduate Program in Neuroscience<sup>2</sup>, University of Minnesota, St. Paul, MN 55108 and Department of Entomology and Neuroscience Program<sup>3</sup>, University of Illinois at Urbana-Champaign, Urbana, IL

61801. Motoneuron 12 (MN-12), located in the abdominal ganglia of *Manduca* sexta, undergoes developmental cell death within four days of adult ecdysis. Histological studies have demonstrated that MN-12 can be spared from Histological studies have demonstrated that MN-12 can be spared from neuronal death by isolating the abdominal ganglia from adjacent anterior neuronal input (Fahrbach and Truman, 1987, J. Neurobiol., 18: 497-508). We wanted to determine the degree of this sparing effect by examining the electrical activity and morphology of control and spared MN-12 neurons. To accomplish this, we recorded from and dye-filled MN-12 neurons using Neurobiotin-filled electrodes. Adult male moths were ligated above the abdomen just prior to adult ecdysis to spare the MN-12 cells from death. MN-12 neuron seconded them introduction. 12s were recorded from intracellularly four or more days later. Control motoneurons, from adult males, were impaled before the occurrence of cell motoneurons, from adult males, were impaled before the occurrence of cell death. The morphology of Neurobiotin-filled MN-12 cells was visualized by binding the Neurobiotin with a monoclonal anti-biotin antibody conjugated to the cyanine flourophore, Cy-5. MN-12 cells were subsequently examined with a laser scanning confocal microscope equipped with a krypton/argon laser. Even though the spared MN-12s had no muscle target and experienced the normal decline in steroid levels that triggers' such death, both intracellular recordings and morphological data showed no discernable differences between spared and control MN-12s. This is the first demonstration that a neuron can be fully spared from developmental cell death and maintain its normal morphological and electrical properties. We are currently examining the functional role that MN-12 plays in the performance of adult behavior.

IS THERE A NEURON-KILLING FACTOR IN THE MANDUCA SEXTA NERVOUS SYSTEM? M. K. Choi and S. E. Fahrbach\*. Department of Entomology and the Neuroscience Program, University of

Illinois at Urbana-Champaign, Urbana, IL 61801
The emergence of the *Manduca sexta* moth is accompanied by the death of half of the neurons in the abdominal nervous system. In the case of the MN-12 motoneurons, this cell death is regulated both by case of the Mn-12 motionerorist, tins cell death is regulated both by hemolymph concentrations of a steroid hormone, 20-hydroxyecdysone, and by actions exerted by adjacent ganglia (Truman and Schwartz, 1984; Fahrbach and Truman, 1987). To characterize this signal, we have developed culture conditions in which the extent and pattern of cell death parallels that seen in intact animals. The culture condition that produced a profile of neuronal degeneration most similar to the intact control ganglia of the same age was the supplementation of Grace's insect medium with 20% heat-inactivated FBS. We have replicated, in vitro, the sparing effect on MN-12 of cutting the ventral nerve cord anterior to the first unfused abdominal ganglion (A3). This effect was affective that is unusue abdominar garginar (AS). This elect was most readily seen when the cultures were initiated between 21 and 24 h after adult ecdysis. There was a significant increase in the percentage of MN-12 motoneurons dying in A3 when the pterothoracic ganglion was co-cultured with the isolated abdominal nerve cord instead of being co-cultured with the isolated abdominal nerve cord instead of being removed entirely after transection. We also systematically varied the length of connectives left attached to A3 in our cultures. Longer connectives were always associated with a higher proportion of dying MN-12 neurons. Heterochronic cultures have been used to study the developmental expression of the ability of the pterothoracic ganglion to kill neurons in A3. A rather broad range (Day -1 to Day +1) of the killing effect was detected. These results suggest the existence of a soluble neuron-killing factor in the pterothoracic ganglion of the *M. sexta* nervous system.

NEURONAL DEATH: TOXINS

A DECOMPOSITION PRODUCT OF THE CONTAMINANT IMPLICATED IN L-TRYPTOPHAN EOSINOPHILIA MYALGIA SYNDROME KILLS SPINAL CORD NEURONS BY STEREOSPECIFIC, INTERLEUKIN-1 DEPENDENT MECHANISMS. E.M. Sternberg\*, S.W. Page, M. Schultzberg, F.S. Thomas, P. Zelazowski, R. Avidor and D.E. Brenneman Clinical Neuroendocrinology Branch, NIMH; Center for Food Safety and Applied Nutrition, FDA; National Institute of Child Health and Disease; Bethesda MD 20892 and Washington D.C.20204; Clinical Research Center, Division of Basic Science in Dementia, Karolinska Institute, Huddinge Hospital, S-141 86 Huddinge, Sweden.

The L-Tryptophan eosinophilia myalgia syndrome (L-TRP-EMS), related to ingestion of impure L-tryptophan (L-TRP), occurred in epidemic proportions in the United States in 1989. The most frequent cause of death during the acute phase of the illness was respiratory failure in the context of a degenerating axonal neuropathy. In the present study, two diastereoisomeric metabolites of 1,1<sup>1</sup> ethylidenebis[L-tryptophan] (EBT), the impurity most highly associated with development of L-TRP EMS, were compared for evidence of neurotoxicity in vitro. In one month old spinal cord cultures derived from fetal mice, synthetic (-)-(1S,3S)-1-methyl-1,2,3,4-tetrahydro-β-carboline-3-carboxylic acid (1S-β-C) produced a 30-35% loss in numbers of neurons. Toxicity was not apparent after produced a 30-39% loss in numbers of neurons. Toxicity was not apparent attreatment with the R-isomer of the same compound or with the parent compound, EBT. Co-treatment of cultures with 1S- $\beta$ -C and neutralizing antiserum to interleukin-1 alpha (IL-1  $\alpha$ ), or with 1S- $\beta$ -C and neutralizing antiserum against the murine IL-1 receptor, prevented neuronal cell death associated with 1S- $\beta$ -C. Recombinant IL-1  $\alpha$  also produced neuronal killing that was not additive to that observed with the 1S- $\beta$ -C treatment. These studies strongly implicate 1S- $\beta$ -C as one potential causative neurotoxic agent in the axonal degenerating neuropathy of L-TRP EMS and suggest that the mechanism of this effect is receptor-mediated and

REDUCTION OF INTRAMUSCULAR NERVE BRANCHING RESULTS IN DECREASED MOTONEURON SURVIVAL J. Tang\* and L. T. Landmesser. Dept. Physiology & Neurobiology, University of Connecticut, Storrs, CT 06269

Blockade of neuromuscular activity during the period of naturally occuring cell death increases intramuscular nerve branching, synaptogenesis, and survival of embryonic chicken motoneurons. Therefore enhanced motoneuron survival following activity blockade may result not only from increased production of trophic factor by the target, but also from enhanced ability of motoneurons to take up trophic factor via additional branches and/or synapses. Since removal of polysialic acid (PSA) by a PSA specific endoneuraminidase (Endo-N) during the period of nerve ingrowth and motoneuron cell death has been shown to reduce intranuscular nerve branching, we wished to determine if this would also affect motoneuron survival. When PSA was removed from St 30 to 35 by injecting Endo-N into the limb of chicken embryos, total motoneuron counts at both St 33 (day 8, middle of the naturally occurring cell death period) and St 36 (day 10, close to the end of the cell death period) were significantly decreased compared to controls. Therefore a reduction of intramuscular nerve branching and possibly in synapse formation as well (currently under investigation) affects motoneuron survival. Further, since removal of PSA does not appreciably alter spontaneous neuromuscular activity, these experiments avoid the complication of activity blockade which may alter motoneuron survival by affecting events other than / or in addition to intramuscular nerve branching. Supported by NIH grant NS 19640.

EFFECT OF CURARE ON NATURALLY OCCURRING CELL DEATH OF MUSCLE SENSORY NEURONS. P. Wenner, K. Sharma, . Hory-Lee, and E. Frank, Dept. of Neurobiology, Anatomy & Cell Science, University of Pittsburgh School of Medicine, Pittsburgh, PA

Motoneurons that naturally die during embryonic development can be spared by chronic applications of d-tubocurarine (dTC) in developing chick embryos (Pittman & Oppenheim, '78). In contrast, the total number of sensory neurons is not changed by this treatment, as determined by counts of sensory axons in dorsal roots (Oppenheim & Chu-Wang, '83). It is not known, however, whether specific subpopulations of sensory neurons, such as those innervating skin or muscle, respond differently to the application of this drug. We have examined this possibility by labeling fibers in a muscle nerve in the hindlimb of developing chick embryos in

control and dTC-treated embryos.

Curare was applied daily to the chorioallantoic membrane during the period of naturally occurring sensory neuron cell death between E5 and El 1. The spinal cord, with attached peripheral nerves, was isolated and the obturator nerve was labeled with HRP. Counts of labeled neurons were made in 10 µm paraffin sections.

Preliminary results show that muscle sensory neurons projecting in the obturator nerve are <u>reduced</u> in number in dTC-treated embryos. Because the <u>total</u> number of sensory afferents is not changed in such embryos (Oppenheim & Chu-Wang, '83), these results suggest that the survival of different groups of sensory neurons may be differentially affected by

NMDA-RECEPTOR BLOCKADE RESULTS IN INCREASED SURVIVAL OF DEVELOPING CHICK SPINAL MOTONEURONS. F. Hory-Lee and E. Frank\*, Dept. of Neurobiology, Anatomy & Cell Sci., Univ. of Pittsburgh Medical School, Pittsburgh, PA 15261.

Developing spinal motoneurons are dependent on their peripheral targets for survival. Neuromuscular blockade by d-tubocurarine (dTC) during the period of normally occurring cell death results in increased survival of motoneurons (Pittman and Oppenheim, '78). Developing motoneurons are spontaneously active during this period however, and this activity is also blocked by dTC (Landmesser & Szente, '86). Because high levels of neural activity can lead to cell death in the mature nervous system, we wondered if the blockade of spontaneous activity by dTC might be responsible for the drug's effects on motoneuronal survival. We are therefore examining the effects of reduced electrical activity on cell death, both in vitro and in voy. by blocking receptors that mediate excitatory transmission in the CNS.

Bstablished cultures of dissociated spinal neurons from E6 chick embryos were transferred to media without muscle extract, and with or without APV, a competitive antagonist of the NMDA receptor. Such cultures normally display high levels of spontaneous activity which is decreased by APV (O Brien and Fischbach, 1986). Motoneurons were prelabeled on E5 by injecting fluorescent latex beads into limb buds in oyo. Surviving retrogradely labeled motoneurons were counted 2-3 days after the transfer. Preliminary results indicate that motoneuronal survival in cultures containing APV is higher than in cultures where the drug is absent. To test the effect of APV on naturally occurring cell death in oyo, we applied the drug daily to the chorioallantoic membrane of embryos from E5 to E11, as in the earlier experiments with dTC.
Surviving motoneurons within the LMC of segments L3&4 were counted in transverse sections. APV results in a large increase in the number of surviving motoneurons, comparable to the rescue

THE EFFECT OF [K+] DURING CULTURE ON THE APPEARANCE OF SPONTANEOUS [CA2+], OSCILLATIONS IN RAT CEREBELLAR GRANULE CELLS. A.J. Irving., J.G. Schofield and G.L. Collingridge. Spept of Pharmacology Univ of Birmingham and \*Dept of Biochemistry Univ of Bristol, UK.

The induction of epileptiform activity associated with spontaneous [Ca2+], oscillations can result in hippocampal cell death (Abele & Miller 1990, Neurosci.Lett. 115,195-200). We have investigated the appearance of [Ca2+]; oscillations in cerebellar granule cells cultured under conditions that favour either cell survival (25 mM K+) or cell degeneration (5.4 mM K+). The [Ca<sup>2+</sup>], was measured in individual cell bodies using Fura-2 microfluorimetry

When cells were cultured for beyond 5 days in 5.4 mM K+ large fluctuations in [Ca<sup>2+</sup>], (200-1500 nM) were observed on superfusion with Mg<sup>2+</sup>-free, glycine supplemented media. However, similar activity was not observed in cells cultured for up to 7 days in 25 mM K+. The [Ca<sup>2+</sup>], oscillations were blocked with 1  $\mu$ M TTX and were highly synchronised, indicating that they are synaptically generated. The fluctuations were also blocked by nitrendipine and AP5, but not CNQX (in 10 μM glycine), indicating the involvement of voltage-gated Ca2+ channels driven by NMDA receptor activation. These [Ca2+]; oscillations were not mimicked by agents that mobilise intracellular Ca<sup>2+</sup> stores. In conclusion the tendency of neurons cultured in 5.4 mM  $K^+$  to display epileptiform activity may underlie their enhanced cell death during culture.

DOES DOXORUBICIN INDUCED MUSCLE INJURY RESULT IN LOSS OF FACIAL MOTOR NEURONS? L.K. McLoon\*, S

Cameron and J.D. Wirtschafter. Dept. of Ophthal., Univ. of MN, Mpls, MN 55455.

We have been developing a novel permanent non-surgical treatment for blepharospasm, hemifacial spasm and related facial dystonias. Doxorubicin injected directly into the eyelid can result in a permanent muscle loss of up to 90% of the orbicularis oculi muscle (McLoon et al., '91). A first clinical trial has resulted in its successful use in human patients, where 10 out of 20 treated with this protocol had long term relief of their muscle spasms (Wirtschafter, '91). Doxorubicin can be retrogradely transported from an injection site to the brain. We examined the effect of injection of 2 mg doxorubicin in the eyelids of rabbits on the number of facial motor neurons. Five New Zealand white rabbits were injected with 2 mg doxorubicin into their right lower eyelids. One month later, both eyelids were injected with 400 ul horseradish peroxidase (30% in 2% DMSO in isotonic saline). Two days later, the rabbits were deeply anesthetized and perfused with 2% glutaraldehyde in phosphate buffer. The brains were removed, sectioned and processed for visualization of HRP using the metal intensified DAB technique. The number of HRP labeled facial motor neurons in both facial motor nuclei were quantified. Despite extensive and permanent muscle loss, there was no significant difference between the numbers of facial motor neurons on the treated and untreated sides. Thus, this dose of doxorubicin injection into the eyelids does not result in a significant loss of facial motor neurons

POLY (ADP-RIBOSE) POLYMERASE: AN EARLY MARKER OF GLUTAMATE MEDIATED NEURONAL DEATH. C. Cosi\*, GLUTAMATE MEDIATED NEURONAL DEATH. C. Cosi\*, H. Suzuki¹, L. Facci, D. Milani. and S.D. Skaper. Fidia Research Labs, Abano Terme, Italy and ¹ Istituto di Chimica Biologica, Università di Verona, Verona, Italy. Glutamate neurotoxicity (GNT) is correlated with an increase of cytosolic free Ca\*+. Activation of Ca\*+-dependent endonucleases can damage DNA and activate the enzyme poly (ADPP-ribose)polymerase activate the enzyme poly (ADP-ribose)polymerase (ADPRP). We have investigated if ADPRP may be involved (ADPRP). We have investigated if ADPRP may be involved in GNT. Cerebellar granule cells, 12 days in culture, were treated with a toxic dose (100uM) of glutamate (Glu) and inhibitors of ADPRP (3-aminobenzamide, benzamide, luminol, 5mM) or endonucleases benzamide, luminol, 5mM) or endonucleases (aurintricarboxylic acid). Inhibitors added to the culture 60 min before and during the 30 min of Glu treatment prevented neuronal death by 60-100% as treatment prevented neuronal death by 60-100% as tested 24hr after Glu, without affecting Glu-induced Ca<sup>2+</sup> influx. Using polyclonal antibodies against the polymer of ADPribose as an index of ADPRP enzyme activity the number of immunopositive cells progressively increased, reaching a maximum 30 min after Glu addition. Immunostaining was heterogeneous, decreasing to controls levels 60 min post Glu. Non-toxic levels of Glu were ineffective. Activation of the above cascade may represent an early index of

LACK OF A PERSISTENT EPILEPTIC DEPOLARIZATION FOLLOWING LOW MAGNESIUM INDUCED SEIZURES RECORDED FROM THE GERBIL HIPPOCAMPUS IN VITRO. James D. Stittsworth. Jr.\* and Thomas H. Lanthorn Neurological Diseases Research, Searle, Skokie, IL 60077.

It has been shown that ischemia and ischemia-like events will lead to a massive depolarization known as "anoxic depolarization" (AD). similar event has been shown to occur with some types of severe seizure and has been termed "epileptic depolarization" (ED). It has further been suggested that AD and ED are preludes to neuronal death. The gerbil is widely used to study both ischemia and epilepsy. A population spike (mean amplitude = 7.4 ± 1.0 mV) was recorded from CA1 region of the gerbil dorsal hippocampus, in vitro, in response to stimulation of the Schaeffer collateral/CA3 region. Following a period of equilibration in the recording chamber a low magnesium aCSF was introduced. Both evoked and spontaneous epileptiform activity was observed in the gerbil slices. However, differences were observed between the gerbil and rat hippocampus when the glucose concentration of the aCSF was lowered to 2 mM. In the rat hippocampal slice, a spontaneous ED (14.4  $\pm 1.9$  mV) occurred within 4.9  $\pm$  1.9 min., however a spontaneous ED was never observed in the gerbil hippocampal slice under the same conditions. In 1 of 6 gerbil slices studied an ED (12 mV) was produced following a high frequency stimulation with a concomitant loss of synaptic responses. Recovery from the depolarization in the gerbil slice was seen in 2 min and 75 % recovery of synaptic response was observed at 20 min post-ED. These results suggest that gerbil hippocampal slice is resistant to ED induced by low magnesium seizures.

CHOLINE ACETYLTRANSFERASE ACTIVITY IN THE RAT HIPPOCAMPAL FORMATION AFTER CHRONIC ALCOHOL CONSUMPTION. A Cadete-Leite, M.M.Paula-Barbosa\*, A.Ribeiro-da-Silva\*\* and N. Sousa. Dept. of Anatomy, Porto Medical School, Porto 4200, Portugal; \*\* Dept. of Pharmacology and Therapeutics, McGill University, Montreal, Canada.

Choline acetyltransferase (ChAT) activity is reduced in the aged brain and changes in cholinergic mechanisms are known to play a role in cognitive functions such as memory. As we demonstrated that the hippocampal formation (HF) is affected after chronic alcohol consumption (CAC) with correlated memory disfunctions similar to those observed in advanced age, we designed this study to evaluate whether ChAT activity in the HF was affected by CAC. Fibers and neurons were analysed in alcohol-fed rats and ribers and neurons were analysed in alcohol-fed rats and controls. Immunohistochemistry was performed with a monoclonal antibody against ChAT. We found a global reduction in the immunostaining of the fiber plexus, which was more evident in the supragranular zone and in the outer portion of molecular layer of the dentate gyrus. The areal density of ChAT immunoreactive (ChAT-IR) neurons was reduced too. Differences were particularly striking in the stratum lacunosum moleculare of regio inferior, the zone of the HF where ChAT-IR neurons are more abundant. We concluded that CAC leads to an impoverishment of cholinergic fiber plexus as well as to marked death of the acetylcholine secreting neurons. These findings might be of importance to explain the cognitive disfunctions observed after CAC. (Supported by JNICT - Project PMCT/C/SAU/32/90).

MULTIPLE EFFECTS OF MPP+, A POSSIBLE INDUCER OF PARKINSON'S DISEASE, ON PC12 CELLS. Y. Nomura

Y. Kitamura and Y. Itano. Dept. of Pharmacology, Fac. Pharmaceutical Sci., Hokkaido Univ., Sapporo 060, Japan. To clarify cytotoxic effects of MPP\* (1-methyl-4phenylpyridinium ion, a proposed toxin to Parkinsonism) on PC12 cell, a model of dopamine (DA) neuron, we examined effects of MPP<sup>+</sup> on 1) the content of DA and its metabolites, 2) induction of tyrosine hydroxylase (TH) mRNA and 3) leakage of lactate dehydrogenase (LDH). MPP<sup>+</sup> (100 µM) treatment for 24 hr increased DA but decreased 3,4-dihydroxyphenylacetic acid, suggesting an inhibition of MPP\* (100 µM) on monoamine oxidase (MAO). A result that MPP\* (1 mM) decreased DA and protein content indicates that MPP\* causes cell death at a high concentration. In contrast, Northern blot analysis showed that MPP<sup>+</sup> (100 µM) increased TH mRNA expression. Thus MPP<sup>+</sup>(100 µM)-induced DA elevation is provably due to TH induction as well as MAO inhibition. Treatment with MPP+ at 1 mM for 24 hr caused a significant leakage with MPP\* at 1 mM for 24 hr caused a significant leakage of LDH. The leakage was suppressed by NGF (100 ng/ml), dibutyryl cAMP (1 mM), cycloheximide (0.3  $\mu$ M) or aurintricarboxylic acid (100  $\mu$ M, a DNase inhibitor). It is suggested that MPP\* does not exert cytotoxic effects when the cells are differentiated by NGF or cAMP and that unknown proteins involved in "programmed" neuronal death could be induced by MPP\* stimulation in PC12

INVOLVEMENT OF URIC ACID IN IN VIVO DOPAMINERGIC NEURODEGENERATION. W.H. Church<sup>1\*</sup>, V. Ward<sup>1</sup>, and J.F.McGinty<sup>2</sup>, Depts. of Chemistry<sup>1</sup> and Anatomy and Cell Biology, School of Medicine<sup>2</sup>, East Carolina University, Greenville, NC 27858-4353

The effect of endogenous levels of uric acid on FeCl<sub>3</sub>-induced dopaminergic

neurodegeneration in male guinea pigs was investigated. Uric acid is an antioxidant present in brain which is a potent chelator of ferric ion (K = 1.1x10<sup>11</sup>) and can inhibit Fe<sup>+3</sup>-catalyzed DA autoxidation. Iron has been shown to increase the generation of free hydroxyl radicals and the rate of lipid peroxidation, events which lead to increased cell death. Post-mortem analysis of brain tissue from Parkinsonian patients has revealed an increase in iron content in the substantia nigra. Injection of FeOla into the substantia nigra of rats can produce behavioral and biochemical parkinsonian-like effects. The iron chelator desferrioxamin, when injected into rats can retard 6hydroxydopamine deneneration of nigrostriatal dopamine cells. Twelve male guinea pigs were divided into two groups; a) six animals with normal brain levels of uric acid and b) six animals with reduced brain levels of uric acid Uric acid levels were reduced by injecting the animal with the xanthine oxidase inhibitor allopurinol. Both groups were then given injections of FeCl, (0.5<sub>µ</sub>L of a 100 mM solution) into the substantia nigra. The animals were sacrificed three weeks later and tissue collected from the substantia nigra, striatum, and frontal cortex. Tissue samples (approx. 1 mg) were analyzed for uric acid, ascorbic acid, and dopamine by HPLC with electrochemical detection. Dopamine levels were used in conjunction with neuroanatomical staining methods to determine the extent of neurodegeneration. The results are discussed in relation to uric acid's role in dopamine neurodegeneration

EXTRACELLULAR ATP INDUCED CYTOTOXICITY IN PC-12 CELLS. A.Y. Sun\*, Y. Cheng, P. Wixom, H.D. Kim and G.Y. Sun. Depts. of Pharmacology and Biochemistry, Univ. of Missouri, Columbia, MO 65212

Extracellular ATP has been implicated in the regulation of norepinephrine (NE) uptake (Hardwick et. al., J. Neurochem. 53: 1512, 1989) and voltage-dependent calcium influx (VDCI). Using PC-12 cells as a model of catecholaminergic neurons, we have examined the effect of heavy metal ions on the viability of these cells. We have found that  $Mn^{2+}$  and  $Fe^{2+}$  ions in micromolar concentrations induced lipid peroxidation and cell death, as measured by the amount of thiobarbituric acid reactive substance (TBARS) formed and the amount of lactic acid dehydrogenase (LDH) released to the medium, respectively. When 1 mM ATP was added to the culture medium, a 2.5-fold increase in cell lysis was observed, as indicated by LDH released, as compared with controls containing Fe<sup>2+</sup> alone. By using fura 2 as a calcium probe, we also observed the increase in [Ca<sup>2+</sup>], upon addition of ATP. Whether ATP induced cell viability is due to the alteration of Ca<sup>2+</sup> homeostasis or through other mechanisms remains to be seen. Nevertheless, our finding may have important implications for the effect of stimulated release of ATP on neurodegenerative processes. (Supported in part by AA02054 from NIAAA)

# NRURONAL DRATH: AXOTOMY

BOTH SELEGILINE AND PARGYLINE REDUCE THE DEATH OF IMMATURE MOTONEURONS CAUSED BY AXOTOMY W.G. Tatton, P.T. Salo\*, P.H. Yu, D.P. Holland, M.M. Kwan and K.S. Ansari Center for Research in Neurodegenerative Diseases, Univ. of Toronto, Toronto, Ontario and Neuropsychiatric Res. Unit, Univ. of Saskatchewan, Saskatoon, Saskatchewan. Selegiline reduces the death of murine dopaminergic substantia nigra neurons (GSNns) after MPTP exposure, even if selegiline administration is delayed until MPTP conversion to MPP+ is completed (J. Neurosc. Res. 30:666,1991) and MPTP conversion to MPP+ is completed (J. Neurosc. Hes. 30:1666, 1991) and also increases the survival of raf facial motioneurons (FMns) axotomized at age 14 days (J. Neurosc. Res. 31:394,1992). We counted ChAT immunopositive and Nissl stained FMn somata 21 days after a unilateral facial nerve transection camed out at 14 days of age. During the 21 days either saline, selegiline (10 or 0.01 mg/kg) or pargyline (10 mg/kg) were administered intraperitoneally every second day.

# 27.2

LEUKEMIA INHIBITORY FACTOR (LIF) PREVENTS THE DEATH OF AXOTOMIZED SENSORY NEURONS IN NEWBORN RAT DORSAL ROOT GANGLION (DRG) IN VIVO. S.S. Cheema\*, L. Richards, M.Murphy and P.F.Bartlett. The Walter & Eliza Hall Institute, Parkville, Victoria. Australia 3052.

LIF acts as a survival factor in vitro for neonatal sensory neurons and is retrogradely transported *in vivo* into murine DRG (Murphy et al.,1991 <u>P.N.A.S</u>, 88:3498; Hendry et al., 1992 <u>J.Neurosci</u> in press). To test if LIF is a neuronal survival factor in vivo, we examined its action on axotomised sensory neurons in the DRG of the newborn rat

pup.
Newborn (P0) Wistar rat pups were anesthetised on ice and the left sciatic nerve exposed and cut. The sciatic nerve received a single dose of either the diluent or recombinant murine LIF. LIF was soaked in gelfoam (20 µg) or injected directly (5µg) into the sciatic nerve a few minutes prior to the axotomy. After 1-36 days the animals were perfused with buffered paraformaldyde. The L5 DRGs were dissected out, embedded in paraffin, cut at 8µm sections and stained in 0.1% cresyl violet. Neurons were counted in every 10th section and the T-test

was used to determine statistical differences between groups.

In the control animals, 5% of the ipsilateral L5 DRG neurons were lost after 12 h and between 2-7 days the reduction was about 50% and up to 80% after 36 days. At 2 days, a single exposure to LIF resulted in a statistically significant reduction in the death of axotomised sensory neurons. In these animals, only 17% of the sensory neurons were lost compared to 50% in the controls. These experiments suggest that LIF, a survival factor for sensory DRG neurons in vitro, can act as a survival factor for the same population in vivo.

DISSOCIATION OF THE RESPONSES OF MOTONEURONS AND THEIR TARGET MUSCLES TO DEVELOPMENTAL AXOTOMY IN THE HORMONE-SENSITIVE SNB. J.L. Lubischer\* & A.P. Arnold, UCLA Brain Research Inst. and Dept. Psychol., Los Angeles, CA 90024-1563

Neonatal axotomy results in motoneuron death and permanent muscle atrophy, in contrast to the virtually complete recovery seen after adult axotomy. Axotomy-

induced cell death in neonates might be due to a greater dependence on muscle-derived trophic support at this age. In this view, loss of contact with the muscle results in motoneuron death, with muscle atrophy secondary. A second possibility is that the primary effect of axotomy in development is a severe denervation-induced muscle atrophy, reducing the trophic factor available to motoneurons and resulting in their death. We now report evidence arguing against the latter hypothesis.

Spinal nucleus of the bulbocavernosus(SNB) motoneurons innervate the levator

ani (LA) and bulbocavernosus (BC) muscles through the pudendal nerve. nerve was cut unilaterally in male rats at one of five ages from postnatal day 1 (P1) to P28. After perfusion at about P55, the spinal cord and LA/BC muscle complex were removed. SNB nucleoliwere counted (reported previously) and LA/BC muscle complexes from axotomized and contralateral sides were weighed and compared.

The massive SNB cell death that follows axotomy at P1 or P7 is matched by severe LA/BC atrophy (80% at P1; 83% at P7). The lack of significant cell death after axotomy at P21 or P28 is accompanied by moderate muscle atrophy (26% at P21; 31% at P28). Interestingly, compared to these older ages, axotomy at P14 results in the same degree of muscle atrophy (37%), but extensive cell death. Thus, the extent of neonatal axotomy-induced motoneuron death is not determined by target muscle atrophy. P14-axotomized muscles are innervated by half as many motoneurons as are comparably-sized P21-axotomized muscles, suggesting an interesting alteration in the pattern of innervation after P14 axotomiz. If fiber counts show equal numbers of fibers in these muscles, then SNB cells axotomized at P14 might have expanded motor units and/or less overlap between motor units. TRANSIENT APPEARANCE OF GRANULAR CELLS IN SPINAL GANGLIA AFTER NEONATAL AXOTOMY IN RATS. M. DeSantis and M. Dibble. Dept. of Biological Sciences and WAMI Medical Program. University of Idaho, Moscow, ID

Cell bodies of neurons in spinal ganglia (SG) degenerate in massive number if their axons are cut in neonatal as opposed to adult mammals (e.g. Exp. Neurol. 1981. 74:597-604; 1983 82:568-580). Aldehyde fixed SG from the lesioned and unoperated sides of neonatal rats were incubated in osmium tetroxide. Cells with granules in them were apparent in aqueous mounts of frozen sections (30 um) of the SG from the experimental, but not the control, side. There were very few granular cells in SG at 3 or 11 days after a similar sciatic nerve resection in young adult rats. Our hypothesis a similar sciatic nerve resection in young adult rats. Our hypothesis is that the granular cells reflect the presence of dying neurons. In order to study the time course of their appearance, we counted the total number of granular cells in serial sections of the L4-6 SG between 8 and 288 hours after a unilateral resection of the sciatic nerve done on postnatal day 3. Values were compared to those for the contralateral side where the sciatic nerve had been either unoperated or sham operated. The number of granular cells in ganglia from the lesioned side exceeded that from the control side for all times from 20 to 260 hours after the lesion. They occurred in greatest numbers from 30 to 150 hours after resection. The number of granular cells in SG from the lesioned side fluctuated in a way which suggested that axotomy-induced neuronal death in SG may be episodic. (Supported by USPHS grant NS 27253).

# EFFECTS OF OPTIC NERVE CUT OR CRUSH ON THE SHORT AND LONG-TERM SURVIVAL OF RAT RETINAL GANGLION CELLS. M. Berkelaar, A. Cohen, G.M. Bray\*, A.J. Aguayo.

McGill University Centre for Research in Neuroscience, Montreal General Hospital Research Institute, 1650 Cedar Avenue, Montreal, Quebec, H3G 1A4.

To investigate further the conditions that influence the loss of axotomized retinal ganglion cells (RGCs) in mammals, we determined the density of RGCs at several times after an intracranial optic nerve (ON) cut or crush at one single distal level situated 8-10 mm from the posterior pole of the eye of adult rats. The RGCs were identified by retrograde labelling with Fluorogold(R) applied to the superior colliculus one week prior to ON injury.

An early and marked loss of RGCs was observed 2 weeks after both types of ON injury. This early loss was more than twice as severe following ON cut than ON crush: 42% and 18%, respectively. Although less pronounced, the rates of RGC loss observed between 2 weeks and 3 months after axotomy were persistently greater after ON cut than

Thus, while the type of ON injury (cut or crush) affects neuronal survival soon after axotomy, these two lesions also have different effects on the long-term viability of RGCs. It is possible that the alterations in cut ONs, which differ from those in crushed ONs (Berkelaar et al., Soc. Neurosci. Abstr. 17:555, 1991), affect RGC survival by mechanisms that may include a disruption of the local supply of trophic factors or the production of molecules that induce cell death.

# 28.2

Accelerated neuronal death and differentiation in the developing Quail retina S.W. Wang and I.E. Johnson \*. Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, N.C. 27157-1010

The Japanese quail, Coturnix coturnix japonica, has a greatly accelerated ontogeny when compared with the domestic chick Gallus domesticus (ie. hatching occurs at approximately 16 days of incubation as compared with 21 days in the chick). The aim of this study was to determine the rate of developmental changes in neuronal death and differentiation in the quail retina

Retinas were sectioned or whole-mounted for basophilic staining and the total surface area and volume of retinas were measured on embryonic days 4 through 15 (E4-E15). The number of mitotic figures, the number of pyknotic nuclei, the thickness of each retinal layer and the density of cells in the retinal ganglion cell (RGC) layer were also measured. In addition, RGC soma and dendritic arbors were retrogradely labeled from the optic nerve with the flourescent dye Dil.

Retinal development in the quail closely paralleled development in the chick during the first six days of incubation. The retinal ganglion cell layer was segregated from the more compact ventricular layer on E7. The accumulation of retinal ganglion cells rapidly accelerated er. The accumulation of retinal gangiton tens rapidly accelerated reaching a peak at E-9 in the central retina with a very rapid subsequent loss of cells. At least three types of RGC could be distinguished by soma and dendritic properties. These results suggest that both the normal neuronal death and differentiation of RGC is rapidly accelerated in quail retinal development.

# 28.3

RETINAL GANGLION CELL DEGENERATION AFTER OPTIC NERVE LESION AND NERVE GROWTH FACTOR PROTECTIVE EFFECT IN THE

S.A. Rabacchi\*, M. Ensini, A. Gravina, M. Fagiolini, L. Bonfanti and L. Maffei.

Ist. di Neurofisiologia del CNR and Scuola Normale Superiore, Pisa (ITALY).

Section of the optic nerve in mammals induces degeneration of most ganglion cells both in the adult and developing retina. In neonatal rats ganglion cell death has been reported to be completed 2-3 days after the lesion (Perry et al, 1983). Our experimental model consists in performing the lesion in vivo both prenatally in utero (E18 approximately) and postnatally (P0), and analyse morphologically whole-mounted retinas stained with cresyl

Our results show that, when the optic nerve is transected at P0, the first signs of degeneration (increase of pyknotic nuclei) appear 12-14 hours ostoperatively, with a peak at 24 hours and a decline after 48 hours; no pyknotic nuclei were seen after 72 hours, because of macrophage endocytotic activity. Degeneration occurs much earlier when the optic nerve is transected prenatally (E16-19).

Previous studies have shown that Nerve Growth Factor (NGF) promotes the survival of retinal ganglion cells after optic nerve transection in the adult rat (Carmignoto et al, 1989). In this study, we confirmed that NGF exerts similar protective effects in neonatal rats. When the optic nerve is sectioned at PO and the animals are left to survive for 24 hours, we found that intraocular injections of NGF (0.5ug in 250 nl) cause a reduction in pyknotic nuclei density: 199/mm<sup>2</sup> in NGF treated animals (30 animals) versus 236/mm<sup>2</sup> in the control (20 animals) group (p<0.001). This shows that in neonatal rats NGF exerts protective effects on retinal ganglion cells within a remarkably short time after the axotomy.

# 28.4

AURITRICARBOXYLIC ACID PROTECTS RETINAL NEURONS FROM INJURY-INDUCED DEGENERATION.

L. Colombaioni\*. Istituto di Neurofisiologia del CNR, 56127 Pisa, Italy.

The purpose of this study has been to investigate the cellular events underlying the process of neuronal degeneration following injury. Several morphological modifications, including a widespread chromatin condensation, characterise neuronal death. To test the hypothesis that the activation of endonucleases (enzymes capable of producing DNA fragmentation) can initiate the process of neuronal degeneration, the protective effect of a general inhibitor of endonucleases, the aurintricarboxylic acid (ATA), was examined. Rat retinal neurons during the first postnatal days have been chosen as model system. The experiments were carried out *in vitro* on isolated eye cups cultured for periods variable from 4 hours to 2 days in serum-free medium. In this experimental condition the ganglion cells were axotomized, in fact, in control experiments, they showed the characteristic pattern of DNA fragmentation associated with cellular degeneration. When ATA was added to culture medium, at concentrations between 10-500 µM, the nuclear alterations were clearly reduced and an improvement of cell viability, assessed by trypan blue exclusion, was observed. The effect was dose-dependent. In retinal radial sections it was possible to observe that the increase in neuronal survival was a general phenomenon also extended to retinal neurons other than ganglion cells. It is therefore possible to speculate that, in nervous tissue, the activation of endonucleases plays a critical role in triggering cell degeneration process even if the possibility that ATA prevents cell death by other mechanisms cannot be excluded.

CHANGES IN CAUDATE NUCLEUS MORPHOLOGY AFTER NEOCORTICAL LESIONS IN CATS. <u>L.D.Loopuijt\*, J.R.Villablanca, D.A.Hovda and R.Scola</u>, Ment. Retard. Res. Ctr., UCLA, Los Angeles, CA

After a small unilateral cortex lesion in fetal kittens both caudate nuclei increase in size (Soc. Neurosci. Abstr.16:983,90). To study if this effect occurs postnatally, 8-13 day old kittens received a small left frontal cortex lesion (NF, N=4) or hemidecortication (NH, N=7) while 4 adult cats also were hemidecorticated (AH). After longterm survival (>371 days), thionin-stained coronal sections of these brains (plus 7 intact controls, C) were used to stereologically measure caudate nuclei volumes and neuron/glial cell packing

The mean caudate n. volumes ( $\pm$ SD) at either side of the brain in NF and NH cats did not differ from controls (left: C 199.0  $\pm$  35.0; NF 215.0  $\pm$  41.7; NH cats did not differ from controls (left: C 199.0  $\pm$  35.0; NF 215.0  $\pm$  41.7; NH 197.8  $\pm$  21.0; right: C 199.3  $\pm$  33.9; NF 206.3  $\pm$  26.3; NH 186.0  $\pm$  12.8 mm<sup>3</sup>). However, in AH the caudate of the lesioned side was smaller (155.5  $\pm$  18.5 mm<sup>3</sup>, P< 0.05) with no difference contralaterally, (188.8  $\pm$  19.4 mm<sup>3</sup>). The neuron packing density on the lesioned side did not differ from controls (C 7.00  $\pm$ 3.3;NH 8.1  $\pm$  3.1; AH 7.70  $\pm$  2.7 cells/47300  $\mu$ m<sup>3</sup>; N=2) whereas the glial cell packing density tended to increase in AH (C 15.2  $\pm$  5.5; AH 21.8  $\pm$  5.2 cells/47300  $\mu$ m<sup>3</sup>, N=2) but did not show a consistent trend in NH. These data suggest that in AH there is a loss of neurons with an increase in glia in the caudate n. ipsilateral to hemidecortication which suggests transneuronal degeneration. Unknown events responsible for caudate hypertrophy in prenatal-lesioned may have contributed to sparing in neonatal-lesioned cats. Grants USPHS HD-05958 and 04612.

A NEW TECHNIQUE FOR DEMONSTRATION OF LOCAL

A NEW TECHNIQUE FOR DEMONSTRATION OF LOCAL AND DISTANT CELLULAR DAMAGES AFTER AMYGDALOID KAINATE LESIONS IN THE RAT. A. Hainal, A. Czurkó, B. Faludi, Z. Karádi and L. Lénárd (SPON: European Neuroscience Association) Institute of Physiology, Pécs University Medical School, Pécs, H-7643 Hungary

In order to determine the extent and time-course of local and distant neuronal damage produced by microiontophoretic administration of kainic acid (KA) into the amygdala (AMY), both "conventional" light microscopic staining and a specific silver impregnation method were used. The affected, so-called "collapsed" or "dark" neurons, were visualized by a modified version of the Golgi-like argyrophil III physical developing procedure according to Gallyas et al. (1990). Unilateral iontophoretic KA lesions of the central part of the AMY were accomplished by means of glass micropipettes. The KA microlesions affected neurons not only locally in the AMY but also in broad areas of the rat brain. The regions most vulnerable to KA were the claustrum, hippocampal formation, subiculum and entorhinal cortex, however, the extent and time-course of the degenerations varied. In contrast to the conventional light microscopic staining method that appeared not to be sensitive enough, the spatial and temporal distribution of neuronal degeneration, especially in the early postoperative period and in distant brain regions, could only be revealed by the silver impregnation technique for "collapsed" neurons. impregnation technique for "collapsed" neurons.

IBOTENIC ACID DESTRUCTION OF CAUDATE NUCLEUS AND LATERAL GLOBUS PALLIDUS ARE NECESSARY FOR SUBSEQUENT TRANSNEURONAL DEGENERATION IN SUBSTANTIA NIGRA RETICULATA. M. Saji\*, M. Cohen, B.T. Volpe, Dept. of Neuro. and Neurosci., Cornell Univ. Med. School, at The Burke Institute for Medical Research, White Plains, NY 10605.

In rodents, neurotoxin lesions (ibotenic acid, IBO, or kainic acid)

that destroy the corpus striatum initiate a mechanism, perhaps disinhibition, that leads to death of GABAergic neurons in the substantia nigra reticulata (SNr). In a test of the necessary striatal injury to cause SNr neuron loss, animals were injected unilaterally injury to cause SNr neuron loss, animals were injected unlaterally with IBO ( $10 \mu g/\mu l$ ) in the caudate nucleus (CN, .5  $\mu g$ , N=4) or in the lateral globus pallidus (LGP, .3  $\mu g$ , N=4) or in the CN and LGP (.8  $\mu g$ , N=4). Animals were sacrificed 3 weeks later. Histologic and immunocytochemical analysis of glial fibrillary acidic protein (GFAP) demonstrated that IBO lesions in the CN and LGP reproducibly caused neuron loss and gliosis marked by increased GFAP positive astrocytes in the ipsilateral SNr. The area creased GFAP positive astrocytes in the ipsilateral SNr. The area of neuron loss in the SNr was topographically related to the location of the injury in the CN and LGP. Animals with IBO lesions in the CN or LGP alone had normal SNr. There was no SNr damage contralateral to the IBO injection. These data suggest that injury in the CN and LGP are necessary to cause delayed SNr degeneration. The predictable topography of the SNr neuron loss supports a transneuronal mechanism, perhaps unopposed excitotoxic stimulation or disinhibition or both.

TEN OR MORE WEEKS AFTER T-2 SPINAL CORD HEMISECTION, MOST SURVIVING IPSILATERAL SPINOCEREBELLAR NEURONS HAVE CONTRALATERAL PROJECTIONS TO THE CEREBELLUM. <u>J.C. Morgan, T. Wallace, E.R. Feringa and R.L. McBride\*.</u> VA Medical Center and Medical College of Georgia, Augusta, GA 30910.

We determined if Clarke's column neuron survival following axotomy is influenced by contralateral projections terminating in the cerebellum. In one group of rats, we retrogradely prelabeled spinocerebellar neurons with True Blue, hemisected the spinal cord at T-2 and sacrificed the rats 10 weeks later. 40% of Clarke's column neurons from T-13 to L-2 ipsilateral to the hemisection survived, but only 25% between T-11 and T-12. In another group of rats, we postlabeled spinocerebellar neurons with Fluoro-Gold 12 or 17 weeks after T-2 hemisection. 28% of ipsilateral neurons between T-13 and L-2 were labeled, but only 17% between T-11 and T-12. Ascending axons or collaterals of these neurons must have crossed to the other side of the cord caudal to T-2. Most of the ipsilateral neurons surviving 12 or more weeks are not immediately adjacent to the dorsal funiculus and have contralateral projections, and therefore should not be considered Clarke's column neurons. Supported by the VA.

# NEURONAL DEATH: SYMPATHETIC NEURONS

VERATRIDINE INDUCES NEURITE DEGENERATION BUT DELAYS CELL DEATH IN SYMPATHETIC NEURONS AND DIFFERENTIATING PC12 CELLS. T. Koike \* and S. Tanaka. Department of Natural Science, Saga Medical School, Nabeshima, Saga 849, Japan.

It is well established that afferent inputs regulate neuronal death that occurs during development. Intracellular calcium or Ca2+ influx may be an universal cellular signal for promoting neuronal survival on one hand and causing neuronal death on the other. Since nerve cells exhibit enhanced expression of voltage-dependent Na+ channel upon differentiation, it has been considered that Na+ channel activation may be involved in regulating neuronal survival. However, it has not yet been critically tested whether there is a distinct pathway for Na+ influxmediated neuronal survival independent of trophic support. Dissociated superior cervical ganglion cells from newborn rats were grown in the presence of NGF for 5-7 days, and used for experiments. We found that veratridine (1-2μM) displayed two contradictory effects on these cells: it significantly delayed the onset of cell death after NGF withdrawal, while it promoted neurite dilation and disintegration in control and NGF-deprived neurons. These two effects were blocked by 1  $\mu M$  tetrodotoxin. The L-type Ca2+ channel antagonist nifedipine (2 $\mu M$ ) improved the neurite dilation caused by veratridine, while it did not affect the former effect. In contrast, elevated K+ (35mM) prevented both neurite degeneration and cell death. Similarly, chronic depolarization with high K+ (>35mM) prevented both degenerative processes of differentiating PC12 cells after NGF deprivation, while veratridine (35-45µM) partially prevented degeneration; the effect was blocked by tetrodotoxin (1µM). This system may provide an opportunity to study relationships among voltage-dependent Na+, Ca2+ influxes, and cell survival.

BIOCHEMICAL CHARACTERIZATION OF DEGENERATION AND DEATH OF SYMPATHETIC NEURONS INDUCED BY NEUROTROPHIC FACTOR DEPRIVATION. T.L. Deckwerth\* and E.M. Johnson, Jr. Department of Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO 63110.

During development of the nervous system, neuronal survival is regulated by the availability of target-derived neurotrophic factor. The molecular events that follow neurotrophic factor deprivation and ultimately lead to death were studied in established primary cultures of dissociated rat sympathetic neurons maintained by their physiological trophic factor, nerve growth factor (NGF). After an initial period of 12 h, during which no changes were visible light-microscopically, NGF deprivation caused the onset of degenerative changes of the cell body (50% of all somas were altered after 19 h). Half the neurons were committed to die by 22 h as measured by the ability of NGF-deprived neurons to respond to NGF with long-term survival and lost viability 5 h later as measured by staining with crystal violet. Looking for the molecular events capable of causing these changes, we decided to investigate general metabolic parameters. We found that the rate of glycolysis fell to 20% after 12 hours and that measures of mitochondrial function displayed a slow and steady decline, both indicating a reduced availability of energy for cellular processes. Rapidly decreasing protein synthesis (to 50% after 8 hours) and increasing protein degradation indicated a shift from anabolic to catabolic protein metabolism contributing to soma degeneration. Concurrent with the onset of commitment, the nuclear DNA became fragmented into oligonucleosomes, suggesting a possible role for DNA fragmention in the process of commitment.

Supported by the Washington University ADRC, AG 05861.

SYMPATHETIC TRUNK GANGLIA ARE NORMAL STRUCTURALLY BUT EXHIBIT ABNORMAL GROWTH PATTERNS IN EXPERIMENTAL (THOR-BR) CHICK EMBRYOS. P. Cauwenbergs, J.T. Norton and D.W. Colbur CMCC, Toronto, Ontario, Canada M4G 3E6. Norton and D.W. Colburn

To investigate the development of sympathetic trunk ganglia (STG) in chick embryos the morphology and growth patterns of brachial STG were analysed in a total of 40 experimental and control embryos from embryonic day 8 (day 8E) to day 16E. Experimental (Thor-Br) embryos were prepared by transplanting a donor thoracic neural tube into the site of the extirpated brachial neural tube in host embryos at day 2E. Control embryos either received a brach-ial neural tube transplant (Br-Br) or remained unoperated (UC). To determine brachial ST morphology camera lucida tracings of thionine stained serial cross-sections were used to reconstruct the ST. In all experimental (Thor-Br) embryos analysed brachial ST morphology was comparable to that of control (Br-Br and UC) embryos.Tracings of individual brachial STG were then cut out and weighed to estimate the volume of STG at specific developmental stages. Results show that the growth of STG in experimental (Thor-Br) embryos was reduced significantly from that of control (Br-Br and UC) embryos. This affect of the experimental procedure was most pronounced caudally in the brachial ST and ranged from a 0 to 20% reduction in more cranial ganglia to about 55% in caudal ganglia. Ongoing investigations will determine if this differential growth response is reflected in the number of postganglionic neurons within individual STG. (Funded by CMCC).

### 30.5

THAPSIGARGIN ENHANCES SURVIVAL OF SYMPATHETIC NEURONS BY ELEVATING INTRACELLULAR CALCIUM CONCENTRATION ([Ca<sup>2+</sup>]<sub>i</sub>). P.A. Lampe, E.B. Cornbrooks\*, A. Juhasz, J.L. Franklin, and E.M. Johnson, Jr. Dept. of Mol. Biol. and Pharm., Washington Univ. Sch. of Med., St. Louis, MO 63110

Previous work from our laboratory has suggested that the rise of [Ca2+], in response to K+ depolarization is responsible for depolarization-enhanced survival of NGF-deprived rat sympathetic neurons. As a potential alternative means of increasing [Ca<sup>2+</sup>], and promoting sympathetic neuronal survival in culture, we examined the effects of thapsigargin, an inhibitor of Ca<sup>2+</sup>, sequestration. It was observed that thapsigargin had modest neuronal protective activity with an EC<sub>50</sub> of 10nM in a 5 day survival assay. Fura-2 measurements showed that these concentrations of thapsigargin also produced a modest sustained elevation of [Ca<sup>2+</sup>]. In an effort to augment the survival promoting effect of thapsigargin, treatment with drug was combined with elevated extracellular calcium ( $[Ca^2]_o$ ). Elevating  $[Ca^2^*]_o$  alone did not promote survival and caused little increase of  $[Ca^2^*]_o$ . However, treating cells with both thapsigargin and elevated  $\{Ca^{2+}\}_0$ , produced a much more profound effect on neuronal survival and much greater elevations of  $\{Ca^{2+}\}_0$ . This finding suggests that the source of the increased [Ca2+], induced by thapsigargin is suggests that the source of the increased [Ca<sup>2+</sup>], induced by thapsigargin, but it is thought that depletion of Ca<sup>2+</sup>, stores causes an increase of plasma membrane Ca<sup>2+</sup> permeability. These data are consistent with our hypothesis that elevated [Ca<sup>2+</sup>], (within limits) promotes survival and makes sympathetic neurons trophic factor-independent. Supported by Washington University ADRC# AGO5681.

PROMOTION OF SYMPATHETIC NEURONAL SURVIVAL BY CHRONIC DEPOLARIZATION AND INCREASED [Ca²¹], IS A "THRESHOLD" PHENOMENON. J.L. Franklin\*. A Juhasz, E.B. Cornbrooks, P.A. Lampe, and E.M. Johnson, Jr., Dept. of Mol. Biol. and Pharm., Washington Univ. Sch. of Med., St. Louis, MO 63110

Sympathetic neurons from E21 rats were grown in culture in a medium containing NGF. After 5d NGF was removed causing >90% of the cells to die. This death was prevented by chronic depolarization with elevated [K\*], [Cua²\*], aropped to hear control levels. Long-term survival was promoted only by [K\*], between 25-80 mM. Corresponding [Ca²\*], [and only by [K\*], between 25-80 mM. Corresponding [Ca²\*], measurements showed that survival and the rise of [Ca²\*], caused by 50 mM [K\*], were blocked by low nM concentrations of nifedipine. These data suggest that survival promotion by elevated [K\*], is mediated by a sustained rise of [Ca²\*], was achieved. Both survival and the rise of [Ca²\*], caused by Ca²\* influx through dihydropyridine-sensitive Ca²\* channels and that a "threshold" of [Ca²+], imust be exceeded before survival enhancement occurs. Since the Ca²\* binding protein, calmodulin, can be activated when [Ca²\*], reaches a threshold level, these data suggest that the high [Ca²\*], fect may be mediated by calmodulin. The calmodulin antagonist, calmidazolium, blocked survival promotion by elevated [K\*], at concentrations that did not affect survival of cells maintained in NGF. However, calmidazolium also blocked the sustained rise of [Ca²\*], caused by belevated [K\*], probably due to Ca²\* hinning in sustained rise of [Ca²\*], enhanced survival and caused a sustained increase of [Ca²\*], Nifedipine did not affect this rise. Thus, thapsigargin, in combination with elevated [Ca²\*], enhanced survival and caused a sustained increase of [Ca²\*], by d different mechanism than elevated [K\*]. We are now investigating the affects of calmodulin antagonists on the survival and rise of [Ca²\*], caused by thapsigargin/high [Ca²\*]. Supported by W.U. ADRC# AG05681 survival and rise of [Ca<sup>2+</sup>], caused by thapsigargin/high [Ca<sup>2+</sup>],. Supported by W.U. ADRC# AG05681.

THE ROLE OF THE PERFORANT PATHWAY IN THE DEVELOPMENT AND MAINTENANCE OF THE DENTATE GYRUS. D.C. Snyder\*, C. F. Ide. Dept. of Cell and Molecular Biology, Tulane University, New Orleans, LA 70118

During neural development, afferent fibers have profound influences on both the differentiation and ultimate survival of target neurons. In the development of the cerebral cortex-hippocampal complex in the mouse, fibers from the entorhinal cortex (EC) first innervate the hippocampus between embryonic day 15 (E15) and birth (E20, P0). During early postnatal development (P5-7), fibers from this early pathway enter the hippocampal dentate gyrus to form the perforant path. Placing lesions in the fetal EC at E16 using exo utero surgery methods produced, in adults, massive degeneration in the dentate gyrus and CA3 region of the hippocampus. These data implied that a trophic influence exists between the EC and the hippocampus. However, whether this influence involved specific innervation of the hippocampus was not apparent. Thus, EC lesions were placed in 9 additional E16 embryos. These animals were reared by foster mothers to P20. Histological analysis revealed the absence of the perforant pathway entering the dentate gyrus in the region of the EC lesion. Additionally, granule cells of the lateral blade of the dentate gyrus showed edema, the onset of degeneration, and abnormalities in cell layering. In the most severe cases, the dentate appeared as a bilayered structure indicating altered morphogenesis of the dentate. Thus, specific afferent fibers from the EC are crucial for the development and survival of neurons of the hippocampus.

ISOLATION OF cDNAS FROM A POSTNATAL DAY 1  $\mbox{\it ww/+}$  SUBTRACTED cDNA LIBRARY BY DIFFERENTIAL SCREENING. L.Sangameswaran' K.R.Haddle, B. Ghetti, S.R. Dlouhy and M.E. Hodes.
Depts. of Pathology and Medical Genetics, Indiana University Medical School, Indianapolis, IN 46202

Cerebellar granule cell (GC) precursor degeneration is observed on postnatal day 1(P1) as a consequence of a mutation in the weaver (wv) gene. To obtain molecular probes for analysis of the cerebellum, a subtracted P1 wv/+ cDNA library was constructed. P1 wv/+ cerebellar cDNA was subtracted with mRNA from P31 wv/wv cerebellar vermis, so that the library should be enriched for cDNAs from GC precursors, wv/+ GC and other differentiating cells. After several cycles of screening, 28 cDNA clones were isolated that appeared to be differentially expressed in the screening procedure. End-sequencing by PCR amplification was performed to determine redundancy among the clones and to search for sequence homology with all the entries in GenBank. Seven cDNAs were sequence incliningly with a title entires in Generals. Severe Colves were redundant; one of the clones had a high homology with T-cell receptor 4-1BB and another with mitochondrial genome. Altogether 19 unique cDNAs were found. Northern blot analyses have been done to determine the size, abundance and distribution of the transcripts, and to test for differential expression. The 4-1BB cDNA probe detects 6 transcripts that are expressed in a variety of different brain regions and nonneural tissues. Comparison of transcripts in wv/wv and +/+ cerebella by northern analysis suggests that some of these cDNAs are GC positive. In addition, the cDNAs are being evaluated to find out whether any one of them is a candidate for the wv gene. (Supported in part by USPHS P01 NS 27613 and NS 14426)

IMMUNOHISTOCHEMICAL LOCALIZATION OF UBIQUITIN DURING DEVELOPMENT OF MURINE LUMBAR SPINAL CORD. S. Chaubet. H. L. Stewart\*, M. H. Droge, N. C. Mills. †Department of Biological Sciences, University of North Texas, Denton TX 76203. \*Department of Biology, Texas Woman's University, Denton TX

We are investigating postnatal cell death in murine lumbar spinal cords using a monoclonal antibody against ubiquitin, a cel spinal cords using a monocional antibody against ubiquitin, a ceil death-related protein. Transverse sections (10 µm thin) of freshly dissected lumbar spinal tissue from female Balb/C mice aged 0-14, 21, 28, 35 and 42 days were sliced and incubated with anti-ubiquitin 1° antibody for 24 hours. Additional slices were incubated with heat-inactivated antibody as a negative control. The detection system used was biotin-streptavidin (BSA) with alkaline phosphatase as the enzymatic marker. Standard histochemistry (toluidine blue and AChE) was performed on some

sections of each age to distinguish neuronal from glial cell populations, and cholinergic neurons in particular.

Preliminary results indicate that increased levels of ubiquitin staining occurring at ages 6-8 days and at 10-12 days postnatally may be correlated with periods of postnatal neuronal cell death

Further work will be done to correlate the spatial and temporal distribution of ubiquitin expression in the lumbar spinal cord with other developmental milestones. (NIH1R29 NS 25250-01)

HEAT SHOCK PROTEIN GENE EXPRESSION DURING NEURONAL PROGRAMMED CELL DEATH. S. Estus\* and E. M. Johnson, Jr. Dept. Mol. Biol. and Pharm., Washington Univ. Med. Sch., St. Louis, MO 63110

For several years, our laboratory has investigated the mechanism of programmed cell death (PCD) induced in superior cervical ganglia neurons by NGF deprivation. Induced cell death is viewed increasingly as an active process involving the altered expression of specific gene(s). To evaluate a possible role of heat shock protein (HSP) gene expression, we are engaged in (i) quantitating the mRNA levels of inducible and constitutively expressed members of the HSP family in in vitro cultures of neurons undergoing PCD. and (ii) examining whether HSP induction protects neurons from PCD. Individual mRNA levels were assessed at various times after NGF deprivation by isolating total RNA and subjecting equivalent amounts to a sensitive and specific RT-PCR based technique. As the neurons die, the extracted RNA is increasingly derived from the small percentage of contaminating non-neuronal cells in the culture as demonstrated by the observation of large decreases in the levels of neurofilament M, tyrosine hydroxylase and neuron-specific enolase mRNAs relative to a minor decrease in the ubiquitously expressed mRNA for cyclophilin. Initial results indicate that HSP70 and BIP do not change during PCD. Although HSC73 decreases approximately 70% during PCD, the decrease occurs over a time course that parallels the decline in the neuron-specific messages and cyclophilin, suggesting that the decrease reflects differences in the basal expression between neurons and the non-neuronal cells. Future experiments will examine levels of HSP90 and HSP60 mRNA as well as whether HSP induction protects neurons from PCD. The results of these studies will be presented. Supported by the Washington Univ. ADRC (AG 5P01-A605681-08) and an NIH training grant (5T32-HL07275).

GANGLIOSIDES RESCUE NEURONAL CELLS FROM DEATH AFTER NEUROTROPHIC FACTOR DEPRIVATION G. Ferrari \*1, A. Batistatou and L.A. Greene. Dept. of Pathology, Columbia Univ., New York. 1 Fidia Research Labs., Abano T. (PD), Italy

Serum-free cultures of PC12 cells have been used as a model system for studying neuronal death occurring after neurotrophic factor deprivation. In this system, NGF rescues cells from death and prevents apoptotic DNA fragmentation (Batistatou and Greene JCB 115, 1991). We report here that GM1 also promotes long-term survival of PC12 cells in serum-free medium and prevents internucleosomal cleavage of PC12 cell DNA. These effects of GM1 are concentration-dependent, with near maximal activity at 30  $\mu$ M. Optimal promotion of survival is obtained with multiple additions of GM1. Asialo GM1 and sialic acid do not mimic these actions, indicating a requirement for the intact GM1 molecule. Prevention of serum-free PC12 cell death is also obtained with di-, tri-, and tetra sialo gangliosides. The ganglioside effects on survival and DNA fragmentation appear to be independent of macromolecular synthesis. GM1 is also effective under conditions in which cellular PKC activity is down-regulated by pre-exposure to a high concentration of TPA. Preliminary experiments indicate that GM1 also prevents death of cultured rat sympathetic neurons after withdrawal of NGF. These findings complement prior observations that gangliosides protect cerebellar granule neurons from neurotoxicity caused by exposure to excitatory aminoacids (Favaron et al. PNAS 85, 1988) and extends the actions of gangliosides to rescue of neuronal cells deprived of support by neurotrophic factors.

INHIBITORS OF PROTEIN AND RNA SYNTHESIS PREVENT MOTONEURON CELL DEATH AFTER TROPHIC DEPRIVATION IN VITRO. J.X. Comella, C. Sanz-Rodriguez and J. E. Esquerda. Unitat Recerca Neuromuscular, Fac. Med. Lleida, Univ. Barcelona, E-25006-Lleida, Spain.

During embryonic development, most neuronal populations undergo a process of programmed cell death, which reduces substantially the number of neurons previously generated. Death appears to result from the failure of neurons to acquire an adequate supply of a specific neurotrophic factor produced by their innervation target field. Several reports have provided evidence that neuronal death is not merely a passive consequence of general metabolic failure, but an active process which depends on the synthesis of new macromolecules. Recently Oppenheim et al. (1990) have shown that motoneurons die actively during programmed neuronal death in vivo. In order to study the direct effect of RNA and protein synthesis inhibitors on the process of motoneuronal death, we have established a pure culture of motoneurons and thus overcome the inherent problems of an in vivo system (indirect effects through alteration of muscle motility, presence of non-neuronal cells...). Motoneurons were cultured for 48 h in the presence of muscle extract. Next, they were deprived of muscle extract and RNA or protein synthesis inhibitors were added to the culture media. Cycloheximide, anisomycin and puromycin, three protein synthesis inhibitors acting through different mechanisms, significantly reduced cell death. Actinomycin D and dichlorobenzimidazole riboside, two RNA synthesis inhibitors, caused an important reduction. Chloroquine, PMSF and leupeptin, inhibitors of proteases, had no effect. We conclude that inhibiting transcription and translation directly blocks the suicide program in motoneurons deprived of muscle extract in vitro Quoted reference: Dev. Biol. 138:104-113(1990).

HSP 72 AND UBIQUITIN EXPRESSION IS NOT CORRELATED WITH NEURONAL SURVIVAL AFTER LOW DOSES OF NMDA IN THE RAT ENTORHINAL CORTEX W.M. Yees, D.M. Frim\*s, S.R. Bossis, and Q. Isacsons. Sheuroregeneration Laboratory, McLean Hospital, Belmont, MA 02178 Program in Neuroscience, Harvard Medical School, Boston MA 02115

Stress protein induction is associated with neurodegenerative and neuroprotective events in the CNS. It remains unclear whether expression of certain stress-related proteins is protective for or merely a marker of neuronal injury. Excitotoxic damage mediated through the NMDA receptor, linked to neuronal injury in certain neurodegenerative conditions, is known to elicit a stress protein response. To assess neuronal sensitivity to NMDA in relation to stress protein expression, we stereotactically infused low doses of NMDA into the rat medial entorhinal cortex (EC). At 0.5 hrs to 168 hrs after a 1.25 µl EC infusion of 15 mM NMDA, 30 mM NMDA, or saline, we evaluated neuronal loss and expression of ubiquitin (Ub) and 72kD heat shock protein (HSP 72). Volumes of entorhinal Ub and HSP 72 immunoreactivity peaked between 18 and 48 hrs for both 15 and 30 mM NMDA infusions. Mean maximal volumes of HSP 72 and Ub immunoreactivity in the EC at 48 hrs after 15 mM NMDA infusions predicted the mean maximal volume of neuronal loss seen after 96 hours. In contrast, after infusion of 30 mM NMDA, the mean maximal volume of HSP 72 and Ub immunoreactivity was significantly larger than the maximal volume of neuronal loss, implying that a population of HSP 72 and Ub immunopositive cells survived the NMDA insult. These data show a specific neuronal stress protein response preceding neuronal death after low doses of NMDA. In addition, we have found that HSP 72 and Ub immunoreactivity are not necessarily correlated with neuronal survival in vivo.

### 31.6

PROTEIN SYNTHESIS INHIBITION REDUCES INFARCT VOLUME FOLLOWING FOCAL CEREBRAL ISCHEMIA: EVIDENCE SUPPORTING PROGRAMMED CELL DEATH IN STROKE.

MD Linnik\*. RH Zobrist. Dept. of Pharmacology, Marion Merrell Dow Research Institute, Kansas City, MO 64134.

Cells within the core of an ischemic insult exhibit features consistent with necrotic cell death. However, cells on the perimeter of the ischemic zone can be preserved by various therapeutic regimes. Protein synthesis may contribute to the extent of ischemic injury. Thus, the present experiments examined the effect of protein synthesis inhibition on the volume of the ischemic zone 24 hours after permanent occlusion of the middle cerebral artery in spontaneously hypertensive rats. Continuous intracerebroventricular administration of the protein synthesis inhibitor cycloheximide (1mg/kg/24 hours) initiated prior to ischemia resulted in a significant attenuation (p<0.01) of ischemic brain volume (147  $\pm$  11 mm<sup>3</sup>) vs. matched saline controls (189  $\pm$  7 mm<sup>3</sup>). In addition, electrophoretic examination of cortical DNA from the ischemic zone revealed endonucleolytic degradation of the DNA into nucleosome ladders. These data demonstrate that inhibiting protein synthesis reduces the infarct size following focal cerebral ischemia, and is consistent with the possibility that programmed cell death contributes to the loss of neurons in this model.

CLONING AND MOLECULAR CHARACTERIZATION OF LACHESIN, A NOVEL GRASSHOPPER AND DROSOPHILA SURFACE PROTEIN PRESENT ON CELLS FOLLOWING NEURONAL DEVELOPMENTAL PATHWAYS. Rolf O, Karistrom' and Michael J, Bastiani. Dept. of Biology,

PATHWAYS. Bolf O, Karlstrom\* and Michael J, Bastiani. Dept. of Biology, University of Utah, Salt Lake City, UT 84112.

We have cloned, sequenced and characterized a novel surface molecule present during grasshopper neurogenesis. We call this molecule Lachesin (after one of the three Greek fates) to depict its potential role at points of cellular fate transitions. Lachesin is expressed on those cells which follow a neuronal developmental pathway; those cells which diverge from the neuronal pathway stop expressing the protein. Specifically, at the beginning of neurogenesis Lachesin is expressed throughout the neurogenic ectoderm. As neurogenesis proceeds, expression becomes restricted to neuroblasts and their progeny and then further restricted to a subset of neurons and axonal nathways.

pathways.

PCR primers, based on protein sequence, were used to amplify a specific product from grasshopper and Drosophila cDNA. These PCR products were used to screen cDNA libraries and each pulled out a clone whose DNA sequence predicts the expected protein product. A search of the sequence data bank shows that Lachesin is a novel protein. Lachesin is a 38 kD protein containing immunoglobulin (Ig) motifs and is bound to cell surfaces by a phosphatidylinositol lipid tail. Sequence comparisons show Lachesin belongs to a family of proteins including Drosophila amalgam (ama) and the human polio virus receptor (pvr). These molecules all contain 1 C and two V type Ig domains and are expressed on neurons. It is known that ama expression is regulated during embryogenesis, but nothing is known of its function during development. A Drosophila Lachesin has been cloned which is distinct from amalgam. We are undertaking functional studies to determine the role Lachesin plays in insect neurogenesis.

STRUCTURAL AND FUNCTIONAL PROPERTIES OF MYELINATED AXONS IN POSTNATALLY DEVELOPING RAT MENTAL AND SURAL NERVES. C.S. Johansson, C.M. Bowe<sup>†</sup>, C Hildebrand\*, and N. Evans\*, Dept. of Cell Biology, University of Linköping, S-581 85 Linköping, Sweden, †Section of Neurobiology, Dept. of Clinical Neuroscience, Brown University, Providence, RI,

This study examines the nodal spacing (L) and nodal-paranodal fine structure in the mental (MN) and sural nerves (SN) of developing and adult rats by light and electron microscopy. In addition, the effect of the potassium channel blocking agent 4-aminopyridine (4-AP), on the compound action potential waveform of the MN and SN is analyzed. In the MN, the L-values of conventional internodes increase from 100the MN, the L-values of conventional internodes increase from 100-500µm by two weeks after birth, to 150-600µm in the adult, as fibre diameter (D) ranges expands from 1-6µm to 2-10µm. In the SN the L values are 100-400µm by 2w and 200-1200µm in the adult. Corresponding D-values are 1-5µm and 2-9µm respectively. Thus, the largest internodes in the adult MN are half as long as those in the SN. Both in the MN and the SN of 2-3week-old rat pups some exceptionally short distorted myelin sheaths or very short internodes without signs of myelin debris are seen (L=15-80µm). The adult nodal-paranodal ultrastructure is essentially similar in the two nerves. Developing MN and SN exhibit a marked sensitivity to 4-AP. Although the physiological effects of 4-AP diminish with maturation in both nerves, the MN retains a greater sensitivity than the SN. We conclude that different cutaneous nerve trunks exhibit partly different structural and functional properties.

MOLECULAR EVIDENCE FOR NITRIC OXIDE SYNTHASE-MEDIATED DEVELOPMENT OF MOTOR NEURONS Robert G. Kalb\* Yale University School of Medicine, New Haven, CT 06510

During a critical period in early postnatal life, patterned neuronal activity can regulate the acquisition of mature morphological and electrophysiological neuronal properties. We examined the molecular development of motor neurons and found that the expression of the cell surface proteoglycan recognized by monoclonal antibody Cat-301 depends on neuronal activity during a circumscribed period in early postnatal life. The depends on neuronal activity during a circumscribed period in early postnatal life. Ine development of Cat-301 expression on motor neurons requires activation of N-methyl-D-aspartate (NMDA) receptors at the spinal segmental level. A transient high level expression of NMDA receptors in the ventral horn occurs during this period suggesting the expression of NMDA receptors on motor neurons is essential for their appropriate activity-dependent development. The potential signal transduction pathways that follow NMDA receptor activation during motor neuron development was examined.

Immunohistological studies employing a polyclonal sera to PKC revealed labeling restricted to the substantia gelatinosa in both neonates and adults. Immunohistologic studies employing the 6G9 monoclonal antibody to Ca/Cam Kinase showed labeling only in the adult (but not neonatal) substantia gelatinosa. Histochemical localization of NADPH-diaphorase activity (an excellent marker for NOS) revealed intense labeling in the adult substantia gelatinosa. In the postnatal day 7 (P7) spinal cord, diaphorase activity is present in neurons throughout the spinal grey matter and motor neurons appear intensely labeled. Since both NOS and NMDA receptors appear to be appear intensely labeled. Since both NOS and NMDA receptors appear to be transiently expressed by neonatal motor neurons, NOS may participate in NMDA receptor-mediated signal transduction. We evaluated the effect of the NOS inhibitor nitroarginine (NA) on the development of motor neuron Cat-301 expression and found that NA administered daily from P7 to P21 specifically inhibited the development of Cat-301 expression on motor neurons. These results suggest that NMDA receptor-mediated development of motor neurons employs the NOS signal transduction pathway. Supported by the NIH and the Muscular Dystrophy Association

APLYSIA mRNAs EXPRESSED DURING NERVOUS SYSTEM DEVELOPMENT AND PLASTICITY. S.T. Lockhart. T.M. Hodgson\* and C.W. Pikielny. Brandeis University, Waltham MA

We have developed an improved method which uses PCR to generate representative cDNA populations from very small amounts of RNA. We are using these cDNAs in screens and subtractive hybridizations looking for genes expressed during various forms of CNS plasticity. In a screen for genes regulated by conA, a known modulator of neuronal function, we have identified an mRNA which appears to be specific to glial cells and are currently using it as a marker development. We are also carrying on a screen for genes expressed during a critical stage of development where the structure of the Aplysia nervous system undergoes a radical change both in structure and in function. During this relatively late stage, a disproportional increase in the number of neurons and the volume of the neuropile coincides with the ability of animals to exhibit sensitization and its cellular analog, facilitation of non-decremented EPSPs.

### 32.4

THE DISTRIBUTION OF BOTH THE AMPA AND KAINIC ACID RECEPTORS IS DEVELOPMENTALLY REGULATED IN THE RAT SPINAL CORD. M. W. Jakowec, A. J. Fox, S. Holloway\* and R. G. Kalb Department of Neurology, Yale University, New Haven, CT. 06510.

In early postnatal life, the nervous system demonstrates plasticity during a circumscribed period in early post-natal life. Deprivation of stimulus-evoked neuronal activity during this critical period has a significant effect on neuronal phenotype while deprivation in adults has little effect. This phenomena is most compelling in the cat and primate visual system but it is likely to occur throughout the nervous system. We have shown that motor neurons have an activity-dependent developmental critical period. In the rat and hamster, monoclonal antibodies have identified a proteoglycan (Cat-301) whose expression is dependent upon activity in identified a proteoglycan (Cat-301) whose expression is dependent upon activity in the spinal cord. Recently, we have shown that Cat-301 expression is dependent upon activation of the NMDA subclass of glutamate receptor and that NMDA receptors are transiently expressed in the ventral horn during development. Since activation of the NMDA receptor requires co-activation of non-NMDA receptors, we were interested in examining the distribution of a subclass of non-NMDA receptors. We have used receptor-ligand autoradiography to characterize the distribution of both the AMPA and Kainic acid sub-types of the glutamate receptors in the developing rat single cord. Tissue sections of rats at postnatal day 7 (P7). austraoution of both the AMPA and Kainic acid sub-types of the glutamate receptors in the developing rat spinal cord. Tissue sections of rats at postnatal day 7 (P7), P14, P21, P28, and adult were examined. At P7 the expression of these binding sites is present throughout the gray matter of the spinal cord and over the next three weeks all these binding sites are lost except in the substantia gelatinosa. These results demonstrate synchronous expression of multiple glutamate receptor subtypes in the developing spinal cord. Transient expression of NMDA and non-NMDA receptors is likely to provide a critical mechanism for spinal neurons to mature neuronal features during a critical period in early postnatal life.

Synaptophysin and chromogranin-A are expressed in fetal and adult female rat paracervical ganglion autonomic neurons and SIF cells. H. Traurio. A. Mayerhofer, G. Lahr and M. Gratzl.
Anatomie & Zellbiologie, Univ. Ulm, D7900 Ulm, Germany.
Paracervical ganglia(PG) in uterine cervical perimetrium consist of several subsets of autonomic neurons(AN) and small intensely fluorescent(SIF) cells based on their peptide and transmitter content. Small synaptic vesicles(SSV) and large dense core vesicles(LDCV), organelles present in most neurons and neuroendocrine cells, are components of two different secretory pathways which are involved in uptake, transport and exocytosis of bioactive molecules. In the present study, expressions of synaptophysin(SY), a SSV membrane protein, and chromogranin-A (CGA), a LDCV matrix protein, were used to examine

study, expressions of synaptophysin(SY), a SSV membrane protein, and chromogranin-A (CGA), a LDCV matrix protein, were used to examine development of AN and SIF cell secretory organelles in PG. Sections of PG were analyzed for SY-, CGA- and tyrosine hydroxylase(TH) immunoreactivities (-I) using ABC reactions or specific SY and CGA MRNA in situ hybridization(ISH) with 35S-cRNA antisense probes. Results reveal clusters of intensely SY-I cells in PG on fetal day(FD) 16; serial sections show coincident CGA- and TH-I. These characteristics correspond to SIF cells and remain prominent features in neonatal(NN) and adult PG. SY-I preganglionic terminals appear among AN in PG on FD 18 & 21. By NN days 1 & 5, SY-I terminals of various sizes and number develop axo-somatic relationships with most AN and SY-I postganglionic terminals appear in the uterine cervix. Terminal SY-becomes more prominent in adult PG; in contrast, terminals are not CGA-I. Accumulating ISH data reveal expressions of specific mRNAs for CGA-I. Accumulating ISH data reveal expressions of specific mRNAs for with two different secretory pathways in neural cells develop earlier in SIF cells compared to AN in PG. Supported by: DFG-Ma1080/2-1 (A.M.); DAAD (H.T.).

EXPRESSION OF THE CHICK NEUROFIBROMATOSIS-1 GENE (cNF-1) IN THE DEVELOPING NERVOUS SYSTEM AND NEURAL CREST. A.I. Kayka & K.F. Barald\*, Program in Neuroscience and CMB Program, University of Michigan Medical School, Ann Arbor, MI 48109-0616 and C.M.R.F., University of Sydney, P.O. Box 61, Camperdown 2050, NSW, Australia. Von Recklinghausen's neurofibromatosis type 1 (NF1) is one of the most frequently inherited autosomal dominant disorders in humans. Although the

symptoms and severity of the disease are variable, the majority of tissues affected in NF1 are of neural crest (NC) origin. The chick neurofibromatosis 1 (cNF1) 432-bp cDNA which we have cloned and sequenced is highly (at least 86%) homologous to the human NF1 gene at the nucleic acid level. We are using this probe to establish the normal expression pattern of cNF1 in early chick and quail embryos, and to examine the potential role of cNF1 in neural crest development. In Northern blot analysis we have found two transcripts expressed: a large (12.6kb) cNF1 transcript expressed as early as Hamburger & Hamilton stage 11 (12.080) (NPT trainstript expressed as early as rhamming at a rhammin stage 11 (40.45 hours in ovo) through to adulthood, and a smaller transcript (4kb) which also appears as early as stage 11 but is downregulated by stage 15 (50.55 hours in ovo). In situ hybridization experiments have shown cNF1 to be ubiquitously expressed as early as stage 8; both earlier and later stages are being investigated to determine the onset and pattern of gene expression. Monoclonal and polyclonal antibodies (Gutmann et al, 1991) are also being used to examine protein expression during development. We have produced a src-transformed quail NC cell line with a temperature sensitive mutant of the Rous Sarcoma virus. In its undifferentiated state, the quail NC cell line does not express the cNF1 gene; however, cNF1 mRNA levels increase at least two orders of magnitude after differentiation of the NC cell line into neuron-like cells with retinoic acid. This model system can be used to examine the involvement of cNF1 in NC development and differentiation. Support: NSF BNS8910987 & Fulbright Foundation (KFB); U of M International Research Partnership (KFB& AIK); NIH Developmental Biology & CMB Training Grants (AIK).

A HUMAN HOMOLOGUE OF SC1 (DM-GRASP) IS EXPRESSED IN THE HUMAN EMBRYONIC NERVOUS SYSTEM. David Shelton, Hideaki Tanaka, and Joni Sutherland. Dept. Neuroscience, Genentech, Inc. South San Francisco, and Gunma University, Maebashi, Japan.

SC1 is a 100 kD integral membrane glycoprotein, first identified by monoclonal antibodies generated to chick embryo spinal cord membranes. It has recently been cloned, and predicted amino acid sequence shows that it has five immunoglobulin-like domains, a transmembrane domain and a short cytoplasmine tail. In vitro expression studies have demonstrated that SC1 is capable of mediating intercellular adhesion in a homophilic manner, and also of mediating neurite outgrowth. Because none of the monoclonal or polyclonal antibodies to SCI recognize any proteins of mammalian origin, molecular cloning techniques were used to identify the human homologue of this molecule. Probing of a fetal human brain cDNA library with a chicken SC1 probe at low stringency revealed clones which are highly homologous to chicken SC1. The overall nucleotide sequence identity is approximately 90%. Both the cloning of this molecule from a brain library and preliminary in situ hybridization analysis verify that this human SC1 homologue is expressed in the embryonic human nervous system.

ONTOGENY AND SEX DIMORPHISM OF NEURAL-SPECIFIC mRNA'S IN RAT BRAIN. R.H. Lustig\*, P. Hua. M.A. Wilson, and H.J. Federoff. Dept. Pediatrics, U. Wisconsin, Madison, WI 53792; Scripps Research Institute, La Jolla, CA 92037; and Dept. Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Growth-Associated Protein 43kDa (GAP-43) gene expression is estrogen-regulated in adult ventromedial hypothalamus (VMH) and sexually dimorphic (M:F=1.8:1) in adult cortex (CTIX) (Mol Brain Res. 11:125,1991). Such effects intimate hormonal regulation of synaptic plasticity. This study examined ontogeny of expression of mRNA's encoding 3 neural-specific proteins: GAP-43, SCG10, and synaptosomal-associated protein 25 kDa (SNAP-25); and also glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Male and female rats were sacrificed at 1, 4, 11, 23, and 60 days, levels of specific mRNA's in VMH and CTX were quantitated on slot-blots by <sup>32</sup>P-cDNA hybridization (using cyclophilin (CYC) and poly-dTs<sub>0</sub> (dT) as standards), and peak density (PD) determined by autoradiography and optical densitometry. PD ratios were compared across ages and between sexes.

nsitometry. PD ratios were compared across ages and between sexes.

PD ratios of CYC/dT remained constant in each region over time and sex. PD ratios PD ratios of CYC/dT remained constant in each region over time and sex. PD ratios for other mRNA's were congruous regardless of standard. In VMH, GAP-43 mRNA levels were high on days 1 and 4 with a 3-fold decrease by day 23; in CTX, GAP-43 mRNA increased by 2-fold by day 11, then decreased 2.5-fold by day 23. In VMH, SCG10 mRNA showed only small increases with time; but in CTX, there was a 5-fold drop from days 4 to 23. In VMH, SNAP-25 mRNA was low and changed only slightly; but in CTX there was a 5-fold increase between days 4 and 60. At birth, there was no sex dimorphism in either area, but all 3 neural-specific mRNA's were sexually dimorphic in adult CTX (M:F=1.76 for GAP-43, 1.46 for SCG10, 1.44 for SNAP-25); VMH was not sex dimorphic. GAPDH mRNA levels were regulated developmentally in VMH and CTX, but there was no sex dimorphism in either area.

These results are consistent with other ontogenic studies, show that neural.

These results are consistent with other ontogenic studies, show that neural-specific mRNA's are differentially regulated, and are coincidental with synaptic ontogeny in these areas. They also confirm a sex dimorphism of neural-specific mRNA's in adult CTX, and show that these dimorphisms are not present at birth, but rather become apparent at adulthood, suggesting that they may be hormone-dependent.

COLOCALIZATION OF NERVE GROWTH FACTOR RECEPTOR- AND ACS-IMMUNOREACTIVITY IN EMBRYONIC RAT CORTICAL SUB-PLATE AND BASAL FOREBRAIN NEURONS. Z.-Y. Yu\*, D. E. Anderson, and J. E. Bottenstein, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77555

Double-immunostaining for nerve growth factor receptor (NGFR) and AC3 antigen has been performed in embryonic rat brain. NGFR- and AC3immunoreactive cells were visualized in the same coronal section of embryonic rat brain. Mouse anti-rat NGFR monoclonal antibodies (192) bind to low affinity NGF receptors in embryonic through adult stages; AC3 monoclonal antibodies bind to cytoplasmic antigens in the cortical subplate, basal forebrain, and other regions during embryonic and early postnatal periods but not after P21 (Soc. Neurosci., Abstract 524.9, 1991). Neurons double-immunostained for NGFR and AC3 are present in the cortical subplate and adjacent cortical plate, basal forebrain (especially septum), and medial hypothalamus (especially median and medial preoptic nuclei). The NGFR localization we observed in embryonic rat brain is similar to that

described by Koh and Loy (J. Neurosci., 9:2999-3018, 1989).

Colocalization of NGFR- and AC3-immunoreactivity suggests there may be a functional link between these two cell survival related proteins in the maintenance and development of neocortical, cortical subplate, and basal forebrain neurons

EXPRESSION OF SCG10 AND P19/STATHMIN mRNAs IN THE ADULT RAT BRAIN AND THE EFFECT OF LESION. T. Himi, T. H. McNeill, N. Mori Div. Neurogerontology, Andrus Gerontology Center, University of Southern California, Los Angeles, CA90089.

SCG10 and p19/stathmin are members of a newly identified gene family, which are expressed specifically or preferentially, respectively, in the nervous system. The brain expression of SCG10 and p19 mRNA is maximal in late gestation to early postnatal period and dramatically reduced in the adult rat brain. In this study, we investigated 1) the distribution of SCG10 transcripts in the CNS of the young adult rat in comparison with p19 transcripts and 2) the change in the expression during neural degeneration and regeneration after partial brain lesion. To detect these transcripts by in situ hybridization, we used two kinds of RNA probes respectively: one was transcript from full-length cDNA and the other was transcript from 3'-noncording

1) In 3-month-old rat brains, the expression of both SCG10 and p19 is widespread through most brain regions. The precise distribution patterns at the cellular level are as follows: SCG10 mRNA is expressed strongly in mitral cell layer of olfactory bulb, pyramidal layer of hippocampal CA3 - 4 region, piriform cortex, cerebellar Purkinje cells and magnocellular motor neurons in midbrain and brain stem, and expressed moderately in olfactory tract, nucleus olfactory tract, hippocampal CA1 - 2 region, septum, rhonboid thalamic nucleus, hypothalamus, and substantia nigra. Whereas, p19 mRNA is expressed mainly in external plexiform layer of olfactory bulb, tenia tecta, olfactory nucleus, piriform cortex, thalamic nucleus, raphe and A7 in midbrain, however, weak or no signals were detected in hippocampus, cerebellum or brain stem. The result suggests that SCG10 and p19/stathmin are differentially expressed in young

2) In order to investigate the effect on mitral cells and cells in piriform cortex, we In the order of the old and the state of the old accept by the capression of SCG10 mRNA expression in partial lesion of the olfacotry bulb. The expression of SCG10 in piriform cortex was reduced in the ipsilateral frontal side, which was maximal 3 days after lesion. It is suggested that the change of SCG10 expression is involved in neural degeneration and regeneration.

# 32.12

MOLECULAR CHARACTERIZATION OF A NOVEL CEREBELLAR cDNA, PRENATAL ONTOGENY, AND CELLULAR DISTRIBUTION IN THE BRAINS OF NORMAL, WEAVER, PCD AND REELER MUTANT MICE. M. Kambouris, L. C. Triarhou, \* L. Sangameswaran, S. R. Dlouhy, B. Ghetti and M. E. Hodes. Indiana Univ. Sch. of Med., Indianapolis, 1N 46202.

Following the identification of several novel cDNAs by screening a neonatal wv/+ cerebellar cDNA expression library with an anti-granule cell antiserum (Soc. Neurosci. Abstr. 17: 556, 1991), we characterized and sequenced one cDNA; using in situ hybridization histochemistry, we also studied its expression during prenatal development and its cellular distribution in adult cerebellar mutant mice. This cDNA represents a single-copy gene with a mRNA of 2.4 kb. In normal adult mouse brain, strong hybridization signal is seen *inter alia* in cerebellar granule and Purkinje cells, in hippocampus and in substantia nigra. The message is already present in the CNS of +/+ embryos at E15. In adult wv/wv cerebellum, the signal is seen mainly in Purkinje cells. The transcript is markedly reduced in ww/ww substantia nigra. In pcd/pcd cerebellum, granule cells show hybridization signal, but overall expression is decreased owing to the absence of Purkinje cells. In rl/rl cerebellum, the owing to the absence of Purkinje cells. In nl/nl cerebellum, the strongest hybridization signal is found in a superficial layer, while diffuse grains are observed in the subcortical white matter. The nl/nl hippocampus appears disorganized. In all, the cellular localization in the mutants correlates with their known anatomical deficits. The nature and function of the polypeptide encoded by the cDNA is under study. (Supported by USPHS PO1-NS27613).

SEQUENCE AND CHARACTERIZATION OF A DEVELOPMENTALLY REGULATED PROTEIN DURING EARLY CORTICOGENESIS IN THE RAT. J.E. Mintum\*. H.J.L. Fryer, D. Geschwind, and S. Hockfield. Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT, 06510

Using two-dimensional gel electrophoresis we previously identified an acidic, 64 kd protein (protein 310), that is up-regulated during neurogenesis in the developing rat cerebral cortex (J. Neurosci. 9:4304). Protein microsequencing of purified 310 has been carried out and 5 peptides reveal no significant homology to other previously described proteins.

Polyclonal antisera were raised to synthetic peptide fragments of protein 310 Polyclonal antiscra were raised to synthetic peptide tragments of protein 310 derived from partial sequence data. The antibodies recognize a 64 kd band on immunoblots of cerebral cortex homogenates; the band is eliminated when the antibodies are pre-incubated with their specific peptides. Developmental immunoblot analysis of cortex, spinal cord, liver and lung homogenates from animals of ages ranging from embryonic day 14 (E14) to adult reveals a neural specific expression beginning at E14, peaking at post-natal day 5 (P5), with

markedly diminished staining in the adult.

Immunohistologically the protein is expressed by cells in the developing cortical plate but is not expressed in the ventricular zone, consistent with an expression by early post-mitotic cells. The morphology of antibody-positive cells suggests that they are post-mitotic neurons during their migratory and post-migratory stages. Antibody positive cells are not stained by monoclonal antibody

Rat-401, which is specific for progenitor and radial glial cells.

Antibody probes demonstrate that protein 310 1) increases in abundance during neurogenesis, 2) is expressed in post-mitotic neurons, 3) is down-regulated in the adult, and 4) is enriched in neural tissues. These results suggest that protein 310 may play an important role in cortical neurogenesis. [Supported by NS22807 and the Howard Hughes Medical Institute]

# 32.15

TWO MONOCLONAL ANTIBODIES WITH REGIONAL AND TEMPORAL SPECIFICITY IN THE DEVELOPING CHICK EMBRYO. A. M. SMITH\*, L.C. ELLIS, and I.S. ALVAREZ. Department of Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.

An objective of our research program is to produce monoclonal antibodies specific for proteins which are regulated during early stages of chick development. In particular we are generating molecular markers specific for different classes of cells or different regions of the developing chick embryo. Using an immunization technique which enriches for the production of MAbs against rare antigens (1986, PNAS) 83:4336-4340) we have produced two new MAbs, 2B8 and 1E10. MAb-2B8 is an IgM and stains the cytoplasm of several classes of cells in the developing embryo. At stage 4 only endoderm cells stain and this staining persists in the adult. By stage 10 isolated cells in the auditory staining persists in the adult. By stage 10 isolated cells in the auditory placodes can be detected and by stage 11 positive staining of cells in the roof of the hindbrain can be detected. Also by stage 11 labelled cells aligned below the notochord are apparent. The MAb 1E10 was obtained by immunizing BALB/c with neural plate tissue from early chick embryos. The surface of cells is stained by this antibody. By stage 6 regions of the developing head region is stained by 1E10 and by stage 8 the neural folds stain. (Supported by USPHS grants no. NS 18112 and DC 00144)

#### 32.14

A NOVEL MARKER FOR SELECTED NEURONS IN EMBRYONIC RAT TEL- AND DI-ENCEPHALON. Z.-Y. Yu. D. E. Anderson and J. E. Bottenstein:
Marine Biomedical Institute, University of Texas Medical Branch in Galveston, Galveston, Texas 77555

Our previous work (Soc. Neurosci., Abstract 524.9, 1991) has shown that AC3 monodonal antibody (mAb) is a novel marker for neurons in cortical subplate, medial septal and preoptic nuclei, and some subventricular zone cells in P0-P14 rat brain. The distribution of AC3 immunoreactivity (AC3 IR) was examined in serial coronal sections of embryonic (E15-E19) rat brain. E15: Strong AC3 IR is present in the olfactory tract (LOT), paraventricular hypothalamic nuclei (PHN), and suproptic nudei; medium AC3 IR in septum, medial forebrain bundle (MFB), and medial and lateral hypothalamus; low AC3 IR is shown in the putamen. No AC3 IR is found in the neocortex or ventricular/subventricular zone. E17: Strong AC3 IR is present in the olfactory tubercule (TU), median precipic nuclei (MnPO), and LOT; strongmedium AC3 IR in the cortical subplate, adjacent cortical plate, and septum; medium AC3 IR in the MFB and medial preoptic nuclei (MPO). E19: Strong AC3 IR is present in the TU, LOT, MnPO and optic tract; strong-medium AC3 IR in the cortical subplate, adjacent cortical plate, dorsoventral piriform cortex, septum, and dentate gyrus; medium AC3 IR in the hippocampus, MFB, diagonal band, MnPO, amygdala, PHN, and median eminence. AC3 immunoreactive subplate neurons are detected when the subplate zone first appears but not after P21. AC3 IR is found in the CA1 and CA3 fields of the hippocampus and in the dentate gyrus at E19 but disappears after birth. AC3 IR is not observed in the ventricular/subventricular zone at E15-E19 but is observed in the early postnatal period. No AC3 IR is observed in any brain area after P21.

Our results suggest that the AC3 monoclonal antibody can also be employed as a marker for studying neuronal development in the embryonic rat brain

CHLORAMPHENICOL ENHANCES RIBOSOMAL DISSOCIATION IN DEAFFERENTED NEURONS OF THE CHICK BRAINSTEM. M. Hartlage-Rübsamen. D.E. Cunningham, E.W. Rubel\* Virginia Merrill Bloedel Hearing Research Center, Univ. of Washington, Seattle, WA 98195.
Following cochlea removal approximately 30% of the neurons in the ipsilateral primary auditory nucleus, nucleus magnocellularis (NM), of the chick undergo cell death. Previous studies have shown that by 6 hours after receptor destruction NM neurons destined to die ceased protein synthesis. EM-analysis of these neurons reveals complete dissociation of cytoplasmic ribosomes. In addition, there is a generalized up-regulation of oxidative metabolism throughout the deafferented nucleus. All of these changes are due to the climination of afferent activity. Prevention of up-regulation with chloramphenicol, an inhibitor of mitochondrial protein synthesis, causes increased cell death after deafferentation (Hyde & Durham, Soc. Neurosci. Abs., 16:A 984, 1990). In the present study we used the same drug to assess whether the increased cell death can be traced back to the same early degenerative events as observed in affected NM-neurons following cochlea

whether the increased cell death can be traced back to the same early degenerative events as observed in affected NM-neurons following cochlea removal alone.

Posthatch chicks (P12-14) were given hourly injections of chloramphenicol (250g/kg/6h). Thirty minutes after the first injection, animals were anesthesized and the right cochlea was removed. The birds were sacrificed 6 hours after surgery. EM-analysis of cytoplasmic morphology shows a 3-4 fold increase in the number of cells displaying complete dissociation of ribosomes compared to deafferented, vehicle-injected controls. This suggests that enhanced cell death involves the same cellular events in NM neurons as found after deafferentation alone. These results indicate that up-regulation of mitochondrial function plays a critical role in the survival of neurons following withdrawl of afferent input. (Supported by NIH DC 00520)

CLONAL RELATIONSHIP OF AVIAN BRAINSTEM AUDITORY NUCLEI. E.A. Lachica\* & E.W. Rubel, Dept. of Otolaryngology-Head & Neck Surgery, University of Washington, Seattle WA 98195.

In avians, nucleus magnocellularis (NM) receives a tonoptic projection from the eighth nerve. NM projects tonotopically onto n. laminaris (NL). Topographic connectivity between NM and NL appears to be established early, developing independent of physical or physiological cues conveyed by the ganglion cells of the peripheral sensory receptor. Hence, factors linked to the early development of NM and NL cells may underlie the ontogeny of topographic specificity. In this study we examined the clonal relationship of NM and NL cells by infecting embryos with a replication defective recombinant retrovirus during a period when NM, but not NL cells are proliferating. Embryos developed outside of the shell. When they acquired the features typical of 9 to12 day old embryos, they where exsanguinated, then fixed via transcardial perfusion of 1% acrolein + 4% formaldehyde. Coronal sections of the brainstem 50 µm thick were cut with a cryostat and processed for β-galactosidase (X-gal) histochemistry. X-gal labelled cells in NM and NL suggest that neurons in these two nuclei are clonally related. X-gal-positive cells were also present in the neuropil surrounding NL, and neuropil just subjacent to the floor of the IVth ventricle. GABA-ergic cells are known to reside in these areas. Labelled cells were also present in the ventral vestibular nucleus. Plots of X-gal labelled cells of E9 embryos show that clonally related cells are scattered throughout NM and NL. However, reconstructions of the auditory nuclei of E12 embryos indicate that clonally related cells lie in topologically congruent positions of NM and NL. The Role of Experience in Regulating Myelination in Nucleus Laminaris of the Barn Owl. C. T. Hue\* and C. E. Carr. Dept. of Zoology, Univ. Maryland, College Park, MD 20742.

The adult barn owl uses interaural time differences to localize sound in azimuth. The timing information is processed in the auditory brainstem neural pathway involving nucleus laminaris (NL). Maps of interaural phase difference are formed dorsoventrally in NL by interdigitating axons from the ipsilateral and contralateral nucleus magnocellularis (Carr and Konishi, 1990).

Although this circuit is present at hatching, the magnocellular axons in NL are unmyelinated. The physiological significance is that myelination is critical for their proper functioning in the adult NL. Myelination begins towards the end of the first week post-hatch and is completed at 1 month post-hatch. Thus myelination coincides with head growth, and with the appearance of stable interaural time differences. Schwab and Caroni (1988) showed that oligodendrocytes are nonpermissive substrates for neurite growth, and thus may be important in regulating CNS development. The hypothesis that myelination may be affected by auditory experience was tested by deafening young birds within days of hatching. Immunohistochemistry was used to detect oligodendrocyte proteins.

Preliminary observations from owls deafened at both 1 and 5 days after hatching showed a relatively normal time course of migration of oligodendrocytes into NL, and initial expression of myelin did not appear to be affected by deafening. In summary, myelination of NL circuit may not be regulated by auditory experience of interaural time difference cues, but could be developmentally regulated instead.

THE DEVELOPMENT OF SYNAPTIC INTEGRATION IN THE LATERAL SUPERIOR OLIVE. D. H. Sanes\*. Center for Neural Science, New York Univ., New York, NY 10003.

The development of synaptic integration underlying a simple binaural computation, interaural level difference coding, was studied using an in vitro slice preparation through the gerbil (Meriones unguiculatus) auditory brain stem. The binaural properties of lateral superior olivary (LSO) neurons are available to intracellular analyses by delivering electrical stimuli to the afferent pathway from each ear (Sanes, J Neurosci 10; 3494, 1990). The ipsilateral pathway is largely excitatory, and the contralateral pathway is Long duration synaptic responses (≈100 ms) were largely inhibitory. observed in recordings from neonatal animals (1-8 days postnatal). Short trains of electrical stimuli to either pathway commonly produced a temporally summated response, and membrane potential remained hyperpolarized or depolarized for the stimulus train duration. In neonatal animals, the IPSPs were often large enough to induce an action potential upon repolarization, suggesting the presence of a low threshold Ca\*\* response. The synaptic responses from 10-14 day animals, about the time when airborne sound is first transduced in vivo, remained of longer duration. When the latency of an ipsilaterally evoked action potential was successively advanced through a contralaterally evoked IPSP, by delaying the relative stimulus time, the duration of action potential blockade was found to be up to 10-fold longer than in 18-25 day animals. These results indicate that the temporal integration of synaptic potentials is severely compromised when animals first begin to process acoustic information. (Supported by NIH DC00540)

THALAMOCORTICAL PROJECTIONS IN NEONATALLY DEAFENED CATS. S.G. Stanton\*, R.V. Harrison, A. Nagasawa, and R. Mount. University of Toronto, Toronto, Ont., CANADA, M5G 1X8.

Standard microelectrode recording techniques were used to obtain cochleotopic maps of stimulus frequency representation in the primary auditory cortex (AI) of adult cats deafened at birth. In addition, retrograde tracers were used to examine the cochleotopically organized projection from the medial geniculate body (MGB) to AI. As a consequence of high frequency neonatal cochlear hearing loss, the physiologic map of AI becomes extensively reorganized, with anterior regions of AI normally devoted to high frequencies becoming tuned to a lower frequency. However, tracer injections into different regions in AI labelled separate cell populations in MGB in both deafened animals and controls, suggesting that the cochlectopic organization of the thalamocortical projection is not disrupted in deafened cats, despite extensive physiological reorganization of stimulus frequency representation in the cortical map.

AN ORGANOTYPIC CULTURE OF THE VENTRAL AUDITORY BRAIN STEM. A. Hafidi and D.H. Sanes. Center for Neural Science, New York Univ., New York NY 10003.

While the organotypic culture technique has been successfully applied to several neural systems, the mammalian auditory brain stem nuclei have never been studied in vitro. We report here our preliminary observations on the study of the superior olivary complex (SOC) using a thick slice preparation (Stoppini et al., J Neurosci Meth, 1991). Gerbils (Meriones unguiculatus) of 5-7 days postnatal were used for this study. Gerbils were anaesthetized, the brain was carefully removed, and was cut on a vibratome at a 300  $\mu$ m. Sections of the brain stem containing the SOC were collected in Dulbecco's modified Eagle medium, transferred to serum containing medium and placed in culture plate inserts that contained a microporous membrane. The tissue slices were incubated at 36° C with a 5% CO<sub>2</sub> enriched atmosphere, and transferred to fresh media daily. The slices were processed for electron microscopy after 3, 6 and 15 days in vitro (DIV).

After 3 DIV, SOC slice cultures showed a change in the cross-sectional shape of the nuclei, probably due to the near total deafferentation. Toluidine blue stained semithin sections indicated a great number of degenerative neurons after 3 DIV, but considerably less after 6 DIV. The slices became thinner ( $\approx 80~\mu m$ ) and contained many neurons with a healthy morphology. Preliminary electrophysiological observations confirm that neurons survived up to 10 DIV. This preparation will allow for direct observation and manipulation of developing neuronal connections. (Supported by NIH DCC0640)

TONOTOPY IN THE INFERIOR COLLICULUS SHIFTS BY 1.5 OCTAVES DURING POSTNATAL DEVELOPMENT OF THE MONGOLIAN GERBIL MERIONES UNGUICULATUS. M. Schäfer\* and R. Rübsamen, Dept. for Zoology and Neurobiology, Ruhr-University Bochum, D-4630 Bochum, FRG.

In a comparative study we addressed the question of functional and structural dynamics in the postnatal development of the central hearing system in different mammalian species. Here we report the ontogenesis of the tonotopic organisation in the auditory midbrain nucleus Inferior Colliculus (IC) of the anaesthetised mongolian gerbil Meriones unguiculatus as revealed by stereotaxic multi-unit recordings (ca.200 recording sites/animal) following pure tone stimulation.

At birth, gerbils are deaf. Starting at the 12th day after birth (DAB) a tonotopic organisation in the IC is established first in dorso-lateral parts of the nucleus for frequencies from 0.6 to 3-5 kHz with thresholds of 85-100 dB SPL. At this time other parts (56 Vol.%) of the nucleus do not respond to any stimuli presented. Within the following 6-8 days this partial excitability improves to a consistent tonotopy covering all three subdivisions (ICX, ICP and ICC) of the IC with a low-to-high frequency axis running from dorso-lateral to ventro-medial. Thereby, the formerly unresponsive areas successively become involved into auditory processing. At the 18-20th DAB the hearing range of the animals is adult-like and covers frequencies from 0.2 to 50 kHz with a threshold minimum of -6 dB SPL at 3.7 kHz. Between the 13th and 16th DAB the frequency-place code shifts by 1.5 octaves, e.g. the representation site of 5.6 kHz (13 DAB) shifts to 16.4 kHz (16 DAB). These developmental changes are restricted to frequencies above 5 kHz, i.e. 50 % of the IC volume devoted to the processing of 0.5-5 kHz remain unaffected by spatial rearrangement.

OTOTOXICITY OF NEONATAL RATS TO SINGLE DOSE GENTAMICIN/FRUSEMIDE. S.J. O'Leary and D.R. Moore (SPON: Brain Research Association), University Laboratory of Physiology, Parks Rd., Oxford OX1 3PT, U.K.

Previous investigators have noted that neonatal rats cannot be deafened by aminoglycosides at doses which are ototoxic to older animals. However, these studies have used a treatment regime extending over >= 3 days and it has thus been difficult to correlate susceptibility to deafness with parallel morphological and physiological changes within the cochlea. We have, therefore, determined the susceptibility of agouti rats to ototoxicity with a single dose of gentamicin (200 mg/kg, i.m.) and frusemide (100 mg/kg, i.m.) given prior to the onset of hearing. In rats this occurs at postnatal day (P)11-12 (n=20), as determined by click-evoked brainstem responses. When animals were aged P24-28, brainstem response thresholds to condensation clicks were 26-33 dB peak SPL from untreated controls (n=5, mean=29dB, s=1.8) and from P6 (n=5, mean=29dB) and P7 (n=6, mean=29dB) treated animals. Thresholds were 30-48 dB from P8 (n=5, mean=38dB, s=8.5) treated animals and unrecordable at 87 dB from P10 (n=10) treated animals. These observations are consistent with the hypothesis that ototoxicity requires access to an active hair cell receptor, since susceptibility to the gentamicin/frusemide treatment correlates with the emergence of the cochlear microphonic on P8.

THE DEVELOPMENT OF THE OLFACTORY PLACODE IN THE EMBRYONIC ZEBRAFISH. <u>E.J. Collins and L.S. Ross\*</u>. Dept. of Biological Sciences, Ohio University, Athens, OH 45701. We have examined the early development of the olfactory placode in the zebrafish using light, electron, and video microscopy. Three

We have examined the early development of the olfactory placode in the zebrafish using light, electron, and video microscopy. Three distinct cell types are seen in the developing placode, and each cell type is limited to a specific region within the placode. Darkly staining basal cells form a layer along the deep margin of the placode and a dense cluster in the ventral placode. Bipolar receptor neurons have thick apical dendritic processes extending toward the luminal surface and thin basal axonal processes projecting to the adjacent telencephalon. Receptor cells are found primarily in the central regions of the placode. Lightly staining supporting cells with prominent nucleoli are scattered throughout the placode, but are sparsely distributed in basal cell

Differentiation within the olfactory placode follows a spatial gradient. The styryl dye DASPEI, a vital stain for mitochondria, was used to visualize olfactory cells in living embryos with video microscopy. The first labeled cells appear in the placode between 30 and 32 hours postfertilization. The distribution of DASPEI-labeled cells corresponds to the distribution of differentiated receptor cells in sectioned embryos. At 30-32 hours, the earliest labeled cells are restricted to the caudal region of the placode, directly adjacent to the eye. As the embryo develops, the distribution of labeled cells spreads anteriorly around the circumference of the placode. By 48 hours labeled cells are distributed throughout the placode. These data suggest that there is a caudal to rostral gradient of receptor cell differentiation in the olfactory placode of the embryonic zebrafish. Supported by OURC grant #861.

ODOR STIMULATION OF C-FOS mRNA EXPRESSION IN RAT OLFACTORY BULB DURING POSTNATAL DEVELOPMENT. K.M. Guthrie\* and C.M. Gall, Dept. of Anatomy & Neurobiology, Univ. of Calif., Irvine, CA 92717
We have previously reported that odor stimulation increases c-fos mRNA

We have previously reported that odor stimulation increases c-fos mRNA expression by neurons in spatially discrete regions of the glomerular layer (GL), and in underlying fields of the external plexiform and granule cell layers (GCL) of rat olfactory bulb. Some mitral cells are also labeled. We have proposed that this columnar pattern of neuronal activation defines a basic functional anatomical unit of odor processing in the olfactory bulb. Using in situ hybridization of 35S-labeled c-fos cRNA, we examined changes in this response pattern in normal rats over the course of postnatal development. At postnatal day 4 (PN4), odor stimulation resulted in broad areas of hybridization throughout the developing mitral and granule cell layers. Labeling of spatially discrete regions of the GL was first apparent at the end of the first PN week. At this age, mitral cell labeling was reduced but hybridization in the GCL still occurred over broad regions. By PN14, mitral cell labeling was further diminished, cell labeling in restricted areas of the GL and underlying GCL was robust, and the spatial nature of the odor response was clearly evident. Air-exposed littermates exhibited low levels of hybridization, and unilateral naris occlusion significantly reduced hybridization in the deprived bulb at both PN4 and PN21, indicating that c-fos expression is odor dependent at all ages examined. To determine if gene induction is dependent on NMDA mechanisms (Cole et al., '89), additional rats (PN21) were treated with the NMDA antagonist MK-801 prior to odor stimulation. In these animals, c-fos mRNA levels were dramatically increased in all laminae throughout the entire olfactory bulb, suggesting a disinhibition of c-fos expression with this treatment. Supported by NIDCD grant DC 01534.

IN VIVO ZINC SULFATE (ZnSO<sub>4</sub>) ADMINISTRATION INCREASES THE YIELD OF ADULT MOUSE OLFACTORY RECEPTOR NEURONS IN VITRO. <u>1.</u> Sosnowski, M. Gupta\*, and F. Roisen. Department of Anatomical Sciences and Neurobiology, University of Louisville School of Medicine, Louisville, KY 40292.

Neurobiology, University of Louisville School of Medicine, Louisville, KY 40292.

Adult olfactory receptor neurons are replaced following their fatal damage by an injury-induced mitotic stimulation of resident stem cells (Graziadel and Graziadel, J Neurocytol 8, 1979). In the present study, an in situ ZnSO, insult was applied to the olfactory epithelium prior to its removal for tissue culture to determine if the insult would enhance the in vitro neuronal population. Young adult male C57BL/6 mice were treated with 1% ZnSO, by nasal irrigation and sacrificed by decapitation 5 days following the treatment. The olfactory epithelium was removed and dispersed with a 0.125% trypsin incubation at 37°C for 40 min. After removal of trypsin by centrifugation, the cells were resuspended in Minimum Essential Medium with 10% heat-inactivated fetal bovine serum and cultured on glass coverslips in Maximow chambers. Scanning electron microscopy was used to document chemically-induced degeneration as well as the enhanced regenerative process of the olfactory epithelium after 5 days in situ. Quantitative analysis of cultured cells revealed a significant (P< 0.005) increase in the number of bipolar neurons compared to the untreated sham controls. Immunofluorescent studies demonstrated the heterogeneous nature of the surviving cell population which contained cells in various stages of development. Keratin-positive stem cells that in situ overlie the basement membrane in the olfactory epithelium were present in vitro as nests of keratin-positive cells. The receptor neurons, which normally comprise the majority of cells in olfactory epithelium, appeared in vitro as bloplar cells had partially developed olfactory vesicles on both poles, suggesting that these cells were maturing olfactory receptor neurons. Further immunofluorescent characterization is in progress. This study demonstrates that an in situ took insult of olfactory epithelium with ZnSO, can be used to produce an enriched population of bipolar neurons in vitro. Supported by

NEONATAL PERIPHERAL NERVE SECTION RESULTS IN A REARRANGEMENT OF THE CENTRAL TERMINALS OF ADJACENT AND SURVIVING AXOTOMIZED PRIMARY AFFERENTS IN ADULT RAT SPINAL CORD. P. Shortland, M. Fitzgerald & C.J. Woolf. (SPON: Brain Research Association). Dept. Anatomy & Neurobiology, St. Louis Univ. Sch. Med., St. Louis MO 63104; Dept. Anat. & Dev. Biol., Univ. Coll. London, London WC1E 6BT.

Neonatal peripheral nerve section results in the death of a substantial number of axotomized primary sensory neurons. In addition, adjacent intact peripheral nerve A and C fibres sprout into the denervated central terminal area (Fitzgerald, '85; Fitzgerald et al., '90). Here we examine the fate of the central terminals of axotomized and adjacent intact A-fibres in adult rats following day of birth sciatic nerve ligation and section. Bulk labelling of the sciatic (Sci N=7) or saphenous (Sa, N=6) nerve using B-HRP revealed alterations in the spinal cord somatotopic map. The intact Sa nerve territory expanded from mid L4 to sacral cord compared to the contralateral control Sa nerve. Labelling the axotomized Sci nerve revealed little change in the gross somatotopic organization of the A-fibres, although labelling was less intense overall compared to control nerves. However, invasion of substantia gelatinosa (SG) by axotomized Sci A-fibres was seen in segments L3-5 and a similar invasion of SG by intact Sa A-fibres was seen in L4-5. These reults demonstrate that (1) surviving axotomized Sci primary afferents generate a "normal" somatotopic map in the rostrocaudal plane; (2) surviving axotomized A-fibres sprout into SG; (3) intact Sa A-fibres sprout into SG as well as invading Sci territories; (4) considerable overlap between adjacent nerve territories occurs in the denervated area of the spinal cord. Supported by the MRC.

THE EARLY DEVELOPMENT OF ASCENDING SPINAL PATHWAYS IN THE BRAZILIAN OPOSSUM, Monodelphis domestica. Y.O. Oin, X.M. Wang, X.M. Xu\* and G.F. Martin. Dept. of Anatomy, The Ohio State Univ., Coll. of Med., Columbus, Ohio 43210.

Monodelphis, a marsupial, is born 14-15 days after copulation and is available for

Monodelphis, a marsupial, is born 14-15 days after copulation and is available for experimentation at stages corresponding to those which occur in utero in placental mammals. When injections of orthograde tracers were made into the caudal thoracic or lumbar cord prior to postnatal day (PD)3, few if any axons were labeled at supraspinal levels. By PD3, however, labeled axons were found adjacent to the nucleus gracilis, within the ventrolateral medulla and pons, and within the cerebellar anlage. Many of the axons forming the fasciculus gracilis arose from neurons within dorsal root ganglia as evidenced by the transganglionic transport of cholera toxin-HRP from the hindlimbs. By PD7, a few labeled axons had begun to penetrate the inferior olive. The subsequent growth of spinoolivary axons appeared to be restricted to subnuclei innervated at later stages of development and in the adult animal. It was not until PD16 that labeled axons within the cerebellum began to segregate into the longitudinal zones seen in the adult animal. (Supported by NS-25095 and 10165).

DISCREPANCIES BETWEEN THE MORPHOLOGICAL AND FUNCTIONAL REPRESENTATION OF THE SI FOREPAW MAP FOLLOWING DIGIT REMOVAL IN THE ADULT RAT. C.A. McCandlish\*, C.X. Li, and R.S. Waters. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, Col. of Medicine, Memphis, TN 38163.

The representation of the forepaw in SI cortex of adult rats contains an organization of cell aggregates, or barrels, corresponding to the dorsal and ventral surfaces of the contralateral forepaw. This forepaw barrel map undergoes a critical period of development (McCandlish and Waters, 1989) whereby removal of afferent input, prior to the critical period, disrupts the normal barrel pattern. After the critical period deafferentation produces no change in the barrel pattern. This report addresses the relationship between structure and function by examining the consequences of deafferentation on the electrophysiological and morphological representation of the forepaw barrel subfield in adult rat.

Adult rats having undergone amputation of the third digit (D3) were compared to normal controls. Five days after surgery, both groups were anesthetized with Nembutal (40 mg/kg ip), fixed to a headholder, and the parietal cortex was expos Carbon-fiber electrodes were used to record single/multiunit responses following mechanical stimulation of the contralateral forepaw. The cortex was systematically explored at 50-75 µm intervals. Receptive fields recorded at each penetration site were used to generate a physiological map of the forepaw. Lesions marked selected recording sites. Animals were sacrificed, hemispheres removed, flattened and sectioned tangentially, and processed using SDH and Nissl-stain. Our results are as follows

- Morphological maps of deafferents showed a normal forepaw barrel subfield.
- 2. Physiological maps of deafferents showed enlargement of D2 and D4 which expanded into the cortical barrel representation formally served by D3.

These results suggest a mismatch between structure and function in the deafferented adult forepaw barrel subfield. (Supported by NSF Grant BNS 88-02766)

INFLUENCE OF THE THALAMIC PROJECTION PATTERN ON BARREL FORMATION IN RAT SOMATOSENSORY CORTEX. M.Möck\*, I.Kehrer and J.Bolz, Friedrich-Miescher Labor der Max-Planck Gesellschaft, 7400 Tübingen,

In rodent somatosensory cortex the distribution of the contralateral mystacial vibrissae and sinus hairs is represented by groups of neurons in layer 4 that are called barrels. At the time of birth the cortex is still immature and the development of the barrels occurs during the following days. In rat they can be first visualized around postnatal day 3 (P3). It is not yet known which factors are responsible for the formation of the barrels. There is strong evidence that thalamocortical afferents play a crucial role in the barrel development, but other subcortical or cortical influences could also be important. In order to examine the factors required for barrel formation we prepared slice cultures from immature somatosensory cortex alone and slice cultures that in addition contained the ventrobasal (VB) thalamus. We used antisera against the  $\alpha_1$  subunit of the GABA-A receptor as a convenient tool to identify the presence of barrels *in vivo* and *in vitro*. In the somatosensory cortex *in* vivo there was no immunostaining at P0 and P1. Immunoreactivity was first detectable at P2 when the antibody labelled a homogeneous band throughout layer 4, and after P3 the staining became patchy and labelled the barrel hollows. When slices from somatosensory cortex (PO-P2) were cultured alone, after about 4 DIV oreactivity was visible as a continuous band in layer 4, but even after 10 DIV never showed the natchy distribution found in vivo. In contrast cultures from somatosensory cortex of the same age co-cultured with VB thalamus, after 4 or more DIV, often revealed a patchy pattern of immunoreactivity which was very similar to that observed in vivo. These results suggest that the innervation of axons from the VB thalamus is necessary and sufficient for the formation of barrel-like patterns in the somatosensory cortex. Supported in part by DFG.

# AN ACTIVITY-DEPENDENT COMPONENT OF PLASTICITY IN THE DEVELOPING RAT NEOCORTEX. B.L. Schlaggar\* and D.D.M. O'Leary. Molecular Neurobiology Lab., The Salk Institute. La Jolla, CA 92037.

The development of barrels in rat somatosensory cortex (S1) requires an intact periphery during the first postnatal week. Electrocautery of a row of vibrissae follicles during this critical period leads to fusion of the corresponding row of barrels, retraction of that row, and expansion of adjacent rows. These effects are most profound following neonatal cautery, attenuate thereafter, and are not evident after P5 (Woolsey & Wann 76; Belford & Killackey 80). Afferent activity is hypothesized to direct the normal formation of these patterns and to mediate developmental plasticity in S1, as has been demonstrated in visual cortex (V1) (Hubel & Wiesel 65; Stryker & Harris 86; Kleinschmidt et al 87). Yet, application at birth of the activity blocker, TTX, to either the infraorbital nerve (Henderson et al 92) or to S1 (Rhoades et al 92) does not disrupt normal barrel development. We have examined whether plasticity in S1 following peripheral manipulation is dependent upon cortical activity. In PO rats, Elvax (a vehicle suited for prolonged, controlled release of drug - prepared by G. Prusky & M. Constantine-Paton) loaded with either TTX or AP5 (specific antagonist of NMDA receptor) was placed over the right S1. Follicles of the left C-row were destroyed by cautery on either P0, 2, or 3. Row area, visualized with AChE histochemistry in tangential sections, was measured at P7-8, normalized for total barrelfield size, and compared with drug treated, non-lesioned pups and control treated (Elvax with .1 M PBS or L-AP5), lesioned pups. Regardless of the age at cautery, 40-60% of the territorial change is blocked with TTX or AP5. Activity-blockade also interferes with the fusion of Crow in pups lesioned on P2 or 3. Neither AP5 nor TTX disrupted barrel development in non-lesioned animals as determined with AChE. Our results indicate that cortical activity, perhaps mediated through the NMDA receptor, plays a critical role in the developmental plasticity of S1, as in V1. (NIH PO1 NS17763 & RO1 EY07025)

Cortical and Subcortical Components of Plasticity in Rat Barrel Cortex. K. Fox.\* Dept. Neuroscience, Brown University, Providence R.1.02912.

Rats were raised with a single D1 vibrissa from P0 to P60. This procedure causes an expansion of the D1 domain in the barrel cortex (Fox, (92) J. Neuroscience 12). To estimate the proportion of plasticity due to cortical changes versus a passive relay of subcortical changes, the D1 barrel was ablated at P60 with 2 to 3 lesions (15 - 25µA, 10s). This procedure abolishes the D1 representation in the cortex of normal animals and would be expected to do the same in uni-vibrissa animals if all the plasticity were of cortical origin. In control animals, the volume of D1 ablated was directly proportional to the loss of D1 responses in adjacent barrels, in close correspondence to previous reports (Armstrong-James et al. (91) J. Comp. Neurol. 202). Inputs from principal and adjacent intact barrels were unaffected. In uni-vibrissae animals, the same linear relation was found between lesion size and reduction of D1 representation, but the slope was steeper. D1 lesions caused a greater proportional reduction in D1 representation in uni-vibrissae animals than in controls. Cells were far less likely to respond to D1 if the lesion was interposed between the cell and the D1 barrel. This *masking effect* was studied further in univibrissa animals by leaving D1 intact, forming a wall of lesions between D1 and D2 and then recording in D2. This type of lesion was the most effective in abolishing D1 responses in the D2 barrel. However, cells in barrels surrounding D1 behind the wall of lesions exhibited the usual large D1 input. These experiments suggest that a large component of the plasticity induced by uni-vibrissae rearing is cortical in origin. Any subcortical plasticity that may occur does not appear to be transmitted to cortex under the conditions prevailing in these experiments. (NS-27759).

# TARGETING SPECIFICITY OF PRIMARY SENSORY THALAMOCORTICAL AXONS IN DEVELOPING RAT CORTEX. J.A. De Carlos\*, B.L. Schlaggar, and D.D.M. O'Leary. Molecular Neurobiology Laboratory, The Salk Institute, La Jolla CA 92037.

Thalamocortical afferents promote the differentiation of the developing neocortex into functionally and architecturally distinct areas. We have studied the degree of precision in the matching of axons from the primary sensory thalamic nuclei to their appropriate target regions in developing rat cortex. In adult rats, neurons in the ventrobasal (VB), dorsal lateral geniculate (dLG), and medial geniculate (MG) thalamic nuclei project to S1, V1 and A1, respectively. The fluorescent tracers, FB, DY, Dil, were injected into presumptive somatosensory (S1), visual (V1) and auditory (A1) regions of rats aged from E17, when thalamic axons are growing to their appropriate regions, to P7, well after thalamic axons have arborized in the cortical plate (E0 is day of insemination, P0 is the day of birth). At P7, the specificity of thalamocortical relationships is adult-like; injections into a primary sensory area did not label neurons in "inappropriate" sensory thalamic nuclei. However, at embryonic and neonatal ages, thalamic neurons can be retrogradely labeled from inappropriate cortical regions; although found in every case, these neurons are rare. This finding indicates that a very small proportion of VB, dLG and MG axons grow to inappropriate cortical regions. What is most striking, though, is the high degree of precision in the targeting of these primary sensory thalamic axons to appropriate cortical regions and their subsequent invasion of the cortical plate. The targeting specificity of thalamocortical axons suggests the operation of a highly effective marking system that matches thalamic axons with their appropriate cortical region, and is consistent with the crucial role of these axons in the differentiation of cortical areas. Support: NIH fellowship F05 TW04401 and grant EY07025.

NON-LINEAR CORTICAL FUNCTIONAL REPRESENTATION CHANGES FOLLOWING PARTIAL DEAFFERENTATION OF RAT FACIAL VIBRISSAE. D.M. Liu. D.A. Sirois, K.M. Gallo and P.J. Hand, Dept. Animal Biology, Sch. Vet. Med., and Mahoney Institute of Neurological Sciences Sch. Med., Univ. of Pennsylvania., Phila., PA. 19104.

Previous studies in this laboratory have shown the expansion of a deafferentation spared C3 vibrissa (SC3) representation in first somatosensory cortex (SI). Currently, an important issue in neocortical plasticity is whether cortical neuronal networks alone are sufficient for plasticity or whether subcortical components of a system contribute to the plasticity. In the present study, we investigate the interrelation of functional (metabolic) reorganization in the sical central vibrissa-trigeminal-SI cortical pathway using the 14C-2-deoxyglucose (2DG) method. Unliateral subtotal vibrissa deafferentation sparing C3 (SC3) was performed in Sprague-Dawley rats at postnatal day 2. Ninety days post-deafferentation, central functional representations and local glucose utilization rates (LCGU) produced by activation of SC3 and contralateral control C3 vibrissae (CC3) were compared. Preliminary results revea % increases of the central representation of the SC3 (as compared to CC3) in the trigeminal nuclear complex, ventrobasal thalamus, and SI cortex were 39.13  $\pm$  5.71, 193.26  $\pm$  32.53, and 388.30 ± 35.84 %, respectively. Conversely, the LCGU was attenuated (12.72%) in SI, but showed no significant changes in the above subcortical structures when compared to CC3. The present results demonstrate that chronic vibrissa deafferentation, sparing C3 vibrissa, produced a different magnitude of SC3 representation expansion at the different levels of the central vibrissa-trigeminal pathway. This results in a non-linear increment in SC3 SI cortical functional representation changes that suggest both an autonomous intracortical and a subcorticallydependent plasticity. Supported by NIH grant NS-22283.

PATTERNED SEROTONERGIC PROJECTIONS TO S1 ARE NOT DEPENDENT UPON CUES IN THE NEONATAL CORTEX. <u>C.A. Bennett-Clarke,\*M.H. Hankin and R.W. Rhoades.</u> Dept Anatomy, Medical College of Ohio, Toledo, OH.

In normal perinatal rats, serotonin-immunoreactive (5-HTIR) axons from the dorsal and median raphe nuclei form dense patterned terminal projections in sensory cortices that show a spatial correspondence with the terminal arbors of thalamocortical afferents (TCA). An important issue is how the patterned 5-HTIR projections are established. A previous study (Soc Neurosci Abstr 17:745) showed that there was not sufficient topography within the raphe nuclei to account for the establishment of patterned 5-HTIR. Alternatively, developing 5-HT axons may be influenced by cues residing within the developing cortex or by interactions between growing 5-HT axons and elements along the raphe-cortical pathway (e.g., TCAs or cues in the cortical subplate/developing white matter)

residing within the developing cortex of by interactions between growing 5-H1 axons and elements along the raphe-cortical pathway (e.g., TCAs or cues in the cortical subplate/developing white matter).

To address this issue, we transplanted fetal raphe tissue (E16-18 rat) to the superficial cortex adjacent and caudal to somatosensory cortices in P1 recipient rats. One day prior to transplantation, recipient pups were depleted of endogenous 5-HT by injections of the neurotoxin 5,7 DHT (either intracranial or subcutaneous), or by lesions of the ascending scrotonergic pathway (medial forebrain bundle). Control recipient animals received no lesion. Pups were killed at P7-8, cortices and brainstems were processed for 5-HT immunohistochemistry. Animals with a complete loss of patterned 5-HTIR in the cortex contralateral to the transplant were considered for further analysis.

Transplanted tissue usually contained numerous 5-HTIR cells which formed

Transplanted tissue usually contained numerous 5-HTIR cells which formed projections that extended as much as 2mm beyond the boundaries of the graft. Transplant-derived 5-HT projections clearly invaded adjacent \$1 cortex, but did not, in any case, form a patterned projection.

One explanation for these observations is that the cortex does not contain intrinsic cues that establish the formation of patterned projections of 5-HTIR cortical axons. Further studies will examine whether patterning cues for 5-HT axons are found at subcortical levels.

Mapping The Developing Rat Trigeminal Complex for Somatostatin and Calbindin D-28k.E.M.Mikota, C.Welt\* and S.C.Feldman. Depts. of Orthodontics, Neuroscience and Anatomy,Cell Biology &Injury Sciences. UMDNJ- New Jersey Dental School and New Jersey Medical School, Newark, N.J. 07103.

The trigeminal nuclei contain the neuropeptide somatostatin (SS) and the calcium binding protein Calbindin D-28K. In this study we examined the temporal and spatial changes in the distribution of these proteins at representative ages from embryonic day 15 (E15), the stage at which the trigeminal nuclei are clearly identifiable, to adulthood. Both SS and Calbindin D-28k were demonstrated using previously characterized antisera. SS was not seen at E15. but small numbers of immunoreactive neurons and fibers were present in all three nuclei at birth (day 0). Scattered Calbindin D-28k neurons and fibers were demonstrable in the nuclei at E15 and showed a marked increase at birth. On day 7 the pattern and density of SS- and Calbindin-containing neurons and fibers was not significantly different from that seen in adulthood. The developmental pattern of SS differs from that in cerebral cortex where SS is expressed in neurons which are morphologically immature and are possibly still migrating. However, Calbindin levels in the neocortex and cerebellum peak after migration is complete. The possibility must be entertained that the relationship between expression and neuronal maturity differs for different parts of the CNS.

TRIGEMINAL (V) PRIMARY AFFERENT STRUCTURE-FUNCTION RELATIONSHIPS AFTER DEAFFERENTATION OF RAT MOLAR PULP. B.J. Sessle\*, J.W. Hu and M.F. Jacquin. Faculty of Dentistry, University of Toronto, Ont. M5G 1G6, Canada; Dept. of Anatomy & Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104. Prior studies have documented changes in V brainstern neuron

properties 1-2 wks after molar pulpotomy in the adult rat (Hu et al Neurosci. Abst., 91) including increases in mechanoreceptive field size and the expression of inputs from more than one V division. To test the hypothesis that pulp deafferentation induces altered V primary afferent projections that account for these changes in V brainstem neurons, intraaxonal recording and HRP labeling methods were applied to 21 V primary afferents 10-14 days following pulpotomy of the 3 mandibular molars in adult rats and their collateral and terminal arborization patterns in subnucleus interpolaris were compared to functionally equivalent fibers in normal animals (Jacquin et al, J. Comp. Neurol., 88). All 21 fibers had A-beta conduction velocities and low-threshold mechanoreceptive fields restricted to a single whisker, or a small patch of hairy skin or guard hairs. They gave rise to arbors whose shapes were similar to those of comparable fibers in normal rats. Vibrissa afferents (N = 17) were subjected to quantitative analysis. Total numbers of their collaterals in deafferented rats (mean  $\pm$  SD: 7.4  $\pm$  1.3) did not differ from those in normals (8.2  $\pm$  1.7). Transverse arbor areas (5945  $\pm$  2215  $\mu$ m²) also did not differ from normals (6130  $\pm$  2060  $\mu$ m²). Preliminary data also failed to reveal changes in the total numbers of boutons/collateral Collaterals in, or bordering upon, mandibular regions also were indistinct from normal. These data suggest that spared A-beta primary afferents may maintain normal central morphologies in interpolaris 1-2 wks after mandibular pulp deafferentation. Supported by NIH Grant DE04786.

### 34.12

ORGANIZATION OF THE PROXIMAL SEGMENT OF THE INFRA-ORBITAL NERVE AT MULTIPLE INTERVALS AFTER AXOTOMY AT BIRTH: A QUANTITATIVE EM STUDY IN THE RAT. J.Z. Rana, J.P. Golden, J. Davis, W.E. Renehan\*, D.S. Zahm & M.F. Jacquin. Anatomy & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

Although much is known of the effects of infraorbital nerve (ION) section at birth, little is known about the short- and long-term effects of this lesion upon the ION itself. 19 newborn rats were subjected to left ION section and perfused 1, 2, 4, 7, 17 or 90 days later. Left IONs were removed proximal to the lesion and axon #, types and fasciculation patterns were assessed with EM methods. The axotomized ION contained 13,945  $\pm$  10,335, 14,112  $\pm$  $3,501, 16,531 \pm 1,904, 9,045 \pm 1,465, 7,018 \pm 4,212$  and  $8,672 \pm 1,030$ axons (mean + SD) at these respective ages. These values are below the 33,059 reported for the normal adult ION and the 42,219 reported for the newborn ION. At the above-listed ages there were unusually low %s of myelinated axons in the axotomized ION:  $8\pm2$ ,  $17\pm7$ ,  $8\pm5$ ,  $8\pm0$ ,  $18\pm5$ and  $27\pm6$ , respectively, vs. the  $60\pm6\%$  reported for the normal adult ION. The vast majority of the remaining fibers were unmyelinated, whereas degenerating myelinated axons never accounted for more than 2% of all axons. The # of fascicles in the axotomized ION ranged from 3-23 on day 1, 16-24 on day 7, and 11-20 on day 17. These values overlap with those from the newborn ION (5-15) and the normal adult ION (18-25). Thus, 1) extensive, though variable, axon loss occurs within 1 day of neonatal ION section, 2) the 74% fiber loss at 90 days is not achieved until 7 days after the lesion, 3) the preferential survival of unmyelinated axons may underly some CNS effects of this lesion, and 4) CNS pattern alterations induced by ION section do not reflect gross changes in ION fasciculation patterns. DE07734.

THE TIME COURSE OF FIBER OUTGROWTH IN GRAFTED HUMAN DOPAMINERGIC CELLS DOES NOT SEEM TO OBEY ESTABLISHED PRINCIPLES 11, López-Lozano\* and B. Brera Neurobiology Unit, Dept. of Neurology, and Exp. Surgery, Clínica Puerta de Hierro, 28035 Madrid, Spain

Parallel to our program of human ventral mesencephalon transplantation in parkinsonian patients begun in 1988, we undertook a series of experiments in which human fetal ventral mesencephalic tissue (HFVM) obtained on the same day and under the same conditions as that used for the clinical trials (Restor Neurol 1991;4) was implanted, in cellular suspension form (Brain Res 1989;86:351), into the denervated striatum of immunosuppressed rats (CyA, 10 mg/kg/ip). Our initial aim was to assess the tissue viability and analyze its in vivo behavior as an indirect way of determining the viability of the transplants done in humans. However, after histological and immunohistochemical processing of the tissue (TH and GFAP) and analysis of the results under an Olympus microscope interfaced to an IMCO-10 (Kontron)-MIP operating system (Micron), we observed that not only do the HFVM neurons survive transplantation (as had been reported by other authors), but they are capable of producing long processes (up to 300 µm in flat 40 µm sections) in less time than that reported to date (24 wk). This contradicts, in principle, earlier results showing that the time course of fiber outgrowth appeared to be slower for human fetal substantia nigra cells than for other similar animal cells, and leads to the hypothesis that, somehow, the HFVM neurons retain the capacity to govern their ontogenic development and maturation even when isolated from their natural environment. This finding suggests that the tissue management and/or the procedure for procuring the cellular suspension may be important factors in the behavior of the transplanted tissue, and that the environmental conditions (neural cultures or brain implants) may play a significant role in the morphological changes and in the time course of development observed in these cells. These findings merit further investigations.(Supported by CACYT 86/0461 and CO 29/91).

EFFECTS OF MPTP ON HUMAN NIGRAL TISSUE GRAFTED TO DOPAMINE DEPLETED RATS.

<u>I. Strömberg</u><sup>1\*</sup>, <u>P. Almqvist<sup>2</sup>, M. Bygdeman<sup>3</sup>, E. Sundström<sup>2</sup></u>
Departments of <sup>1</sup>Histology & Neurobiology, <sup>2</sup>Geriatrics, and <sup>3</sup>Obstetrics & Gynecology, Karolinska Institute, Stockholm, Sweden.

The neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) is known to cause Parkinson's disease in man. Human fetal tissue was examined for its sensitivity to MPTP. Human ventral mesencephalic tissue was grafted to the lateral ventricle of unilateral dopamine denervated immunosuppressed rats. Rotational behavior was monthly tested and when apomorphine induced rotations were reduced, subcutaneous injections of MPTP were performed. In two out of seven rats tested, the rotational pattern reappeared, and in the rest, apomorphine induced rotations stayed low. Histological evaluations of these two rats with increased turning behavior revealed surviving grafts using antibodies against human specific Thy-1. Few tyrosine hydroxylase-(TH) positive neurons were seen within the graft area, but no TH-positive nerve terminals could be detected in dorsal striatum. However, ventrally a TH-positive network was found. In rats that still had reduced rotational behavior after the MPTP-treatment, both TH-immunoreactive neurons within the grafts as well as a dense TH-positive network was found in dorsal striatum. When using antirat antibodies to detect extravasation of serum proteins, indicating a disturbance in the blood brain barrier, immunoreactivity was detected in parts of the grafts only in those animals with increased rotational behavior after MPTP-treatment. In conclusion, MPTP can affect human nigral tissue grafted to the immunosuppressed rats.

SHORT TERM CORTICOSTEROID TREATMENT IMPAIRS SURVIVAL OF FETAL DOPAMINE CELLS TRANSPLANTED INTO A RAT MODEL OF PARKINSON'S DISEASE. P. Patino\*, EH Kriek, CJ Hutt, JX Qi, and CR Freed. Univ. of Colo. Sch. Med., Denver, CO. In order to see if the antiinflammatory action of corticosteroids can help survival of fetal dopamine cells following transplant into dopamine depleted striatum, we have injected embryonic ventral mesencephalic tissue (ED OHDA lesions of the medial forebrain bundle. For 4 days after transplant, tapering doses of 30 to 15 mg/kg per day methylprednisolone were administered. Concurrent control animals were transplanted in the same fashion but did not receive steroid injections. expectations, animals which received methylprednisolone had lower quality transplants, both as assessed behaviorally with methamphetamine 5 mg/kg i.p. three months after transplant and as measured by tyrosine hydroxylase immunocytochemical staining of the transplant Using a histologic scale we have developed in = 1-10 TH positive cells per section and 5 = >which I=1-10 in positive certs per section and 0=7 150 cells per section, control animals had an average score of 4.17 + 0.24 while treated animals had 2.55 + 0.27. These data indicate that short term corticosteroid administration impairs transplant survival, possibly by reducing inflammation at the time of transplant.

### 35.5

MORPHOLOGICAL OBSERVATIONS OF FETAL DOPAMINERGIC CELLS TRANSPLANTED IN THE SINGLE DOPAMINERGIC OR COMBINED DOPAMINERGIC/SEROTONERGIC DENERVATED RAT STRIATUM. H.W.M. Steinbusch, F.L. van Muiswinkel, J.G.J.M. Bol. and J. De Vente Dept. Pharmacology, Faculty of Medicine, Free University, Amsterdam, The Netherlands

Dopaminergic denervation of the caudate putamen complex with 6-OHDA is often associated with an animal model for Parkinson's disease. However, from clinical studies it is known that the disease is not only affecting the dopaminergic system, but that also the serotonergic system is implicated. Due to this discrepancy between the clinical observations and the animal model we investigated the effects of the denervation of both the dopaminergic as well as the serotonergic system on the survival and outgrowth of fetal dopaminergic cells. On the basis of this study we hope to develop a more elaborate model which better reflects the actual state of this disease. Rats were divided into three groups. One group receives only an unilateral 6-OHDA lesion both in the medial forebrain bundle as well as in the vta. The second group receives a single unilateral 6-OHDA lesion in the vta and a combined unilateral mixture of 5,7-DHT and 6-OHDA in the medial forebrain bundle. The third group serves as control. After two weeks group one and two received an injection of a fetal dopaminergic cell suspension (E 15) in the denervated caudate-putamen. After 4 months survival all rats were perfused with paraformaldehyde or glutaraldehyde and processsed for tyrosine hydroxylase-, dopamine- and serotonin-immunohistochemistry. For morphological analysis we used an IBAS 2000 system in which we counted the total number of surviving dopaminergic cells and the total area of newly formed dopaminergic fibres. In both groups we observed a good cell survival and outgrowth of the implanted dopaminergic cells. Possible differences between the two groups will be discussed.

INCREASED DYNORPHIN LEVEL IN SNR AFTER L-DOPA TREATMENT IS NORMALIZED WITH FETAL DOPAMINERGIC GRAFT. E. Roy. P.-Y. Côté, L. Grégoire. D.P. Gaudin, A. Parent\* and P.J. Bédard Neurobiology Res. Center, Fac of Med., Laval Univ., Québec, CANADA

Recently, observations by Engber et al. (Brain Res. '91) show increased dynorphin levels in substantia nigra pars reticulata (SNR) on in the lesioned side following chronic intermittent treatment with L-DOPA in 6-hydroxydopamine (6-OHDA) -lesioned rats. The purpose of this study was to confirm whether or not a dopaminergic graft is able to reverse the increase in dynorphin observed with L-DOPA treatment. Female rats were lesioned with 6-OHDA, selected with apomorphine and amphetamine circling tests and distributed in 2 groups: half received a striatal fetal nigral graft. Half of each group was treated chronically with L-DOPA and benserazide. The other group received benserazide and saline and served as control. All brains were processed immunohistochemically to visualize dynorphin (DYN-IR) in the SNR. The results were analysed by computerized image-analysis system using grey scale. The SNR on the lesioned side was compared to that on the grey scale. The SINK on the lesioned side was compared to that on the unlesioned side. Among lesioned animals, only the levodopa-treated group showed increased DYN-IR on the lesioned side. This increase was abolished by the fetal nigral graft. These results confirm that a fetal nigral graft can correct not only the changes in neurotransmitters due to denervation but also those induced by L-DOPA treatment. [Supported by MRC and Canadian Network of Centres of Excellence]

EVIDENCE FOR HOST-DERIVED GLUTAMATE AFFERENT MODULATION OF INTRASTRIATALLY TRANSPLANTED DOPAMINE NEURONS. T. Kondoh\*and W.C. Low. Departments of Neurosurge Physiology, and Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN 55455.

Grafted dopamine neurons have been shown to form functional graft-to-host fiber connections when transplanted into the host striatum. The present study was designed to determine whether fibers from the host brain, in turn, can modulate graft-derived dopamine release. In normal animals glutamatergic afferents to the striatum from the cortex have been shown to regulate nigrostriatal dopamine neurotransmission via axo-axonic connections. We have used methods of in vivo microdialysis and electrochemical detection to determine whether similar regulatory mechanisms are established between host glutamatergic afferents and fibers from grafted dopamine neurons. Three groups of animals were studied: rats with unilateral 6-OHDA lesions of the nigrostriatal pathway; rats with unilateral 6-OHDA lesions and grafts of ventral mesencephalic dopamine neurons; and rats with intact nigrostriatal fiber systems. Extracellular dopamine levels in the striatum were determined in each group under basal conditions and following the administration of dihydrokainic acid (DKA), a glutamate uptake blocker. DKA administration in the perfusate (5 mM) resulted in a substantial elevation in dopamine release in normal animals, a modest elevation in animals with 6-OHDA lesions, and intermediate levels in animals with dopamine grafts. Analysis of variance revealed significant group effects [F(2,12)=46.52; p<0.05]. Post-hoc pair-wise comparisons further revealed that dopamine levels in the intact animals were greater than that of 6-OHDA and transplant animals (p < 0.05). Moreover, striatal dopamine levels in transplant animals were significantly greater than that of 6-OHDA animals (p < 0.05). These results suggest that glutamatergic afferents from the host brain are capable of regulating dopamine release by grafted mesencephalic neurons. (Supported by NIH RO1-NS-24464).

EFFECT OF CHRONIC LEVODOPA TREATMENT ON THE DEVELOPING NIGROSTRIATAL DOPAMINE SYSTEM. David M. Yurek' and John R. Sladek, Jr.<sup>2</sup> 'Univ. of Kentucky College of Med., Div. of Neurosurgery and Dept. of Anatomy & Neurobiology, Lexington, Kentucky 40536, and <sup>2</sup>Neuroscience Institute, UHS/Chicago Med. Sch., Chicago, Illinois 60064. Recent studies suggest that developing dopaminergic neurons may be adversely affected by chronic exposure to dopamine (DA) agonist treatment. For instance,

affected by chronic exposure to dopamine (DA) agonist treatment. For instance, neurite outgrowth of cultured embryonic DAergic neurons appears to be impaired when levodopa is added to culture media. A similar effect is also observed in the development of embryonic DAergic neurons that are grafted into the DA-denervated striatum of animals receiving chronic levodopa treatment. These findings suggest that levodopa treatment may be contraindicative in neural grafting studies that utilize embryonic DAergic neurons as a source of DA replacement therapy.

These studies were designed to examine what effect levodopa might exert on the development of immature DAergic neurons in the normally developing DAergic nigrostriatal pathway. At gestation day 10, pregnant female Sprague Dawley rats began either a chronic regimen of levodopa treatment or saline treatment and these treatments were continued until the day of parturition; tablets of Sinemet® (10:1 levodopa-carbidopa) were pulverized, suspended in 0.9% saline, and administered to the pregnant female rats at a dose of 50 mg/kg (s.c.) twice daily. Subsequently, rat pups exposed to levodopa treatment as fetuses continued to receive levodopa (50 mg/kg, j., twice daily) on day 2 and this treatment was maintained for a four week period. After four weeks of treatment these animals were sacrificed and brains were removed for morphological analysis. Both tyrosine hydroxylase immunocytochemical analysis and catecholamine histofluore-scent analyses were performed to examine and compare if there were any qualitative and/or quantitative differences between animals exposed to there were any qualitative and/or quantitative differences between animals exposed to chronic saline and those exposed to chronic levodopa. Preliminary TH ICC analysis indicates that exposure to chronic levodopa produces incongruent patterns of TH staining in the striatum and substantia nigra. These data will be presented with additional morphometric data and the results obtained from histoflourescent studies. This research was supported by the Univ. of Kentucky Med. College Research Fund.

FETAL DOPAMINERGIC MICROGRAFTS IMPLANTED INTO THE NEONATAL AND ADULT SUBSTANTIA NIGRA OF 6-OHDA LESIONED RATS. G. Nikkhah, M.G. Cunningham+, W.-M. Duan, K. Wictorin, A. Björklund\*. Dept. of Medical Cell Research, University of Lund, S-223 62 Lund, Sweden; +Dept. of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139,

Dopaminergic (DA) micrografts have been implanted homotopically into the substantia nigra in the developing and the mature CNS to investigate 1) the patterns of morphological integration; 2) spontaneous and drug induced behaviour; and 3) differences related to the state of development induced behaviour; and 3) differences related to the state of development and plasticity of the host. Postnatal-day-one (P1) animals recieved bilateral intraventricular injections of 6-OHDA (2x55µg), whereas in the adult rats the right ascending mesostriatal pathway was lesioned stereotactically with 6-OHDA (16µg). Using a glass capillary (OD 50 µm), 200nl deposits of E14 ventral mesencephalic cell suspension were grafted into the right substantia nigra (40-60.000 cells/rat) in P3 pups and adult rats. Different behaviours were tested in the neonatal hosts including expertances; stress and days induced relation and party acceptances. including spontaneous, stress and drug induced rotation and paw reaching, 3 and 6 weeks post grafting. In the adult recipients drug induced rotation and paw reaching was tested between 6 and 16 weeks post grafting. The brains were then processed for TH-immunohistochemistry. Our results indicate that intranigral DA micrografts can exert functional effects on behavioral deficits both in neonatal and adult 6-OHDA lesioned rats. The grafts were more efficiently integrated into the neonatal than in the adult hosts, and induced a wider spectrum of behavioral recovery. This suggests, that the dynamic influence of the developing brain may promote the anatomical and functional capacities of intranigral DA grafts.

DOES DISCONTINUATION OF CHRONIC LEVODOPA ADMINISTRATION IN A RAT MODEL OF PARKINSONISM ALLOW RECOVERY OF FUNCTION OF GRAFTED EMBRYONIC DOPAMINE NEURONS? K. Steece-Collier\*1, T.J. Collier<sup>1</sup>, F.S. Junn<sup>1</sup>, D.M. Yurek<sup>2</sup>, and J.R. Sladek, Jr.<sup>3</sup>; <sup>1</sup>Dept. of Neurobiol. & Anat, Univ. of Roch, Sch. of Med., Roch, NY 14642; <sup>2</sup>Dept. Neurosurg., Univ. of KY, Lexington, KY, 40536; <sup>3</sup>The Neurosci.Inst., Univ. Health Sci./Chgo Med. Sch., North Chicago, IL 60064.

We have been exploring the extent to which chronic levodopa therapy may interact with the beneficial effects of embryonic nerve cell grafts in rats with unilateral mingrostriatal lesions. We have previously shown that chronic levodopa (50 mg/kg, b.i.d.,i.p., for 6 weeks) impairs morphology (Steece-Collier et al., 1990, Exp, Neurol. 110:201), decreases effectiveness of grafted neurons to reverse dopamine (DA) agonist-induced rotational abnormalities which accompany unilateral lesions (Yurek tet al., 1991, Exp. Br. Res. 86:97), and reduces the ability of grafts to reverse striatal DA receptor changes (Steece-Collier et al., 1990, Soc. Neurosci. Abst. 275.11), We are currently examining whether discontinuation of drug treatment after an initial 6 week administration results in recovery of the aforementioned parameters. Preliminary data from amphetamine-induced rotational studies, again, confirm that a graft in the presence of levodopa is less effective in reversing rotations (14.0%). reduction from baseline, n=5) compared to grafts in saline injected controls (69.5% reduction) 6 weeks after transplantation. These same animals were then withdrawn from their respective injection paradigm for another 6 weeks and subsequently tested for response to amphetamine. Overall, there appeared to be functional recovery in the tor response to amphetamine. Overail, there appeared to be functional recovery in the levodopa treated animals (76.4% reduction). However, it should be mentioned that 2 of the 5 animals in this group showed no sign of recovery. Control animals retained approximately the same level of behavioral improvement compared to 6 weeks after grafting. Definitive conclusions regarding the reversibility of the detrimental effects of levodopa subsequent to withdrawal of drug therapy is pending completion of behavioral analysis. We are also examining histological and receptor parameters of these animals. Supported by United Parkinson Foundation.

INFLUENCE OF DONOR AGE ON SURVIVAL OF HUMAN EMBRYONIC NIGRAL GRAFTS T. B. Freeman\*, G. M. Nauert. P. R. Sanberg, D. W. Cahill, C. W. Olanow, J. H. Kordover.

Div. Neurosurgery, Univ. of S. Florida, College of Medicine, Tampa, Fl. 13606

The age of embryonic donors is critical for graft survival in animal models of parkinsonism. The optimal period for rodent graft harvesting occurs when the substantia nigra is undergoing its early development, but before the nigrostriatal pathway has developed. Transplants harvested after this period are axotomized in the process of graft preparation leading to markedly diminished graft viability. Solid rodent grafts have a slightly prolonged "window" for harvesting when compared to suspension grafts. We compared the ability of solid and suspension grafts of human embryonic dopaminergic neurons at different embryonic stages to survive grafting into 6-OHDA lesioned immunosuppressed rats. Suspension grafts survived best when donor age was between 14 and 56 postovulatory days. Implants displayed numerous healthy tyrosine hydroxylase immunoreactive (TH-TR) neurons which sent extensive neuritic processes into the host striatum. Suspension grafts survived poorly when donor age was greater than 65 days.

Solid implants of human ventral mesencephalic tissue displayed good-excellent survival of TH-TR neurons when donor rissue was older than 72 days.

These results demonstrate that the upper limit for survival of human embryonic dopaminergic suspension grafts correlates well with the period of development of the human nigrostriatal pathway. The "Window" for donor age of solid human embryonic dopaminergic grafts appears to be extended by about nine days in comparison to suspension grafts:

Many clinical protocols that use neural grafts in the treatment of Parkinson's disease use fetal donors that are older than 65 days. Our data suggests that these protocols are likely to result in transplantation of nonviable grafts. (Funded by a grant from UPF).

ALTERATIONS IN MORPHOLOGY AND ELECTROPHYSIOLOGY OF TRANSPLANTED NEOSTRIATAL NEURONS IN RATS: DOPAMINE AND TRANSPLANTED NEOSTRIATAL NEURONS IN RATS: DOPAMINE AND EXCITATORY AMINO ACIDS. E.A. Nansen, R. Cohen, Z. Radisavljevic, M.A. Ariano<sup>1</sup>, D.R. Sibley<sup>2</sup>, R.S. Fisher and M.S. Levine MRRC UCLA L.A. CA 90024, Neurosci. Inst. Chicago Med. Sch. N. Chicago IL 60064<sup>1</sup>, Mol. Pharmacol Unit ETB NINDS Bethesda MD 20892<sup>2</sup>.

Experiments were designed to assess the presence of dopamine (DA) D<sub>2</sub> receptors on transplanted neostriatal neurons (TSNs) and to determine the functional responses of TSNs to iontophoretic application of DA and excitatory amino acids (EAAs). Standard methods were used to transplant fetal neostriatal cells into the host neostriatum. Some TSNs were first incubated in the fluorescent dye, fast blue to distinguish transplant from host cells. After 12 months, fast blue-containing neurons were found in the transplant. Sections were immunostained with rabbit antisera raised against a 54-peptide sequence of the D2 DA receptor (PNAS, 1991, 88:1441-1445). Immunoreactivity was visualized in the neuropil and in cells of the transplant as well as the host. However, immunoreactivity was decreased in TSNs compared to the host neostriatum. Previous studies from our laboratory have demonstrated that TSNs become hyperresponsive to synaptic activation. In the present experiment standard brain slice techniques were used to assess the responses of TSNs to application of EAAs and DA. Both TSNs and host neostriatal cells were excited by application of glutamate (GLU) or N-methyl-d-aspartate (NMDA). Threshold currents to induce these responses were significantly lower in TSNs compared to host cells. DA attenuated responses evoked by GLU or NMDA in TSNs. However, while DA attenuated responses evoked by GLU it potentiated responses evoked by NMDA in host cells. Together, the morphology and electrophysiology provide evidence that TSNs display alterations in both DA and EAA systems. Supported by USPHS HD05958

QUANTITATIVE ANALYSIS AND SERIAL RECONSTRUCTION OF DOPAMINE NERVE CELL GRAFT'S FROM EARLY GESTATION FETAL. MONKEY BRAIN. J.R. Sladek, Jr. \*S.J. Cooper, P.E. Hawkins, T.J. Collier J.D. Elsworth J. R. Taylor<sup>2</sup>. R.H. Roth<sup>2</sup> and D.E. Redmond, Jr.<sup>2</sup> Neuroscience Institute and Department of Physiology & Biophysics, The Chicago Medical School, North Chicago, IL 60064; <sup>1</sup>Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642 and <sup>2</sup>Departments of Psychiatry and Pharmacology, Yale University School of Medicine,

We developed two approaches for more fully analyzing the geometry and 3-dimensional orientation of nerve cell grafts. We examined grafts from two early gestational stages placed into the head of the caudate nuclei in MPTP-treated monkeys. Animals were sacrificed three months after implantation of solid, ventral mesencephalic grafts. One animal received tissue from a 44 day donor; two others from a single 49 day donor. Tissues were stained for tyrosine hydroxylase and photographic impressions were scanned into a computer-operated microdensitometer where they were aligned, assembled, and edited for 3-dimensional reconstructions and rotations. The second approach allowed direct microscopic video input into a Macintosh Quadra interfaced with a Canon CLC color printer. Percentages were calculated from these digitized, outlined images of each graft and target. The animal that received the full complement of mesencephalic DA neurons contained large, well-circumscribed grafts with over 13,000 DA neurons in total. These six grafts respectively occupied on average 2.6, 7.3, 6.3, 6.4, 6.9, and 8.9 percent of the caudateas seen in two dimensions. At individual coronal levels, grafts occupied as much as 14.8 percent of the area of the caudate. An animal that received one-half of the mesencephalon from a 49 day old embryo had four grafts that could be measured. They averaged 2.5, 5.4, 5.0, and 2.4 percent of the caudate. DA cell numbers in this animal were on the order of 1,300 in total. The use of this technology aids correlations between graft size, number of surviving cells, and degree of improvement from MPTP-induced toxicity as a next step toward developing more optimal transplant procedures Supported by USPHS Grants PO1 NS 24032, BRSG RR-05366 and the Axion Research Foundation. TYROSINE HYDROXYLASE AND C-FOS IMMUNOREACTIVITY IN FETAL TISSUE TRANSPLANTS FOLLOWING TREATMENT WITH D-AMPHETAMINE. Mantana K. Norman', Sunny Y. Lu, Jennifer M. Klug, S. Murthy Ammisetti, Robert B. Norgren and Andrew B. Norman. Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267

Transplanted fetal striatal tissue survives and grows within the adult host striatum and can be innervated by host dopaminergic afferents. It has been suggested that such afferent connections are functional in nature and may mediate the reversal of lesion-induced behavioral deficits. The expression of the immediate-early response gene c-fos in striatal neurons is stimulated by dopamine released from presynaptic terminals by psychomotor stimulants such as d-amphetamine. The expression of the fos protein can act as a neurochemical marker of functional postsynaptic activation. We investigated the relationship between tyrosine hydroxylase (T-OH) immunoreactive fibers and for immunoreactive cells in fetal tissue transplants. Male Sprague-Dawley rats received unilateral or bilateral intrastriatal transplants of fetal (E 15-17) rat striatum or fetal rat cortex into unlesioned striatum. Five weeks after transplantation, rats were administered d-amphetamine (5 mg/kg i.p.) and perfused three hours later. Individual brain sections were double-labeled for fos and T-OH immunoreactivity using DAB and indophane blue, respectively as chromogens. There was no specific concordance between the fos immunoreactive cells and T-OH containing fibers in either the striatal or cortical transplants. These data may suggest a lack of functional connectivity between T-OH immunoreactive fibers and transplant neurons with respect to the expression of c-fos at five weeks post-transplant. REDUCTION OF MOTOR IMPAIRMENT BY ADRENAL MEDULLARY TRANSPLANTS (AMT) IN AGED RATS. F. García-Hernández M.T. Pacheco-Cano and R. Drucker-Colín. Postal 70-600, México, D.F.

We have reported that L-DOPA and D-Amphetamine

substantially improve the motor performance of aged rats in the inclined beam test (IBT). Here we report the effect of AMT upon the motor performance of aged rats in the IBT. Twenty male Wistar rats, mean age 25.6  $\pm$  0.9 months were used. Rats were grafted with 300,000 cultured fetal chromaffin cells, placed into the head of the left caudate nucleus (Group A) or into both caudates (Group B). Group C was grafted with one fresh fetal adrenal medulla as a block into the lateral ventricle. Group D sustained sham grafting. Rats were evaluated for 3 months after grafting. Our results show that cultured AMT and sham grafts had no effect upon the motor deficits of aged rats. Only the block grafted group showed a significant recovery of motor impairment. Cultured cell grafts had poor survival rates with few chromaffine cells. Block AMT showed abundant chromaffine cells with round and neuron like shapes. Results suggest that fresh AMT reduce the motor impairment of aged rats for as long as 84 days. Cultured cell grafts may not induce recovery at least in the aging brain, maybe do to an unfavorable environment.

EXPRESSION OF MAJOR HISTOCOMPATIBILITY COMPLEX LAND IL IN BOVINE CHROMAFFIN CELL GRAFTS INTO RAT MIDBRAIN. G.J. Rice, R.P. Becker, J. Sagen, and G.D. Pappas\*. Department of Anatomy and Cell Blology, University of Illinois at Chicago, Chicago, IL 60612.

Rats received isolated bovine chromaffin cells into periaqueductal gray (PAG), with or without daily i.p. injections of cyclosporin A (CsA). Rat CNS and lymph nodes were fixed with 4% formaldehyde, cryosectioned at  $0.5\mu m$ and treated with monoclonal antibodies (MoAb) against rat MHC I or MHC II. Donkey anti-mouse F(ab'), conjugated to Texas red was used as a secondary antibody for fluorescent light microscopy. For negative controls, the primary MoAb was replaced by non-specific mouse IgG. Lymph node, in which all nucleated cells express MHC I, and in which B cells, macrophages and dendritic cells express MHC II, was used for positive controls.

Normal rat PAG and sham-operated PAG with CsA showed neither MHC I, nor MHC II expression. Eight week transplants of chromaffin cells to PAG without CsA contained few chromaffin cells. In these grafts, MHC I was found associated with endothelial cells, while cells, presumed to be infiltrating leukocytes and/or resident glia, showed staining for both MHC I and MHC II. In contrast, eight week transplants to PAG in rats with CsA contained numerous chromaffin cells, with MHC I staining similar to that of grafts without CsA. In

these grafts, however, no MHC II expression was found.

These results show that MHC expression in xenografts of bovine chromaffin cells to PAG, either with or without CsA, is induced by the donor tissue; sham injections do not produce expression of MHC. In CsA animals, MHC II is absent and transplants are robust. In animals without CsA, both classes of MHC are found in the grafts, and chromaffin cells are largely absent. These results suggest that xenograft survival depends, at least in part, on suppression of MHC II expression. (Supported in part by NS25045 and NS28931)

COMPARISON OF BOVINE ADRENAL MEDULLARY GRAFTS AND ISOLATED CHROMAFFIN CELL IMPLANTS IN RATS AND HEMIPARKINSONIAN MONKEYS. S.B. Schueler\*, I.D. Ortega, I. Sagen, and I.H. Kordower<sup>1</sup>, Dept. Anat. & Cell Biol. Univ. of Illinois Sch. Med., I Department of Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago, IL 60612 USA.

Our present study compared the survival of intrastriatal implants of

whole bovine adrenal medullary suspension with isolated adrenal chromaffin cell suspensions, and isolated adrenal chromaffin cells suspensions recombined with their supporting cells (endothelial cells and fibroblasts). Immunosuppressed rats receiving intrastriatal isolated chromaffin cell suspensions displayed robust grafts containing numerous healthy-appearing tyrosine hydroxylase (TH)- and dopamine-B-hydroxylase (DBH)-immunoreactive chomaffin cells. In contrast, smaller, more necrotic grafts with TH and DBH immunoreactivity were seen in animals receiving whole bovine adrenal medullary suspensions. Interestingly, no surviving chromaffin cells were seen in rats receiving isolated chromaffin cells recombined with adrenal medullary support cells (endothelial cells and fibroblasts). However, rats receiving these latter implants displayed dense TH-immunoreactive fibers in surrounding the graft. Isolated bovine chromaffin cell suspensions were also intrastriatally transplanted into immunosuppressed, hemiparkinsonian Rhesus monkeys. Robust survival of TH- and DBHimmunoreactive xenografts were observed which is in contrast to the poor survival seen previously with whole adrenal medullary autografts. This data suggests that adrenal medullary supporting cells may compromise the chromaffin cell survival. (Supported by the UPF)

THE DIFFERENTIAL RESPONSIVENESS OF CULTURED VS. GRAFTED BOVINE CHROMAFFIN CELLS TO TROPHIC SUBSTANCES. J.D. Orlega\*, J. Sagen, and G.D. Pappas. Dept. of Anat. and Cel Biol., Univ. of II at Chicago, Chicago, II 60612.

Sagen, and G.D. Pappas. Dept. of Anat. and Cel Biol., Univ. of il at Chicago, Chicago, Il 60612.

Previous work in our laboratory has demonstrated the long term survival of bovine chromaffin cells grafted into the CNS parenchyma of adult rats. Our studies reveal that bovine chromaffin cell xenograft survival is not compromised by the placement of these grafts into CNS regions lacking in NGF content. In contrast, studies in other laboratories suggest enhanced survival of chromaffin cells in adrenal medullary tissue transplanted in rat CNS by either the cografting of NGF-producing cells or by the continuous infusion of exogenous NGF. In addition, it has also been reported that these grafted chromaffin cells respond to trophic factor supplementation by sprouting processes into the host parenchyma. The purpose of this study was to determine whether exogenous trophic factors could enhance the survival and differentiation of isolated bovine chromaffin cells. Studies on cultured bovine chromaffin cells revealed that a complex combination of factors may lead to enhanced survival and process formation in vitro. For example, while cells maintained in serum-free media with no added trophic factors, or with NGF or bFGF alone did not survive well or sprout processes, the combined addition of NGF and bFGF, or pieces of sciatic nerve markedly increased both chromaffin cell survival and process formation. In contrast, chromaffin cell survival and sprouting did not appear to be enhanced in the CNS grafts. These results suggest that the survival of chromaffin cells in culture is dependent on one or more serum factors and that process outgrowth from cultured cells may be dependent on the combined effects of these serum factors with other growth factors. Furthermore, grafted cells survive transplantation without exogenous trophic factors suggesting that endogenous host factors exist that enhance graft survival. In contrast, it does not appear that the appropriate factors or combination of factors for the promotion of process outgr

NEURONAL TRANSFORMATION OF CHROMAFFIN CELLS BY CO-CULTURE WITH PURIFIED SCHWANN CELLS. C. Paramore, S. Meadows\*, R. D. Madison, and D. A. Turner. Neurosurgery and Neurobiology, Duke Univ. Med.

Ctr., and VA Medical Center, Durham, NC 27710.

Transplantation of adrenal chromaffin cells into the striatum has been proposed as a treatment of Parkinson's disease. Recent experiments have focused on co-grafting chromaffin cells with peripheral nerve, thus providing trophic factors to support the graft. The co-culture of chromaffin cells with cultured, activated Schwann cells may generate phenotypically neuronal chromaffin cells which can survive transplantation and integrate better than standard peripheral nerve co-grafts

We have tested the hypothesis that purified Schwann cells can rapidly induce chromaffin cells to assume a neuronal phenotype. Neonatal rat chromaffin cells were co-cultured with purified rat Schwann cells. Chromaffin cells were observed to accumulate in clumps on Schwann cells and to extend processes within one week. This effect was much more pronounced than that seen with chromaffin cells cultured solely with 100 ng/ml NGF. Schwann cell-conditioned medium was as effective as NGF in eliciting neurite outgrowth from chromaffin cells. However, these Schwann cell-mediated effects were not blocked by antibodies to NGF. Chromaffin cells co-cultured with dissociated peripheral nerve did not clump or extend neurites. We have demonstrated that purified Schwann cells are able to profoundly influence chromaffin cells to aggregate and differentiate into a neuronal phenotype in vitro. This effect is dependent on both soluble factors produced by Schwann cells and on direct contact between cells. We conclude that chromaffin cells may be easily induced to assume a neuronal phenotype in the presence of purified Schwann cells. Striatal grafts of these co-cultures may prove superior to currently utilized techniques of adrenal medulla transplantation in Parkinson's disease.

RESTORATON OF STRIATAL PRE- AND POSTSYNAPTIC SYMMETRY FOLLOWING ADRENAL MEDULLA GRAFTS. E.J. Curran\* and J.B. Becker. Neuroscience Program and Psychology

Department, The University of Michigan, Ann Arbor MI 48109.
Intraventricular adrenal medulla grafts differentially effected the rotational behaviors induced by amphetamine and apomorphine in rats with unilateral lesions of the nigrostriatal dopamine pathway. Some animals showed a graft-induced decrease in the behavioral response to both amphetamine and Induced decrease in the behavioral response to both amphetamine and apomorphine, whereas other animals had a graft-induced decrease only in the response to amphetamine or apomorphine. Bilateral *in vivo* microdialysis experiments revealed that animals with a graft-induced decrease in the behavioral response to amphetamine (AMPH RECOV) expressed an increased symmetry in presynaptic dopamine activity between the two striata. This enhanced presynaptic symmetry was not observed in animals that had a decrease exclusively in the behavioral response to apomorphine (APO RECOV). Examination of postsynaptic D1 and D2 dopamine receptor binding densities with in vitro autoradiography revealed a significant increase in D2 receptor binding within the dopamine denervated striatum whereas no in D2 receptor binding within the dopamine denervated striatum whereas no lesion effect was observed in D1 receptor binding density. AMPH RECOV animals had a decrease in D2 receptor binding density within the denervated striatum; this effect was most prevalent within the dorsomedial quadrant of the denervated striatum. A slight but significantly smaller decrease in D2 receptor binding was observed in APO RECOV animals. It is concluded that more than one mechanism is promoting the behavioral effects of intraventricular adrenal medulla grafts. AMPH RECOV is associated with increased presynaptic dopamine function and a decrease in postsynaptic D2 dopamine receptor up-regulation. APO RECOV animals do not, however, exhibit increased symmetry in the pre or postsynaptic dopamine measures; indicating that different mechanism(s) may be involved in APO RECOV. (NS22157)

ENCAPSULATED CHROMAFFIN CELLS ISOLATED FROM BOTH MPTP-LESIONED AND UNLESIONED PRIMATES AMELIORATES A RAT EXPERIMENTAL PARKINSON MODEL. S.A. Tan\*, B.A. Zielinski, S.R. Winn, P.A. Tresco, P. Aebischer. Brown University, Providence, RI 02912

Adrenal chromaffin cell autographs implanted in patients afflicted with Parkinson's disease have been shown to only mildly ameliorate motor deficits. Low Dopamine (DA) content of the adrenals of parkinsonian patients may explain the paucity of improvement. Monkey adrenal chromaffin (MAC) cells isolated from animals rendered parkinsonian by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) and from unlesioned primates were selected to study the potential harmful effect of MPTP on chromaffin tissue. Following isolation of the adrenal tissue, the chromaffin cells were encapsulated in an anionic and a cationic polyelectrolyte respectively. HPLC analysis of capsules maintained in vitro revealed release of epinephrine and norepinephrine in tissue isolated from both lesioned and unlesioned animals. Dopamine release, however, was undetectable from both types of isolations and encapsulations. Anionic polyelectrolyte-encapsulated MAC cells were evaluated in the unilateral 6-OHDA lesioned rat model and were shown to reduce appomphine-induced rotational asymmetry by 40% as compared to empty capsules. DBH and PNMT immunopositive cells were found in animals exhibiting a rotation reduction. MAC cells isolated from MPTP-lesioned and unlesioned primates release comparable levels of catecholamines. Dopamine release, however, is undetectable. The improvement of rotation asymmetry suggests an alternative mechanism of action in the amelioration of rat experimental parkinsonism.

FUNCTIONAL RECOVERY IN HEMIPARKINSONIAN PRIMATES TRANSPLANTED WITH POLYMER ENCAPSULATED CELLS M. Goddard, A. P. Signore, Roxanne L. Timpson, P. Aebischer\*, Section of Artificial Organs, Biomaterials, and Cellular Technology, Brown University, Providence, R.I. U.S.A. 02912

Brown University, Providence, R.I. U.S.A. (2912)

Neural grafting using cellular xenografts which are protected from immune rejection by permselective membrane capsules provides an unlimited potential source of neuroactive substances for the treatment of degenerative neurologic diseases. The therapeutic potential of this approach was evaluated in a non-human primate model of Parkinson's disease. Eight macaca fascicularis monkeys exhibited a contralateral, Parkinson-like movement disorder following unilateral intra-carotid injection of MPTP. In order to allow quantitative behavioral assessment of the lesion before and after neural grafting, primates were chaired and trained to pick food rewards from multiwell plates prior to MPTP lesioning. The functional deficit was evaluated daily by measuring the time required for each upper limb to independently empty trays loaded with food treats. All animals showed significant unilateral impairment of their ability to pick food from the tray following MPTP injection. PC12 cells, a dopaminergic cell line, were encapsulated and transplanted into the striatum of 5 hemiparkinson monkeys. Four out of 5 of these animals showed a significant behavioral improvement. Tyrosine hydroxylase positive, encapsulated PC12 cells were observed in the lesioned striatum for up to 5 months post-implantation. The three remaining monkeys were implanted with either encapsulated bovine chromaffin cells or empty polymer envelopes and showed no amelioration of their behavioral deficit. These results suggest that the delivery of dopamine through cell encapsulation technology represents a promising avenue for the treatment of Parkinson's disease.

ENHANCED CATECHOLAMINE OUTPUT FROM ENCAPSULATED CHROMAFFIN CELLS IN LESIONED VS. NON-LESIONED RAT STRIATUM.S.R. Winn\*, A.M. Bertino, P.E. McDermott, M.P. Lavoie, I. Marszalkowski, P.M. Krueger, T.R. Flanagan, and D.F. Emerich, CytoTherapeutics, Inc. 2 Richmond Square, Providence, RI 02906

Polymer-encapsulation provides an immunoisolatory retrieval system

Polymer-encapsulation provides an immunoisolatory retrieval system to evaluate the influence that site-specific and/or lesion effects may have on transplanted cells in the CNS. The present study analyzed the catecholamine release profile of encapsulated bovine adrenal chromatfin (BAC) cells prior to and following a 6 week implantation period in lesioned vs. non-lesioned rat striatum. Rat striatum was lesioned with either 20 nm of 6-OHDA in ascorbate, or 225 nm quinolinic acid in PBS. Controls were injected with vehicle alone. Three weeks after the striatal injections, the 6-OHDA (n=6) and quinolinic acid (n=6) animals were bilaterally implanted with 5 mm long tubular polymer capsules containing BAC cells. The capsules were pre-qualified and matched according to basal, 20 μM nicotine-evoked, and 56 mM potassium-evoked release of norepinephrine (NE) and epinephrine (EPI). Six weeks after implantation the capsules were retrieved, placed in PBS, and re-assayed. In contrast to pre-implant values, the retrieved capsules, irrespective of striatal treatment, released proportionally more NE and EPI than their *in vitro* counterparts. Furthermore, capsules retrieved from lesioned striatum revealed at least a 10 and 5 fold increase in the output of nicotine-evoked NE and EPI, respectively, when compared with their *in vivo* controls. These results suggest that the lesioned conditions provide an environment that enhances BAC cell survival and/or functionality as assessed by an apparent up-regulation of nicotinic receptors.

INTRASTRIATAL DELIVERY OF NERVE GROWTH FACTOR WITH BIODEGRADABLE MICROSPHERES. A. Mendez, P. Camarata. G. Friehs\*, K. Abtin, T. J. Ebner. Depts. of Neurosurgery and Physiology, Univ. of Minnesota, Minneapolis, MN 55455, Univ. of Graz, Austria. The survival and behavioral effect of adrenal medulla (AM) grafts in the

The survival and behavioral effect of adrenal medulla (AM) grafts in the striatum improve with the prolonged, local administration of NGF. We have developed biodegradable, biocompatible polymeric microspheres for the sustained delivery of NGF. Microspheres (3-25 µm diameter) were prepared with Poly(L-Lactide)-Co-Glycolide 70:30, according to Ogawa's method, with 0.025% (w/w) NGF (mouse 7S, Sigma). In vitro release was detected up to 5 weeks using enzyme-linked immunosorbent assay. NGF biological activity was preserved throughout this period as demonstrated by the chick embryo dorsal root ganglion assay, which was blocked with rabbit anti-2.5S NGF. The in vivo release was shown with immunohistochemical detection of NGF inside and surrounding microspheres implanted in the cat striatum. The effect of these microspheres on the behavioral recovery after stereotaxic AM grafts in 6-OH-dopamine lesioned male Sprague-Dawley rats is currently being studied. In our preliminary experiment three groups of 4 rats each received either 1) AM fragments, 2) AM with 5 mg of NGF microspheres or 3) 5 mg of microspheres solely. Followed for 5 months, significant (p < 0.01) reduction of apomorphine (0.1 mg/kg SQ) induced rotations compared to the preoperative performance was observed only in the first two groups, although NGF microspheres did not increase the magnitude of this reduction. Although this initial result is possibly due to the low concentration of NGF used, the results show that growth factors can be delivered with this approach. Supported by the United Parkinson Foundation and the American College of Surgeons.

IMMUNOCYTOCHEMICAL ANALYSIS OF PC12 CELL IMPLANTS INTO RODENT AND MONKEY STRIATUM. <u>B.R.Frydel\* P.E. McDermott.</u> M.J.Donegan, P.M.Krueger, F.A.Kaplan, M.Goddard, A.Signore, D.F.Emerich. CytoTherapeutics, Inc. Providence, RI 02906 PC12 cells encapsulated within polymeric membranes have been reported to survive

PC12 cells encapsulated within polymeric membranes have been reported to survive in xenogeneic hosts for extended periods of time and alleviate the behavioral deficits in both rodent and primate models of Parkinson's disease (PD) (Aebischer et al.Exp. Neurol 111:269, 1991). The safety of this approach in treating human disease depends on the rejection of xenogeneic PC12 cells in discordant hosts. The present study evaluated the survival of unencapsulated PC12 cells following transplantation in allo- and xenogenic recipients. Using methods described previously (Frydel et al. Soc. Neurosci. Abst. 17:569,1991) we injected PC12 cells at a concentration of 106 cells/4u1 of PBS into rodent striata (Sprague-Dawley rats and Hartley guinea pigs), and 106 cells/50u1 into 4 different sites of cynomolgus monkey putamen and caudate. Rodents were sacrificed at 1, 2, 4, 12 and 24 weeks, and monkeys at 12 and 24 weeks after injections. All animal brains were processed and stained for tyrosine hydroxylase, glial fibrillary acidic protein, a cell surface marker for PC12 cells (Thy1.1), Nissl substance, and hematoxylin and cosin. All rats showed surviving PC12 cells 1 week after injection and about half developed tumors by two weeks. Guinea pigs with PC12 cell implants showed surviving PC12 cells 1 week after the surgery, but beyond this time point only glial scars with scattered moreophages and no surviving PC12 cells were observed. In monkey brains, after 12 and 24 weeks, all four injection tracks were visible because of residual scarring. Histological analysis demonstrated macrophages, glial cells, and scattered to occasional eosinophils. No traces of PC12 cells were detected. These data indicate that PC12 cells do not survive unencapsulated in a xenogenic host, suggesting that the use of encapsulated PC12 cells and safe approach for treating human diseases such as PD.

ENCAPSULATED PC12 CELLS PROMOTE RECOVERY OF MOTOR COORDINATION AND BALANCE IN AGED RATS. <u>D.F. Emerich.\* 1 B. Frydel. 1 P.E. McDermott. 1 P. M. Krueger. 1 M.P. Lavoie. 1 P.R. Sanberg² and S.R. Winn 1. CytoTherapeutics Inc., 2 Richmond Square, Providence, RI 02906. 1 Div. of Neurological Surgery, Univ. of South Florida Coll. of Med., Tampa, FL 33612. 2 Aged rats exhibit disturbances in balance and coordinated movement together with a</u>

Aged rats exhibit disturbances in balance and coordinated movement together with a generalized decrease in locomotion. Previous studies have demonstrated that these agerelated deficits may be partially corrected by the systemic administration of dopaminerpic agonists or implantation of dopamine-rich nigral grafts into the striatum. The following studies evaluated the ability of encapsulated dopamine-rich PC12 cells to reduce the motor deficits in aged rats. Prior to surgery, aged (24 months) and young (6 months) rats were tested on a battery of tests to evaluate locomotion, strength, coordination and balance. Relative to young animals, the aged animals were: (1) hypoactive; (2) remained suspended from a horizontal wire for less time; (3) were unable to descend a wooden pole covered with wire mesh in a coordinated manner; (4) fell more rapidly from a rotating rod and (5) were unable to maintain their balance on wooden beams of varying widths. PC12 cell-loaded capsules were sectioned into 4 mm lengths and cultured in vitro to establish a basal level of dopamine release using HPLC. Following testing, the aged animals were randomly divided into one of three experimental groups (N=6-8/group) and received either no implant, empty capsule implants or PC12 cell-loaded implants. All implants were bilateral into the striatum and animals were retested three weeks following surgery. Following implantation of encapsulated PC12 cells, animals exhibited a significant (p < 0.05) amelioration of coordination and balance when tested on the rotating rod and wooden beams. No recovery was observed on the other behavioral tests and no effects were observed in any of the animals receiving empty capsule implants. Immunocytochemical analysis revealed the presence of numerous tyrosine hydroxylase-positive PC12 cells within the implantated envortamsmitter-secreting cells may provide a useful treatment for age-related human degenerative diseases.

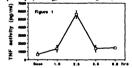

EFFECT OF ARGININE ANALOGUES ON INDUCIBLE NITRIC OXIDE SYNTHASE ACTIVITY OF RAT ASTROCYTES. S.F. Roberts\*, E. Galea, D.J. Reis and D.L. Feinstein. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

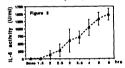

Primary astrocyte cultures express a Ca<sup>2+</sup>-independent NOS in response to treatment with lipopolysaccharide (LPS) (Galea et al., Soc. Neurosci. Abstr., 1992). We examined the subcellular distribution and effects of inhibitors of the induced enzyme. Astrocyte cultures were prepared from neonatal rat cortex, exposed to LPS (600ng/ml for 24 hr), harvested, and NOS activity was determined by the conversion of <sup>14</sup>C-L-arginine to <sup>14</sup>C-L-citrulline. Both the cytosolic and membrane fractions contained NOS of similar specific activity, but the total activity recovered for the membrane-associated form was less than 50% of that recovered for the soluble enzyme. The apparent  $K_m$  and  $V_{me}$ values obtained for membrane astrocyte NOS were 15.3 µM and 93.2 pmol min 1mg 1, respectively, and were comparable to those of the soluble enzyme The arginine analogs  $N^{c}$ -methyl-L-arginine (NMA),  $N^{c}$ -amino-L-arginine (NAA) and  $N^{c}$ -nitro-L-arginine (NNA) inhibited the soluble astrocyte NOS with comparable potencies, with NAA giving the lowest IC $_{50}$  (11.7  $\mu$ M in the presence of 20  $\mu$ M L-arginine). The IC $_{50}$ S obtained for NNA and NAA inhibition of the membrane astrocyte NOS were nearly identical to their respective values for soluble astrocyte NOS, but NMA exibited a lower IC<sub>50</sub> with the membrane NOS (3.1  $\mu$ M compared to 12.8  $\mu$ M with the soluble enzyme). When assayed under the same conditions, NNA was a much more potent inhibitor of the constitutive, Ca2+-dependent NOS from bovine cerebellum (IC<sub>50</sub> 0.95 μM). We conclude that (a) inducible astrocyte NOS is distributed into both membrane and soluble fractions; and (b) the induced astrocyte NOS enzymes show an inhibition pattern that closely resembles that of the macrophage inducible NOS and is distinct from the brain constitutive type.

HUMAN ASTROCYTE CYTOKINE PRODUCTION IN RESPONSE TO ENDOTOXIN. S.Sharif, I.B.G. Chajar, R. Wang and R.J. Hariri, Aitken Neuro-surgery Laboratory, Cornell University Medical College, New York, N.Y. 10021

Recent evidence indicates that astrocytes perform various functions essential to homeostasis in the CNS. A relatively new role ascribed to these cells involves homeostasis in the CNS. A relatively new role ascribed to these cells involves immunocompentency, suggesting that astrocytes function in a similar fashion to macrophages. We recently reported that human astrocyte cultures generate leukotrienes in response to mechanical injury, and exposure to LPS (Shepard, etal 1991). We sought to determine whether the response of human astrocytes in culture to LPS included cytokine production characteristic of intracranial inflammation. Human astrocyte cultures were established from normal human brain surgical specimens (Harriri, etal, 1980). 1989). Primary through tertiary confluent cultures were exposed to 0.5 lg/ml LPS (E coli 0127:B9, Difco Labs, Detroit, Mich) and serial supernatant collections were mads Studies were performed in 4 cell lines run in duplicate. Levels of TNF-a were determined by a cytotoxicity assay (WEHI-164 clone fibrosarcoma cell line) (Espevik determined by a cytotoxicity assay (W.F.H.1-194 clone intotactoms cell line) (Espetial et al., 1986). IL-6 bioactivity was determined using IL-6 dependent B cell hybridoma B9 as previously described (Aardon et al., 1987). Il-1b activity was measured by an enzyme linked immunoassay (Cayman Chemical, Mich.) We observed an increase in TNF-a as early as 1 hr after exposure which peaked by 2.5 hrs and declined by 8 hrs (figure 1). IL-6 activity was detectable 2 hrs after exposure to LPS and continuously rose thoughout the 8 hr experimental period.(Figure 2) IL-1b activity was detectable 4 to 24 hrs after LPS exposure. These data suggest that human astrocyte production of immunoregulatory molecules following exposure to LPS may play a role in the pathophysiology of neurologic dysfunction associated with the sepsis syndrome.

ROLE OF EXTRACELLULAR CARBONIC ANHYDRASE IN CNS. M. Chesler\* & ICT Chen. Dept. of Neurosurg. & Dept. of Physiology & Biophys., NYU Med. Ctr., 550 First Ave., NY, NY 10016.

In brain, carbonic anhydrase (CA) is localized mainly within glia (1), yet, its inhibition with acetazolamide markedly increased extracellular pH transients associated with neural activity (2). These effects are difficult to reconcile with a role of intracellular CA, but can be readily explained by a

reconcile with a role of intracellular CA, but can be readily explained by a decreased rate of buffering, due to inhibition of putative extracellular CA. We addressed this issue in rat hippocampal slices using a dextranconjugated inhibitor of CA. Extracellular alkaline transients, detected with double-barreled pH microelectrodes, were elicited in three ways: (a) by repetitive stimulation of the Schaeffer collaterals, (b) by pressure ejection of glutamate or (c) by pressure ejection of NaOH. Superfusion of slices with 10  $\mu$ M acetazolamide enhanced extracellular alkalinizations evoked by all three methods. The enhancement of the alkaline shifts evoked by NaOH ejection (405  $\pm$  74 % over control) suggested that this was mainly an extracellular effect. This was confirmed using a CA inhibitor (CL 13475) conjugated to a high molecular wt dextran (3) This compound, superfused at 1 mg/ml, enhanced stimulus and glutamate evoked alkaline shifts by 232  $\pm$  29 % over control. Pressure ejection of the dextran conjugate caused a reversible, 4-5 fold

glutamate evoked alkaline shifts by 232 ± 29 % over control. Pressure ejection of the dextran conjugate caused a reversible, 4-5 fold enhancement of alkaline shifts evoked by glutamate or NaOH ejection. We conclude that brain extracellular space has sufficient CA activity to significantly speed the rate of buffering by CO2 and bicarbonate. Our results suggest that extracellular CA is necessary to rapidly buffer alkaline shifts that accompany excitatory synaptic transmission. (1) Giacobini (1962) J. Neurochem. 9:169-177. INDUCTION OF CALCIUM-INDEPENDENT NITRIC OXIDE SYNTHASE ACTIVITY IN PRIMARY RAT ASTROCYTE CULTURES. E. Galea\*, D.L. Feinstein and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Nitric oxide synthase (NOS) is constitutively expressed as a Ca2+ dependent form in brain. We sought to determine whether an inducible (Ca2+independent) form of NOS, characteristic of macrophages, can be expressed in cells of the CNS. Primary cultures of neonatal rat cortical astrocytes or neurons were exposed to bacterial lipopolysaccharide (LPS). Incubation of glia with LPS resulted in the appearance, within 8h, of NOS activity directly related to duration of exposure and dose of LPS, with exposure of 1h sufficient to induce enzyme. Induction was potentiated by interferon- $\gamma$  and blocked by actinomycin-D indicating de novo transcription. Cytosol of LPS-treated cultures produced a Ca<sup>\*\*</sup>-independent conversion of L-arginine to L-citrulline completely blocked by  $N^G$ -monomethyl-L-arginine, indicating the presence of induced NOS. This enzyme had an apparent  $K_m$  of 16.7  $\mu M$  for L-arginine, and was dependent on NADPH, FAD and tetrahydrobiopterin. A polyclonal antibody to inducible mouse macrophage NOS (courtesy C. Nathan) stained 20% of cells in culture in which the content of microglia/macrophages is < 5%. Thus, only a subpopulation of astrocytes express NOS protein. In C6 glioma cells, LPS alone had no effect but coincubation with TNF-α and/or IL-1β significantly increased NOS activity. LPS did not induce NOS in primary neuron cultures. We conclude that astrocytes can express an inducible form of NOS differing from the Ca\*\*-dependent constitutive form of neurons, but similar to inducible NOS of macrophages. The expression of the enzyme may be modulated by cytokines. Inducible NOS of glia may contribute to the neuronal damage associated with ischemic, degenerative and/or demyelinating diseases.

ARACHIDONIC ACID INDUCES INCREASE IN CYTOSOLIC CALCIUM CONCENTRATION IN RAT BRAIN ASTROCYTES

(RBA-1). <u>T.I. Peng<sup>\*1</sup> T.C. Jou<sup>2</sup> P.D. Coleman<sup>3</sup> S-S. Sheu<sup>4</sup> <sup>1</sup>Neurosci. Prog.</u> <sup>3</sup>Dept. Neurobiology & Anatomy. <sup>4</sup>Dept. Pharmacology, Univ. Rochester, Rochester, NY 14642. <sup>2</sup>Yang-Ming Medical College, Taipei, Taiwan

Arachidonic acid (AA) has been shown to be released from neurons upon neurotransmitter stimulation and been implicated to play important roles in synaptic plasticity. The effect of AA on cytosolic Ca++ concentration ([Ca++]I) was studied in an astrocyte cell line (RBA-1) which was isolated and purified from neonatal rat cerebrum. [Ca++]i was measured with fluorescent Ca++ indicator Indo-1. A slow, progressive rise of [Ca++]I was observed when AA was applied exogenously. Latency of onset of rise of [Ca++]i was about 30 seconds to 1 minute, while time needed to reach to the plateau ranged from 3 to 5 minutes. ED50 of this response is about 20µM which elevated [Ca++]i into low micromolar range. With 35μM AA, the response started to get saturated. The action of AA was unaffected by inhibitors of cyclo-oxygenase (indomethacin), lipoxygenase (eicosatetraynoic acid) (ETYA), cytochrome P450 epoxygenase (proadifen). Other unsaturated fatty acids also exerted similar effect but with much less potency; whereas saturated fatty acids had

little effect. Increase of [Ca++]i was mainly due to Ca++ influx across plasma membrane, which could be blocked by Ni++, but not by Cd++ or nifedipine '(voltage sensitive channel blockers). In conclusion, these data show that arachidonic acid induces a rise of [Ca++]i via influx of Ca++ across plasma membrane, probably through receptor operated calcium channel. The effect of arachidonic acid is not mediated via its metabolites, but by a direct action of arachidonic acid.

ANALYSIS OF THE QUANTITATIVE RELATIONSHIP BETWEEN RECEPTOR DENSITY AND CALCIUM REGULATION IN ASTROGLIA. Y. Shao and K.D. McCarthy. Dept. of Pharmacology, The University of North Carolina, Chapel Hill,

Alpha<sub>1</sub>-adrenergic receptor (a<sub>1</sub>-AR) agonists elevate [Ca<sub>1</sub>++] in 60-80% of astroglia in vitro. Likewise, 60-70% of astroglia exhibit specific binding sites for the  $a_I$ -AR selective antagonist,  $^{125}$ I-HEAT. The density of  $a_I$ -AR binding sites varies parkedly on individual astroglia, ranging from a few to over 2,000 binding sites per 1,000 um<sup>2</sup> surface area. In the present study, we examined the relationship between the density of  $a_1$ -AR binding sites on astroglia and their ability to respond to  $a_1$ -AR agonists with a rise in  $[Ca_1^{++}]$ , using a video-based imaging system combined with receptor autoradiography. The ability of a given concentration of phenylephrine (PE) to elicit a calcium response correlated well (r = 0.98) with  $a_1$ -AR density, the higher the receptor density the greater the probability that a given astroglial cell would respond to PE. However, the amplitude of the Ca<sup>++</sup> response did not would respon to r E. However, the amplitude of the Ca response and not correlate with the  $a_1$ -AR density. Cells with a low  $a_1$ -AR density (< 10 binding sites/1,000 um<sup>2</sup>) could generate a rapid Ca<sub>1</sub> + response with a similar amplitude to that of cells with a high  $a_1$ -AR density (> 1,000 binding sites/1,000 um<sup>2</sup>). To evaluate the relationship between receptor occupancy and calcium response, we varied PE concentrations and a<sub>1</sub>-AR density while monitoring the calcium response of individual cells. Interestingly, for a given cell the PE dose range required to move from zero to maximal increases in [Ca<sub>i</sub><sup>++</sup>] was very narrow (< 5x). Over this same dose range the latency between exposure to PE and the Ca<sub>i</sub><sup>++</sup> response decreased. Irreversible inactivation of up to 90% of a<sub>1</sub>-ARs by treatment with phenoxybenzamine reduced the potency of PE but not the maximal Ca<sub>1</sub><sup>++</sup> response obtained. In summary, our results indicate that most of astroglial cells express a substantial level of 'spare' a<sub>1</sub>-ARs that increase the sensitivity of these cells to a1-AR agonists. Once activated, individual astroglial cells tend to generate a maximal calcium elevation which is independent of the total  $a_1$ -AR density

SPREADING DEPRESSION, TO A GREATER EXTENT THAN SEIZURE ACTIVITY ALONE, UPREGULATES LEVELS OF mRNA FOR GLIAL FIBRILLARY ACIDIC PROTEIN. <u>D.J. Bonthius\*. J.L. Stringer. E.W. Lothman and O. Steward</u>. Departments of Neuroscience, Pediatrics and Neurology, University of Virginia. Charlottesville. Virginia 22908.

University of Virginia, Charlottesville, Virginia 22908. It has been shown that spreading depression and seizure activity can each lead to upregulation of mRNA for gliaf librillary acidic protein (GFAP). The purpose of this study was to compare the relative strengths of spreading depression and seizure activity as signals for upregulation of mRNA for GFAP. Stimulating electrodes were placed bilaterally in the angular bundle, and glass microelectrodes were placed bilaterally in the angular bundle, and glass microelectrodes were placed bilaterally in the dentate gyrus granule cell layer of urethane-anesthetized rats. One of the recording electrodes was a double barrel electrode with the second side filled with potassium exchanger for detection of the level of extracellular potassium. Stimulus trains of 20 Hz were delivered through the right angular bundle stimulating electrode. Stimuli were given every 5 minutes for a total of 18 stimuli. The duration of seizure activity, was measured. Some of the animals (n=5) had only seizure activity, while others (n=3) had seizure activity accompanied by spreading depression, as documented by a large DC shift and an increase in extracellular potassium concentration to greater than 15 mM. The animals were killed 24 hours after the last stimulus, and levels of GFAP mRNA were assessed by *in situ* hybridization. Seizure activity in the absence of spreading depression induced a 4-fold increase in the level of GFAP mRNA in the dentate gyrus hilus, dentate gyrus molecular layer and hippocampal stratum lacunosum. Spreading depression induced a 10-fold increase in these same regions. The degree of upregulation correlated with the occurrence, but not the duration, of seizure activity and spreading depression. The results suggest that spreading depression is a substantially stronger signal than seizure activity for GFAP mRNA expression. Supported by NIH Grants NS12333 and NS28877.

A PATCH-CLAMP STUDY OF ION CHANNEL EXPRESSION BY ASTROCYTES IN SITU. B.A. Clark\* and P.Mobbs. Dept. Physiology, University College London, Gower St., London, WC1E 6BT, UK.

The expression of voltage-gated and receptor-operated ion channels by astrocytes has been extensively investigated in glial cultures obtained from different regions of the central nervous system. However, much less is known about the channels expressed by astrocytes in vivo. We have developed a whole-mount preparation of the intact isolated rabbit retina in which a population of astrocytes are readily accessible for whole-cell patch-clamping. This population of cells were identified as astrocytes by labelling with an antibody directed against glial fibrillary acidic protein and also by filling the cells with Lucifer Yellow during recordings. We have previously shown that these astrocytes have non-NMDA-type glutamate-gated channels and GABA<sub>A</sub>-type chloride channels (I.Neurosci. Feb 1992). Since these agonists depolarise astrocytes in vivo we have investigated the expression of voltage-gated currents in these cells. Whole-cell patch-clamp experiments revealed the presence of a tetrodotoxin-sensitive fast sodium current, time dependent and time independent potassium currents and an L-type calcium current.

The functions of these channels are unknown, however, the combination of receptor-operated and voltage-gated channels found in these astrocytes provides a means by which neurons may influence potassium buffering and other proposed glial cell functions.

DEHYDRATION-INDUCED PROLIFERATION OF SUPRAOPTIC NUCLEUS (SON) AND POSTERIOR PITUITARY ASTROCYTES REVISITED.

P. Murugaiyan\*, P.S. Klinkhachorn and A.K. Salm, Dept. of Anatomy, West Virginia University, Morgantown, WV 26506.

Previous studies have shown a proliferation of astrocytes in the posterior

pituitary and SON after a prolonged period of slight dehydration (Exp. Neurol, 1968, 20:460; JCN, 1977, 175 (4):373). We are examining this model system in order to gain insight as to the factor's governing adult astrocyte mitogenesis in vivo. The proliferation marker bromodeoxyuridine (BrdU) was used to study mitogenesis in astrocytes and other cells in the SON and pituitary of dehydrated rats. Ten adult male rats were dehydrated by substitution of 2% NaCl for water for periods ranging from 1,3,6 and 9 days. During this time, these animals and their paired controls were injected with 20mg/kg of BrdU every day. Following fixation and histological processing, 6µm sections of SON and pituitary were labelled with fluorescent antibodies to BrdU and the astrocyte marker glial fibrillary acidic protein (GFAP). Observations of sections in each group revealed a dose-dependant increase in the number of BrdU+ cells in both the SON and posterior pituitary of dehydrated rats as compared to controls. Many of these cells were also GFAP+. The onset of proliferation was observed in posterior pituitary as early as 24 hours following saline substitution. In addition to the above findings, we also saw a substantial proliferation of cells in the anterior pituitary under all conditions as well as a decrease in the basal level of BrdU+ cells in the intermediate lobe of dehydrated subjects relative to their controls. These results suggest that astrocytes in the SON and posterior pituitary are very rapidly sensitive to mitogens accompanying dehydration and that this sensitivity continues as the stimulus persists. # GLIAL CELLS IN SITU IN HIPPOCAMPAL SLICES EXPRESS VOLTAGE-ACTIVATED Na<sup>+</sup> AND K<sup>+</sup> CHANNELS

H. Sontheimer\* and S.G. Waxman Dept. of Neurology, Yale Univ. School of Med., New Haven CT 06510 and VAMC, West Haven CT 06516

Glial cells in culture express a large range of ion channels. To assess whether such channels are also expressed *in vivo* we obtained whole-cell recordings from both thin (100-150 μm) and standard (400-500 μm) slices of 4-28 day old rat hippocampi. Recordings from both preparations showed voltageactivated ion channels to be expressed in astrocytes and oligodendrocytes. Oligodendrocytes typically had low input resistances and large K+ conductances at rest. Resting potentials were between 60-70 mV. The predominant current recorded was an inwardly rectifying K+ current (Kir) with little time-dependence. Astrocytes expressed up to 3 types of time- and voltageactivated K+ currents: i. activating, non-inactivating outwardly rectifying K+ currents (Kd), ii. transient, "A"-type K+ currents, and iii. inwardly rectifying K+ currents. Resting potentials in astrocytes were highly variable (-40 to -95 mV in 2.5 KCl), and appeared to differ within hippocampal subregions, being more negative in stratum moleculare than in radiatum or the cell layers of the CA regions. Different K+ channel complements were also observed in astrocytes in these regions. Although most astrocytes only expressed K+ currents, in a few instances, small transient inward Na+ currents were recorded in addition to (Kd-type) K+ currents. Na+ current amplitudes in astrocytes (30-100pF, corresponding to current densities of 1-3 pA/pF) were much smaller than in hippocampal neurons which had Na+ currents > 20nA, corresponding to current densities of up to 300 pA/pF. POST-SYNAPTIC POTENTIALS RECORDED FROM GLIAL CELLS OF THE PITUITARY PARS INTERMEDIA. L.A. Mudrick-Donnord P.J. Williams, O.J. Pittman, and B.A. MacVicar. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Although glial cells have historically been considered passive elements, they have been shown recently to possess both voltage dependent and ligand gated ion channels. We have now observed that at least one type of glial cell, the stellate cell of the pituitary pars intermedia (PI), can, like neurons, respond to synaptic input with post-synaptic potentials. The stalk attched-whole pituitary preparation was used with a stimulating electrode placed on the pituitary stalk to activate afferent fibres. The PI is divided into discrete lobules and comprised primarily of melanocytes and stellate cells; intracellular recordings were obtained from both cell types. Whereas melanocytes demonstrated a neuron-like profile, the stellate cells possessed electrophysiological characteristics of macroglia. Stellate cells were identified by a resting potential more negative than -65mV, low input resistance (<50 MΩ), and no detectable voltage activated conductances. Stalk stimulation evoked a Ca<sup>2+</sup>-dependent post-synaptic response in the stellate cells consisting of a short depolarization (<100 ms) and a long lasting hyperpolarization (45-75 s). The depolarization was mimicked by GABA application and blocked by the GABA, antagonist bicuculline (10  $\mu$ M). The hyperpolarization was mimicked by dopamine and blocked by the D<sub>2</sub> antagonist sulpiride (2  $\mu$ M). To confirm the glial nature of these cells, neurobiotin was injected into the impaled stellate cells and subsequently visualized. The tissue was then immunostained for GFAP, Desitive double staining was observed in all stellate cells from which post-synaptic potentials had been recorded. These data provide the first demonstration of synaptically-evoked potentials in glial cells. Tonic synaptic modulation of glial K<sup>+</sup> and Cl<sup>+</sup> permeability could regulate both extracellular homeostasis and melanocyte excitability.

ASTROGLIAL "ENSHEATHMENT" OF INERT, NEURON-SIZED BEADS. A. K. Salm.\*Dept. of Anatomy, West Virginia University, Morgantown, WV 26506.

Neurons in the central nervous system are extensively ensheathed by astrocytic processes, except in regions where synaptic, or other, contacts are made with adjacent cells. What factors influence where and how this ensheathment is accomplished? In these studies, astroglia were co-cultured with inert, 23  $\mu m$  diameter, polystyrene beads to examine how these cells interact with beads in the presence or absence of neuron-derived biochemical cues. Beads added to astroglial cultures floated. However, some began to have contact with underlying astroglia within 4 hours. By 12 hours, numerous beads were firmly adherent to cells; even when cells were plated sparsely, suggesting that a dynamic interaction united them. After 4 days, many beads were almost entirely surrounded by astrocytic processes. microscopy, 3-dimensional confocal microscopic reconstructions of fluorescently immunostained material, and scanning EM, shows that the "ensheathment" appears to be accomplished by a contortion of the astroglia, coupled with the extension of numerous processes around the beads. When doubly labelled with antibodies to the astrocyte marker GFAP and BODIPY-phalloidin, both GFAP+ and actin filaments were seen to be present in s, although their distribution differed. In parallel studies, when beads were plated onto confluent rat meningeal fibroblasts or alveolar macrophages; only infrequent bead-cell complexes developed after 2 weeks in culture. In other experiments, beads were plated onto astroglia that had been previously co-cultured with neurons, and then the neurons removed. Such cells displayed an elongated morphology and failed to form any complexes with beads. Initial results with this model system suggest that astrocytes may constituatively act to ensheath neuron- like objects in their environments, and that this process may be modulated by neuron-derived cues. D.E. Brenneman\*, A. Buonanno\* "W.B.Anderson\* and D.V. Agoston\*.

Laboratory of Celular Oncology, NCI. 2 Laboratory of Developmental Neurobiology, NICHD, National Institutes of Health, Bethesda, MD 20892, Astrocytes synthesize and secrete trophic substances critical to development and function of the central nervous system (CNS); however, the extra-and intracellular signalling pathways are poorly understood. Here we demonstrate that treatment of neonatal cortical astrocytes with vasoactive intestinal peptide (VIP), which has been demonstrated to act as secretagogue in this system, and the adenylate cyclase activator, forskolin, caused the redistribution of protein kinase C isoforms (PKC) from the cytoplasm to the nucleus. Primary cortical astrocytes derived from rat pups were treated with various concentrations of VIP and forskolin, PKC activity, subcellular distribution and the presence of various PKC-isotypes were measured in Western-analysis using polyclonal antibodies specific to different isoforms of PKC. Western-blot analysis revealed that rat cortical astrocytes possess the classical PKC α, but PKC β or PKC γ isotypes were not detected. In addition, we identified two novel isotypes (δ and ζ) present in rat cortical astrocytes while PKC α isoform was found to be predominantly cytosolic in localization, PKC δ was associated with the plasma membrane and nuclear fractions. Following exposure to either VIP (subnanomolar-to-nanomolar range) or forskolin (micromolar range) most of the PKC-activity become nuclear in a concentration-dependent manner. Exposure of astrocytes to 1 μM PMA for 24 h caused the down-regulation of both PKC α and δ protein levels in the nuclear fraction, while the subcellular distribution of PKC ζ and δ protein levels in the nuclear fraction, while the subcellular distribution of PKC α and δ protein levels in the nuclear fraction, while the subcellular distribution of PKC α and δ protein levels in the nuclear localization of PKC α and δ protein levels in the nuclear localization of PKC α

LASER CYTOMETRY OF POTASSIUM STIMULATED CHLORIDE ION UPTAKE IN CCF-STTG1 HUMAN ASTROCYTOMA CELLS USING MQAE M. Patricia Leuschen\* Joint Division of Newborn Medicine, Creighton University - University of Nebraska Medical Center, Omaha, NE. 68198

CCF-STTG1, a human astrocytoma cell line, responds in a dose dependent manner to increased extracellular potassium (HiK) with cell swelling as measured by "C-3-O-methyl-D-glucose studies and cell injury as monitored by LDH efflux and MTT cytotoxicity studies. When evaluated using "CI, the K" stimulated cell swelling was accompanied by chloride uptake. MOAE, a chloride sensitive fluorescent indicator (Molecular Probes, Eugene, OR) was used with an ACAS 570 laser cytometer (Meridian, Okemos, MI) to monitor the Ci exchange in response to HiK. CCF,STTG1 cells grown on #1 glass were loaded with 5mM MQAE in 1:1 buffer-distilled water. Single cells were identified, scanned continuously at 410nM and monitored for 15 min under control conditions then 60mM HiK was added and scans continued for 15 min; KSCN and valinomycin were added to quench MQAE fluorescence. Standard curves were constructed to quantitate [Ci]. Control cells lost <5% fluorescence in 15 min; autofluorescence was minimal. MQAE studies documented a rapid exchange of Ci (millisec) followed by a slower (min) sustained influx in response to HiK. The MQAE probe and ACAS laser cytometer are extremely sensitive to changes in pH and temperature but allow very specific monitoring of single cell anion exchange. The system has dramatic potential as a tool for evaluating release of neurotransmitters such as glutamate or HiK.

Astrocyte-dependent inhibition of C6 glioma cell growth in cultures treated with B-Xyloside. <u>D. Lorton\*, M. Dority, and K. Brunden.</u> Gliatech, Inc., Cleveland, OH 44122.

Previous studies support a role for proteoglycans (PG) in tumor cell growth and metastasis. In this study, a culture paradigm was developed to determine the effects of a PG biosynthesis inhibitor on glioma growth and migration. C6 glioma cells were seeded in a defined area onto a confluent monolayer of neonatal rat astrocytes and grown in medium that contained 1 mM 4-methyl-umberiferyl \( \beta - \text{Dyloside} \) (\( \beta - \text{yloside} \)) or in medium without this agent. \( \beta - \text{yloside} \) the reatment results in a decreased synthesis of PG and an accumulation of free glycosaminoglycan (GAGS) in the culture medium.

xyloside (B-xyloside) or in medium without this agent. B-xyloside treatment results in a decreased synthesis of PG and an accumulation of free glycosaminoglycan (GAGS) in the culture medium.

C6 cells grown in the absence of B-xyloside developed into a mass of thick cell clumps which grew laterally over the astrocyte monolayer. The glioma "tumor" diameters in the untreated group were 14.7 mm, 30.8 mm, and 36.7 mm by days 9, 16, and 21, respectively. The C6 cells grown with B-xyloside remained a monolayer throughout the study period and had slower lateral growth than the untreated cells. The diameter of treated tumors were 7.4 mm, 11.6 mm, 14.1 mm and 16.5 mm by days 9, 16, 21 and 28, respectively. The B-xyloside effects were astrocyte-dependent since C6 cells seeded onto dishes in the absence of the astrocyte monolayer covered the plates by 28 days regardless of the presence of the PG inhibitor. A similar slowing of growth and migration were observed when U 87 MG human astrocytoma cells were treated with B-xyloside. These data suggest that an alteration of PG biosynthesis or an increased release of GAGS can affect the growth and/or spread of glioma cells in vitro.

CYTOKINE INDUCTION OF L-ARGININE-DEPENDENT cGMP PRODUCTION IN GLIAL CELLS. M.L. Simmons\* and S. Murphy Dept. of Pharmacology, College of Medicine, Univ. of Iowa, Iowa City, IA 52242

Primary astrocyte cultures and the C-6 rat glioma cell line can both be induced by lippoplysaccharide (LPS) to express a calcium-independent nitric oxide synthase (NOS). Such nitric oxide production has been previously demonstrated in crude cell homogenates using a bioassay for cGMP production, as well as by L-arginine dependent cGMP production in the intact glial cells themselves. In support of these previous findings, NOS-induction can also be demonstrated by increases in L-[3-H]-citrulline production from LPS-treated cells loaded with L-[3-H]-arginine. The NOS can also be induced in both primary cultures and C-6 cells by 17-18 hour treatment with the cytokines interferon- $\gamma$  (IFN- $\gamma$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ), or tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), as demonstrated by L-arginine-dependent (N\u00fa-nitro-1-arginine methyl ester inhibited) cGMP production in intact cultures. While dexamethasone (1\u00fcM) could strongly attenuate or prevent NOS induction by LPS in either cell type, it had little or no effect on induction by cytokines alone or in combination. Induction by maximal concentrations of a single cytokine could often be potentiated by concurrent treatment with an additional cytokine or LPS, implying that multiple mechanisms of induction may be involved. These findings suggest that astrocytic nitric oxide production may play a role in immunological responses within the CNS. Supported by NS 29226 and the Life and Heath Insurance Medical Research Fund.

INTRACELLULAR pH REGULATION IN PRIMARY RAT ASTROCYTES AND C6 GLIOMA CELLS. <u>L.D. Shrode, R.W. Putnam and J.B. Dean</u>. Dept. of Physiol. & Biophys., Wright State Univ. School of Medicine, Dayton, OH 45435. Intracellular pH (pH<sub>i</sub>) was studied in cultures of neonate rat brain astrocytes and

C6 glioma cells (at 80-90% confluency) using the pH-sensitive fluorescent dye BCECF. Steady state pH<sub>1</sub> (pH<sub>2</sub>=7.4, CO<sub>2</sub>-free, 37°C) in astrocytes was  $7.01 \pm 0.03$  (n=58) (mean  $\pm$  SE) and in C6 cells was  $7.28 \pm 0.02$  (n=83). Upon removal of 30 mM NH<sub>4</sub>Cl, astrocytes acidified to a pH<sub>4</sub> of 5.97 ± 0.04 (n=24) and then recovered at a rate of 0.21  $\pm$  0.02 pH units/min (n=8), while C6 cells acidified to 6.08  $\pm$  0.04 (n=28) and recovered at a rate of  $0.31\pm0.03$  pH units/min. In both cell types pH, recovery was abolished by 1 mM amiloride or by a Na-free solution (N-methyl-Dglucamine). Upon exposure to 5% CO<sub>2</sub> (24 mM HCO<sub>3</sub>, pH<sub>o</sub>=7.4), astrocytes acidified to 6.84  $\pm$  0.04 (n=18) and subsequently recovered at a rate of 0.31  $\pm$  0.03 pH units/min to a new steady state pH of  $7.29 \pm 0.04$ . C6 cells exposed to CO<sub>2</sub> alkalinized at a rate of  $0.23 \pm 0.04$  pH units/min (n=9) to a new steady state pH of 7.56 ± 0.02. CO<sub>2</sub>-induced alkalinization was abolished by Na-free solutions in both cell types. Prolonged exposure to Cl-free solutions inhibited CO2-induced alkalinization in astrocytes by 62% and in C6 cells by 61%. The remaining Cl-independent recovery was nearly abolished by DIDS in both cell types. Preliminary experiments, with acute exposures of cells to Cl-free CO<sub>2</sub>-containing solutions, showed that under such conditions pH, alkalinized from 6.91 to 7.34 at a rate of  $0.35\pm0.02$  pH/min in primary astrocytes and from 7.1 to 7.53 at a rate of  $0.26\pm0.06$  pH/min in C6 cells. These are similar to the cell pH responses to CO<sub>2</sub> exposure in the presence of Cl. In C6 cells, this alkalinization is abolished by Nafree solutions (0.04 ± 0.01 pH/min). In summary, pH, regulation is similar in C6 cells and primary astrocytes, and is mediated by Na-H exchange and by two types of Na/HCO<sub>2</sub>-dependent transporters (Cl dependent and Cl independent). Naindependent Cl/HCO3 exchange, if present in these cells, has very low activity.

THE ROLE OF A GLYCOPEPTIDE INVOLVED IN HOMOPHILIC ADHESION OF THE TRANSFORMANT EXPRESSING PO. T.Yazaki 1-2, H.Asou\*, K.Kitamura, M.Miura, S.Toya² and K.Uyemura¹ Depts. of ¹Physiology and ²Neurosurgery, Keio University School of Medicine, Shinjuku-ku, Tokyo 160, Japan, ³Dept. of Physiology, Saitama Medical School, Saitama 350-04, Japan. Protein zero(P0), a major glycoprotein in mammalian peripheral

Protein zero(P0), a major glycoprotein in mammalian peripheral myelin, is a member of the immunoglobulin superfamily and plays a role in the formation and maintenance of peripheral myelin by homophilic adhesion, and in the promotion of neurite outgrowth of dorsal root ganglion neurons [T.Yazaki et al, Biomed. Res. 1991]. To determine its functional domains, P0 protein was expressed in C6 glioma cells by transfection with rat P0 cDNA. Dissociated cells were resuspended in complete medium and incubated for various times, and the number of particles at each time point was measured. The total number of particles decreased to 24% in 60 min for transformant (C6P0) cells, in contrast to only 68% for control (C6P0') cells. To clarify the mechanism of adhesion, mixed-cell aggregation experiments with Dil-labeled C6P0 cells and DiO-labeled C6P0 cells were performed. P0-expressing C6P0 cells adhered predominantly to each other to form aggregates, with the exception of attachment to a few C6P0' cells at the periphery. The purified glycopeptide of P0 protein inhibited adhesion by 80%, while synthesized peptides (amino acid sequences 83-90 and 100-107) did not cause a significant inhibition. These results suggest that the glycopeptide portion of P0 protein is an important domain in homophilic adhesion. [Supported by grants-in-aid for Scientific Research from the Ministry of Education, Science and Culture in Japan.]

THE RESUMPTION OF RAPID AXONAL TRANSPORT FOLLOWING A REDUCTION IN TEMPERATURE. R.E. Snyder\* and R.S. Smith. Department of Applied Sciences in Medicine, and Department of Anatomy and Cell Biology, University of Alberta, Edmonton, Canada T6G 2G3.

Although it has been determined that the rapid axonal transport of protein ceases at low temperatures, little is known regarding transport following a return to normal temperatures. In this study we report on the transport of both protein and organelles subsequent to a reduction in temperature. All studies were performed using an *in vitro* sciatic nerve preparation of *Xenopus laevis*. Nerves were cooled to 1.0-2.5 °C for 1.5-13 h followed by a return to room temperature (23 °C). Transport of <sup>35</sup>S-methionine-labeled protein was studied using a position-sensitive detector of ionizing radiation and liquid scintillation analysis, and transport of organelles was studied in isolated axons using computer-enhanced video DIC microscopy.

Upon return to room temperature protein was found to resume anterograde transport within <30 min, but at a velocity of only 25-50% of its pre-cooling value. Up to 90% of the protein observed moving prior to cooling did not resume transport upon warming, and that protein which did resume transport underwent deposition to a stationary phase at a rate 5-10 times greater than normal. Anterograde organelle transport resumed within <15 min following warming, but with a reduced flux that gradually increased with time. Fifteen minutes following warming organelles were observed to move at normal velocities, however with long pauses between movements. We conclude that a reduction in temperature affects both the axonal transport mechanism and the relationship that exists between the carrier organelles and transported protein. (This work was supported by the Medical Research Council of Canada and the University of Alberta Central Research Fund.)

TRANSPORT KINETICS OF NEUROFILAMENTS IN MOUSE OPTIC AXONS. P. Paggi\*1,2, R. J. Lasek <sup>1</sup> and M. J. Katz<sup>1</sup>. <sup>1</sup>Bioarchitectonics Cntr. CWRU School of Med icine, Cleve. OH 44106. <sup>2</sup>Dip. Biologia Cellulare e dello Sviluppo, Univ. "La Sapienza" 00185 Roma, Italy.

In mouse optic axons, there are relatively few neurofilaments (NFs)  $\,$ and the NF proteins are more lightly labeled than other slowly transported SCb proteins, which, however, move faster than the NFs; thus the radio label of some of the faster-moving SCb proteins may confuse NF proteins analyses that use one dimensional SDS/polyacrylamide gel electrophoresis (1D-PAGE). To test this possibility, 35S- or 3H-labeled amino acids were injected into the right vitreous body of anesthetized mice. At 1-198 days after the injection, the mice were killed and 2 mm segment of the right optic nerve (at 3-5 mm from the posterior of the eye) was removed to compare the NF kinetics obtained by 1D-PAGE and by the higher resolution two dimensional isoelectric focusing/PAGE (2D-PAGE). We found that 1D-PAGE is insufficient for definitive NF kinetics in the mouse optic axons. By contrast, 2D-PAGE provides essentially pure NF kinetics. In mice, more than 97% of the labeled NFs were distributed in a unimodal wave that moved at a continuum rates, between 3.0 and 0.3 mm/day, and less than 0.1% of the  $\,$ NF population traveled at very slowest rates of less than 0.005 mm/day. These results are inconsistent with the proposal (Nixon & Logvinenko, J. Cell Biol. 102: 647, 1986) that 32% of the transported NFs remain within the optic axons in an entirely stationary state. As has been found in oth er axons, the axonal transport system of mouse optic axons moves NFs relentlessly from the cell body to the axon tip.

# MEMBERS OF THE MYOSIN I FAMILY IDENTIFIED IN EMBRYONIC RAT BRAIN TISSUE. C. Ruppert\*, J. Reinhard, J. Godel and M. Bähler. Friedrich-Miescher Laboratorium of the Max-Planck Society,

7400 Tübingen; Germany.

7400 Tübingen; Germany. Myosin I molecules are single headed motor-molecules which produce force along actin filaments. There is suggestive evidence that myosin I's are involved in organelle movements and growth cone motility, processes playing an important role during neuronal development. Therefore, we have begun to investigate the presence and identity of myosin I motor molecules in the developing rat brain. Degenerate oligonucleotide primers matching to different conserved sequence regions of known myosin molecules were used to amplify several cDNA fragments by PCR from embryonic rat brain RNA. With these fragments we have screened cDNA libraries and isolated clones corresponding to three different myosin I molecules myr.1 myr.2 and myr.3 nave screened cDNA horaries and isolated clones corresponding to three different myosin I molecules, myr.1, myr.2 and myr.3 (myosin I rat). The expression pattern of these clones in various rat tissues was analysed by northern blotting. All the clones under investigation exhibited a mRNA size of 4-5kb. All three showed a complex nonidentical expression pattern with a noticeably high expression in lung tissue. The message of myr.1 is highly expressed in embryonic brain tissue but downregulated in adult brain. Therefore, myr.1 may play a role during neuronal development. Furthermore, our data provide evidence that there exists a family of myosin I molecules in mammalian brain.

TEMPERATURE DEPENDENCE OF RAPID ANTEROGRADE AND RETROGRADE AXONAL TRANSPORT IN AMPHIBIAN NERVE R.S. Smith\*, R. Oates and R. E. Snyder, Department of Anatomy and Cell Biology and Department of Applied Sciences in Medicine, University of Alberta, Edmonton, Canada T6G 2H7

We have determined the temperature dependence of the velocity of rapid anterograde and retrograde organelle transport in sciatic axons of Xenopus laevis in order to compare the transport properties of organelles with those of radiolabeled proteins in the same animal. Organelle motion in isolated myelinated axons was proteins in the same animal. Organetie motion in isolated myetinated axons was detected using computer-enhanced video DIC microscopy. To control specimen temperature, the microscope was cooled in a cold room and heated with an infra-red lamp. Specimen temperature was measured with a thermocouple inside the glass nerve chamber in the vicinity of the isolated axons.

Organelles were classified on the basis of their direction of transport, their apparent size (sub or supraresolution), and shape (circular or rod-shaped). apparent size (such as the subresolution) and apparent of a happen of the subresolution organelles (images  $^{\circ}$ 0.2 µm dia.) showed an exponential dependence of velocity (V µm/s) on temperature (T  $^{\circ}$ C) over the range 0-35  $^{\circ}$ C: V = 0.23 exp (0.0843 T), with a Q<sub>10</sub> of 2.3 and apparent activation energy, E, 14 kcal. Retrograde subresolution organelles had a similar exponential temperature dependence of velocity: V = 0.157 exp (0.0976 T), with a Q10 of 2.7 and E, 16 kcal. Supraresolution circular organelles moved slightly slower than subresolution organelles, but otherwise had identical temperature dependencies. Velocities of these organelles had a coefficient of variation that was large (36 ± 2%) and independent of temperature. Rod-shaped organelles (presumptive mitochondria) had velocities that were poorly correlated with temperature. We conclude that subresolution organelle transport has characteristics similar to those described for rapid protein transport with two notable exceptions: the coefficient of variation of organelle transport is much larger than that of protein transport, and unlike protein transport organelle transport continues uninterrupted below 5°C. DENDRITIC TRANSPORT OF NEWLY SYNTHESIZED RNA IS DISRUPTED BY MICROTUBULE POISONS. R. Kleiman, G. Banker, and O. Steward, Dept. of Neuroscience, Univ. of Virginia, Charlottesville, VA., 22908.

Neurons transport newly synthesized RNA into dendrites via an energydependent mechanism. Some newly synthesized RNA is retained in dendrites following detergent extraction, suggesting that RNA that is in transit is associated with elements of the cytoskeleton (Davis et al., 1987, Nature, 330:477-479). We were interested in determining whether microtubules or microfilaments play a role in the dendritic transport of RNA. Rat hippocampal neurons maintained in culture for 14 days were treated with nocodazole to disrupt microtubules, or cytochalasin D to disrupt actin microfilaments. Neurons were pulse-labeled with <sup>3</sup>H-uridine for one hour to label newly synthesized RNA, then transferred to medium containing an excess of unlabeled uridine for an additional six hours to allow for dendritic transport. Neurons maintained in cytochalasin D exhibited essentially normal RNA synthesis and dendritic transport. Neurons treated with nocodazole 3 hours before the start of labeling and maintained in nocodazole until the end of the experiment did not transport the recently synthesized RNA out of the cell body. To determine if the effects of nocodazole were reversible, neurons were treated with nocodazole for 9 hours and then returned to control medium to allow for microtubule re-assembly. Neurons were then pulse labeled with <sup>3</sup>H-uridine for one hour and maintained in unlabeled medium for 13 hours before being fixed and processed for autoradiography. Under these conditions there was a partial recovery of dendritic transport, although the distance of RNA transport was less than in control neurons. These findings are consistent with the hypothesis that dendritic transport of RNA depends upon microtubules. Supported by NIH grant NS23094. RK was the recipient of predoctoral fellowship HD07323.

AXOPLASMIC PROTEINS MICROINJECTED INTO AXONS ARE RETROGRADELY TRANSPORTED TO THE CELL SOMA AND IMPORTED INTO THE NUCLEUS. R. Schmied, C.-C. Huang and R.T. Ambron\*. Dept. Anatomy & Cell Biol. and Otolaryngology, Columbia Univ. P&S, New York, NY

An unresolved question is how the distal axon communicates with the cell body to cause the changes in gene transcription required for regeneration and plasticity. We recently discovered a novel transport pathway that conveys proteins retrogradely from the axon to the nucleus (J. Neurosci., in press). This was shown using human serum albumin (HSA) coupled to a nuclear import signal peptide (sp) and rhodamine (r). When microinjected into axons of Aplysia neurons in vitro, rHSA-sp was rapidly transported along the axon and then into the nucleus; transport was blocked by co-injection of r-HSA-sp with sp, indicating that this process is dependent upon a saturable sp-recognizing receptor. To see if this pathway has physiological relevance, Aplysia axoplasm was extruded from nerves and the soluble proteins were separated by size. When fractions were microinjected into axons in vitro, one contained protein that was conveyed to the nucleus. This fraction had an 83 kDa protein that can also be isolated from the nucleus and is recognized by an anti-sp IgG. This protein is likely to be a retrogradely transported component.

The axonal transport phenomenon was observed *in vivo* in two different preparations. rHSA-sp was retrogradely transported within axons of nerves after application to their cut ends and after microinjection into the varicosities of neurons innervating heart muscle. These findings suggest that neurons *in* vivo use this transport mechanism for certain axonal proteins to signal the nucleus of events acting at the periphery.

ENDOCYTOSIS AND TRANSPORT OF CON A-COATED LATEX BEADS BY GROWING NEURITES. Q. Zheng, B. Lu\*+ and M.M. Poo. Dept. of Biol. Sci., Columbia Univ., N.Y., NY 10027; †Lab. Mol. Cell. Neurosci., Rockefellor Univ., N.Y., NY 10021.

Transport of a specific population of endocytic organelles was examined using Con A-coated latex beads as a probe. The latex beads (100 800 km) wars coated with whole mice consequential A

beads (100-800 nm) were coated with rhodamine-concanavalin A (Con A). After a brief incubation with the cultured *Xenopus* spinal neuron, the Con A-beads were endocytosed by the neuron and transported within the neuritic processes, as monitored by highfound that most beads were collected by the motile filopodia of the growth cone and were transported to the base of growth cones on the filopodia surface, as shown by the effective quenching of bead fluorescence with membrane-impermeant ions. Bead movement on the filopodia surface  $(0.15-0.2 \, \mu \text{m/s})$  was independent of the bead size and was actin-based, since it was inhibited by cytochalasins. The beads became internalized at the growth cone base, which appears to be the primary site of endocytosis. Internalized beads initially moved in retrograde direction. At later times, both anterograde and retrograde motions along the neurite were observed. Bead transport along the neurite is microtubule-based, since colchicine inhibited the motion, and the transport rate reached a maximum of about 1 2µm/sec, a value similar to that of rapid axonal transport in other systems. With limited number of endocytosed beads in each neurite and unambiguous tracing of individual beads over prolonged periods, the present method offers an useful approach for studying the regulatory mechanisms for the transport of cytoplasmic organelles.

# 38.9

FORWARD FLOW OF PLASMA MEMBRANE ALONG THE LENGTH OF GROWING NEURITES. S. Popov and M-m. Poo\*. Dept. of Biol. Sci., Columbia Univ., N.Y., NY 10027.

It is generally accepted that neurite grows by membrane insertion at the growth cone. In this study we have examined the pattern of new membrane addition in growing *Xenopus* neurites. The bulk membrane flow on the neurite surface was studied by monitoring the distribution of fluorescent lipid molecules, which were locally inserted into a small segment of the neurite within 60-70 µm from that the cone. Results of quantitative digital imaging showed that the center of diffusion profile of these lipids shifted forward with an average rate of  $2.0 + 0.2 \,\mu\text{m/min}$  (s.e., n = 12), a value close to the rate of neurite extension in these cultures, suggesting that forward flow of plasma membrane along the neurite may account for membrane extension at the growth cone. Further evidence of membrane flow was provided by the observation of yolk granules attached to the surface of neurites. These granules moved forward with the same speed as lipid flow, suggesting that they can be used as markers of bulk membrane movement. We found that the rate of forward movement of the granules increases linearly with the distance from the soma, resulting in increases linearly with the distance from the soma, resulting in increasing separation with time between yolk granules on the same neurite. This increase in the distance between granules cannot be accounted for simply by the thinning of neurite, and membrane insertion must occur along the neurite. The data also suggest that on the average 35% of membrane extension in the neurite can be attributed to membrane flow from soma to the neurite and little or no preferential addition of new membrane occurred at the growth

PROTEIN MAINTENANCE IN AXOTOMIZED CRAYFISH MEDIAL GIANT AXONS. S. L. Tanner, E. E. Storm, R. A. Sheller, and G. D. Bittner\*. University of Texas, Austin, TX 78712

Axotomy of the medial giant axon (MGA) of the crayfish, Procambarus clarkii, produces a distal anucleate segment of axon which remains intact and functional for at least 6 months. The total protein banding pattern (as assessed on 1D SDS-PAGE silver stained gels) is very similar in intact and anucleate MGAs until about 7 months post-severance. At this time, proteins of apparent molecular weights of 33, 55 (tubulin), and 71kd are decreased in anucleate MGAs while many other proteins are not decreased. The similarities in the protein banding pattern between intact and anucleate MGAs severed for less than 7 months suggest that protein maintenance in anucleate MGAs is the result of suppressed protein turnover and/or local uptake of protein from extraaxonal sources, e.g. glial cell synthesis of protein which is taken up by the MGA (Sheller and Bittner, Brain Res., In Press).
When fast axonal transport proteins from anucleate MGAs are examined by SDS-PAGE/fluorography, most protein bands are much less detectable after 28

days compared to 1 day, i.e., the half-life of most fast transported protein is less than 1 month. This result indicates that many proteins in anucleate MGAs are degraded long before the degeneration of anucleate MGAs. Therefore, local uptake of proteins may be an important mechanism for protein maintenance of anucleate MGAs. However, when proteins in slow transport are examined, the most heavily labeled bands are located at 33, 55, and 71kd, presumably the same species of proteins which are decreased in 7 month anucleate MGAs. Furthermore, the 55kd band (tubulin) is generally not taken up by the MGA from local sources. These data suggest that some proteins delivered by slow axonal transport may not be derived from local sources and may exhibit slow protein turnover (possibly as long as the survival of the anucleate MGA). Supported by ATP grant to G.D.B.

CHARACTERIZATION OF THE INTERMEDIATE FILAMENT PROTEIN PERIPHERIN IN THE RAT SCIATIC NERVE. S. Chadan, K.L. Moya, M.M. Portier, L. DiGiamberardino\* and G. Filliatreau INSERM U334 and CNRS URA 1285, C.E.A., S.F.H.J., Orsay, and Cellular

Biochemistry Lab, Collège de France, Paris, France.
Peripherin (56kD, pl 5.6), a neuron specific type III intermediate filament protein, is expressed in primary sensory, sympathetic and motor neurons. Intermediate filament proteins share a common molecular structure which is thought to contribute to their ability to form filamentous networks in a coil-coil complex stabilized by disulfide bonds. We used metabolic labeling and gel electrophoresis to study the axonal transport of peripherin in rat motor axons. The results show that peripherin is transported in two waves in the slow component a (SCa) of anterograde axonal

is utansported in two wates in the saw component a (car) of anticigrate axional transport. In the faster wave, peripherin is cotransported with NF-L.

In experiments using non reducing conditions, we observed by electrophoresis analysis, a high molecular weight protein (120kD, pl 5.6; Pl20) that was recognized by a peripherin-specific polyclonal antibody. In order to characterize Pl20 further, we used monoclonal antibodies that recognize epitopes common to intermediate filament proteins. Under non-reducing conditions, P-120 is recognized by all antibodies used, suggesting that P120 is also an intermediate filament protein. The prevention of *in vitro* disulfide bond formation by the use of iodoacetamide shows that P-120 is not an artifact of the sample preparation conditions. Furthermore, incubation of P-120 in the presence of  $\beta$ -mercaptoethanol resulted in a single 56kD band recognized by all the antibodies.

In general, there is a diminution of peripherin after birth, while relative levels of

in general, incre is a diminishmoor applied than those of the monomeric form. It is noteworthy that the induction of sciatic nerve regeneration leads to a marked increase in peripherin levels in the dorsal root ganglia starting 7 days after the nerve crush. The increase in P120 is greater than for monomeric peripherin. Our results show that peripherin is co-transported with NF-L and that it can form homodimers, which may record an increase in P120 is the property of the pro may provide an important building block for the intermediate filament network

ULTRASTRUCTURAL LOCALIZATIONS OF A NEURONAL GROWTH-ASSOCIATED PROTEIN, SCG10 IN THE ADULT RAT BRAIN Y.SUGIURA, K.IKEDA# and N.MORJ\* Division of Neurogerontolgy, Andrus Gerontology Center, Univ. Southern California, Los Angeles, CA 90089-0191, #Neuroscience, Beckman Research Institute, City of Hope, Duarte, CA91010

Neuronal growth-associated proteins(nGAPs), such as GAP-43/B-50, MAP2 and Neuronal growth-associated proteins(nGAPs), such as GAP-43/B-50, MAP2 and synapsin, contributes to the development and maturation of the nervous system. SCG10 is one of the nGAPs, which was initially identified as a neuronal marker in the developing peripheral nervous system. The brain expression of SCG10 was maximum in mid to late gestation of embryo but dramatically reduced in the adult. However, the expression persisted at low but significant levels in many areas of adult brain(see the abstract by T.Himi). These areas included the hippcampus, the cerebellar Purkinje cells, and the mitral cells of the olfactory bulb. These data suggest that SCG10 might play a role in maintaining the plasticity of nervous system. On the other hand, amino acid sequences of SCG10 (see the abstract by T.Okazski) showed a hydropholic region and a region with (see the abstract by T.Okazaki) showed a hydrophobic region and a region with interesting similalities, though segmentally, to cytoskeletal molecules, including myosin, keratin and laminin. The predicted structure suggests that SCG10 may be myosin, keratin and laminin. The predicted structure suggests that SCG10 may be involved in neuronal vesicle-cytoskeletal interactions. In order to explore this possibility we examined the subcellular localization of SCG10 in adult rat cerebellum using specific antibodies by immunoelectron microscopy. In the cell body, immunoreactivity of SCG10 was observed around the endoplasmic reticulum. The Golgi apparatus, mitochondria, lysosomes and other membranous structure were devoid of immunoreactivity of SCG10. In the molecular layer of cerebellum, the immunoreactivity of SCG10 was restricted to a region near the neuronal terminals adjacent to the plasma membrane. A small vesicle-like structure in dendrites or axons also showed a positive reaction.

The existence of SCG10 protein in neuronal terminals raises the possibility that SCG10 is involved in synaptic interactions.

SCG10 is involved in synaptic interactions.

HIGH NEUROFILAMENT PACKING DENSITY IN LESIONED LAMPREY GIANT AXONS IS CORRELATED WITH NEURO-FILAMENT SIDEARM PROTEOLYSIS. G.F. Hall\*1, L. Chen² and V.M-Y. Lee². 1 Dept of Neurology, Harvard Med. School, Brigham and Women's Hosp., Boston, MA 02115 and 2 Dept. of Pathology, Univ. Penn. School of Med., Philadelphia, PA 19104.

Axotomy of giant Muller and Mauthner axons in the lamprey spinal cord results in the rapid formation of dense filamentous masses (DFMs) in the cut axons within 150 µm of the lesion site (McHale and Cohen 1983). We show that monoclonal antibodies (RMO14, RMO44, RMO48) specific for the neurofilament "core" strongly stain amorphous masses corresponding to DFMs while failing to recognize neurofilaments elsewhere in the axon. Antibodies rating to recognize neuroniaments eisewhere in the axon. Antibodies specific for the neurofilament C terminal "sidearm" domain (RMO34, RMO270) fail to recognize DFMs, but stain other axonal neurofilaments. We prepared Western blots from SDS denatured total protein preparations of 3 mm segments of the spinal cord at the lesion site at 1 day post lesion and compared them to blots of unlesioned and cord rates from a site distant from the lesion. cord and cord taken from a site distant from the lesion. We found that the "core" antibodies RMO14 and RMO44 labelled several the "core" antibodies RMO14 and RMO44 labelled several neurofilament breakdown products present in the lesion site preparation that were not present in the controls. Other low molecular weight bands were recognized by a C terminal antibody (RMO270). We conclude that axotomy leads to proteolysis of the "sidearm" region of some neurofilaments in the vicinity of the lesion, and suggest that the loss of the sidearm may be responsible for the high packing density reported for neurofilaments near the lesion site in this system. Supported by NIH gray NS 2029. system. Supported by NIH grant NS29281.

NEUROFILAMENT-GENE EXPRESSION ABERRANT ACRYLAMIDE NEUROPATHY. S. Kittur 1 H. Endo 1, P.S. Spencer 2, M ACRYAMIDE NEUROPAITI. S. NILLIA II. EMBO 1. S. SPERGE II.

Sabri 2. 1 Molecular Neurobiology, NIA/NIH, Baltimore, MD 21224,

2 Oregon Health Sciences University, Portland OR 97201. The molecular mechanisms by which acrylamide produces pathological changes in central and peripheral neurons are not understood. The most widely accepted hypothesis is that acrylamide progressively inactivates certain neuronal component(s) and thereby compromises neuronal integrity. Recent studies from our laboratory show that acute and subacute intoxication with acrylamide causes depletion of microtubule-associated proteins (MAP1 and MAP2) and activates immediate-early gene (c-fos and c-fun) expression in rodent brain. This study examined the expression of mRNAs for light (L), medium (M), and heavy (H) chains of 10-nm neurofilaments (NF) in the brains of acrylamide-treated rats. Adult male Sprague-Dawley rats were treated with a single (100 mg/kg, i.p.) dose or repeated (0.03% w/v in drinking water) oral doses of acrylamide. Animals were sacrificed by decapitation 6 hours after a single injection or 4 weeks after repeated oral dosing. Brains were excised, total mRNA isolated and Northern blot analysis performed by hybridization with 32P-labeled cDNA probes for NF-L, NF-M and NF-H. Acute Sabri<sup>2</sup>. <sup>1</sup>Molecular Neurobiology, NIA/NIH, Baltimore, MD 21224, 32P-labeled cDNA probes for NF-L, NF-M and NF-H. Acute acrylamide treatment significantly increased (approximately 50%) the expression of NF-M mRNA with no apparent change in either NF-Lor NF-H mRNA. In contrast, repeated doses of acrylamide caused a significant increase in NF-L mRNA (approximately 22%); no changes were observed in NF-M and NF-H mRNAs. The expression of mRNA for β-actin was not altered significantly by acrylamide. These results show that acrylamide causes aberrant NF-gene expression in rat brain. Supported in part by NS 19611.

DISTRIBUTION OF  $\gamma$  TUBULIN IN THE NEURONS: IMPLICATIONS FOR THE ORIGINS OF NEURITIC MICROTUBULES. H. C. Joshi\* and P. W. <u>Baas'</u>. \*Dept. of Anat. & Cell Biol., Emory Univ. Sch. of Med., Atlanta, GA 30322; 'Dept. of Anat., The Univ. of Wisconsin Med. Sch., Madison, WI 53706. Axons and dendrites contain dense microtubule (MT) arrays that are not attached

to a traditional MT nucleating structure such as the centrosome. Nevertheless, the MTs within these neurites are highly organized with respect to their polarity, and consist of a regular 13-protofilament lattice, the two known characteristics of MTs nucleated at the centrosome. These observations suggest either that axonal and dendritic MTs arise at the centrosome, or that they are nucleated locally, following a redistribution of MT nucleating material from the centrosome during neuronal development. To begin distinguishing between these possibilities, we have determined the distribution of  $\gamma$ -tubulin within cultured sympathetic neurons.  $\gamma$ -tubulin, a newly discovered protein which is specifically localized to the pericentriolar region of non neuronal cells (Zheng, Y., M.K. Jung, and B.R. Oakley, 1991, Cell 65:817-823; Stearns, T., L. Evans, and M. Kirschner, Cell 65:825-836), has been shown to play a critical role in MT nucleating in vivo (Joshi, H.C., M.J. Palacios, L. McNamara, and D.W. Cleveland, 1992, Nature 356:80-83). Because the γ-tubulin content of individual cells is extremely low, we relied principally on the high degree of resolution and sensitivity afforded by immunoelectron microscopy. Our studies reveal that, like the situation in nonneuronal cells, \( \gamma\)-tubulin is restricted to the pericentriolar region of the neuron. Furthermore, serial reconstruction analyses indicate that the minus ends of MTs in both axons and dendrites are free of  $\gamma$ -tubulin immunoreactivity. The absence of  $\gamma$ -tubulin from the axon was confirmed by immunoblot analyses of pure axonal fractions obtained from explant cultures. The observation that  $\gamma$ -tubulin is restricted to the pericentriolar region of the neuron suggests that MTs destined for axons and dendrites are nucleated at the centrosome, and subsequently released for translocation into these neurites.

IDENTIFICATION OF A NEURAL-SPECIFIC HOMOLOG OF CLATHRIN-COATED VESICLE-ASSOCIATED MEDIUM CHAINS. J. Peysner\*, W. Volknandt and R.H. Scheller. HHMI, Dept. Molec. & Cell. Physiol., Stanford U. Medical Center, Stanford CA 94305.

Neurotransmitters are packaged and stored in vesicles in the presynaptic nerve terminal. Following exocytosis synaptic vesicle proteins are believed to be selectively endocytosed by a pathway involving clathrin-coated pits and vesicles. We have used an antiserum directed against electric ray synaptic vesicles to isolate a cDNA clone encoding a 47 kDa protein, ray We subsequently isolated rat homologs p47A which is expressed in all tissues examined, and p47B, which is neural-specific. These three proteins share 85% amino acid identity among each other and 30% identity to the medium chains (AP50, AP47) of adaptor complexes associated with clathrin-coated vesicles. These adaptor complexes mediate functions such as the internalization of proteins from the cell surface. We propose that p47A and p47B are constituents of novel adaptor complexes. p47B may be present in an adaptor complex in the nerve terminal mediating the recycling of synaptic vesicles.

NO EFFECTS OF PROPOFOL ON THE ACTIN AND TUBULIN ORGANIZATION OF RAT NEURONS AND GLIAL CELLS. A. G. Jensen. M. Lindroth. K. Björnström and C. Eintreit. Departments of Anaesthesiology and Pathology II, Linköping University Hospital, S - 581 85 Linköping, Sweden.

Neurons and glial cells from 14 - 16 - day - old rat embryos (Sprague-Dawley) were cultured in modified Eagles Minimum Essential Medium (Hansson E, in A Dissection and Tissue Culture Manual', Alan R Liss Inc. 1989, pg 92), supplemented with 10% fetal calf serum, glucose, insulin, amino acids and antibiotics. The cells were attached to Poly - L - Lysin coated coverglasses placed into a 24 multiwell tissue culture plate for ten days at 37° C in a humidified atmosphere of 5% carbon dioxide/95% air. Thereafter the cells were atmosphere of 5% carbon dioxide/95% air. Thereafter the cells were exposed to three different concentrations of propofol (0.3 µg/ml. 3µg/ml and 10µg/ml) for 30 min., extracted for 10 min. with 0.5% Triton X-100 in a microtubule stabilizing buffer, and fixed for 15 min. in 4% PFA. We then studied the organization of actin in the cells using rhodamin - conjugated phalloidin, which is specific for filamentous actin, and observed the cells using fluorescence microscopy. The organization of tubulin was studied using indirect immunofluorescence

No major changes could be observed, neither in the actin architecture nor in the arrangement of tubulin, after incubation with propofol. The increase in propofol concentration from 0.3 to 10  $\mu g/ml$  had no effects on tubulin or actin organization. These preliminary results indicate that propofol has no effects on the neuron or glial cell cytosskeleton

IDENTIFICATION OF A 38 KD PROTEIN BINDING TO NEUROFILAMENT SUBUNITS IN VITRO. L.D. Errante\* and G. Shaw. Department of Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610.

To examine the interactions of neurofilaments (NFs) with cytosolic proteins, five different types of NF affinity columns were made with: (1) crude spinal cord intermediate filament preparation; made with: (1) crude spinal cord intermediate filament preparation; (2) purified NF triplet proteins; (3) purified NF-H; (4) purified NF-M; and (5) purified NF-L. A cytosolic preparation from fresh pig spinal cord was cycled through each affinity column and bound proteins were eluted with a linear salt gradient (0-0.5M NaCl). Bound proteins were visualized using SDS polyacrylamide gel electrophoresis (SDS-PAGE) and relative mobilities were determined. The most abundant protein binding to all NF affinity columns was a 38 KD protein. Depending on the NF affinity column used, the 38 KD protein was eluted off at salt concentrations ranging from 0.1M to 0.2M NaCl. Recently, we have identified the 38 KD protein as glyceraldehyde-3-phosphate dehydrogenase (GAPDH) by: (1) virtual identity of amino acid have identified the 38 KD protein as glyceraldehyde-3-phosphate dehydrogenase (GAPDH) by: (1) virtual identity of amino acid composition with GAPDH; (2) co-migration on one dimensional SDS-PAGE with GAPDH; (3) production of cyanogen bromide cleaved fragments similar to those produced from GAPDH; and (4) immunoreactivity of the 38 KD protein with a mouse polyclonal antibody to GAPDH. GAPDH is a glycolytic enzyme which has been shown to associate with microtubules and actin *in vitro*. Current studies are focusing on determining the binding constants and *in vivo* interactions of GAPDH with the NF network.

CHARACTERIZATION OF AN INOSITOL POLYPHOSPHATE RECEPTOR FROM BRAIN: SIMILARITY TO THE CLATHRIN ASSEMBLY PROTEIN AP-2. <sup>1</sup>S.M. Voglmaier, <sup>2</sup>J.H. Keen, <sup>3</sup>G.D. Prestwich, <sup>1</sup>S.H. Snyder, and <sup>4</sup>A.B. Theibert. <sup>1</sup>Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205, <sup>2</sup>Jefferson Cancer Inst., Thomas Jefferson Univ. Sch. of Med., Philadelphia, PA 19107, <sup>3</sup>Dept. of Chemistry, SUNY, Stony Brook, NY 11794, <sup>4</sup>Neurobiol. Res. Ctr./Dept. of Cell Biology, Univ. of Alabama, Birmingham, AL 35294. Highly phosphorylated inositols, including IP4, IP5, and IP6, (IPs) are present in mammalian brain. Changes in

and IP6 (IPs) are present in mammalian brain. Changes in the levels of several IPs are elicited by neuro-transmitter action. IPs may regulate calcium levels, modulate ion channels, or regulate other activities in the cell. Using IP-affinity probes, several high affinity inositol polyphosphate receptors have been isolated from rat brain. One of these, designated the IP<sub>6</sub>R, binds IP<sub>6</sub>(K<sub>d</sub>-12nM)>IP<sub>3</sub>-IP<sub>4</sub>(K<sub>d</sub>-50-100nM)>IP<sub>3</sub>(K<sub>d</sub>>1uM). Several subunits comprise the IP<sub>6</sub>R, with IP binding sites contained in the 105-115 kDa subunits. Partial amino acid sequence was obtained from two peptides generated by tryptic cleavage of the 105-115 kDa subunits. These peptides weighted identical to sequences 499-515 and 914-924 contained in the  $\alpha_A$  subunit of the clathrin assembly protein AP-2 ( $\alpha$ adaptin). In immunoblot analysis, antibodies to both the AP-2  $\alpha$  and  $\beta$  subunits recognize proteins in the pure IP  $_6R$ fractions. These results indicate that the IP6R is very similar and may be identical to the plasma membrane associated AP-2, and suggests that IPs may be involved in regulation of vesicle transport in neurons.

DIFFERENTIAL SUBCELLULAR LOCALIZATION OF SNAP-25 PROTEINS MAY BE DIRECTED BY ALTERNATIVE SPLICING. C. Bark\* & M. C. Wilson, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The presynaptic nerve terminal protein SNAP-25, (synaptosomal associated protein of 25 kD), is a 206 amino acid polypeptide that contains two domains which may play important roles for biological function and targeting of the mature protein. The amino terminus can form an amphipathic helix and at least one out of four clustered cysteine residues is substrate for posttranslational palmitoylation. SNAP-25 is a component of fast axonal transport, however, in rodents the cellular localization of the protein undergoes a developmental switch. In neonates SNAP-25 accumulates in axons and perikarya, whereas in adults it appears selectively in terminal fields. We recently reported the presence of two distinct transcripts encoding the SNAP-25 protein. The two mRNAs, SNAP-25a & b, are developmentally regulated and encode proteins that only differ in 9 amino acids (Bark & Wilson, Neurosci. Abs. 211.9, 1991). The two isoforms are generated by alternative splicing between two exons which span the only cysteine residues in the polypeptide. While SNAP-25a is a minor earlier form, the expression of SNAP-25b appears to be coincident with neuronal maturation.

To investigate whether regulated subcellular localization and targeting of the protein to presynaptic terminals is determined within the 9 amino acid differencies between the two isoforms, we are examining their expression in the pheochromocytoma cell line PC12. We have shown that undifferentiated PC12 cells express small amounts of endogenous SNAP-25a mRNA and that dBcAMP and/or NGF treatment induces increased mRNA levels and a change in exon utilization which correlates with the translocation of the protein into neurite terminals. To define the minimal signal sequence encoded by the alternative exons required for differential cellular localization, the distribution of both isoforms and of mutated proteins are being examined after transfection into cultured cells. Supported by Swedish NSRC B-PD9714-303 (C.B.) and BNS9121121 (M.C.W.).

THE COMPLETE SEQUENCE FOR BRAIN B-SPECTRIN INDICATES A RELATIONSHIP WITH HEME BINDING PROTEINS (GLOBINS). Y. Ma. W.E. Zimmer, B.M. Riederer and S.R. Goodman\*Department of Structural and Cellular Biology, College of Medicine, University of South Alabama, Mobile, AL 36888.

Brain spectrin (fodrin), a major ubiquitous cytoskeletal protein participates in cell morphogenesis, neurotransmitter release and regulation of the lateral mobility of N-CAM 180. It consists of α and β subunits that form antiparallel 100 nm long fibrous heterodimers, and the heterodimers associate head-to-head to form 200 nm tetramers. The β subunit of spectrin is functionally important because it interacts with other molecules including F-actin, ankyrin and synapsin I. Elucidating the details of the primary structure of β spectrin will facilitate understanding its functional interactions and may predict new functions for this molecule. We have determined the first full length sequence of nonerythroid β spectrin (β Splla) from mouse brain cDNA libraries. The nucleotide sequence contains 7165 basepairs encoding 2363 amino acid residues, which comprise 17 typical repeat units which share 59% identity with β Spla (β subunit of human rbc spectrin). The predicted molecular weight of brain β spectrin from the derived amino acid sequence is 274,449 dattons. Combining the knowledge of previously reported functional studies with our β Splla primary structure, it is possible to make a number of predictions regarding functional sites within this β spectrin molecule. Interestingly, the analysis of the β Splla sequence indicated striking homology and similar structural characteristics of brain β spectrin repeat β11 and β12 to the heme-binding domain of globins. We have demonstrated that purified brain β spectrin binds heme in vitro, suggesting possible new functions in electron transfer, oxygen binding, or heme scavenging. Supported by NIH grant RO1NS19357 to SRG.

REGULATION OF PROTEIN SYNTHESIS WITHIN SYNAPTO-DENDROSOMES: EFFECT OF POTASSIUM-INDUCED DEPOLARIZATION ON THE SYNTHESIS OF SYNAPTIC PLASMA MEMBRANE PROTEINS. A. Rao' and O. Sieward, Dept. of

MEMBRANE PROTEINS. A. Rao' and O. Steward. Dept. of Neuroscience, Univ. of Virginia, Charlottesville, VA 22908. We have previously proposed that some synaptic proteins are locally synthesized by subsynaptic polyribosomes. This conclusion is based on the observation that some proteins synthesized by isolated "synaptodendrosomes" become associated with the synaptic junction (Rao and Steward, 1991, J. Neurosci., 11, 2881-2895). Other studies have revealed that protein synthesis in synaptosomes is increased by depolarization (Weiler and Greenough, 1991, Mol. Cell. Neurosci., 2, 305-314). This effect on protein synthesis could be a generalized increase in translation or a differential increase in the synthesis of particular protein species. In this study, we examined whether the synthesis of particular synaptic plasma membrane proteins was differentially affected by depolarization.

proteins was differentially affected by depolarization.

Synaptodendrosome fractions were pulse-labeled with <sup>35</sup>S methionine in the presence of 2, 25, or 40 mM extracellular potassium concentrations. A synaptic plasma membrane (SPM) subfraction was obtained from the synaptodendrosomes and labeled proteins within the SPM subfraction were analyzed by SDS-PAGE and fluorography. There was a monotonic increase in labeling of all bands with increasing potassium concentrations. This difference in labeling was greater comparing the 2 and 25 mM condition than between the 25 and 40 mM conditions. These results suggest that depolarization leads to a general increase in protein synthesis within synaptosomes of proteins that associate with the synaptic junction, although the synthesis of some proteins may be affected more than others. Supported by NIH NS12333.

NEUROFILAMENTS OCCUR IN NEURONS OF THE SEA ANEMONE CONDYLACTIS GIGANTEA (Cnidaria: Anthozoa) C. DellaCorte and W.O. McClure. Dept. Biol. Sci., Univ. of Southern California., Los Angeles, CA 90089

Neuronal processes in most organisms contain filamentous cytoskeletal structures. In vertebrates, annelids and molluscs, neurofilaments (NFs) (10 nm intermediate filament cytoskeletal elements) are a major component of the nervous system and play mechanical, structural and dynamic roles. Mammalian neurofilaments are composed of three polypeptides with molecular weights of 200kD, 150kD and 70kD. Non-mammalian NFs may also exist as a triplet, but in some only a single NF protein is seen. In these cases, the single protein is typically immunologically cross-reactive with the mammalian 150kD and 200kD subunits of Antisera to the 150kD and 200kD subunits of Antisera to the 150kD and 200kD subunits of Antisera to the 150kD and 200kD subunits of an every system in the subtropical sea anemone C. giqantea. At the level of light and electron microscopy, staining of neural components was found in an ectodermal nerve net and plexus. A detergent-insoluble protein of 190kD was isolated. Antisera absorbed with this 190kD protein no longer stained neuronal structures. The data indicate that neurons of C. qiqantea possess neurofilaments, and that this family of neuronal proteins is of great antiquity. (Supported by the NIH, ARCS Foundation Inc., and the Hedco Foundation.)

REGULATION OF THE 66 KILODALTON NEUROFILAMENT PROTEIN GENE EXPRESSION DURING DIFFERENTIATION OF PC12 AND EMBRYONAL CARCINOMA P19 CELLS.

L. Feng. F.C. Chiu, H.J. Federoff\*. Albert Einstein College of Medicine Person NY 10061

OF PC12 AND EMBRYONAL CARCINOMA P19 CELLS.
L. Feng. F.C. Chiu. H.J. Federoff. Albert Einstein College of Medicine, Bronx, NY. 10461
The 66 kDa neurofilament protein (NF-66) and 70 kDa neurofilament protein (NF-L) share homology and are co-expressed to varying extents within CNS neurons but are encoded by separate genes. NF-66 expression in vivo is correlated with periods of axonal growth, whereas NF-L expression becomes maximal after the period of axonal growth and synapse formation. To begin to explore the mechanisms underlying the regulation of NF-66 we have investigated the pattern of NF-66 transcript and gene product expression during differentiation in two model systems; NGF inducible PC12 cells and retinoic acid (RA) inducible embryonal carcinoma P19 cells. In undifferentiated PC12 cells NF-66 mRNA and protein levels were very low. However, upon NGF reatment NF-66 mRNA levels increased markedly by 6 hours and reached a plateau at 24 hours; thus induction kinetics of NF-66 is faster than that of GAP-43 mRNA, which encodes another axonal growth related protein. Western blotting for NF-66 of mRNA and protein. In P19 cells, RA differentiation for 3, 5 and 7 days induced the robust expression of NF-66 mRNA and protein. Indirect immunofluorescent staining of NF-66 in RNA and protein. Indirect immunofluorescent staining of NF-66 in RNA and protein. Indirect immunofluorescent staining of NF-66 in RNA and protein. BASIC HELIX-LOOP-HELIX AND Id-LIKE TRANSCRIPTION FACTORS IN NEUROGENESIS. T. Neuman, A. Keene, M.X. Zubert, H.O. Nornes\*. Dept. of Anatomy & Neurobiology and Dept. of Biochemistry, Colorado State University, Fort Collins, CO 80523.

The helix-loop-helix (HLH) transcription factors play important roles in specifying cell fate. In the mouse CNS, different HLH transcription factors are expressed from the early stages of neurogenesis to adulthood. Class A basic-HLH (bHLH) transcription factors ME1 and ME2 are expressed at high levels in proliferating neuroblasts. The expression of ME1 decreases dramatically when the genesis of neurons is finished. ME2 continuous to be expressed at high levels in certain structures (hippocampus) during differentiation. At least two Id-like proteins, which lack the basic, DNA binding domain have high expression levels in specific cell types during neurogenesis. Id2 is expressed in large neurons of cortical structures from the moment of their genesis to adulthood. In the cerebral cortex, it is expressed at high levels in layers II,III and V, in the olfactory bulb in mitral cells, and in the cerebral transcription postnatal days 7-10. B11 gene has different transcripts in pre- and postnatal development. The presence of different bHLH and Id-like transcription factors in the CNS indicates that they have important regulatory roles in neurogenesis.

THE TYPE 1 NEUROFIBROMATOSIS GENE PRODUCT IS ENRICHED IN DENDRITES OF SUBPOPULATIONS OF CNS NEURONS. N. Ratner, M. Shipley, and M. Nordlund. Dept. of Anatomy & Cell Biology, University of Cincinnati College of Medicine, Cincinnati, OH 45267-0521.

Von Recklinghausen's neurofibromatosis (NF1) is an inherited human disease that has multiple manifestations in the CNS. Patients with NF1 exhibit certain types of CNS tumors, learning disabilities, MRI abnormalities, and headaches. To begin to understand the function of the NF1 gene product (neurofibromin) in the normal CNS, we have surveyed its distribution in the rat brain using polyclonal and monoclonal antibodies (Daston et al., Neuron E: 415-429). Neurofibromin expression is limited to oligodendrocytes and neurons in the brain. Staining of oligodendrocytes defines a caudo-rostral gradient; oligodendrocytes defines a caudo-rostral gradient; oligodendrocytes defines a caudo-rostral gradient; oligodendrocytes defines a caudo-rostral gradient; prevented to the brain stem but not in the forebrain. Subsets of neurons possess neurofibromin immunoreactivity. Pyramidal neurons are the only cells that express neurofibromin in the cerebral cortex. Purkinje cells are the major cell type labelled in the cerebellum. Subpopulations (75-80%) of neurons in brain stem, thalamus, and deep cerebellar nuclei contain significantly elevated levels of the protein. Dendrites, especially proximal dendrites, are prominently labelled in immunoreactive neurons. These data are consistent with the hypothesis that neuronal abnormalities, resulting from dysfunction of a metabolic process localized primarily in dendrites of specific neurons, underlic CNS-associated disease manifestations in NF1. Supported by NS28840.

### 39.5

IDENTIFICATION OF THE POSSIBLE MOLECULAR BASIS FOR INHERITED DIFFERENCES IN HUMAN CATECHOL-O-METHYLTRANSFERASE. MH Grossman\*1, J B Littrell¹, R Weinstein¹, CL Szumlanski² and RM Weinshilboum². 1-Dept. of Pediatrics, Temple Univ. Sch. Med., St. Christopher's Hosp. for Child., Phila., PA 19134 and 2-Dept. of Pharmacol., Mayo Clinic, Peabases MN 55005 Rochester, MN 55095.

Inherited variations of human catechol-O-methyltransferase (COMT) activity levels in humans are controlled at a two allele, autosomal locus. The "low" activity enzyme is also relatively thermolabile, compared to the "high" activity form. The cloning of thermolabile, compared to the "high" activity form. The cloning of the human COMT gene has enabled us to examine the molecular basis of these inherited variations. Liver specimens from three individuals with presumed L/L genotypes and three with presumed H/H genotypes were obtained, total mRNA isolated and cDNA prepared. Sequence analysis of PCR-amplified COMT coding region was performed on multiple M13 subclones. A single nucleotide change at position #472 has been identified, with all L/L individuals change at position  $H^2/2$  has been identified, with all  $D^2/2$  having an adenosine and all H/H individuals having a guanosine. A corresponding change occurs in amino acid #158, with L/L having a methionine and H/H having a valine. The nucleotide difference identified here may represent the molecular basis of normal variations that contribute to an individual's ability to metabolize endogenous as well as administered catechol-like substances. (Supported by NIH grant NS24066 to MHG).

CHARACTERIZATION OF THE RAT AROMATIC L-AMINO ACID DECARBOXYLASE GENE. <u>V, R, Albert\*, M, R, Lee, R, C, Silverman, R, Wurzburger and A, Aguanno</u>. Dept. of Neuroscience, Roche Institute of Molecular Biology, Nutley, N.J. 07110.

Aromatic L-amino acid decarboxylase (AADC) is the enzyme which catalyzes the decarboxylation of L-dopa to dopamine in catecholamine cells and 5-hydroxytryptophan to serotonin in serotonin-producing neurons. AADC is also expressed in relatively large quantities in non-neuronal tissues such as liver and kidney, where its function is still unknown. Although the enzyme itself appears to be identical in both neuronal and non-neuronal tissues, it has been shown that in rat neuronal and non-neuronal tissues express AADC messages with distinct 5' untranslated regions (Krieger et al., PNAS, 88; 2161, 1991). In order to understand

how this is accomplished at the genomic level, and to learn more about its regulation, we have isolated rat genomic DNA encoding AADC.

The neuron-specific form of rat AADC cDNA was used to screen an EMBL3-SP6/T7 rat genomic library. Eight overlapping clones of 12-16 kb were obtained. These clones encompass approximately 50 kilobases of the rat AADC gene. Included in this DNA is most of the AADC coding sequence.

The organization of the AADC gene suggests that there are two separate promoters specific for the transcription of neuronal and non-neuronal forms of the AADC message. A small exon containing 68 bases of the neuronal-specific 5'end is located 9.5 kb upstream of the translation start site, which is contained in the third exon. Approximately 6 kb upstream from the neuron-specific promoter is another small exon containing 71 bases of the 5' end of the non-neuronal AADC message. These data suggest that the expression of neuronal and non-neuronal forms of the AADC message is controlled by transcription initiating at distinct promoters, followed by alternative splicing to exon 3 which contains the common promoters of the second translation start site.

THE PATTERN OF EXPRESSION OF THE NEUROFIBROMATOSIS TYPE 1 GENE PRODUCT IN THE ADULT AND DURING DEVELOPMENT Maryellen M. Daston\* and Nancy Ratner, Department of Anatomy and Cell Biology. University of Cincinnati, College of Medicine, Cincinnati, OH 44267

Neurofibromatosis type 1 (NF1 or von Recklinghausen's disease) is a com inherited neurological disorder affecting 1 in 3500 people. The predominant manifestations of NF1 are benign tumors of peripheral nerves comprised mainly of Schwann cells (neurofibromas), tumors of the iris, learning disabilities and hyperpigmentation of melanocytes. In addition, NF1 patients have an increased risk for certain neural malignancies. These symptoms can arise throughout life, but their initial onset is usually during infancy or early childhood. Knowledge of the distribution of the normal NF1 gene product during development should improve our understanding of the pathogenesis of this disease

We have raised antibodies, against peptides encoded by portions of the human NF1 cDNA, which specifically recognize a 220 kDa protein (neurofibromin) in both human and rat spinal cord (Daston et al., 1992, Neuron (8):415). In adult animals very little neurofibromin is expressed outside the nervous system. In contrast, in embryonic rats neurofibromin is widely distributed. Unlike most cell types, in which neurofibromin expression decreases with maturation, neurons begin to express high levels neurofibromin around the time of terminal differentiation. Immunostaining in the embryonic central and peripheral nervous systems is most intense in growing fiber tracts.

The broad distribution of neurofibromin in embryos suggests that it may play a general role in cell growth or differentiation. The localization of neurofibromin to specific cell types of mature neural tissue suggests a separate role in the normal functioning of the nervous system, consistent with the predominance of neurological symptoms in NF1. Supported by NIH NS28840.

ANALYSIS OF THE PROMOTER SEQUENCE AND THE TRANSCRIPTION INITIATION SITE OF THE MOUSE SEROTONIN 1C RECEPTOR GENE. L. J. Bloem, J. Liu, Y. Chen, L. S. Bye and L. Yu. Dept. of Medical & Molecular Genetics, Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

The serotonin 1c (5-HT<sub>1c</sub>) receptor is found in many brain regions, but is particularly enriched on the epithelial cells of the choroid plexus. A major goal of neurobiology is to define the molecular processes that regulate the regional expression pattern of neuronal genes. As an initial step towards identifying cis-acting DNA sequences that control the expression of the 5-HT<sub>1c</sub> receptor, we have isolated the promoter sequence of the 5-HT<sub>1c</sub> gene and sequenced a 1.8 kb fragment. Primer extension experiments using mouse brain poly A+ RNA mapped the transcription initiation site in this region. There are a number of sequence elements upstream from the transcription initiation site that are homologous to enhancer elements found in other eucaryotic genes. A plasmid containing the promoter region and a reporter gene, when injected into the nucleus of Xenopus oocytes, resulted in functional expression of the reporter gene. Primer extension reactions using the RNA extracted from the injected oocytes indicated a single transcription initiation site of the reporter mRNA.

# 39.8

CHANGES IN GENE EXPRESSION DURING INCUBATION OF HIPPOCAMPAL SLICES. P.J. Voulalas<sup>1</sup>, T.S. Nowak, Jr.<sup>2</sup>, and J.M. Sarvey<sup>1</sup>\*, <sup>1</sup>Dept. Pharm, USUHS Bethesda, MD 20814 and <sup>2</sup>Dept. Neurology, Univ. Tenn., Memphis, TN 38163.

Slices of brain tissue are subjected to mechanical and ischemic stresses in the course of preparation. Previous studies have noted that the heat shock protein hsp70 accumulates in the vascular elements of incubated slices from various tissues, while ischemia is well known to induce neuronal expression of c-fos and hsp70 in brain. In the present study  $400\mu m$  thick hippocampal slices from male Sprague-Dawley rats were prepared on a tissue chopper male Sprague-Dawley rats were prepared on a tissue chopper and placed in a perfusion chamber (artificial cerebrospinal fluid/95% O<sub>2</sub>, 5% CO<sub>2</sub>, 34 C, 3 ml/min); slices were removed at 0,30,60,90 and 120 min, and frozen sections were prepared and analyzed by in situ hybridization, using anti-sense probes for c-fos and hsp70. Striking increases in c-fos were observed in dentate, CAl and CA3 at 60 to 120 min. Hsp70 followed a similar pattern of increased expression, but was less strikingly induced. The distribution of altered gene expression in hippocampal slices is comparable to that observed following ischemia in vivo. The longer duration of c-fos mRNA expression in slices than in intact tissues, perhaps may reflect the slow metabolic recovery of slices in vitro. We suggest that changes in gene expression can be useful markers for assessing the status of slices used for electrophysiological work.

EFFECT OF NICOTINE ON TYROSINE HYDROXYLASE AND DOPAMINE B-HYDROXYLASE GENE EXPRESSION IN PC12 CELLS. B.K. Hiremagalur, J. Nitahara, A. McMahon, and E.L. Sabban. Dept. Biochem. and Mol. Biol. New York Med. Coll., Valhalla, NY 10595.

Nicotine, a cholinergic agonist, stimulates catecholamine secretion and raises tyrosine hydroxylase (TH) gene expression in adrenal medullary cells. The latter is associated with increased cAMP levels although nicotine is reported to induce c-fos in PC12 cells. This study investigated the effect of nicotine on expression of TH and dopamine ß-hydroxylase (DBH), two enzymes whose activity can be regulated by prolonged nicotine treatment in vivo

PC12 cells were treated with nicotine (200  $\mu$ M) for various times, and TH and DBH mRNA analyzed by Northern blots. Transcriptional regulation was studied using transfected PC12 cells in which expression of chloramphenicol acetyl transferase (CAT) was under control of the 5' region of the TH gene. Nicotine induced both TH and DBH mRNA about 3-4 -fold, with a maximum at 48 hrs. The effect on TH was transcriptional since PC12 cells transfected with pTH-5' (-773/+27) and (-272/+27) showed a 4 fold induction of CAT activity with nicotine. Nicotine mediated CAT activity was inhibited by H89, a protein kinase A inhibitor. Both the TH mRNA and CAT activity were not induced by nicotine in a mutant PC12 cell line deficient in protein kinase A activity. These results show that both TH and DBH are regulated in PC12 cells by prolonged periods of nicotine treatment. The effect on TH is transcriptional and appears to require a cAMP-dependent protein kinase.

DNASE I HYPERSENSITIVE SITES 5' OF THE RAT

DNASE I HYPERSENSITIVE SITES 5' OF THE RAT PROENKEPHALIN GENE. M. Holloway. E.F. La Gamma\*. Dept. of Pediatrics, SUNY at Stony Brook, NY 11794.

Extracellular stimuli affecting mechanisms of transcriptional control of the proenkephalin gene link stimulus-secretion-synthesis coupling to transmitter phenotypic expression. In order to define distal and proximal genomic regions that might participate in transcriptionally active protein-DNA interactions, DNase I hypersensitivity assays were conducted. Four DNase I hypersensitive regions were identified at -3000, -2500, -1800 and -200 bp relative to the somatic start site. The appearance of a site over the proximal promoter/enhancer region (-200 bp) is of interest since we and others have published a detailed footprint and functional analysis of this region using rat tissues (Mol. Cell. functional analysis of this region using rat tissues (Mol. Cell. Neurosci. 2:517, 1991 and 2:427, 1991). While liver (which does not express proenkephalin mRNA) displays essentially does not express proenkephalin mRNA) displays essentially no hypersensitivity here, adrenal gland preparations show a strong signal and striatal tissue a significantly weaker signal. Cholinergic induction of proenkephalin mRNA was not associated with a change in hypersensitivity pattern. When analyzed, the -1800 bp region displays tissue-specific binding in gel shift assays. Cholinergic induction and the -3000 and -2500 bp regions have not yet been studied by gel shift. We are in the process of determining the extent that these regions are involved in the adrenal-specific regulation of proenkephalin involved in the adrenal-specific regulation of proenkephalin expression and the choice of transmitter phenotype during development.

# 39.13

IS GAD, EXPRESSION REGULATED BY TWO MECHANISMS? K. Rimvall and D. L. Martin . Wadsworth Center for Labs and Research, New York State Health Dept., Albany, NY 12201.

Glutamate decarboxylase (GAD) activity is decreased by ca. 30% in cerebral cortex in vivo and 60-70% in cerebral cortical cultures following elevation of intracellular GABA levels by treatment with y-vinylGABA (GVG) or GABA itself. In both systems the reduction in activity is due to a marked reduction of expression of GAD<sub>67</sub> protein, as demonstrated by quantitative immunoblotting with selective antisera. Expression of GAD<sub>65</sub> protein is unaffected. GAD<sub>67</sub> mRNA was unchanged in rats treated with GVG despite a 75-80% reduction in GAD<sub>67</sub> protein, suggesting that in this system the expression of GADe7 is regulated at the level of translation or protein degradation. GAD activity in cultures of striatal neurons is increased from 48  $\pm$  7 nmol • h<sup>-1</sup> • mg prot<sup>-1</sup> to 64  $\pm$  7 by 10- $\mu$ M quinpirole (a D<sub>2</sub> agonist), and 66  $\pm$  7 by 10- $\mu$ M SCH23390 (a D, antagonist). Others have demonstrated that the levels of GAD<sub>67</sub> mRNA are altered in the striatum when rats are treated with quinpirole or SCH23390 or are lesioned with 6-hydroxydopamine. The contrast between the latter findings and the lack of change in GAD<sub>67</sub> mRNA following GVG treatment suggest that the expression of GAD<sub>67</sub> is controlled by at least two mechanisms. Supported by grant MH35664 from USPHS/DHHS.

Mechanisms of Enkephalin Regulation by Haloperidol. C.Konradi\*, L.A.Kobierski, T.V.Nguyen, W.T. Dauer, and S.E. Hyman, Molecular Neurobiology Department, Massachusetts General Hospital, Harvard Medical School. Chronic administration of D2 receptor antagonist antipsychotic drugs, such as haloperidol, are known to increase mRNA and protein levels of proenkephalin in rat striatum. Using proenkephalin gene regulation as an endpoint, we have examined haloperidol-induced changes in intracellular signal transduction in striatal neurons. We find that proenkephalin mRNA is induced rapidly by haloperidol, with a time course suggesting that constitutively expressed transcription factors may play a critical role in the induction. Moreover, in longterm treatment paradigms, proenkephalin mRNA levels remain elevated at time points at which immediate early genes (IEG's), such as c-Fos, are no longer fully inducible. Gel shifts using crude nuclear extracts of rat striata treated chronically (12 daily injections of 2mg/kg haloperidol) or acutely (11 daily injections of saline, 1 injection of 2mg/kg haloperidol 2 hours before sacrificing), showed increased binding to consensus AP-1 sequences, but not to the enkephalin CRE-2 element which is known to be critically involved in gene activation. In contrast to levels of other IEG mRNAs, levels of junD (the protein product of which has been shown to bind to the CRE-2 element) do not change with chronic haloperidol treatment. We have therefore begun an analysis of the state of Jun D phosphorylation in response to acute and chronic haloperidol treatment

# 39.12

DOPAMINERGIC REGULATION OF PREPROENKEPHALIN GENE EXPRES-SION IN STRIATAL ASTROCYTES J.DECRISTOFARA\*, G.WEISINGER, E. LAGAMMA PEDS & NEUROBIOL, SUNY STONY BROOK, NY 11794. Dopaminergic pathways regulate preproenkephalin (ppENK) gene expression in the rat striatum in vivo. Treatment with either a Dl antagonist SCH 23390 or a D2 preproenkephalin agonist quinpirole increases striatal ppENK mRNA levels. Since both primary neurons and astrocytes express ppENK RNA, we sought to determine whether dopaminergic pathways regulate ppENK mRNA in non-neuronal cells. Striatal astrocytes isolated from neonatal rats and grown in astrocytes isolated from heonatal rats and grown in culture for 2-3 weeks were then exposed to dopamine, 10-1000 uM. ppENK mRNA levels increased to a maximum of 3-fold at 100 uM. Astrocytes exposed to D1 agonist SKF38383 had a greater increase in ppENK mRNA than when exposed to D2 agonist quinpirole. The effects in culture were opposite to those seen in the intact striatum in were opposite to those seen in the intact striatum in vivo. Dl and D2 agonists given together were not synergistic. Using dopamine antagonists plus dopamine (100uM), neither Dl antagonist SCH 23390 nor D2 antagonist (sulpride or spiperone) alone or together completely blocked the effect of dopamine induced ppENK expression. These observations may be due to differences in dopamine receptor type binding specificity or may reflect activation of other dopamine receptor pathways (D3,D4,D5). Hence, ppENK mRNA is differential regulated by dopaminergic pathways in both neuronal and non-neuronal striatal cells. supported by NIH RRO5736.

TISSUE AND DEVELOPMENTAL EXPRESSION OF SLO. A CLONED DROSOPHILA CA<sup>2+</sup>-ACTIVATED K<sup>+</sup> CHANNEL GENE. Robert Brenner, Yu-Yang Yu and Nigel Alkinson\*. Dept. of Zoology, The University of Texas at Austin, Austin TX 78712-1064.

We are interested in how ion channel gene expression is regulated to generate the diverse electrical properties of excitable cells. Our focus is on the Drosophila Ca<sup>2+</sup>-activated K<sup>+</sup> channel that conducts a current called ICF. This current has been characterized in adult and larval muscles and in larval neurons. The channel has a and farvat muscles and in farvat neurons. The enannet has a relatively high single channel conductance and is sensitive to block by charybdotoxin, is not blocked by apamin and plays a major role in shaping the action potential. The Drosophila slowpoke (slo) gene encodes a structural component of this Ca<sup>2+</sup>-activated K<sup>+</sup> gene encodes a structural component of this Car factivated K channel. Slowpoke was cloned by employing the well-developed genetics of Drosophila (Atkinson et al. 1991. Science 253: 551).

Alternative mRNA splicing of slo mRNA transcripts produce a number of messages that encode distinct but related polypeptides.

We are characterizing the developmental and tissue specific expression pattern of these alternative products using *in situ* hybridization and RNA/PCR. A *slo* fusion protein has been expressed in bacteria and is being used to generate antibodies that recognize the  $\text{Ca}^{2+}$ -activated K+ channel. Antibodies will be used to characterize the polypeptide and to determine the subcellular localization of this Ca<sup>2+</sup>-activated K<sup>+</sup> channel.

### 40.3

CA2+-ACTIVATED K+ CHANNELS FROM RAT BRAIN EXPRESSED IN MAMMALIAN CELL LINES AND XENOPUS OOCYTES . P.H. Reinhart E. Shimony and F.M. Schmalz. Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710 and Dept. of Biochemistry Brandeis University, Waltham, MA 02254.

We have characterized two types of large-conductance Ca2+ activated K+ channels from rat brain cortex plasma membrane vesicles, and shown them to be modulated by protein kinases, protein phosphatases, and ATP (Chung et al., Science 253:560; Reinhart et al., J. Neurosci. 11:1627). Expression of potassium currents in *Xenopus* oocytes by injection of rat cortex mRNA has indicated that Ca<sup>2+</sup>-activated K<sup>+</sup> channels only constitute a fraction of this current (approximately 5%). The expressed channels are blocked by iberiotoxin and charybdotoxin, high affinity blockers for some Cat' activated K' channels. Size selection of the mRNA demonstrated that the message coding for this current component was larger than 5.5 kb, but the enrichment of Ca2+-activated K+ channels in this fraction was less than 2-fold. To improve the signal to noise ratio we have developed an alternative screening protocol for Ca<sup>2+</sup>-activated K<sup>+</sup>-channels expressed in mammalian cell lines. The assay is based on the binding of fluorescent toxins to channels expressed in mammalian cell-lines. Site-directed mutagenesis was used to prepare iberiotoxin and charybdotoxin mutants suitable for labelling with rhodamine. These modified toxins blocked Ca2+ activated K+ channels incorporated into planar lipid bilayers with affinities similar to wild-type toxins. Transformed COS cells, and oocytes injected with size-selected mRNA exhibited specific fluorescence signals. Cells transformed with a size-selected, uni-directional rat brain cDNA library are being screened for Ca2+-activated K+ channel expression.

CALCIUM- & PHOSPORYLATION-DEPENDENT K CHANNELS IN NERVE TERMINALS. K. Bielefeldt\* & M.B. Jackson, Dept. of Physiology, University of Wisconsin, Madison, WI 53706.

Potassium channels can modulate hormone release from the neurohypophysis. We characterized a Ca-dependent K current in the rat posterior pituitary with patch clamp techniques. Prolonged depolarizations evoked a slowly activating outward current that could be blocked by Cd. In inside-out patches, a Ca-activated K channel (conductance: 161 ± 6.2 pS) could be identified. Channel openings depend on voltage and [Ca] on the cytosolic surface: The open probability increases e-fold for each 7 mV step; an increase in cytosolic [Ca] shifts the activation curve to more negative potentials (potentials for half-activation: 73 mV, 1.7 mV, and -25.7 mV for 100 nM, 250 nM, and 500 nM Ca, respectively). The channel exhibits complex gating behavior with two distinct open and close states; voltage and [Ca] affect the open probability by decreasing the mean duration of long closures and increasing the frequency of prolonged openings. Channel activity disappears within 30 s to 5 min. This run down can be reversed by addition of MgATP to the cytosolic side. A non hydrolyzable ATP analogue (AMP-PCP) does not restore activity. Nerve endings in the posterior pituitary express a highly Ca-sensitive K channel which may be involved in the development of fatigue during high frequency stimulation. This channel is covalently modulated through phosphorylation which can be catalyzed by a closely associated kinase

#### 40.2

CHARACTERISTICS AND MODULATION OF A CLONED CALCIUM-ACTIVATED POTASSIUM CHANNEL EXPRESSED IN XENOPUS OCCYTES. K.-Z. Shen,\*A. Lagrutta, M.P. Kavanaugh, Y.-N. Wu, C.T. Bond, J.P. Adelman and R.A. North Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

A calcium-activated potassium channel was expressed in Xenopus oocytes by injection of RNA transcribed in vitro from a complementary DNA cloned from the slowpoke locus of Drosophila melanogaster. Unitary and macroscopic currents were studied in inside-out membrane patches. Channel opening required calcium ions on the cytoplasmic side, and activity increased both with depolarization and with increasing calcium concentration. The single channel conductance was 120 pS in symmetrical 120 mM potassium. This channel had a selectivity sequence of K\* > Rb\* >> Na\*, Li\* and Cs+. It was apamin- and charybdotoxin-insensitive, but blocked by TEA, which was more sensitive when applied externally ( $K_D$  0.15mM). The functional expression of  $(K_0$  0.15mM). The functional expression of calcium-activated potassium channels will allow the elucidation of structural features involved in the regulation and modulation of channel.

REGULATION OF  $Ca^{2+}$ -ACTIVATED  $K^{+}$  CHANNEL IN NERVE TERMINALS OF THE RAT NEUROHYPOPHYSIS. NEUROHYPOPHYSIS. G. Worcester Foundation and J.R. Lemos. Experimental Biology, Shrewsbury, MA 01545.

A slowly-gating, large conductance (type II)

Ca<sup>2+</sup>-activated K<sup>+</sup> channel was recorded from nerve
terminals of the rat neurohypophysis using the
patch clamp technique.

While it was not sensitive to charybdotoxin

While it was not sensitive to charybdotoxin (at up to 360 nM), this channel could be blocked (IC<sub>50</sub> = 0.2 µM) by externally applied tetrandrine, a bis-benzylisoquinoline alkaloid. Tetrandrine, however, appeared to have no effect on the Ca²+activated K+ current of pars intermedia cells, which seems to be mediated by the type I channel. Interestingly, addition of 200-400 µM ATP, but only in the presence of Mg²+, to the cytoplasmic side of inside-out patches increased the open probability of the type II channel by an average of 729%. Thus, it is possible that phosphorylation of the channel results in its upregulation.

regulation.

In conclusion: (1) tetrandrine may be a specific blocker of the type II Ca<sup>2+</sup>-activated K channel; (2) up-regulation of the type II Ca<sup>2+</sup>-activated K<sup>+</sup> channel is possibly catalyzed by a kinase closely-associated with the channel. (Supported by grants from NIH and NSF.)

MAXI K+ CHANNEL IN SINGLE ISOLATED EFFERENT NERVE TERMINALS FROM THE COCHLEA IS INHIBITED BY THE SCOR-PION VENOM CHARYBDOTOXIN AND THE AMINOGLYCOSIDE ANTIBIOTIC NEOMYCIN. Ph. Wangemann, S. Takeuchi, D.C. Marcus and D.L. Sinex. Cell Physiology Lab and Biophysics Lab, Boys Town National Research Hospital, Omaha, NE 68131

Nerve terminals belonging to the medial efferent system of the gerbil were isolated in vitro from the organ of Corti under visual control. Patch clamp recordings were made from nerve terminal membranes. In 85% of seals, 2.0 ± 0.1 (average ± SEM; 33 seals) maxi K+ channels (220 pS) were found and characterized in inside-out and outsideout patches. The open-probability ( $P_o$ ) was close to zero when on the cytosolic side (CS) the free Ca<sup>++</sup> concentration (Ca) was  $\leq$ 10<sup>-7</sup> M and when the voltage was negative on CS. There was no effect of Ca on  $P_{\rm o}$  from the extracellular side (ES). Tetraethylammonium (20 mM) and charybdotoxin (10<sup>-7</sup> M) reduced  $P_{\rm o}$  from ES but not from CS. The ototoxic aminoglycoside antibiotic neomycin (2.5\*10<sup>-5</sup> and 2.5\*10<sup>-4</sup> M in the presence of 0.7 mM Ca) inhibited the single channel current amplitude (i) at positive but not negative voltages from CS but not ES. Neomycin (2.5\*10-3 M in the presence of 0.7 Ca) inhibited i at both positive and negative voltages from CS but not ES. Neomycin had no effect on Po at positive voltages on CS. The high incidence of this maxi K+ channel suggests physiologic relevance which may include protection from noise-induced overstimulation. [Supported by NIH grants P01-DC00215-09, R29-DC01098, and R01-DC00212]

BIOTINYLATED CHARYBDOTOXIN BLOCKS CALCIUM ACTIVATED POTASSIUM CHANNELS IN FROG SACCULAR HAIR CELLS. M.M. Hagedom\* and W.M. Roberts, Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403

Most calcium channels and calcium-activated potassium [K(Ca)] channels in frog saccular hair cells occur in clusters that may correspond to presynantic active zones In search of anatomical evidence of this presynaptic localization, we have tested several biotinylated scorpion toxins for their ability to block K(Ca) currents. In low ionic strength extracellular saline (90% sucrose), addition of 100 nM biotinylated charybdotoxin (gift of Dr. K. Angelides) blocked nearly all of the K(Ca) current within 5 min. The channels remained blocked for >30 min after the toxin was removed. To rule out the possibility of blocking by an unbiotinylated contaminant, the toxin was analyzed by HPLC (C-18 column, 0.1% TFA, 5-30% acetylnitrile gradient over 50 min), which revealed two peptide fractions. Each reacted positively for biotin by an alkaline phosphatase dot-blot assay and each blocked the K(Ca) current. The entire biotinylated toxin was premixed with avidin-labeled latex microspheres (300 nM; Mol. Probes) for 8 hr, then pelleted at 13,000 x g. The supernatant and the pellet were tested separately for activity. supernatant produced no blockage whereas the pellet partially blocked the channels. We conclude that biotinylated toxin is responsible for the observed channel blockade. To localize these channel areas at the level of the light and electron microscope, we are using 1.4 nm streptavidin gold particles (Nanoprobes). When complexed with the biotinylated charybdotoxin for 4 hr, this complex shows the same physiological characteristics as uncomplexed toxin. The anatomical visualization of these channels is in progress.

This work was supported by NIH grant NS27142 and grants from the Sloan and McKnight Foundations to WMR.

A PHYLOGENETIC COMPARISON OF THREE POTASSIUM CHANNEL BINDING SITES. <u>S.E. Perschke, C.W. Bauer, K.C. Swick\*, and P.M. Sweetnam</u>. NovaScreen®, Baltimore, MD. 21224.

There are a variety of potassium channels which fulfill important functions in excitable tissues. The pharmacological value of these channels include protection from ischemia, modulation of secretory actions, smooth muscle relaxation, and antiarrhythemia. We have developed receptor binding assays for three functionally different potassium channel binding sites. The phylogenetic distributions of these potassium channel binding sites in neural tissue were determined in seven distinct vertebrates from shark to human. Binding characteristics for the radioligands, [3H]Glibenclamide (ATP dependent), [126]Japamin (Ca\*\* activated, low conductance), and [126]Charybdotoxin (Ca\*\* activated, high conductance) were determined. Receptor densities of each channel increased with species complexity ([126]Charybdotoxin B<sub>max</sub>: shark 0, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49, rat 0.8 fmoles/mg tissue; [3H]Glibenclamide B<sub>max</sub>: shark 0.49,

ANTIARRHYTHMIC DRUG ACTIONS ON A CALCIUM-ACTIVATED POTASSIUM CHANNEL IN MOTONEURONS. J.G. McLarnon\*, D. Sawyer, M. Michikawa and S.U. Kim. Dept. of Pharmacology & Therapeutics and Div. of Neurology, Dept. of Medicine, The University of British Columbia, Vancouver, B.C. V6T 123.

Previous studies in this laboratory have shown that a number of drugs, generally classified as Class III antiarrhythmic compounds, block a calcium-dependent potassium channel K(Ca) in hippocampal neurons. We have recently studied the actions of one of these agents, tedisamil, on a K(Ca) channel in mouse motoneurons. Using inside-out patches with the bath solution containing 0.2 mM Ca²+ and 140 mM K+ and the pipette solution containing 5 mM K+, a K(Ca) channel with a conductance of 100 pS was isolated. The mean open time of the K(Ca) channel, with the patch held at 0 mV, was near 15 ms. Addition of tedisamil to the bath solution (0.1-10  $\mu$  M) caused dose-dependent decreases in the channel mean open time. The mean open times were not significantly changed when the patch potential was varied. The drug action was consistent with open channel block of K(Ca) with the onward (blocking) rate constant in excess of 5 x 107 M-1s-1. These results would suggest that Class III antiarrhythmic drugs may have utility in the study and characterization of properties of K(Ca) channels in various

COCALIZATION OF POTASSIUM CHANNELS LABELLED BY [1251]-CHARYBDOTOXIN IN RAT BRAIN D. R. Gehlent S.L. Gackenheimer and D.W. Robertson Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285 and Ligand Pharmaceuticals, San Diego, CA.
The study of potassium (K) channel subtypes in neuronal function has been facilitated by the availability of specific peptide toxins. Charybdotoxin (ChTx), a 37 amino acid peptide isolated from scorpion venom, has been described as an

The study of potassium (K) channel subtypes in neuronal function has been acalitated by the availability of specific peptide toxins. Charybdotoxin (ChTx), a 37 amino acid peptide isolated from scorpion venom, has been described as an inhibitor of both Ca++-dependent and voltage-gated K channels. In rat brain homogenates, [125],ChTx has been reported in bind only to a single population of voltage-gated K channels (Vázquez et al., J. Biol. Chem. 265: 15564-71, 1990). In order to map the distribution of [125],ChTx binding sites in the rat brain, we performed a quantitative autoradiographic localization. We also compared the localization with ligands for the low conductance Ca++-activated ([125],-apamin) and ATP-sensitive ([125],-iodoglyburide) K channels.

and ATP-sensitive ([<sup>125</sup>])-iodoglyburide) K channels. [<sup>125</sup>]-ChTx bound to sections of rat forebrain with a K<sub>d</sub> of 1.1 nM and a B<sub>max</sub> of 80 fmoles/mg protein. Routine binding studies were performed at a concentration of 300 pM at which greater than 90% of the binding was specific. The highest density of binding was observed in several white matter containing regions including fasciculus retroflexus and the lateral offactory tract. High levels were seen in regions such as the paranigral nucleus, the deep layers of the superior collicular and the ventral limb of the diagonal band. This distribution was distinctly different from that seen for other K channel ligands. In the hippocampus, a high level of [<sup>125</sup>]-apamin binding was seen in the CA1 region in stratum oriens and radiatum. [<sup>125</sup>]-ChTx binding was low in these regions with a moderate amount in stratum lacunosum moleculare. [<sup>125</sup>]-iodoglyburide binding was high in the pyramidal cell layer of CA2-3 and moderate in CA1.

These results indicate the distribution of the K channel labelled by [125]-ChTx in the brain is distinctly different from that seen with other K channel ligands and suggests differing effects of K channel modulators on brain function.

CHARACTERIZATION OF APAMIN-SENSITIVE K-CHANNELS IN CULTURED RAT SKELETAL MUSCLE. S.R. Sampson\* and S.V. Alboim. Otto Meyerhoff Center and Health Sciences Research Center, Bar-llan University, Ramat Gan 52900, Israel.

K-channels, of which there are several different types, play an important role in the regulation of electrical activity of excitable tissue. Little is known, however, of the factors that regulate their expression.

K-channels, of which there are several different types, play an important role in the regulation of electrical activity of excitable tissue. Little is known, however, of the factors that regulate their expression. Here, we have reported on some basic properties of apamin-sensitive Ca<sup>2+</sup>-dependent K+channels in cultured skeletal muscle obtained from the limbs of neo-natal rat pups. In studies performed with <sup>125</sup>I-apamin on whole-cell preparations, we found that the myotubes possess a single binding site for the ligand with a K<sub>d</sub> of approximately 100 pM; the B<sub>max</sub> was found to be of the order of 50 fmol/mg protein. These values differ from those previously reported for cultured mammalian myotubes (Hughes et al., EMBO Journal, 1:1039-1042, 1982). The number of <sup>125</sup>I-apamin binding sites increases with age to reach a plateau level at 4-5 days after plating. The largest increment occurs with fusion of myoblasts into multinucleated myotubes. The number of sites remains relatively constant after fusion, and prevention of fusion with 2.7 mM EGTA results in a steady decline in number of binding sites from prefusion to nearly undetectable levels. Apamin, in concentrations up to 100 nM had no effect on the rate of resting efflux of <sup>86</sup>Rb from mature myotubes. The results are consistent with the concept that apamin sensitive Ca<sup>2+</sup>-dependent K+channels are of little importance in resting K-permeability in skeletal muscle but may be involved in generation of action potential-related changes in K-efflux. (Supported by the Krown Fund for Health Sciences Research, the Raber Fund for Neuroscience Research, and the Otto Meyerhoff Center).

LOOSE COUPLING OF (Ca); TO Ca-DEPENDENT POTASSIUM CURRENT DURING MUSCARINIC ACTIVATION. S. H. Thompson\*, Stanford University, Hopkins Marine Station, Pacific Grove, CA 93950.

Muscarinic receptor agonists initiate a complex signaling cascade in N1E-115 cells that includes Ca influx, internal Ca release, and the activation of Ca-dependent potassium channels (19-24 pS). Potassium current and (Ca); were monitored simultaneously by combining perforated-patch voltage clamp with fura-2 imaging. The Ca signal in response to carbachol peaks at about 400nM. 50% of the cells that express Ca-dependent potassium channels (determined by voltage clamp analysis of tail currents) fail to respond to the (Ca); change with an increase in current. In cells that do respond with an increase in current, the current waveform is often substantially different than the waveform of the average intracellular Ca signal. Potassium channels respond to (Ca) changes in the immediate vicinity of the membrane which allows the (Ca) change in this compartment to be measured with much greater resolution than is possible with fluorescence imaging. We can draw two conclusions from our work; 1) in some cases, the near-membrane compartment is protected from the Ca release signal, 2) in other cases, processes localized to the near-membrane modify the time course of the Ca signal in that compartment.

PROPERTIES OF THE SLOW CALCIUM-ACTIVATED K+ CURRENT IN RAT LOCUS COERULEUS NEURONS. S. S. Osmanović and S. A. Shefner. Dept. of Physiol. & Biophys., University of Illinois, College of Medicine, Chicago, IL 60612.

Trains of action potentials in locus coeruleus (LC) neurons are followed by a Ca2+ dependent post-stimulus hyperpolarization (PSH) which is composed of an early component (PSH<sub>E</sub>) and a late component (PSH<sub>L</sub>). The aim of the present study was to investigate the properties of the slow outward current underlying PSH<sub>L</sub> (i<sub>L</sub>). Intracellular recordings were made from rat LC neurons in completely submerged brain slices. The current underlying PSH was measured with single-electrode voltage clamp using the "hybrid clamp" protocol. Apamin (200 nM) or d-tubocurarine (200  $\mu$ M) were added to block the early component of the outward current tail (i<sub>E</sub>). i<sub>L</sub> reversed at -111  $\pm$  2 mV (n=5) and was reduced by decreasing external Ca<sup>2+</sup>, addition of Cd2+, or intracellular EGTA. The time course of i<sub>L</sub> could be fitted with a single exponential  $(\tau_1)$ . Values of  $\tau_L$  varied from 2.4 to 6.0 s with a mean of 4.3 s  $\pm$  0.4 s (n=12). The time course of decay of i showed a weak voltage dependency; depolarization decreased and hyperpolarization increased  $\tau_L$ . If the number of spikes in the train was kept constant, bath application of 4-AP,  $Ba^{2+}$ , or TEA prolonged action potentials and increased the size and duration of  $i_L$ . The amplitude and duration of  $i_L$  was increased by caffeine (10 mM), and decreased by ryanodine (100  $\mu$ M) and dantrolene (20 μM). it was not affected by noradrenaline (10 μM), 5-HT (100 μM), histamine (100  $\mu$ M) or adenosine (100  $\mu$ M). Superfusion of membrane permeable analogs of cAMP, 8-Br-cAMP and dibutyryl-cAMP (1 mM) did not affect i Muscarine (1-10 μM) strongly enhanced i, without affecting individual action potentials

in the train. Enhancement of  $i_L$  by muscarine was blocked by pirenzepine (1  $\mu$ M). These results suggest that  $i_L$  is a Ca<sup>2+</sup>-activated K<sup>+</sup> current with an unusually long duration, which could be partly due to the release of Ca<sup>2+</sup> from intracellular stores. Its slow time course, voltage sensitivity and distinct pharmacological properties distinguish i<sub>L</sub> from other types of Ca<sup>2+</sup>-activated K<sup>+</sup> currents in central neur Grant support: PHS AA05846-09 to S.A.S.

PROPERTIES AND ABUNDANCE OF Ca<sup>2+</sup>-ACTIVATED K+ CHANNELS IN HUMAN PERIPHERAL T LYMPHOCYTES. A. Nguyen, M. D. Cahalan \*, and S. Grissmer. Dept. Physiol. & Biophys. UC Irvine, CA 92717.

Using excised patch and whole-cell recording we have characterized properties and abundance of  $Ca^{2+}$ -activated  $K^+$  channels  $(K_{Ca})$  in resting and activated human peripheral T lymphocytes. In contrast to Jurkat leukemic T cells, we found that the most common type of K<sub>Ca</sub> channel is sensitive to block by CTX, but not by apamin. The expression of  $K_{Ca}^{-}$  channels increases dramatically as a function of activation. Freshly isolated resting CD4+CD8 (helper T cells) and CD4-CD8+ (suppressor/cytotoxic T cells) peripheral blood T lymphocytes express on the order of ten  $K_{Ca}$  channels per cell, whereas T-cell blasts activated with the mitogenic lectin PHA for more than 1-2 days express hundreds. The calcium sensitivity of the channel in T-cell blasts was determined by simultaneous fura-2 measurement of  $Ca^{2+}$  and patch-clamp measurement of  $K_{Ca}$ -channel activation. The activation is highly sensitive to the intracellular  $Ca^{2+}$  concentration,  $[Ca^{2+}]_i$ , suggesting that several  $Ca^{2+}$  must bind to the channel or an associated molecule suggesting that several  $Ca^{++}$  must bind to the channel or an associated molecule in order to open the channels. The  $Ca^{2+}$  concentration at which half of the channels are activated is 500 nM. The  $K_{Ca}$  channels show little voltage dependence over a potential range from -100 mV to 0 mV and have a unitary conductance of ~30 pS in symmetrical 170 mM K<sup>+</sup>.  $K_{Ca}$  channels are blocked by tetraethylammonium (TEA<sup>+</sup>) and charybdotoxin (CTX) with half blocking doses of 40 mM and 3 nM, respectively. Both drugs also block voltage-gated type n channels with half blocking doses for TEA<sup>+</sup> and CTX of 10 mM and 3 nM, respectively. type n channels with that blocking does not sensitive to block by noxiustoxin (NTX), 4-aminopyridine (4-AP), or Ni<sup>2+</sup> at concentrations that block type n channels in the same cells. We conclude that although  $K_{Ca}$  and type n channels in the same cells. share several similarities in ion permeation, the differences in gating mechanisms and pharmacological sensitivities indicate that the proteins are rather different. A Voltage-Dependent Calcium-Dependent Outward Current in Medial Pontine Reticular Formation Neurons of the Rat In Vitro. D.R. Stevens\*. R.W McCarley and R.W.Greene. Dept of Psychiatry, Harvard Medical School and Neurosci. Lab. VAMC, Brockton, MA 02401 USA

The primary action of NE in most medial pontine reticular formation neurons is to reduce a voltage dependent potassium conductance. Using intracellular recording methods in a brainstem slice, this conductance was examined under voltage clamp in 71 neurons. Depolarizing step commands (-70 to -40 mV) activate a time-dependent non-inactivating outward current. This current is suppressed in low calcium or high magnesium medium. Cadmium (100 µM) and barium (100 µM) also block this current and the associated tail current, as does TEA. The tail current is voltage sensitive, with decreased conductance near -70 mV. When extracellular potassium is raised to 15 mM, the tail current reverses polarity near -50 mV, consistent with a K\* conductance.

These results are consistent with the presence of a calciumdependent potassium conductance which is voltage-dependent. This current resembles I<sub>c</sub> of hippocampus but does not appear to contribute to action potential repolarization. This conductance contributes to the resting membrane potential and the interspike interval of medial pontine reticular formation neurons, resulting in an increased initial responsiveness to excitatory input as well as an increased non-adaptive repetitive firing rate

ETHANOL REDUCES MAXI-K\*CHANNEL ACTIVITY IN FROG SKIN GLANDS. B.J. Harvey, V. Urbach and J.J. McArdle\*. Lab. Jean Maetz, CEA, BP 68, F-06230 Villefranche-sur-mer, FRANCE and \*Dept. Pharmacol & Toxicol, New Jersey Medical School (UMDNJ), Newark, NJ 07103-2714, USA.

We have investigated the acute effects of a low concentration of ethanol (0.12% v/v) on the activity of charybdotoxin-sensitive, Ca<sup>2+</sup>-dependent, outward-rectifier maxi-K<sup>+</sup> channels (200 pS) recorded from basolateral membranes of gland cells in intact epithelial sheets isolated by collagenase treatment from frog skin and mounted in Ussing chambers. Channel activity was defined as the product of the maximum number of open channels (N) and open probability (Po) calculated from N.Po =  $\Sigma(n.t_n)$  where n represents the channel state, 0=closed, 1= 1 channel open etc,  $t_n$  is the duration of state n. Maxi-K+ channels were activated by adding carbachol (10  $\mu$ M) to the bath NaCl Ringer solution or by superfusing the gland cells with KCl Ringer. In cell-attached patches, ethanol reduced NPo within 5 min from 2.94  $\pm$  0.18 to 1.83  $\pm$  0.12 (n=11). The maximum inhibitory effect of alcohol was reached after 2 min. In membrane patches where  $n \le 1$  for periods of 5 min, the Po of control and alcohol states were  $0.89 \pm 0.09$  and  $0.61 \pm 0.03$  (n = 8), respectively. Mean single channel open and closed times were, respectively, in control  $108 \pm 12$  ms and  $4.9 \pm 0.3$  ms, and in ethanol 13.2±1.5 ms and 50.1±6ms. Since ethanol reduced maxi-K+ channel activity in intact gland cells but had no effect on NPo in excised inside/out patches our results are consistent with inhibition mediated by cytoplasmic factor(s). CYCLICAL POTENTIAL CHANGES RECORDED FROM RAT CENTRAL AND PERIPHERAL AXONS: A MECHANISM FOR ECTOPIC IMPULSE GENERATION R. Kapoor. K. I. Smith. P.A. Felts. and M. Davies. Enst. of Neurology, Queen Sq., London, WCIN 3BG and WLM.D.S., Guy's Campus, London, SE1 9RT.

The internodal axolemma of myelinated fibres is not usually considered

as a site for the generation of positive symptoms in neurological disorders. We have examined the possibility that the internodal axolemma may

contribute to the production of ectopic impulses.

Using micropipettes filled with KCl (0.2-3M), recordings were obtained from the dorsal columns and spinal roots of normal, anaesthetized rats. In addition to intra-axonal recordings (n=31; V<sub>rest.</sub> -56.7+/-11.6mV) action potential (AP) amp. 54.2+/-11.2mV) we also recorded APs (n=18, 42.3+/-10.9mV) in the absence of an appreciable DC potential (-4.1+/-12.7mV). In such recordings, interpreted as periaxonal, we observed cyclical negative shifts in potential (to -27.3+/-12.2mV, duration 0.1-10s) which were accompanied by a decrease in input resistance. These shifts either occurred spontaneously (0.1-5Hz), or in response to propagated APs or inward current commands. Notably, the shifts were sometimes associated with the generation of ectopic spikes. *In vitro*, similar potential shifts were inhibited by the application of TEA (2-10mM) or 4AP (1-5mM), and were absent using micropipettes filled with 3M NaCl.

The periaxonal recordings were probably made from internodal sites containing a high K<sup>+</sup> concentration, with the negative potential shifts arising from periodic increases in axolemmal K<sup>+</sup> conductance (David, et al, J. Physiol. 445:277-301, 1992): the resulting inward K<sup>+</sup> current would initiate the generation of ectopic impulses. We suggest that a high periaxonal K<sup>+</sup> concentration may similarly account for ectopic discharges in certain pathological conditions.

VARIATION IN  $I_{\rm Hr}$ ,  $I_{\rm IR}$ , AND A LEAK CURRENT BETWEEN DIFFERENT DIAMETER ACUTELY ISOLATED ADULT RAT SENSORY NEURONS. R.S. Scroggs\*\*, S.Todorovica, E.G. Andersona, and A.P. Fox\*, \*Dept. of Pharm/Phys, University of Chicago, Chicago, IL 60637. \*Dept. of Pharmacol., University of Illinois at Chicago, Chicago, IL 60612.

Inward rectifiers, leak currents and action potentials (APs) were studied in acutely isolated adult rat dorsal root ganglion (DRG) neurons. A slowly activating mixed Na<sup>+</sup>/K<sup>+</sup> current, which was inwardly rectifying, was evoked by hyperpolarizing voltage commands in large (42-54 $\mu$ m), medium  $(32-37\mu\text{m})$  and 46% of small  $(18-27\mu\text{m})$  diameter neurons held. current was selectively blocked by 1mM CsCl versus 1mM BaCl<sub>2</sub>, and thus, resembled  $I_{\rm H}$ . Neurons which expressed this slow current had short duration APs and exhibited time-dependent rectification in response to hyperpolarizing current commands, similar to A-type DRG neurons. 54% of small diameter neurons did not express the slowly activating current. These neurons had long duration APs and lacked time-dependent rectification, similar to C-type DRG neurons. The data suggest that timedependent rectification results from activation of In-

In most medium diameter neurons, hyperpolarizing voltage commands evoked a rapidly activating current which became inwardly rectifying around the K+ reversal potential (-94mV), was blocked by 100µM BaCl<sub>2</sub>, and thus, resembled I<sub>IR</sub>.

In most large diameter DRG neurons, superfusion with 100µM to 4mM BaCl<sub>2</sub>, produced an increase in inward holding current. This indicated the presence of a standing outward "leak" current in these neurons which was sensitive to blockade by BaCl<sub>2</sub>. Variation of ion current expression may be involved in shaping the electrical properties of different types of sensory neurons and the selective neuromodulation of assorted sensory modalities.

PROPERTIES OF SINGLE CHANNELS AND BACKGROUND CURRENT IN ACUTELY DEMYELINATED RAT SCIATIC NERVE. F.N. Quandt\*, Multiple Sclerosis Center and Dept. of Physiology, Rush University, Chicago, IL 60612

Clinical signs and symptoms in multiple sclerosis are caused by block of propagating action potentials due to demyelination of nerve fibers in the central nervous system. In order to determine ways by which conduction can be restored following demyelination, more specfic information is needed regarding the electrical properties of the internodal axon membrane which is exposed during demyelination. Techniques developed by Jonas et al., 1989 (toad, Proc. Natl. Acad. Sci. USA 86: 7328); and Wilson & Chiu, 1990 (rat, J. Neurosci. 10: 3263) were used to expose the axon membrane in the internode for patch clamp recording. Rat sciatic nerve was incubated in collagenase followed by protease. Fibers were then placed in Kglutamate internal solution and dissociated using a "rolling pin" made from tygon tubing. Under this condition Schwann cells retract exposing the axon membrane, but only in a minority of fibers. Recordings have been made from intact membranes, as well as those in the inside-out configuration. The pipette solution contained normal physiological saline. Membrane current from one patch can exhibit both inward Na (50 pA peak) and outward K components. More than one type of K channel appears to contribute to the outward current. One type exhibited a conductance of 50 pS and a short open time (1 ms, 0 mV, 22° C), while the other had a 50% lower conductance and a prolonged open time. The background conductance which generates current not associated with gated channels was found to increase as the membrane was depolarized. Supported by the National Multiple Sclerosis Society.

INWARD AND OUTWARD CURRENTS IN SLOW MUSCLE FIBERS OF THE CHICKEN. M. HUERTA\*., X. TRUJILLO., C. VASQUEZ AND J. LOMELI. CENTRO UNIVERSITARIO DE INVESTIGACIONES BIOMEDICAS, UNIVERSIDAD DE COLIMA. APDO. POSTAL 199, 28000: COLIMA, COL., MEXICO.

COLIMA, COL., MEXICO.
The <u>anterior latissimus dorsi</u> muscle (ALD) of the chicken posses only slow fibers. The slow muscle fibers posses the ability to generate action potentials. Patch clamp of sarcolemmal spheres from stretched muscle fibers of the ALD muscle (Stein & Palade, Am. J. Physiol, 25:434-440, 1989) are a convenient preparation to study ionic currents in slow muscle of the chicken. In the present study, macroscopic inward and outward currents were recorded using the giant excised sarcolemmal patches (Hilgemann, Pflügers Arch. 415:247-249, 1989) variation of the patch electrode voltage clamp technique. The pipete solution contained in (mM): 172 Na(qluconate); 7 Mq(qluconate); 10 Dextrose and the bath solution contained (mM): 172 Cs(gluconate). The pH was adjusted with HEPES around to 7.4. In these conditions we found an inward current. It had a mean threshold of -60 mV, it follows to a peak in about 5 ms and it declines slowly to a new stable value in about 25 ms. This current is partially blocked by TTX (1X10-6M). If we use in the bath a solution in (mM): 172 K(CH3SO3) and the pipete solution in (mM): 172 TEA(CH3SO3); 7 Mg(CH3SO3)2; 10 Dextrose, we found and outward current who activates slowly with pulses of depolarization (25 ms) and its threshold is -40 mV. The current does not show inactivation. It suggest the presence of Na+ and K+ channels.

NOVEL HYPERPOLARIZATION-ACTIVATED CURRENT MEDIATES INWARD RECTIFICATION IN CRAYFISH MUSCLE. W. Buño\*and A. Araque: Instituto Cajal, Doctor Arce 37, Mudrid Soein

The ionic current mediating inward rectification in opener muscle fibres was studied under two-electrode voltage-clamp. Hyperpolarizing pulses from -60 mV evoked an instantaneous voltage-independent current ( $I_{\rm L}$ ) followed by a time- and voltage-dependent inward current ( $I_{\rm LA}$ ). The mean reversal potential of  $I_{\rm AB}$  ( $E_{\rm AB}$ ) at an extracellular K' concentration ([K\*]<sub>e</sub>) of 5.4 mM was -61.8 mV.  $E_{\rm AB}$  shifted towards positive potentials by 50.8 mV for a tenfold increase in [K\*]<sub>e</sub>. The conductance underlying  $I_{\rm AB}$  ( $G_{\rm AB}$ ) increased sigmoidally with hyperpolarization, starting close to the resting potential, saturating at a  $G_{\rm AB}$ -m of about -140 mV and showing a mean half activation at -94.4 mV. The activation curve of  $G_{\rm AB}$  shifted 53.6 mV towards positive potentials with a tenfold increase of [K\*]<sub>e</sub>.  $G_{\rm AB}$ -med did not increase in raised [K\*]<sub>e</sub>. The activation and deactivation kinetics of  $I_{\rm AB}$  were accurately described by single exponentials (time constants <100 ms).

by single exponentials (time constants <100 ms).

1.a was not modified in: (1) Na'- and Ca'-free solutions; (2) intracellular EGTA; (3) extra or intracellular TEA; (4) extracellular Cs', Rb', Ba' or Mn'.

Low concentrations of  $Cd^{2\star}$  or  $Zn^{2\star}$  (<5 mM) strongly and reversibly reduced both  $I_L$  and  $I_{AB}.$ 

Inward rectification in crayfish muscle is generated by a voltageand time-dependent K current  $I_{AB}$  which displayed many characteristics which distinguish it from all others.

ACTIVATION OF VOLTAGE-DEPENDENT K CHANNELS, REDUCES CYCLIC AMP FORMATION IN INTACT CELLS. M.Pizzi\*, M.Memo, M.Belloni, PF. Spano. Div. Pharmacol., Toxicol., Exper. Therap.; Dept. Biom.Sci.Biotech.University of Brescia 25124 -I.

of Brescia 25124 -I.

Dopamine D-2 receptor agonists, including BHT 920 and bromocriptine, and the K channel opener minoxidil share the property to hyperpolarize the plasma membrane by activating voltage-dependent K channels. We tested the capability of these drugs to inhibit the cAMP formation induced by forskolin either in intact or in broken pituitary cells. While bromocriptine was active in both experimental conditions, BHT920 and minoxidil inhibited cAMP formation in intact but not in broken cells. The concentration-dependent response of BHT 920 showed an IC-50 value of 0.7 µM and was specifically blocked by 1-sulpiride. The effect of BHT 920 was not additive to that induced by minoxidil and less effective in the presence of K channels blockers. We suggest that BHT 920- and minoxidil-induced inhibition of cAMP formation is mediated by the activation of voltage-dependent K channels.

RAT AND GUINEA PIG VAGAL NEURONS HAVE DIFFERENT ELECTROPHYSIOLOGICAL PROPERTIES. P. Sah and E. M. McLachlan\*. Dept of Physiology and Pharmacology, University of Oueensland, Old 4072. Australia.

We have compared the electrophysiological properties of neurons in the dorsal motor nucleus of the vagus(dmv) in rats and guinea pigs in transverse slices of brainstem maintained in vitro. Minor differences in the passive electrical properties of neurons between the species were consistent with the slightly larger dimensions of the guinea pig neurons revealed by intracellular injection of biocytin. However, action potentials in the guinea pig had a faster rate of rise, larger amplitudes and longer durations. In guinea pig neurons, two Ca-activated K currents were activated following calcium influx during the action potential (Neuron,7,257). These two currents accounted for the full duration of the afterhyperpolarization (AHP). In rat neurons an AHP of similar duration resulted in the absence of the second Ca-activated K current; instead the early apamin-sensitive current activated a transient voltage dependent K current (\tau-400ms). These differences meant that in response to a step of depolarizing current, neurones in the guinea pig only discharged once or twice and then ceased firing. In rat neurones, this manoeuvre produced repetitive firing. In guinea pig neurons hyperpolarization of the cell beyond -60mV activated an inward current which could be blocked by Cs but not by Ba. This current was always much smaller in rat neurons. We conclude that, despite many similarities of size and electrical properties, DMV neurones in the two species differ in terms of several voltage and calcium dependent conductances which determine their active electrical behaviour.

SINGLE CHANNELS IN STOMATOGASTRIC NEURONS IN CULTURE. W. D. Krenz and F. Nagy. LNPC, Univ. Bordeaux I, CNRS, 33120 Arcachon, France (SPON: European Neuroscience Association).

We have studied two membrane currents, a fast transient (IA) and a Ca2+dependent ( $I_{O,C}$ ) outward current in neurons from the stomatogastric ganglion (STG) of adult crabs (*Cancer pagurus*) in primary culture. Both have been shown previously to be present in STG neurons in situ and are supposed to be of importance in the generation and regulation of oscillatory discharge patterns. Single channel currents were measured in the cell-attached and inside-out natch configuration (Hamill et al., 1981: Pflügers Archiv 391) on cell bodies and growing neurites. In general the channel density was low. A voltage-dependent, transiently activated channel with voltage-dependent inactivation similar to that of IA K current was identified in few patches only. In cell-attached mode and with a physiological K<sup>+</sup> gradient its conductance was ~17 pS. Ca<sup>2+</sup>-dependent channels were more abundant in membrane patches on the cell body as well as on neurites and growth cone veils. Their voltage dependence and sensitivity to  ${\rm Ca^{2+}}$  at the intracellular membrane surface was similar to that of  ${\rm I_{K,C}}$  described in many other systems. In cell-attached mode and with physiological concernation gradients for K<sup>+</sup> and Ca<sup>2+</sup> ions the single channel slope conductance of the linear region of the iV-plot was ~130 pS. During oxotremorine-induced membrane potential oscillations the single channel current changed in parallel with the membrane potential due to the cyclic changes in the driving force for the K+ ion. In addition the open probability increased during the depolarized phase of the oscillation and in some cases additional channels were recruited, suggesting the influx of  ${\rm Ca}^{2+}$  during the oscillations. In some patches small amplitude low conductance channels were found that may represent the channel of the Hodgkin-Huxley type delayed rectifier current. The functional implications of these results will be discussed.

VOLTAGE DEPENDENT GATING OF A SODIUM-ACTIVATED POTASSIUM CHANNEL FROM MAMMALIAN BRAIN. M. Esguerra\* and I.B. Levitan. Graduate Dept. of Biochemistry & Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Intracellular sodium activates a large-conductance (~170pS) potassium  $(K_{Na})$  channel in neurons cultured from the rat brain (Egan et al., 1992, J. Neurosci., in press). As part of ongoing studies of this channel's modulation, we recorded  $K_{Na}$  channel activity in inside-out patches excised from cultured rat olfactory bulb neurons and determined kinetic rate constants for channel openings and closures under varying levels of [Na+]; (0-150mM) and transmembrane voltage (+60 to -100 mV, inside negative). As reported previously, the open probability  $(Np_o)$  of  $K_{Na}$  channels increased with depolarization at all sodium concentrations (n=6). In the hyperpolarized range of membrane voltages, further hyperpolarization by about 30 mV induced up to 5-fold increases in mean open time duration (n=7), particularly under conditions of low [Na+];. These changes were associated with a decrease in the frequency of shortduration closures within bursts of channel activity. These results suggest that membrane voltage modulates the sensitivity of  $K_{Na}$ channels to internal sodium concentration. A similar mechanism has been shown to confer voltage sensitivity on  $K_{Ca}$  channels; this functional similarity between  $K_{Ca}$  and  $K_{Na}$  channels supports the hypothesis that ion-gated potassium channels comprise a family of related membrane proteins.

THE MINK POTASSIUM CHANNEL IS INWARDLY RECTIFYING. E. M. Blumenthal\* and L. K. Kaczmarek Interdepartmental Neuroscience Program, Yale Univ. Sch. of Med., New Haven, CT 06510.

The minK protein produces a very slowly activating voltage-dependent potassium current when expressed in Xenopus laevis oocytes. This protein is profoundly different from other cloned potassium channels, both in its small size (130 amino acids) and the slow kinetics of the expressed current. We used the oocyte expression system to study the current-voltage relationship of the minK channel.

Because single minK channels have not yet been seen, we studied the instantaneous changes in the active current in response to voltage jumps. This procedure should yield the single channel I-V relationship. We found that minK is strongly inwardly rectifying. In 2mM external potassium, steps from -60mV to between -20mV and 60mV showed the current saturating with increasing driving force. In addition, comparison of tail currents in 2mM and 113mM external potassium showed that the inward slope conductance is 6.3-fold higher than the outward slope conductance. No other cloned potassium channel is known to exhibit this property. MinK promises to be an excellent system for studying the structural basis for rectification.

OVEREXPRESSION OF A NEW CLASS OF K' CHANNEL ABOLISHES THE SPONTANEOUS BURSTING ACTIVITY IN APLYSIA NEURON R15. B. Zhao\*, B.-K. Kaang, E. R. Kandel, and Tai Kubo. Ctr. Neurobiol. & Behav., Columbia P&S, and HHMI, NY, NY 10032.

Potassium channels make important contributions to the control of the membrane excitability and firing pattern in neurons. The ability to express various cloned Aplysia K 'channels in identified Aplysia neurons has allowed us to analyze the relative contributions of specific K 'channels to different aspects of the behavior of individual identified cells. By examining the H5 region, the putative pore-forming region, in several cloned Aplysia K 'channels, a remarkable conservation in codon usage was found at several potentially highly degenerate positions. Using this region-specific codon usage, we designed oligonucleotide probes based on the H5 region and scceeded in cloning two new K\* channels (AK04 and AK05). Each seems to represent a new class of K\* channel. We here describe AK05 When expressed in *Xenopus* oocytes this current showed no inactivation even with long depolarizing pulses. We therefore subcloned AK05 into pNEX, a neuronal expression vector and expressed AK05 in the bursting Aplysia neuron R15. Twenty-four hours after microinjection of AK05 into R15 a non-inactivating K\* current of about 2-3 µA developed. This current completely eliminated the spontaneous bursting activity of neuron R15, so that the cell became silent. This is in marked contrast to the effects we see in the same cell (R15) with AK01a overexpression. AK01a is a transient current that mainly affected the duration and afterhyperpolarization of action potentials. This suggests that by using overexpression of different channels one can selectively redesign the different components of electrical excitability in neurons

SODIUM-ACTIVATED POTASSIUM CHANNEL OF AVIAN NEURONS: SUBCONDUCTANCE LEVELS AND GATING PROPERTIES STUDIED BY A NOVEL ANALYSIS PROCEDURE.

ROPER HES STUDIED BY A NOVEL ANALYSIS PROCEDURE.

R. Fesce and C. Haimann (Spon: European Neuroscience Association)

"B. Ceccarelli" and CNR Cytopharmacol. Centers, Scient. Inst. San Raffaele, Dept. of Pharmacology, Univ. of Milano, 20129 Italy.

Sodium-activated potassium channels (K<sub>Na</sub>) in neurons and heart are characterized by a main open channel conductance varying from 100 to 210 pS, in the different preparations, and by frequent transitions to other conductance levels or substates. This behaviour seems not to depend an Net generatories preparation. depend on Na<sup>+</sup> concentration near the plasmalemma (Na<sub>i</sub>), and it has been suggested to arise from conformational changes of a single pore channel.  $K_{Na}$  openings occur in bursts, and previous data from open time distributions indicate that  $Na_i$  promotes the opening of the channel but has little influence on the durations of individual openings.

In order to investigate the mechanisms of the action of Na<sub>i</sub>, and of

In order to investigate the mechanisms of the action of  $Na_i$ , and of other ions affecting neuronal  $K_{Na}$ , we developed a novel procedure to identify subconductance levels and to determine their gating properties. The procedure is based on the detection of minima in the signal variance for identification of conductance levels (Patlak, J. Gen. Physiol. 92, 413, 1988) and on automated analysis of the transitions between levels. The analysis gave consistent and reliable estimate of the number of substates (at least five), of the corresponding conductances, dwell times, and probability of exiting towards each other level other level.

Our data confirm that  $Na_i$  mainly affects the kinetics of closed states and help defining a kinetic model for neuronal  $K_{Na}$  channel to study the mode of action of blockers and modulators.

EXPRESSION AND MODULATION OF THE Kv1.5 POTASSIUM CHANNEL IN A RAT ANTERIOR PITUITARY CELL LINE. D. Saal, S. Chung and L.K. Kaczmarek\*, Interdepartmental Neuroscience Program and Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The rat anterior pituitary cell line, GH4, has been shown to have both A-type and delayed rectifier voltage-gated potassium channels. The cells express mRNA for the Shaker -like potassium channel Kv1.5. It has previously been shown that the steroid hormone dexamethesone increases the level of the steroid normone dexametnessone increases the level of Kv1.5 mRNA, as well as the magnitude of the A-type current, in GH4 cells. We now have found that the delayed rectifier current is also increased by dexamethesone. In addition, we have used the PGEX system to generate a glutathione S nave used the FOEL system to generate a guitatinous Stransferase - fusion protein that contains the N-terminal 165 amino acids of Kv1.5. Using antibodies raised against this fusion protein, immunoflorescent staining has been detected in GH4 cells as well as Kv1.5 transfected fibroblasts. By using florescence activated cell sorting, we have demonstrated that the Kv1.5 protein level is also changed by dexamethasone. In ongoing experiments we are attempting to determine whether the Kv1.5 protein contributes to the A type or delayed rectifier current by applying antisense oligonucleotides to the cells to block translation of the Kv1.5 mRNA.

PROTEIN KINASE MODULATION OF APLYSIA POTASSIUM CHANNEL ACTIVITY EXPRESSED FROM A CLONED CONA AND ITS PHOSPHORYLATION SITE MUTANTS. T. Kubo\* and Y. Furukawa. Ctr. for Neurobiology & Behavior, Columbia P&S, New York, NY 10032; Hiroshima Univ. Integrated Arts & Sciences, Hiroshima, 730 Japan.

Ion channels are known targets for protein kinases, and the modulation of channel activities by phosphorylation is thought to be critical for controlling many aspects of neuronal activity. To explore the molecular basis of ion channel modulation, we have started to examine the effects of kinase activators on the current expressed by cloned *Aplysia* K\* channel (AK01a, a homologue of *Drosophila Shaker* channel). This channel produces a fast Aplysia neurons (B.-K. Kaang et al., PNAS, 89:1133, 1992). Application to oocytes expressing AK01a of protein kinase C (PKC) activators, β-phorbol 12-myristate 13-acetate (PMA), phorbol-12, 13-dibutyrate (PDBU), or 1-oleoyl-2-acetyl-sn-glycerol (OAG) increases the inactivation time constant of the current, and the total charge movement through the channels.  $I_{Adepol}$ , which was identified as corresponding to the AK01 in native current in Aplysia neurons, was also modulated similarly by PMA. Inactive phorbol ester produced no change. The primary structure of AK01a contains three putative PKC phosphorylation sites and one putative cAMP-dependent protein kinase phosphorylation site. We now are examining mutants in these phosphorylation sites to determine how these residues contribute to

EXPRESSION OF SHAKER FAMILY K<sup>+</sup> CHANNEL mRNA IN THE SPINY LOBSTER, PANULIRUS INTERRUPTUS. D.J. Baro\*, C. Cole, M. Tapia, A. Zarrin, A. Chen, T.R. Podleski and R.M. Harris-Warrick. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

We are investigating the role of intrinsic neuronal properties in the generation of the pyloric motor pattern in the spiny lobster, Panulirus Interruptus. The transient K+ current (I<sub>A</sub>) helps regulate the firing phases of the pyloric neurons and is expressed differentially in these neurons. We are extending the exploration of I<sub>A</sub> to the molecular level in order to eventually quantitate the expression of the I<sub>A</sub> channel gene(s) and manipulate the expression of I<sub>A</sub> in the individual neurons of the pyloric central pattern generator. We used an RNA PCR-based approach to determine which members of the Shaker family of K+channels are expressed in the spiny lobster. Thus far we have isolated portions of the lobster Shaker, Shab, Shaw and Shal genes. Each gene shows a very high degree of homology to its Drosophila homologue. Limited regions within the conserved core of the proteins display between 82% and 100% amino acid identity to the Drosophila homologue, and 74-80% identity at the nucleotide level. Not surprisingly, the PCR data indicate the existence of only one gene in each of the Shaker subfamilies, as opposed to the multiple genes found in the subfamilies of higher vertebrates. We are now in the process of isolating complete open reading frames for each gene using a PCR-based approach as well as the more conventional screening of cDNA libraries. Supported by NIH grant NS25915.

DRK1 mRNA IS INDUCED BY NGF IN RAT PHEOCHROMOCYTOMA PC12 CELLS. B. Rudy\*. D. Lau, J.W. Lin, J. Pollack, and C. Kentros; Dept. Physiology and Biophysics and Dept. of Biochemistry, NYU School of Medicine, NY NY 10016

The DRK1 gene encodes transcripts which express voltage-dependent delayed rectifier type K currents which activate relatively slowly and are resistant to TEA and CTX. Rat pheochromocytoma PC12 cells express several Sh transcripts, including DRK1. Northern blot analysis of RNA isolated from PC12 cells at various time points following NGF stimulation reveals NGF-mediated induction of transcripts of the DRK1 gene. The levels of DRK1 transcripts have also been found to increase markedly following denervation of rat skeletal muscle (Trimmer et al, 1990 Soc. Neurosci. Abst. 16,3). Analysis of patch-clamp recordings reveals a current in PC12 cells (I<sub>TEA-CTXP</sub>) which has electrophysiological and pharmacological properties quite similar to those of channels formed by injection of DRK1 cRNA into Xenopus oocytes. I<sub>TEA-CTXP</sub> is also induced by NGF in a manner that is temporally consistent with the hypothesis that proteins encoded by the DRK1 gene are a major component of this channel in situ. When hybridized to Northern blots of PC12 cell mRNA, DRK1-specific probes label three bands approximately 4.3kB, 9kB, and 10kB in length. Interestingly, only the 10kB band is significantly induced by treatment with NGF. Experiments investigating the possible nature of this seemingly transcript-specific induction will be discussed.

IDENTIFICATION OF A K\* CHANNEL SUBFAMILY SPECIFIC OLIGOMER-IZATION DOMAIN. N.V. Shen\* and P.J. Pfaffinger. Div. of Neuroscience, BCM, Houston, TX 77030.

We are investigating how K\* channel subunit proteins form the set of ion channels made by particular neurons. The great diversity of identified K\* channel subunit proteins poses a critical problem in understanding how the electrical properties of neurons are determined, yet little is known about how specific K\* channels are formed. Our work focuses on the analysis of K\* channel subunit proteins synthesized in vitro from the Aplysia Shaker cDNA AK01a. In this system, K\* channel subunit proteins are synthesized into membranes and form spontaneous oligomers with an apparent N of 4 (Pfaffinger and Chen, 1992). We have now analyzed nine C-terminal truncation constructs, covering the entire AK01a channel protein, in this expression system. All proteins extending past the S1 putative transmembrane domain were incorporated into the mem branes. We have identified two glycosylated sites located between S1 and S2 We also tested if these constructs could associate into oligomers of wild-type K\* channel subunit proteins. The nine truncation constructs were made with a novel epitope fused at the C-terminus (Tag 1). The Tag 1 truncation mutants were co-translated with the wild-type AK01a, which lacks a Tag 1 site, and with a *shaw* subfamily cDNA, AK20. To test for oligomerization, we attempted to coimmunoprecipitate the wild-type, non-tagged channel proteins, with the anti-Tag 1 antiserum after solubilization in CHAPS. Most of the truncation mutants co-immunoprecipitated wild-type AK01a protein with high efficiency; only the shortest protein, lacking a conserved N-terminal domain failed to do so. AK20 protein, however, does not co-immunoprecipitate in these assays. These results indicate that an important domain for K\* channel subunit protein oligomerization is located in this conserved N-terminal domain and is subfamily-specific. Supported by NIH-NINDS training grant T32NS07352

ANALYSIS OF PRODUCTS OF TWO GENES ENCODING HIGH-VOLTAGE ACTIVATING, TEA-SENSITIVE, A-TYPE K \*\* CURRENTS. E. Vega-Saenz de Miera . H. Moreno, K. Sen, D. Lau and B. Rudy. Dept. of Physiology and Biophysics and Dept. of Biochemistry, New York University Medical Center. 550 First Avenue. New York, N. Y. 10016

Recently we and others cloned several cDNAs encoding voltage-gated K channels that are distantly related to the Drosophila Shaw gene: KShIIIA, NGK2-KV4, KShIIIC-Raw3 and KSHIIID. Products of the last two genes encode transcripts that express in Xenopus oocytes high-voltage activating, TEA-sensitive, transient K<sup>+</sup> currents. Both KShIIIC and KShIIID differ from currents. Both KShIIIC and KShIIID differ from sensitive, transferr & currents. Both Ashirite and Ashiri inserts have a similar cysteine-containing sequence near the amino end. In Raw3 this sequence has been suggested to be involved in the modulation of inactivation by oxidation (Ruppersberg et al, 1991, *Nature* 352,711). Both channels have the same voltage dependence of inactivation but the midpoint of the steady state As a result of this difference KShIIID channels conduct in the steady-state over a much broader window of potentials. In addition, the inactivation of KShIIID channels proceeds with significantly slower kinetics than that of KShIIIC. Based on analysis of heteromultimers and chimeras we conclude that the different amino terminal inserts determine the observed differences in inactivation. Inactivation from the closed state appears more significant for these channels than for inactivating Shaker channels. In the case of KShIIIC and KShIIID there is a correlation between inactivation rate and the voltage-dependence of steady-state inactivation. ShIII proteins expressing noninactivating channels may be components of inactivating channels when forming heteromultimers with KShIIIC or KShIIID. In situ hybridization studies exploring whether these transcripts are expressed in the same cells will be shown.

### 41.18

EXPRESSION AND PURIFICATION OF A RAT BRAIN DELAYED RECTIFIER POTASSIUM CHANNEL (Kv2.1) IN Sf9 INSECT CELLS. F.A. Sorondt, M. Ladnert, A.E. Lacerda, A.M. Brownt\*. Depts. of Molecular Physiology & Biophysics and †Neuroscience, Baylor College of Medicine, Houston, TX 77030, and ‡Chiron Corp., Emeryville, CA 94608.

The Kv2.1 channel has been expressed in Sf9 insect cells using a tagged construct subcloned into the baculovirus expression vector. The tag is an eight amino acid peptide (KT3) engineered on the carboxy terminus of the protein. Tagged and untagged constructs expressed similar currents. Whole cell recordings from the Sf9 cells have demonstrated that the tag does not alter the electrophysiological properties of the channel. The current densities were more than 60 pA/pF. Antibodies against the tag were used to purify the expressed protein from the transfected SF9 cell membranes using affinity chromatography. The purification of the channel protein has been confirmed using Western blots. Work is presently under way to analyze the channel properties of the expressed protein.

N- AND C-TERMINAL CYTOPLASMIC DOMAINS ALTER A PARTICULARLY SLOW INACTIVATION OF THE NGK2 (Kv3.1) CHANNEL. T. Kawamura: #, S. Yokoyama, J. Yamashita # and H. Higashida\*Departments of Biophysics and #Neurosurgery, Kanazawa Univ. Sch. of Med., Kanazawa 920, Japan.

In voltage-dependent potassium channels, N- and C-terminal domains have effects on various types of inactivaton. The Shaw-related voltage-dependent potassium channel, NGK2 (Kv3.1), exhibits a particularly slow inactivation during several seconds (Ito et al., Proc. R. Soc. B., in press, 1992). This type of inactivation has been also identified in NG108-15 cells, mouse neuroblastoma cells and rat hippocampal neurons. To determine whether N- and/or C-terminal cytoplasmic domains of the NGK2 channel alter this slow inactivation, we made deletion mutants in either or both of N- and C-terminal cytoplasmic domains. We also constructed the chimeric potassium channel formed by replacing C-teminal region of the NGK1 (Kv1.2) channel, which belongs to the Shaker-related subfamily, with that of the NGK2. These mutant channels were expressed stably in B82 mouse fibroblast cells. and analyzed using discontinuous whole-cell voltage clamp technique. We found that the slow inactivation was removed in all of the deletion mutant channels tested. Furthermore, the chimeric channel did not show the NGK2-specific inactivation. But the steady-state activation curves of the mutant channels were nearly same as that of intact NGK2 channels. These results suggest that both of the N- and C-terminal cytoplasmic domains may play an important role in the slow inactivation of the NGK2 channel

REGULATION OF NEURONAL VOLTAGE-DEPENDENT K\* CHANNELS BY CAMP-DEPENDENT PROTEIN KINASE: STUDIES WITH FIBROBLAST CELLS STABLY TRANSFECTED WITH KV1.2 K\* CHANNEL cDNA. T.R. Werkman\* 1. T. Kawamura\* S. Yokoyama\* H. Higashida\* and M.A. Rogawski. ¹ Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892, and ² Neuroinformation Research Institute, Kanazawa University, Kanazawa 920, Janan

In CL1023 fibroblast cells stably transfected with Kv1.2 cDNA, K<sup>+</sup> currents with delayed rectifying properties were recorded using the whole-cell recording technique. The expressed channel protein has a stretch of amino-acids (putatively located intracellularly) which could be a potential phosphorylation site (McKinnon, *J. Biol. Chem.* **264**: 8230, 1989). We therefore investigated whether one or more protein kinases are involved in the regulation of this K<sup>+</sup> channel. In recordings with the perforated patch method (Amphotericin B as pore forming agent), application of 1 mM dibutyryl-cAMP caused ~20% increase in the K<sup>+</sup> current. Smaller effects (<10% enhancement) were observed when the K<sup>+</sup> currents were recorded with the normal whole-cell technique which allows the intracellular contents to be exchanged with the electrode solution. However, the larger potentiation was retained when cAMP-dependent protein kinase (PKA) was included in the intracellular perfusion solution. With both the whole-cell and perforated patch techniques no significant effects of dibutyryl-cGMP (1 mM) or the protein kinase C activator phorbol 12-myristate 13-acetate (TPA) (100 nM) were observed. In addition, dibutyryl-cgMP had no effect on the K<sup>+</sup> currents in cells intracellularly perfused with cGMP-dependent protein kinase. We conclude that PKA is a likely candidate as a regulator of the Kv1.2 channel protein.

### 41.23

EVOLUTIONARY RELATIONSHIPS WITHIN THE POTASSIUM CHANNEL MULTIGENE FAMILY.

Michael Strong\* and George A. Gutman. Departments of Physiology and Biophysics and Microbiology and Molecular Genetics, University of California, Irvine. CA 92717.

Ion transport across the lipid membrane was probably of critical importance for primordial cells in volume regulation and control of cellular processes. We have previously analyzed the molecular evolution of members of the ion channel multigene superfamily including Na<sup>+</sup>, Ca<sup>++</sup>, K<sup>+</sup> and cyclic nucleotide gated channels (M. Strong, K.G. Chandy and G.A. Gutman, submitted). We have aligned sequences manually and with the help of algorithms such as Clustal and Macaw, and have used several phylogenetic tree reconstruction methods including maximum and weighted parsimony, maximum likelihood and neighbor joining, to more confidently estimate the correct tree. Here we report the addition of new gene sequences to the K<sup>+</sup> channel phylogenetic tree. A branching order was found using a tree computed from nucleotide sequences whereby the rat K13 gene branches off of the Shab/DRK1 node followed by the branching order which makes neighbors of Shab/Shaw and Shake/Shal. Furthermore, an amino acid alignment which compares widely diverged K<sup>+</sup> channel sequences (courtesy of R. Guy; Science 254: 730) shows that the cAMP and cGMP gated channels cluster strongly with eag, slo and Shal, and, more weakly with Shaker, Shaw and Shab which progressively branch off of this tree. This tree can not be confidently rooted at present due to the lack of gene sequences from more distantly related organisms. Thus we are left to speculate on the rooted branching order of the gene family using voltage clamp data from organisms such as jellyfish, Paramecium, Saccharomyces, plants, and E. coli.

HOST-DEPENDENT SHAKER cDNA EXPRESSION IN CULTURED DROSO-PHILA "GIANT" NEURONS BY GERMLINE TRANSFORMATION. M.-L. Zhao, E. Sable<sup>1</sup>, M. Saito. C.-F. Wu and L. Iverson<sup>1</sup> Dept. of Biol., Univ. of Iowa, Iowa City, IA 52242 and <sup>1</sup>Div. Neurosci., Beckman Res. Inst., Duarte, CA 91010

Alternative splicing of *Drosophila Shaker* gene transcripts generates a number of functionally distinct K\* channel subunits that can interact to form both homo- and heteromeric K\* channels in *Xenopus* oocytes. How distinct K\* channels assemble in the fly is unknown. In neurons, voltage-dependent A-type K\* channels may assemble from a single *Sh* subunit type, from multiple *Sh* subunits. Or from the products of other loci, alone, or in combination with *Sh* subunits. Allele-specific differences, suggestive of heteromeric assembly, have been observed: *Sh\*No120* and *Sh\** mutations show similar hyperexcitability at the neuromuscular junction, but voltage-clamp studies reveal different K\* channel defects in muscle (*Sh\*M* eliminates 1, while *Sh\*No120* reduces it). The *Sh\*M* mutation results from an insertion in the constant region of the gene, while *Sh\*No120* is apparently a point mutation at an undetermined site. We have investigated the functional expression of *Sh\*120* + cDNA is driven by the *hsp70* promoter. K\* currents expressed in cultured embryonic "giant" neurons from several, independently derived, transformed lines have been studied by whole-cell patch-clamp recordings at different times following heat shock. All transformed lines express a "neat-induced" current that is characterized by a higher sensitivity to 4-AP than the "native" A current in the same neuron, and a slower rate of recovery from inactivation than either the "native" *Sh* K\* current or the current expressed from *Sh* 29-4 mRNA in *Xenopus* cocytes. This component shows similar inactivation kinetics in all lines, but is about 3 times greater in amplitude, and slightly more sensitive to 4-AP, in *Sh\*No120* than in *Sh\*Nosts*. Our results indicate that expression of *Sh* 29-4 cDNA in *Drosophila* neurons may be independent of the insertion site but is clearly dependent on the mutant background. The mechanism by which different host backgrounds influence the expression of individual *Sh* subunits is unknown, and the possibility that

### 41.24

MOLECULAR COMPONENTS OF LOW-VOLTAGE-ACTIVATING A CURRENTS. P. Serodio , E. Vega-Saenz de Miera. D. Lau, and B. Rudy; Dept. Physiology and Biophysics and Dept.of Biochemistry, NYU Med. Ctr., NY. 10016

Transient K currents which activate and inactivate at voltages near the threshold for Na action potential generation [low-voltage activating A-currents or  ${}^1A_{\{LV\}}$ ] are widespread in mammalian neurons, where they play an important role in modulating spike frequency as well as delaying the initiation of bursts of action potentials. Several mammalian cDNA's have been identified that express transient A-type currents: RCK4, KShIIIC and KShIIID, and the mammalian homologues of the Drosophila Shal gene. We will present companisons of the currents expressed by these cDNAs in Xenopus oocytes and neuronal  ${}^1A_{\{LV\}}$ . KSIIIC and KShIIID are not likely to be components of  ${}^1A_{\{LV\}}$  because they express channels which activate at very positive potentials and are very sensitive to TEA. RCK4 and, in particular, mammalian Shals may be components of some  ${}^1A_{\{LV\}}$ ; they express currents with voltage-dependence, kinetics and pharmacology similar to some  ${}^1A_{\{LV\}}$ . Furthermore, the time constants of inactivation of the currents expressed by known mammalian Shals  ${}^1A_{\{LV\}}$  are not voltage-dependent as is the case for many  ${}^1A_{\{LV\}}$ . However,  ${}^1A_{\{hal\}}$  are not voltage-dependent as is the case for many  ${}^1A_{\{LV\}}$  burthermore, which has a prolonged slow component of inactivation and recover from inactivation extremely slowly, unlike  ${}^1A_{\{LV\}}$  in many neurons. Xenopus oocytes injected with rat whole brain poly-A RNA, express a fast recovering  ${}^1A_{\{LV\}}$ , which lacks this very slow phase of inactivation. This current is the result of a not yet understood combination of components some of which can be separated by sucrose-gradient fractionation. Antisense hybrid arrest experiments exploring the role of Shal proteins in the  ${}^1A_{\{LV\}}$  channels seen with whole rat brain mRNA, and experiments aimed at reconstituting this  ${}^1A_{\{LV\}}$  will be presented.

# ACETYLCHOLINE: NEURONAL NICOTINIC RECEPTORS I

# 42.1

PHARMACOLOGICAL CHARACTERIZATION OF NICOTINIC ACETYLCHOLINE RECEPTORS IN THE MEDIAL HABENULA NUCLEUS OF THE RAT. IN VITRO.

NUCLEUS OF THE RAT, IN VITRO.

S.K. Norris, G.N. Woodruff and P. Boden.\*
Parke-Davis Neuroscience Research Centre,
Addenbrookes Hospital Site, Hills Road,
Cambridge CB2 2QB, U.K.
Previous studies have demonstrated nicotinic

Previous studies have demonstrated nicotinic acetylcholine receptors in the rat medial habenula (MHb) nucleus. We have investigated the pharmacology of the nicotinic response in intact MHb neurones using extracellular recordings. 350µm slices of rat brain were cut and recordings were made from single neurones using conventional electrophysiological techniques.

Carbamyl choline (carbachol) excited all MHb neurones recorded from with an increase in firing rate that was rapid in onset and dose dependent. The cholinergic response was blocked by the nicotinic antagonists hexamethonium and mecamylamine while the muscarinic antagonists atropine and pirenzepine were ineffective. In addition, an excitatory response was evoked by low concentrations of the ganglionic agonists nicotine, cytisine and 1,1-Dimethyl-4-phenylpiperazinium iodide.

# 42.2

FUNCTIONAL PRESYNAPTIC NICOTINIC RECEPTORS ON SYNAPTIC TERMINALS ATTACHED TO ACUTELY ISOLATED CENTRAL MEUROMS. C. Mulle and Jean-Pierre Changeux Lab. Neurobiologie Moléculaire, Institut Pasteur, 25 rue du Dr Roux, Paris, 26015

Presynaptic nicotinic receptors (nAChR) are thought to play an important role in the central nervous system by regulating transmitter release, but the mechanism of action of these receptors is far from established. We show that the action of presynaptic nAChR can be studied on a preparation of acutely isolated neurons that have retained synaptic terminals attached to their cell body. Neurons of rat interpeduncular nucleus were dissociated by mild enzymatic treatment and gentle mechanical dissociation in a medium containing a low concentration of calcium (0.2 to 0.5mM) and used on the same day. The presence of synaptic boutons on these isolated neurons was assessed by the presence of clusters of synaptophysin immunoreactivity. Furthemore, in whole-cell patch-clamp experiments, we frequently observed spontaneous synaptic currents. In part of these neurons, nicotine, acetylcholine and cytisine at concentrations of 10-30µM not only activated a typical postsynaptic cationic current but also elicited a rapid and massive increase in the frequency of synaptic currents which were GABAerqic since they were blocked by bicuculline (10µM). Due to rectification, the postsynaptic nicotinic current was not observed at positive membrane potentials while the presynaptic effect persisted. This effect could be blocked by d-tubocurarine (10µM) and mecamylamine (10µM). Presynaptic action of nicotine required the presence of calcium in the external medium. These experiments should help to better understand the mechanism of action of presynaptic nAChR.

RELATIVE SELECTIVITY OF AGONISTS FOR BRAIN PRE-SYNAPTIC AND GANGLIONIC NICOTINIC RECEPTORS. J. GORDON, J. Blosser\*, S. McCreedy and R. Simmons. Fisons Pharmaceuticals. Rochester. NY 14623.

Gordon, J. Blosser\*, S. McCreedy and R. Simmons. Fisons Pharmaceuticals, Rochester, NY 14623. Multiple nicotinic receptors (nAchrs), composed of  $\alpha$  and  $\beta$  subunits, exist in the central nervous system (CNS). Since the biological function and pharmacology of these subtypes are poorly defined, the potencies of 7 nicotinic agonists for 2 neuronal nAchrs were compared. Rb flux into nerve growth factor-treated PC12 cells was used to measure ganglionic nAchr agonist activity. [H]Dopamine (DA) release from superfused rat striatal slices was used as a measure of a presynaptic CNS nAchr function. Potencies: striatal assay [cytisine(CY] = azetidine(AZ) > nicotine(N) = methylcarbachol(M) > dimethylphenylpiperazinium(D) 2 carbachol(C) 2 acetylcholine(A)]; PC12 assay [CYEA 2 D>NEAZ>MeC]. The rank order of  $A_{\rm SO}$  (PC12)/ $A_{\rm SO}$  (striatal) ratios was  $AZ \ge CY \ge M > N \ge O$  (range 1-100). The  $A_{\rm SO}$  values from striatal (r=.8), but not from PC12 assays (r=.3), correlated with K, values for [H]nicotine binding to rat brain membranes. These results suggest that 1) the presynaptic striatal and ganglionic nAchrs have distinct pharmacological profiles and 2) the agonist profile at the latter receptor is consistent with that of the \$a482\$ subtype.

### 42.5

TRIMETHAPHAN ACTS AS AN AGONIST AT THE INHIBITORY NICOTINIC RECEPTOR ON RAT DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS. E.M. Sorenson' and J.P. Gallagher. Dept. of Pharm. and Tox., Univ. of Texas Med. Br., Galveston, TX 77555.

This laboratory has previously shown that the nicotinic agonists dimethylphenylpiperazinium (DMPP), nicotine and acetylcholine produce a direct inhibitory response at DLSN neurons by activation of a Ca<sup>2+</sup> dependent K+ channel (Wong and Gallagher, Nature 341:439,1989 and J. Physiol. (Lond.) 436:325, 1991). We now report that trimethaphan camsylate (TMP), an antagonist at excitatory nicotinic receptors in ganglia, appears to be an agonist at the inhibitory nicotinic receptor on DLSN neurons.

Standard intracellular recording methods were used to record from DLSN neurons in vitro. DLSN neurons which hyperpolarized in response to DMPP also showed concentration dependent hyperpolarizations in response to superfusions of 0.1 to  $1000~\mu M$  TMP. The EC<sub>20</sub> for TMP from the dose response curve was  $10~\mu M$  which produced a hyperpolarization of 3.5~mV (n=4) from a membrane potential of -60 to -67 mV. The hyperpolarization in response to TMP persisted in the presence of 0.1  $\mu M$  TTX (n=2), indicating that it is a direct response of DLSN neurons. During continuous superfusion with TMP, the hyperpolarization of DLSN neurons gradually faded and the membrane potential returned to baseline. The fading of the response to TMP appears to be due to desensitization of the inhibitory nicotinic receptor also activated by DMPP, since the neurons were unresponsive to DMPP during this time. The responses to DMPP recovered after washing off the TMP for 30-60 min. The responses to superfusion of  $10~\mu M$  DMPP and  $10~\mu M$  TMP were examined in the same neuron. The ratio of the hyperpolarization due to TMP over the hyperpolarization caused by DMPP in the same neuron was 1~(n=3) indicating that TMP has a similar efficacy for the inhibitory receptor as DMPP. Supported by DHHS 1F32 DA05447-01 and The Council for Tobacco Research-USA, Inc.

# 42.7

PHARMACOLOGICAL CHARACTERIZATION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS USING WHOLE-CELL PATCH CLAMP IN CHICK BRAIN SLICES <u>L.L. McMahon\*</u> and <u>V.A. Chiappinelli</u>. Dept. of Pharmacological and Physiological Science, Saint Louis University School of Medicine, St. Louis MO 63104.

Neurons in the lateral spiriform nucleus (SPL) of chick mesencephalon contain functional nicotinic receptors which have high affinity for <sup>3</sup>H-nicotine and are likely to contain a2 and/or a4 along with B2 subunits (Morris et al., Mol. Brain Res. 7:305, 1990). In this nucleus, we have previously reported marked depolarizations in response to the nicotinic agonists carbachol and nicotine that were significantly attenuated by classical nicotinic receptor antagonists d-tubocurarine (50  $\mu$ M) and dihydro- $\beta$ -erythroidine (100  $\mu$ M) but were insensitive to blockade by either kappa- or alpha-bungarotoxin (Sorenson and Chiappinelli, Neuron 5:307, 1990). To further characterize these receptors, we have used whole-cell patch clamp recording techniques to measure agonistinduced nicotinic currents. Reversal potentials were obtained using voltage ramps and ranged from -20 to 0 mV. The relative potency of several nicotinic receptor agonists was estimated by comparing the current amplitude evoked by bath perfusion of a particular agonist to that evoked by the same concentration  $(1 - 100 \ \mu M)$  of carbachol. The relative rank order is 1,1-dimethyl-4phenylpiperazinium > carbachol≥nicotine > cytisine. Current amplitudes range from less than 100 pA for cytisine to 200-300 pA for nicotine and carbachol. With cytisine, recovery of responses to agonists was prolonged or absent, suggesting that cytisine may have a complex interaction with these receptors. Muscarinic responses were blocked in all experiments with 1 µM atropine. Supported by NIH Grant NS17574 to VAC.

A MECHANISTIC STUDY OF NICOTINE-EVOKED NEUROTRANSMITTER RELEASE IN RAT BRAIN SYNAPTOSOMES. <u>K.G. Fernandes\*', S. L. Yates², E.N. Fluhler', P.M. Lippiello'</u>. R. J. REYNOLDS TOBACCO CO.', Research and Development, Winston-Salem, NC 27102 and Duke Univ. Med. Center ², Integrated Tox, Prog., Durham, NC 27710

Nicotine acts presynaptically to induce a dose-dependent release of <sup>3</sup>H-dopamine (DA) from rat and mouse striatal synaptosomes. However, the steps involved in evoking DA release following binding of nicotine to the nicotinic acetylcholine receptor (nAChR) are not well characterized. In particular, the role of Ca2+ and other ions in the DA release process is poorly understood. The effects of nicotine on intrasynaptosomal calcium concentration ([Ca2+],) were studied using fura-2. While K+ evoked a dose-dependent increase in [Ca²¹], nicotine had no measurable effect. To further investigate the role of Ca²¹ in this process, the effects of Ca²¹ removal and specific/nonspecific channel blockers on DA release from rat striatal synaptosomes were examined. This process is Ca2+-dependent, since in the absence of Ca2+ (+ EGTA), K+-induced DA release was greatly attenuated and nicotine-induced release was completely blocked. Cobalt, a nonspecific Ca2+ channel blocker, decreased DA release in response to nicotine (15-fold) and K+ (8-fold), while the L-type Ca2+ channel blocker, nicardipine, reduced nicotine-stimulated DA release by 50%. Tetrodotoxin (2µM) did not alter nicotine-induced DA release, suggesting that the release process is not amplified through recruitment of voltage-gated Na\* channels. These data show that Na2+ flux through the nAChR is sufficient to induce DA release in a Ca2+ -dependent fashion, and that this dependence is in part associated with the activation of the L-type Ca2+ channel

NEURONAL NICOTINIC RECEPTOR HETEROGENEITY AND SYNAPTIC TRANSMISSION IN THE AVIAN BRAIN. W.R. Weaver\* and V.A. Chiappinelli. Department of Pharmacological and Physiological Science, Saint Louis University School of Medicine, St. Louis, MO 63104.

Neurons in the chick lateral spiriform nucleus (SPL) respond to nicotinic agonists with depolarization and increased excitability. Nicotinic receptors in the SPL have high affinity for  $^3H$ -nicotine but are insensitive to blockade by either kappa-bungarotoxin or  $\alpha$ -bungarotoxin (Sorenson and Chiappinelli, Neuron 5:307, 1990). Using intracellular recording in chick brain slices, we have shown that stimulation of a cholinergic fiber tract lateral to the SPL elicits excitatory postsynaptic potentials (EPSPs) in SPL neurons through nicotinic synapses (McMahon, et al., Soc. Neurosci, Abstr. 17:359,1991). In situ hybridization suggests that SPL receptors may consist of  $\alpha 2$  and/or  $\alpha 4$  subunits in combination with  $\beta 2$  subunits (Morris, et al., Mol. Brain Res. 7:305, 1990).

We now report that the nicotinic receptor antagonist trimethaphan appears to distinguish different receptor subtypes located on SPL neurons. Widely different concentrations (50, 200, or 500 µM) of trimethaphan are required to block nicotinic responses in different cells. Within a given SPL neuron, similar levels of this antagonist are needed to block responses to both exogenously applied nicotinic agonist and to endogenous transmitter released by stimulation of the cholinergic fiber tract. These results demonstrate that heterogeneity of nicotinic receptors exists in the SPL and that these receptor subtypes can be pharmacologically distinguished. Supported by NIH Grant NS17574 to V.A.C.

PERSISTENT BLOCKADE OF CNS NICOTINIC RECEPTORS AFTER IN VIVO OR IN VITRO ADMINISTRATION OF CHLORISONDAMINE.

H. El-Bizri \*and P.B.S. Clarke. Dept of Pharmacology and Therapeutics, McGill Univ., Montreal, Canada H3G 1Y6.

Chlorisondamine (CHL) blocks behavioural responses to CNS nicotinic receptor activation in a quasi-irreversible fashion. The mechanism of this blockade was investigated in vitro by examining nicotine-induced 3H-dopamine release from rat brain striatal synaptosomes. Synaptosomes were prepared from the crude P2 pellet, incubated with 3H-DA, and superfused; 1 min samples were collected. Following 25 min wash, a brief pulse of nicotine and then of high K' buffer were given 10 min apart. Nicotine (0.01 - 100  $\mu$ M) induced 3H-DA release in a concentration dependent and Ca' dependent manner. Release evoked by nicotine (1  $\mu$ M) was blocked in a graded fashion by in vitro administration of mecamylamine, dihydro-beta-erythroidine and CHL (0.01 - 100  $\mu$ M); blockade by CHL was not surmounted by a high concentration of nicotine (100  $\mu$ M). In vivo administration of CHL (10 mg/kg sc) 1, 7, 21 or 42 days before sacrifice completely blocked release induced by 1  $\mu$ M nicotine administered in vitro. These results suggest that chlorisondamine's persistent in vivo blockade does not solely result from retention of this bisquaternary amine by the blood-brain barrier. Funded by NIDA.

CENTRAL NICOTINIC RECEPTOR BLOCKADE NEITHER BLOCKS NOR MIMICS CHRONIC NICOTINE-INDUCED \*H-NICOTINE BINDING UPREGULATION IN RAT BRAIN. P.B.S. Clarke \*and H. El-Bizri. Dept of Pharmacology and Therapeutics, McGill Univ., Montreal, Canada H3G 1Y6.

Univ., Montreal, Canada H3G 1Y6.

It has been proposed that the paradoxical upregulation of <sup>3</sup>H-nicotine binding induced by chronic in vivo nicotine reflects long term receptor blockade (through desensitization). The nicotinic antagonist chlorisondamine (CHL) blocks nicotine's CNS effects quasi-irreversibly after central or systemic We tested whether chronic CNS administration. aumanistration. we tested whether chronic CNS nicotinic blockade by CHL alters <sup>3</sup>H-nicotine receptor binding or alters chronic nicotine-induced Rats were randomly allocated to 4 groups (n=12) and were pretreated with CHL (10 mg/kg sc) or saline, and treated chronically with nicotine (0.6 mg/kg sc bid for 10 days) or saline. Persistent central blockade was shown in tests of nicotine-induced locomotion given just before and after chronic treatment. Central blockade exerted by CHL was not reversed by chronic nicotine. Forebrain <sup>3</sup>H-nicotine binding density  $(B_{\rm max})$  but not affinity  $(k_{\rm D})$  was increased by chronic nicotine (19% increase, p < 0.001). CHL neither altered  $^3{\rm H-nicotine}$  receptor binding density when given alone nor did it alter upregulation induced by nicotine. Supported by NIDA.

TOLERANCE TO CHRONIC NICOTINE TREATMENT MEAS-URED BY DOPAMINE AND RUBIDIUM RELEASE. <u>S.R.Grady</u>, <u>M.J.Marks\*</u>, <u>D.A.Farnham</u>, <u>and</u> <u>A.C.Collins</u>. Institute for Behavioral Genetics, University of Colorado, Boulder, CO 80309.

Chronic treatment of mice with nicotine elicits tolerance to the effects of the drug and results in increases in the number of nicotinic binding sites. However, the functional state of nicotinic receptors after chronic nicotine treatment has not been intensely studied. Therefore, C57BL/6 mice were continuously infused with nicotine (4 mg/kg/hr), withdrawn from treatment for various amounts of time, and assayed for nicotine-induced release of dopamine from striatum and of rubidium from cortex and midbrain. The binding of [³H]nicotine was increased by chronic drug treatment and returned to normal levels during withdrawal. Nicotine-induced dopamine release from striatial synaptosomes from treated mice was 20-25% lower than that of control mice immediately after cessation of treatment and remained lower for at least four days. Nicotine-induced rubidium release from midbrain was 30-35% lower in treated animals than in controls and remained lower for several days after withdrawal. However, nicotine-stimulated rubidium release from cortical synaptosomes of treated mice did not differ from that of control animals. The results suggest that tolerance develops to at least two different biochemical measures of nicotinic receptor function.

# 42.13

TOLERANCE AND RECEPTOR CHANGES AFTER CHRONIC TREATMENT WITH NICOTINE AND MECAMYLAMINE. Y.Luo, S.Selvaag, M.J.Marks, and A.C.Collins\*. Institute for Behavioral Genetics, University of Colorado, Boulder, CO.

Mecamylamine blocks nicotine effects in vivo but response to chronic exposure to mecamylamine on behavioral or biochemical measures of nicotinic systems is not well understood. Therefore, DBA/2 mice were chronically infused with mecamylamine either alone (4 mg/kg/hr) or in combination with nicotine (4 mg/kg/hr) and compared to mice treated with saline or nicotine (4 mg/kg/hr). Mice treated with nicotine, mecamylamine, or both drugs were apparently tolerant to the effects of nicotine 4 hours after cessation of drug treatment. However, the apparant tolerance to mecamylamine probably resulted because the antagonist had not been completely metabolized. Mice that had been chronically treated with nicotine tested 2 days after cessation were still tolerant, while those chronically treated with mecamylamine were not. Treatment with nicotine or mecamylamine resulted in significant increases in nicotinic binding sites measured either 4 hr or 2 days after cessation of chronic treatment. Increases in ligand binding observed after treatment with both drugs were additive. These results suggest that chronic treatment with either nicotinic agonists or antagonists increases nicotinic receptors, but that the mechanisms underlying these increases differ. Supported by DA-03194 and DA-00116.

DIFFERENTIAL EFFECTS OF CHRONIC NICOTINE INFUSION AND CORTICOSTERONE TREATMENT ON BRAIN NICOTINIC RECEPTORS AND TOLERANCE TO NICOTINE. <u>J.R. Pauly</u>, <u>S.R. Robinson</u>, <u>E.U. Grun and A.C. Collins</u>, Inst. for Behavioral Genetics and Dept. of Psychology, Univ. of Colorado, Boulder CO 80309.

and A.C. Collins. Inst. for Behavioral Genetics and Dept. of Psychology, Univ. of Colorado, Boulder CO 80309.
Previous studies from our laboratory have shown that behavioral and physiological tolerance to nicotine following chronic agonist exposure is correlated with an increase in the number of brain nicotinic receptors (nAchRs). Mice that are chronically treated with corticosterone (CCS) are also tolerant to nicotine, although this treatment reduces the number of brain nAchRs. The present study examined tolerance to nicotine and changes in CNS nAchRs following chronic nicotine infusions that were combined with prolonged exposure to CCS. Female C57BL/6 mice were implanted with jugular catheters and subcutaneous hormone pellets comprised of 60% CCS and 40% cholesterol (controls received pure cholesterol) and then infused with saline or nicotine (6.0 mg/g/hr) for a period of 7 days. Sensitivity to nicotine was determined using a battery of tests (Y-maze activity, heart rate and body temperature). Homogenate receptor binding assays using 3H-nicotine and alpha-125I-bungarotoxin (BTX) were performed in 8 grossly dissected brain regions. Mice that were infused with nicotine were tolerant to an acute drug challenge as indicated by shifts to the right in nicotine dose-response curves; CCS-treated animals developed similar tolerance. Combining these treatments however had an additive effect on tolerance to nicotine. CCS did not significantly alter nicotine-induced increases in 3H-nicotine binding in any brain regions. CCS exposure decreased 1251-BTX binding in several brain regions but nicotine infusions reversed this effect. These data suggest that agonist treatment and glucocriticid exposure produce tolerance to nicotine via independent mechanisms. Supported by DA-00116, DA-05131 and a grant from RJ Reynolds Tobacco Co.

ANALYSIS OF NICOTINIC RECEPTORS BY QUANTITATIVE AUTORADIOGRAPHY AND IN SITU HYBRIDIZATION FOLLOWING CHRONIC TREATMENT WITH NICOTINE AND MECAMYLAMINE. J.L.van de Kamp\*, J.R.Pauly, S.R.Robinson, M.J.Marks, and A.C.Collins. Institute for Behavioral Genetics, University of Colorado, Boulder, CO. 80309. Continuous infusion of DBA/2 mice with either the nicoti-

Continuous infusion of DBA/2 mice with either the nicotinic agonist, nicotine, or the nicotinic antagonist, mecamylamine, results in increases in nicotinic receptors measured by high affinity [³H]nicotine binding. Simultaneous treatment with these drugs causes larger increases in receptor number than treatment with either drug alone. DBA/2 mice were chronically treated with saline (control), 4.0 mg/kg/hr nicotine, 4.0 mg/kg/hr mecamylamine, and a combination of mecamylamine and nicotine. Subsequently, [³H]nicotine and alpha-[¹2⁵s]lbungarotoxin binding sites were measured by quantitative autoradiography, and the levels of mRNA encoding the alpha-4, alpha-7, and beta-2 nicotinic receptor subunits were measured by in situ hybridization. Chronic treatment with either drug evoked increases in [³H]nicotine binding; even greater increases were observed after treatment with both drugs simultaneously. Chronic treatment had less effect on alpha-[¹2⁵s]lbungarotoxin binding. Levels of mRNA encoding alpha-4, beta-2 or alpha-7 nicotinic receptor subunits were unchanged, suggesting that regulation of the number of nicotinic receptors by chronic treatment with nicotinic agonists or antagonists may occur posttranscriptionally. Supported by DA-03194 and DA-00116.

A HYBRID PBPK/PD MODEL FOR NICOTINIC RECEPTOR DYNAMICS IN THE RAT BRAIN. <u>E.N. Fluhler\*</u>, <u>D.R. Plowchalk</u>, <u>P.M. Lippiello and J.D. deBethizy</u>. Duke University Medical Center, Durham, NC and RJ Reynolds Tobacco Co., Winston-Salem, NC.

We have examined the in vivo time-course of nicotine binding to rat brain receptors and the resulting effects on receptor dynamics by linking a physiologically-based pharmacokinetic model (PBPK) for nicotine to a twophysiologically-based prialinacontribute in body (R.) in model (1.5.4) in state receptor binding model. The receptor model assumes that brain nicotinic receptors exist in either high (R') or low (R) affinity states and that binding of nicotine can shift the relative proportions of the receptor states via isomerization reactions. Rate constants for nicotine binding and conformational changes in the receptor (k1...k8) were estimated from kinetic measurements of S-(-)-[3H]nicotine binding to rat brain homogenates. Temperature dependence of the rate constants was addressed by scaling each constant from 0 to 37 °C based on a subset of binding data obtained at 37 °C. The concentration of nicotine in the brain compartment of the PBPK model was used as the input for the receptor model. Simulations were conducted using an administration paradigm that mimics a single puff from a cigarette (1 puff, 0.1 mg nicotine). Results of simulations predict rapid nicotine binding (<30 sec) to both R and R' followed by rapid conversion (<60 sec) of nearly all receptors (97%) to the high affinity conformer (proposed to be a desensitized state). The t<sub>1/2</sub> for the return of receptors to their original distributions was 3-4 hours. These results are consistent with the prolonged desensitization of some physiological responses to nicotine (e.g. prolactin release) and indicate that this hybrid model provides a unique tool with which to study rat nicotinic receptor dynamics in vivo.

NICOTINE TOLERANCE IN ADRENAL CHROMAFFIN CELLS AFTER EXPOSURE TO SMOKING RELATED NICOTINE CONCENTRATIONS. A.E. Bullock and A.S. Schneider. Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208

Nicotine tolerance and dependence have been demonstrated in animals by many investigators, however the cellular mechanisms underlying these processes are not well known. Repeated nicotine exposure has been previously shown to reduce the levels of evoked catecholamine release from cultured bovine adrenal chromaffin cells at concentrations well above that of the estimated tissue levels of nicotine in smokers. We have demonstrated the development of nicotine tolerance at concentrations related to those found in the tissues of smokers (0.1 - 1.0 \( \mu M \)). Cells are preincubated with varying concentrations of nicotine and subsequently challenged with a nicotinic agonist. Adrenal chromaffin cell function is measured as nicotine-stimulated <sup>45</sup>Ca uptake and catecholamine release. Decreased nicotine-evoked calcium uptake and catecholamine release is seen in minutes after preexposure with both 0.1 and 1.0 µM nicotine at 37°C but not at 20°C. Consistent with desensitization of the secretory response, this decrease in nicotine-evoked catecholamine release is dependent on extracellular calcium, nicotine dose, temperature and is cross tolerant to other nicotinic agonists. Chronic exposure to nicotine results in a decrease in the secretory response that is sustained over a seven day period. The above results are being considered in relation to mechanisms of chronic nicotine tolerance and dependence.

### 42.17

EFFECTS OF NICOTINIC AGONIST PRETREATMENT ON NICOTINE-INDUCED HYPOTHERMIA AND HYPOLOCOMOTION. M.J. Buckley\*. M.W. Decker, and S.P. Americ. Neuroscience Research, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL 60064.

In mice, acute treatment with nicotine produces substantial reductions in body temperature and locomotor activity. In these experiments, we investigated the effects of pretreatment with nicotinic agonists and antagonists on this nicotine-induced reduction of body temperature and locomotor activity in male, CD-1 mice. Each mouse was given an injection of a nicotinic agent 3-4 min. prior to an injection of saline or (-)nicotine (6.2 μmol/kg IP). Four min. after this second injection, the mouse was placed in an activity cage for 10 min. to measure horizontal activity. After the activity session, temperature was measured using a rectal probe. Nicotinic agonists used for pretreatment included (-)lobeline, (-)cytisine, and (-)nicotine (0, 0.062, 0.62, and 6.2 μmol/kg IP). Antagonists used were mecamylamine (1.5, 5, and 15 μmol/kg) and hexamethonium (3 and 30 μmol/kg).

As expected, nicotine by itself dramatically reduced locomotor activity and body

As expected, nicotine by itself dramatically reduced locomotor activity and body temperature. Mecamylamine attenuated these effects, but hexamethonium did not. Similar but slightly less pronounced reductions were found with cytisine, whereas lobeline had no effect by itself. Cytisine effects did not appear to be additive with those produced by nicotine, as pretreatment with cytisine did not significantly alter the effects of nicotine. Pretreatment with lobeline, however, dose dependently potentiated nicotine-induced hypothermia without affecting nicotine's reduction of activity. Interestingly, pretreatment with 0.62  $\mu$ mol/kg nicotine significantly attenuated the hypothermia effect of a subsequent injection of 6.2  $\mu$ mol/kg of nicotine.

These results suggest that nicotinic agonist effects on temperature and locomotor activity differ and are not simply additive. The different patterns of behavioral and physiological effects elicited by these agonists may be related to preferential activity at one or more nicotinic receptor subtype(s).

NICOTINE AND cAMP ENHANCE <sup>3</sup>H-NICOTINE BINDING TO PC 12 CELLS. T.C. Madhok\* and B.M. Sharp, Endocrine-Neuroscience Laboratory and Departments of Medicine, Hennepin County Medical Center and Univ. of Minnesota, Minneapolis, MN 55404.

Recently, we reported that nerve growth factor (NGF) increased the number of <sup>3</sup>H-nicotine binding sites on PC 12 cells (*Endocrinol*. 1992; 130:825). To further delineate mechanisms regulating the expression of neuronal nicotinic cholinergic receptors (nChRs) in response to nicotine or cAMP, the following studies were conducted. PC 12 cells were grown in nicotine hemisulfate (0.001-1.0 mM) or dibutyryl-cAMP (0.01-1.0 mM) or vehicle for 7 days, with daily replenishment of these agents. Cells were then harvested and specific <sup>3</sup>H-nicotine binding was measured. Specific binding was enhanced by nicotine (up to 2.5-fold with 1.0 mM) or dbcAMP (up to 5-fold with 1.0 mM); this was dose and time-dependent. Maximal stimulation by dbcAMP occurred earlier (by 3 days) than that achieved by nicotine (5-7 days). Concurrent treatment with mecamylamine (0.01mM) prevented up-regulation by nicotine. Forskolin (10-100 µM), in combination with IBMX (1 mM), enhanced <sup>3</sup>H-nicotine binding; forskolin alone was ineffective. Specific <sup>3</sup>H-nicotine binding on PC 12 cell mutants (A126.1B2), lacking a cAMP-responsive system, was unaffected by dbcAMP. Finally, enhanced <sup>3</sup>H-nicotine binding did not appear to be related to cell differentiation, since nicotine only induced receptor up-regulation, whereas dbcAMP or NGF also stimulated neurite outgrowth. These studies provide an *in vitro* model for elucidating the mechanism of nChR up-regulation by nicotine and suggest that this may involve, in part, activation of protein kinase A. (Supported by DA 04446)

## EXCITATORY AMINO ACIDS: EXCITOTOXICITY I

### 43.1

CYCLOHEXIMIDE TREATMENT PREVENTS NEUROTOXICITY AND C-FOS EXPRESSION IN ADULT RAT BRAIN FOLLOWING KAINIC ACID TREATMENT. S.S. Schreiber\*, I. Naim, G. Tocco and M. Baudry. Dept. of

Neurology and Neurosciences Program, Univ. So. Calif., Los Angeles, CA 90033. Recent evidence has suggested a link between cell death mechanisms and macromolecular synthesis. Kainic acid (KA) causes a distinct seizure syndrome in adult rats and is selectively toxic to neurons in the pyramidal cell layers of the hippocampus and the piriform cortex. Systemic administration of KA also results in a rapid elevation of c-fos messenger RNA (mRNA) in multiple brain regions. In regions not damaged by KA the time course of c-fos induction is relatively brief, whereas elevated levels of c-fos mRNA are maintained for at least 16 hours in regions selectively vulnerable to KA, suggesting a role for Fos protein in KA-induced cellular damage. Therefore, we studied the effects of cycloheximide (CHX), a protein synthesis inhibitor, on KA-induced cell damage and c-fos expression. Adult male Sprague-Dawley rats were given CHX (2 mg/kg) 1 hour prior to KA (10 mg/kg), both by subcutaneous injection, and were sacrificed 1 and 16 hours, or 5 days following the onset of behavioral seizure activity. Either CHX or KA alone were given to control animals. Frozen brain sections were prepared for in situ hybridization using a <sup>35</sup>S-labeled c-fos cRNA probe. In animals that did not receive CHX pretreatment, increased c-fos mRNA was consistently observed in CA3 and CA1 pyramidal cells, as well as the piriform cortex 16 hours following seizure onset. Furthermore, histological examination revealed no hippocampal cell loss in CHX-pretreated animals at 16 hours of 3 days after seizure onset. These results suggest that protein synthesis is required for KA-induced neurotoxicity, and that prolonged expression of c-fos mRNA in KA-vulnerable regions may be a marker for subsequent cell death.

## 43.2

KAINATE-ACTIVATED COBALT UPTAKE IDENTIFIES A SUBPOPULATION OF CULTURED CORTICAL CELLS THAT ARE PREFERENTIALLY VULNERABLE TO KAINATE-INDUCED DAMAGE. D.M. Turetsky\*, M.P. Goldberg and D.W. Choi. Dept. of Neurology, Washington Univ. School of Med., St. Louis, MO 63110.

Pruss et al. found that cerebellar granule or hippocampal neurons exposed to kainate for 20 min in the presence of 5 mM CoCl<sub>2</sub>, take up  $\mathrm{Co^{2+}}$ , visualizable by precipitation with (NH<sub>2</sub>)<sub>2</sub>S and silver enhancement (Neuron 7:509, 1991). Murine cortical cell cultures exposed to 100-500  $\mu$ M concentrations of kainate for 20 min exhibited  $\mathrm{Co^{2+}}$  uptake in only a subpopulation of neurons (about 15% of the total). The idea that such  $\mathrm{Co^{2+}}$  uptake is a marker for AMPA/kainate receptors linked to  $\mathrm{Ca^{2+}}$ -permeable channels suggests the prediction that  $\mathrm{Co^{2+}}$ -positive cortical neurons should have heightened vulnerability to kainate toxicity. Indeed, cortical cultures exposed to  $100~\mu$ M kainate plus  $10~\mu$ M MK-801 for 10 min developed minimal overall neuronal death 24 hrs later, as assayed by LDH release, whereas the  $\mathrm{Co^{2+}}$ -positive subpopulation in the same cultures was decreased by 60-70%. Removing  $\mathrm{Ca^{2+}}$  from the bathing medium during kainate exposure resulted in an almost complete preservation of the  $\mathrm{Co^{2+}}$ -positive subpopulation. No such selective loss of  $\mathrm{Co^{2+}}$ -positive cells was seen after NMDA exposure. These observations suggest that a distinct subpopulation of cortical neurons has AMPA/kainate receptors linked to  $\mathrm{Ca^{2+}}$ -permeable channels, and that this characteristic does convey vulnerability to kainate-induced,  $\mathrm{Ca^{2+}}$ -mediated, damage.

THE INTERACTION BETWEEN BMAA AND BICARBONATE CREATES A NEW AGONIST SPECIES. C.N. Allen 1, P.S. Spencer 1 and D.O. Carpenter<sup>2</sup>. <sup>1</sup>Cntr for Res. on Occup. & Environ. Toxicol., OR Hlth. Sci. Univ., Portland, OR; 2Wadsworth Cntr. for Lab. & Res.,

New York State Depart. Hlth. & Sch. of Pub. Hlth., Albany, NY. BMAA (N-methylamino-L-alanine), a component of the neurotoxic Cycas circinalis plant, requires the presence of NaHCO<sub>3</sub> for Cycas circinatis plant, requires the presence of NanCO3 for excitotoxicity. BMAA neurotoxicity has been linked to activation of NMDA, quisqualate (QA) and kainate (KA) receptors. We used cultured hippocampal neurons and whole cell patch clamp recording to identify the receptors activated by BMAA in the presence of NaHCO3. identify the receptors activated by BMAA in the presence of NaHCO<sub>3</sub> BMAA activates ionic currents in 0.1 mM calcium which are reduced 50% in 0.5 mM extracellular calcium and 92% in 3.0 mM calcium. The BMAA-activated currents were not antagonized by APV (10-100 μM) nor by CNQX (1-10 μM). Addition of NaHCO<sub>3</sub> to BMAA (500 μM) potentiated the BMAA currents 224% for 10 mM NaHCO and 578% for 20 mM. NaHCO<sub>3</sub> had no effect on QA-, NMDA- or KA-activated ionic currents. The addition of NaHCO<sub>3</sub> alkalinizes the activated ionic currents. The addition of NaHCO3 alkalinizes the extracellular Ringer's solution which did not alter the NaHCO3 potentiation of BMAA-activated currents. The BMAA+NaHCO3 activated currents were unaffected by APV (10-100  $\mu$ M) but were reduced 49% by CNQX (1  $\mu$ M) and 80% by CNQX (10  $\mu$ M). These data indicate that the interaction between BMAA and bicarbonate that a indicate that the interaction between BMAA and dicatoliate produced a new agonist species, possibly an  $\alpha$ -carbamate which activates QA/KA type of glutamate receptors and may be responsible for the neurotoxicity of BMAA in NaHCO<sub>3</sub> solutions. This work is supported by NIH grants NS-23807 and NS19611.

BLOCKING NON-NMDA RECEPTORS REDUCES TISSUE LOSS AFTER EXPERIMENTAL SPINAL CORD TRAUMA. J. R. Wrathall\*, D. Choiniere and Y. D. Teng, Dept. of Anatomy and Cell Biology, Georgetown Univ., Washington, DC 20007.

We have recently found that administration of the potent non-NMDA antagonist NBQX (Sheardown et al., Science 247:571, 1990)

results in reduced hindlimb functional deficits after a standardized contusive injury of the thoracic cord. We have now analyzed spinal cord tissue from these experiments with quantitative morphological and immunocytochemical techniques. Cross-sections of the cord representing the epicenter (region of maximal damage) and tissue at specified distances rostral and caudal to the epicenter were stained with lead for the head to the cord representing the section of the se with luxol fast blue-hematoxylin and eosin and used for morphometric analysis as previously described (Noble and Wrathall, Exp. Neurol., 88: 134, 1985). In addition, sections 5 mm rostral and caudal to the epicenter were processed for 5-HT immunoreactivity readd to the epicenter were processed for 3-F1 Immunoreactivity and quantitatively assessed with an image analysis system. The results showed that 4 weeks after injury there were significantly larger areas of residual gray matter in spinal cords of the NBQX-treated group in sections 1, 2, and 3 mm caudal to the epicenter. The effect on total white matter showed a similar trend with a significant difference 2 mm caudal to the epicenter. Further, 5-HT immunoreactivity, a marker of descending pathways from the brainstem, below the lesion was almost twice as great in the NBQX-treated group as compared to vehicle controls. These results suggest that the reduction in functional deficits by NBQX may be mediated by sparing of tissue loss resulting from traumatic injury. (Supported by NIH-P O1-NS28130).

L-PROLINE-LIKE EXCITOTOXICITY OF THE CYANIDE METABOLITE, 2-ICA (2-IMINOTHIAZOLIDINE-4-

L.PROLINE-LIKE EXCITOTOXICITY OF THE METABOLITE, 2-ICA (2-IMINOTHIAZOLIDINE-4-CARBOXYLIC ACID). R.S. Bitner, G.E. Isom and G.K.W. Yim'. Dept. Pharm. Tox., Sch. Pharm. & Pharmacal Sci., Purdue Univ., W. Lafayette, In 47907.

The amino acid L-proline, despite its monoacidic structure, produces neurotoxic damage to CA1 pyramidal neurons following intrahippocampal administration (Nadler al. 1988). Our earlier study indicated that 2-ICA, a cyanide metabolite structurally similar to L-proline, induces EAA-like seizures in mice. To determine if 2-ICA could neurotoxicity seen with L-proline, the cyanide metabolite structurally similar to L-proline, induces EAA-like seizures in mice. To determine if 2-ICA could also induce the neurotoxicity seen with L-proline, the cyanide metabolite was infused i.c.v. in rats for seven days at a sub-convulsant dose (50 ug/hr). Histological examination revealed extensive loss of CA1 pyramidal neurons of the hippocampus in 2-ICA treated rats. In addition, icv injections of L-proline in mice produced EEA-like seizures at doses comparable to those required for 2-ICA. These findings emphasize the possibility of excitotoxicity with compounds possessing only one acidic group, and may constitute another excitotoxic mechanism involved in chronic cyanide neurotoxicty. (Supported in part by NIH grants ES4140 & RRO586.)

NON-NMDA RECEPTOR-MEDIATED DAMAGE TO NADPH-D(+) NEURONS IS CA<sup>2+</sup> DEPENDENT. <u>J.H. Weiss\*, 1 and D.W. Choi<sup>2</sup>.</u> Dept. Neurology, U.C. Irvine, Irvine, CA 92717 and Dept. Neurology, Washington Univ. Med. Sch., St. Louis, MO 63110. Studies in cortical culture have revealed

that the neurodegeneration that occurs after brief periods of intense NMDA receptor activation is Ca<sup>2+</sup> dependent. Similar experiments aiming to clarify the role of Ca<sup>2+</sup> entry in non-NMDA receptor-mediated damage to cortical neurons are more difficult, as Ca<sup>2+</sup> removal for the several hours needed for AMPA or kainate to produce widespread neurodegeneration is in itself damaging. We thus examined the Ca<sup>2+</sup> dependence of non-

NMDA receptor-mediated damage to a small subpopulation of cortical neurons with unusual vulnerability to non-NMDA receptor-mediated injury, those containing high concentrations of injury, those containing high concentrations of the enzyme, NADPH-diaphorase (NADPH-d(+) neurons). Brief (30 - 40 min) exposures of cortical cultures to either 50  $\mu$ M AMPA or to 100  $\mu$ M kainate caused little overall neuronal loss, but destroyed over 70% of the NADPH-d(+) neurons. Ca<sup>2+</sup> ion removal during the toxic exposure decreased NADPH-d(+) neuronal loss by captage 50% (n < 0.05 M; 2-tailed t text) over 50% (p < 0.05 by 2-tailed t test).

BRAIN METABOLISM OF β-N-METHYLAMINO-L-ALANINE (BMAA) AND PROTECTION OF EXCITOTOXICITY BY GABA-UPTAKE INHIBITORS. G.E. Kisby, V. Nottingham, R. Kayton, D.N. Roy \*, P.S. Spencer. Center for Research on Occupational and Environmental Toxicology, Oregon Health Sciences University,

 $\beta$ -N-Methylamino-L-alanine (BMAA), a weak excitotoxic amino acid, is one of the many potentially toxic agents in cycad seed which is under study as a possible etiological factor for western Pacific amyotrophic lateral sclerosis (ALS). BMAA uptake into neural tissue is sodium-dependent, sensitive to temperature and pH, dependent on protein concentration, and saturates with increasing concentration of neurotoxin (Kisby et al., 1992). Pretreatment of mouse cortical explants (2-3 weeks in vitro) with the non-selective GABA-uptake inhibitor nipecotic acid (100 µM and 1.0 mM) blocked BMAA uptake and BMAA-induced excitotoxicity (respectively). Metabolism of BMAA and aminopyrine by purified brain microsomes and mitochondria was inhibited by the P450 inhibitors SKF 525A and piperonyl butoxide. Brain microsomal metabolism of aminopyrine, BMAA, and MPTP (all at 1.6 mM) was inhibited by deprenyl (0.1-0.5  $\mu$ M). Rat brain DNA was radiolabeled when incubated (0.5 h) with purified brain mitochondria and 1.6 mM L-[-N<sup>14</sup>CH<sub>3</sub>]-BMAA (0.2 µCi). These studies demonstrate that (a) BMAA is metabolized by brain tissue, (b) the metabolite(s) can interact with brain tissue macromolecules and (c) BMAA excitotoxicity is blocked by inhibitors of GABA uptake. Further study is needed before conclusions can be drawn about the potential role of BMAA in western Pacific ALS. [Supported by a grant from AHAF and NS19611]

## 43.R

NMDA ANTAGONISTS HAVE LIMITED PROTECTION AGAINST AMPAINDUCED INJURY IN THE IMMATURE BRAIN. W.H. Trescher\* and M.Y. Johnston, Kennedy Krieger Research Institute, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Medicine, Baltimore, MD 21205.

Sensitivity to N-methyl-D-aspartate (NMDA) and  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazole propionate (AMPA) mediated injury is enhanced in the immature brain, and the age of peak neurotoxicity is distinct but overlapping for the two agonists. It is unclear to what extent in-vivo AMPA-induced injury is mediated through NMDA receptor activation in the immature brain. Therefore, we investigated the activity of NMDA antagonists in AMPA-induced brain injury. On postnatal day (PND) 7, rat pups under deep anesthesia received a unilateral, intrastriatal injection of 10 nmol/0.5 th of NMDA or AMPA. Antagonists were administered i.p. 15 min. after the intracerebral injections. The brains were removed on PND 14 and the severity of damage was determined by comparing the wet weights of the cerebral hemispheres ipsilateral (I) and contralateral (C) to the injection site according to the formula 100 X (C-1)/C (% damage). Neuroprotection was calculated as %protection, a term that reflects the degree of damage in drug treated vs saline treated groups. Data are presented as mean  $\pm$  SEM. Intracerebral injection of 10 nmol NMDA produced 25.4  $\pm$  1.6% damage compared to 16.4  $\pm$  2.1% damage after intracerebral injection of 10 nmol AMPA (p = 0.003). Administration of three doses of MK-801 (0.01-1.0 mg/kg) produced dose related protection against NMDA induced injury (ANOVA, p = nmol AMPA (p = 0.003). Administration of three doses of MK-801 (0.01-1.0 mg/kg) produced dose related protection against NMDA induced injury (ANOVA, p = 0.0001) with maximal protection of 86.5  $\pm$  3.6%. 1 mg/kg of MK-801 was only partially protective against AMPA-induced injury (24.1  $\pm$  5.5%). The competitive NMDA receptor antagonist, CGS-19755 (10 mg/kg) was protective against NMDA induced injury (82.2  $\pm$  8.8% protection, p = 0.0034, vs control), but only partially protective against AMPA-induced injury (31.6  $\pm$  12.2% protection, p = 0.24 vs control). The glycine receptor antagonist HA-966 (50 mg/kg) was partially protective against NMDA-induced injury (43.5  $\pm$  12.5% protection, p = 0.059) and AMPA-induced injury (45.6  $\pm$  7.6%, p = 0.3). The data indicate that a major portion of AMPA-induced injury in the immature brain is independent of NMDA mediated mechanisms. Supported by NIH grants NS01482 (WHT) and NS28208 (MVD. mechanisms. DETECTION OF TOPA (6-OH DOPA) AND TOPA QUINONE BY HPLC REVEALS A SPONTANEOUS DOPA TO TOPA CONVERSION IN AQUEOUS SOLUTIONS

TA Newcomer\*, AM Palmer, PA Rosenberg & E Aizenman, Depts of Physiology and Psychiatry, University of Pittsburgh Sch Med, Pittsburgh, PA 15261, and Dept of Neurology, Children's Hospital and Harvard Med Sch, Boston, MA 02115.

2,4,5-Trihydroxyphenylalanine (TOPA) oxidizes in solution to form a quinone derivative that is a non-NMDA agonist and excitotoxin (Rosenberg et al., P.N.A.S. 88:4865; 1991). A HPLC analysis of TOPA quinone-containing solutions was performed in an effort to characterize its behavior under physiological conditions. A dual electrode coulometric detector was utilized. Factors such as potential (-400 to 400 mV), pH (3-8), methanol concentration (8-15%) and buffer (HEPES, phosphate) were varied. We have successfully defined optimal conditions to detect TOPA quinone and clearly distinguish it from closely related catechols. Under physiological pH, DOPA-containing solutions showed a partial conversion (0.1%) to TOPA and TOPA quinone. This conversion was greatly delayed by acidic conditions (pH 3). We are currently examining circumstances that may increase this conversion and which may explain some of the neurotoxic properties that other investigators have attributed to DOPA (Olney et al., Exp. Neurol. 108:269; 1990).

CHARACTERIZATION OF GLUTAMATE EXCITOTOXIC ACTIVITY USING WHOLE BRAIN TISSUE CULTURE.

<u>David Deupree\*</u>, <u>Mina Yarom</u>, <u>Yi-Hsuan Lee</u> and <u>Jang-Yen Wu</u>. Physiology and Cell Biology, University of Kansas, Lawrence, KS 66045.

Cultured neurons obtained from fetal rat brain homogenates were exposed to various glutamate agonists for prolonged periods (24 hrs). So far, non-NMDA agonists have produced the greatest degree of neurotoxicity, as measured by increased lactate dehydrogenase (LDH) activity following the exposures. This neurotoxic effect does not appear to be mediated via glutamate metabotropic receptors, as trans-ACPD produced no effect on LDH activity. Preincubation with trans-ACPD was ineffective in modulating quisqualate induced neurotoxicity. Thus the metabotropic modulation of NMDA induced neurotoxicity reported in the literature was not seen on quisqualate neurotoxicity in the present experiments. Further characterization and testing will continue and reported at the

Research supported by NIH grant #NS-20978 and the Marion Merrell Dow Foundation.

Similarities between ischemia and metabotropic receptorinduced injury in organotypic hippocampal cultures. J. J. Vornov\* and R. C. Tasker Depts. Neurology and Anesthesiology The Johns Hopkins School of Medicine, Baltimore, MD 21205

We have described a model of ischemia in organotypic cultures of hippocampal slices that reproduces the characteristic regional nippocampai sinces that reproduces the characteristic regional vulnerability to ischemic injury. Ischemic conditions are created pharmacologically with 2-deoxyglucose and potassium cyanide. As in vivo, ischemic injury can be reversed if NMDA receptors are blocked during recovery. The distribution of injury caused by glutamate or simulated ischemia is distinct from NMDA or hypoglycemic injury.

Trans-ACPD, the selective agonist of the glutamate metabtropic receptor, reproduces the anatomic distribution of ischemic injury in the cultures and shares pharmacologic properites with ischemia and glutamate induced injury. Propidium iodide fluorescence was used to observe early membrane injury as it occured in the living culture. Several hours following a 30 min exposure to trans-ACPD (100  $\mu$ M), injury was observed in the CA1 and hilar regions of the cultures, the regions most vulnerable to ischemic injury. Most of CA3 and the dentate gyrus were spared. We hypothesize that glutamate, released during and after ischemia, triggers injury at metabotropic receptors. The distribution of these receptors may determine the distribution of ischemic injury. TTX or MK-801 blocked ischemic, trans-ACPD or glutamate-induced injury. The toxicity of NMDA itself was not blocked by TTX. Thus, the injury appears indirect, mediated through secondary NMDA receptor activation. The secondary toxic effect may be sympotically mediated as it is blocked by TTX. be synaptically mediated as it is blocked by TTX.

INTERPLAY BETWEEN IONOTROPIC AND METABOTROPIC GLUTAMATE RECEPTORS AFFECTS N-METHYL-D-ASPARTATE (NMDA)-INDUCED NEUROTOXICITY IN THE ADULT RAT RETINA. R. Siliprandi\*, J. Sautter, E. Fadda, M. Lipartiti, N. Schiavo and H. Manev. Fidia Research Laboratories, 35031 Abano Terme, Italy.

We have recently shown (Siliprandi et al., Visual Neuroscience, in press) that a single intraocular (i.o.) injection of NMDA in the adult rat resulted in a dosedependent loss of retinal ganglion cells and a decrease of retinal choline acetyltransferase activity (ChAT). These effects were inhibited in a dose dependent manner by a single i.o. injection of MK-801, a noncompetitive NMDA receptor antagonist. Now we report that a complete protection can also be achieved by an intravenous injection of MK-801 (0.8 mg/Kg) given either 5 min before or within 15 min after i.o. administration of 12 numoles of NMDA, suggesting a narrow time-window for rescuing treatments. (1S,3R)-1-Aminocyclopentane-1,3-dycarboxilc acid [(1S,3R)-ACPD)], a selective agonist dycarboxilc acid [(1S,3R)-ACPD)], a selective agonist for the metabotropic glutamate receptors, injected i.o. 30 min before NMDA (12 nmoles) did not cause any histological retinal damage or decrease in retinal ChAT activity, but reduced by 30% the NMDA-induced loss of ChAT activity. These results suggest that the interplay between metabotropic and NMDA-sensitive glutamate receptors is operative in the 'in vivo' retina, and that it may play a crucial role in the outcome of the pathological NMDA receptor over-activation. pathological NMDA receptor over-activation.

### 43.12

NEUROTOXICITY LINKED TO THE GLUTAMATE METABO-

NEUROTOXICITY LINKED TO THE GLUTAMATE METABO-TROPIC RECEPTOR MT Price\*. C. Ikonomidou, J. Labruyere, Y. Izumi, and J.W. Olney, Washington University Medical School, St. Louis MO 63110. Activation of the glutamate (Glu) metabotropic receptor by Glu, quisqualate or the more selective agonist, trans-ACPD, triggers phosphoinositide hydrolysis, intracellular Ca++ mobilization and protein kinase C activation. These 2nd messenger functions can be blocked by AP3 (2-amino-3-phosphonopropionic acid). Subcutaneous treatment of infant rodents with AP3 for several consecutive days causes degeneration of virtually all nerve cells in the retina and some neurons in the brain (Tizzano et al, 1991). Moreover, when AP3 is infected directly into the adult rodent brain it results in deepeneration of AP3 is injected directly into the adult rodent brain it results in degeneration of many neurons at the site of injection (Schoepp and Olney, unpublished). These findings suggest that under normal physiological circumstances, the Glumetabotropic receptor through its 2nd messenger functions may provide vitally important support for neurons either during development or in adulthood, and

important support for neurons either during development or in adulthood, and that disruption of this support can have lethal consequences for CNS neurons. Here we report that *trans*-ACPD, when injected directly into the lateral ventricle of either the immature or adult rat brain, causes acute degeneration of specific neurons in the lateral septal nucleus. The 1S, 3R isomer of *trans*-ACPD, which acts as a pure agonist in driving the Glu metabotropic receptor and stimulating its 2nd messenger functions (Schoepp et al., 1991), potently reproduces this toxic action. When organotypic cultures containing the hippocampus and lateral septal nucleus are exposed to *trans*-ACPD, it causes an acute neurotoxic reaction localized to the lateral septum. Excessive activation of the 2nd messenger functions of the Glu metabotropic receptor is apparently responsible for the toxic effects on septal neurons in that AP3, which prevents excessive activation of these functions, prevents these toxic effects. It appears that the Glu metabotropic receptor harbors neurotoxic potential that can be that the Glu metabotropic receptor harbors neurotoxic potential that can be unleashed either by suppression or hyperstimulation of this receptor. ## 43.14

OCULAR AND OPTIC NERVE PATHOLOGY IN ADULT RATS ASSOCIATED WITH NEONATAL EXPOSURE TO D.L-2-AMINO-3-PHOSPHONOPROPIONIC ACID (D.L-AP3) AND 1-AMINOCYCLO-PENTANE-TRANS-1,3-DICARBOXYLIC ACID (TRANS-ACPD). A. S. Fix\*.

PENTANE-TRANS-1,3-DICARBOXYLIC ACID (TRANS-ACPD). A. S. Fix. K. I. Griffey. J. A. Johnson, and J. P. Tizzano. Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN 46140.

Metabotropic glutamate receptors are considered important in synaptic plasticity and nervous system development. D.L-AP3, a metabotropic receptor antagonist, produces developmental behavioral deficits and widespread acute neurodegenerative changes when administered to neonatal rats (Tizzano et al., NS Abstr., 1990 and 1991). Included in these changes are degeneration of retina and optic nerve. The present study describes the ocular lesions in adult rats associated with neonatal D.L-AP3 exposure and evaluates the effects of trans-ACPD, a metabotropic receptor agonist, on this D.L-AP3-induced developmental abnormality. Neonatal rats were dosed intraperitoneally on postnatal days 3-10 with saline (n = 5). agonist, on this D,L-AP3-induced developmental abnormality. Neonatal rats were dosed intraperitioneally on postnatal days 3-10 with saline (n = 5), 25 mg/kg/day trans-ACPD (n = 3), 400 mg/kg/day D,L-AP3 (n = 4), or a combination of 25 mg/kg/day trans-ACPD followed 15 minutes later by 400 mg/kg/day D,L-AP3. At 60 days of age, morphologic examinations were made of eyes and optic nerves. All D,L-AP3-treated rats had total atrophy of optic nerve and chiasm. Microscopically, these rats had severe retinal atrophy, retinal detachment, and cataract formation. Similar lesions occurred in all rats treated with a combination of trans-ACPD and D,L-AP3; however, the optic neave atrophy was less propounced in those arts than in these the optic nerve atrophy was less pronounced in these rats than in those treated with D,L-AP3 alone. There were no differences between saline-treated control rats and those treated with trans-ACPD alone. These data suggest that a metabotropic receptor agonist, trans-ACPD, can reduce the severity of D,L-AP3-induced neonatal optic nerve atrophy. Early postnatal exposure to metabotropic receptor agonists/antagonists clearly alters normal development of the cities of the control of the cities of the control of the cities of the citie development of the rat eye and optic nerve.

ACTIVITY STIMULATES THE POLYAMINE INTERCONVERSION PATHWAY IN RAT LIMBIC SYSTEM

A. Bruce\*, I. Najm, S. Hauge, S.S. Schreiber, G. Tocco, and M. Baudry. Neuroscience Program, USC, Los Angeles, CA 90089-2520.

The roles of the polyamines putrescine, spermidine, and spermine following injury in the adult mammalian CNS is still a matter of controversy. Although it has been repeatedly demonstrated that a variety of manipulations can produce a rapid induction of ornithine decarboxylase (ODC), the rate limiting enzyme in the polyamine synthesis pathway, little information is available concerning the induction of the interconversion pathway, which involves the activities of the enzymes spermine/spermidine acetyl transferase (SAT) and polyamine oxidase. We report here that the interconversion pathway is rapidly activated in the rat limbic system following kainic acid (KA)-induced seizure activity.

Groups of rats were sacrificed at various time intervals following systemic KA administration, and the brains were either dissected for biochemical analysis or frozen and used for in situ hybridization studies. SAT activity was increased several fold and up to 16 hours following KA administration in the hippocampus and piriform cortex. In situ hybridization using a 35S-labelled SAT cRNA probe showed a rapid increase in SAT mRNA throughout the rat limbic system. By 16 hrs after KA treatment the increase in SAT mRNA was still present in CA3, CA1 and piriform cortex. Pretreatment of the animals with the polyamine oxidase inhibitor MDL 72527 resulted in larger accumulations of Nacetylspermine and N-acetlyspermidine in KA treated animals than in control animals. The results indicate that seizure activity in limbic structures is accompanied by a rapid induction of SAT, an increased activity of the enzyme and therefore an increased polyamine interconversion. ### 43.17

ATP DEPLETION RELEASES GLUTAMATE PRIMARILY FROM

ATP DEPLETION RELEASES GLUTAMATE PRIMARILY FROM AXONAL TERMINALS OF HIPPOCAMPAL SLICES. I.E. Madl\*. Dept Anatomy & Neurobiology, CSU, Ft. Collins, CO 80523.

Glutamate (Glu) may be released from synaptosomes during ATP depletion by reversal of normal uptake systems. However, immunocytochemical studies suggest much of the Glu in the CNS is found in neuronal cell bodies and dendrites. Whether both of these pools contribute to release induced by ATP depletion remains unknown. Release of Glu from rat hippocampal slices during ATP depletion was measured by HPLC and compared with loss of Glu-like immunoreactivity (GLIR) from neuronal cell bodies and axonal terminals. Slices incubated in from neuronal cell bodies and axonal terminals. Slices incubated in oxygenated Hank's balanced salt solution (with 10 mM HEPES and 10 mM glucose; HBSS) for 1 hr showed GLIR primarily in terminal-like structures with little staining of cell bodies or dendrites. Addition of Glu (1 mM) with Glu antagonists to the HBSS produced greater retention of GLIR in cell bodies and dendrites. ATP depletion induced by dinitrophenol, azide, or other inhibitors produced dose-dependent releases of Glu. In slices preloaded with the transportable Glu analog D, L-threo-3-Hydroxyaspartate (OH-Asp), Glu and OH-Asp were released in a similar Co. independent means during ATP depletion (22.20 00). similar, Ca-independent manner during ATP depletion (R<sup>2</sup>>0.90), suggesting releases occurred by reversal of Na-Glu cotransporters. Immunocytochemical localization of Glu in ATP-depleted slices suggests release was primarily from axonal terminals. ATP depletion reduced GLIR in structures with morphology consistent with axonal terminals while GLIR was retained in neuronal cell bodies and dendrites. ATP depletion also resulted in increased GLIR in some glia. These results suggest Glu is released primarily from axonal terminals and not neuronal cell bodies and dendrites during ATP depletion.

## 43.19

STRIATAL DAMAGE CAUSED BY 3NP INDUCED ENERGY COMPROMISE IS POTENTIATED BY AGING. E. Brouillet, J.R. Simpsons, S.R. Bossis, W.S. Rosenberg\*\$\\$\, B. Hyman\\$\, O. 

3-Nitropropionic acid (3NP) produces excitotoxic lesions in the striatum by impairing energy metabolism (Beal et al., this volume). Since many neurodegenerative diseases, like Huntington's disease, are age dependent we hypothesized that striatal damage induced by 3NP may increase with age. We treated male rats systemically (30 mg/kg/i.p.) or intrastriatally (500 nmol) with 3NP. One week after treatment, rats were evaluated for striatal damage by histological and neurochemical methods. Systemic administration of 3NP rarely caused striatal damage in rats younger than 3 months of age (12% of cases) while rats above that age either died or showed severe striatal damage (87% cases). Lactate increases and ATP depletions at 3 hours following intrastriatal injections of 3NP were significantly greater in 4 month old than in 1 month old animals. There (87% cases). Lactate increases and ATP depletions at 3 hours following intrastriatal injections of 3NP were significantly greater in 4 month old than in 1 month old animals. There was a significantly greater depletion of striatal neurochemical markers in older than in young rats. Mild lesions showed sparing of NADPH-diaphorase neurons consistent with an NMDA-like excitotoxic lesions. Our results demonstrate an age dependent susceptibility of rats results demonstrate an age dependent susceptibility of rats to striatal neuronal damage induced by energy compromise.

EXTRACELLULAR POLYAMINES IN OUINOLINIC ACID-INJECTED STRIATUM. C. Speciale\*, M. Marconi, L. Raimondi, A. Bianchetti and R.G. Fariello. Farmitalia Carlo Erba-Erbamont Group. CNS/CV Research Group, 20014 Nerviano, Italy.

Disposition of endogenous polyamines (PA) is relevant for studying their modulatory role on the N-methyl-D-aspartate receptors. Recently, we showed the extracellular presence of striatal putrescine (PUT), spermidine (SPD), and spermine (SPM) by using the microdialysis in awake rats (Speciale et al., Soc. Neurosci. 17:106.11). We now report PA extracellular content during nerve cell loss. Wistar rats (200-225 g) were used in all experiments. Animals were injected intrastriatally with quinolinate (QUIN, 120 nmoles/2 µl) or saline (SAL, 2 µl). Seven days later, dialysis was performed by delivering Krebs buffer in the injected striatum for 320 min at the speed of 2  $\mu$ l/min. At the beginning of perfusion (but not later on), lesioned rats (n=11) dialysate levels were significantly higher than controls (n=12) for PUT and SPD, and lower for SPM. A depolarizing stimulus was given by perfusing with isotonic Krebs buffer containing 75 mM KCl. In SAL-injected rats (n=6), PUT did not change; SPD rose from  $1.41\pm0.25$  to  $3.61\pm0.58$  pmoles/40  $\mu l$ dialysate, and SPM from  $0.19\pm0.05$  to  $2.54\pm0.79$  pmoles/40  $\mu$ l dialysate. In QUIN-injected rats (n=5), depolarizing stimuli did not affect PUT content, but, unlike controls, the rise of SPD and SPM was not observed. Data show changes of extracellular PA content consequent to excitotoxic nerve cell death and suggest the involvement of neurons in the liberation of SPD and SPM upon depolarization.

### 43.18

KYNURENIC ACID AND DIZOCILPINE DIFFERENTLY MODULATE GLUTAMATE-INDUCED ENERGY FAILURE IN LIVE NEONATAL BRAIN SLICES. M.T. Espanol, Y. Xu, L. Litt\*, G-Y Yang, L-H Chang, T.L. James, P.R. Weinstein and P-H Chan, University of California, San Francisco, 94143.

Acute energy failure and recovery were compared in live 350µ brain slices perfused with different concentrations of glutamate (GLU) and GLU-receptor antagonists. Slices were perfused for sixty minutes with ACSF containing GLU in the range 0.5 mM to 10 mM and then immediately reperfused for sixty minutes with GLU-free ACSF. Interleaved <sup>31</sup>P/<sup>1</sup>H NMR spectra were determined every five minutes. Perfusion with 0.5 mM GLU in the absence of Mg+2 decreased PCr to ≈75% of control but did not affect ATP. Inclusion of 1.2 mM Mg+² prevented detectable NMR changes. Perfusion with 2.0 mM GLU (no Mg+2) decreased PCr (≈60%) and ATP (≈60%); perfusion with 2.0 and 3.0 mM GLU in the presence of 1.2 mM Mg+2 caused a similar but partially recoverable decrease in PCr and ATP. Perfusion with 5.0-10.0 mM GLU caused larger nonrecoverable decreases. Two cerebroprotective agents, kynurenate (1.0 mM) and dizocilpine (150µM MK801), prevented the immediate energy failure caused by 2.0 mM GLU. Additionally, kynurenate and dizocilpine each ameliorated GLU-induced depletion of PCr and ATP, while accelerating recovery after reperfusion. During the first 20 minutes of GLU administration kynurenic acid improved metabolic response while dizocilpine did not. After 30 minutes of GLU administration dizocilpine-treated slices showed almost complete recovery, while kynurenate-treated slices did not. Acute energy failure thus appears linked to activation of more than one type of GLU receptor.

## 43.20

LOCAL AND SYSTEMIC ADMINISTRATION OF 3-NITROPROPIONIC ACID RESULTS IN EXCITOTOXIC STRIATAL

M. Flint Beal\*, Emmanuel Brouillet, Bruce Jenkins, Rachana Srivastava, Deborah Samanta Roy, Bruce R. Rosen and Bradley T. Hyman. Neurology Service, Mass. General Hospital, Boston, MA 02114.

3-Nitropropionic acid (3NP) is an irreversible inhibitor of results in striatal lesions

and dystonia in man. In the present study we characterized the neurochemical effects of lesions produced by either intrastriatal or systemic administration of 3NP. Intrastriatal injections resulted in dose-dependent depletions of GABA, substance P, somatostatin, neuropeptide Y and dopamine. At 3 hours there were significant decreases in ATP and increases in lactate concentrations. Following systemic administration of 3NP striatal concentrations of dopamine and serotonin were spared. Systemic and local administration of 3NP resulted in selective striatal lesions with metals of the New York and NORM. administration of 3NP resulted in selective striatal lesions with marked depletion of both Nissl stained and NADPH-diaphorase neurons. Chemical shift magnetic resonance imaging, showed focal increases in lactate in the striatum following systemic administration of 3NP. Prior decortication attenuated both intrastriatal and systemically induced 3NP lesions. These results show that both local and systemic administration of 3NP results in excitotoxic striatal lesions as a consequence of impairment of oxidative phosphorylation.

MODULATION OF KAINATE-INDUCED IMMEDIATE EARLY GENE EXPRESSION IN RAT BRAIN. X, Li\*, L, Song, K, Kolasa and R,S, Jope, Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL

Immediate early genes (IEG) have a critical role in the stimulus-response process of many cells by virtue of their protein products regulating gene transcription. Because of the importance of IEG in neuronal function, endogenous agents which modulate stimulation of IEG transcription, if they exist, could have profound effects. We used as model stimuli relatively low doses of kainate and pentylenetetrazole (PTZ). The dose (4 mg/kg) of kainate used does not cause convulsions and induces relatively slight increases in the IEG mRNA levels. Therefore, the results obtained should be relevant to other stimuli that only mildly

Therefore, the results obtained should be relevant to other stimuli that only mildly induce IEG expression.

Kainate or PTZ increased c-fos, c-jun, jun B and jun D mRNA levels in rat brain dose-dependently. Kainate increased these mRNA levels predominantly in the hippocampus and PTZ was more effective in the cortex. Adrenalectomy (3 days) was used to eliminate endogenous glucocorticoid hormones. Compared with increases caused by kainate (4 mg/kg) alone, adrenalectomy significantly potentiated kainate-induced increases in the hippocampal mRNA levels of c-fos and jun B by 6.5-fold, of jun D by 2-fold, and tended to augment c-jun. Corticosterone administration blocked the potentiated stimulation of these mRNA levels caused by adrenalectomy. Adrenalectomy also significantly increased PTZ-induced c-fos mRNA in the cortex. These results demonstrate that glucocorticoids modulate IEG expression in the brain, raising the possibility that this interaction contributes to intermeuronal and interindividual differences in responses to stimuli and to the effects of stress- or disease-induced changes in glucocorticoid concentrations.

These observations may be relevant in psychiatric disorders in which altered responses to external stimuli and/or abnormal glucocorticoid function have been implicated as well as to age-related neurodegeneration which is adversely influenced

EFFECT OF THE NON-NMDA ANTAGONIST, GYKI 52466, ON ISCHEMICALLY-INDUCED INTRACELLULAR AND EXTRACELLULAR ASPARTATE AND GLUTAMATE CHANGES IN RAT

CELLULAR ASPARTATE AND GLUTAMATE CHANGES IN RAT HIPPOCAMPUS AND STRIATUM. A.G. Chapman\*, J.L. Graham, C. Moncada, B. Arvin and B.S. Meldrum. Dept. of Neurol., Inst. of Psych., De Crespigny Park, Denmark Hill, London SE5 8AF, England. GYKI 52466 protects against striatal, but not significantly against hippocampal cell loss when assessed 7 days after 20 min of transient global (4VO) ischemia (1). GYKI also selectively inhibits 4VO-induced glu (but not asp) release (2). During 20 min of 4VO ischemia the striatal microdialysate levels of asp and glu increase 4-6 fold. and there are significant increases in the microdialysate levels of asp and glu increase 4-6 fold, and there are significant increases in the intracellular striatal levels of glu (25%) and asp (50%) following ischemia (at 0hr), with return to control levels by 72 hrs postischemia. GYKI (20 mg/kg) pretreatment blocks the ischemic increases in striatal intracellular glu and asp, and the increased striatal glu release. AVO and the increased striatal glu release. 4VO ischemia produces prolonged (0-72hrs) decreases in hippocampal intracellular glu (25-30%) and asp (30-45%), and increased hippocampal glu and asprelease. GYKI does not reverse the hippocampal intra- and extra-cellular asp and glu changes.

PENTOBARBITAL BLOCK OF KAINATE- AND QUISQUALATE-INDUCED CURRENTS. W. Marszalec and T. Narahashi\* Dept of Pharmacol., Northwestern Univ. Med. Dept of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611. Mechanisms underlying the inhibition of non-

NMDA currents by Na pentobarbital (PB) were studied in cultured rat cortical neurons. The block of whole-cell kainate-induced currents by PB (ED50=75µM) was facilitated by receptor activation (use dependent). Currents evoked by 40 µM kainate were reduced 50±3% when 100 µM PB was co-applied for 5 sec. In contrast, kainate currents following a 10 min perfusion with PB alone were inhibited by <10%. Recovery from PB inhibition was use dependent, reversing within inhibition was use dependent, reversing within 5 sec of kainate application, but persisting longer than 10 min in its absence. Currents evoked by 10 µM quisqualate were rapidly desensitized to a steady state. Repeated applications of 100 µM PB reduced peak quisqualate currents 19±5% while inhibiting the smaller sustaining phase 49±5%. The onset of and recoversions of 100 µM PB reduced peak quisqualate currents 19±5% while inhibiting the smaller sustaining phase 49±5%. The onset of and recoversions of the content of the conten ery from PB's inhibition of kainate currents were use dependent, suggesting a PB binding site within the channel. The smaller inhibition of quisqualate currents may reflect a decreased access to the channel due to receptor desensitization. Supported by NIH grant NS14144.

γ-D-GLUTAMYLAMINOMETHYL SULFONIC ACID (GAMS) DISTINGUISHES AMPA- FROM KAINIC ACID-INDUCED RESPONSES IN XENOPUS OOCYTES EXPRESSING CHICK BRAIN GLUTAMATE RECEPTORS N. Zhou\*, L. G. Hammerland and T. N. Parks. Depts. of Anatomy and Biology, Univ. of Utah, Salt Lake City, UT 84132.

In the chick cochlear nucleus, we recently found both GAMS-sensitive and GAMS-insensitive glutamate receptor-mediated responses, with the latter mediating synaptic transmission (Hear. Res., in press 1992). To further characterize the actions of GAMS, its effects on AMPA- and KA-induced responses were studied in 49 Xenopus oocytes injected 3-5 days previously with mRNA from the brains of E16-17 chick embryos and voltage-clamped at -60 mV (cf. Mol. Pharm. 34: 298, 1988). Both AMPA and KA induced smooth inward currents with Hill coefficients of 1.46 (AMPA) and 1.90 (KA). GAMS, at concentrations up to 1 mM, had no reliable effect on AMPA-induced currents but showed a consistent, dose-dependent and reversible effect on KA-induced responses; the slope of the Schild plot was 0.76 and the pA2 value (± S.E.M.) -4.3 ± 0.2. We then compared the selectivity of quinoxalinedione antagonists with that shown by GAMS. DNQX, CNQX and NBQX all blocked the effects of both agonists completely, competitively, reversibly and dose-dependently, with Schild-plot slopes very close to 1.0. Against AMPA, observed pA2 values were -6.6 ±0.1 for DNQX, -6.43±0.07 for CNQX and -6.8±0.1 for NBQX. Against KA, pA2 values were -6.4 ±0.1 for DNQX, -6.6±0.2 for CNQX and -7.2 ± 0.3 for NBQX. Although these data show that NBQX and CNQX are significantly more In the chick cochlear nucleus, we recently found both GAMS-sensitive and GAMS-NBQX. Although these data show that NBQX and CNQX are significantly more potent antagonists of KA- than of AMPA-induced effects, GAMS shows much higher potent anagonists of NA- induced responses and may therefore be a useful tool in studying the diverse types of glutamate receptors in the CNS.

Supported by USPHS grant DC00144 to T.N.P. We thank Prof. D. Yoshikami for generous help and Dr. T. Honore for the gift of NBQX.

ANIRACETAM POTENTIATES KAINATE- AND AMPA-INDUCED CURRENTS IN OOCYTES EXPRESSING CLONED GLUTAMATE RECEPTORS. <u>I.F. McGurk\*</u>, <u>R.S. Zukin and M.V.L. Bennett.</u> Dept. Neurosci., A. Einstein Coll. Med., Bronx, NY 10461.

Kainate/AMPA receptors encoded by "flip" and "flop" splice variants of rat GluR1 and GluR3 RNAs show little desensitization to

the agonist kainate and marked desensitization to the agonist AMPA, with "flop" variants desensitizing more than "flip". The nootropic drug aniracetam potentiated both kainate- and AMPA-induced currents in Xenopus oocytes injected with GluR1 "flip", GluR1 "flop" or GluR3 "flop" cRNA. For all receptor subtypes aniracetam (2mM) increased kainate (300µM) responses to ~140% of control. For GluR1 "flip" receptors aniracetam (2mM) increased AMPA (30µM) responses to 140% of control, while for GluR1 and 3 "flop" receptors potentiation by aniracetam was to ~200% of control. Aniracetam may reduce desensitization of AMPA responses, which could account for the greater potentiation observed for the "flop" variants. Onset and washoff time of aniracetam were sufficiently fast (<1s) to indicate an extracellular site of action. Potentiation did not depend on extracellular Ca<sup>2+</sup> concentration or transmembrane voltage. In oocytes injected with rat brain mRNA, aniracetam generally did not potentiate kainate responses, although potentiation to ~120% of control was sometimes seen. In the same oocytes, aniracetam increased AMPA responses to ~280% of control regardless of its effect on kainate responses. The difference in effects of aniracetam on homomeric GluR receptors and receptors encoded by brain mRNA may be due to heteromeric composition of the latter receptors or the presence of additional subunits.

ANTAGONISM OF ATPA AND AMPA-INDUCED DEPOLARIZATIONS IN THE RAT CORTICAL WEDGE BY NBQX, CNQX, AND PD 140532. L.J. Robichaud\*, S.J. Hays, R.J Chang and P.A. Boxer. Neuroscience Pharmacology, Parke-Davis Research, Warner-Lambert Co. Ann Arbor, MI 48105

Selective affinity of NBQX and CNQX for AMPA versus kainate receptors has been reported in cortical membranes using specific radiolabeled ligands. In similar studies (RS)-α-amino-3-tert-butyl-4 isoxazolepropionic acid (ATPA) has been identified as a new agonist of the AMPA subclass of glutamate receptors. In the rat cortical wedge model, we obtained depolarizations to cumulative concentrations of ATPA, AMPA, and kainate. ATPA was the least potent agonist and produced depolarizations with a slow onset and offset that were qualitatively different from AMPA or kainate. Repeated depolarizations to ATPA, AMPA, or kainate (at their respective EC70s) were obtained before and after thirty min treatment with varying concentrations of antagonist. NBQX, CNQX and the novel compound 6,7-dichloro-3,4dihydro-3-oxo-N-(phenylsulfonyl)-2-quinoxalinecarboxamide (PD 140532) were potent and effective inhibitors of ATPA (IC $_{50}$ s=0.12, 1.6, and 0.6  $\mu$ M respectively) and AMPA ( $IC_{so}$ =0.17, 0.4, and 3.3  $\mu$ M respectively), but less potent against kainate. These data indicate that ATPA is a functional agonist in the cortical wedge, with responses antagonized by NBQX, CNQX and PD 140532 at concentrations similar to those inhibiting responses to AMPA but not kainate. The results are consistent with the assumption that ATPA is an agonist of the AMPA subtype of glutamate receptors.

GUANOSINE COMPOUNDS DECREASE 3H-KAINATE BINDING AND INHIBIT KAINATE RESPONSES IN MAMMALIAN CEREBELLUM. C. Poulopoulou\* and L.M. Nowak, Department of Pharmacology, Cornell University, Ithaca, NY 14853.

Kainate is known to dramatically increase intracellular levels of

cGMP in cerebellum. For this study we examined some possible effects of cGMP on kainate receptors using radioligand binding and patch clamp recording methods. Crude synaptosomal membranes from rabbit cerebellum were used in binding assays and modulation of kainate responses was examined in cerebellar neurons cultured from 1-8 day responses was examined in cerebeilar neurons cultured from 1-8 day old mice. Direct and Scatchard plots of  $^3$ H-kainate binding revealed that kainate binds to two distinct sites with a 10 fold difference in affinity ( $K_{D_1} = 17nM$  and  $K_{D_2} = 1.6nM$ ) and a ratio of high to low affinity sites of 1: 2. This binding profile was altered by the inclucion of 2.5 mM cGMP in the incubation mixture; direct plots were now best fitted by one binding site with a  $K_D$  of 17nM. This may mean that either cGMP preferentially competes for binding to the high affinity kainate binding site, or possibly the high affinity site is converted to a lower affinity. The pharmacological specificity of this effect was tested with guanosine and adenosine nucleotides (0.75-5mM) in displacement assays. All guanosine nucleotides (GMP, cGMP, GDP, GTP), were assays. All granishine indebtines (GMP, GMP, GMP, GMP, GMP), were nearly equipotent in displacing <sup>3</sup>H-kainate binding while adenosine analogs apparently had no effect. Preliminary whole cell recording experiments on cerebellar neurons indicate that coapplication of cGMP with kainate in the bath has inhibitory effects on whole cell kainate currents, suggesting that cGMP exerts this inhibitory action at a site on the extraorbitation. Supported by 18C3467 the extracellular surface of the receptors. Supported by NS24467.

ATPA DRUG DISCRIMINATION: A MODEL OF AMPA AGONISTIC EFFECTS IN VIVO? M.D.B. Swedberg\* and P. Jacobsen. Novo Nordisk, CNS Division, Novo Nordisk Park, DK-2760 Malov, Denmark.

(2-amino-3-(3-hydroxy-5-tert-butylisoxazol-4yl)propionate) is an agonist at AMPA (2-amino-3-(3hydroxy-5-méthylisoxazol-4-yl)propionate) receptors. To determine whether ATPA could serve as an in vivo model of AMPA agonism, rats were trained to discriminate ATPA at 10 mg/kg, i.p., 15 min after injection from no drug. The ATPA discrimination was easily acquired, and yielded a dose dependent generalization curve. The excitatory amino acid agonists NMDA (10-40 mg/kg), kainic acid (0.3 and 1 mg/kg) and AMPA (3 and 10 mg/kg), did not produce ATPA-like discriminative effects. These results indicate that the discriminative effects of ATPA are not mediated by NMDA or kainiate receptors. The failure of AMPA to generalize to ATPA may be attributable to AMPA's poor ability to penetrate the blood brain barrier. Excitatory amino acid antagonists are currently being investigated for their ability to reverse the discriminative effects of ATPA.

CHARACTERIZATION OF KAINATE RECEPTORS IN RAT DORSAL ROOT

CHARACTERIZATION OF KAINATE RECEPTORS IN RAT DORSAL ROOT GANGLION(DRG) NEURONS USING NOVEL S-WILLARDIINE ANALOGS.

L.A. Wong\*. M.L. Mayer, D.E. Jane† and J.C. Watkins†. Lab Cell & Molec Neurophysiol, NICHD, NIH and †Dept of Pharmacology, School of Medical Sciences, Univ of Bristol, UK.

Glutamate receptors in DRG neurons differ from those in the CNS in their desensitizing response to kainate and greater affinity for agonists (Huettner, Neuron 1990, 5:255). The present study further investigates the pharmacology of these receptors by testing the action of a series of S-willardiine analogs. Whole cell patch clamp recordings using fast perfusion techniques were performed on acutely dissociated neonatal (P2-P10) rat DRG neurons. Dose-response analysis revealed the following potency relationship: S-lodo-Willardiine(I-W)>S-Bromo-Willardiine(Br-W)>S-Chloro-Willardiine(I-W)>S-Bromo-Willardiine(Br-W)>S-Chloro-Willardiine(F-W). Application of saturating concentrations of these agonists (100 x EC50) resulted in peak responses of similar amplitude for all willardiine analogs but were smaller than those to Kai. With 2s agonist applications, all willardiine analogs evoked -90% desensitization; in contrast, there was only a 50-70% reduction in peak amplitude for Kai. The rate of onset of desensitization in response to willardiines could be fitted by the sum of two exponentials, 1,1-100 ms and 2,2-900 ms. The potency sequence in our experiments is consistent with the rank order of agonist potency for depolarizing rat dorsal root C fibers (Blake et al., Br. J. Pharm. Suppl. 1991, 104:334P) but is the reverse of that observed in cultured hippocampal neurons: F-Ws-N-W-C-W-Br-W-I-W-S-N-I-W-Kai (Patneau et al., J. Neurosci. 1992, 12: 595). Willardiines exhibit strikingly different pharmacology in hippocampal and DRG neurons and may be useful as tools for the differentiation of glutamate receptor subtypes in other parts of the CNS.

INHIBITION OF SELECTED POPULATIONS OF KAINATE-ACTIVATED RECEPTOR-CHANNELS BY nonNMDA AGONISTS: AMPA, IBOTENATE AND L-GLUTAMATE. L.M. Nowak\* and C. Poulopoulou,

Pharmacology, Cornell University, Ithaca, NY 14853.
Inhibition of kainate responses by L-glutamate, quisqualate and AMPA has been observed in different neuronal cell preparations. Several mechanisms of inhibition have been proposed, with one hypthesis being that some nonNMDA agonists decrease kainate responses by increasing desensitization of a common receptor. Having observed that kainate activates a variety of ion channels, we investigated the inhibition of kainate-activated channels in outside-out patches and asked: 1) are one or more populations of kainate-activated channels affected by these agonists, and 2) do all of the agonists affect the same channels. Patches were taken from cortical and cerebellar neurons grown in primary dissociated cell culture. Pipettes  $(3-8M\Omega)$  typically contained (in mM): 145 CsCl, 10 Hepes-K (pH 7.2), 10 EGTA/1.0 CaCl2, and 2-4 ATP-Mg. Extracellular solutions contained (in mM): 150 NaCl, 2.8 KCl, 1.0 CaCl2, 10 Hepes-Na (pH 7.2) and 300 nM TTX. Kainate, AMPA, L-glutamate and ibotenate were applied alone, or in combination by slow or fast perfusion. Kainate opened channels with conductances of  $\sim$ 1, 2-4, 13, 25, and 36 pS, which where observed in different patches, and which had different kinetics, suggesting they represent different receptor-channels. AMPA, applied to some of these patches, activated the 13, 25 and 36 pS channels, and ibotenate activated the 25 and 36 pS channels. Coapplication of AMPA or L-glutamate with kainate primarily inhibited low conductance kainate channels, whereas ibotenate primarily inhibited the 13 pS channels activated by AMPA and kainate. Supported by NS24467.

SELECTIVE DISPLACEMENT OF LOW AFFINITY 3H-KAINATE BINDING

CORRELATES WITH ANTAGONISM OF DOMOIC ACID TOXICITY.

E.Ø. Nielsen\*1, T.H. Johansen\*1, R.A.R. Tasker\*2, S.M. Strain\*1, L.H. Jensen\*1, F. Wätjen\*1 and J. Drejer\*1. NeuroSearch A/S, Smedeland 26, 2600 Glostrup, Denmark; \*Adiantic Veterinary College, Charlottetown, Prince Edward Island, Canada, CIA 4P3.

Binding sites for non-NMDA excitatory amino acid receptors have generally been studied using <sup>3</sup>H-AMPA and <sup>3</sup>H-kainate (<sup>3</sup>H-KA). <sup>3</sup>H-KA binding sites can be studied using 'H-AMPA' and 'H-Kaniate ('H-KA). 'H-KA binding sites can be separated into high- and low affinity sites, respectively, and be studied on the basis of the sensitivity of these two sites to Ca<sup>2+</sup>. High affinity 'H-KA binding sites may represent distinct KA receptors whereas low affinity 'H-KA binding sites probably represent binding of KA to AMPA receptors. Most non-NMDA agonists and antagonists studied so far in 3H-KA binding have shown little or no selectivity between high- and low affinity sites. One exception is domoic acid (DOM) which relative to KA has a higher affinity for low affinity 'H-KA binding sites. From a scries of novel isatinoximes developed as non-NMDA antagonists a few compounds have been characterized as potent and selective displacers of low affinity <sup>3</sup>H-KA binding. High affinity <sup>3</sup>H-KA binding was studied at 2 nM <sup>3</sup>H-KA (-Ca<sup>2</sup>) whereas low affinity binding was performed at 20 nM (+20 mM Ca<sup>2+</sup>). NS102 displaced low affinity <sup>3</sup>H-KA binding with an IC<sub>50</sub> of 0.7 µM with only partial inhibition of high affinity binding at 10 µM. NS102 showed non-NMDA antagonism in several in vitro functional tests. In vivo NS102 (10 mg/kg ip) antagonized behavioral effects including seizures induced by systemic DOM administration and blocked DOM induced neurodegeneration. However, NS102 only offered partial protection of behavioral responses to KA and could not block KA induced neurodegeneration. These findings indicate that DOM activation of non-NMDA receptors differs from activation by KA. This difference might be explained by an apparent selectivity of DOM for low affinity 3H-KA binding sites. The identification of new non-NMDA antagonists such as NS102 with high selectivity for low affinity 3H-KA binding sites may be valuable tools in the characterization of the functional importance of these binding sites.

DIAZOXIDE POTENTIATES AMPA/KAINATE RECEPTOR CURRENTS ALLOSTERICALLY. <u>J.C.R. Randle\*</u> and <u>J.M. Lepagnol</u>, Institut de Recherches Servier, 92150 Suresnes, FRANCE.

Diazoxide (DZX) was recently reported to enhance and

Diazoxide (DZX) was recently reported to enhance and prolong excitatory synaptic currents and L-glutamate or quisqualate-induced (but not kainate-induced) current in hippocampal cell cultures (Yamada and Rothman, Soc. Neurosci. Abstr. 17:896 (1991), independent of its actions on ATP-sensitive K+ channels. We have examined this phenomenon in two-electrode voltage-clamp experiments on rat cortex mRNA-injected Xenopus oocytes. DZX (10-560 uM) had no effect on membrane current when applied alone, and only weakly inhibited responses to NMDA (30 uM) plus glycine (3 uM) or GABA (100 uM). However, DZX induced a rapidly appearing and reversible 2 to 3-fold increase in current responses evoked by all concentrations of AMPA (1-1000 uM); the EC50 of AMPA (8 uM) was unchanged. Curiously, DZX induced a leftward shift of the kainate concentration response curve (EC50; control 100; um; DZY (1-1000 uM); the EC50 of AMPA (8 uM) was unchanged. Curiously, DZX induced a leftward shift of the kainate concentration-response curve (EC50: control, 100 uM; +DZX, 30 uM). DZX increased responses to 3-30 uM kainate 3 to 5-fold but those to high (1-3 uM) concentrations only 10-15% (accounting for the lack of effect reported by Yamada and Rothman). DZX had little effect on the inhibition of kainate/AMPA currents by NBQX. Furthermore, DZX (1 uM - 1 uM) did not displace [3H]AMPA or [3H]kainate binding. Our data indicate that DZX acts allosterically to induce kinetically distinct potentiation of activation by AMPA and kainate of the AMPA/kainate receptor/channel.

PENTOBARBITAL ANTAGONIZES AMPA AND KAINIC ACID BUT NOT DNOX-SENSITIVE SYNAPTIC RESPONSES. E.W. Harris\* Biology DNQX-SENSITIVE SYNAPTIC RESPONSES. <u>E.W. Harris</u>, B Dept., Fisons Pharmaceuticals, Rochester, NY 14603

Glutamate appears to be an excitatory neurotransmitter in the mammalian CNS, acting at receptors denoted by selective agonists, for example, NMDA, kainic acid (KA), selective agonists, for example, NMDA, kainic acid (KA), and AMPA or quisqualate. Many excitatory synaptic responses appear to have a large AMPA and/or KA receptor-mediated component because they are reduced by AMPA/KA competitive antagonists (e.g., DNQX). Pentobarbital has also been reported to antagonize quisqualate and KA more than NMDA. Therefore, its effects on responses to AMPA, KA, and excitatory synaptic responses have been examined.

In area CA1 of rat hippocampal slices, pentobarbital (10-100 $\mu$ M) antagonized the effects of bath-applied AMPA and KA, but not NMDA, similar to the effects of 10 $\mu$ M DNQX. Antagonism by pentobarbital was unaffected by bicuculline (30 $\mu$ M), or reducing Ca<sup>++</sup> (0.2mM Ca<sup>++</sup> & 5.8mM Mg). Therefore, pentobarbital appears to be acting as a direct AMPA/KA antagonist. However, 1000µM pentobarbital had no effect on excitatory synaptic field potentials, which were almost abolished by 10µM DNQX. In contrast, the NMDA antagonists AP5 and MK-801 did antagonize responses to bathapplied NMDA as well as NMDA-receptor-mediated synaptic responses (recorded in low-Mg<sup>\*\*</sup>/DNQX-containing medium).

The effects of pentobarbital seem inconsistent with competitive antagonism or channel blockade.

α-AMINO-3-HYDROXY-5-METHYLISOXAZOLE-4-PROPIONATE(AMPA) EXCITATORY AMINO ACID RECEPTOR ANTAGONISTIC PROPERTIES OF YM900 (6-(1-imidazolyi)-7-nitro-quinoxaline-2,3(1H,4H)-dione). M. Okada, K. Hidaka, J. Togami, K. Ohno, S. Tada, J. Ohmori, S. Sakamoto, and T. Yamaguchi\*. Central Research Laboratories, Yamanouchi Pharmaceutical Co. LTD., 21 Miyukigaoka, Tsukuba, Ibaraki 305, Japan. and T. Yamaquchi\*

We have synthesized a series of imidazolylquinoxaline-2,3-diones to develop a potent and selective AMPA excitatory amino acid receptor antagonist. Among of these compounds, we discovered YM900 which had high affinity for AMPA binding sites(S. Sakamoto et.al., XIIth International Symposium on Medicinal Chemistry, 1992.). Here we report YM900 is an antagonist at AMPA-type receptor.

YM900 with a Ki for the displacement of <sup>3</sup>H-AMPA=0.058μM, <sup>3</sup>H-Kainate=2.2μM, L-3H-Glutamate(NMDA-specific site)>100μM and Glycine(strychnine-insensitive site)=19µM had the highest affinity for AMPA binding sites. AMPA elicited a concentration-dependent increase in intracellular Ca<sup>2+</sup> in cultured hippocampal neurons, and YM900 inhibited AMPA-induced Ca<sup>2+</sup> increase. Injection of AMPA into the rat striatum resulted in a loss of enzyme marker for cholinergic neurons 7 days later, and YM900 co-injected with AMPA protected cholinergic neurons from AMPAneurotoxicity. All of these data shows that YM900 is a novel and potent antagonist at AMPA-type receptor.

THE NEUROPROTECTIVE ACTIONS OF YM900, A NOVEL AND POTENT α-AMINO-3-HYDROXY-5-METHYLISOXAZOLE-4-PROPIONATE (AMPA) RECEPTOR ANTAGONIST, IN A GERBIL GLOBAL ISCHEMIA MODEL AND A RAT FOCAL ISCHEMIA MODEL. M. Shimizu-Sasamata's. Kawasaki, S. Yatsuqi, J. Ohmori, S. Sakamoto, K. Koshiya, S. Usuda and K. Murase. Central Research Laboratories, Yamanouchi Pharmaceutical CO. LTD., 21 Miyukigaoka, Tsukuba, Ibaraki 305, Japan.

Glutamate is thought to mediate the neurodegeneration following cerebral ischemia by acting on N-methyl-D-aspartate(NMDA) and non-NMDA sub-

ischemia by acting on N-methyl-D-aspartate(NMDA) and non-NMDA subtypes of excitatory amino acid receptors. We have investigated the neuroprotective actions of YM900 [6-(1-imidazolyl)-7-nitroquinoxaline-2,3(1H,4H)-dione], a novel and potent AMPA receptor antagonist (Okada et al., this meeting), in a gerbil global ischemia model and a rat focal ischemia model. Male Mongolian gerbils were subjected to 5 min of transient cerebral ischemia induced by bilateral common carotid occlusion. After 4 days, the CA1 subfield of the hippocampus was assessed for neuronal loss using a 4 point rating scale (from 0 = no damage to 3 = almost total damage). The mean score of the control animals was  $3.0 \pm 0.0$ . When administered at 60, 70, and 85 min or 360, 370, and 385 min after recirculation, YM900 (30 mg/kg i.p.) significantly prevented delayed neuronal death in the CA1 area mg/kg i.p.) significantly prevented delayed neuronal death in the CA1 area (the scores were  $0.7 \pm 0.2$  and  $1.8 \pm 0.4$ , respectively).

Male Fischer rats were subjected to permanent occlusion of the left middle cerebral artery. After 24 hr, the volume of ischemic brain damage was assessed quantitatively using an image analyzer. When administered by an continuous i.v. infusion of 20 mg/kg/h for 4 hr starting at post-ischemia, YM900 significantly reduced the volume of ischemic damage in the cerebral hemisphere by 31%.

Our data demonstrate that blockade of non-NMDA receptor decreases neuronal damage following both global and focal ischemia models and suggest that YM900 may be useful in the treatment of human stroke.

EXCITATORY AMINO ACIDS: RECEPTORS I

STRUCTURE AND SUBUNIT COMPOSITION OF AMPA RECEPTORS IN THE RAT BRAIN. C.D. Blackstone\*, L.J. Martin, D.L. Price and R.L. Huganir, Dept. of Neuroscience, Howard Hughes Med. Inst., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205 The oligomeric structure and regional distribution of AMPA-preferring

The oligomenc structure and regional distribution of AMPA-preterring glutamate receptors were studied using antipeptide antibodies to the receptor subunits GluR1-GluR4. These antibodies, which were generated against divergent regions of GluR1-GluR4 as well as a domain common to GluR2 and GluR3 (GluR2/3), detected distinct proteins ranging from 102-108 kDa on SDS-PAGE of rat CNS membranes, but not in peripheral tissues. Chemical cross-linking studies in cerebellar membranes revealed a fully cross-linked product of M<sub>r</sub>=520,000 as detected by immunoblotting with the the GluR1 antibodies. This finding is consistent with the previously reported native CHAPS-solubilized receptor M<sub>r</sub>=610,000 [*J. Neurochem.* 58, 1118, (1992)] and suggests that AMPA receptors are pentameric complexes of these subunits. Immunocytochemical localization in the rat CNS using the GluR1, GluR2/3, and GluR4 antibodies showed a partially overlapping Gluk2/3, and Gluk4 antibodies showed a partially overlapping distribution of these subunits, with enrichment in hippocampus, striatum, cerebellar cortex, and cerebral cortex. Immuno-electron microscopy demonstrated that these receptors are post-synaptic, with enrichment in the post-synaptic densities of dendritic spines. Interestingly, the Gluk4 subunit was localized primarily to astrocytes in hippocampus, olfactory bulb, and cerebral cortex, and was most prominant in the cerebellar Bergmann glia. These results indicate that AMPA receptors may exist as both hetero- and homo-oligomers on neurons and glia within the CNS. Supported by the NIH and HHMI.

CHARACTERIZATION OF THE GLUTAMATE RECEPTOR SUBUNIT GluR1 IN HUMAN POSTMORTEM TISSUE. C.R. Breese', T.M. Bartel, S.W. Rogers, M.D. Browning, S. Leonard, Denver Veterans Administration Medical Center; and Department of Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80220. Antibodies to the functional GluR1 glutamate receptor subunit were utilized as probes to characterize glutamatergic receptors in human post-mortem brain tissue. Antibodies were raised in rabbits to the extracellular (residues 185-449) and putative intracellular (residues 658-889) domains of the rat GluR1 receptor protein (Rogers, et al., J. Neurosci. 11:2713). Crude membranes from rat and human hippocampus were fractionated by SDS-PAGE and electrotransferred to Immobilon-P membranes. Using these antisera raised against rat antigen, we have been able to detect specific bands on western blots in both human and rat hippocampal membranes. These antisera recognized previously described bands at 105kDa and 97kDa in both humans and rats. Additional bands were observed at 180kDa from the antibody to the intracellular domain and at 145kDa from the antibody to the extracellular domain. Our studies demonstrate that glutamatergic receptors may be examined in human postmortem tissue by western blotting techniques utilizing antibodies raised to the rat protein, suggesting a high degree of homology in these receptors. These antibodies can thus be utilized in human postmortem tissue to examine receptor protein changes in various human disease states. [Supported by USPHS grant MH14212 and Veterans Affairs Medical Research Service.]

ANTIBODIES TO THE Glur-A AMPA RECEPTOR SUBUNIT LABEL 98 AND

ANTIBODIES TO THE GluR-A AMPA RECEPTOR SUBUNIT LABEL 98 AND 57 KDa PROTEINS CONCENTRATED IN PSDs. D.T. McOuade, B.A. Bahr, M. Kessler, E.T. Esteban, B.L. Bakus, R.A. Hall, P.W. Vanderklish, G.L. Shaw\*, K. Sumikawa, and G. Lynch. Center for the Neurobiology of Learning and Memory and Dept. of Psychobiology, University of California, Irvine, CA 92717-3800 The AMPA-selective glutamate receptor, a member of the ligand-gated channel family, is comprised of several subunits. Polyclonal antibodies (anti-GluR) against an extracellular domain (amino acids 163-188) of the GluR-A subunit was used to screen subcellular fractions from rat brain. Postsynaptic densities (PSDs) and synaptosomes were prepared in the presence of broad spectrum protease inhibitors and subsequently analysed by immunoblot. Affinity purified anti-GluR labeled two proteins of 98±2 and 57±2 kDa (S.D., n=8) that were highly concentrated in PSDs as compared to brain homogenates. The molecular mass of the larger antigen (98 kDa) is similar to that expected for the GluR-A subunit on the basis of its amino acid sequence. This protein was most concentrated in PSDs from the hippocampus, with lower amounts in neocortex > mesencephalon > cerebellum > cer ippocampus, with lower amounts in neocortex > mesencephalon > cerebellum > rain stem. The density of the 57 kDa antigen had a partially reversed order with nuppocampus, with lower amounts in necorrex > mesencephation > cerebellum > brain stem. The density of the 57 kDa antigen had a partially reversed order with mesencephalon > cerebellum > brain stem > hippocampus > neocortex. Crude synaptosomes from forebrain were fractionated by equilibrium density centrifugation and assayed by immunoblot and [<sup>3</sup>H]AMPA binding. The two antigens showed distinct profiles across the gradient, the smaller one being more concentrated in the denser fractions. [<sup>3</sup>H]AMPA binding had two maxima which appeared to coincide with the immunoreactivity peaks. This suggests the possibility that a 57 kDa AMPA-binding protein exists with a size and brain distribution similar to that of a glutamate-binding protein in chick. It is noteworthy that two similar antigens (99 and 61 kDa) have also been identified in the mouse telencephalon and that their density decreased equally with age (3-25 months). A comparable reduction was also found for the B<sub>MAX</sub> of [<sup>3</sup>H]AMPA binding (Bahr et al., Brain Res., in press). This further suggests that the smaller antigen is not a proteolytic fragment but represents a component of some AMPA receptor complexes. (This work was supported by grant AFOSR 89-0383 and the HFSP).

AMPA-SELECTIVE GLUTAMATE RECEPTOR SUBUNITS IN HIPPOCAMPAL NEURONAL CELLS. N. Eshhar<sup>1</sup>, R.S.Petralia<sup>1</sup>, C.A. Winters<sup>2</sup> and R.J. Wenthold 1\*. 1Lab. of Neurochemistry, NIDCD and 2Lab. of Cell. and Molec. Neurophysiology, NICHD, NIH, Bethesda, MD 20892.

Recent immunoelectron microscope studies on rat brain sections using antibodies directed against the C-termini of AMPA-selective glutamate receptor anutoones curected against the C-termini of AMPA-selective glutamate receptor (GluR) submits revealed their localization to the postsynaptic membrane and density, dendritoplasm, and cell body, but not within the synaptic cleft. Tissue culture systems may provide further information concerning topology and distribution of GluR molecules in neuronal cells. In this study, a variety of methodologies such as immunohistochemical analysis utilizing immunofluorescence and enzyme-linked immunoassays, electron microscopy, and in-situ hybridization were used. The distribution of GluR immunoreactivity on in-stat hydrodrzabul where used. The distinuous of China himilario-cartiny of infixed hippocampal neuronal cells (derived from 22 day old rat embryos) grown on hippocampal glial cells was observed in the cell body and dendrites but not in the axon. Staining was dense with antibodies to GluR1 and GluR2/3 (antibody recognizing GluR2 and 3) and light with antibody to GluR4. Visualization of receptor sites on live cells under light microscopy was not observed. Staining with antibodies to GluR1, 2/3 and 4 was detected in both cell bodies and dendrites 2 hours following their plating. In comparison, microtubule-associated protein (MAP-2) has been visualized in cells only 6 hours following their plating (MAP-2) has been visualized in cells only 0 nours rollowing liter planing indicating that MAP-2 is not required for the initial distribution of GluR subunits into neurities. At one week in culture, several morphological types of neurons were present, although not all types were labeled consistently. The number of cells labeled with antibodies to GluRs increased with time in culture.

The relationship between where the protein is localized and where it is synthesized was revealed by preliminary in-situ hybridization analysis. We observed significant grain density in cell bodies only, indicating that synthesis of GluR subunits is limited to the neuronal cell body and segregation of GluR obbatists and the determinant of the control of the cont subunits in dendrites may be determined after translation.

IMMUNOSTAINING FOR AMPA-SELECTIVE GLUTAMATE RECEPTORS IN THE SPINAL CORD OF RATS

A. Rustioni\*1, C.D. Blackstone<sup>2</sup>, R.J. Wenthold<sup>3</sup> and R.J. Weinberg<sup>1</sup> <sup>1</sup>Dept. Cell Biology & Anatomy, U North Carolina, Chapel Hill; NC 27599; <sup>2</sup>Dept. Neuroscience, The Johns Hopkins U., Baltimore, MD 21205; <sup>3</sup>Laboratory of Neurochemistry, NIH, Bethesda, MD 20892.

We have employed recently characterized antisera that recognize four receptors subunits, GluR1-4, that respond to AMPA, kainate and four receptors subunits, Guiki 1-4, that respond to AMFA, kanate and glutamate when expressed in oocytes and cultured cells (Blackstone et al., 1992; Wenthold et al., 1992). Nembutal-anesthesized Sprague-Dawley rats were perfused with 4% paraformaldehyde and 0.1% picric acid with or without 0.2% glutaraldehyde. The addition of glutaraldehyde was required for good tissue preservation for electron microscopy. Fifty µm thick Vibratome sections were processed for immunocytochemistry. Best results were with primary antibody concentrations in the range of 1:1,000 to 1:10,000. Observations to be reported deal primarily with the results in the dorsal horn. In this part of the spinal cord stained cells bodies were small and concentrated in lamina II (substantia gelatinosa). Within this lamina, GluR1-positive cells were located more superficially than GluR2-3. Electron microscopy confirmed the staining of cell bodies and revealed immunostaining especially of dendrites contacted by axon terminals of various morphology. Less selective staining for neuronal somata was obtained with the use of GluR4. The distribution of immunostaining suggests a relation between the receptors expressed by neurons in different sublaminae of substantia gelatinosa and their anatomical and functional features.

ANTIBODIES TO THE GluR-A, GluR-B/C, GluR-D, AND NMDA-R1

ANTIBODIES TO THE GIUR-A, GIUR-B/C, GIUR-D, AND NMDA-R1 GLUTAMATE RECEPTOR SUBUNITS: WESTERN BLOT STUDIES.

M. Hennegriff\*, B.A. Bahr¹, R.A. Hall¹, K.M. Guthrie³, R.S. Yamamoto², M. Kessler¹, C.M. Gali³, and G. Lynch¹. Center for Neurobiology of Learning & Memory¹, Department of Molecular Biology and Biochemistry². Department of Anatomy and Neurobiology³, University of California, Irvine, CA 92717.

The recently reported cloning of NMDA receptors has expanded the list of excitatory amino acid receptors already characterized. In this study, polyclonal antibodies were raised against synthetic peptides corresponding to carboxyterminal regions of the AMPA receptor subunits GluR-A, GluR-B/C, GluR-D, as described by Petralia & Wenthold (J. Comp. Neurol. 318:329, 1992), and against the corresponding carboxyterminal region of the putative NMDA receptor cloned by Nakanishi et al. (Nature 354:31, 1991). As in previous studies, affinity purified antibodies to AMPA receptor subunits labeled antigens of about 100 kDa in rat brain homogenates samples. This molecular mass closely agrees with that deduced from the corresponding amino acid sequences. In contrast, antibodies to the NMDA receptor labeled 75±2 and 81±1 kDa (SD, n=7) doublet proteins which are much smaller than expected from sequence data (105.5 kDa). Of these, the lower 75±2 and 81±1 kDa (SD, n=7) doublet proteins which are fructi shaller than expected from sequence data (105.5 kDa). Of these, the lower molecular weight band was labeled more intensely. Prolonged staining led to the appearance of additional faint bands of 42, 48, and 62 kDa. Pre-immune serum subjected to affinity purification steps did not label any bands. In order to determine the regional distribution, the 75/81 kDa doublet was quantitated by laser densitometry in homogenate samples prepared from seven brain regions. The doublet was most abundant in neocortex, followed by hippocampus > striatum >> thalamus > olfactory bulb > cerebellum >> brain stem. The same regional distribution was found in synaptosomal membranes and resembles that seen in autoradiographic studies measuring NMDA-sensitive [3H]qlutamate binding (Monaghan & Cotman, J. Neurosci. 5:2909, 1985).

### 45.6

ULTRASTRUCTURAL LOCALIZATION OF AMPA-SELECTIVE GLUTAMATE RECEPTOR SUBUNITS. R.S. Petralia\* and R.J. Wenthold, Lab. of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

Previous ultrastructural studies using polyclonal antibodies made against different glutamate receptor (GluR) subunits have indicated that these subunits are localized in postsynaptic densities as well as in the dendritoplasm and cell bodies (Petralia and Wenthold, J. Comp. Neurol. 318:329, 1992). These studies which utilized a preembedding avidin-biotin-peroxidase immunocytochemical method, indicated that the antigenic site might be introcally the interesting the supervised for twem prestriend. site might be intracellular since the synaptic clefts were unstained. However, it was not possible to distinguish between receptor molecules incorporated in the membrane and those of the cytoplasmic pool. Further, the antibodies were made against peptides representing the C-terminus, which is believed to be extracellular.

Consequently, we have begun studying ultrastructural localization of GluR subunits with postembedding immunocytochemistry. In this study, we compared the localization of GluR subunits with preembedding and postembedding immunocytochemistry in a number of brain structures including the cerebral cortex and cochlear nuclei of the rat.

A number of postembedding techniques were used to show localization of antibodies to GluR1 and GluR4, and a third antibody which recognizes both GluR2 and 3 (GluR2/3) and which gave the most distinctive labeling. When 75 nanometer sections were incubated with antibody to GluR2/3 using aldehyde fixation and LR White embedment, 10 nanometer gold particles were localized most commonly along the center of the synaptic cleft, and less commonly adjacent to the post- and presynaptic membranes or within the postsynaptic density. Cytoplasmic labeling was low to moderate, and showed a preference for a subset of neurites.

## 45.8

DETECTION OF NMDA RECEPTOR MRNA BY HYBRIDIZATION USING RADIOACTIVE AND NON-RADIOACTIVE LABELED SYNTHETIC OLIGONUCLEOTIDE PROBES.

W.M. Al-Ghoul<sup>1</sup>, D.E. Millhorn<sup>2</sup> and A. Rustioni<sup>1</sup>. <sup>1</sup>Dept. Cell Biol. and Anat., and <sup>2</sup>Dept. Physiol., University of North Carolina at Chapel Hill, Chapel Hill, NC 27599

The nucleotide sequence of a rat brain cDNA that encodes a protein (NMDAR1) with NMDA receptor functional characteristics has been published recently by Moriyoshi et al. (Nature 354:31-37, 1991). Based on this sequence, we developed three synthetic oligodeoxyribonucleotide probes against highly conserved regions of NMDA receptor mRNA. The 29-, 32-and 48-nucleotide probes did not recognize any other mammalian cDNA or gene sequence registered in GCG database. Probes were 3'-labeled with α-thio-[<sup>48</sup>S]dATP or digoxigenin-11-dUTP/dATP. <sup>28</sup>S- or digoxigenin-labeled probes were used in parallel *in situ* hybridization experiments performed on cryostat sections of quick-frozen rat CNS tissue. Hybridization was performed overnight at 37° C using a mixture of the probes. The hybridization signal was detected with autoradiographic (using NTB3 emulsion; Kodak) or immunohistochemical (using anti-digoxigenin antibody; Boehringer Mannheim) methods. High levels of hybridization were detected in selected neuronal populations in the hippocampus, dentate gyrus, cerebellum and cerebral cortex. The distribution of hybridization with our synthetic oligonucleotide probes was similar to the distribution described by Moriyoshi et al. using a 1,431-nucleotide \*S-labeled RNA probe. Further experiments are underway in our laboratory using this method to detect changes in NMDA receptor mRNA levels under various experimental conditions.

SWITCH IN KAINATE/AMPA RECEPTOR SUBUNIT GENE EXPRESSION FOLLOWING GLOBAL ISCHEMIA IN RATS. <u>D.E. Pellegrini-Giampietro\*</u>, R.S. Zukin, S. Cho<sup>1</sup> and W.A. Pulsinelli<sup>1</sup>. Dept. of Neuroscience, A. Einstein Coll. Med., Bronx, NY 10461, and <sup>1</sup>Dept. of Neurology, Cornell Univ. Med. Ctr., New York, NY 10021.

Severe, transient forebrain ischemia induces delayed damage to specific neuronal populations. Sustained Ca<sup>2+</sup> influx through EAA receptors is thought to be responsible for this damage. AMPA receptors, in particular, are implicated in the pathogenesis of CA1 pyramidal cell postischemic death: whereas NMDA receptor blockers are ineffective, the AMPA receptor antagonist NBQX attenuates CA1 ischemic injury. It has been demonstrated that kainate/AMPA channels expressed from GluR1 and/or GluR3 cRNAs are permeable to Ca2+; the GluR2 subunit acts as a switch to shutoff Ca2+ permeability. To investigate the molecular mechanisms underlying delayed postischemic cell death, kainate/AMPA receptor subunit gene expression was examined by in situ hybridization in the hippocampus of rats subjected to 10 min of global ischemia. Our results show that GluR2 expression postischemia is reduced in CA1 neurons at a time point (24 hrs) which precedes their degeneration, whereas GluR1 and GluR3 are not significantly changed. Immunocytochemistry indicates that the GluR2 protein is preferentially reduced in CA1 at 48 hrs. The switch in expression of kainate/AMPA receptor subunits precedes an increase in Ca<sup>2+</sup> influx into CA1 cells. Timing of the switch suggests that it might play a causal role in postischemic cell death.

## 45.13

GLUTAMATE RECEPTOR SUBTYPES ARE DIFFERENTIALLY EXPRESSED IN CULTURED HIPPOCAMPAL ASTROCYTES. D. Fan, A.B. Johnson\*, J.A. Kessler and R.S. Zukin. A. Einstein Coll. Med., Bronx, NY 10461.

The cloning of cDNAs encoding kainate/AMPA and NMDA receptors makes it possible to use techniques of molecular biology to examine the expression patterns of these receptors in cultured cells. Electrophysiological and pharmacological studies indicate that non-NMDA glutamate receptors occur in astrocytes, whereas NMDA receptors do not. However, glutamate-induced swelling in primary astrocyte cultures can be blocked by the NMDA receptor antagonist MK-We used in situ hybridization to examine the pattern of kainate/AMPA and NMDA receptor expression in astrocytes. Astrocytes from 1-2 day old neonatal rat hippocampi were maintained in culture for eight days. Monolayer cultures were hybridized under conditions of high stringency with riboprobes directed against GluR1, GluR2 and GluR3 (Kainate/AMPA) and NMDAR1 receptor mRNAs. Under these conditions, there is no detectable cross-hybridization among these probes. In cells hybridized to GluR1, labelling was prominent in the nuclear region and at a low level in the cytoplasm. In contrast, GluR2 and GluR3 expression was not detectable. The cells exhibited NMDAR1 mRNA labelling at a very low level, suggesting that NMDA receptors may be expressed in rat hippocampal astrocytes. These results indicate that GluR1 is the predominant glutamate receptor subunit mRNA expressed in rat hippocampal astrocytes.

#### 45.10

EXPRESSION AND DISTRIBUTION OF AMPA-SELECTIVE GLUTAMATE RECEPTORS IN CULTURED RAT HIPPOCAMPAL NEURONS. A.M. Craig¹, C.D. Blackstone², R.L. Huganir² and G. Banker¹\*, ¹Dept. of Neuroscience, University of Virginia, Charlottesville, VA 22908 and ²Dept. of Neuroscience, Howard Hughes Medical Institute, The Johns Hopkins University, Baltimore, MD 21205

Anti-peptide antibodies and oligonucleotide probes were used to study the expression and localization of some of the non-NMDA ionotropic glutamate receptor subunits in hippocampal neurons cultured from E18 rats. In situ hybridization was performed with oligonucleotides directed against the immediate 3' untranslated region of GluR 1, and against the divergent loop between TM1 and TM2 for GluR 2, 3, and 4. GluR 1 and 2 mRNAs were abundant in over 80% of the neurons, whereas the expression of GluR 3 and 4 was more restricted. The level of expression of all subtypes increased between 2 days and 2 weeks in culture. At all ages, the mRNAs were largely restricted to the cell body. Immunolocalization with an affinity-purified subtype-specific antibody against GluR 1 yielded selective staining of cell bodies and dendrites, as defined by morphology and co-staining for MAP2, with little or no staining of axons. The staining was blocked by pre-incubation of the antibodies with the specific peptide. Within the soma and dendrites, GluR 1 staining was not homogeneous. There were numerous small, densely stained spots superimposed on a more diffuse staining. By double label immunofluorescence, these spots colocalized with a subset of synaptophysin-rich puncta that have previously been identified by electron microscopy as presynaptic specializations. appears to be most concentrated at synaptic sites. An antibody which recognizes GluR 2/3/4c gave a staining pattern similar to that for GluR 1. We are currently studying localization of these glutamate recentors as neurons develop and form synaptic contacts in culture. Supported by NIH grant NS17112, the Howard Hughes Medical Institute, and an MRC of Canada fellowship.

### 45.12

GLUTAMATE RECEPTOR GENE EXPRESSION IN SPINAL CORD OF ARTHRITIC RATS. S.G. Fan. R.S. Zukin\*, D. Pellegrini-Giampietro, and B. Ault¹. Dept. Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461 and 'Sterling Winthrop Pharmaceuticals Research Division, Rensselaer, NY 12144.

Injury to peripheral tissue leads to inflammation and increased sensitivity to noxious stimuli. Hyperalgesia following peripheral injury is thought to be mediated in part by spinal cord plasticity. We used in situ hybridization to examine glutamate receptor gene expression following induction of inflammation by a unilateral intra-articular injection of lipopolysaccharide (10 µg) into the ankle. In control rats GluR1 expression was prominent throughout the layers of the gray matter of the spinal cord. Microscopic examination revealed labeling of neuronal cell somata in all major nuclei, with highest intensity over motoneurons. GluR2 was abundant in substantia gelatinosa and motor nuclei; emulsion dipped sections exhibited intense labeling over densely packed neurons in the superficial laminae of dorsal horn and individual motoneurons of ventral horn. GluR3 was expressed at low levels in layers IV - VI of dorsal horn and (most prominently) in the motor nuclei. GluR5 expression was of low abundance and selectively localized to the motor nuclei. One day after injection GluR1 expression was decreased by ca. 30% in the substantia gelatinosa (n = 4). In contrast, no significant change was apparent in GluR2, GluR3, or GluR5 expression in any nucleus of the cord. At 72 hrs after injection, all four transcripts were expressed at near control levels. These findings provide evidence for a specific decrease in GluR1 expression in the cord in response to inflammation.

## 45.14

EXPRESSION OF GLUTAMATE RECEPTOR SUBUNITS IN CHICK  $\alpha$ -MOTONEURONS. D. Lowe\*, P. Leach, R. Temkin, D.O. Smith. Neuroscience Training Program, Univ. WI, Madison, WI 53706. Whole cell recordings from 6.5 day embryonic

Whole cell recordings from 6.5 day embryonic chick  $\alpha$ -motoneurons indicate the presence of AMPA, kainate and NMDA glutamate receptor subtypes within each motoneuron tested. However, in excised membrane patches, no more than two subtypes were ever detected. AMPA and NMDA or kainate and NMDA were found together. AMPA and kainate were never in the same patch. Recent cloning of the glutamate receptor has led to the molecular cloning and electrophysiologic characterization of eight ionotropic subunits: GluR 1-4 (AMPA), GluR 5-7 (kainate) and NMDAR1. Using PCR based gene amplification, we have found GluR 1, 2, 4 and 6, and NMDAR1 in chick  $\alpha$ -motoneurons. This well defined cell population appears to contain most if not all of the glutamate receptor subunits. If all subunits are present, functional specificity may not be determined by subunit expression. Specificity may arise from differential post-translational or post-transcriptional modifications, or subunit insertion may occur in specific configurations. Supported by NIH grant NSI3600.

#### 45 15

EXPRESSION OF GLUTAMATE RECEPTOR SUBTYPES IN MAMMALIAN SPINAL CORD. R. Temkin\*, P. Leach, D. Lowe, D.O. Smith. Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

Ionotropic receptors for glutamate are classified into three groups: NMDA, kainate, and AMPA channels. In patch clamp electrophysiologic recordings of rat ventral spinal cord, each individual cell responds to all of these agonist types. Receptors of all three types have been cloned from rat brain, but some of the receptor subtypes have not been shown definitively in spinal cord using hybridization detection techniques. Using the more sensitive polymerase chain reaction to amplify a portion of cDNA of each receptor sequence, we have shown the presence of mRNA for all three classes of glutamate receptor, including some subtypes not previously shown in spinal cord. We have amplified AMPA selective channels GluR 1-4, kainate selective channels GluR 5 and 6, and the NMDA receptor, as well as the quisqualate sensitive metabotropic receptor, thus providing a molecular basis for the electrophysiologic responses. We are now looking for similar expression of glutamate receptor subtypes in human spinal cord of normal and pathological states. Supported by NIH grant NS13600.

#### 45.17

INCREASED EXPRESSION OF GLUTAMATE RECEPTOR mRNAs IN HUMAN EPILEPTIC HIPPOCAMPUS. N. W. Kleckner', Z. Cao, C. Moll, B. Bettler, S. Heinemann, and J. O. McNamara. Duke University and VA Medical Centers, Durham NC, 27710, and The Salk Institute, Latella CA 92186.

and VA Medical Centers, Durham NC, 27710, and The Salk Institute, LaJolla, CA, 92186.

A 2-fold increase in radioligand binding to the AMPA subtype of glutamate receptor has been identified in the dentate region of hippocampi surgically removed from patients with medically refractory complex partial epilepsy (Hosford, et al., 1991). We hypothesized, therefore, that the mRNAs encoding the non-NMDA glutamate receptors would also increase in epileptic tissue. Epileptic hippocampi (n=10) were surgically removed from patients with medically refractory complex partial epilepsy, and control hippocampi (n=5) were obtained from rapid autopsy of patients with non-neurological causes of death. <sup>35</sup>S-labelled antisense and sense RNA probes were synthesized from plasmids containing a portion of the coding region of glutamate receptor cDNAs isolated from rat or human brain. The probes were hybridized to 10 µm sections of human hippocampus. Specific binding Itotal - nonspecific (sense probe) in attomoles/neuron] of RNA probes synthesized from rat and human GluR1 and GluR2 cDNAs was increased 2 or 3-fold in the dentate granule cell layer of epileptic hippocampi compared to rapid autopsy controls. The increase was specific in that no significant differences were observed in the CA1 and CA3 regions using either human or rat GluR1 and GluR2 RNA probes, and no significant change in the level of GluR3 mRNA was observed in any region of the hippocampus in human complex partial epilepsy. Increases in the GluR1 and GluR2 subunit, and not the GluR3 subunit, may underlie the previously observed increase in [³H]AMPA binding (supported by NS08992, NS17771, NS24448).

Lab Molec. Neurobiol., Salk Inst., La Jolla, CA 92186.
Glutamate has received relatively little attention
for its contribution to hypothalamic regulation. To

Glutamate has received relatively little attention for its contribution to hypothalamic regulation. To examine the expression of glutamate receptor subtypes, we used in situ hybridization with 3-S-labeled RNA probes complementary to mRNA coded by seven of the glutamate receptor genes. GluR1 and -R2 were expressed in many hypothalamic areas including, but not restricted to, the ventromedial, arcuate, and dorsomedial nuclei, and in the preoptic area and mammillary region. GluR4 was weakly expressed in the supraoptic, paraventricular, and arcuate nuclei. GluR5 and -R6 labeling was detected in the suprachiasmatic nucleus, with a greater label density over the ventrolateral part which receives retinal input. Although detectable in other CNS regions, we found little GluR3 or -R7 label in hypothalamus. Controls with unrelated probes not expected in the hypothalamus were negative. Since the receptors may manifest different physiological properties, these data suggest in the hypothalamus, and together with other data, underline the widespread role of glutamate in hypothalamic and neuroendocrine regulation.

### 45.18

Glutamate Receptor Expression Changes in Rat Hippocampus after Entorhinal Cortex Lesion. M.J. Velardo, G.M. Rose, E.S. Deneris, M.J. Marks, and S.W. Rogers\*. Dept. Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262, Denver VAMC, Case Western Reserve Medical School, and Institute for Behavioral Genetics. University of Colorado.

Glutamate serves as a major excitatory neurotransmitter in the mammalian brain, and dysfunction of this system has been related to a variety of neurodegenerative diseases. cDNAs encoding subunits of the AMPA/kainate-type (GluR 1-4) and kainate-type (GluR 5-7) glutamate receptors have been identified. Each subunit is expressed in distinct but overlapping brain regions, and different subunit combinations confer specific physiological properties to the receptor. We have used in situ hybridization histochemistry to examine the expression of GluR1, GluR2, GluR3, and GluR5 RNA in the rat hippocampus for up to 14 days after partial deafferentation by unilateral entorhinal cortex lesion. We observed an increase in GluR1 but not GluR3 or GluR5 in the hippocampus of lesioned animals. The increase in GluR1 expression was predominantly in the molecular layer, and it occurred both ipsilateral and contralateral to the lesion. Surrounding the lesion site itself, GluR2 and GluR3 are expressed but not GluR1 or GluR5. We will report our findings in terms of glutamate receptor gene expression by neuronal cells and by glia in the partially deafferented hippocampus and in regions of glial scarring. Supported by a grant to SWR from the Pharmaceutical Manufacturers Association and NIDA grant DA03194 to MJM.

## SEROTONIN RECEPTORS: 5HT1A SUBTYPES

## 46.1

STEREOSPECIFIC EFFECTS OF THE SELECTIVE AND SILENT 5-HT<sub>1A</sub> RECEPTOR ANTAGONIST, WAY100135, ON RAT HIPPOCAMPAL 5-HT LEVELS: A MICRODIALYSIS STUDY. C. T. Dourish\* J. Gurling, I. Wright, C. Routledge. Wyeth Research (U.K.) Ltd., Huntercombe Lane South, Taplow, Maidenhead, Berkshire SL6 0PH, U.K. WAY100135 is the first example of a selective, silent, 5-HT<sub>1A</sub> receptor antagonist

WAY100135 is the first example of a selective, silent, 5-HT<sub>1A</sub> receptor antagonist (Fletcher et al., 1991, Soc. Neurosci. Abstr., Vol 17, P92). Thus, the compound has high affinity and selectivity for 5-HT<sub>1A</sub> receptors in vitro and is also a potent inhibitor of the behavioural effects of the 5-HT<sub>1A</sub> agonist 8-OH-DPAT. The action of WAY100135 at the 5-HT<sub>1A</sub> receptor is stereospecific, the activity residing in the (+) isomer; in the present study we examined the effects of WAY100135 and its enantiomers on the in vivo release of 5-HT in the rat hippocampus using microdialysis. Dialysis probes were implanted into the ventral hippocampus using microdialysis. Dialysis probes were implanted into the ventral hippocampus of male rats, and 24 h later were perfused with artificial CSF (1 ul/min). Following a 2.5 h stabilisation period 20 min samples were collected; 3 control samples were taken prior to s.c. administration of antagonist or vehicle. (±)-WAY100135, (+)-WAY100135, and (-)-WAY100135, (all at 10 mg/kg) had no significant effect on extracellular levels of 5-HT in the rat hippocampus. Increases in extracellular levels of 5-HT were observed in a number of animals following administration of (±)-WAY100135 and (+)-WAY100135 but this response did not reach statistical significance. In contrast, the 5-HT<sub>1A</sub> receptor partial agonists BMY7378 (5 mg/kg) and buspirone (1 mg/kg), and the potent agonist 8-OH-DPAT (100 ug/kg) all significantly decreased extracellular 5-HT. Pre-treatment with (±)-WAY100135 and (+)-WAY100135 (but h0 mg/kg, 30 min) completely blocked the inhibitory effect of 8-OH-DPAT (100 ug/kg) on 5-HT release. (-)-WAY100135 (10 mg/kg) had no effect on the 8-OH-DPAT response. These data demonstrate that (±)-WAY100135 and (+)-WAY100135 and selective and silent 5-HT<sub>1</sub>A receptor antagonists, at presynaptic 5-HT<sub>1</sub>A receptors in vivo, as they did not decrease 5-HT release. On the contrary, there was evidence of an increased 5-HT release, indicating that (±)-WAY100135 and (+)-WAY100135 may block a tonic inhi

## 46.

ELECTROPHYSIOLOGICAL STUDIES ON THE EFFECTS OF THE 5-HT<sub>1A</sub> RECEPTOR AGONIST / 5-HT REUPTAKE BLOCKER BMY 42568 ON THE 5-HT SYSTEM. <u>C. de Montigny\*, P. Blier and A. Lista</u>. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada H3A 1A1.

BMY 42568 is a buspirone derivative endowed with nanomolar affinity for 5-HT<sub>1A</sub> receptors as well as for the 5-HT reuptake carrier. In anesthetized rats, microiontophoretic applications of BMY 42568 produced a current-dependent suppression of the firing activity of dorsal hippocampus CA<sub>3</sub> pyramidal neurons, which was blocked by the 5-HT<sub>1A</sub> antagonist BMY 7378. The suppression of iring of these neurons by 5-HT applications was not prevented by the concurrent ejection of BMY 42568, indicating that this drug is a full agonist of these postsynaptic 5-HT<sub>1A</sub> receptors. A two-day treatment with BMY 42568 (5 mg/kg/day, s.c.) reduced the firing activity of dorsal raphe 5-HT neurons. There was a partial recovery after 7 days, and a complete one after 14 days of treatment. At this point in time, there was a marked shift to the right of the dose-response curve of the effect of i.v. LSD on 5-HT neuron firing activity, indicating a desensitization of their somatodendritic autoreceptors. The same 14-day treatment left unaltered the responsiveness of CA<sub>3</sub> pyramidal neurons to 5-HT, but enhanced the effectiveness of the electrical stimulation of their afferent 5-HT pathway. This enhancement was attributable to a desensitization of the terminal 5-HT autoreceptor, as indicated by the lack of an attenuated effectiveness of the stimulations when increasing the frequency from 1 Hz to 5 Hz. Interestingly, BMY 42568 is the first drug which displays a full agonistic activity electrophysiologically at postsynaptic 5-HT<sub>1A</sub> receptors, Since its long-term administration induces a desensitization of somatodendritic and terminal 5-HT autoreceptors, but not of postsynaptic 5-HT<sub>1A</sub> receptors, and since it exents full agonistic activity at the latter, BMY 42568 is thus expected to be a potent antidepressant drug.

AGONIST OCCUPATION OF 5-HT<sub>1A</sub> RECEPTORS PREVENTS THEIR INACTIVATION BY PERTUSSIS TOXIN. <u>V Hadrava\*, P. Blier and C. de Montigny</u>. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec. Canada H3A 1A1.

Pertussis toxin (PT) drastically reduces the responsiveness of extrasynaptic 5-HT<sub>1A</sub> receptors of dorsal hippocampus CA<sub>3</sub> neurons, but has no effect on the responsiveness of intrasynaptic 5-HT<sub>1A</sub> receptors (*P. Blier et al.*, *Neurosci. Abst. 16-462.5, 1990*). Since activation of G protein-linked receptors renders the Gi/o α subunit refractory to ADP ribosylation by PT (*M. Diversé-Pierluissi et al., Neurosci. Abst. 17:232. 14, 1991*), the tonic activation of intrasynaptic 5-HT might protect them from PT inactivation.

Abst. 16:462.5, 1990). Since activation of G protein-linked receptors renders the Gi/o α subunit refractory to ADP ribosylation by PT (M. Diversé-Pierlussis et al., Neurosci. Abst. 17:232.14, 1991), the tonic activation of intrasynaptic 5-HT<sub>1A</sub> receptors by endogenous 5-HT might protect them from PT inactivation. To test this hypothesis, we studied the effect of PT on the extrasynaptic 5-HT<sub>1A</sub> receptors in Sprague-Dawley rats treated with the potent 5-HT<sub>1A</sub> agonist flesinoxan (5 mg/kg/day, s.c.) for 14 days by osmotic minipumps, starting 3 days prior to a unilateral intrahippocampal injection of PT (1 μg). The responsiveness of ipsilateral CA<sub>3</sub> dorsal hippocampus pyramidal neurons to microiontophoretic applications of 5-HT and of the selective 5-HT<sub>1A</sub> agonist 8-OH-DPAT was nearly abolished by PT in control rats. In flesinoxan-treated rats, the reduction of these responses by PT was significantly attenuated. This suggests that the occupation of 5-HT<sub>1A</sub> receptors prevented the inactivation of their G proteins by PT. We then investigated whether such protection may be extended to GABA<sub>B</sub> receptors which share the same G proteins (*R. Andrade et al., Science 234:1261, 1986)*. PT abolished the inhibitory effect of the GABA<sub>B</sub> agonist baclofen on the firing activity of CA<sub>2</sub> neurons in control rats. In flesinoxan-treated rats, the reduction of the responsiveness to baclofen by PT was also attenuated. This suggests that the tonic activation of 5-HT<sub>1A</sub> receptors prevents the PT-induced ADP ribosylation of the Gi/o α subunit and thereby protects an amount of G proteins sufficient to maintain the function of GABA<sub>B</sub> receptors.

EFFECT OF ADRENALECTOMY ON BRAIN 5-HT1A RECEPTOR mRNA EXPRESSION. D.T. Chalmers\*, S.P. Kwak, A. Mansour, H. Akil and S.J. Watson. Mental Health Research Inst., University of Michigan, Ann Arbor, MI 48109.

Corticosteroids have been shown to modulate hippocampal 5-HT1 receptor binding density. The present studies were designed to investigate the possibility of altered hippocampal 5-HT<sub>1A</sub> receptor mRNA expression in response to acute or chronic adrenalectomy (ADX). After 24 hours ADX, 5-HT<sub>1A</sub> receptor mRNA expression was significantly increased in all hippocampal subfields in ADX animals relative to SHAM. The magnitude of the increase was most pronounced within CA2 (127%) and CA3/4 (94%) subfields of dorsal hippocampus, intermediate in the dentate gyrus (73%) and least within CA<sub>1</sub> (60%). Administration of exogenous CORT at the time of ADX maintained the level of 5-HT<sub>1A</sub> receptor mRNA expression within the range of SHAM animals. Autoradiographic analysis of 5-HT1A receptors in adjacent sections indicated a simultaneous increase in 5-HT<sub>1A</sub> binding throughout the hippocampus in response to ADX. 5-HT<sub>1A</sub> binding increased uniformly (30%) in CA subfields and dentate gyrus but remained within SHAM levels in CORT replaced animals. Similar increases in both 5-HT<sub>1A</sub> receptor mRNA expression and 5-HT<sub>1A</sub> binding were evident after 1 week ADX treatment. Hippocampal 5-HT<sub>1</sub>C receptor mRNA and dopamine D<sub>1</sub> receptor mRNA expression were not significantly altered by either acute or chronic ADX treatment. These data indicate that adrenal steroids may selectively regulate hippocampal 5-HT1A receptors at the level of 5-HT<sub>1A</sub> receptor mRNA expression. Supported by NIMH 422251.

## 46.7

DIFFERENTIAL EFFECTS OF NOVEL 8 OH-DPAT AND NAN-190 ANALOGUES ON CENTRAL 5-HT<sub>1A</sub> RECEPTORS. H.Hecimovic\*. J.P.Hodgkiss, I.M.Dawson, J.S.Kelly, Dept. of Pharmacology, Univ. of Edinburgh, 1 George Square, Edinburgh EH8 91Z, Scotland.

We have examined the action of a variety of analogues of 8 OH-DPAT and NAN-190 on 5-HT<sub>1A</sub> receptors in rat dorsal raphe (DR) and hippocampal CA1 pyramidal neurones usin intracellular recording in vitro

in vitro.

The NAN-analogue compound, 5.20 [Iodo-NAN-190] (10-100μM, K<sub>D</sub>=10.3nM) hyperpolarised and reduced input resistance (Rm) in DR and CA1 neurones. The hyperpolarisation of DR neurones elicited by 8 OH-DPAT (10μM) was reversed in a dose-dependent fashion by the same analogue.

We also tested the 8 OH-DPAT analogue 8.9 [Bis-C<sub>6</sub>-8MeOPAT] (0.5.10μM K<sub>-</sub>-7mM) It caused a hyperpolarisation and fall in Pm in

We also tested the 8  $\bar{\text{O}}\text{H-DPAT}$  analogue 8.9 [Bis- $C_6$ -8MeOPAT] (0.5-10 $\mu$ M,  $K_D$ =7nM). It caused a hyperpolarisation and fall in Rm in DR neurones and occluded the action of 5-HT (100 $\mu$ M). In CA1 neurones, in contrast, a small depolarisation was seen accompanied by either no change or a small fall in Rm; the hyperpolarisation elicited by 5-HT was unaffected by this compound.

by 5-HT was unaffected by this compound.

The differences seen with these compounds support the idea that the populations of 5-HT<sub>1A</sub> receptors on DR and CA1 pyramidal neurones possess different properties (Sprouse, J.S. & Aghajanian, G.K.: Neuropharmacol. 27:707-715, 1988.). (Supported by the Wellcome Trust.)

#### 46.4

EFFECT OF LOCAL INFUSIONS OF 8-OH-DPAT ON EXTRACELLULAR LEVELS OF 5-HT IN THE ANAESTHETISED GUINEA-PIG. M. Skingle\*, A.J. Sleight and D.J. Rosser (SPON: Brain Research Association) Department of Neuropharmacology, Glaxo Group Research, Ware, Herts, SG12 ODP, UK

The effects of the 5-HT<sub>1A</sub> receptor agonist 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) on extracellular levels of 5-HT in the CNS of the anaesthetised guinea-pig were studied using the technique of in vivo microdialysis with HPLC/ECD. Dialysis probes were inserted into frontal cortex or into the area adjacent to the median and dorsal raphe nuclei. 8-OH-DPAT was given systemically or infused directly via the probe. It is likely that the measured 5-HT in these experiments is from neurones since the sodium channel blocker tetrodotoxin (1 µM) markedly reduced basal levels of extracellular 5-HT when infused into frontal cortex.

Peripheral injections of 8-OH-DPAT, 0.01 and 0.5 mg/kg s.c., caused reductions in the levels of extracellular 5-HT in the frontal cortex (39% and 47% reduction respectively). When infused into the area adjacent to the median and dorsal raphe nuclei, which contain the somatodendritic 5-HT $_{\rm IA}$  autoreceptors, much lower doses of 8-OH-DPAT (1 and 10 nM) reduced cortical levels of 5-HT. By implanting microdialysis probes into the frontal cortex and raphe region of the same guinea-pig it was possible to demonstrate that intra-raphe injection of 8-OH-DPAT, 10 nM, caused a marked reduction in extracellular 5-HT in both frontal cortex (87  $\pm$  13% inhibition) and in the raphe region (86 + 14% inhibition).

These data suggest that 5-HT $_{1A}$  receptors are involved in the control of extracellular levels of 5-HT in the guinea-pig and that, as in the rat, these receptors appear to be located in the cell body regions of the 5-HT neurones.

THYROID HORMONE (TH) MODULATION OF SEROTONIN-1A (5-HT-1A) RECEPTORS IN RAT BRAIN. S.M Tejani-Butt,\* J.Yang & A. Kaviani. Department of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Although a link between the hypothalamic-pituitary-thyroid (HPT) axis and affective disorder has been established, the mechanism

Although a link between the hypothalamic-pituitary-thyroid (HPT) axis and affective disorder has been established, the mechanism underlying this relationship remains unclear. Since the 5-HT system appears to be involved in the pathophysiology of mood disorders, we examined the effects of thyroidectomy (Tx) with T4 replacement (euthyroid (EU), 15 µg/kg, hyperthyroid (HY), 200 µg/kg) and without T4 replacement (Tx) for 7, 14 or 35 days on the binding of 3H-DPAT to 5-HT-1A receptors in rat brain by quantitative autoradiography. Tx caused a significant decrease (F=12.9; p<0.01) in 3H-DPAT binding to 5-HT-1A receptors in the dorsal raphe nucleus (DRN) at 7 days, with a time-dependent recovery in 3H-DPAT binding 35 days post Tx. HY animals showed a significant increase (F=6.8; p<0.05) in 3H-DPAT binding to 5-HT-1A receptors in the DRN at 35 days. In contrast to the results seen in the DRN, Tx caused a significant increase (F=11.7; p<0.01) in 3H-DPAT binding to 5-HT-1A receptors in the molecular layer of the CA1 region of the hippocampus (HIP) at 7 days. At 14 days post Tx, the binding normalized to sham levels; however at 35 days post Tx, a significant increase (F=5.5; p<0.05) in 3H-DPAT binding to 5-HT-1A receptors was observed. No significant differences were seen in 3H-DPAT binding to 5-HT-1A receptors in the HIP in the HY or EU animals. These results suggest that a neuromodulatory link may exist between the HPT axis and 5-HT-1A receptor system in at least two distinct regions of the rat brain. (Research funds from USPHS grants MH 45472 and MH 44210).

## 46.8

ACTION OF RU24969 ANALOGS ON THE INHIBITION OF FORSKOLIN-STIMULATED ADENYLATE CYCLASE IN RAT HIPPOCAMPAL MEMBRANES. H. B. Li, L. J. Comfield, G. Lambert, A. A. Lettes'. J. W. Regan and A. R. Martin. Departments of Pharmacology & Toxicology and Pharmaceutical Sciences, College of Pharmacy, University of Arizona, Tucson, AZ 85721

The serotonergic efficacy of several RU24969 analogs was evaluated in rat hippocampal membranes. Inhibition of forskolin-stimulated adenylate cyclase (FSC) was used to assay the functional activity of these putative 5-HT1A agonists and antagonists. Compounds were chosen on the basis of having high binding affinity for the 5-HT1A receptor using the displacement of [3H]8-OH-DPAT. Most analogs produced complex inhibition curve consisting of a high potency component that could be shifted to the right by the antagonist pindolol. This sensitivity to pindolol is characteristic of agonist activity at the 5HT1A receptor. For many of the RU24969 analogs, high concentrations of drug inhibited FSC greater than 10µM 5-HT itself. This low potency component could not be shifted by pindolol suggesting that it did not include the activation of 5HT1A receptor. The compound, SN26 (5-carboxamido-(1-methyl-1,2,5,6-tetrahydro pyridin-4-yl)indole), had the highest binding affinity and cyclase potency. For most of the RU24969 analogs, the binding affinity and the cyclase activity had the same rank order. A few compounds including TD60 (5-carboxamido-(1-propyl-1,2,5,6-tetrahydro pyridin-4-yl)indole), however, displayed high binding affinities but low cyclase activities, and thus could be classified as weak agonists. Additional compounds related to these weak agonists are being examined to identify possible antagonists of the 5-HT1A receptor.

EFFECT OF EEDQ TREATMENT ON THE RECOVERY OF 5-HT<sub>1A</sub> RECEPTORS AND THE LEVEL OF 5-HT<sub>1A</sub> RECEPTORS AND THE LEVEL OF 5-HT<sub>1A</sub> RECEPTOR mRNA. D. Brousseau. R.A. Habboushe and P. McGonigle\* Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

The density of post-synaptic 5-HT<sub>1A</sub> receptors in the CNS does not change significantly in response to standard pharmacological manipulations. Depletion of 5-HT<sub>1A</sub> receptors and chronic agonist treatment does not decrease receptor density. To further examine the plasticity of the 5-HT<sub>1A</sub> receptor system, male Sprague Dawley rats were treated with 10 mg/kg EEDQ to irreversibly inactivate a significant proportion of 5-HT<sub>1A</sub> receptors. The animals were sacrificed 1,2,4,7 and 14 days after treatment and coronal sections of brain at the level of the dorsal raphe and the hippocampus were labelled with sacriticed 1,2,4,7 and 14 days after freatment and coronal sections of brain at the level of the dorsal raphe and the hippocampus were labelled with [<sup>3</sup>H]-8-OH-DPAT. Adjacent sections were labelled with a 183 base <sup>35</sup>S-labelled riboprobe complementary to rat 5-HT<sub>1A</sub> receptor mRNA. Quantitative autoradiographic analysis revealed that the percentage of receptors remaining compared to control ranged from 11% in the entorhinal cortex to 25% in the parietal cortex one day after the treatment. Seven days after the treatment, the density of receptors in the dorsal raphe had returned to control levels whereas the density in all other regions ranged between 55% and 75% of control levels. *In situ* hybridization histochemistry revealed that there were no significant changes in the level of mRNA for the 5-HT<sub>1A</sub> receptor at 1,2 or 4 days after treatment despite the significant increase in the density of receptors during this period. These results indicate that the mechanism by which neurons increase the expression of 5-HT<sub>1A</sub> receptors does not require increasing the level of receptor mRNA. These results also suggest that the mechanism regulating expression of autoreceptors in the dorsal raphe may be different from the mechanism in cells expressing post-synaptic receptors. (Supported by USPHS MH 43821)

### 46.11

EFFECTS OF THE 5-HT  $_{\rm IA}$  ANTAGONIST WAY-100135 ON MEDULLARY 5-HT CELL FIRING AND SYMPATHETIC NERVE DISCHARGE IN THE CAT N.A. Escandon, R.B. McCall\* and D.C. Zimmermann. Cardiovascular Diseases Research, Upjohn Laboratories, Kalamazoo, MI 49001.

It has proven difficult to find a selective, pure 5-HT1A receptor WAY-100135 (WAY), a novel phenylpiperazine derivative, has been reported to bind with high affinity and selectivity to the central 5-HT1A site and to display only 5-HT1A antagonist activity in both presynaptic and postsynaptic models (Neurosci. Abstr. 17:91,92). The present study utilized standard neurophysiological techniques to demonstrate that WAY acts as an agonist at the  $5\text{-HT}_{1A}$  autoreceptor site, but retains antagonist activity postsynaptically. We observed inhibitory effects of WAY on medullary raphe 5-HT cell firing in the cat with an ED $_{50}$  of 105 μg/kg and with complete inhibition occurring at 300μg/kg. Neither pre nor posttreatment with WAY (100 µg/kg i.v.) had a significant effect on 8-OH DPAT-induced inhibition of unit firing. Inferior cardiac sympathetic nerve discharge was not significantly inhibited by WAY in doses up to 1 mg/kg i.v. WAY pretreatment (300 μg/kg) caused a fourfold rightward shift in the 8-OH DPAT dose response curve, while WAY posttreatment reversed the effects of 8-OH DPAT (100-300 µg/kg i.v.) up to 90% of baseline activity. These data indicate that although WAY is a 5-HT1A antagonist postsynaptically, it possesses agonist activity at the presynaptic autoreceptor site.

REGULATION OF 5-HT<sub>1A</sub> RECEPTOR-MEDIATED INHIBITION OF ADENYLYL CYCLASE IN TRANSFECTED CELLS. <u>J.G. Hensler\* & P.B. Molinoff.</u> Depts. of Psychiatry & Pharmacol., Univ. of Pennsylvania School of Medicine, DVA Med. Center, Phila., PA. 19104.

Changes in second messenger function linked to the 5-HT<sub>1A</sub> receptor, specifically the inhibition of forskolin-stimulated adenylyl cyclase activity, have not been consistently observed to follow antidepressant or agonist treatments in vivo. We have studied this phenomenon in vitro using human embryonic kidney (293) cells and Chinese Hamster Ovary (CHO) cells transfected with the human 5-HT<sub>1A</sub> receptor gene. Expression of the 5-HT<sub>1A</sub> receptor in either cell line was determined by measuring the specific binding of <sup>3</sup>H-DPAT (Kd = 1-2 nM). Bmax values were 100-800 fmol/mg protein for 293 cells, and 50-200 fmol/mg protein for CHO cells. 5-HT and DPAT inhibited forskolin-stimulated cyclic AMP cells. 5-HT and DPAT inhibited forskolin-stimulated cyclic AMP formation in CHO cells with EC<sub>50</sub> values of approximately 3 nM. Maximal inhibition by both agonists (1 μM) was approximately 90%. Incubation of CHO cells with 5-HT (100 nM) for 18 hrs resulted in an attenuation of the inhibition of forskolin-stimulated cyclic AMP formation by an EC<sub>50</sub> concentration of DPAT (3 nM), with no change in the maximal inhibition produced by 1 μM DPAT. In 293 cells, 5-HT and DPAT also inhibited forskolin-stimulated cyclic AMP formation with EC<sub>50</sub> values of approximately 1 nM. Maximal inhibition by both agonists was approximately 70%. Incubation of 293 cells with 5-HT (100 nM) for was approximately 70%. Incubation of 293 cells with 5-HT (100 nM) for 18 hrs resulted in an attenuation of the maximal inhibition of forskolin-stimulated cyclic AMP formation by 5-HT. These data suggest that chronic exposure of the 5-HT<sub>1A</sub> receptor to 5-HT can result in desensitization of this second messenger response in CHO and 293 cells. (Supported by USPHS grant MH 48125).

CHARACTERIZATION OF THE 5HT-1C RECEPTOR BINDING USING A RAT RECOMBINANT EXPRESSED IN THE BACULOVIRUS SYSTEM. K. Barron, P. Payette', P. Dionne', J. Lancaster and P. Sweetnam. 'Biosignal, Montreal, Quebec, Canada and NovaScreen®, Baltimore MD 21224.

When attempting to establish the 5HT-1C binding assay there are several technical issues which need to be addressed. First; the selectivity of drugs used to characterize the site demands a thorough examination of the numerous serotonin-like drugs and a comparison of their affinities at the 5HT-1C site. We have determined that eight drugs routinely used to pharmacologically define other serotonin receptor subtypes have K's under 50 nM. Second; the use of either rat or pig choroid plexus will place a strain on animal and financial resources. We report here the use of a rat recombinant 5HT-1C receptor expressed in the baculovirus system as a means to reduce if not eliminate these technical difficulties. Binding characteristics for this clone using <sup>3</sup>H-mesulergine are similar to those reported for pig and rat choroid plexus (K<sub>D</sub> = 2 nM; B<sub>max</sub> = 75 pmol/mg prot). The rank order of potency established using select serotonin drugs was mesulergine > methysergide > mianserin > ketanserin > 5HT. For expression of the 5HT-1C receptor the baculovirus system provides a high yield of receptor protein with a binding profile similar to that reported for rat and pig choroid plexus.

### 46.12

DIFFERENTIAL CONTRIBUTION OF PRE- AND POSTSYNAPTIC 5HT1A RECEPTORS TO THE ANXIOLYTIC, ANTIDEPRESSIVE AND DISCRIMINA-TIVE EFFECTS OF 8-OH-DPAT AND IPSAPIRONE IN THE RAT. T. Glaser, R. Schreiber, J.M. Greuel\* and J.De Vry. Inst. for Neurobiology, Troponwerke GmbH & Co. KG, Berliner Str. 156,5000 Köln 80, Germany.

8-OH-DPAT (D) and ipsapirone (I) show high affinity for 5-HT<sub>1A</sub> receptors.

These receptors are located presynaptically in the raphe nuclei and postsynaptically in the projection areas including lateral septum (LS) and hippocampus (HIP). In rats, predominantly presynaptic receptors appear to be involved in the anxiolytic (ANX) effects of D and I (shock-induced ultrasonic vocalization test and Geller-Seifter conflict test); whereas predominantly postsynaptic receptors appear to be involved in the antidepressive (AD) effects (forced swimming test) and, possible also, discriminative stimulus (DS) effects of rats trained on 8-OH-DPAT (0.1 mg/kg, i.p.). First, for D and I, the potency difference between IP and central application (dorsal raphe nucleus (DRN) is at least 10-times greater in case of the ANX effects, as compared with the AD and DS effects. In addition, the potency difference between administration in the DRN and in the HIP or LS is much greater in the case of the ANX effects, as compared with the AD and DS effects. Second, after application of I (0.3 - 10 mg/ kg, s.c.), the time-effect curves reflecting the ANX effects, those reflecting the 5-HT cell firing inhibitory effects (DRN) and those reflecting the nhibitory effects (HIP), correlate well with each other. Third, depletion of brain 5-HT by means of 5,7-DHT (150  $\mu$ g, i.c.v.) or pCPA (2 x 150 or 2 x 350 mg/kg, i.p.) induces ANX effects (50 %, 56 % and 97 %, respectively), but hardly AD effects (17 %, 25 % and 23 %, respectively). Fourth, pretreatment with the (postsynaptic) partial agonist I results in an attenuation of the AD effects of the full agonist D when both compounds are administered either i.p. or in the LS, but not after microinjection in the DRN. No attenuation of the ANX and DS effects were obtained after combined IP administration of both compounds.

## 46.14

DESENSITIZATION AND COUPLING OF CLONED HUMAN 5-HT1A AND 5-HT2 RECEPTORS. <u>F. Van Huizen<sup>1\*</sup></u>, <u>N.J. Stam<sup>2</sup></u>, <u>M. Bansse<sup>1</sup> and J.A.D.M. Tonnaer<sup>1</sup> Depts. of <sup>1</sup>Neuropharmacology and <sup>2</sup>Biotechnology & Biochemistry,</u> Organon Intl. BV, PO Box 20, 5340 BH Oss, The

Swiss 3T3 cells were transfected with the human 5-HT<sub>1A</sub> or 5-HT<sub>2</sub> receptor genes. Sub-type specific pharmacological profiles were obtained for the competition of [<sup>3</sup>H]8-OH-DPAT and [<sup>3</sup>H]ketanserin, respectively. Buspirone and NAN-190 behaved as typical partial agonists in the cAMP assay: cAMP levels were inhibited with an intrinsic CAMP assay: CAMP levels were infibited with an intrinsic activity of about 70 % as compared to 5-HT, but the inhibition of cAMP levels by 5-HT itself was antagonized. The reducing effect of GTPyS on [3H]8-OH-DPAT binding was directly related to the expression level of the 5-HT<sub>1A</sub> rerectly related to the expression level of the 5-HT<sub>1A</sub> receptor, while EC<sub>50</sub> values for the inhibition of forskolin-stimulated cAMP levels were inversely related. These data suggest that the coupling of the receptor to G-proteins is dependent on receptor number. Preincubation of the cells with 8-OH-DPAT generated a doseand time-dependent decrease in [3H]8-OH-DPAT binding, while the potency of 5-HT in the cAMP assay was diminished. Pilot experiments indicated that the 5-HT<sub>2</sub> receptor could also be desensitized by agonist pre-incubation. The present experiments indicate that desensitization and uncoupling of cloned human 5-HT<sub>1A</sub> and 5-HT<sub>2</sub> receptors uncoupling of cloned human 5-HT $_{
m 1A}$  and 5-HT $_{
m 2}$  receptors occurs after agonist exposure.

MONDAY AM

AUTORADIOGRAPHIC LOCALIZATION OF 5-HT<sub>1A</sub> RECEPTORS IN PIGEON BRAIN. <u>David J. Bucci\*</u>1, <u>Cathy D. Mahle\*</u>1, <u>Harvey J. Karten</u>2, and <u>Richard B. Carter</u>1, \*Department of Neuropharmacology, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492 and \*Department of Neuroscience, University of California San Diego, La Jolla, CA 20203.

Behavioral paradigms used to predict the clinical anxiolytic efficacy of novel agents often employ pigeons because of the unique sensitivity of this species to compounds that act through 5-HT<sub>1A</sub> mechanisms. Unlike rodents, however, little is known about the distribution and density of specific 5-HT receptors in pigeon brain. In the present study, pigeon brain slices (15 μM coronal sections) were incubated with 2 nM [3H-I-8-OH-DPAT in the presence or absence of 1 μM BMY 7378 to specifically label the 5-HT<sub>1A</sub> receptor. Concentrations of 5-HT<sub>1A</sub> receptors were highest in the medial caudal neostriatum (NC, excluding Field L); visual nuclei, including optic tectum (TeO), nucleus geniculatus lateralis - pars ventralis (GLV), and the nucleus pretectalis (PT); the dorsal raphe complex (R), and locus ceruleus (LoC). Densities of 5-HT<sub>1A</sub> receptors in the NC, GLV, R, and LoC were 49.3, 24.3, 36.7, and 35.2 fmol/mg tissue, respectively. Other regions exhibiting 5-HT<sub>1A</sub> binding include the rostral region of the nucleus et tractus descendens nervi trigemini (nTTD) and nucleus solitarius (S). These data will serve as the basis for further studies directed toward identifying the neuronal regions through which 5-HT<sub>1A</sub> agents produce their anxiolytic-like actions in the pigeon, and thus may aid in elucidating the specific mechanisms by which this class of molecules produces their therapeutic effects.

### 46.17

DORSAL RAPHE 5-HT<sub>1A</sub> RECEPTORS REGULATE SOMATODENDRITIC AND HIPPOCAMPAL RELEASE OF SEROTONIN (5-HT). <u>F-Fatima Matos\*</u>, <u>Carolyn Brown and Frank Yocca</u>, Department. of Neuropharmacology, Bristol-Myers Squibb Pharmacolurical Research Institute Wallingford. CT (640)

Squibb Pharmaceutical Research Institute, Wallingford, CT 06492.

It is well accepted that the effects of a 5-HT<sub>1</sub>A agonist on 5-HT release in terminal areas are due to activation of 5-HT<sub>1</sub>A receptors localized on 5-HT rell bodies and dendrites in the midbrain raphé nuclei. Previous microdialysis data have shown that 5-HT<sub>1</sub>A agonists decrease extracellular 5-HT in the ventral hippocampus (Sharp et al. 1989). We tested whether buspirone (5-HT<sub>1</sub>A agonist) effects upon hippocampal 5-HT release were mediated by somatodendritic 5-HT<sub>1</sub>A receptors by directly perfusing (-) pindolol (8, 5-HT<sub>1</sub>A antagonist) into the dorsal raphé to block somatodendritic receptors. Two microdialysis probes were implanted in each rat, one in the dorsal raphé and one in the hippocampus, to allow the simultaneous measurement of 5-HT in both areas. Experiments were conducted the next day in awake rats. The dialysis probes were perfused at lµL/min with Ringer (dorsal raphé) or Ringer containing 10 µM fluoxetine (hippocampus). Extracellular levels of 5-HT, 5-HIAA and HVA were simultaneously analyzed by HPLC-ECD. Buspirone (1.0-5.0 mg/kg, s.c.) induced a dose-related decrease in hippocampal 5-HT (maximal decrease 40% of control). Levels of 5-HTAA decreased by 20%, while HVA increased 2.5 fold. Extracellular 5-HT in the dorsal raphé changed in a similar fashion as in the hippocampus after 2.5 mg/kg buspirone; 5-HT decreased to 40%, 5-HIAA decreased by 30% and HVA increased 2.5 fold. Local perfusion of (-) pindolol (1 mM) into the dorsal raphé produced a sustained increase in 5-HT in the dorsal raphé and hippocampus (2.5 and 1.5 times basal levels, respectively). When buspirone (2.5-mg/kg) was injected during continuous perfusion with (-) pindolol into the raphé, the hippocampal and dorsal raphé decrease in 5-HT were completely antagonized; 5-HT levels remained elevated above controls. These data provide evidence that extracellular 5-HT in the dorsal raphé is under tonic control of the activity of 5-HT<sub>1</sub>A receptors and that buspirone decre

## 46.19

UNCOUPLING OF THE RAT SEROTONIN-1A RECEPTOR BY A POINT MUTATION IN THE SECOND CYTOPLASMIC LOOP. P. Lembo, M. Quik\*, P.R. Albert. Department of Pharmacology and Therapeutics, McGill University, Montreal, Canada H3G-1Y6.

When expressed in fibroblasts, such as Ltk- cells, the serotonin-1A (5-HT1A) receptor couples negatively to adenylyl cyclase and positively to phospholipase C via pertussis toxin-sensitive G proteins. Activation of protein kinase C (PKC) by phorbol ester (TPA) phosphorylates the receptor, and selectively blocks receptor-nediated activation of phospholipase C and calcium mobilization, but not inhibition of forskolin-stimulated cAMP accumulation. To test whether putative PKC phosphorylation sites on the 5-HT1A receptor are involved in uncoupling the receptor, each of four sites (THR149 in the second cytoplasmic loop) was mutated from SER—GLY or THR—ALA. Each mutant was transfected into Ltk- cells and stable transfectants expressing high levels of receptor RNA were isolated. In cells expressing the THR149 mutant, 5-HT induced calcium mobilization and inhibition of cAMP were abolished; on the other hand, specific [3H]-DPAT binding was present. However, for each of the other mutant receptors except THR149, 5-HT inhibited cAMP accumulation and enhanced calcium mobilization, as observed for the wild-type receptor. Acute (4-minute) pretreatment with TPA (10-100 nM) abolished the action of 5-HT to enhance calcium levels without altering cAMP accumulation, as for wild-type receptor. We conclude that the second cytoplasmic loop is crucial for coupling of the 5-HT1A receptor. Funded by the FCAR, FRSQ, and NCI, Canada.

A high density of 5-HT1<sub>A</sub> sites are present in hippocampus, but a considerable number of <sup>3</sup>H-8-OH-DPAT sensitive sites are also present in other regions. Recent evidence suggests that biochemical (Yocca, et al., 1992) and pharmacological (Radja et al., 1992) properties of the 5-HT1<sub>A</sub> receptor exhibit regional differences in the CNS, suggesting the possibility of multiple 5-HT1<sub>A</sub> sites in the CNS. Autoradiographic examination of <sup>3</sup>H-8-OH-DPAT binding revealed a typical pattern of distribution, however while nearly all binding in the hippocampus was displaced by the 5-HT1<sub>A</sub> partial agonist BMY 7378, a high percentage of the sites located in the amygdala were insensitive to BMY 7378 (1µM). We were therefore interested in examining the possibility of multiple 5-HT1<sub>A</sub> sites in rat amygdala. Displacement studies in rat amygdala and hippocampal homognates, utilizing <sup>3</sup>H-8-OH-DPAT (1nM) and BMY 7378, resulted in a biphasic curve in amygdala with an almost even distribution of high and low affinity sites; while hippocampus yielded a near monophasic displacement. Earlier reports have shown <sup>3</sup>H-8-OH-DPAT to label the 5-HTP<sub>Pre</sub> site, concentrated in rat striatum (Gozlan, 1983). Pharmacologically, the 5-HTP<sub>Pre</sub> site has a reported lower affinity for the azapirone anxiolytics, is insensitive to guanine nucleotides, and its binding is inhibited in the presence of manganese (Mn<sup>2</sup>+). GppNHp causes a concentration dependent inhibition of <sup>3</sup>H-8-OH-DPAT binding in both hippocampus and amygdala. No decrease in binding in either region was observed in the presence of 1 mM Mn<sup>2</sup>+. Furthermore, this site displays no affinity for the selective 5-HT uptake inhibitor, fluoxetine. This raises the possibility that multiple subtypes of the 5-HT1<sub>A</sub> receptor exist in CNS.

ONTOGENY OF 5-HT, RECEPTORS IN THE HUMAN BRAIN: AN AUTO-RADIOGRAPHIC STUDY. A. Pazosl, E. del Olmol, A. Díazl, C. del Arcol, M. Guirao-Piñeyro<sup>3</sup> and M. Lafarga<sup>2\*</sup>. Depts of lPhysiology and Pharmacol, and <sup>2</sup>Anatomy and Cell Biol., Univ. Cantabria, Santander, Spain; and <sup>3</sup>Dept. Morphology, Univ. of Granada, Spain.

The ontogenetic appearance of brain 5-HT<sub>1</sub> receptors was studied by autoradiography in 8 fetal brains (gestational ages between 25 and 40 weeks). H-8-OH-DPAT was used as a ligand. At the gestational age 25, 5-HT<sub>1</sub> receptors were present at relevant densities in areas such as the neocortex, hippocampus and brainstem (raphe nuclei), among others, showing a good correlation with the distrition found in the adult brain. A progressive increase in the amount of receptors was observed along the prenatal period in these areas, up to reach adult levels. In contrast, high densities of these sites were found in the fetal cerebellar cortex, an area completely devoid of such receptors in the adult brain. These results illustrate on the developmental pattern of 5-HT<sub>1</sub> receptors in the human brain. In addition, the transient expression of these receptors in the cerebellum support a role for 5-HT in central development, in line with previous physiological and biochemical findings.

CHEMICAL NEUROANATOMY OF THE CHOLINERGIC CONTROL OF RAT AND HUMAN STRIATAL NEURONS.

<u>V. Bernard, E. Normand, I. Aubert, B. Dumartin, E. Lamy, B. Bloch\*</u> URA CNRS 1200-Laboratoire d'Histologie-Embryologie, Université de Bordeaux II, 146 rue Léo-Saiyanat, 33076 Bordeaux, France.

Acetylcholine (ACh) plays a major role in the control of striatal neuronal activities. In order to bring informations about the cellular basis of such control, we have 1) characterized phenotypically the neurons expressing muscarnic receptor (mR) genes in rat and human, 2) identified in rats the neurons expressing c-fos protein after stimulation or inhibition of mR. By using several combinations of in situ hybridization (ISH) with immunohistochemistry, we demonstrated that in the striatum, several neuronal populations express one or several mR genes with specific patterns: most cholinergic neurons contain m1, m2 and m4 receptor (m1R, m2R and m4R) mRNA. All substance P (SP) neurons contain m1R and m4R mRNA and enkephalinergic (Enk) neurons present a labelling with a m1R probe, but 39% of them only with m4R probe. The m1R mRNA is detected in most somatostatin (SRIF) and neurotensin (NT) neurons, but m4R mRNA is present in only a small part of them. These results show that ACh acts directly in a complex manner on the main cell populations of the striatum through mR. This suggests that ACh could mediate directly the release or synthesis of the neurotransmitters produced by these neurons. Use of several muscarinic agonists or antagonists demonstrated that neurons in the rat striatum react by c-fos expression to muscarinic receptor manipulation. After stimulation of the muscarinic receptors by oxotremorine, c-fos immunoreactivity (IR) was restricted to the striosomes. About 80% of the c-fos immunoreactive neurons was identified by ISH as Enk neurons and about 30% as SP neurons. This c-fos IR was inhibited by blockade of the muscarinic receptors by atropine. The c-fos induced seemed independent of the dopaminergic or opioid influences. These results demonstrate that cellular and molecular basis exist for complex influences of ACh on the activities of the main neuronal populations of the striatum.

CLASSICAL NONCHOLINERGIC NEUROTRANSMITTERS AND THE VESICULAR TRANSPORT SYSTEM FOR ACETYLCHOLINE E.D. CLARKSON\*, B.A. Bahr and S.M. Parsons. Neuroscience Research Institute, Univ. of California, Santa Barbara, California 93106 Several classical noncholinergic neurotrans-

Several classical noncholinergic neurotransmitters or their biosynthetic enzymes have been reported to be present in cholinergic nerve terminals. Potential interactions of classical noncholinergic neurotransmitters with cholinergic synaptic vesicles purified from electric organ were studied. No active transport of [3H] serotonin, [3H]noradrenaline or [3H]glutamate occurred. Serotonin and noradrenaline inhibited active transport of [3H]acetylcholine by the vesicles. Dopamine previously had been shown to inhibit transport. L-Glutamate and \( \mathcal{T}\)-aminobutyric acid did not. Noradrenaline was competitive with respect to active transport of [3H]acetylcholine. The aromatic neurotransmitters also inhibited binding of [3H]vesamicol to the vesicles, and dopamine was a competitive inhibitor. Vesamicol is an allosteric ligand of the acetylcholine transporter. The results indicate that dopamine, noradrenaline and serotonin bind to the acetylcholine site but are not transporter.

ENDOGENOUS DOPAMINE PRIMARILY CONTROLS D1 RECEPTOR MEDIATED FACILITATION OF IN VIVO ACh RELEASE FROM STRIATUM S. Consolo\*, R. Bertorelli, P.Girotti, G. Russi and G. Di Chiara\*. \*Istituto di Ricerche Farmacologiche "Mario Negra" Milan, Italy; \*Dipartimento di Tossicologia, Università di Cagliari, Cagliari, Italy.

Striatal cholinergic activity is inhibited by stimulation of D2 receptors and is facilitated by stimulation of D1 receptors. In this study we show (1), that the D1 receptor regulation of striatal ACh release in vivo occurs locally in the striatum; (2), the D1 facilitatory control of DA on striatal ACh release is more sensitive to changes in DA transmission than is the inhibitory D2 mechanism. Thus, the D1 antagonist SCH 23390 (20 µM) infused or (0.45 nmol/side) locally injected, decreased striatal ACh release by about 35%, as it did after s.c. administration. Raising extracellular DA with d-amphetamine (2 mg/kg s.c.), or pargyline (75 mg/kg i.p.) resulted in a time-dependent increase in striatal ACh output. The effects were antagonized by SCH 23390 (10  $\mu$ M) infused. Prolonged (16 h) depletion of DA by a-MpT treatment markedly decreased basal ACh release and prevented the effects of the D1 antagonist. SCH 23390 but not that of the D2 antagonist, REM, on ACh release.

### 47.2

INTERACTIONS BETWEEN THE EFFECTS OF ENRIVONMENTAL MANIPULATIONS AND BENZODIAZEPINE RECEPTOR LIGANDS ON CORTICAL ACETYLCHOLINE RELEASE. H. Moore\*, M. Sarter and J.P. Bruno. Neuroscience Program & Dept. of Psychology, Ohio State Univ., Columbus, OH 43210

In vivo microdialysis was used to measure the ability of benzodiazepine receptor (BZR) ligands to bidirectionally modulate acetylcholine (ACh) release in the frontoparietal cortex of freely moving rats. When animals were tested during the light phase. the BZR agonist chlordiazepoxide (CDP, 1-10 mg/kg, ip) did not inhibit ACh release, whereas the BZR selective inverse agonists ZK 93 426 (1 or 5 mg/kg, ip)and MDL 26,479 (1-10 mg/kg, ip) led to modest and insignificant increases in ACh release, respectively. It was found that a brief exposure to darkness during the light phase produced a 128% increase in cortical ACh efflux. Interestingly, CDP (10.0 mg/kg), which had no effect on ACh release during the light phase, inhibited the darkness-induced increase in ACh efflux. We are currently determining whether administration of BZR selective inverse agonists are able to potentiate the stimulating effects of exposure-to-darkness on cortical ACh release. Collectively, these experiments are designed to test the hypothesis that the ability of drugs presumably acting at the GABA-BZR complex to modulate cortical ACh release depends upon the state of activity in cortical cholinergic afferents.

### 47.4

ULTRASTRUCTURAL RELATIONS BETWEEN NIGROSTRIATAL DOPAMINERGIC NEURONS AND CHOLINERGIC NERVETERMINALS IN THE HUMAN BRAIN. P. Anglade¹, S. Tsuji², E.C. Hirsch¹, F. Javoy-Agid¹ and Y. Agid¹\*, ¹INSERM U.289, Hôpital de la Salpêtrière, 75013 Paris, France and 2Département de Cytologie, Institut des Neurosciences, Université P. et M. Curie, 75005 Paris, France.

The connections between cholinergic nerve endings and nigrostriatal dopaminergic neurons were studied at ultrastructural level in the substantia nigra and the striatum in the human brain postmortem. Immunocytoperoxidasic reaction evidencing tyrosine hydroxylase (TH) was followed by ionic fixation of acetylcholine-like cation by silicotungstic acid in the form of punctiform precipitates in synaptic vesicles. Subsequent post-osmification with silicotungstic acid and embedding in araldite allowed TH immunoreactivity and punctiform precipitates of acetylcholine-like cation to be observed simultaneously on ultrathin sections. In substantia nigra, numerous synaptic contacts were observed between nerve endings with or without punctiform precipitates and TH-immunoreactive dendrites or neuronal cell bodies. In striatum, most of nerve endings displaying punctiform precipitates were not in contact with TH-immunoreactive nerve fibers. These results suggest that, in human, cholinergic nerve endings modulate the activity of nigrostriatal dopaminergic neurons essentially at the level of their dendrites and cell bodies in substantia nigra.

MK-801 POTENTIATES THE d-AMPHETAMINE-INDUCED INCREASE IN STRIATAL EXTRACELLULAR DOPAMINE LEVELS. <u>D.W. Miller\*, D.R. Anderson. and E.D. Abercrombie</u>. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Numerous studies indicate an interaction, either direct or indirect,

Numerous studies indicate an interaction, either direct or indirect, between striatal dopaminergic and glutamatergic systems. The present experiments analyzed this relationship pharmacologically by measuring, via *in vivo* microdialysis, the effects of the non-competitive NMDA receptor antagonist, MK-801, on basal and d-AMPH-induced efflux of dopamine (DA) and DA metabolites in striatum of freely-moving rats. MK-801 (0.5 mg/kg; i.p.) administration significantly increased extracellular DA and dihydroxyphenylacetic acid (DOPAC) levels by approximately 60% and 20%, respectively (n=7). Although not quantified, MK-801-induced increases in locomotor activity and rear limb ataxia were observed. Administration of d-AMPH (2.0 mg/kg; i.p.), produced a 20-fold increase in extracellular DA that was associated with a 70% decrease in DOPAC levels (n=7). When animals were pretreated with MK-801 30 minutes prior to d-AMPH, the magnitude of the subsequent d-AMPH-induced increase in extracellular DA levels was significantly potentiated to 35-fold (n=7). The d-AMPH-induced decline in extracellular DOPAC was not significantly affected by MK-801 pretreatment. Because d-AMPH acts primarily to increase release of newly synthesized DA from a cytoplasmic pool, these data suggest that MK-801 administration potently stimulates DA synthesis in striatum. In summary, the present data indicate that systemic MK-801 enhances both the spontaneous release and the synthesis of DA in nigrostriatal neurons. The synthesis-modulating effects of NMDA receptor blockade appear to be greater than its release-modulating effects under the present conditions. Finally, these results suggest that endogenous excitatory amino acids may exert a tonic inhibitory influence upon nigrostriatal DA synthesis and release. (Supported by USPHS Grant NS 19608)

STRESS INCREASES DOPAMINE SYNTHESIS IN STRIATUM AS MEASURED BY IN VIVO MICRODIALYSIS. <u>S.L. Castro\*, K.A. Keefe, A.F. Syed, E.D. Abercrombie</u> <sup>1</sup>, and M.J. Zigmond. Dept. of Cellular and Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260 and ¹Center for Molecular and Behavioral Neuroscience, Rutgers Univ., Newark, NJ 07102.

Acute stressors increase dopamine (DA) release in striatum as evidenced by increases in extracellular DA and, in some cases, increases in the turnover of DA in striatal tissue. To delineate further the factors associated with the stressinduced release of DA in striatum, we examined the effects of 30 min of low intensity, intermittent tail shock on DA synthesis in striatum. A concentric microdialysis probe (4 mm) was implanted in rostromedial striatum and perfused with artificial cerebrospinal fluid containing NSD-1015 (100  $\mu$ M), an inhibitor of aromatic amino acid decarboxylase. The concentration of DOPA in the striatum of freely moving rats after inhibition of the decarboxylase was used as an *in vivo* index of DA synthesis. In control rats, NSD-1015 increased extracellular DOPA from an undetectable level to  $0.37 \pm 0.04$  ng/20  $\mu$ l (mean  $\pm$  SEM, n=10) 2 hours after the infusion of NSD was begun. Continued infusion of NSD did not significantly increase extracellular DOPA over the next 1.5 hours. Rats exposed to the stressor had a basal extracellular concentration of DOPA of 0.83  $\pm$  0.37 ng/20  $\mu$ l, which was not significantly different from controls. The application of the stressor 2 hours after the start of the NSD infusion significantly increased the amount of DOPA in striatal extracellular fluid by 64%. These data indicate that acute stress can increase not only DA release in striatum, but DA synthesis as well. Our recent studies suggest that stressinduced release of DA is mediated by activity in DA neurons rather than by excitatory amino acid input to the DA terminal (see Keefe et al., Soc. Neurosci. Abs., 1992). We currently are determining whether this also is the case for stress-induced changes in DA synthesis. (Supported in part by USPHS grants MH45156, MH43947, MH00058, and MH09972).

### 47.9

GABA RELEASE AND CORTICAL EXCITATION OF CELLS IN STRIATUM IS INFLUENCED BY NMDA AND AMPA RECEPTORS IN MULTIPLE WAYS. Bernath\*, M.J. Zigmond, A.A. Grace, and T.W. Berger¹. Univ. Pittsburgh,

Pittsburgh, PA 15260 & 'Univ. Southern California, Los Angeles, CA 90089

These experiments examined the contribution of the AMPA and NMDA subtypes of excitatory amino acid (EAA) receptors to excitation of putative GABAergic neurons and GABA efflux in striatum. Electrophysiological activity of single striatal cells evoked by direct electrical stimulation of corticostriatal afferents was recorded extracellularly in a corticostriatal slice. In parallel experiments [3H]GABA efflux from striatal slices was measured. CNQX (1µM) abolished synaptically-evoked action potentials in striatal cells. APV (10 μM) had no inhibitory effects either in the presence or absence of external Mg<sup>2\*</sup> (1.5 mM), although NMDA (1 mM) elicited a rapid burst of spike firing. Quisqualic acid (QA, 10 μM) and NMDA (1 mM) promoted [3H]GABA efflux in striatal slices that was not blocked by removal of external Ca2+ (2 mM). TTX (1 µM) increased the QA-evoked release of GABA 7-fold in the presence of Ca²+, but not in its absence. Neither bicuculline nor phaclofen had any significant effects on QA-evoked release of GABA at 10  $\mu$ M concentration. In contrast, sulpiride (0.5  $\mu$ M) elevated QA-evoked GABA efflux 3-fold. Together, these results suggest that EAA receptors influence GABAergic cells in striatum in several ways: (a) corticostriatal excitation of striatal cells is mediated via AMPA receptors as previously described (Herrling, Neuroscience, 14, 417, 1985), although both AMPA and NMDA receptors are present on striatal neurons; (b) direct stimulation of AMPA or NMDA receptors on GABAergic neurons also elicits Ca2+-independent GABA efflux; and (c) AMPA receptor stimulation triggers an inhibition of GABA release by dopaminergic afferents. (Supported by MH00343, MH00058, MH439547, and MH45156.)

## 47.11

IN VIVO DOPAMINE RELEASE IN THE ANTERIOR NUCLEUS ACCUMBENS OF THE RAT IS INCREASED BY STIMULATING CCK-B RECEPTORS IN THE VENTRAL TEGMENTAL AREA. R. Morgenstern, T. Reum, H. Fink and B. J. Cole. Inst. of Pharmacology and Toxicology, Humboldt Univ. at Berlin and Dept. of Neuropsychopharmacology, Schering AG, Berlin, Germany.

The neuropeptide cholecystokinin-8s (CCK-8s) has been shown to modify the activity of mesolimbic dopamine neurones projecting from the ventral tegmental area (VTA) to the nucleus accumbens septi (NAS) of the rat. It is unclear whether its effects are mediated by CCK-A or CCK-B receptors. Using differential pulse voltammetry with electrically pretreated carbon fiber electrodes placed in the anterior NAS of anesthetized rats (400 mg/kg chloralhydrate IP) we measured peak 2 after stereotaxic microinjection into the VTA of CCK-8s, CCK-4 and IP injection of selective CCK-A and CCK-B antagonists, with or without pretreatment with pargyline (75 mg/kg IP).
Whereas without pargyline CCK-8s did not produce any change of peak 2, following pargyline pretreatment CCK-8s increased peak 2 dose dependently (1, 10 and 100 ng) indicating no change in DOPAC but increase in dopamine release. The CCK-B agonist CCK-4 produced a smaller increase of peak 2. The CCK-8s induced increase of peak 2 could be blocked by the CCK-B antagonist L-365,260 (25 µg/kg IP) but not by the CCK-A antagonist L-364,718 (250 µg/kg

Our results indicate that dopamine release from neurones projecting from VTA to the anterior NAS may be induced by activation of CCK-B receptors in the

STRESS-INDUCED DOPAMINE RELEASE IN STRIATUM: EXCITATORY AMINO ACID STIMULATED OR ACTION POTENTIAL DEPENDENT? K.A. Keete\*, A.F. Sved, M.J.Zigmond, and E.D. Abercrombie<sup>1</sup>. Dept. of Cellular & Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15260 & <sup>1</sup>CMBN, Rutgers Univ., Newark, NJ 07102.

Studies indicate that stress increases dopamine (DA) release in striatum, yet does not seem to alter the electrophysiological activity of nigrostriatal DA neurons. We find that stress also increases extracellular concentrations of glutamate and aspartate in striatum (+50% and +38%, respectively). Because excitatory amino acids (EAAs) can presynaptically stimulate DA release in striatum, we used *in vivo* microdialysis to examine whether DA release induced by 30 min of intermittent tail-shock stress is initiated locally by EAAs or is dependent on action potential propagation through nigrostriatal DA neurons. To this end, the EAA receptor antagonists APV or CNQX (0.1 mM) were administered via a microdialysis probe in striatum to block local effects of EAAs. In addition, tetrodotoxin (TTX;  $10~\mu\text{M}$ ) was infused via a microdialysis probe in in addition, teriodotxin (117, 10 µm) was indused via a finiciotalysis probe in the medial forebrain bundle (MFB) to block action potential propagation in nigrostriatal DA neurons. Stress alone increased the extracellular concentration of DA in striatum by 2.8 ± 0.7 pg/20 µl (+50%; mean ± SEM; n=6). During local infusion of APV or CNQX to striatum, stress increased extracellular DA by 2.9  $\pm$  0.8 pg/20  $\mu$ l (+80%; n=5) and 2.4  $\pm$  0.6 pg/20  $\mu$ l (+68%; n=6), respectively. The stress-induced increases in extracellular DA were not significantly different between the groups. In contrast, infusion of TTX into MFB reduced basal extracellular DA from 4.7  $\pm$  0.7 pg/20  $\mu$ l (n=6) to less than 0.5 pg (limit of detection) and eliminated the stress-induced increase in extracellular DA. The data therefore suggest that both the basal and stress-induced release of DA in striatum are largely, if not exclusively, determined by action potential propagation through the MFB.(Supported in part by USPHS grants MH45156, MH43947, MH00058, and MH09972.)

### 47.10

AND METHAMPHETAMINE (METH)-INDUCED ENDOGENOUS (DA) RELEASE FROM MOUSE NEOSTRIATAL SLICES: EFFECT OF ADENOSINE. K.T. DelleDonne' and P.K. Sonsalla. Dept. of Neurology, UMDNJ-RWJ Medical School, Piscataway, NJ 08854

Proper regulation of DAergic activity in the neostriatum is critical for appropriate control of motor and mental functions. Adenosine is thought to act as a neuromodulator of this DAergic system. In order to evaluate the effect of adenosine on endogenous DA release, a method using a Brandel Superfusion 600 has been devised which permits the reliable discernment of even small drug effects on DA release. Inclusion of 10mM Mg2+ in the slice preparation buffer, increased flow rate, and the addition of a debubbler to the superfusion system were critical factors in maximizing reproducibility. Each chamber serves as its own control due to the application of three consecutive stimulations (S1,S2,S3) in which S2 is preceded by constant perfusion of the test drug; return of DA release in S3 to similar values elicited by S1 is assurance of tissue viability. The peak of  $K^*$ -induced DA release is found almost exclusively in a single 2.5 minute collection fraction whereas the peak of METH-induced DA release is found in two fractions. Amfonelic acid (10 $\mu$ M) blocked METH (35 $\mu$ M)-induced release; 35mM K\*-induced release was prevented by removal of Ca² and addition of 1mM EGTA and 10mM Mg². Perfusion of slices with 0.5 $\mu$ M Nº-cyclopentyladenosine (CPA), a selective adenosine A1 receptor agonist, for 30 minutes prior to S2 inhibited DA released by 35mM K $^{\circ}$  by about 20% but did not affect release by 35 $\mu$ M METH. In preliminary experiments, chronic treatment of mice with caffeine, an adenosine receptor antagonist, produced a slight increase in the inhibitory effect of CPA on 35mM K\*-induced DA release. These data are consistent with other findings using rat tissue and indicate a neuromodulatory role for adenosine on neostriatal DAergic activity.

## 47.12

SEROTONIN IN THE NUCLEUS ACCUMBENS SUPPRESSES ACETYLCHOLINE OUTPUT IN FREELY MOVING RATS. P.V. Rada, G.P. Mark and B.G. Hoebel\*. Department of Psychology, Princeton University, Princeton, NJ 08544.

The purpose of this study was to characterize the interaction between 5-HT and ACh in the NAC of freely behaving animals. 5-HT and related agonists were either applied locally to the NAC by reverse microdialysis or injected systemically while extracellular ACh was simultaneously measured. Locally applied 5-HT or fluoxetine significantly decreased ACh in the NAC. This decrease was blocked by a β-adrenergic and 5-HT, antagonist, propranolol, but not by a 5-HT<sub>2</sub> antagonist, methysergide. The block by propranolol was probably due to its 5-HT<sub>1</sub> antagonistic properties because the β-adrenergic agonist isoproterenol did not change extracellular ACh. Systemic and local administration of 8-OH-DPAT dose-dependently decreased extracellular levels of ACh. These results suggest an inhibitory effect of 5-HT on ACh release in the NAC, and this effect is probably mediated, at least in part, through a 5-HT<sub>1</sub> receptor.
Supported by USPHS DA 03597 and NS 30697.

SEROTONIN 5-HT<sub>1A</sub> RECEPTORS MEDIATE INHIBITION OF TYROSINE HYDROXYLASE ACTIVITY IN RAT STRIATUM. <u>E.A. Johnson\*</u>, C.E. Tsai, and A.J. Azzaro, Depts. of Behavioral Med./Psych., Neurology, and Pharmacology/Tox., West Virginia University School of Medicine, Morgantown, WV 26506

D<sub>2</sub> dopamine autoreceptor mediated control of dopamine synthesis, through modulation of tyrosine hydroxylase (TH) activity, has been well documented. However, recent data indicate that other presynaptic receptors also modulate dopamine synthesis. We have demonstrated 5-HT<sub>1A</sub> receptor mediated inhibition of rat striatal TH in an in-vitro synaptosomal preparation and in in-vivo experiments measuring dihydroxyphenylalanine (DOPA) accumulation following inhibition of aromatic amino acid decarboxylase (NSD-1015, 100 mg/kg, i.p.). In synaptosomes, both 8-OHDPAT, the selective 5-HT<sub>1A</sub> agonist and serotonin, exhibited dose-dependent inhibition, with EC  $_{50}$  values of 7.0 uM and 8.4 uM, respectively. The effects of 8-OHDPAT were antagonized with NAN-190, a 5-HT, /alpha, selective antagonist, propranolol, alprenolol, and pindolol (p<0.01) but not by (-)-sulpiride, a D2 selective antagonist. The effects of serotonin were blocked by propranolol, but not by spiperone, a mixed  $5-HT_2 > 5-HT_1$  antagonist, or ketanserin, a  $5-HT_2$ antagonist. 8-OHDPAT was more potent as an inhibitor of rat striatal DOPA accumulation in-vivo (ED<sub>20</sub> 0.3 mg/kg, s.c.). This effect was antagonized by pindolol (16 mg/kg, s.c.) and by NAN-190 (3 mg/kg, s.c.). These results support a role of 5-HT, receptors in modulation of dopamine synthesis in rat striatum.

### 47.15

STRIATAL DOPAMINE RECEPTORS INTERACTION IS LOST AFTER MPTP ADMINISTRATION. MR. Luquin\*, J. Guillen, J. Laguna, J. Guridi, MT, Herrero, JA. Obeso. Movement Disorders Unit. Department of Neurology. Clinica Universitaria. Apdo. 192-31080 Pamplona-Spain.

Spain.

We studied 3 previously normal monkeys and 1 parkinsonian monkeys. Hemiballism was induced by Kainic acid injection into the STN. Administration of a range of doses of SCH 23390 (0.8-3.2 mg/kg) abolished ballism in the MPTP-lesioned monkey while sulpiride (60 and 120 mg/kg) had no effect. In the 3 other animals neither SCH 23390 nor sulpiride given alone stopped ballism but co-administration of both drugs reduced it significatively. These results indicate that motor responses mediated D-1 and D-2 striatal receptors can only be dissociated after DA nigro-striatal lesion.

## 47.17

FUNCTIONAL INTERACTION OF DOPAMINE AND GLUTAMATE IN NUCLEUS ACCUMBENS IN THE REGULATION OF LOCOMOTION.

M. Wu and S. M. Brudzynski\*, Dept. of Physiology, Univ. of Western Ontario, London Ontario, Capata, Nea Sci.

London, Ontario, Canada N6A 5C1.

It has been shown that excitatory inputs from limbic structures to nucleus accumbens neurons, mediated by glutamate, implicate the initiation of locomotion (Yang & Mogenson, 1987; Yim & Mogenson, 1989). Earlier electrophysiological evidence suggests that these glutamatergic inputs were inhibited by dopamine (Yang & Mogenson, 1987; Yim & Mogenson, 1988). It was also shown that the locomotion induced by injecting glutamatergic receptor agonists, N-methyl-D-aspartic acid (NMDA) or α-amino-3-hydroxy-5-methyl-isoxazole-4-propionate (AMPA) into accumbens may be dopamine-mediated (Boldry & Uretsky, 1988; Imperato et al., 1990). However, the site of this interaction between dopamine and glutamate in accumbens is still unclear. The dopamine and glutamate in accumbens is the regulation of locomotion.

The locomotion (measured in an Opto-Varimex-3 activity cage) induced by unilateral injections of NMDA or AMPA into accumbens was significantly reduced, in the dose-dependent manner, by the pretreatment of dopamine D<sub>2</sub> agonist quinpirole while the dopamine D<sub>1</sub> agonist SKF 38393 had little or no effect. When the axon terminals of mesolimbic DA neurons in accumbens were destroyed by injecting 6-OH-DA into the ventral tegmental area (VTA), NMDA- and AMPA- induced locomotion were reduced substantially. These results suggested that A<sub>10</sub> DA terminals may be the sites for dopamine and glutamate interaction. By activating glutamate receptors located on DA terminals, NMDA and AMPA may influence DA terminals and subsequently increase locomotion.

(Supported by MRC and NSERC of Canada)

### 47 14

CORTICAL REGULATION OF STRIATAL CATECHOLAMINE RELEASE IN THE RHESUS MONKEY Bhaskar S. Kolachana\*, Richard C. Saunders and Daniel R. Weinberger, NIMH Neuroscience Center at St. Elizabeths, Washington, DC. 20032

Extracellular neurotransmitter levels in the caudate nucleus (cd) and the dorsolateral prefrontal cortex (pfc) of the Rhesus monkey were measured using intracerebral in vivo microdialysis coupled to microbore HPLC-EC. Adult Rhesus monkeys (N=3) were sedated with isofluorane gas anesthesia. Microdialysis probes, built in-house, were inserted into the cd and pfc through guide cannulae and were perfused continuously with artificial cerebrospinal fluid (csf). Perfusate was collected every 25-30 minutes at 1 ul/min flow rate and was assayed for catecholamines. After a 4-hr baseline d-amphetamine (amp) or cocaine hydrochloride (coc) dissolved in csf was infused into the pfc region for 25-30 min. Both amp and coc infusions into pfc resulted in elevation (150-400%) of cortical dopamine (DA) and reduction (20-40%) of metabolites Dopac, HVA and HIAA. In contrast, levels of DA, Dopac, HVA and HIAA in the caudate nucleus were markedly reduced (35-50%) following pfc infusion. Perfusate collected from the pfc was analyzed for aminoacids. Following coc infusion there were significant increases (250-400%) in cortical aspartate and glutamate levels as well as several other amino acids. These data demonstrate that in primates cortico-caudate projections regulate the release of striatal catecholamines and this cortico-striatal regulation may be mediated by excitatory amino

GABAergic INHIBITION OF DOPAMINE AND ACETYLCHOLINE OUTPUT IN THE NUCLEUS ACCUMBENS OF BEHAVING RATS. G.P. Mark\*, P.V. Rada and B.G. Hoebel. Department of Psychology, Princeton University, Princeton, NJ 08544.

The influence of local application of GABA on dopamine (DA) and acetylcholine (ACh) output was studied by reverse dialysis in the nucleus accumbens (NAC). Addition of GABA (500  $\mu$ M) to the perfusion medium caused an average 27% reduction in extracellular DA in the NAC. Perfusion with the GABA<sub>A</sub> receptor antagonist bicuculline (BIC; 50  $\mu$ M) had the opposite effect, resulting in an average 89% increase in DA. Both the GABA<sub>B</sub> receptor agonist baclofen (1-50  $\mu$ M) and the GABA<sub>A</sub> agonist muscimol (1-50  $\mu$ M) dose-dependently decreased ACh output. The inhibitory effect of muscimol was more pronounced and more persistent than that of baclofen at all doses. Infusion of BIC increased ACh levels by 83% (10  $\mu$ M) and 148% (50  $\mu$ M). These results provide evidence for a local, inhibitory influence of GABA on the release of both ACh and DA within the nucleus accumbens.

DOPAMINE GLUTAMATE INTERACTION IN THE ADAPTIVE RESPONSE TO REPEATED STRESSFUL EXPERIENCES. A. Mele\*, S. Cabib, S. Puglisi-Allegra and A. Oliverio. Dip. Genetica e Biologia Molecolare, Dip. Psicologia, Universita' 'La Sapienza' Roma, I-00185 and Ist. Psicobiologia e Psicofarmacologia, C.N.R., I-00198 Roma, Italy.

Repeated exposure to a stressful event produces a modification in the response to DA agonists. Ten days of a two hours daily immobilization stress has been shown to increase the responsiveness of C57 mice to low, presynaptic, doses of Apomorphine in the climbing test.

The glutamatergic (Glu) system sends dense afferents to both the striatum and the n. accumbens, sites of afferents of the DA system. A close interaction between the two systems has been proposed in the regulation of the output of this two nuclei. Therefore the effects of systemic injections of the non-competitive NMDA antagonist, MK801, on the adapted response to low doses of Apomorphine in the C57 strain of mice were investigated. One daily injection of (+)MK 801 prior the exposure to the stressfull experience, is able to antagonize the effects of repeated stress on the sensitivity to Apomorphine. In a series of preliminary experiments we tested also the effects of chronic exposure to stress on the MK 801 induced locomotor activity. In this study no changes in the sensitivity of the Glu system by itself were found. Therefore if on one side the NMDA sensitivity does not change in response to repeated stressful events, on the other the blockage of the NMDA receptor with MK801 is able to exert a protective effect on the DA system.

LOCALIZATION OF ANDROGEN RECEPTORS IN THE BRAIN AND PITUITARY GLAND OF <u>Xiphophorus maculatus</u>.

L. <u>Magliulo Cepriano and M. P. Schreibman\*</u>.

Graduate School-University Center and Brooklyn
College Biology Department, C.U.N.Y., Brooklyn,

The distribution of androgen receptors in the brain and pituitary gland of <u>X. maculatus</u>, the platyfish, was studied, in animals of different ages and stages of development, by different ages and stages of development, by immunocytochemistry. Immunoreactivity to antisera generated against androgen receptors was observed in the nucleus lateralis tuberis (NLT) in pubertal and pre-pubertal animals but not in neonatal animals. Immunoreactivity in the NLT was restricted to nuclei. The NLT, an ir-GnRH containing nucleus, has a demonstrated role in the maturation and function of the reproductive system. In the pituitary gland, animals of all ages demonstrated an immune response in the pars intermedia (PI). Immunoreactivity was seen in both the cytoplasm and nuclei of reactive cells. In pre-pubertal and pubertal animals, immunoreactivity was also observed in cells in the ventral caudal pars distalis and at the caudal-rostral pars distalis boundary. ENDOGENOUS COMPOUNDS FROM PORCINE BRAIN BIND TO THE CANNABINOID RECEPTOR AND BLOCK VAS DEFERENS CONTRACTION. W. A. Devane\*, L. Hanuš, R. G. Pertwee\*, L. A. Stevenson\*, G. Griffin\*, and R. Mechoulam. Dept. of Natural Products, Hebrew Univ., Jerusalem 91120, Israel and \*Dept. of Biomedical Sciences, Univ. of Aberdeen, Aberdeen AB9 1AS, Scotland.

To screen for endogenous cannabinoid compounds lo screen for endogenous cannabinoid compounds we employed a binding assay using tritiated 11-hydroxy-hexa-hydrocannabinoi-dimethylheptyl ([3H]-HU-243). Beginning with an organic soluble extract from porcine brain, fractions from a silica gel column were tested for their ability to inhibit the binding of [3H]-HU-243 to rat synaptosomal membranes. Promising fractions were further purified using normal and reverse phase chromatography.

purified using normal and reverse phase chromatography.

We have isolated a group of three compounds from porcine brain which were able to inhibit the specific binding of [3H]-HU-243 to synaptosomal membranes in a manner typical of competitive ligands. Two of the compounds have been tested for their ability to inhibit the electrically evoked twitch response of the mouse isolated vas deferens, a characteristic effect of psychotropic cannabinoids. Both compounds were active in the vas deferens, their IC-50's being similar to those observed in the binding assay. These findings strongly support the existence in the brain of pharmacologically active endogenous cannabinoids.

DISTRIBUTION OF PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE AND ITS BINDING SITES IN THE SPINAL CORD AND SPINAL

POLYPEPTIDE AND ITS BINDING STIES IN THE SPINAL UND AND SPINAL TRIGEMINAL NUCLEUS. G. Légrádi. T. J. Görcs and A. Arimura. "U.S. Japan Biomedical Research Laboratorics, Tulane Univ. Hebert Ctr. Belle Chasse, LA70037. Pituitary Adenylate Cyclase Activating Polypeptide (PACAP) is a new member of the secretin/glucagon/VIP family of peptides that exists in two forms with 38 (PACAP38) and 27 (PACAP27) residues, and it shows the greatest homology to VIP. PACAP is present in the brain and several peripheral tissues as demonstrated by radioimmunossay and immunocytochemistry. There are two types of receptors for PACAP; Type I which is specific for PACAP, and Type II, which is shared with VIP. Anterior pituitary, brain, spinal cord, adrenal medulla and testis, contain Type I PACAP receptors, and lung, liver, gut and other peripheral tissues Type II receptors. In the present study, we investigated the distribution of PACAP and its binding sites in the rat spinal cord by means of immunocytochemistry, RIA and receptor autoradiography. Immunocytochemistry revealed a terminal-like arborization of nerve fibers in the spinal trigeminal nucleus, the laminae I-III and in lamina X of the spinal cord. R1A for PACAP38 showed extremely high concentrations of PACAP-like immunoreactivity in the spinal trigeminal nucleus (23 ng per mg protein) and in the dorsal horn (33 ng for cervical, 13 ng for thoracic, 19 ng for lumbar, and 17 ng for sacral levels per mg protein). The ventral horns contained much less PACAP (2 ng for sactar levels per ing protein). The vention norms contained intent less PACAP (2.fg for cervical, 0.4 ng for thoracic, 10 ng for lumbar, and 1.6 ng for sacral levels). The trigeminal ganglion and the dorsal root ganglia contained lower concentrations of PACAP (2.6 ng for the trigeminal ganglion 0.8 ng for cervical, 2.8 ng for thoracic, 0.7 ng for lumbar, and 1 ng for sacral dorsal root ganglia per mg protein) Using [125][PACAP27 for autoradiography, the spinal trigeminal nucleus, laminae 1-III and X throughout the spinal cord and the intermediolateral cell column of the thoracic part A unroughout me spinal covid and the intermetablateral cent column of the indiract part showed the highest density of binding. All the other areas of the spinal cord gray matter were moderately labeled, and the white matter was not labeled. One thousand-fold molar excess of unlabeled PACAP27, but not VIP, displaced the binding. These data suggest that PACAP is involved in the sensory information processing.

NEURONAL TYPES AND SUBDIVISIONS OF THE HUMAN INTERMEDIATE RETICULAR ZONE. X-F. Huang, G. Paxinos and I. Törl\* Schools of Anatomy and Psychology, University of New South Wales, P.O. Box 1, Kensington, N.S.W., 2033, Sydney, Australia.

The cytoarchitecture and chemoarchitecture of the intermediate reticular zone (IRt) of the medulla oblongata were examined in eight humans. Nissl stained preparations revealed that the majority of neurons in the IRt orient themselves in a dorsomedial to ventrolateral fashion, in line with the axis of the IRt. Four types of neurons were identified but there was no evidence that the specific types of neurons were differentially distributed within the IRt. Based on chemoarchitectonic examinations, the IRt was divided into two parts, external and internal. The external part is a narrow band lateral to the ambiguus nucleus while the internal part encompasses the ambiguus nucleus and extends dorsomedially to the dorsal motor nucleus of the vagus nerve. Both parts extend ventrolaterally to nearly the surface of the wagus lieve. Both pairs extend wettholacturally to learly the surface of the medulla. Both external and internal parts of the IRt displayed tyrosine hydroxylase immunoreactive fibers while only the external part displayed substance P-like immunoreactive fibers. Computer reconstructions of the cel populations enabled the determination of the relative positions of tyrosin-hydroxylase- and substance P-like immunoreactive neurons within the subdivisions of the IRt. The substance P-like immunoreactive neurons were only found in the external part of the IRt rostral to the obex, while the tyrosine hydroxylase-like immunoreactive neurons were found throughou. both segments of the IRt. The above findings indicate that the subdivisions of the IRt can best be revealed by chemoarchitectonic methods. The chemical differences between the subdivisions are likely to be important  $\phi$ the functional differences between the different regions of the IRt.

PUTATIVE RECEPTOR FOR STEROID ANESTHETICS IDENTIFIED IN MOUSE BRAIN SYNAPTOSOMES. <u>C.Bukusoqlu and N.R.Krieqer\*</u>
Dept. of Anesthesia, Harvard Medical School, Brigham and
Women's Hospital, Boston, MA 02115.

Binding of the anesthetic steroid 3a-hydroxy-5apregnan-20-one (3α) to synaptosomal membranes from mouse brain was specific, reversible, and saturable with respect to time and 3 $\alpha$  concentration. The association of [ $^3$ H]3 $\alpha$  (5 nM) was rapid and completed within 5 min. Incubations were carried out with 5-50 nM [ $^3$ H]3 $\alpha$  (60 Ci/mmol) at 24°C in the absence and in the presence of unlabeled  $3\alpha$ . Binding was stopped by rapid centrifugation (12,000 g/3 min/4°C). Aliquots from the supernatant fraction were used to quantitate the amount of bound 3a.

The dissociation of  $[^3H]^3\alpha$  (5 nM) was rapid and completed within 5 min.  $[^3H]^3\alpha$  (10 nM) was displaced by unlabeled  $3\alpha$  (IC<sub>50</sub> 60 nM) but not by 2  $\mu$ M of progesterone,  $3\beta$ -hydroxy- $5\alpha$ -pregnan-20-one,  $5\alpha$ -pregnan-3,20-dione or  $5\alpha$ -pregnan-3,20 diol. Receptor density estimated from displacement studies was twice as high in hindbrain as in forebrain. This work was funded by a grant (GM 42672) from the NIH.

# INOSITOL TRIPHOSPHATE (IP3) RECEPTOR AND PROTEIN KINASE C (PKC) LOCALIZATION IN THE HUMAN EYE

N. Gupta \*\*\*, Rob McAllister #, S.M. Drance #, M. S. Cynader #
#Department of Ophthalmology, University of British Columbia,
Vancouver, British Columbia, V5Z 3N9, CANADA \*Department of
Ophthalmology, University of Toronto, Ontario, CANADA
Using in vitro autoradiography, Inositol 1,45 triphosphate, D[inositol-1-3H(N)] ([3H]IP3) and Phorbol-12,13-dibutyrate, [203H(N)] ([3H]PDBu) were used to determine the distributions of IP3
recentors and PKC in nost morter human are sections. IP3

receptors and PKC in post-mortem human eye sections. IP3 receptors were clearly localized in the trabecular meshwork and ciliary muscle, ciliary epithelium, iris, and corneal epithelium and endothelium, with the highest density in the ciliary muscle. In the posterior segment, the retinal pigment epithelium, the choroid and retina were each labelled. <u>PKC</u> was also present in each of these structures with highest concentrations in the ciliary muscle and retina. <u>Both IP3 receptors and PKC</u> were abundantly contary muscle and retina. Both 173 receptors and PKC were abundantly localized in the ciliary muscle. The presence of each of these molecules which identify a branch of the phospholipase C (PLC) second messenger pathway strongly suggests the involvement of PLC mediated signal transduction in human ciliary muscle. In our previous work, we localized the M3 muscarnic receptor subtype in ciliary muscle (21st Soc. Neurosci. Abst. 234.5, p.587, 1991). Co-localization of the IP3 receptor, PKC, and the M3 muscarnic receptor subtype in the ciliary muscle suggests that the M3 receptor subtype is involved in PLC pathway activation leading to ciliary muscle contraction.

NITRIC OXIDE (NO) IN THE THALAMUS AND UPPER BRAINSTEM: A HISTOCHEMICAL STUDY IN THE RAT AND THE CAT. G. Bertini, K.A. Koralek\* and M. Bentivoglio. Institute of Anatomy, University of Verona, Italy. (Spon: EBBS)

The upper brainstem and thalamus have been investigated in the adult cat and rat with the histochemical staining for NO synthase (NOS). In the former region, a basic similarity was observed in the two species at the mesopontine junction, in which the cell bodies of both the laterodorsal tegmental and pedunculopontine nuclei displayed an intense NOS-staining. The distribution of fibers and terminals was also largely consistent in the thalamus of the rat and cat. Intensely positive fibers and terminals were observed in the anterior, midline and intralaminar nuclei, as well as in the reticular nucleus and in the cat perigeniculate nucleus. However, although the number of positive cell bodies was relatively limited, their distribution displayed species differences: stained neurons were present in the midline and intralaminar nuclei in the rat but not in the cat. In the latter species, however, small-sized positive cell bodies were seen in some domains, such as the pulvinar and lateroposterior nuclei, either scattered or grouped in clusters. By contrast, in both the rat and cat primary somatosensory and visual relay neurons do not appear to contain NO at thalamic level, whereas NO is expressed by prethalamic inputs, including the brainstem cholinergic one. Preliminary findings indicate a differential sequence of maturation of NOS expression in different systems during postnatal development of the rat thalamus.

### 48.9

GABAERGIC, CHOLINERGIC AND SEROTONINERGIC INPUTS TO THE ANTERIOR THALAMIC NUCLEI (ATTN) OF THE ADULT RAT.
A. Gonzalo-Ruiz\*, M. Sanz and A.R. Lieberman. Dept. of Human Anatomy, School of Physiotherapy, Soria, Spain and Dept. of Anatomy, UCL, England.

We have examined the topographic organization and transmitter-related characteristics of projections to the ATN from the thalmic reticular nucleus (TRN), pedunculopontine nucleus (PPN), laterodorsal tegmental nucleus (LDTN) and dorsal and median raphe nuclei (DR, MR). Iontophoretic injections of HRP were placed in the anteroventral (AV) or anterodorsal (AD) subnuclei of the ATN in adult albino rats anaesthetized with Nembutal (45mg/kg). The animals were reanaesthetized 1-2d later, and perfused with fixative. Brains were sectioned coronally at 50/am using a Vibratome. The sections were reacted sequentially for HRP using DAB as the chromogen and with antibodies against GABA, ChAT, or serotonin, using the ABC method. (i) In every animal, all HRP-labelled cell bodies in ipsilateral TRN were also GABA+. (ii) After injections in AV, ChAT+ HRP-labelled neurons were present predominantly in the ipsilateral LDTN, with fewer in PPN. Between 60 and 70% of ChAT+ neurons in LDTN were HRP-labelled and 90-95% HRP-labelled cells in LDTN were ChAT+. In the contralateral LDTN, 30-40% of ChAT+ neurons were HRP-labelled. After injection confined to AD, no HRP-labelled cells were present in LDTN or PPN. (iii) Injections into AV and AD produced HRP-labelled 5HT+ cells throughout the rostrocaudal extent of DR and MR, predominantly in the ventromedial part of DR and also close to the midline in the MR. Thus we have shown that there are topographically precise (see Gonzalo-Ruiz et al., 1991) GABAergic inputs to ipsilateral AD and AV, that the brain stem cholinergic projection is predominantly from LDTN to ipsilateral AV, and that the serotonin projection is to the entire ATN and is derived predominantly from the ipsilateral DR.

## 48.11

LOCALIZATION OF  $a_{2A}$ -ADRENERGIC RECEPTORS IN CULTURED CELLS AND RAT BRAIN USING A SUBTYPE-SPECIFIC POLYCLONAL ANTIBODY. D.L. Rosin', D. Zeng, T. Riley, R. Stornetta, P.G. Guyenet, K.R. Lynch-Depts. of Pharmacology and Biochemistry, Univ. of Virginia Sch. of Med., Charlottesville, VA 22908.

Three subtypes of the  $a_2$ -adrenergic receptor ( $a_2$ -AR) have been cloned to date. The amino acid sequence of these molecules is highly conserved with the exception of the third intracellular (i3) loop. Because of our interest in studying the function and distribution of  $\alpha_2$ -AR in brain, we have developed a subtype-specific polyclonal antibody directed against the rat  $a_{2A}$ -AR. A nucleotide fragment encoding 50 amino acids of the  $a_{2A}$ -AR i3 loop was subcloned into the pGEX.KG vector downstream of the gene for a 26-kDa helmintic glutathione S-transferase (GST). The resulting GST/a<sub>2A</sub>-AR i3 fusion protein was expressed in  $\underline{E}$ .  $\underline{coli}$ , purified, and used to immunize rabbits. The specificity of affinity-purified antibody was tested by western blot and immunocytochemical analysis of COS cells transfected with the gene encoding either the  $a_{2A}$  or  $a_{3C}$ -AR subtype. Immunoreactivity was present only in  $a_{2A}$ -transfected COS cells and not in  $a_{2C}$ -transfected cells. The apparent molecular weight of the recombinant  $a_{2A}$ -AR decreased from 65 kDa to 45 kDa following treatment with N-Glycanase<sup>R</sup> suggesting that the molecule is glycosylated in COS cells. Western blots of crude membrane fractions of rat brain cortex, medulla, and hypothalamus revealed a single immunoreactive band of 55 kDa which was still present following preabsorption of antibody with GST but not with fusion protein. We are currently investigating the utility of this antibody for immunocytochemical studies of the  $a_{2A}$ -AR in rat brain. (Supported by U.S. P.H.S. Grant DA 07216).

Anatomical relations between NADPH-diaphorase (ND), tyrosine hydroxylase (TH) and serotonin (5-HT) containing neurons of the guinea pig mesopontine tegmentum: A quantitative light microscopic study. C.S. Leonard\*, I. Kerman, G. Blaha and E. Taveras. Center for Neural Science New York Injugersity. 6 Wash Pl. New York NY 10003

microscopic study. C.S. Leonard\*. I. Kerman, G. Blaha and E. Taveras. Center for Neural Science, New York University. 6 Wash. Pl., New York, NY 10003. Interactions between brainstem cholinergic and monoamine systems have long been hypothesized to control behavioral state yet little evidence regarding their interconnectivity has been available. We have begun to investigate this issue in guinea pig. Neurons containing ND (mesopontine cholinergic neurons), TH and 5-HT were labelled using diaphorase histochemistry in combination with immunochemical staining. Soma sizes, shapes and distributions as well as fiber patterns were measured and compared. ND positive cells in the laterodorsal tegmentum (LDT) had mean soma diameters of 23.9µ, mean areas of 459.8µ² and form factors of 0.644 which were similar to ND cells in the pedunculopontine tegmentum (PPT). The PPT also contained tightly packed clusters of ND neurons that were smaller (19.5µ diam.,303µ² area) than average. TH neurons in the locus coeruleus (LC) and rostral-LC were slightly smaller than ND cells (21.7µ diam., 395.1µ² area) and 5-HT cells within the dorsal raphe (DR) were smaller yet (16.8µ diam., 231.8µ² area). Cell locations were plotted in frontal sections to assess the degree of overlap in soma distributions. There was a striking degree of overlap in the distribution of TH cells and ND cells in medial PPT and LDT. As much as 78% of the area occupied by ND cells of LDT was contained within the area occupied by TH cells of rostral-LC. A large overlap between laterally displaced 5-HT cells and ND cells of LDT was also observed. TH and 5-HT immunoreactive processes were also observed in both LDT and PPT. Fine varicose fibers as well as thicker, possibly dendritic processes were often seen in close apposition to ND somata and proximal dendrites. These results suggest that ND cells of both the PPT and LDT receive input from catecholamine and 5-HT containing terminals. Moreover, given the restricted volume and high degree of overlap of these populations, a di

### 48.10

SEROTONIN 1B RECEPTORS ON THALAMOCORTICAL AXONS FORM A VIBRISSAE-RELATED PATTERN IN THE SOMATOSENSORY CORTEX OF PERINATAL RATS. M.J. Leslie\*, C.A. Bennett-Clarke, N.L. Chiaia and R.W. Rhoades, Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Serotonin immunoreactive (5HT-IR) axons from nucleus raphe dorsalis (NRD) and perhaps the median raphe nucleus (MRN) transiently form a dense, patterned distribution in the primary visual (area 17) and somatosensory (SI) cortices of perinatal rats. The proposed effects that 5HT axons may have on the development of thalamocortical projections [Blue et al. (1991) Cerebral Cortex 1: 380-389] may be mediated by specific 5HT receptors. Receptor binding autoradiography using [125]cyanopindolol (ICYP) in the presence of isoproterenol was used to determine the distribution of one 5HT receptor subtype, 5HT<sub>1B</sub>, in the cortices of perinatal and adult rats. In perinatal (P-8) rats, binding of ICYP is very dense in lamina IV of SI and area 17. It forms an ordered representation of the body surface which includes patches matching the distribution of the mystacial vibrissae in SI and a very dense patch which encompasses all of area 17. In adult rats ICYP binding was lower in SI and area 17 than in surrounding cortex even though patterned 5HT-IR is no longer present. Additional experiments were done to establish the location of these receptors. Subcutaneous injection of the neurotoxin 5,7-dihydroxytryptamine made on P-0 eliminated the dense and patterned 5HT-IR in area 17 and SI cortex of rats killed n P-8, but had no qualitative effect upon the distribution of 5HT<sub>18</sub> receptors. In contrast, lesion of the dorsal thalamus made on P-6 resulted in complete loss of the dense 5HT<sub>IB</sub> receptor pattern on P-8. Thus, in perinatal rats, 5HT<sub>IB</sub> receptors are present transiently on thalamocortical afferents in area 17 and SI and have a spatial distribution similar to that of serotonergic axons arising from NRD and MRN. EY08661

## 48.12

LOCALIZATION AND QUANTIFICATION OF THE DOPAMINE TRANSPORTER: COMPARISON OF [<sup>3</sup>H]WIN 35,428 AND [<sup>125</sup>I]RTI-55. C.L. Coulter, H.K. Happe, D.A. Bergman, L.C. Murrin<sup>4</sup>. Dept. of Neurology, Creighton Univ. Sch. Med., Omaha, NE 68131 and Dept. of Pharmacology, Univ. Nebraska Med. Sch., Omaha, NE 68198.

A number of radioligands have been identified that are useful for study of the dopamine transporter (cocaine-binding site). Data suggest that the ligands do not always label the same number of sites, leading to differences in the reported density of transporter. We here compare results using two ligand in use in our lab, [3+1]WIN 35,428 and [125]1RTI-55, both with a high affinity for the transport site. Rat brain was sectioned at 16 1 and thawmounted onto subbed slides. Characterization of the binding of ligands to sections used the tissue-swipe method. Based on these studies, sections were incubated in 10 mM sodium phosphate buffer, 0.1 to 0.32 M sucrose, 120 mM NaCl, pH 7.4 at RT for 60-120 min. Tissue was rinsed 2 X 2 min in ice-cold buffer and sections apposed to Hyperfilm. Analysis of autoradiograms gave essentially the same localization for both ligands. Prefrontal cortex was somewhat higher in binding sites than frontal cortex, though both were relatively low. Highest binding was in the caudate-putamen, where there was a gradient decreasing from anterior to posterior and lateral to medial. The ventrolateral region of the posterior striatum was more heavily labelled than the dorsomedial region. The anterior to posterior gradient was less apparent with WIN. The nucleus accumbens had about twice as many sites as the n. accumbens shell. There was also an anterior to posterior gradient in the olfactory tubercles. Based on studies with one concentration of ligand, WIN gave approximately 5 times as many sites as RTI. A detailed analysis will be required to determine the reason for this discrepancy. Supported by NS23975.

MOSAIC DISTRIBUTION OF D<sub>1</sub> RECEPTOR mRNA IN PRIMATE STRIATUM. M.S. Rappaport\* 1, 3, 1, H. Morrison 1, A. Prikhozhan 1, G.W. Huntley 1 and S.C. Scalfon 1, 2. 1 Fishberg Center for Research in Neurobiology and 2 Department of Neurology, The Mount Sinai School of Medicine, NY 10029; 3NYS Psychiatric Institute, NY 10032

The distribution of dopamine D1 receptor (D1R) mRNA in monkey striatum (Macaca Fascicularis) was studied by in situ hybridization using a [355]-labeled monkey D1R cRNA probe. Film autoradiograms revealed a distinctly heterogeneous distribution of D1R mRNA in the caudate nucleus. Comparison with adjacent sections stained for the matrix-predominant 28 kd calcium-binding protein (calbinden), which was used to define striosomal and matrix compartments in striatum, showed that D1R mRNA was largely restricted to calbindin-poor striosomes. Moreover, emulsion autoradiography revealed that the D1R cRNA probe did not hybridize with all neurons in the caudate striosomes, possibly reflecting another level of compartmental organization. In the putamen, D1R mRNA-containing cells were not concentrated in calbindin-poor striosomes but were distributed more homogeneously. In the transition from putamen to ventral striatum the presence of D1R mRNA declined sharply. While generally sparse in the ventral striatum, D1R mRNA labeling usually appeared on film autoradiograms as dense, irregularly shaped islands (approx. 0.1-0.5 mm diameter) most prevalent in the nucleus accumbens and adjacent basal forebrain, particularly in the olfactory tubercule. Nissl counter-stained sections revealed these to be clusters of closely packed D1R mRNA-containing cells. Given the known differences in chemoarchitecture and connectivity of the dorsal and ventral striatum as well as of the striosomal and matrix compartments, the distribution of D1R mRNA suggests that this receptor subtype subserves a unique function in intrastriatal neuronal processing in the nonhuman primate. (Supported by the Aaron Diamond Foundation and NIH Schizophrenia Fellowship).

DISTRIBUTION AND REGULATION OF DOPAMINE RECEPTORS IN THE NUCLEUS ACCUMBENS OF THE RAT. A.l. Jongen-Rėlo, H.J. Groenewgen\* and P. Voorn. Dept. of Anatomy and Embryology, Vrije Universiteit, Amsterdam, The Netherlands.

The distribution of dopamine D-1 and D-2 receptors in the nucleus accumbens (Acc) was investigated by means of in vitro receptor autoradiography using [3H]-SCH-23390 or [3H]-raclopride, respectively. Both D-1 and D-2 receptors were heterogeneously distributed in the Acc. D-1 binding in rostral areas was higher in the shell than in the core, whereas caudally in the Acc binding was higher in the core than in the shell. D-2 binding was lower in the shell than in de core throughout the rostrocaudal extent of the nucleus. A rostrocaudal high-to-low gradient for both D-1 and D-2 binding was found over the Acc as a whole. The effects of unilateral 6-OHDA lesions of the ascending dopaminergic system on D-1 and D-2 mRNA levels and the ligand binding to the dopamine receptors were studied by means of quanti-tative in situ hybridization and receptor autoradiography, respectively. Two weeks after the lesion D-1 mRNA levels were 15% lower in both the Acc and the caudate-putamen (CP) in the lesioned side compared to the control side. The levels of D-2 mRNA had increased 13% in the Acc and 36% the CP. Preliminary results show similar changes in the D-1 and D-2 binding, viz. a decrease in D-1 and an increase in D-2 binding in the lesioned side, both in the Acc and the CP. These findings indicate that the D-1 and D-2 receptors are differentially distributed in the subregions of the Acc and that dopaminergic inputs from the midbrain may exert opposite regulatory effects on the tow receptor subtype

DISTRIBUTION OF [125I]NCQ 298 BINDING TO DOPAMINE D2 RECEPTORS IN HUMAN BRAIN. A M Murray\*  $^1$ . K A Neve $^2$  and JN  $\underline{\text{Loyce}}^1$ . Departments of Psychiatry and Pharmacology, Univ Penn Sch Med, Philadelphia, PA $^1$ ; Research Service, VA Medical Center, Portland,  $\text{OR}^2$ .

The binding of D2 receptors in human brain was measured using quantitative receptor autoradiography with the substituted salicylamide [125I]NCQ 298 and was compared to the distribution observed with [1251]epidepride as previously described (Joyce et al., JPET, 235;1253,1991). Tissue sections were incubated with 250 pM [125]]NCQ 298 at RT for 60 min. Non-specific binding was similar with butaclamol or raclopride. The pattern of [125]]NCQ 298 distribution was very similar to that seen with [125]]epidepride and is expressed as fm/mg protein. The highest binding was seen in the striatum (77 caudate, 85.5 putamen) and in the pallidal complex, with binding in the external segment (33.2) higher than the internal segment (12), and is equivalent to the binding of 80 pM [125]]epidepride. Within the midbrain the binding distribution of [125]]NCQ 298 correlated well with the distribution of DA containing cell bodies and was approximately 50% of epidepride binding. The SNpc (21), SNpl (13) and A10 (6.3) exhibited higher binding than the A8 (2.3) or central grey (4.8). Binding of [1251]NCQ 298 in the superior colliculus (10.6) equaled 30% of epidepride binding in this region. Binding in the frontal cortex was highest in the internal layers(I-II 1, III-IV 1.29, V-VI 2.4). Binding in the motor cortex was highest in lamina IIIb (I-II 0.9, IIIb 1.8, V-VI 1.2) and low throughout somatosensory cortex (I-II 0.6, III-IV 1.2, V-VI 0.7). Highest levels of cortical binding were seen in the temporal cortex (I-II 3.9, III-IV 3, V-VI 3.6). Binding was higher in external layers of perirhinal cortex (I-II 8.1, III-IV 4.1, V-VI 4.5). Within the hippocampal complex, binding was present in subiculum (3.2), CA3 (3.5) and dentate gyrus (3.3). Binding in cortical regions was 2-3 fold lower than that observed with 80 pM [125]]epidepride. Further characterization experiments of NCQ 298 are in progress. This work was supported by the NPF, MH43880 and AG09215.

MULTIPLE DOPAMINE RECEPTOR SUBTYPE mRNAs IN HUMAN AND MONKEY MOTOR CORTEX AND STRIATUM. G.W. Huntley'. S.C. Sealfon. A. Prikhozhan. & J.H.Morrison. Fishberg Res. Ctr. for Neurobiology, The Mount Sinai School of Medicine, New York, NY 10029.

Dopamine is thought to play a critical role in motor and cognitive function through actions mediated by specific receptors, multiple subtypes of which have recently been identified. *In situ* hybridization was used to examine the expression and distribution of mRNAs encoding D<sub>1</sub>, D<sub>2</sub> and D<sub>5</sub> receptors in the motor cortex of humans and in the motor cortex and striatum of macaque monkeys. Hybridization to each receptor probe yielded labeled cells throughout layers II-VI in the motor cortices from both primate species, with virtually all of the large pyramidal (Betz) cells showing significant hybridization to each of the three receptor probes. Thus, many different functional classes of motor cortex output neuron may be In monkey striatum, in directly involved in dopamine circuits. contrast to motor cortex, only the D<sub>1</sub> and D<sub>2</sub> receptor probes showed significant hybridization. Both probes gave a distinct mosaic pattern of hybridization. Thus, primate neocortex possesses a broader representation of the dopamine receptor subtype mRNAs examined in comparison with striatum. Moreover, the unexpected presence and widespread distribution of D $_2$  and D $_5$  receptor mRNAs in cortex suggests that all three receptors play a crucial role in the dopaminergic modulation of cognition and motor behavior and in dopamine dysfunction associated with neuropsychiatric disorders. Supported by NIMH grants MH48603 and MH45212.

DIFFERENTIAL ALTERATIONS OF D1, D2 DOPAMINE AND A2 ADENOSINE RECEPTOR mRNA IN RAT STRIATUM FOLLOWING A VOLKENSIN LESION OF STRIATONIGRAL NEURONS.

A.E. Pollack\*. M.B. Harrison. G.F. Wooten and J.S. Fink.
Depts. of Neurology, Mass. Gen. Hospital, Boston, MA 02114
and Univ. of Virginia Health Sci. Center, Charlottesville, VA 22908.
A2 adenosine receptor (A2R) mRNA is abundantly co-expressed in

A2 adenosine receptor (A2R) mRNA is abundantly co-expressed in the same striatal neurons as D2 receptor (D2R) mRNA; A2R mRNA is never expressed in the same cells as D1 receptor (D1R) mRNA (Mol. Brain Res., in press). Using the retrogradely transported toxic lectin volkensin injected unilaterally in the substantia nigra (SN), Harrison et al. (Brain Res. 1990, <u>528</u>: 317) showed that striatal D1Rs are predominantly localized to striatonigral neurons. We used the same technique to test the hypothesis that A2R-expressing striatal neurons were not part of the striatonigral pathway. Volkensin (2.5ng) was injected unilaterally into the SN of six rats. At 10 days post lesion, 10-12u sections were processed for in <u>situ</u> hybridization using <sup>35</sup>S-labeled riboprobes for D1R, D2R, and A2R mRNAs. Striatal D1R mRNA ipsilateral to the volkensin injection was reduced 24% while D2R and A2R mRNA were reduced 2 and 3%, respectively. D1R mRNA was reduced 14 and 12%, respectively. The parallel changes in D2R and A2R mRNA after SN volkensin lesion support the colcalization of A2 and D2 receptors in the striatum. The differential changes in D1R, D2R and A2R mRNAs confirm D1R localization on striatonigral neurons, and suggest that a small population of striatonigral neurons express D2R and A2R mRNAs.

## 48.18

THE PATTERN OF DOPAMINE D2 RECEPTORS IN MEDIAL TEMPORAL LOBE OF HUMANS AS COMPARED TO RAT AND CAT. S.K. Goldsmith\* and J.N. Joyce. Dept. Psychiatry, Lab Chemical Neuroanatomy, Univ. Pennsylvania School of Medicine, Philadclphia, PA, U.S.A. In our initial reports of the distribution of D2 receptors in human temporal lobe we

In our intial reports of the distribution of D2 receptors in human temporal lobe we described a complex pattern with unique features to humans (Goldsmith et al, 1991). Further study of the D2 family of receptors using 1252 peidperide autoradiography, immunohistochemical (IHC) localization of dopaminergic innervation (comparative anti-TH & anti DBH), and nissl and Timms histochemistry revealed new observations. Timms stain for zinc and heavy meatals revealed a comlementary pattern to that of D2 receptors in cat and human, but not rat. D2 receptors are visible in the facia dentata, region of the dendrites of the granule cells, capping the dense Timm's stain of the DG granule cells. Timms staining is intense throughout hilus, whereas D2 binding is low in external hilus and higher where mossy fibers exit the hilus. D2 receptor numbers are greater in CA regions more distal to the DG, whereas Timms stain ends obliquely at the CA3-CA2 border. In human tissue only, dense bands of D2 receptors are observed in temporal association cortex. The bands either cross all cortical layers, or show a paucity of binding in the mid-layers. They have a mean width of 2.75mm (+/-0.62), and are continuous for an A-P distance of at least 1500 µm. The location of the bands are in good concordance with the observations of Penfiled and Perot (1963) on regions giving auditory experiential responses upon stimulation. In the 8 cases studied to date, the majority of bands were observed in the lateral and inferior aspects of the superior temporal gyrus, with occassional bands observed on the lateral surface of the middle temporal gyrus, with occassional bands observed on the lateral surface of the middle temporal gyrus and on the parahippocampal cortices (Brodman's 22,41,42 and 20,21,37). No bands of D2 binding were observed in any cases in anterior Heschl's gyrus, with bands found in one case in the posterior primary auditory cortex. IHC of adjacent slabs of temporal cortex, reveal minimal levels of dopmanergic innervation, with no increase in

D3 DOPAMINE RECEPTOR GENE EXPRESSION IN RAT AND HUMAN STRIATUM. C. Le Moine\*: I. Aubert: M.P. Mattres+. P. Sokoloff+: J.C. Schwartz+ and B. Bloch, URA CNRS 1200- Laboratoire d'Histologie-Embryologie, Université de Bordeaux II, 146 rue Léo Saignat, 33076 Bordeaux, France; + Unité de Neurobiologie et Pharmacologie, INSERM U 109, Centre Paul Broca, 2 rue d'Alesia, 75014 Paris, France.

The D3 dopamine receptor genes from rat and human have been The D3 dopamine receptor genes from rat and human have been recently cloned and it has been demonstrated that the D3 receptor displays both specific pharmacology and pattern of expression, as compared to others identified dopamine receptor genes, particularly the D1 and D2 receptors (Sokoloff et al.,1990; Bouthenet et al., 1991). We used rat and human D3 RNA probes labeled with S35-UTP to study D3 receptor gene expression in rat and human striatum. We developed various strategies of double in situ hybridization on same sections and/or 3µm-thick adjacent sections to identify the phenotype of neurons expressing the D3 mRNA in the rat and human striatum, especially with respect to the main striatal populations, enkephalin/GABA and substance P/GABA neurons. In addition, comparison with D1 and D2 receptor gene expression were performed on adjacent sections in order to study potential co-localization of several receptor mRNAs within same neurons. In the rat striatum, D3 mRNA were detected in the accumbens nucleus, the islands of Calleja and the olfactory tubercle. Double in situ hybridization experiments show the presence of D3 mRNA in part of the enkephalin neurons of the olfactory tubercle.

SUBSTANCE P BINDING IN THE GUT: DIFFERENCES BETWEEN CAT AND BB RAT. O. Yu\* and A. Ouyang. Gl Division, Department. of Medicine., University of Pennsylvania, Philadelphia, PA 19104.

Substance P (SP) plays an important role in the control of gut motility in health and disease. With the aid of emulsion and film autoradiography, we investigated the distribution of SP binding in the gut of cat and BB rat. The binding of 100 pM  $^{125}\text{I-SP}$  to 10  $\mu m$  sections was performed at 20 °C for 2 hr.

In the cat gut, SP binding was dense in the ileum, ileocecal sphincter and colon. Lower level of binding was observed in the pylorus and duodenum. A negligible amount of binding was observed in the esophagus, lower esophageal sphincter, cardiac and antral areas of the stomach, jejunum and rectum. Emulsion autoradiography demonstrated dense patches of binding in the myenteric plexus of several gut regions (antrum, pylorus, duodenum, ileum, and colon). In the muscle layers, SP binding was confined to the circular muscle and to a much lesser extent the longitudinal muscle. Some binding was observed in the deep muscular plexus of the ileum and colon. A negligible amount of binding was observed in the muscularis mucosa, submucus plexus, and mucosa. These results are in contrast to those found in the rat gut, where dense binding of SP was found from the stomach to the colon. The binding was negligible in the esophagus. In the rat antral pyloric area, SP binding was found mainly in the circular muscle, with a lesser amount in the myenteric plexus and muscularis mucosa, and even less in the longitudinal muscle. SP binding to small intestine was primarily in the deep muscular plexus, and to a lesser extent in the circular muscle and myenteric plexus. SP binding in the colon was confined to the circular muscle, the myenteric plexus, and deep muscular plexus. Therefore, in different gut regions of these two animal species, the innervation of SP neurones may be different and SP may contribute differently to the control of gut motility.

LOCALIZATION OF ENKEPHALINASE (EC 3.4.24.11) mRNA IN RAT BRAIN BY IN SITU HYBRIDIZATION. F. Gaudoux, G. Boileau, G. Lavigne\* and P. Crine. Département de biochimie, Faculté de médecine, Université de Montréal, Montréal, Québec, Canada. H3C 3J7.

The enkephalinase (EC 3.4.24.11) messenger RNA (mRNA) in adult rat brain presented a markedly heterogeneous localization among various brain regions. A strong signal was observed in the glomerular layer of the olfactory bulb, the olfactory tubercle, the caudate putamen, the habenular, anterior pretectal, interpeduncular, red, dorso tegmental, pontine and vestibular nuclei, the mammillary bodies, the Purkinje cells and the choroid plexus of the fourth ventricle. A large number of areas such as the cortex, the Dentate gyrus, the accumbens and the arcuate nuclei, the superior and inferior colliculi and a few regions in the thalamus at the mesencephalic level provided a moderate or low signal of hybridization. The majority of these regions are also known to contain the enkephalinase protein. On the other hand, the globus pallidus, the substantia nigra and the central gray matter which show a high or a moderate amount of enkephalinase respectively did not contain any enkephalinase mRNA. Comparison of the regional distribution of enkephalinase mRNA with that of its translation product provides insight into enkephalinase neuronal pathways in the central nervous system.

PATTERNS OF ENKEPHALIN EXPRESSION IN THE AVIAN

PATTERNS OF ENKEPHALIN EXPRESSION IN THE AVIAN BRAIN. M. Molnar. G. Fontanesi, G. Casini, B.M. Davis, P. Bagnoli, N. Brecha\*, Depts. Anat. & Cell Biol. and Med., BRI, CURE, UCLA and VAMC-West Los Angeles, Dept. Physiol. & Biochem., Univ. Pisa, Univ. Kentucky, & Dept. Environ. Sci., Univ. Tuscia. Enkephalin (ENK) peptides are widely distributed in the vertebrate central nervous system. Using in situ hybridization histochemistry with a chick prepro-ENK RNA probe, we studied the distribution of ENK peptides in the visual system, limbic system and basal ganglia of chick and pigeon brains. We also mapped ENK immunoreactivity in the pigeon brain using a polyclonal antibody directed to met-ENK. In the pigeon visual system, ENK mRNA was present in a few scattered cells in the hyperstriatum accessorium of the Wulst, in the n. lateralis anterior thalami and in the optic tectum (TeO). In the limbic system, cells expressing ENK mRNA were (TeO). In the limbic system, cells expressing ENK mRNA were found in the hippocampal complex, septum and n. of the diagonal band. Finally, hybridization signal was very high in the basal gang in the n. tegmenti peduncolopontinus pars compacta, and in the n. spiriformis lateralis, which is a relay nucleus for the basal ganglia efferents to the TeO. Immunohistochemical studies confirmed the presence of ENK containing cell bodies in these areas. In addition, immunolabeled fibers were observed in the hyperstriatum dorsale (HD) of the Wulst and in the superficial layers of the TeO. In the chick brain, the distribution of the ENK mRNA showed the same general pattern observed in the pigeon, with the addition of strong hybridization signal in the HD. The pattern of ENK expression in avian brains appears remarkably similar to that of mammals. Supported by NEI grant EY04067 and VA Medical Research Funds.

## 49.4

DIFFERENTIATION OF BOMBESIN RECEPTOR SUBTYPES IN THE RAT GASTROINTESTINAL TRACT. E.E. Ladenheim\*, R.T. Jensen, S.A. Mantey, J.E. Taylor and T.H. Moran, Dept. Psychiatry, Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205, NIDDKD, NIH, Bethesda, MD

Univ. Sch. Med., Baltimore, MD 21205, NIDDKD, NIH, Bethesda, MD 20892 & Biomeasure, Inc., Hopkinton, MA 01748.

Two distinct bombesin (BN) receptor subtypes have recently been identified. One subtype, characterized in pancreatic tissue, has a high affinity for gastrin-releasing peptide (GRP) and a low affinity for neuromedin B (NMB) (GRP-preferring). The other, characterized in esophagus, has a higher affinity for NMB than for GRP (NMB-preferring). We have previously demonstrated the presence of both receptor subtypes in rat brain. To determine whether BN receptor heterogeneity is also present in the rat gastrointestinal (GI) tract we examined the competitive inhibition of <sup>125</sup>I-(Tyr<sup>4</sup>)BN binding by NMB and [D-Fs-Pha6 D-Ala<sup>11</sup>IBN(6-13)Q-methyl ester (ME) NMB and [D-F5-Phe6, D-Ala11]BN(6-13)O-methyl ester (ME) using receptor autoradiography. Although 1251-(Tyr4)BN binds using receptor autoraclography. Although "Earl-(197") BN binds equally to both receptor subtypes, NMB inhibits binding to NMB-preferring receptors while ME inhibits binding to GRP-preferring receptors. In the stomach, high densities of BN binding sites were observed in the circular muscle of the fundus and corpus. This binding was completely inhibited by ME but only partially inhibited by NMB. A similar pattern of binding was observed in the descending colon. In contrast, binding in the duodenum, ileum and jejunum was localized to the submucosal layer and this binding was completely inhibited by NMB. Therefore, BN receptors in the circular muscle layer were predominantly GRP-preferring, while those in the submucosal layer were NMB-preferring. Our results show that, as in rat brain, BN receptor heterogeneity is present in the rat GI tract.

PROLACTIN-RECEPTOR LOCALIZATION IN THE BRAIN BY IN SITU HYBRIDIZATION. S. Chiu, R.F. Bulleit and P.M. Wise.
Department of Physiology, University of Maryland School of Medicine, Baltimore, MD 21201.

Recent evidence shows that prolactin may mediate parental behavior or influence pituitary hormone secretion by direct actions on the brain. We demonstrated previously using PCR actions on the brain. We demonstrated previously using PCR that hypothalamic and pituitary tissues express prolactin-receptor mRNA (Endocrinology 130:1747, 1992). To localize the expression of prolactin-receptor mRNA at the individual cell level in the brain, we performed in situ hybridization. Two separate regions (180 and 247 by long) of the prolactin-receptor cDNA (gift of PA Kelly), both of which are common to the long and short forms of the receptor, were subcloned and used to transcribe <sup>36</sup>S-labeled cRNA probes. We maximized the sensitivity and specificity of the in situ hybridization by altering several steps including increasing We maximized the sensitivity and specificity of the *in situ* hybridization by altering several steps including increasing (a) specific activity of the probe, (b) hybridization stringency, (c) wash stringency and (d) wash time. Our preliminary results reveal that the choroid plexus contains the highest level of prolactin-receptor mRNA expression. Scattered cells in the suprachiasmatic nucleus, dorsomedial hypothalamic nucleus, ventromedial hypothalamic nucleus and subfornicai organ also contain prolactin-receptor mRNA. Therefore, prolactin may mediate its actions on the brain by a known prolactin-receptor. Supported by NIH HD 15955 and AG02224.

### 49.7

FIRST EXTENSIVE VISUALIZATION OF GLYCINE IMMUNOREACTIVE FIBERS AND PERIKARYA IN THE RAT BRAIN, P.H. Luppi\*, P. Fort and M. Jouvet, CNRS UA 1195, INSERM U52, Dept. Med. Exptl., Fac. Med., Univ. C. Bermard, 8 Av. Rockefeller, 69373, IYON, CEDEX 08, France.

There is strong evidence that glycine (GLY) is a major inhibitory neurotransmitter in the mammalian central nervous system (CNS). However, extensive description regarding the distribution of GLY-immunoreactive (IR) elements within the CNS is surprisingly lacking, By combinational means of a highly specific antiserum to GLY (a gift from D' WENTHOLD) and a very sensitive immunohistochemical method with streptavidin-HRP, we attempted to fill this gap in the rat brain. Animals under deep nembutal anesthesia were perfused with a fixative containing 4% paraformaldehyde, 0.25% glutaraldehyde and 0.2% picric acid. Cryostat (20µm) free floating sections were incubated 3 days in rabbit GLY antiserum (1/2000) followed by the abiotinylated donkey-anti-rabbit IgG (1/2000) and streptavidin-HRP (1/40 000) overnight at 4°C. The sections were then immersed in 0.02% DAB and 0.6% nickel ammonium sulfate in Tris-HCI buffer (0.05M, pH 7.6) with 0.003% H<sub>3</sub>Q<sub>2</sub>. The antiserum has been characterized elsewhere (Neuroscience, 1987, 22:897-912) and by us with immunoblot analysis. We visualized a considerable number of GLY-IR fibers are started to the bulbar reticular formation, the nucleus of the solitary tract and the spinal trigeminal nucleus. More rostrally, dense plexus of GLY-IR fibers appeared in the raphe nuclei, the lateral preoptic and hypothalamic areas and the basal forebrain. With regard to the perikarya, in addition to the cellular groups already described, GLY-IR neurons were observed in a large number of Structures such as gracilis and cuneaus nuclei, the nucleus raphe magnus, the ventral part of the portine and parvicellular bulbar reticular rare large number of positive cells in the magno- and parvicellular bulbar reticular nuclei, the nucleus raphe magnus, the ventral

## 49.9

EARLY CO-EXPRESSION OF GABA, RECEPTOR SUBUNIT mrnas in the developing rat spinal cord and dorsal root GANGLIA. W. Ma, M. Poulter, P. Saunders and J.L. Barker, Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

The anatomical localization and relative abundance of diverse GABA receptor subunit ( $\alpha 1$ ,  $\alpha 2$ ,  $\alpha 5$ ,  $\beta 2$ ,  $\beta 3$  and  $\gamma 2$ ) mRNAs were examined in neurons of the spinal cord and dorsal root ganglia (DRG) of embryonic and postnatal rats by in situ hybridization histochemistry with oligonucleotide probes. During embryogenesis, the mRNAs encoding  $\alpha 2$ ,  $\beta 3$  and  $\gamma 2$  subunits were the most abundantly expressed of those examined, \( \beta 2 \) subunit mRNA was moderate, while  $\alpha 1$  and  $\alpha 5$  subunit mRNAs were barely detected in both the spinal cord and DRG. The  $\alpha 2$ ,  $\beta 3$  and  $\gamma 2$  subunit mRNAs were clearly expressed at E13 in motoneurons of the cervical cord, but were not detectable in the germinal zone. The mRNAs then extended from the ventral to dorsal portions of the mantle zone and became abundant in all types of spinal neurons between E17-20. After birth, all mRNAs declined in abundance. A marked reduction in α2 and γ2 subunit mRNAs was observed in the dorsal hom, whereas β2 and β3 subunit mRNAs were eliminated in the ventral hom. Four weeks after birth, α2 and γ2 subunit mRNAs were highly expressed in motoneurons, whereas  $\beta 2$  and  $\beta 3$  subunit mRNAs were more concentrated in the superficial dorsal horn. The expressions of most mRNAs in DRG roughly paralleled those in the spinal cord, but appeared 1-2 days latter. β3 subunit mRNA expression, however, was detected in the cervical DRG at E13. These results reveal a heterogeneous and transient co-expression of specific GABA, subunit mRNAs during the development of the spinal cord and DRG.

COMPARISON OF THE LOCATION OF VITAMIN D RECEPTOR SITES AND CALBINDIN 28kD-IMMUNOREACTIVITY IN BASAL FOREBRAIN REGIONS OF THE SIBERIAN HAMSTER. I.M. Musiol\*, M. M. Perez-Delgado, H.-J. Bidmon, A. Bartke and W.E. Stumpf. Dept. Cell Biology & Anatomy, Univ. of North Carolina, Chapel Hill,NC 27599-7090 and Dept. Physiology, Southern Illinois University, Carbondale,

The present study aims at investigating wether or not vitamin D receptor sites correlate with the topography of neurons producing calbindin 28 kD [ 28kD CaBP] in the brain of the Siberian hamster (Phodopus sungerus), a species strongly adapted to the annual cycle. For the autoradiographic experiment adult animals were injected sc with tritiated 1,25-dihydroxyvitamin D<sub>3</sub> (Musiol et al., Neuroscience,1992). To locate 28kD CaBP-immunoreactive cells, a monoclonal mouse antibody (Sigma) was used on 50 µm vibratome sections. Regions in which both vitamin D receptor sites and calbindin 28kD-like cells are present include the diagonal band of Broca and the bed nucleus of the stria terminalis in the anterior basal forebrain and the intralaminar and midline nuclei in the thalamus. There are several regions containing calbindin 28kD-positive neurons which apparently do not contain vitamin D target neurons, e.g. the reticular thalamic nucleus (although a target in rat and mouse) and the mediodorsal thalamic nucleus. In general there is only limited regional correspondence between vitamin D target neurons and calbindin 28kD-immunoreactive neurons, which are more widely distributed.

### 49.8

Differential expression of Glutamate decarboxylase and GABA Transporter messenger RNAs in rat brain.

Catherine Jomary\*, Dawn Savery, Pei-Ying Wu, Glen Wotherspoon, Sharon Averill, John V. Priestley and Marcus Rattray. Divisions of Biochemistry and Physiology, United Medical and Dental Schools, University of London, St Thomas's Hospital, London SE1 7EH, U.K. Molecular cloning has produced several markers which can be used to elucidate the distribution and regulation of presumptive GABA neurones such as the rate-limiting enzyme of GABA synthesis, glutamate decarboxylase (GAD65 and GAD67) and a GABA transporter (GAT1). The relative distributions of expression of these genes can be used to reveal phenotypic differences which may underlie differences in physiological function and regulation of GABA neurones.

genes can be used to reveal phenotypic differences which may underlie differences in physiological function and regulation of GABA neurones.

Using 35-S labelled oligonucleotide probes directed against rat GAD67 and GAT1 messenger RNAs, we have carried out in situ hybridization analyses using liquid emulsion techniques to detect mRNA in presumptive GABA neurones. GAT1 mRNA was found many neurones. In some brain regions, including hippocampus, and cerebral cortex, the distribution of expression of both genes was similar, as expected. However, in other regions gross differences in gene expression were observed. For example, in the thalamic reticular nucleus, striatum, and cerebellar purkinje cells high levels of GAD67 mRNA were expressed in the absence of significant GAT1 expression. Conversely, high levels of GAT1 mRNA with low levels of GAD67 mRNA were found in other regions, including the molecular layer of the cerebellum.

The study shows that neurones differ in their expression of mRNAs which produce proteins involved in presynaptic aspects of GABA neuroransmission. The consequences of this phenotypic subdivision of GABA neurones is not clear, but may offer insight into the selective regulation of GABA neurones by drugs such as benzodiazepines.

henzodiazepines.

## 49.10

NEURONS WITH GLUTAMIC ACID DECARBOXYLASE mRNA IN THE HUMAN HIPPOCAMPUS. G. Zhang\* W.S. Young. III and R.E. Powers. UAB Brain Resource Program, University of Alabama at Birmingham, Birmingham, Alabama 35294 and NIMH, Bethesda, MD 20892.

The distributions of neurons that contained mRNA encoding gamma amino decarboxylase (GAD) were mapped in hippocampus from five normal human subjects using hybridization histochemistry performed with a 35S-oligodeoxynucleotide probe. Neurons with GAD transcripts were identified in multiple rostrocaudal levels of human hippocampus and entorhinal cortex. Many neurons in the granule cell layer and the polymorphic layer of the dentate were labeled. Approximately 20% of granule cells were labeled. A modest number of medium sized and small multipolar and bipolar neurons was present in the CA<sub>4</sub> region. Few pyramidal neurons were labeled in the CA<sub>3</sub> through CA<sub>1</sub>, but a modest number of small fusiform and large basket shaped neurons were present in the stratum oriens. A modest population of labeled neurons was present in the subiculum and entorhinal cortex.

The types and distribution of these neurons are similar to those stained with antisera to GAD or GABA in monkey and rodent hippocampus in previous studies. These data support GABA as a hippocampal neurotransmitter in the human hippocampus.

AN ELECTRON MICROSCOPIC QUANTITATIVE ANALYSIS OF GABA AXON TERMINALS ON CELL BODIES, PROXIMAL DENDRITES AND INITIAL SEGMENTS OF ABDUCENS MOTONEURONS IN THE RAT. G.Chazal\*, H. Bras, F. Lahjouji and A. Barbe, CNRS UPR 418, 280 Bd Ste Marguerite, 13009 Marseille (France). Electrophysiological investigations suggested that ipsilateral abducens motoneurons receive an inhibitory GABAergic input from the vestibular formation. The aim of this study was to describe the location, frequency and synaptic covering of GABAergic and unlabeled axon terminals (ATS) on

toffination. The airror tills study was at destrict in total of the synaptic covering of GABAergic and unlabeled axon terminals (ATs) on identified abducens motoneurons. We developed a double labeling technique:

identified abducens motoneurons. We developed a double labeling technique: the motoneurons were stained retrogradely or intracellularly with HRP, GABA ATs were visualized with a post-embedding procedure. The somata were serially cut and we analyzed 7 to 12 levels per soma.

We identified 1560 ATs on 76 levels of 9 somata and 1176 ATs on 63 proximal dendritic profiles. At each level, all the ATs were randomly distributed. The relative frequency of GABA ATs greatly varied between levels (ranging between 0 to 47%) but the mean average for each somata varied between 5 to 25%. This frequency was slightly lower on the proximal dendrites. The synaptic covering for the labeled ATs was in the range of 2.5 to 14% for the somata while it varied from 4.2 to 8.9% for the dendrites. The to 14% for the somata while it varied from 4.2 to 8.9% for the dendrites. I ne lowest values were always found on the somata and dendrites located in the rostral part of the nucleus. The postsynaptic membrane length devoided of apposition was about 60% for both somata and dendrites. GABA ergic ATs filled with pleomorphic vesicles were observed making symetrical synaptic contacts on axons. They were more numerous on the axon hillock than on the initial segment.

This study demonstrated that the distribution of GABAergic ATs is higher on the somata than on the proximal dendrites. The presence of such ATs on the initial segment raises the question of inhibitory input on the modulation of efferent messages

### 49.13

EXPRESSION OF GAD ISOFORMS IN THE ENDOCRINE

EXPRESSION OF GAD ISOFORMS IN THE ENDOCRINE PANCREAS. C. Sternini\*, R. De Giorgio, M. Lai and K. Anderson. CURE, Dept. of Medicine, Brain Research Institute, UCLA, and VAMC at Wadsworth, Los Angeles, CA 90073.

GAD, the GABA biosynthetic enzyme, consists of two major forms, GAD<sub>65</sub> and GAD<sub>67</sub> that are derived from separate genes. In addition to neurons, GABA is found in endocrine structures, including the pancreas. We examined the expression of GAD<sub>65</sub>. and GAD<sub>67</sub> isoforms in the rat endocrine pancreas using specific RNA probes and antibodies. *In situ* hybridization histochemistry with <sup>35</sup>S-labeled rat antisense GAD<sub>65</sub> and GAD<sub>67</sub> RNA probes showed that both isoforms are expressed in the core of the islets, where B-cells are located. In general, the GAD<sub>65</sub> probe gave a stronger signal than the GAD<sub>67</sub> probe. Hybridization signal above background levels was not observed with sense RNA probes. When using an RNA probe complementary to somatostatin (a marker for D-cells), labeling was observed on cells at the peripheral margin of the islets, where D-cells are located, but not over the core of the islets. This further supports the specificity of the GAD labeling. Antibodies specific for each GAD isoform labeled B cells; staining was stronger with the  $GAD_{65}$  than with the  $GAD_{67}$  antibody. Double-labeling confirmed the colocalization of GAD and issuling. The present results together with the identification of insulin. The present results, together with the identification of GAD<sub>65</sub> as a key autoantigen in type I diabetes, suggest a role for the GABA system in islet cell function and dysfunction. Supported by NIH grant DK38752. We thank Drs. A.J. Tobin & D. L.

Kaufman for the GAD cDNAs and GAD<sub>67</sub> antibody.

DISPARITY BETWEEN DIAZEPAM-INSENSITIVE GABA RECEPTOR BINDING AND mRNA DISTRIBUTIONS

Paul A, Saunders, Michael O. Poulter\*, Wu Ma, and Jeffery L. Barker Laboratory of Neurophysiology, NINDS/NIH Bethesda,MD Molecular biological experiments have previously shown that non-neuronal cells transfected with cloned GABA<sub>A</sub> receptor α4 or α6 subunits express GABA<sub>A</sub> receptors which bind [3H]RO 15-4513 with high affinity but not classical benzodiazepines (Wisden et al. FEBS 289:227, 1991; Luddens et al. Nature 346:648, 1990). The reported distribution of [3H]RO 15-4513 binding to benzodiazepine-insensitive sites in the rat brain (Sieghart et al. J. Neruochem. 48:46 1987), however, was consistent with the localization of  $\alpha 6$  subunit in the cerebellum but not the broader distribution of the  $\alpha 4$  subunit. In cerebellum but not the broader distribution of the  $\alpha$ 4 subunit. In order to clarify the disparity, in situ hybridization signals of DNA probes against the  $\alpha$ 4 and  $\alpha$ 6 subunit mRNAs were compared with [3H]RO15-4513 binding on sections from the same adult male rat. The  $\alpha$ 4 mRNA was highly expressed in thalamus, cerebellum, hippocampus, and striatum. The  $\alpha$ 6 subunit mRNA was found exclusively in the cerebellum. Autoradiograms of [3H]RO15-4513 exclusively in the cerebellum. Autoradiograms of [3H]RO15-4513 binding showed strong labelling of many structures in the rat brain. Diazepam-insensitive binding of [3H]RO15-4513 was measured by the addition of 10 uM diazepam to the incubation solution. Autoradiograms of diazepam-insensitive binding produced intense graining over the cerebellar granule cell layer, but structures which were positive for the α4 but not the α6 subunit mRNA showed very that for the cerebellar granule cell layer, but structures which little if any graining. These data suggest that the  $\alpha 4$  subunit is found in combination with other subunits which mask its diazepaminsensitive characteristics.

MEASUREMENT OF REGIONAL KINETICS OF LIGAND BINDING TO THE GABAA RECEPTOR BY QUANTITATIVE AUTORADIOGRAPHY. A. M. Mans\*and K. M. Kukulka. Dept. Physiology and Biophysics, The Chicago Medical School, North Chicago, IL 60064.

The GABAA/benzodiazepine receptor mediates inhibitory

GABA neurotransmission throughout the brain. Earlier studies led to the conclusion that the affinity of binding to the GABA and benzodiazepine sites is regionally homogeneous; however in these studies only a few regions were analyzed. We used quantitative autoradiography to measure ligand binding density  $(B_{max})$  and affinity  $(K_d)$  in more detail. Consecutively cut brain sections containing common regions were incubated in a range of different concentrations of each ligand to enable kinetic parameters to be calculated. ligands used were a GABA site agonist (3H-muscimol) and two benzodiazepines (<sup>3</sup>H-flunitrazepam and <sup>3</sup>H-Ro15-1788). The affinity of binding was clearly regionally heterogeneous with all three ligands measured. The range of values among areas was three- to eight-fold and appeared to be continuous. The densities, as expected, also showed differences among brain regions. The results are consistent with the presence of multiple subtypes of the GABA<sub>A</sub>/benzodiazepine receptor distributed heterogeneously throughout the brain.

HUMAN MELANOMA (M-6) CELLS EXPRESS HIGH-AFFINITY RECEPTORS FOR MELATONIN. LP. Niles\* S.-W. Ying and C. Tenn. Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

A high-affinity receptor for melatonin has been localized and partially characterized in vertebrate brain and other tissues. This receptor exhibits both high- and low-affinity states, and it is sensitive to guanine nucleotides and monovalent cations. Moreover, melatonin signalling via this receptor is transduced by a pertussis toxin-sensitive G protein, resulting in inhibition of forskolin-stimulated adenylate cyclase activity in brain membranes. In order to further study this receptor, we have examined various cell lines for its presence. We now report that human malignant melanoma (M-6) cell membranes bind [1251]melatonin with a pharmacological profile (IMEL>6-Cl-MEL≥MEL>>NAS>5-HT) which is similar to that of the above-mentioned receptor. Saturation which is similar to that of the above-mentioned receptor. Saturation binding experiments revealed the presence of two affinity states  $(K_{d1} = 290 \pm 85 \text{ pM}, B_{max}) = 2.5 \pm 0.4 \text{ fmol/mg protein}; K_{d2} = 6.5 \pm 1.1 \text{ nM}, B_{max}) = 2.4 \pm 5 \text{ fmol/mg protein}$ , with abolishment of the high-affinity state in the presence of GTP. Similarly, GTP caused a rightward shift in agonist competition curves, with conversion of all high-affinity state in the presence of GTP. sites to a low-affinity state. More importantly, in intact M-6 cells, melatonin caused a significant suppression of forskolin-stimulated cAMP

accumulation with an EC<sub>50</sub> value of ~5 nM.

These findings indicate that the M-6 melatonin receptor is pharmacologically and functionally similar to that in the brain. The M-6 cell line should be useful for further characterization of this G protein-

coupled melatonin receptor.

## 50.2

METABOTROPIC GLUTAMATE RECEPTORS COUPLED TO ADENYLYL CYCLASE DECREASE FORSKOLIN-STIMULATED CAMP FORMATION IN CEREBELLAR GRANULE CELLS. J. T. Wroblewski\*1, M. Majewska1 and B. Wroblewska<sup>2</sup>. <sup>1</sup>Fidia-Georgetown Institute for the Neurosciences and <sup>2</sup>Department of Biology, Georgetown University, Washington D.C. 20007.
 In primary cultures of cerebellar granule cells, glutamate was shown to

enhance the accumulation of cGMP mediated through the formation of nitric oxide. Now we report that these neurons express glutamate receptors which contribute to the regulation of cAMP concentrations. Incubation of granule cells with forskolin caused a concentration-dependent increase in cAMP accumulation which was decreased in a dose-dependent manner by the simultaneous addition of either glutamate, ibotenate, trans-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD) or quisqualate. The inhibition reached about 50% of the forskolin-stimulated cAMP accumulation and was not prevented by antagonists of ionotropic glutamate receptors. The nonselective phosphodiesterase inhibitor 3-isobutyl-1-methylxantine increased the forskolin-stimulated cAMP production but failed to reduce the inhibition elicited by glutamate receptor agonists. This indicates that glutamate decreases cAMP levels by inhibiting its production rather than enhancing its degradation and suggests an inhibitory coupling of glutamate receptors with adenylyl cyclase. This possibility was further investigated in a preparation of washed membranes isolated from granule cells where the activity of adenylyl cyclase was stimulated by GTP and measured by cAMP accumulation in present of phosphodiesterase inhibitors. Under these conditions glutamate, quisqualate and ACPD decreased the GTP-stimulated adenylyl cyclase activity. These results suggest that cerebellar granule cells in primary culture express metabotropic glutamate receptors which are negatively coupled through G proteins to adenylyl cyclase and show an agonist pharmacology similar to that reported for the cloned mGluR2 receptor (Tanabe et al., Neuron 8:169, 1992).

CYCLIC ADENOSINE 3'5'-MONOPHOSPHATE POTENTIATES EXCITATORY AMINO ACID AND SYNAPTIC RESPONSES OF RAT SPINAL DORSAL HORN NEURONS. M. Randic. R. Cerne, G. Gerber and M.C. Jiang. Dept. of Vet. Physiology and Pharmacology, Iowa State University, Ames, IA 50011. Intracellular recordings were made from rat dorsal horn (DH) neurons in the

Intracellular recordings were made from rat dorsal horn (DH) neurons in the in vitro slice preparation to study the actions of cyclic adenosine 3',5'-monophosphate (cyclic AMP). In the presence of TTX, bath application of the membrane permeable analogue of cyclic AMP, 8-Br cyclic AMP (25-100µM) caused a small depolarization of the resting membrane potential, a long-lasting increase in the spontaneous synaptic activity and the amplitude of presumed monosynaptic excitatory postsynaptic potentials (EPSPs) evoked in the substantia gelatinosa neurons by orthodromic stimulation of a dorsal root. In the presence of TTX, 8-Br cyclic AMP enhanced in a reversible manner, the depolarizing responses of a proportion of DH neurons to N-methyl-D-aspartic acid (NMDA), \(\sigma\) amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid, quisqualic acid and kainic acid. The effects of 8-Br cyclic AMP on the resting membrane potential and the NMDA responses of DH neurons were mimicked by reducing phosphodiesterase activity with 3-isobutyl-1-methylxanthine, but not by cyclic AMP-applied extracellularly. Intracellular application of a protein inhibitor of cyclic AMP-dependent protein kinase (PKI) into DH neurons prevented the 8-Br cyclic AMP-induced potentiation of the NMDA response of these cells. Moreover, we have found the enhancement of the NMDA induced current responses upon i.c. application of the catalytic subunit of protein kinase A in the whole-cell voltage-camped isolated rat DH neurons. These results suggest that in the rat spinal dorsal horn the activation of the adenylate cyclase-cyclic AMP-dependent protein kinase system may be involved in the regulation of the sensitivity of postsynaptic excitatory amino acid (NMDA, AMPA, KA) receptors and primary afferent neurotransmission, including nociception. (Supported by BNS and USDA).

### 50.5

MOLECULAR CHARACTERIZATION OF A 63 kDa CALMODULIN-DEPENDENT PHOSPHODIESTERASE THAT IS HIGHLY EXPRESSED IN STRIATUM. Joseph W. Polli and Randall L. Kincaid\*. Section on Immunology, NIAAA, Rockville, MD 20852. Two classes of calmodulin-dependent phosphodiesterase

Two classes of calmodulin-dependent phosphodiesterase (CaM-PDE) have been identified biochemically in neuronal tissue (i.e. 61 and 63 kDa isoforms). We have cloned a cDNA for the 63 kDa isoform from mouse brain by using PCR of mRNA isolated from micropunched Purkinje and granule cell layers. Deduced protein sequence showed ≈60% homology with that of the 61 kDa isoform, indicating that these proteins are products of different genes that diverged long ago. Southern blot analysis suggests high nucleotide sequence conservation of the 63 kDa CaM-PDE among mammalian and avian species. Northern blots showed a single 3.6 kb transcript in all brain regions; weak hybridization also was seen in lung, spleen, thymus and testes. Remarkably, striatum contained an 8-fold higher CaM-PDE mRNA concentration than cortex, hippocampus, olfactory bulb and midbrain, and 40-fold more than cerebellum. This finding, in conjunction with electron microscopy studies demonstrating a postsynaptic localization of CaM-PDE, would suggest that the 63 kDa isoform has an important role in Ca\*-modulated regulation of cyclic nucleotides in striatal neurons. Studies to determine which subpopulation of striatal neurons express the 63 kDa isoform and how this isoform may be regulated by neuronal input are in progress.

## 50.7

REMOXIPRIDE ACTION ON DOPAMINE D2 RECEPTOR MEDIATED INHIBITION OF CYCLIC AMP IN RAT STRIATUM.

A.I. Westlind-Danielsson\*, K. Gustafsson and I. Andersson.

Department of Neuropharmacology, CNS R&D, ASTRA ARCUS AB, S-151 85 Södertälje, Sweden.

The ability of the novel neuroleptic compound remoxipride to block dopamine (DA) D2 receptor mediated inhibition of cyclic AMP (cAMP) formation was studied in rat striatal tissue pieces. The action of remoxipride was compared to the effect of the high affinity D2 antagonists, haloperidol, (-)sulpiride, raclopride and NCQ 298. In addition, four of the main metabolites of remoxipride, identified in rat but not man, were also examined. The compounds were assessed either in the presence of (1) DA (100 µM) (2) SKF 38393 (100 µM) + pergolide (1 µM) or (3) DA (100 µM) + forskolin (1 µM). Remoxipride along with one of the metabolites (up to 100 µM) did not prove as potent in blocking the D2 mediated inhibition of cAMP accumulation as the other compounds tested. Furthermore, neither remoxipride or any of the metabolites had any significant action (100 µM) on either basal or SKF 38393 stimulated cAMP levels, making antagonistic or agonistic properties of these compounds at e.g. the DA D1 receptor unlikely. The inclusion of a D2 antagonist in (3) was found to be expressed as a

The inclusion of a D2 antagonist in (3) was found to be expressed as a large (>2-fold) augmentation of cAMP formation. Block of the D2 receptor could be thought to liberate a growing D2 mediated inhibitory constraint following increased DA receptor-effector coupling provided by (3). Thus, the span available for carrying out pharmacological manipulation of D2 receptor mediated inhibition of cAMP provided by this system greatly facilitates the study of D2 antagonistic properties of different compounds.

NAAG DECREASES FORSKOLIN-STIMULATED cAMP FORMATION IN CEREBELLAR GRANULE CELL. <u>B. Wroblewska\* and J.H. Neale,</u> Department of Biology, Georgetown University, Washington, DC 20057.

N-Acetylaspartylglutamate (NAAG) fulfills several criteria for action as a peptide neurotransmitter. We tested the ability of NAAG to activate metabotropic "glutamate" receptors in cultured cerebellar granule cells under conditions of negligible extracellular conversion of NAAG to glutamate and NAA. In contrast to glutamate, NAAG failed to stimulate Pl turnover in these cells. However, NAAG produced a dose-dependent decrease in forskolin-stimulated cAMP, while having no effect on basal levels of this cyclic nucleotide. Similar inhibition of cAMP levels was obtained with L-glutamate, ibotenate, and trans-ACPD, consistent with activation of mGluR2 or a related receptor. The potencies of glutamate and NAAG were similar. These effects were obtained in the presence of NMDA receptor blockade and phosphodiesterase inhibition. The NAAG-induced reduction in forskolin-stimulated cAMP formation was restricted to the alpha-linked peptide, beta-NAAG did not affect cAMP levels. These data support the hypothesis that NAAG is an agonist for the subclass of metabotropic "glutamate" receptor(s), acting via G-protein to inhibit adenylate cyclase, while not activating directly those related glutamate receptors which are coupled to Pl turnover (supported by NS 28130).

#### 50.6

CHARACTERIZATION OF cAMP EFFLUX FROM RAT STRIATUM AS MEASURED BY IN VIVO MICRODIALYSIS K.Suyama, M.I.Masana, I.N.Mefford\*, H.Manji and W.Z.Potter. Section on Clinical Pharmacology, ETB, NIMH, Bethesda, MD, 20892

It has been demonstrated that activation of postsynaptic receptors can be monitored by in vivo microdialysis of adenosine 3'5'monophosphate (cAMP). We report the application of this technique to examine the effect of dopaminergic and adrenergic agents on the efflux of cAMP from rat striatum. Microdialysis probes with a 3 mm membrane tip were stereotaxically inserted into the anterior striatum (AP +0.7 mm, L +2.7 mm, V-7.0 mm) of chloral hydrate-anesthetized rats. Probes were perfused with artificial cerebrospinal fluid at a flow rate of 2 µl/min. Two hours after insertion of the probe, samples were collected every 20 min and analyzed for cAMP by RIA. Basal cAMP was taken as the average cAMP concentration for the 1 h prior to drug administration  $(1.00 \pm 0.09)$ fmol/min, n=29). As reported by others, infusion of dopamine (up to 100 μM) did not significantly alter cAMP efflux, whereas a D1 receptor agonist (+) SKF 38393 (100  $\mu$ M) increased. We also observed that a D2 receptor antagonist (-) sulpiride (100 µM) modestly increased cAMP. Interestingly, the beta-adrenergic receptor agonist (-) isoproterenol produced a concentration-dependent increase in cAMP efflux. These data raise the possibility that non-neuronal elements and/or stimulation of extrasynaptic receptors contribute to the cAMP response observed by in vivo microdialysis in the striatum.

## 50.8

ATTENUATION OF AFTERHYPERPOLARIZATION IN LOCUS COERULEUS NEURONS BY CAMP IS INDEPENDENT OF PROTEIN KINASE ACTIVATION. G. Aston-Jones\* and R. Shiekhattar, Department of Mental Health Sciences, Division of Behavioral Neurobiology, Hahnemann University, Broad and Vine, Philadelphia, PA 19102, U.S.A.

Mental Health Sciences, Division of Behavioral Neurobiology, Hahnemann University, Broad and Vine, Philadelphia, PA 19102, U.S.A.
Afterhyperpolarizations (AHPs) that follow action potentials are a prominent mechanism for the control of neuronal excitability. The AHP amplitude of locus coeruleus (LC) neurons recorded in brain slices was reduced by superfusion of 20 μM forskolin (FSK; AHP amplitude=17.0±0.7 mV before vs 11.5±0.6 mV following 10-20 min FSK, p<0.001, n=11), an activator of adenylate cyclase, or by membrane permeable analogs of adenosine 3',5'-cyclic monophosphate (cAMP, p<0.01; n=7). Furthermore, superfusion of the phosphodiestrase inhibitor, Ro20-1724, also attenuated the AHP (p<0.05, n=4). In contrast, superfusion of 1,9-dideoxyforskolin (DFSK), the FSK analog that does not activate adenylate cyclase, had no effect on these AHPs (16.7±1.5 mV before vs 16.7±2.3 mV following DFSK, n=4). Co-application of a protein kinase inhibitor (H-8, KT 5720, or RpcAMPS) with either FSK or 8-Br-cAMP failed to block the reduction of AHP amplitude, but blocked the cAMP-dependent protein kinase (PKA)-mediated enhancement of opiate responses in the same LC neurons (reported in Shiekhattar and Aston-Jones, this volume). Furthermore, the AHP amplitude was significantly reduced (to 88% of control, n=11 for each treatment) in LC neurons taken from chronically morphine-treated rats, a treatment known to increase adenylate cyclase activity. These results indicate that elevation of intracellular cAMP reduces the AHP amplitude in LC neurons during local opiate withdrawal (Kogan et al., Eur. J. Pharmacol. 211;47 (1992) and Hirata et al., this volume). Supported by PHS grants NS 24698 and DA 06214.

CYTOSKELETAL REGULATION OF NEURONAL SIGNAL TRANSDUCTION: TRANSFER OF GTP FROM TUBULIN TO  $G\alpha$  IN A RECONSTITUTED SYSTEM M.M. Rasenick\* and S. Roychowdhury, Dept. of Physiology and Biophysics, U. Illinois College of Medicine, Chicago, IL 60680

This laboratory has suggested that synaptic membrane tubulin elicits a receptor-independent activation or inhibition of adenylyl cyclase. Previous studies have shown that tubulin binds specifically to the signal transducing proteins, Gs $\alpha$  and Gi $\alpha$ 1, and a direct nucleotide transfer from tubulin to G-protein is the mechanism for adenylyl cyclase regulation (*Biochemistry 30*: 110957-10965, 1991). In order to identify the participants in the nucleotide transfer process in detail, the tubulin-AAGTP was incubated with purified Gi/o or recombinant ail in solution. Transfer of the hydrolysis-resistant photoaffinity GTP analog, AAGTP, from tubulin to  $\alpha i$  was observed, and AAGTP was bound to tubulin or  $G\alpha$  (no AAGTP was released into the medium). Free Gpp(NH)p in 10-100 fold excess of tubulin-AAGTP did not affect the transfer significantly. The addition of  $\beta\gamma$  subunits to  $\alpha$ , did not influence the transfer. Two well defined monoclonal antibodies against tubulin, whose epitopes are located near the C-terminal of  $\alpha$  and  $\beta$  subunits respectively, partially blocked the transfer of nucleotide to the G protein, but did not disrupt the physical complex formed between these proteins. This suggests multiple sites of interaction between tubulin and G protein may be required for the nucleotide transfer process. The results also suggest that the complex formation between tubulin and G protein  $\alpha$  subunits allows for the direct transfer of GTP from tubulin to  $G\alpha$ . It is suggested that synaptic membrane tubulin, with GTP bound, is capable of bypassing the receptor to activate G protein mediated cellular processes.

## 50.11

PHOSPHORYLATION OF RAT DARPP-32 BY CASEIN KINASE I. F. Desdouits, D. Cohen, P. Greengard, and J.-A. Girault INSERM U114, Chaire de Neuropharmacologie, Collège de France, Paris, and The Rockefeller University, New York, 10021 NY

DARPP-32 (dopamine- and cAMP-regulated phosphoprotein, apparent Mr-32 000) is an inhibitor of protein phosphatase 1, enriched in striatonigral neurons, and activated by cAMP-dependent phosphorylation on Thr<sub>2</sub>. On immunoblots prepared with SDS extracts of rat striatum, DARPP-32 migrates as a doublet. The lower band of the doublet disappears when the tissue is incubated at 30°C before homogenization. When DARPP-32 is immunoprecipitated from <sup>32</sup>Pi-labeled striatal slices, the lower band of the doublet contains an acidic phosphopeptide phosphorylated on serine, and not found in the upper band. Recombinant rat DARPP-32 has been subjected to site-directed mutagenesis, expressed in Escherichia coli, and purified to homogeneity. When it is phosphorylated in vitro by casein kinase I, wild type DARPP-32 migrates as a doublet on SDS-PAGE. The lower band of this doublet contains an acidic phosphopeptide, which has the same migration on 2-dimensional peptide maps as the phosphopeptide derived from the lower band of DARPP-32 labeled in striatal slices. When mutated DARPP-32, in which Ser<sub>137</sub> has been replaced by an alanine, is phosphorylated by casein kinase i, the appearance of a doublet and the acidic phosphopeptide are not observed. These results demonstrate that rat DARPP-32 is phosphorylated on Ser,137 by casein kinase I, and that this phosphorylation is responsible for a slightly faster migration of the protein on SDS-PAGE. Partial phosphorylation by casein kinase I in intact neurons is likely to account for the migration of striatal DARPP-32 as a doublet.

## 50.13

REGULATION OF CYCLIC AMP-DEPENDENT PHOSPHORYLATION IN RAT FRONTAL CORTEX BY CHRONIC LITHIUM: IDENTIFICATION OF DARPP-32 AND OTHER LITHIUM REGULATED PHOSPHOPROTEINS. X. Guitart and E.J.Nestler. Lab. of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

In contrast to other psychotherapeutic drugs, lithium acts on postreceptor components of signal-transduction pathways. Most studies of lithium concern its acute actions, with relatively little information available on its chronic effects on the nervous system. As chronic lithium treatment has been shown to alter adenylate cyclase and G-protein expression in brain (Colin et al., PNAS & & 10634, 1991), we studied the next step in the cyclic AMP pathway: cyclic AMP-dependent protein phosphorylation.

By use of back phosphorylation and immunoblotting techniques, we found that among a number of lithium-regulated phosphoproteins, chronic lithium increases by 25% the levels of DARPP-32 in rat frontal cortex. This effect was also seen using other chronic antidepressant treatments (imipramine, tranylcypromine) and was specific to the frontal cortex. In contrast, chronic treatment with haloperidol, morphine, or cocaine did not alter DARPP-32 levels. Chronic lithium was also shown to alter the subcellular distribution of cyclic AMP-dependent protein kinase activity in frontal cortex, as observed previously for other antidepressants (Nestler et al., J. Neurochem. 53, 1644, 1989). These findings suggest that regulation of the cyclic AMP pathway, including increased levels of DARPP-32, could reflect a common functional effect of long-term exposure to lithium or other antidepressant treatments. antidepressant treatments

### 50.10

ISOFORMS OF NEURONAL PROTEIN PHOSPHATASE 1

ISOFORMS OF NEURONAL PROTEIN PHOSPHATASE 1

E.F. da Cruz e Silva and P. Greengard\*. Laboratory of Molec. & Cellular Neuroscience, The Rockefeller University, New York, 10021

DARPP-32 (dopamine- and cAMP-regulated phosphoprotein, M, = 32,000) is a member of a family of related proteins which includes inhibitor-1 (I1) and G-substrate. Whereas I1 is found throughout most brain regions and peripheral tissues, DARPP-32 is particularly enriched in the medium spiny neurons of the striatum and G-substrate is most abundant in the cerebellum. Both DARPP-32 and I1 can be phosphorylated in response to increased intracellular cAMP, and thus become potent inhibitors of protein phosphatase 1 (PP1). Given the abundant in the cerebellum. Both DARPP-32 and 11 can be phosphorylated in response to increased intracellular cAMP, and thus become potent inhibitors of protein phosphatase 1 (PP1). Given the central role of reversible protein phosphorylation in the control of neuronal function, it is important to determine which phosphatases are expressed in brain, and in particular, which isoforms of PP1 are co-expressed with DARPP-32 in the striatum. To this end, a rat striatum cDNA library was screened at low stringency using a rabbit cDNA encoding the alpha isoform of protein phosphatase 1 (PP1a). Clones encoding two different isoforms of PP1 were isolated and characterized. One was identical to PP1a, whereas the other was identical to PP1, Isoform-specific peptides were designed based on the deduced amino acid sequences which were used to raise antibodies. The availability of isoform-specific antibodies allowed us to investigate the distribution of the two PP1 isoforms by Western blotting. Although detected in all brain regions and peripheral tissues analyzed, both were found to be particularly abundant in the striatum. Their distribution was similar in various brain regions with only three notable exceptions. That is, PP1y was relatively more abundant than PP1a in the olfactory bulb, olfactory tubercule and pineal gland. The PP1y-specific antibody also identified an alternatively spliced isoform in the testis which could not be detected in any of the other tissues or brain regions tested. We have also recently isolated a PP1ß cDNA from a rat cortex library.

### 50.12

PHOSPHORYLATION OF DARPP-32 BY FORSKOLIN IS POTENTIATED BY GABA IN STRIATAL SLICES. G.L.Snyder\*, G. Fisone, and P. Greengard. The Rockefeller Univ., NY, NY 10021

DARPP-32, a dopamine and cAMP-regulated phosphoprotein, Mr= 32,000) is highly enriched in the medium spiny-type striatal neurons that comprise the striato-nigral projection. Phosphorylation of DARPP-32 at a single threonine residue is cAMP-dependent and is increased in striatal slices by forskolin, an activator of adenylyl cyclase. Recently, we reported that GABA (100 µM) increased the threonine phosphorylation of DARPP-32 either alone, or in combination with 1-DOPA (100 µM), precursor of dopamine which in turn activates dopamine D-1 receptors that are linked to adenylyl cyclase (Snyder et al., Soc. Neurosci. Abst. 21:988). Using an antibody able to selectively detect the phosphorylated form of DARPP-32, we are examining the mechanism by which GABA increases phosphorylation of DARPP-32. We have found that GABA (100 µM) also potentiates DARPP-32 phosphorylation in striatal slices in which cAMP-dependent phosphorylation is increased by forskolin (10 µM). Since GABA is known to hyperpolarize neurons, thereby decreasing calcium influx, and since DARPP-32 is dephosphorylated by a calcium-dependent phosphatase (i.e., calcineurin), these data are consistent with the hypothesis that GABA may increase DARPP-32 phosphorylation by inhibiting calcium-dependent dephosphorylation.

## 50.14

EFFECT OF ORAL-ADMINISTRATION OF UCB 29427, A NEW POTENTIAL ANTIDEMENTIA DRUG, ON THE CYCLIC AMP (cAMP) GENERATING SYSTEM IN RAT BRAIN.

El Tamer\*, K. Raikoff, E. Wulferta and I. Hanin. Loyola Univ. Chicago Stritch Sch. Med., Dept. Pharmacology, Maywood, II, 60153 and \*UCB s.a., Pharmaceutical R&D, Brussels, Belgium.

Ucb 29427 (2-cyclopropyl-4-cyclopropyl amino-6-morpholino-1,3,5triazine), is a close structural analog of ucb 11056. Since ucb 11056 has been shown to have a strong potentiating effect on the cAMP generating system in rat brain (El Tamer et al. Soc. Neurosci. Abstr. 17:605, 1991), we decided to investigate whether ucb 29427 has similar activity. Fifteen min. post-oral administration of ucb 29427 (3 mg/Kg) we observed a significant increase in vivo, in cAMP levels in the hippocampus (26%, P<0.05), septum (9.2%, N.S), hypothalamus (19%, P<0.05) and cortex (10%, N.S). In-vitro studies showed that ucb 29427 (0.1 and 1 µM) induced 50% and 120% of an additional increase, respectively, in norepinephrine (NE)-stimulated response of cAMP in hippocampal slices. Acute, oral treatment of rats with ucb 29427 (3 mg/Kg) or longer periods of treatment for 4, 7, 14 and 28 days, twice a day did not alter or modify NE-stimulated cAMP formation in hippocampal slices. These combined data demonstrate that: 1) ucb 29427 has a strong potentiating effect on the cAMP generating system in the rat brain; 2) this effect is measured at doses 3 times (in-vivo) and 100 times (in-vitro) lower than ucb 11056; and 3) long-term oral treatment with ucb 29427 does not after the cAMP generating system in the rat brain.

ROLE OF THE NEUROSPECIFIC CALMODULIN SENSITIVE ADENYLYL CYCLASE IN NEUROPLASTICITY. D. R. Storm\*, Z. Xia, and E. J. Choi. Department of Pharmacology, University of Washington, Seattle, WA 98195.

Mammalian tissues express at least eight distinct adenylyl cyclases including two calmodulin sensitive enzymes, type I and III. One of these enzymes, the type I adenylyl cyclase is thought to be important for learning and memory. The present study demonstrates that expression of mRNA for this enzyme is limited to neural tissues, including brain, retina, and adrenal medulla. *In situ* hybridization indicates that mRNA for this enzyme is expressed in specific areas of brain that have been implicated in learning and memory, including the neocortex, the hippocampus, and the olfactory system. Although it has been generally assumed that calmodulin sensitive adenylyl cyclases can function to couple increases in cellular free calcium to elevation in cAMP in vivo, this had not been experimentally demonstrated. This question was examined by expressing the type I adenylyl cyclase in human 293 cells. Cellular cAMP in 293 cells expressing type I numan 293 cells. Cellular CAMP in 293 cells expressing type I adenylyl cyclase was markedly elevated by a calcium ionophore, A23187. Furthermore, the muscarinic agonist carbachol also increased cAMP in 293 cells expressing the type I enzyme, due to increases in cellular free calcium. These data indicate that the type I adenylyl cyclase can be stimulated by calcium in vivo. We propose that the calcium stimulation of type I adenylyl cyclase may provide synergistic regulation by calcium and cAMP of a variety of neuronal structions, either because of convergence of cAMP and calcium stimulated phosphorylations, or because of stronger or more persistent cAMP signals caused by increased calcium level.

DISTRIBUTION OF ADENYLATE CYCLASE mRNA SPECIES IN RAT BRAIN. M.N. Gannon\* and B.S. McEwen. Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

We have previously shown that manipulation of the hypothalamic-pituitary-adrenal axis modulates the activity of calmodulin (CaM) -dependent adenylate cyclase(s) (AC), in a regionally selective manner (e.g. J.Neurochem. 55:276-284,1990). We are interested in determining whether parallel changes occur in AC mRNA species, since many effects of glucocorticoids are ascribed to a genomic site of action. Towards this end, we are developing selective oligonucleotide probes to identify the distribution of CaM-dependent (AC1), CaM-independent (AC2) and olfactory-selective (AC3) mRNA species for different isoforms of AC. Preliminary northern analysis suggests that high levels of AC1 mRNA are present in the cortex, hippocampus, cerebellum and olfactory bulb: In contrast, high levels of AC2 mRNA are only observed in the olfactory bulb, with moderate levels in the hippocampus. Lower levels of both AC1 and AC2 mRNA were observed in other brain regions. By northern analysis, AC3 mRNA was only present in olfactory bulb. Preliminary in situ hybridization analysis confirms the heterogeneous distribution of different AC mRNA species, and suggests that AC3 mRNA might be also be present in a discrete population of hippocampal

LOCALIZATION OF cGMP-STIMULATED PHOSPHODIESTER-ASE mRNA IN RAT BRAIN. J.G Corbin, D.R Repaske, M. Conti, and M.F. Goy\*. Departments of Physiology and Pediatrics, and Neuriobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599

The cyclic GMP stimulated phosphodiesterase (cG-PDE) is a member of a larger family of enzymes that break down cAMP and cGMP to their respective 5'-nucleotide monophosphates. The cG-PDE

cGMP to their respective 5'-nucleotide monophosphates. The cG-PDE preferentially hydrolizes cAMP, and is powerfully stimulated by cGMP (thereby producing cAMP decreases in response to cGMP increases). Using PCR amplification, with PDE-specific primers, a 350bp cDNA clone of part of the cG-PDE gene was obtained from rat liver mRNA. The sequence of this clone is 93% homologous to the corresponding region of a previously cloned bovine brain and cardiac cG-PDE (Sonnenburg et al., J. Biol. Chem. 266: 17655-17661 (1991)). A labelled probe derived from the clone reveals a 4.4 kb mRNA transcript in Northern blots. This transcript is highly enriched in rat brain. In agreement with this result, in situ hybridization analysis demonstrates the presence of cG-PDE mRNA in the hippocampair formation, basal ganglia, habenular nucleus, and pyriform, entorhinal demonstrates the presence of CO-PDE MKNA in the hippocampal formation, basal ganglia, habenular nucleus, and pyriform, entorhinal and cerebral cortices. This suggests that within these specific populations of neurons, the cG-PDE is important in the regulation of intracellular levels of cAMP, and that this enzyme (perhaps via the nitric oxide/cGMP pathway) may play a role in the synaptic plasticity that is a prominent feature of several of these regions.

HUMAN FETAL BRAIN ADENYLYL CYCLASE: CLONING, CHROMOSOMAL MAPPING, AND EXPRESSION.

E.C. Villacres. <sup>1,2</sup> L. H. Bookbinder. <sup>1</sup> Z. Xia. <sup>1\*</sup> S. Edelhoff. <sup>3</sup> D.A. Adler. <sup>3</sup> C.M. Disteche. <sup>3</sup> and D.R. Storm <sup>1</sup> Departments of Pharmacology <sup>1</sup>, Psychiatry & Behavioral Sciences <sup>2</sup>, and Pathology <sup>3</sup>, Univ. of Washington School of Medicine, Seattle, Washington 98195.

The neural specific calmodulin-sensitive adenylyl cyclase (Type I),

which was first cloned from bovine brain, has been implicated in memory and learning. A 2.2 kb fragment from the bovine cDNA was used to screen a human fetal brain cDNA library. A resulting clone with a 3.8 kb insert, contains sequence which coincides with the 3' end with a 3.8 kb insert, contains sequence which coincides with the 3 end 2522 basepairs of the bovine open reading frame. This clone has been fully sequenced and shows 87% nucleic acid and 92% translated amino acid sequence identity to the bovine clone. Comparison of the amino acid sequence from our human clone to the bovine clone shows that most differences are in the carboxy-terminal 100 amino acid residues. This region contains the only putative cyclic AMP-dependent protein kinase phosphorylation site in the molecule. To determine if these sequence differences reflect differences in the regulation of the human cyclase activity, a chimera was constructed which contains the 5' half of the bovine type I cyclase and the 3' half corresponding to the human type I cyclase. The activity of this chimera has yielded no significant type I cyclase. The activity of this chimera has yielded no significant difference in calmodulin and calcium sensitivity when compared to the wild type bovine adenylyl cyclase. In situ hybridization was used to localize the human type I adenylyl cyclase to the proximal portion of the short arm of chromosome 7, using both the human 3.8 kb insert, and a bovine probe which is specific for the brain type I calmodulinsensitive adenylyl cyclase.

### 50.18

PROTEIN KINASE A AND PROTEIN KINASE C REGULATE THE TYROSINE HYDROXYLASE mRNA LEVEL IN HYPOTHALAMIC NEURONS. Kedzierski, N. Aguila-Mansilla, G.P. Kozlowski\*, and J <u>Porter</u>. Depts. of Obstetric and Gynecology and Physiology, University of Texas Southwestern Medical Center, Dallas TX.

Long-term regulation of catecholamine synthesis is based on changes in the synthesis of tyrosine hydroxylase (TH). TH synthesis is, in turn, determined by the level of TH mRNA. The TH mRNA level may be influenced by extracellular many. The In many level may be influenced by extracellular factors, which mediate their actions through second messenger pathways. The purpose of these studies was to investigate the roles of protein kinase A and protein kinase C in regulating TH mRNA level in hypothalamic neurons cultured in serum-free medium. TH mRNA was quantified by an S1 nuclease protection assay. Activation of the protein kinase A pathway by treatment of cultured neurons with 8-bromo cyclic AMP, forskolin or 3-isobutyl-1-methyl-xanthine caused a 1.5-2 fold increase in TH mRNA level. TH mRNA was also increased by 12-0-tetradecanoylphorbol 13-acetate or diacylglycerols, synthetic and natural activators of protein kinase C, respectively. Inhibition of protein kinase C for 16h with 0.05  $\mu$ M or 0.5  $\mu$ M calphostin C decreased the amount of TH mRNA to 67% or 56% respectively of that in unstimulated cultured in serum-free medium. TH mRNA was mRNA to 67% or 56%, respectively, of that in unstimulated cells. These data suggest that both protein kinase A and protein kinase C pathways are involved in the regulation of the TH mRNA level in hypothalamic neurons. Supported by DK-01237, AG-08173, AG-04344, and DK-01237.

TRANSFECTED G-PROTEIN SUBUNITS AND MUSCARINIC ACETYLCHOLINE RECEPTORS. J.C. Migeon, K.A. Hegewald, and N.M. Nathanson\*. Department of Pharmacology, University of Washington School of Medicine, Seattle, WA 98195.

We have used a luciferase reporter gene under the transcriptional control of a cAMP response element (CRE) as a monitor of intracellular cAMP levels and cAMP regulated gene expression. Treatment of transfected JEG cells with forskolin to activate adequipate cyclase (AC) resulted in a greater than 10 fold increase in luciferase activity.

(AC)resulted in a greater than 10 fold increase in luciferase activity. Transfection with the oncogenic  $G_{i}\alpha 2$  mutation in which glutamine 205 Transfection with the oncogenic  $G_1\alpha 2$  mutation in which glutamine 205 is replaced with leucine decreases forskolin-stimulated expression from the CRE- luciferase gene by up to 75%. This is consistent with previous experiments demonstrating constituitive activation of  $G_1\alpha 2$  by this mutation. In addition, mutation of glycine 43 (corresponding to glycine 12 in p21 ras (G43V) to valine also decreases forskolin stimulated expression from the CRE luciferase gene by a maximum of 50%.

Treatment with the muscarinic agonist carbachol resulted in an increase in luciferase activity in JEG 3 cells transiently transfected with mouse m1 (8-10 fold) and chick m4 (3-5 fold) mAChRs. Treatment with the calcium ionophore A23187, the phorbol ester PMA, or both together increases luciferase activity by only 1.7, 1.5, and 2.4-fold suggesting that calcium-regulated pathways are not responsible for the

together increases further as a activity by only 1.7, 1.3, and 2.4-10Id suggesting that calcium-regulated pathways are not responsible for the observed increase in reporter gene activity. These data demonstrate that the  $G_i\alpha 2$  G43V mutation can constituitively inhibit expression at CRE regulated genes while various transfected mAChR subtypes can increase expression of these genes in a carbachol dependant manner.

LEUCINE ZIPPER MUTATIONS IN CREB CAUSE SELECTIVE PATTERNS OF HETERODIMERIZATION. M.M. Loriaux, R.P. Rehfuss, R.G. Brennan, R.H. Goodman\*. Vollum Institute for Advanced Biomedical Research, Oregon Health Sciences University, Portland, OR 97201.

Transcription factors in the CREB gene family have been implicated in virtually all aspects of second messenger mediated gene expression. These factors have three functional domains, an activator region, a basic DNA-binding domain, and a leucine zipper region which functions as a dimerization interface. CREB can form homodimers as well as heterodimers with related factors, and, in some instances, the process of heterodimerization can dramatically alter the biological properties of the transcription factor complex. Because of the ability of these transcription factors to combine in various patterns it is difficult to ascertain the functional capabilities of selected heterodimer combinations. Our studies are directed toward engineering factors that will pair in predictable patterns so that their functional contribution to the regulation of neuroendocrine gene expression can be determined.

The recently solved crystal structure of the yeast transcriptional activator GCN4 suggests that the Asn residue in the a3 position of the leucine zipper, which is conserved in all CREB related factors, functions by destabilizing the hydrophobic dimer interface. Presumably this destabilization is important in allowing CREB-like factors to exchange partners under physiological conditions. By using molecular modeling, we predicted that substitution of this Asn in the CREB leucine zipper with His would further destabilize homodimer formation while enhancing heterodimer formation. Gel shift assays in which full length mutant CREB was mixed with a truncated wild-type protein showed an elimination of mutant His homodimers and an enhancement of His:Asn heterodimer formation. This strategy of directing selective transcription factor pairing should be generally applicable to all CREB-related factors and should enable us to ascribe specific transcriptional properties to specific heterodimer combinations.

Immunohistochemical Localization of Calcium/Calmodulin Dependent Protein Kinase-Gr in Mouse Brain. K. F. Jensen\* and M. M. Bland, Neurotoxicology Division, HERL, US EPA, Research Triangle Park, NC 27711 and Cell Biology Division, Wellcome Research Laboratory, Research Triangle Park, NC 27709

Calcium/calmodulin dependent protein kinases are involved in the regulation of a variety of neuronal processes including neurotransmitter release, cytoskeletal alterations and gene expression. One such kinase, CaM kinase-Gr, is particularly abundant in the rat cerebellum and is present in both the nuclei and axons of granule cells. To determine if a similar pattern of distribution occurs in other species we extended our investigation to the mouse brain. We have used a rabbit polyclonal antibody made against a peptide of a highly conserved sequence at the carboxyl terminus of human CaM kinase-Gr. We observed a pattern of staining in the mouse brain similar to what we have previously reported in the rat using an polyclonal antibody against rat CaM kinase-Gr. Immunoreactivity was apparent in all major brain regions and was most prominent in the perikaryon of small neurons. As in the rat, the immunoreactivity was most dramatic in the granule cells of the cerebellum and was most prominent in the nucleus of these neurons. Immunoreactivity was also apparent in the molecular layer, presumably due to staining of the parallel fibers of granule cells. No nuclear staining was visible in Purkinje cells. The similarity in the pattern of distribution in mouse and rat brain suggests that CaM kinase Gr may mediate calcium signaling in similar neuronal circuits in the two rodent species.

## 50.2

EXTRACELLULAR CYCLIC AMP, SECRETED BY ASTROCYTES IN RESPONSE TO BETA-ADRENERGIC STIMULATION, IS A SOURCE OF EXTRACELLULAR ADENOSINE IN CORTICAL CULTURES. P.A. Rosenberg\* and Ya Li, Children's Hosp & Harvard Med Sch, Boston MA 02115.

We have previously shown that stimulation of cortical cultures with the beta-adrenergic agonist isoproterenol results in the efflux of significant quantities of cAMP into the extracellular medium, and an increase in extracellular adenosine concentrations. In the current studies, we address the question of whether the adenosine that accumulates in response to beta-adrenergic stimulation of cortical cultures actually derives from extracellular cAMP.

We found in a total of thirty-four experiments in which astrocyterich cultures were stimulated with 1  $\mu M$  isoproterenol, and medium was assayed at thirty minutes, a significant increase (p < 0.05) of 65  $\pm$  53% in the extracellular adenosine concentration in addition to the appearance of extracellular cAMP. If the adenosine that accumulates in response to beta-adrenergic stimulation was actually derived from extracellular cAMP, then one would expect that agents which block cAMP secretion, such as probenecid, should block this accumulation of adenosine. We found that 1 mM probenecid blocked both the extracellular accumulation of cAMP as well as the accumulation of adenosine in cultures stimulated with isoproterenol. This suggests that the extracellular adenosine which accumulates in response to beta-adrenergic stimulation is derived from extracellular cAMP.

A FUNCTIONAL EXPRESSION CLONING STRATEGY FOR G-PROTEIN COUPLED, ADENYLYL CYCLASE ACTIVATING RECEPTORS EXPRESSED IN XENOPUS OOCYTES -- USING THE CYSTIC FIBROSIS TRANSMEMBRANE CONDUCTANCE REGULATOR (CFTR) GENE AS A SENSOR. Y. Uezono\*. J. Bradley, J.R. Riordan\*, N. Davidson, H.A. Lester and K. Zinn Division of Biology, Caltech, Pasadena, CA 91125: "Hospital for Sick Children, Tronto, Ontario, Canada Functional expression cloning is widely used in isolating 7-helix G protein-

Functional expression cloning is widely used in isolating 7-helix G protein-activating receptor cDNAs with the *Xenopus* oocyte expression system. These receptors are coupled to 2nd messenger pathway such as the phospholipase  $C/P_2/DAG$  or the adenylyl cyclase/cAMP pathway. The *Xenopus* oocyte system is remarkably sensitive for electrophysiological assays of receptors that couple to the phospholipase C pathway, because of the robust  $Ca^{2r}$ -activated CI current. However there has been no comparably sensitive assay for changes in cAMP concentration. Here we show a fast and sensitive electrophysiological assay for changes in cAMP concentration by expressing the human cystic fibrosis transmembrane conductance regulator (CFTR) gene in oocytes. The CFTR acts as a CI channel which is opened by phosphorylation via cAMP-dependent protein kinase. Several days after a CFTR transcript is injected into oocytes, CI currents can be detected after activation of adenylyl cyclase by forskolin. Furthermore, after coinjection of CFTR and human  $B_2$  adrenergic receptor transcripts, stimulation with the  $B_2$  agonist isoproterenôl elicits a robust CI current.

This assay for activation of the cAMP pathway is currently being used in studies of the cloning of functional olfactory receptors (see abstract J. Bradley et al.). In addition, this method may be useful for cloning other cAMP-G protein-coupled receptors. (Support: GM-29836, NF-28182, CFF, Drawn Foundation)

DIFFERENT DISTRIBUTION OF CA2+/CALMODULIN-SENSITIVE AND INSENSITIVE ADENYLATE CYCLASE mRNAs IN RAT HIPPCCAMPUS. N. MONS<sup>1,2</sup>, M. YOSHIMURA<sup>2</sup>, P. MOLLARD<sup>\*,3</sup> and D.M.F. COOPER<sup>2</sup>.

1. URA-CNRS 339, Avenue des Facultes, 33405 Talence, France.

2. UCHSC, Dept of Pharmacology, 4200 East Ninth Avenue. Denver (CO) 80262, USA. 3. URA-CNRS 1200, 146 rue Leo Saignat, 33076 Bordeaux cedex, France.

The pattern of Ca2+/calmodulin (CaM)-sensitive (Type 1) and Ca²+/CaM-insensitive (Type 2) adenylate cyclase (AC) mRNAs expression has been examined in rat hippocampal formation using in situ hybridization. Cryostat sections were hybridized with <sup>35</sup>S-labeled synthetic oligonucleotide rat probes. A quantitative comparison among the signals obtained with the two probes was done after using the same concentration of probes and the same exposure protocol. Both Type 1 and Type 2 AC mRNAs were seen to be predominantly expressed in the granular cell layer of the dentate gyrus., but Type 1 AC mRNAs were much more expressed than type 2 AC mRNAs. The most notable difference between the signals obtained with the two probes occurs specifically in the pyramidal cell layers of CA1-CA4 fields. Examination of Type 1 AC mRNAs expression showed a moderate labeling that was restricted to the pyramidal cells of CA1-CA2 layers, as neither CA3 nor CA4 displayed appreciable specific labeling. By contrast, Type 2 AC mRNAs are expressed along CA1-CA4 fields, with no significant variation of hybridization density observed across the different CA fields and the dentate gyrus. These results provide an anatomical basis for studying factors that regulate expression of these isoforms, such as hormonal status, or in association with learning.

## 50.26

STIMULATION OF THE CAMP SYSTEM POTENTIATES THE EXCITATORY EFFECTS OF NMDA IN THE RAT HIPPOCAMPUS, IN VIVO. N. Ludvig\*, S.M. Lasley and P.C. Jobe. Dept. of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria IL 61656.

The combined EEG - intracerebral microdialysis technique

The combined EEG - intracerebral microdialysis technique (Ludvig et al., *Synapse*, in press) was used to determine whether the predominantly postsynaptically localized cAMP system (Ludvig et al., *Neuroscience*, 44 [1991] 491-500) modifies the NMDA receptor-mediated excitation in the hippocampus of freely behaving rats. The microdialysis parameters were: probe tip: 1 mm; flow rate: 10 µl/min; drug efflux rate: 15%; and dialysis area: 1 mm³, as determined with (³H)cAMP autoradiography.

Intrahippocampal microdialysis with 0.1 mM NMDA was performed for 5 min, followed by a 30 min washout period, and a subsequent 30 min microdialysis with 1.0 mM dibutyryl cAMP (dcAMP). These pharmacological manipulations caused no EEG changes. However, a subsequent 5 min microdialysis with the combination of 0.1 mM NMDA and 1.0 mM dcAMP resulted in repetitive EEG spike-waves, which were associated with limbic type behavioral seizures. Additional experiments showed that 0.1 mM NMDA alone was not able to produce such events, even if it was microdialysed repeatedly. Also, 1.0 mM dcAMP alone was unable to induce seizures, even if it was microdialysed for 60 min.

This study supports the hypothesis that in the hippocampus, in vivo, the cAMP system may amplify NMDA receptor actions.

STATE-DEPENDENT OPERANT STIMULUS CONTROL: CUEING PROPERTIES OF ETHANOL "HANGOVER" IN RATS. D.V. Gauvin\*, K.L. Goulden & F.A. Holloway. Univ. of Okla. Hlth. Sci. Cntr., Dept. Psychiat. & Beh. Sci., Oklahoma City, OK 73190.

Twelve Sprague-Dawley rats were trained in a two-choice foodreinforced drug discrimination task (FR-10, 10 min sessions) using the state-dependent interoceptive stimulus properties of experimentally-induced ethanol (ETOH) hangover vs "normal" basal homeostasis. Rats were injected with either: a) 4 g/kg ETOH, or b) equiv. vol. of saline (SAL) 18 hrs prior to training sessions. Each rat was injected with an additional 1 ml/kg injection of SAL 15 min prior to the sessions. "Hangover" training sessions were always followed by a "day-off". SAL sessions were conducted from between 36 to 90 hrs after a "hangover" training session.

Rats demonstrated > 90% discriminative performance accuracy. Test sessions showed a time-dependent, cyclic, return from the "hangover" to the "normal" state, by 48 hrs. The acute (immediate) effects of ETOH (15 min pretreatments) did not crossgeneralize with the "hangover" state. Both low dose ETOH and chlordiaze-poxide pretreatments blocked the stimulus properties of "hangover". All subjects responded exclusively on the "hangover"-appropriate lever at one of a selected range of pentylenetetrazole doses. The data demonstrated the "anxiogenic" dimensionality of experimentally-induced "hangover" in rats.

### 51.3

ANIMAL-TO-HUMAN EXTRAPOLATION: I. ETHANOL EFFECTS ON COMPENSATORY TRACKING PERFORMANCE IN RHESUS D. W. Blick<sup>1</sup>, S. A. Miller<sup>2</sup>, G. C. Brown<sup>1</sup>, and M. R. Murphy<sup>2</sup>. Systems Research Laboratories, Inc.<sup>1</sup> & U.S. Air Force Armstrong Laboratory<sup>2</sup>, Brooks AFB, TX 78235

This is the first in a series of experiments in which animals and humans doing essentially identical tasks will be tested under the influence of the same pharmacological agents. We hope to develop and validate a set of models for extrapolating from animal performance data to changes in human performance induced by agents and other stressors that cannot be tested directly in human subjects.

Twenty adult male (4.8-7.5 kg) rhesus monkeys (M. mulatta) ingested various doses of ethanol mixed in orange-flavored drink (10% by volume). After each dose, 4-5 venous blood samples were analyzed to determine peak blood alcohol level (BAL), so as to estimate a dose-response function for each animal. Then, in different (but balanced) random orders, each animal received ethanol doses estimated to produce BALs of 0.00, 0.08, 0.12, 0.16, and 0.20%. Performance of a well-trained compensatory tracking task, the Primate Equilibrium Platform (PEP) task, was tested for 2 hr, commencing 30 min after the beginning of ethanol ingestion (which was completed in <15 min). BAL was determined at 30 min intervals before, during, and after PEP testing. The significant and doserelated performance decrements induced by alcohol varied in severity from nearly undetectable at the lowest dose to periods of incapacitation in many subjects at the highest.

## 51.5

EFFECT OF ETHANOL ON LOCOMOTOR ACTIVITY INTIATED BY MESOLIMBIC ACTIVATION. G.V. MILTON. C.K. ERICKSON\* AND P.K. RANDALL. Division of Pharmacology and Toxicology, College of Pharmacy, University of Texas, Austin, TX 78712.

Our objective was to study the interaction of a low dose of ethanol (0.5 gm/kg, i.p.) with drugs that increase locomotor activity by acting through DA, GABA and opiopeptidergic neurotransmitter systems in the mesolimbic system (MLS). After drug treatments the locomotor activity was measured in a doughnut shaped circular arena locomotor activity was measured in a doughnut shaped circular arena for 1 hr in male Sprague-Dawley rats. Amphetamine (0.25-1.0 g/kg, i.p.) increased locomotor activity in a dose-related manner and ethanol attenuated this amphetamine-induced locomotor activity. In bilaterally cannulated rats, the GABAA antagonist picrotoxin (0.025-0.1 µg/side) and mu receptor agonist DAGO (0.025-0.1 (0.025-0.1 µg/side) and mu receptor agonist DAGO (0.025-0.1 µg/side) given into the ventral tegmental area (VTA) increased locomotor activity in a dose-dependent manner. Ethanol attenuated picrotoxin-induced locomotor activity, but did not modify DAGO-induced locomotor activity. Thus, ethanol modified DA agonist-and GABAA antagonist-induced locomotor activity, but did not modify opiopeptide-induced locomotor activity. These results suggest that ethanol may act directly to decrease DA levels in the MLS or indirectly by increasing GABA levels in the VTA. (Funded by NIDA grant 7355.)

DIFFERENTIAL TOLERANCE TO THE ANTICONVULSANT, HYPOTHERMIC, AND ATAXIC EFFECTS OF ETHANOL. C.K. Kim, S. Dalal, J.P.J. Pinel\*, G.J. Payne and L.E. Kalynchuk. Departments of Anatomy and Psychology, University of British Colombia, Vancouver, B.C., Canada.

The amygdala-kindling model of epilepsy was used to examine contingent tolerance to the anticonvulsant, hypothermic, and ataxic effects of the color of the

effects of ethanol (1.5 g/kg, IP) in adult male Long-Evans rats. Rats were assigned to one of three experimental conditions: ethanol 1 hr before a convulsive stimulation and saline 1 hr after the stimulation (Before-group), saline 1 hr before a stimulation and ethanol 1 hr later (After-group), or saline 1 hr before and after a stimulation (Saline-group). Following 10 such bidaily tolerance-development trials, all rats received a tolerance test in which ethanol was administered 1 hr before a convulsive stimulation. Tolerance to the anticonvulsant effect of ethanol was observed only in the Before-group. In contrast, tolerance to the hypothermic and ataxic effects of ethanol was observed in both the Before- and After-groups. These results support the <a href="mailto:drug-effect">drug-effect</a> theory of drug tolerance: Tolerance does not develop to drug exposure per se, but rather to the effects of the drug; and the development of tolerance to a particular drug effect is facilitated by the expression of that drug effect. In this experiment, tolerance developed to the anticonvulsant effect of ethanol in the Before-group only: These rats had convulsive stimulations delivered in the drugged state on each tolerance-development trial, whereas those in the After-group did not. Tolerance to the hypothermic and ataxic effects of ethanol developed in both the Before- and After-groups: These rats experienced these drug effects on each tolerance-development trial.

## 51.4

SENSITIZATION TO ETHANOL DEMONSTRATED IN PLACE-SENSITIZATION TO ETHANOL DEMONSTRATED IN PLACE-PREFERENCE AND LOCOMOTOR ACTIVATION. K.R. Goldstein, D.I. Knapp, E.I. Saiff\*, L.A. Pohorecky, and D. Benjamin, Center of Alcohol Studies, Rutgers University, Piscataway, NJ 08855. As opposed to the place preference (PP) for cocaine, PP for ethanol (ET) does not occur after a single exposure, but must be acquired. To characterize this, 4 groups of male Long-Evans rats were tested for conditioned PP to ET

this, 4 groups of male Long-Evans rats were tested for conditioned PP to ET using a new one-trial conditioning procedure. The groups were: naive, 3 days forced drinking, 6 days forced drinking and 1 month forced drinking followed by 1 month 6% ET choice drinking. 24h after removing ET, rats were given tap-water (3ml) by gavage and placed in one side of a 3 chambered PP apparatus for 30 min. Rats were then given ET by gavage (1g/kg 20% v/v) and placed in the opposite chamber for 30 min. 24 hrs later the subject was placed in the center chamber and allowed free access to all chambers for 30 min. and placed in the center chamber and allowed free access to all chambers for 30 min, the time spent in each side was recorded. To aid discrimination, the opposite chambers differed in visual cues To control for side bias, the side paired with ET was switched for each rat. ET-naive rats showed no PP while rats given a 4% ET solution as their drinking water for 3 days showed a nonsignificant PP to the ET side (p<0.05). Long term drinking rats also showed a significant PP (o<0.05). Locomotor activity, increased over time of ET pre-exposure during ET conditioning sessions (controls vs. long term drinkers p<0.05). These results do not suggest tolerance to the aversive effects of ET, as rats with 6 days pre-exposure to 4% ET show no change in performance on a roto-rod test 10, 30, 60 and 120 min after administration of 2g/kg (20% v/v) ET. These results demonstrate sensitization to ET-induced PP and suggest that the development of PP (as opposed to aversion) is not the result of conditioning per se, but reflect underlying neurochemical changes (see Benjamin et al., this volume). (Supported by Smithers Prevention and NIAAA grants AA05306 and AA08499)

## 51.6

GABAERGIC REGULATION OF MALE SEXUAL BEHAVIOR IN RATS. R. C. Eaton\* L. A. Lumley,
L. Matuszewich, D. S. Lorrain, and E. M. Hull. Department of
Psychology, Program of Behavioral Neuroscience, State
University of New York, Amherst, NY. 14260 USA.

The amino acid gamma-aminobutyric acid (GABA) is typically The amino acid gamma-aminobutyric acid (GABA) is typically an inhibitory neurotransmitter of the mammalian brain and has been implicated in the regulation of masculine sexual behavior (Fernandez-Guasti et al., 1986). We studied the effects of the GABA<sub>A</sub> antagonist (-)-bicucculline methiodide (BIC), microinjected into the MPOA, on male rat sexual behavior. BIC (0, 30, 60 ng / 1  $\mu$ l) produced a biphasic effect on ejeculation latency. BIC (30 ng) significantly reduced the ejaculation latency (p<.05), while BIC (60 ng) was similar to the control value. Several animals exhibited stereotyped behavior after injections of the higher dose. Both doses of BIC decreased

after injections of the higher dose. Both doses of BIC decreased the number of intromissions required to achieve ejaculation (p<.05). In addition, BIC reduced the post ejaculatory interval (p < .05).

These experiments confirm and expand the role of GABA in regulating sexual behavior in the male rat. Further experiments are presently underway to determine the effects of the GABA agonist THIP, and the possible interaction of GABA with the neurotransmitter dopamine (DA) in the regulation of male sexual behavior

Supported by NIMH grant 40826 to EMH.

DISCRIMINATIVE STIMULUS EFFECTS OF THE DIRECT GABA, AGONIST MUSCIMOL. Doreen M. Grech\* and Robert L. Balster, Dept. of Pharmacology and Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298.

The discriminative stimulus effects of a direct GABA<sub>a</sub> agonist, muscimol, were compared to those of other GABAergic drugs. Ten male Sprague-Dawley rats were trained in 2-lever operant chambers to discriminate 1.0 mg/kg muscimol from saline. Responding was maintained under an FR-20 food reinforcement schedule. Subjects required a mean of 73 training sessions before achieving criterion. Substitution testing was completed with doses of muscimol (0.03-3.0 mg/kg), the direct GABA<sub>a</sub> agonist THIP (0.30-10 mg/kg), pentobarbital (0.03-17.3 mg/kg) and the GABA<sub>b</sub> agonist baclofen (1-10 mg/kg). Doses of muscimol produced dose-dependent substitution for the training dose. THIP substituted for muscimol and decreased response rates at doses greater than 5.6 mg/kg. Baclofen failed to substitute for muscimol, producing no greater than 24% muscimol-lever responding. Pentobarbital produced, at best, partial substitution for muscimol with a maximum of 45% muscimol-lever responding. These data suggest that the discriminative stimulus properties of muscimol are mediated by selective GABA<sub>a</sub> receptor activation. The lack of complete substitution with pentobarbital is consistent with the results of other studies showing a lack of complete substitution by direct GABA, agonists in rats trained with indirect agonists, showing that these classes of GABAergics can be distinguished in drug discrimination models. THE B-CARBOLINE, DMCM, INHIBITS SHOCK-INDUCED AGGRESSION AND

THE β-CARBOLINE, DMCM, INHIBITS SHOCK-INDUCED AGGRESSION AND POSITIVELY MODULATES A POPULATION OF GABA-A RECEPTORS. A.H. Yaidya. R. P. Shank. and B. Dubinsky². CNS Research, The R. W. Johnson Pharmaceutical Research Institute, Spring House, PA 19477-0776. DMCM (methyl-6,7-dimethoxy-4-ethyl-β-carboline-3-carboxylate) traditionally has been regarded as having inverse agonist (negative modulatory) properties at the GABA-A receptor complex. Recent evidence, based on recombinant receptor expression (Puia et al., Mol. Pharmacol. 39: 691, 1991) indicates that DMCM may negatively or positively modulate GABA-A receptor function depending on the subunit composition. Results of the present study suggest that DMCM may exert a positive modulatory effect at some GABA-A receptors, in vitro, which may be expressed in vivo, as an inhibition of agressive in vitro, which may be expressed, in vivo, as an inhibition of aggressive behavior. Using a shock-induced aggression paradigm, pairs of rats received DMCM (0.63 to 10 mg/kg, s.c.) 20 min prior to testing and were placed on a metal grid floor through which a mild footshock (0.7 mA) was delivered for a nettal grid floor inrough writing a mile tootshock (0.7 mA) was delivered for a one minute test duration. The number of pairs of animals displaying aggressive behavior (converging abruptly, and standing face-to-face on their hind limbs, in an upright boxing posture) was recorded. DMCM blocked shock-induced aggression in rats (ED<sub>50</sub> = 2.5 mg/kg, s.c.), an effect consistent with positive modulation of a population of GABA-A receptors. Unlike DMCM, abecarnil, an modulation of a population of GABA-A receptors. Unlike DMCM, abecarnii, an anxiolytic \$\beta\$-carboline, did not block shock-induced aggression when administered alone (1-30 mg/kg, p.o.). However, abecarnil pretreatment reversed (ED50=0.3 mg/kg p.o.) DMCM (2.5 mg/kg s.c.) blockade of aggression suggesting a competitive interaction. Potent (ED50=0.1 mg/kg i.p.) reversal of DMCM (2.5 mg/kg s.c.) blockade of aggression by RO-15-1788, a benzodiazepine antagonist, suggests the involvement of benzodiazepine receptors. Furthermore, DMCM concentration-inhibition curves (complex 20 point curves) in flunitrazepam binding studies revealed that DMCM produced a biphasic GABA shift indicative of mixed agonist/inverse agonist activity

TOLERANCE AND CROSS-TOLERANCE STUDIES TO µ OPIOID STIMULUS EFFECTS IN PIGEONS. S.A. Vanecek\* and A.M. Young. Department of Psychology, Wayne State University, Detroit, MI 48202.

Experiments were conducted to assess the ability of repeated treatment with morphine to produce tolerance and cross-tolerance to the stimulus effects of morphine (MS) and the MS-like effects of fentanyl (FE). Pigeons (N=13) were trained to discriminate among i.m. injections of saline (SAL), 1.8 mg/kg MS, and 10 mg/kg MS under FR 30 schedules of food reinforcement. Prior to repeated treatment, MS (.18 to 56 mg/kg) and FE (.001 to .56 mg/kg) evoked dose-dependent generalization with both the low and the high MS training doses during tests of cumulative doses. Following two weeks of repeated treatment with 56 mg/kg MS, b.i.d., the doses of MS and FE required to generalize with both the low and the high training doses were increased approximately 10-fold. After this treatment, the dose of MS required to suppress rates increased 3- to 5-fold, whereas the dose of FE required to suppress rates increased only 2-fold. Repeated treatment with 10 mg/kg MS, b.i.d., for two weeks produced no increase in the doses of MS or FE required to evoke generalization with either training dose, however, changes in the sensitivity to rate-altering effects were comparable to those obtained following repeated treatment with the higher MS dose. These results demonstrate that repeated treatment with a large dose of MS induces tolerance and crosstolerance to the stimulus effects of MS and MS-like effects of FE. ### 51.8

INVOLVEMENT OF GABAERGIC MECHANISMS IN ENHANCED SENSITIVITY TO NALTREXONE IN RATS? M. Gewiss, R. J. Marley, S. R. Goldberg and C. W. Schindler\*. Beh. Pharmacol. and Genetics Lab., NIDA Addiction Research Center, Baltimore, MD 21224.

Rats treated weekly with cumulative doses of naltrexone develop enhanced sensitivity to the operant response rate decreasing effects of naltrexone (JPET 252: 8-14). As naltrexone at high doses can function as a GABA antagonist and 222. 0-19). As nativotile at high does can function as a GABA antagonist and the development of enhanced sensitivity is associated with an up-regulation in GABA receptor function (Life Sci. 50: PLI-PL6), we investigated whether the enhanced sensitivity could be altered by specific GABA agonists or antagonists, or whether the effects of those GABA agents would be altered by the development of enhanced sensitivity to naltrexone. Rats were trained to respond on a fixed-ratio schedule of food reinforcement and then were made respond on a fract-ratio scientific product of the response rate decreasing effect of naltrexone by treatment once per week with cumulative doses (1-100 mg/kg) of naltrexone for a period of 8 weeks. Initially, only the 100 mg/kg dose decreased operant responding, however, by the end of 8 weeks a dose as low as 10 mg/kg produced clear decrements in response rate. Pretreatment prior to the determination of the naltrexone dose-effect function with either the GABAA agonist muscimol (1 mg/kg) or the GABAA antagonist bicuculline (1 mg/kg) failed to alter the enhanced sensitivity. Further, the dose-effect functions for neither bicuculline (0.03-2 mg/kg) nor the GABAB agonist baclofen (0.05-5 mg/kg) were altered by the development of enhanced sensitivity to naltrexone. However, the dose-effect function for muscimol (0.03-2 mg/kg) was shifted to the left by the development of enhanced sensitivity. This result suggests that the function of GABAA receptors is altered by the development of enhanced sensitivity to naltrexone. However, the potential role for GABA in the development of enhanced sensitivity to naltrexone remains unclear.

SEX DIFFERENCES IN THE DELAYED ANTI-CONFLICT EFFECT OF MK-801 IN RATS. Z.C. Xie\* and R.L. Commissaris. Pharmaceut. Sci., Wayne State Univ., Detroit, MI

In female rats, MK-801 exerts anti-conflict effects when tested 24 hours after administration, but not when tested at pretreatment (preTx) intervals of 10~min-12~hr (Neurosci. Abstr. 17:1493, 1991). In the present study, a thorough time course (10~min-48~hr in 2-hr intervals) for the effects of MK-801 on conflict behavior was determined in both male and female rats. In daily 10-min sessions, thirsty rats drank from a tube which was occasionally electrified (0.5 mA shocks signaled by a tone). Acute challenges with MK-801 were conducted at weekly intervals. Overall, MK-801 was found to be 3-4times more potent in females when compared to males. females, 0.1 mg/kg MK-801 failed to exert anti-conflict effects when tested after preTx intervals of 10-min - 12 hr; this dose did increase punished responding at preTx intervals of 14 - 32 hr, but not at 34 - 48 hr. A qualitatively similar, but much more abbreviated, time course was produced by 0.4 mg/kg MK-80l in males: i.e., no anti-conflict effect at preTx intervals of 10 min - 2 hr, significant anti-conflict effects for preTx intervals of 4 - 14 hr, followed by no effect for preTx intervals of 16 - 48 hr. In both sexes, the peak and duration of the anti-conflict effect increased with increasing dose of MK-801. The mechanism for the delayed anti-conflict effect of MK-801 remains undetermined. (USPHS MH 47181).

## 51.12

BEHAVIORAL AND PHARMACOLOGICAL EFFECTS OF PHENCYCLIDINE (PCP) METABOLITES ON RAT. A. Baba¹, T. Yamamoto¹, H. Yamamoto¹, H. Nagase<sup>1</sup>, T. Hori<sup>1</sup>, T.Moroji<sup>1</sup> and H.Nakata<sup>2</sup>. Dept of Psychopharmacology, Tokyo inst. of Psychiatry, Tokyo 156, 2Dept. of Mol. Biol., Tokyo metropolitan Inst. for Neurosci., Tokyo 183, Japan

In order to better understand the prolonged delirious state beyond the drug half-life in human, which caused by phencyclidine (PCP), we evaluated behavioral and pharmacological activities of PCP metabolites, (trans)-40Hcyclohexyl PCP, (cis)-4OH-cyclohexyl PCP, (trans)-3OH-cyclohexyl PCP and (cis)-3OH-cyclohexyl PCP. Systemic injection of (trans)-4OH-cyclohexyl PCP (10-50mg/kg i.p.), major metabolite of PCP, induced an increased locomotor activity and stereotyped behaviors on rats. Additionally, in vitro binding experiments to sigma and NMDA/PCP-receptor were performed using [3H]DTG, [3H]SKF10047, [3H]TCP and [3H]3OH phrnyl PCP as their ligands to examine the exact site of action. However, we failed to demonstrate that these metabolites have the affinities to sigma and NMDA/PCP site. On the other hand, (trans)-4OH-cyclohexyl PCP have an activity of the dopamine uptake inhibition similar to PCP. These observation indicate that the major metabolite of PCP, (trans)-40H-cyclohexyl PCP, may produce some of the psychotomimetic effects of PCP not through the binding site of PCP/NMDA receptor and sigma site but through the dopamine uptake inhibition.

EFFECT OF INTRACAROTID INJECTIONS OF LIDOCAINE ON THE RAT VISUAL SYSTEM AS COMPARED WITH AMOBARBITAL. K.Nakai\* T.Terada, M.Nakai, T.Itakura, K.Komai, Dept. Neurol. Surg. Wakayama Med.

Col., Wakayama, Japan 640
Effects of two kinds of anesthetic agents, lidocaine and amobarbital a

Effects of two kinds of anesthetic agents, lidocaine and amobarbital a non-specific blocking agent of nerve conduction and depressant of nervous activity in the central nervous system, respectively, were examined electrophysiologically using the rat visual system.

Under urethane anesthesia, male Sprague-Dawley rats weighing 500-600g were fixed to the stereotactic frame. Various doses (lidocaine: 0.5, 1.0, 2.0, 4.0 mg/kg, amobarbital: 1.0, 2.0, 4.0, 10.0 mg/kg) of either chemicals were injected through the cannula placed in the left carotid artery. Before and after the injection, single unit recordings were done from the left lateral geniculate body (LGN) for recording antidromic activity from the visual cortex.

Latencies of antidromic spikes in the LGN from the visual cortex were prolonged significantly (-20 %) for 10 minutes by the injection of lidocaine (1.0 - 4.0 mg/kg). Whereas those of animals injected with amobarbital (1.0 - 4.0 mg/kg) were unchanged. Spontaneous firing rate of LGN neurons were suppressed significantly by the injection of amobarbital (2.0, 4.0, 10 mg/kg) for 10 minutes, whereas the lidocaine injection showed valid reaction from excitation to his his interest and the state of the

excitation to inhibition even under high doses.

The present study not only indicates that intravascularly applied lidocaine can prevent conduction as was demonstrated by the perineural application in the peripheral system, but also that the technic is a useful method to examine the effect of intravascularly applied chemicals in the central nervous system.

EVIDENCE THAT CHOICE BEHAVIOR IN DRUG-DISCRIMINATION STUDIES REFLECTS A CONTINUOUS RATHER THAN A QUANTAL PROCESS. W. F. Caul\*, R. J. Barrett, R. L. Smith, and E. M. Huffman. Dept. Psych. and Pharmacol., Vanderbilt Univ., and V. A. Medical Center, Nashville, TN 37240.

Debate continues as to whether stimulus generalization reflects underlying stimulus-response relationships that are quantal or continuous. This issue is especially important in determining the appropriate interpretation of the results of

determining the appropriate interpletation of the results of drug-discrimination studies that rely on choice behavior to assess the nature of drug-induced interoceptive stimuli.

The data consistent with the quantal view were generated by animals trained to respond using FR schedules of reinforcement. This outcome may have been produced by constraints on choice behavior imposed by such schedules. The use of Variable schedules of reinforcement may be more appropriate because the pattern of responding does not preclude results consistent with either of the competing interpretations.

Data from studies that used VI schedules were analyzed:

Steranka & Barrett, 1983, Amphetamine vs. Saline; Barrett, & Sanders-Bush, 1981, 5-HTP vs. Saline; Barrett & Smith, 1988, Diazepam vs. Pentylenetetrazol; Barrett, Caul, & White, 1992, Amphetamine vs. Haloperidol. In every case, when experimental conditions produced a group mean intermediate to that for the training drugs, the distribution of scores for individual animals was normally distributed. This result is in contrast to the bimodal distribution that would be observed if the underlying stimulus-response process was quantal.

## 51.17

BUSPIRONE - EVIDENCE OF AN ANTIPSYCHOTIC-LIKE PROFILE IN THE RAT CRyan, J Evenden, M. Nielsen\* and K. Ensler
Behavioural Pharmacology, Astra Arcus, S- 15 185 Södertälje, Sweden
Buspirone, which is both an agonist at 5-HT1<sub>A</sub> receptors and an
antagonist at dopamine D<sub>2</sub> receptors, has been successfully used in the clinic antagonist at dopamine 12 receptors, has over soverstand, and an anxiolytic (see Taylor et al., 1985). Although buspirone blocks dopamine receptors, it is not a clinically effective antipsychotic (Cimino et al. 1983). To examine the behavioural profile of the drug after repeated administration, it was compared to a series of more selective 5-HT<sub>1A</sub> agonists or a D<sub>2</sub> antagonist in active avoidance and schedule induced polydipsia (SIP). Rats were first trained to stable performance and then treated daily with a range of doses of each drug just before testing for 16-18 days. In the above tests, 5-HT<sub>1A</sub> receptor agonists had an activating effect after repeated administration. Thus, flesinoxan, isapirone and 8-OH-DPAT, increased avoidance of shocks in the active avoidance test, where rats are trained to avoid an electric shock (0.2 mA) by shuttling from one side of a chamber to another in response to the conditioned stimulus (CS, a tone). In direct contrast, buspirone reduced the number of avoidances, revealing a profile similar to ouspinors reduced the infinite of avoidances, revealing a priori is similar to that induced by antipsychotics. When buspirone was compared to raclopride or 8-OH-DPAT in SIP, a similar picture emerged. All three drugs reduced excessive drinking induced by a FT-60 secs schedule of food delivery, at high doses, but 8-OH-DPAT increased investigatory entries into the food tray after repeated treatment. In contrast, both buspirone and raclopride reduced entries into the food tray weakly following acute treatment but to a greater degree following repeated treatment. In conclusion buspirone acts like an degree following repeated treatment. In conclusion buspirone acts like an antipsychotic in both active avoidance and schedule induced polydipsia and thus, although the drug may have SHT<sub>1A</sub> agonist activity in selective procedures, its D<sub>2</sub> antagonist properties appear to predominate in the rat. #### 51.14

AGONISTIC ENCOUNTERS BETWEEN MALE R SUBSTITUTE FOR THE PENTYLENETETRAZOL CUE. RATS Vivian\* and K.A. Miczek. Department of Psychology, Tufts University, Medford, MA 02155.

The drug discrimination paradigm involving pentylenetetrazol (PTZ) has been proposed as a preclinical model of anxiety. However, questions of validity have arisen as primarily compounds which are proconvulsant generalize to the PTZ "cue" and the nature of the PTZ cue remains unclear. Attack and threat of attack encounters between conspecifics may produce an anxiety-like state which engenders PTZ responding and would provide further support for the PTZ cue as an anxiety cue, as well as provide evidence that anxiety is a component of agonistic interactions. Male Long-Evans rats (Rattus norvegicus) or agonistic interactions. Male Long-Evans rats (Kathus norvegicus) were trained to discriminate 20 mg/kg PTZ from saline in a two-choice drug-discrimination task. After two brief defeats consisting of defensive and submissive postures as well as audible and ultrasonic vocalizations (Ss serving as intruders), administration of saline engendered approximately 80 and 56% PTZ-appropriate responding. Subsequently, during four exposures to the threat of attack (Ss protected from physical contact with a wire mesh cage), saline generated 54, 47, 59 and 34% PTZ-appropriate responding. These results suggest that an anxiety-like state: (1) is induced during attack and threat of attack encounters and (2) appears to be the primary component of the PTZ cue.

### 51.16

BEHAVIORAL EFFECTS OF NITROUS OXIDE (N2O) IN THE CONDITIONED DEFENSIVE BURYING (CDB) TEST. D.A. Czech,\*<sup>1</sup> R.M. Quock,<sup>2</sup> and J.S. Sundstrom.<sup>1</sup> IDept. of Psychology, Marquette Univ., Milwaukee, WI 53233 and Dept. of Biomedical Sciences, Univ. of Illinois College of Medicine, Rockford, IL 61107.

The present study was conducted to determine whether an anxiolytic effect of N<sub>2</sub>O was demonstrable in the CDB test, a paradigm that exploits a species-typical propensity of rats to bury objects associated with aversive stimulation Tats to our objects associated with actions of single, brief electric "shock" was delivered to male hooded rats on contact with a wire-wrapped prod in a conditioning chamber. Rats were subsequently tested (15 min) under several concentrations of a N2O and O2 mixture (0-40% N2O), or room air, in a polycarbonate test unit with an inactive prod. Measures included height and duration of prod-directed burying with floor bedding material. Both behaviors were attenuated in a dose-related manner. Pretreatment with 20 mg/kg of the benzodiazepine (BZP) receptor blocker, flumazenil, which alone had no effect, did effectively antagonize 30% N20-induced burying. Locomotion and rearing in an open field were not affected at concentrations of  $N_2O$  that attenuated burying. Tests with chlordiazepoxide (CDP) (0-10 mg/kg) also resulted in dose-related attenuation of burying. All behaviors were videotaped for "blind" review. These findings suggest that  $N_{20}$  can induce an anxiolytic effect and implicate a BZP mechanism. (Supported by NIH Grant DE-09378)

STIMULATION OF LH SECRETION BY CCK: POSSIBLE RELATION TO VISCERAL MALAISE. D. A. Schreihofer\*, G. A. Golden, J. G. Verbalis and J. L. Cameron. Departments of Behavioral Neuroscience, Medicine, and Psychiatry. University of Pittsburgh, Pittsburgh, PA 15260.

We have recently shown that systemic administration of cholecystokinin (CCK; a peptide released from the gut and the hypothalamus in response to a meal) causes a rapid large magnitude release of luteinizing hormone (LH) in adult male rhesus monkeys (Schreihofer, et. al., Endo. Soc. Abst. 191, 1992). CCK also causes visceral malaise and emesis in humans and monkeys, and it has been proposed that these chemotoxic-like effects of CCK are responsible for causing the CCK-induced secretion of other peptide hormones, such as AVP and ACTH. We therefore sought to determine whether the chemotoxic-like effects of CCK are important for the CCKinduced stimulation of LH secretion by comparing the LH response to CCK and two other chemical agents which also can cause visceral malaise and emesis. CCK, LiCl, and cupric acetate (CuAc) were administered to monkeys via indwelling venous catheters. Three baseline blood samples were taken at -30, -15, and -1 min prior to i.v. drug administration. Samples were then taken at frequent intervals for 165 min following drug administration to characterize LH secretion. CCK (15µg/kg) caused emesis in 5 of 7 monkeys and produced a significant elevation in LH secretion (from 11.55±0.54 to 30.47±6.42 ng/ml) with a peak response 15 min post-CCK. LiCl (3 mEq/kg) caused emesis in 4 of 4 monkeys and produced a smaller, but significant, rise in LH secretion (from 14.38±0.57 to 19.2±1.92 ng/ml) with a peak response 15 min post-LiCl. CuAc (2.5 mg/kg) caused emesis in 3 of 5 monkeys and produced a large magnitude LH release (from 12.74±0.47 to 45.29±7.68 ng/ml) with a peak response 105 min post-CuAc. In comparison, 6 animals receiving saline vehicle showed no increase in LH secretion after vehicle administration (from 14.71±1.18 to 13.14±1.18 ng/ml). These results suggest that the CCK-stimulated release of LH may be related to activation of neural centers involved in the sensation of visceral malaise

#### 52 3

EFFECTS OF STEROID REPLACEMENT ON NEUROPEPTIDE Y (NPY) GENE EXPRESSION IN THE ARCUATE NUCLEUS (ARC) OF OVARIECTOMIZED (OVX) RATS. J.H. Urban\*, A.C. Bauer-Dantoin, J.E. Levine. Dept. Neurobiology & Physiology, Northwestern Univ.,

EXPRESSION IN THE ARCUATE NUCLEUS (ARC) OF OVARIECTOMIZED (OVX) RATS. J.H. Urban\*, A.C. Bauer-Dantoin, J.E. Levine. Dept. Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208.

We have recently demonstrated that NPY mRNA levels in the ARC are decreased by castration and restored by steroid treatment in male rats. The purpose of the present study was to determine whether estrogen (E) and progesterone (P) similarly modulate NPY gene expression in the ARC of female rats. OVX rats (8d) received sham capsules or doses of E (lxl4mm capsule containing 50µg estradiol/ml oil) or E+P (3x20mm caspules; crystalline P) that were comparable to steroid levels observed on the day of diestrous. NPY mRNA levels were assessed in the ARC using in situ hybridization and quantitative autoradiography. Plasma IH levels were significantly decreased in the OVX+E (p<0.01) treated groups when compared with the OVX group. NPY mRNA levels in the ARC, were significantly increased in the OVX+EP group (70.0± 3.0; p<0.01) but only slightly elevated in OVX+E treated animals when compared with values from OVX animals (OVX:47.9±3.0; OVX+E:59.5±5.8). These results suggest that E and P provide a facilitatory stimulus for NPY gene expression in the ARC and that, as in male rats, steroid effects on NPY gene expression are not directly related to negative feedback regulation of LH secretion. Studies are underway to determine if the effects of E and P on NPY gene expression may instead comprise a component of positive feedback regulation of the LH surge. (NIH HD20677, HD00879 & HD21921)

## 52.5

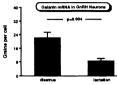

LACTATION BUT NOT PROLACTIN INCREASES THE LEVELS OF PRE-PRONPY MRNA IN THE RAT ARCUATE NUCLEUS. G. Pelletier, Y. Tong and A. Dupont\*. MRC Group in Molecular Endocrinology, CHUL Research Center and Laval University, Québec, G1V 4G2, Canada.

Evidence mostly obtained from pharmacological studies shows that neuropeptide Y (NPY) is involved in neuroendocrine regulation of reproduction functions. In the present report, we have studied the influence of lactation, a physiological condition associated with high plasma levels of prolactin (PRL), as well as the effects of hyperprolactinemia on pre-proNPY gene expression in the rat arcuate nucleus. The amounts of pre-proNPY mRNA were measured by in situ hybridization using a [35S]-labeled cRNA probe encoding for prepronpy. In lactating animals killed 4 days after parturition, pre-pronpy proNPY. In lactating animals killed 4 days after parturition, pre-proNPY mRNA levels were 50% higher than those detected in virgin adult females. Twenty-four hours after pup-removal the mRNA levels returned to those observed in virgin animals. Hypophysectomy performed 2 weeks previously decreased by 50% pre-proNPY mRNA levels. Chronic haloperiold treatment which induced high levels of circulating prolactin increased the amounts of pre-proNPY mRNA by 70% and 66% in intact and hypophysectomized animals, respectively. Intracerebroventricular injections of DNL produced to a virging the produced to the p injections of PRL produced no significant changes in the hybridization signal. Chronic hyperprolactinemia obtained by pituitary implants under mRNA levels. These data demonstrate that pre-proNPY gene expression in the rat arcuate nucleus is increased during lactation and that this effect is probably not a consequence of hyperprolactinemia. Moreover, the stimulatory effect of haloperidol treatment on pre-proNPY mRNA levels does not appear to be mediated by the pituitary gland.

SUPPRESSION OF GALANIN GENE EXPRESSION IN GNRH NEURONS GYN & PBio, U. WA, Seattle WA 98195 & Phys, U. Pitt., Pittsburgh PA 15261.

Lactation in rats is associated with the relative absence of pulsatile GnRH activ-

ity, and GnRH neurons are refractory to exogenous excitation. The decrease in GnRH neuronal activity may be associated with either an inhibition of GnRH syn-GirRH neuronal activity may be associated with either an inhibition of GirRH synthesis or the loss of other colocalized cellular products that enhance GirRH release or efficacy. Galanin is colocalized with GirRH and its expression in these neurons is enhanced at proestrus, a time of activation of GirRH neurons. We tested the hypothesis that the expression of both the GirRH and galanin genes in GirRH neurons decrease during lactation. We sacrificed groups of adult female rats at 1000 h on diestrus-1 (n=5) and on the tenth day of lactation (n=4) and utilized double and single in

situ hybridization and image analysis to compare the level of galanin and GnRH mRNA in GnRH neurons. For double in situ, GnRH mRNA was detected with an antiofficial minimal was detected with an and-sense cRNA probe labeled with the hapten digoxigenin, while the galanin cRNA probe was labeled with <sup>35</sup>S. For single-label *in* situ, the GnRH cRNA probe was labeled

with <sup>35</sup>S. The number of silver grains deposited over a cell body provided an index of mRNA levels in these cells. We observed a 60% reduction in signal for galanin mRNA in the GnRH neurons of lactating animals compared with those of diestrus animals, although levels for GnRH mRNA were not different between these two groups (133.1±14.6 diestrus vs.127.7±8.32 lactation; p>0.7). Conclusion; Galanin groups (153.1214.0 diesulus vis.1217.78.32 actautoit, p20.7). Conclusion, totalanii gene expression in GnRH neurons of the rat is lowered during lactation, but GnRH expression is not. We infer that the extremely low plasma estrogen levels during lactation cannot support galanin gene expression. This decrease in galanin gene expression may lead to the decreased synthesis and secretion of galanin, which, in turn, could diminish the secretion of GnRH or its activity at the pituitary.

ESTROGEN-DEPENDENT NEUROTENSIN IMMUNOREACTIVITY IN THE PREOPTIC AREA OF THE FEMALE RAT. M.J. Alexander\* and S.E. Leeman, Department of Pharmacology & Experimental Therapeutics, Boston University School of Medicine, Boston, MA 02118.

Neurotensin (NT) neurons in the rostral preoptic area may mediate stimulatory

effects of estrogen on preovulatory secretion of gonadotropin-releasing hormone in the female rat. Estrogen markedly increases the abundance of mRNA encoding NT and neuromedin N in the anteroventral periventricular nucleus (AVPv), periventricular preoptic nucleus (PvPO), and medial preoptic nucleus (MPN). To determine if estrogen-dependent expression of NT/N mRNA is indicative of increased NT biosynthesis, we investigated whether estrogen can induce NT-immunoreactivity (NT-ir) in these same cell groups. Ovariectomized (OVX) adult rats were left untreated or were treated with supraphysiological levels of 178-estradiol (E2) for 2 wks, and a subset of each group received an intracerebroventricular injection of colchicine (100  $\mu$ g) 48 hr before transcardiac perfusion. NT-ir was detected in brain sections with a polyclonal antiserum exhibiting negligible cross-reactivity with neuromedin N. E2 caused a dramatic increase in the number of NT-ir cell bodies specifically in the AVPv, rostral PvPO, and extreme medial part of the rostral MPN. There were more than eight times as many NT-ir cell bodies ( $101 \pm 5$  vs.  $12 \pm 1$  in a 40- $\mu$ m bilateral section) in the caudal AVPv of E2-treated OVX rats (n=7) as in the same region of OVX rats (n=7), and a difference of similar magnitude was observed in the adjacent PvPO. Although NT-ir cell bodies were undetectable when colchicine treatment was omitted (n=5 per group), E2 nevertheless caused a pronounced increase in the number of NT-ir fibers in these same regions. The concordant effects of estrogen on steady-state levels of NT/N mRNA and NT-ir in specific neuronal groups of the female preoptic area indicate that estrogen increases NT biosynthesis in these neurons and suggest that estrogen-associated change in NT/N mRNA abundance is a reliable sign of altered NT biosynthesis in this brain area. ## 52.6

NMDA STIMULATES QUIESCENT MU-OPIOID AFFERENTS WHICH MODULATE GNRH RELEASE IN THE INTACT MALE

MOUSE. G.M. Miller\* and M.J.Gibson, Division of Endocrinology, Mount Sinai School of Medicine, N.Y., N.Y., 10029.

We have previously shown that NMDA stimulates LH release in male and female mice (Endocr.128: 2432,'91) and our recent work suggests that NMDA's effect on GnRH secretion is modulated by other afferents. The present study examines mu-opioid interaction with NMDA on LH release. We now report that naloxone (3mg/kg) failed to stimulate LH release in male mice (n=23), yet significantly potentiated NMDA (20mg/kg,iv)-stimulated LH release (p<0.01;n=8). Naloxone methiodide, which does not cross the blood-brain barrier, had a similar effect when administered at the same dose (n=8). Neither opioid antagonist affected GnRH -stimulated LH release, suggesting

These data suggest that NMDA stimulates otherwise quiescent mu-opioid afferents to GNRH neurons, thereby attenuating LH release by decreasing the amount of GnRH released at the median eminence Supported by: T32DK07645 (GMM) and NS20335 (MJG)

GLUCOCORTICOIDS STABILIZE CALMODULIN ASSOCIATION WITH SYNAPTOSOMAL PLASMA MEMBRANE. Zafar Iqbal and Paul Y. Sze.\* Dept. of Pharmacol. & Mol. Biol., The Chicago Medical School, North Chicago, IL 60064, and Dept. of Neurology, Northwestern University Medical School, Chicago, IL 60611.

The synaptic plasma membrane (SPM) from brain is known to have specific binding sites for glucocorticoids. Knowledge about biochemical consequences of the steroid-membrane interaction has only begun to emerge. In the present study, we determined the effects of glucocorticoids on the stability of membrane association of calmodulin (CaM) in vitro in purified SPM from rat cerebral cortex. SPM was first washed with EGTA to deplete endogenously bound CaM, and then reloaded with [125I] CaM. At 37°C, [125I] CaM was found to dissociate rapidly from the membrane, even in the presence of 10 uM Ca<sup>2+</sup>. A fast and a slow component were identified in the first-order dissociation kinetics. In SPM preincubated with 1 uM corticosterone, the fast dissociation of [1251] CaM was markedly decreased, whereas the slow dissociation was not affected. The effect of the steroid was concentration-dependent. In another experiment, RIA was used to determine the dissociation of endogenously bound CaM. Preincubation of SPM with corticosterone showed a similar stabilizing effect against the rapid dissociation of endogenous CaM from the membrane. Our results support the notion that one of the glucocorticoid actions on neuronal plasma membrane is to stabilize the association of CaM with the membrane. Since CaM is involved in a variety of biochemical activities in the plasma membrane, such an action could lead to the regulation of membrane functions.

PULSATILE SECRETION OF LHRH AND 8-ENDORPHIN INTO PITUITARY PULSATILE SECRETION OF LHRH AND β-ENDORPHIN INTO PITUITARY PORTAL BLOOD DURING DIFFERENT DAYS OF THE ESTROUS CYCLE IN RATS. D.K. Sarkar, S. Minami, Q-W Xie, J.P. Advis\* and B.M. Prasad. Dept of VCAPP, Washington State University, Pullman, WA 99164, Dept of Animal Sciences, Rutgers University, New Brunswick, NJ 08903.

Hypothalamic β-endorphin (β-EP) has been implicated in the negative control of

LHRH secretion by acting both at the preoptic-anterior hypothalamus and the median eminence during the rat estrous cycle. We have previously shown that a large amount of β-EP from the median eminence is secreted into the portal blood of female rats. Using Saffan anesthetic (which does not inhibit preovulatory LH and PRL release) and long surgical recovery (60-90 min), we have previously noted that the portal levels of β-EP were negatively associated with the levels of LHRH immediately prior to and during the preovulatory LH surge in female rats. The inverse relationship in the pattern of median eminence  $\beta$ -EP and LHRH secretion prior to the preovulatory LH release has recently been confirmed in conscious female ewes and has provided a physiological evidence for the inhibitory role of  $\beta$ -EP on LHRH secretion. In order to further evidence for the inhibitory role of  $\beta$ -EP on LHRH secretion. In order to further characterize the dynamic interaction between LHRH and  $\beta$ -EP at the median eminence, we determined the levels of LHRH and  $\beta$ -EP in portal plasma samples collected at 10 min intervals between 1000-1800 h on the day of diestrus and proestrus in cyclic female rats. Both LHRH and  $\beta$ -EP are secreted in portal blood in a pulsatile manner on the day of diestrus and proestrus. The pulsatile secretion of  $\beta$ -EP were highest between 1000-1500 h and lowest between 1600-1800 h of proestrus. The pulsatile secretion of LHRH was low during the elevated  $\beta$ -EP secretion, but increased remarkably on the proestrous afternoon. The secretory profiles of these two peptides also showed a diurnal rhythmicity and an inverse relationship on the day of diestrus, although the levels of  $\beta$ -EP and LHRH were in general lower on the this day than on the day of proestrus. These data suggest for the first time that there is a diurnal rhythm in LHRH and  $\beta$ -EP secretion in the cyclic female and that the interaction between these two peptides may be important in governing the timing of this rhythmic  $\delta$ -EP and LHRH release. be important in governing the timing of this rhythmic  $\beta$ -EP and LHRH release.

## 52.11

OPIOID AND DOPAMINERGIC REGULATION OF GNRH GENE EXPRESSION IN THE MALE RAT HYPOTHALAMUS. S. Li. G. Pelletier\*

MRC Group in Molecular Endocrinology, CHUL Research Center and Laval University, Québec, G1V 4G2, Canada.

Compelling evidence indicates that opioid peptides have an inhibitory effect of GnRH secretion while the role of dopamine in the regulation of GnRH secretion is still controversial since both stimulatory and inhibitory effects have been reported. The role of these transmitters on GnRH biosynthesis was investigated by quantitative in situ hybridization involving use of a [35S]-labeled 48 base oligonucleotide complementary to the GnRH coding region of the GnRH DNA. The corresponding mRNA levels were assessed by GRRH DNA. The corresponding mRNA levels were assessed by counting the number of silver grains per labeled neuron. A 14-day treatment with the dopaminergic agonist bromocriptine increased by 67% the number of silver grains overlying GnRH-producing neurons while the dopamine antagonist haloperidol decrased by 31% the value of this parameter. A 24-hour treatment with the opioid drug morphine produced a 33% decrease in the hybridization signal. Conversely naloxone, an opiate receptor antagonist, also administered during a 24-hour period, induced a 22% increase in the number of grains/GnRH neuron. The present data clearly indicate that GnRH mRNA levels are costitively, and negatively, regulated by dopamine and conjects. positively and negatively regulated by dopamine and opiates, respectively. They suggest that these transmitters can not only modified the release of GnRH by also the biosynthesis of this peptide.

NEUROTRANSMITTER REGULATION OF GNRH GENE EXPRESSION: ROLES OF NMA AND OPIATES. Andrea C. Gore\* & James L. Roberts. Fishberg Ctr. for Neurobiology, Mt. Sinai Med. Ctr., NY. NY. 10029.

Numerous neurotransmitters such as N-methyl-D,L-aspartate (NMA) and opiates regulate GnRH release. We were interested in examining whether these neurotransmitters exert their effects by altering GnRH gene expression, particularly transcription, by measuring changes in GnRH primary transcript (PT) and processing intermediate (INT) levels, as well as mRNA levels. NMA (14 mg/kg, i.p.), naloxone (NX, 2 mg/kg i.p.) or saline were injected in intact male or ovariectomized female rats. Rats were decapitated 15 or 60 min later, the brains removed on ice and the preoptic area dissected and frozen. Cytoplasmic and nuclear RNA were extracted and assayed for GnRH mRNA, INT and PT by RNase protection assay. For NMA, cytoplasmic mRNA levels increased significantly 60 min, but not 15 min, after NMA injection compared to control (no treatment or saline) levels. In the nucleus, no significant changes in PT or INT were observed. For NX, a small increase (non-significant) in mRNA was observed in the cytoplasm 60 min after injection. Again, no changes in INT or PT were observed in the nucleus. These studies indicate that GnRH mRNA levels in the cytoplasm can be rapidly increased by NMA and NX, while PT and INT in the nucleus do not change. The results suggest that mRNA levels can increase without concomitant changes in gene transcription, possibly as a result of alterations in mRNA

### 52.10

STEREOLOGICAL AND MORPHOMETRIC EVIDENCE FOR SELECTIVE BETA-ENDORPHIN NEURON LOSS FOLLOWING LONG-TERM ESTRADIOL EXPOSURE

G. Clarissa Desiardins\* James R. Brawer and A. Beaudet, Departments of Anatomy and Neurology & Neurosurgery, McGill U., Mtl., Quebec H3A 2B4.

We have previously shown that the long-term exposure to physiological concentrations of estradiol that follows a single 2 mg IM injection of estradiol valerate (EV) results in the loss of more than 60% of all hypothalamic beta-endorphin immunoreactive (ir) neurons while sparing, somatostatin (SRIF), neurotensin (NT) and tyrosine hydroxylase-(TH) immunoreactive neuronal populations. In order to determine whether this decrement in beta-endorphin-ir neuron number was due to actual cell loss or to a decrease in ir-peptide content, unbiased stereological methods (Gundersen et al., 1988) were used to estimate the total number of neurons in the arcuate nucleus of control and EV treated (n=10) animals. A systematic sampling scheme resulting in a coefficient of error of less than 7%was used. In addition, the morphometry (form factor, area, diameter) of immunolabeled beta-endorphin neurons was analyzed. Mean number of neurons (coefficient of variation) in controls was 23 820 (0.07) consistent with what was previously reported using Golgi staining or classical stereology. In estradiol-treated animals neuron numbers were reduced to 20 249 (0.07), indicating that significant neuronal cell loss had occurred. Furthermore, this neuronal loss (3500 cells) corresponded precisely with the total estimated loss of beta-endorphin neurons (3600), thus confirming the idea that chronic exposure to estradiol results in selective beta-endorphin neuron destruction. Morphometric analysis of beta-endorphin neuron surface area revealed a relatively greater loss of small (25-30 $\mu$ m²) versus large (45-50 $\mu$ m²) neurons in EV-treated animals and a significant decrease in form factor with respect to controls  $(0.45 \pm .02 \text{ vs. } 0.52 \pm .005; \text{ p} < 0.05)$ . Such alterations could reflect early changes associated with neuronal degeneration

## 52.12

FEED RESTRICTION DECREASES ARCUATE MRNA AND IN VIVO MEDIAN EMINENCE RELEASE OF B-ENDORPHINE IN EWE LAMBS. B.M. Prasad, A. C. Gore, J.L. Roberts, D.K. Sarkar, J. Rabii\* and J.P. Advis. Department of Animal Sciences, Rutgers University, New Brunswick, NJ 08903, VCAPP, Washington State University, Pullman, WA 99164, Department of Neurobiology, Mount Sinai Sch Med, NY City, NY 10029, and Dept of Biological Sci, Rutgers University, Piscataway, NJ 08855. Feed restricted (FR) lambs fail to reach puberty and show lower plasma.

LH values than full fed (FF) age-paired controls. We analyzed: a) steady state levels of BEND mRNA in arcuate nuclei using a solution hybridization - RNase LH values than full fed (FF) age-paired controls. We analyzed: a) steady state levels of BEND mRNA in arcuate nuclei using a solution hybridization - RNase protection assay; and b) ME in vivo release of LHRH, BEND, and NPY by push-pull cannula (PPC). FF and FR lambs were sampled at the time each FF age-paired control was in the follicular phase of its 2nd and 4th estrous cycle. FR lambs had decreased in vivo ME-LHRH release (0.87±0.04 vs 0.26± 0.04 pg/100 µl PPC perfusate, sampled at 10-min intervals for 4h, FF vs FR, mean tsem, n=12), lower plasma LH (6.0±1.6 vs 1.3±0.3 ng/ml), and failed to reach puberty when compared to age-matched FF controls. The low LHRH and LH release was caused by a decrease in pulse amplitude (LHRH=1.91± 0.19 vs 0.62±0.14; LH= 7.60±2.42 vs 0.54±0.22) rather than alterations in pulse frequency. These changes occurred in the presence of decreased 8-END (246±44 vs 46± 13) and unchanged NPY release. Exogenous infusion of 8-END in ME decreased in vivo LHRH (in FF but not in FR) and NPY (in FF and in FR) release (LHRH= 2.15±0.67 vs 0.67±0.1; NPY= 331±50 vs 172±42 before vs during infusion) and plasma LH (3.8±0.3 vs 2.09±0.3) in FF lambs. Steady state levels of BEND message were lower in FR than in their FF paired controls (0.83±0.18 vs 0.48±0.10 pg POMC/µg RNA). Thus, FR lowers LH release and prevents pubertal onset by decreasing the amplitude of pulsatile LHRH release. The decreased BEND synthesis and release might represent unsuccessful compensatory mechanisms. The lack of effect of FR on ME-NPY release, supports the specificity of changes induced on ME-LHRH and 8-END release (NJAES-Hatch 06108 & USDA 89-37240-4587 to JP Advis).

MEDIAN EMINENCE IN VIVO RELEASE, INFUNDIBULAR/ARCUATE PEPTIDE CONTENT, AND ARCUATE STEADY-STATE MRNA OF B-ENDORPHINE, BEFORE, DURING AND AFTER A PREOVULATORY LH SURGE IN EWES. C.D. Conover. A.C. Gore, J.L. Roberts, D.K. Sarkar, J. Rabii and J.P. Advis, Dept of Animal Sciences, Rutgers Univ, New Brunswick, NJ 08903, VCAPP, Washington State Univ, Pullman, WA 99164, Dept of Neurobiology, Mount Sinai Sch Med, NY City, NY 10029, & Dept Biological Sciences, Rutgers Univ, Piscataway, NJ 08855. An involvement of 6-endorphine (BEND) at the median eminence (ME)

An involvement of β-endorphine (βEND) at the median eminence (ME) has been suggested to play a role in the neuroendocrine control of preovulatory release of luteinizing hormone (LH) - releasing hormone (LHRH) and LH. Infusion of βEND into the posterior-lateral ME of follicular ewes decreases in vivo release of ME-LHRH and plasma LH. We analyzed: a) ME in vivo release of βEND and LHRH by push-pull cannula (PPC) sampling; b) steady state levels of βEND mRNA in arcuate nuclei by a solution hybridization-RNase protection assay; and c) content of βEND in the infundibular/arcuate area by RIA, before, during, and after an induced follicular phase in adult cycling ewes. Follicular content of tissue βEND was twice (P-0.01) that observed in early luteal ewes (25±3 vs 52±5 pg/μg protein, mean±sem, n=26). The low ME-in vivo pulsatile βEND release (27±6 pg/100 μl PPC perfusate, n=6, sampled at 10-min intervals for 4h) increased a thousand fold to peak levels immediately before the LH surge (27±3±2047, n=4), and was lower in ewes undergoing an LH surge (92±46, n=4). In vivo pulsatile ME-LHRH release increased during the follicular phase (2.8±0.3 vs 24.5±22.2). Increases of in vivo peptide release were associated predominantly with changes in amplitude (βEND=26.9 ±13.9 vs 81.3 ± 23.7; LHRH=1.92 ± 0.29 vs 4.29 ± 0.89). Steady state BEND mRNA levels increased gradually during the follicular phase (0.55±0.06 vs 0.86 ± 0.08 pg/μg RNA, n=25, start vs end, P<0.05). In conclusion, BEND secretion might exert an increasing tonic inhibition on LHRH release until the onset of the preovulatory surge of ME-LHRH and plasma LH (supported by NJAES - Hatch 06108 & USDA 89-37240-4587 to JP Advis).

PLASTICITY IN THE ANTEROVENTRAL PERIVENTRICULAR NUCLEUS OF THE CYCLING AND OVARIECTOMIZED FEMALE RAT. M.C. Langub Jr.\* and R.E. Watson Jr. Department of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, Kentucky 40536.

Estrous cycle-related plasticity has been documented in the preoptic-hypothalamic region (Naffolin, et al., 1990). For example, arcuate nucleus neurons are contactory 31% fewer axosomatic synapses during estrus than during proestrus 24 h earlier (Olmos, et al., 1989). The present study was conducted to determine whether another sexually dimorphic area, the anteroventral periventricular nucleus (AVPv), also exhibits estrous cycle-related changes in morphology and synaptic input. The AVPv is a key site for control of steroid-mediated gonadotropin secretion (Wiegand and Terasawa, 1982) and contains abundant estrogen receptor immunoreactive (ER-ir cells. Tissue sections through the AVPv from cycling and ovariectomized Sprague-Dawley rats were processed for the immunolocalization of ER-ir using monoclonal antibody H222 (Abbott Laboratories) and tetramethylbenzidine (TMB). ER-ir and nonER-ir neurons were photographed on a Hitachi H7000 transmission electron microscope. No differences in perikaryal area of ER- and nonER-ir cells were present across the estrous cycle or following ovariectomy. However, significant decreases in nuclear circumference were present in ER-ir cells at proestrus relative to other cycle stages and to ovariectomized females. Nuclear area was unaffected by cycle stage or ovariectomy in ER- and nonER-ir cells. Significant differences were also present in the number of axosomatic synapses upon AVPv neurons. More synapses were present on nonER-ir neurons was pooled, there was no significant difference in the number of axosomatic contacts across the estrous cycle. However, significantly more synapses were present on ER-ir cells following ovariectomy than during proestrus. This effect was not seen in nonER-ir cells following ovariectomy than during proestrus. This effect was not seen in nonER-ir cells following ovariectomy than during proestrus. This effect was not seen in nonER-ir cells following ovariectomy than during proestrus in the AVPv. MELATONIN SUPPRESSION OF ESTROGEN RECEPTOR PROTEIN AND MESSENGER RNA IN OVARIECTOMIZED OUTBRED LVG SYRIAN HAMSTERS. N.O. Lawson<sup>1\*</sup>, B.E.F. Wee<sup>2</sup>, J.G. Drane<sup>1</sup> and S.M. Hill<sup>1</sup>. <sup>1</sup>Depts. of Anatomy & <sup>2</sup>Psychology, Tulane University, New Orleans, LA 70112.

Melatoniensty, New Orleans, LA 70112.

Melatonien, the major pineal hormone, is a key regulator of the reproductive system of photoperiodic animals such as the hamster. We have previously reported that melatonin suppresses estrogen receptor (ER) expression in the medial preoptic area (MPOA) of inbred LSH/SsLak hamsters. The current study looks at whether this effect on ER is strain specific and the biological level at which this is mediated. Ovariectomized outbred LVG Syrian hamsters held under long photoperiod (14L:10D), were treated with either melatonin or vehicle for 12 weeks. Immunocytochemistry was performed on coronal brain sections of the MPOA, using the H222 monoclonal antibody to the human ER. To examine ER mRNA, total RNA was isolated from blocked hypothalami and RNase protection analysis performed using a cRNA probe generated from a 300 nucleotide cDNA fragment encoding the ligand binding domain of the human ER. The results show that melatonin induced a statistically significant 39% decrease in the number of cells/mm² showing ER-immunoreactivity in the MPOA of these outbred hamsters. This decrease is less than what was observed in the inbred animals (50-70%). Melatonin treatment also induced a significant 31% decrease in steady state ER mRNA levels, suggesting that the effects of melatonin on ER expression may be mediated at the transcriptional level. Thus, it appears that the effects of melatonin are not strain specific, in that both inbred and outbred hamsters responded to melatonin with decreased ER expression and that this effect is at least partially mediated at the level of gene transcription.

53.4

DISTRIBUTION OF ESTROGEN RECEPTOR-IMMUNOREACTIVE CELLS IN THE FOREBRAIN OF THE FEMALE SIBERIAN HAMSTER C.M. Meyers. M.J. Duncan. M.B. Nikitovitch-Winer\*, and R.E. Watson. Jr. Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536.

Center, Lexington, KY 40536.

Gonadal steroids have profound effects on reproduction, thermoregulation, and body weight in Siberian hamsters. To identify potential sites of action of estrogen in this species, we investigated the distribution of estrogen receptor immunoreactive (ER-ir) cells in the forebrain. Ovariectomized hamsters (2 weeks) were perfused with Zamboni's fixative and sections through the forebrain were incubated in monoclonal antibody H222 (Abbott Laboratories) and reacted using nickel-intensified diaminobenzidine. ER-ir cells were identified by the presence of dense reaction product that was localized predominantly in cell nuclei. Many heavily labeled cells were present in the medial preoptic region at its anterior pole immediately adjacent to the third ventrice and at more posterior and lateral levels. ER-ir cells were also present in the ventral part of the lateral septal nucleus and in the adjacent bed nucleus of the stria terminalis (BNST). Further caudally, abundant labeled cells were present in the engapsulated part of the BNST. Fewer ER-ir cells were present in the suprachiasmatic, supraoptic, or paraventricular nuclei. Many ER-ir cells were present in the recordianmatic area, arcuate nucleus and in the ventrolateral pole of the ventromedial nucleus and immediately adjacent to it. Only sparse ER-ir cells were present in the the dorsomedial nucleus. Abundant ER-ir cells were present in the premammillary nuclei. In the amygdala, many heavily labeled cells were present in the medial and cortical nuclei, and posteriorly, the amygdalohippocampal area contained abundant ER-ir cells, finally, labeled cells were also present in the midbrain central gray. These results demonstrate that the overall pattern of ER-ir in this species is very similar to that reported previously for a number of other species, including the rat, guinea pig, and opossum. (Supported by NIH DK 42056 (MJD) and HD 29050 (REW))

VASOPRESSINERGIC SYNAPTIC INPUT UPON ESTROGEN RECEPTIVE NEURONS IN THE ANTERIOR PREOPTIC REGION OF THE RAT: SUPRACHIASMATIC NUCLEUS ORIGIN? R.E. Watson, Jr.\*, and M.C. Langub, Jr. Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536.

Feedback of increasing titers of estrogen and progesterone on the brain during the follicular phase of the estrous cycle stimulates the preovulatory surge of pituitary luteinizing hormone (LH) secretion. Steroid receptive neurons located at the anterior pole of the preoptic area in the anteroventral periventricular nucleus (AVPv) are believed to play a critical role in transduction of the steroid feedback (Wiegand and Terasawa, 1982). The timing of the preovulatory LH surge is evidently governed also by a circadian signal since it occurs at a characteristic time of day relative to the light-dark cycle to which the rat is entrained. Thus, the possibility exists that estrogen receptive neurons in the AVPv receive synaptic input from the suprachiamatic nucleus (SCN). To test this possibility we have employed ultrastructural double label immunocytochemistry to determine whether vasopressin (VP) - immunoreactive (ir) fibers in the AVPv, which arise predominantly in the SCN, provide synaptic input to estrogen receptor-it (ER-ir) neurons. Sections through the AVPv from cycling female rats were stained sequentially for ER-ir using monoclonal antibody H222 (Abbott Laboratories) using tetramethylbenzidine (TMB), while VP-ir was demonstrated with rabbit polyclonal antisera (ICN) and diaminobenzidine (DAB). Ultrastructurally, TMB and DAB reaction products can be readily distinguished from one another. Abundant examples of synaptic interactions between VP-ir terminals and ER-ir neurons throughout the AVPv were present. Thus, these results strongly support the hypothesis that VPergic neurons in the SCN are capable of regulating the activity of ER-ir AVPv neurons, thereby potentially providing a means by which circadian information from the SCN could be integrated with estrogen feedback signals. To further explore synaptic relationships between the SCN and AVPv, PHA-L injections have been made into the SCN and PHA-L-ir synapses documented ultrastructurally in the AVPv. (Supported by NiH HD 29050)

PROGESTERONE RECEPTOR mRNA EXPRESSION IN THE FEMALE RAT HYPOTHALAMUS. Ok.-Kyong Park-Sarge\*, John Mordacq, Jason Rahal, and Kelly E. Mayo, Department of Biochemistry, Molecular Biology and Cell Biology, Nethopoten University, Evaneton, 11, 60208.

Kelly E. Mayo. Department of Biochemistry, Molecular Biology and Cell Biology, Northwestern University, Evanston, IL 60208.

We have previously reported that progesterone receptor (PR) mRNA is transiently expressed in granulosa cells of the rat ovary during the estrous cycle. Unlike PR mRNA in other target tissues for progesterone action (e.g. uterus and mammary gland), ovarian PR mRNA is not induced by estrogen but rather is increased by the pituitary hormone LH. The brain is known to be a target for progesterone action. In the present study, we addressed the question of whether PR mRNA is regulated in the female rat brain during the estrous cycle. We localized PR mRNA using in situ hybridization with "S-labeled antisense RNA to the rat PR. Many areas throughout the brain express PR mRNA but they appeared to be categorized into two groups; Levels of PR mRNA in areas including the cortex and hippocampus appeared not to change throughout the estrous cycle; However, levels of PR mRNA in the medial preoptic nucleus (MPN), arcuate nucleus (Arc), and ventromedial hypothalamus (VMH) were regulated during the estrous cycle. Pm RNA levels in these areas were low on estrus and metestrus, high on diestrus and proestrus, and down regulated during the transition from proestrus to estrus, suggesting that PR mRNA expression in these brain areas using ovariectomized (OVX) and ovariectomized, estrogen-primed (OVX+E) rats. Ovariectomy was for 7 days and estrogen treatment was for 2 days. In situ hybridization showed that PR mRNA levels in the MPN, Arc, and VMH of OVX+E rats were much higher than those of OVX rats. We also utilized a reverse transcription-polymerase chain reaction (RT-PCR) assay to compare PR mRNA levels in dissected hypothalamic fragments of OVX and OVX+E rats. PR mRNA expression in the MPN, Arc, and VMH regions of the brain is induced by estrogen.

## 53.9

CYTOPLASMIC ESTROGEN RECEPTORS IN RAT BRAIN: IMMUNOCYTOCHEMICAL EVIDENCE USING THREE DIFFERENT ANTIBODIES AND EFFECTS OF ESTRADIOL INJECTION.

J.D. Blaustein\*, Neuroscience and Behavior Program and Psychology Department, University of Massachusetts, Amherst, MA 01003.

The existence of cytoplasmic estrogen receptors has been reported in the brains of a variety of species using immunocytochemical techniques Because all previous studies used the same antibody (H 222; Abbott Laboratories), it is possible that this finding is idiosyncratic to one antibody. Therefore, three antibodies directed against diverse epitopes on the estrogen receptor protein were used to immunostain estrogen receptors in rat brain. With each antibody, estrogen receptor-immunoreactivity (ER-IR) was observed in the hypothalamus, preoptic area, amygdala and midbrain central gray. While the darkest reaction product was seen within cell nuclei, in most areas extensive ER-IR was also observed in perikaryal cytoplasm and cytoplasmic processes. Estradiol injection caused a rapid, large decrease in ER-IR when the H 222 antibody was used. This decrease was not due to movement of the receptors to the cell nucleus, as cell nuclear ER-IR decreased too. Furthermore, the extent of loss of immunostaining was greatly influenced by the particular antibody used, suggesting that the decrease in ER-IR is due to a conformational change in the receptor. This study demonstrates the existence of neural ER-IR in perikaryal cytoplasm and cytoplasmic processes in rat brain, it suggests that the cytoplasmic ER-IR is not just a small fragment of the receptor protein, and it suggests that the decrease in ER-IR seen immediately after estradiol injection with some antibodies is due to a conformational change in the receptor. (Supported by NIH NS 19327, RSDA MH 00885, and NSF BNS 11464)

#### 53.6

RESTRICTED COLOCALIZATION OF PROGESTIN RECEPTORS (PR) AND OXYTOCIN (OT) IN HYPOTHALAMIC NEURONS OF STEROID-TREATED MONKEYS S. G. Kohama\* F. Freesh, C. L. Bethea, Div. Reprod. Sciences, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Progesterone (P4) increases PRL secretion in estrogen (E)-primed monkeys, but lactotropes do not have PR. OT directly stimulates PRL secretion. We questioned whether OT neurons are progestin target cells which could mediate the effect of P4 on PRL secretion. Female rhesus monkeys were spayed and implanted with either empty silastic capsules [SPAY], E-filled capsules for 28 days [E], or E-capsules supplemented with P4 capsules for the last 14 of 28 days [E+P]. Hypothalamic sections (10µ) were double-labeled for PR and OT using B39 (2µg/ml) and nickel intensified DAB to visualize PR in the nucleus followed by anti-OT (W.K. Samson) plus DAB to visualize PR in the nucleus followed by anti-OT (W.K. Samson) plus DAB to visualize PR in the orthogonal solve than in other PR+ neurons. Distributions of PR+ cells and OT+ cells overlapped in the paraventricular nucleus (PVN) and the supraoptic nucleus (SON). However, colocalization of PR and OT in the same cells was less than 5% in the PVN and the medial SON regardless of steroid treatment. E-treatment did not significantly alter PR in the SON. Rather, a significant population of lightly staining OT cells with PR was observed in the lateral SON due to an apparent induction of OT immunoreactivity with E. Because PR was evident in other magnocellular neurons, the colocalization of PR and arginine vasopressin (AVP) was explored. Preliminary evidence suggests that the majority of PR-positive magnocellular neurons contain AVP. Hypothalamic OT content by RIA was higher in rostral, medial basal, dorsomedial and mamillary areas of adult male and female monkeys than in juveniles of both sexes. Supported by HD17269, HD18185.

### 53.8

IMMUNOCYTOCHEMICAL COLOCALIZATION OF PROGESTIN RECEPTORS (PR) AND SUBSTANCE P (SP) IN HYPOTHALAMIC NEURONS OF STEROID-TREATED MONKEYS C. L. Bethea\* and F. Freesh. Division of Reproductive Sciences, Oregon Regional Primate Research Ctr., Beaverton, OR 97006.

Progesterone (P4) increases PRL secretion in estrogen (E)-primed monkeys, but lactotropes do not have PR. Substance P is found in high concentrations in the external zone of the median eminence in primates and it stimulates PRL secretion. We questioned whether SP neurons are progestin target cells which could mediate the effect of P4 on prolactin secretion. Female rhesus monkeys were spayed and implanted with either empty silastic capsules (SPAY), E-filled capsules for 28 days [E], or E-capsules supplemented with P4 capsules for the last 14 of 28 days [E+P]. Hypothalamic sections (10µ) were double-labeled for PR and SP using B39 (2µg/ml) and nickel intensified DAB to visualize PR in the nucleus followed by anti-SP (R.L.Eskay) plus DAB to visualize SP in the cytoplasm. SP+ neurons were located in a small caudal periventricular group, in the arcuate/ median eminence and underneath the capsules of the mamillary nuclei in spayed monkeys. In addition, there was a significant induction of SP+ neurons in the VMN and ARC of the E-treated monkey which diminished in the E+P monkey. In the external zone of the median eminence, IR-SP decreased with E and then increased with E+P. ARC/ME Perivent %SP+PR 110/265 (41%) 19/40(47%) 7/29(3%) 0/22(0%) Spay 1495/1495(100%) 31/57 (62%) 3/218 (1%) 224/230(97%) 1/60(0%) 16/21 (76%) E+P 35/36 (97%) 0/93(0%) Hypothalamic SP content by RIA was higher in rostral, medial basal, dorsomedial and mamillary areas of 6 intact female monkeys than in 3 spays, 3 juveniles or 1 pregnant female. Supported by HD17269, HD18185.

## 53.10

IN VITRO EXCHANGE AUTORADIOGRAPHY OF ESTROGEN RECEPTORS: REGIONAL DISTRIBUTION OF ESTROGEN RECEPTOR OCCUPATION IN THE BRAIN OF THE ADULT MALE RAT. M.J., Walters\*, T.J. Brown, K.D.R. Morton, R.B. Hochberg and N.J. MacLusky. Division of Reproductive Science, The Toronto Hospital, Toronto, Canada MSG 1L7, and Department of OB/GYN, Yale University School of Medicine, New Haven, CT 06510.

Conversion of testosterone to estradiol in the diencephalon and limbic system plays an important role in neurochemical and behavioral responses to circulating androgen. The extent to which locally-synthesized estrogen impacts on the estrogen receptor (ER) systems in different regions of the brain has, however, been difficult to determine because of methodological problems. Using a recently-developed in vitro autoradiographic method (Walters et al., Soc. for Neurosci.,17:1410, 1991), we re-examined the distribution of occupied ER in the brain of the male rat. Cryostat sections (20 µm) through the brain were incubated with  $11\beta$ -methoxy- $16\alpha$ -[125]]iodoestradiol, then washed and exposed for 16-24h against Amersham Hyperfilm. The regional distribution of estrogen binding was assessed from the autoradiograms by computerized densitometry. In orchidectomized rats, very little labelling was observed. In intact males, very high levels of ER occupation - 50% or more of the available binding capacity - were observed in the periventricular preoptic area, ventromedial nucleus, amygdala and bed nucleus of the stria terminalis. Much lower levels of occupation were observed in the medial preoptic, arcuate and supraoptic nuclei, all of which have previously been reported to contain aromatase based on biochemical and/or immunocytochemical studies. These studies demonstrate a remarkable specificity in the extent of ER occupation in the brain of the intact male rat. In some regions of the brain, ER occupation in the male is comparable to that observed in cycling females at proestrus. The regional pattern of ER occupation in the male differs in important respects from the predictions of previous studies based on measurement of aromatase activity. LOCALIZATION AND MEASUREMENT OF OCCUPIED ANDROGEN RECEPTORS IN THAW-MOUNTED TISSUE SECTIONS. I.J. Brown\*, M. Sharma, and N.J. MacLusky. Dept. of OB/GYN, Univ. of Toronto, Toronto, ON M5G 1L7.

The study of androgen action in the brain has been severely hampered by the lack of a suitable method to quantify occupied androgen receptors with the necessary degree of anatomical resolution. We now report the development of a quantitative autoradiographic method that uses a binding exchange reaction in thaw-mounted tissue sections (10-20 µm). This method enables the selective measurement of occupied androgen receptors with anatomical resolution approaching the cellular level. The appropriate conditions for the method were established in frozen ventral prostate sections from intact, castrate, or testosterone-treated (500 µg) rats. Sections were incubated with 2.5 nM [3H]R1881 for 0.5-120 hr at either 4, 14, 22, or 37C. All incubates contained triamcinolone acetonide to suppress binding to the progestin receptor and parallel incubations were conducted in the presence of unlabeled R1881 to assess nonspecific binding. After incubation, sections were briefly rinsed before fixation in 4% paraformaldehyde and washed to remove unbound [3H]R1881. After drying, the sections were scraped from the slides and radioactivity and protein content were determined. Optimum binding was achieved with a 72 hr incubation at 4C. Essentially no androgen receptor binding was detected in castrate animals whereas levels in intact and testosterone-treated rats were 79.3 and 143.6 fmol/mg protein respectively, indicating that the method is selective for the occupied receptor. Saturation binding analysis revealed binding to a single class site with a Kdiss = 0.546 nM. Autoradiographic images of androgen binding in the brain were obtained by treating brain sections as described and placing them against emulsion-coated film for a period of 2.5 mo. Essentially no binding was observed in the brain of castrate animals while specific binding was observed in the preoptic and hypothalamic areas of the intact and testosterone-treated animal. This method will enable, with a high degree of anatomical resolution, the quantification of active androgen receptor in specific regions of the brain (or any other tissue) under various physiological conditions. Supported by Canadian MRC grants MT-11235 (to TJB) and PG 11115 (to NJM).

### 53.13

DIFFERENTIAL EFFECTS OF CASTRATION ON ANDROGEN RECEPTOR DYNAMICS IN GUINEA PIG BRAIN. J.V.A. Choate\*, P.B. Connolly and J.A. Resko. Dept. of Physiology, Oregon Health Sciences Univ., Portland, OR 97201, Oregon Reg. Primate Res. Ctr., Beaverton, OR 97006.

We studied the effects of androgen removal on cytosolic (ARc) and nuclear (ARn) androgen receptor dynamics by measuring ARc and ARn levels in preoptic area, septum, medial basal hypothalamus (MBH), amygdala and cortex at different times after castration (Cx, 12 hrs, 1, 2, 3, 5, 7, 10 and 14 days). We compared these results with those from other androgen sensitive tissues, prostate and seminal vesicle. Receptor content was measured by a binding assay using 3Hdihydrotestosterone as a ligand and radioinert methyltrienolone to determine nonspecific binding. In accessory organs of reproduction, ARc was elevated over intact levels at all time periods studied (p<0.05). In brain, only MBH showed elevated ARc content at one time period (3 days post castration). ARn levels, however, declined significantly (p < 0.05) in peripheral tissues and all brain areas, except cortex, at all times after castration. These data provide evidence for a differential effect of androgen withdrawal on AR in target tissues. Differences in the response of brain and peripheral tissues to Cx show up primarily in ARc dynamics. Supported by NIH grants: T32 HD07133 and HD18196

COLOCALIZATION OF ESTROGEN-CONCENTRATING CELLS AND CRF-LIKE IMMUNOREACTIVE NEURONS IN THE MOUSE PVN. K.D.R. Morton\*, M.S. Brownfield and N.J. MacLusky. Dept. of OB/GYN, Univ. of Toronto, Toronto, Ontario M5G 1L7 and Dept. Comp. Biosciences, Univ. of Wisconsin, Madison, WI.

Stimulation of hypothalamic corticotropin-releasing factor (CRF), by stress or other factors, suppresses gonadotropin release. This is mediated, in part, via opioid inhibition of GnRH from the hypothalamus. CRF mRNA in the parvocellular paraventricular nucleus (PVN) varies during the estrous cycle of the female rat, with a significant increase in CRF mRNA levels during the afternoon of proestrus, corresponding with the estrogen-induced ovulatory surge of LH (Bohler et al., 1990). Our studies (Walters et al., 1990) have shown populations of estrogen-concentrating cells in the PVN in mouse brain. These results suggest a role for estrogen as a neuromodulator for CRF. Female CD-1 mice were OVX and given i.c.v. estrogen as a neutrinocolous of the state o injection of DES (1 μg/μl) prior to MIE<sub>2</sub>. Coronal sections (10 μm) were thaw-mounted onto slides precoated with Kodak NTB-3 photographic emulsion. The slides were exposed for 7 days, developed with Kodak D-170 (neutral pH), then immediately immunostained using a primary antibody for CRF (gift of Dr. Mark Brownfield, Madison, WI) and a Vectastain Elite kit. Our findings do not show an extensive colocalization of estrogen-concentrating cells and CRF-like immunoreactive neurons throughout the PVN. However, there are scattered cells within the medial and lateral parvocellular subdivisions of the PVN which show colocalization, and a substantial number in the ventral, periventricular aspects of the PVN. These findings are in agreement with Bohler et al., where the described changes in CRF mRNA message were restricted to the ventral regions of the PVN. Supported by MRC Canada PG11115

### 53.14

ETHANOL EFFECTS ON NUCLEAR ANDROGEN RECEPTORS IN THE HYPOTHALAMUS AND PITUITARY GLAND IN MALE RATS. K.W. Chung and D. J. Gower.\* Dept. Anat. & Surgery, Univ. Okla., Okla. City, OK 73190

The present study was undertaken to investigate ethanol-induced and castration-induced changes in the concentration of nuclear androgen receptors in the hypothalamic(H)-pituitary(P) unit. Young adult male rats were pair fed for 3 months a nutritionally complete liquid diet containing ethyl alcohol (36% of total calories) or an identical liquid diet with the isocaloric substitution of sucrose for ethanol. Rats were castrated and implanted subcutaneously with a 50 mg testosterone pellet 2 weeks prior to being sacrificed. The nuclear androgen receptor contents of the P and H were measured by cell nuclear exchange assay. Scatchard analysis revealed that mean values of androgen receptors of the P and H were significantly altered in ethanol-fed rats (93.4  $\pm$  8.7 and 72.3  $\pm$  6.3 fmol/mg DNA, respectively), when compared to values from the isocaloric controls (182.4  $\pm$  16.7 and 116.8  $\pm$  10.3 fmol/mg DNA). Also, castration decreased the nuclear receptor binding of the P (3.4  $\pm$  0.3 fmol/mg DNA) and the H (6.8  $\pm$  0.5 fmol/mg DNA) in controls. Treatment of castrated control mals with testosterone increased binding sites to 167.6 ± 15.4 fmol/mg DNA for the P and 104.7 ± 9.8 fmol/mg DNA for the H. However, testosterone given to castrated ethanol-fed rats did not significantly alter testosterone given to eastrated ethanol-red rats du not significantly after ethanol-induced reduction of the nuclear receptor sites. Dissociation constants of the 3<sup>11</sup>R1881-receptor complex are similar in all groups. These findings indicate that ethanol not only exerts a suppressive effect on the nuclear receptor contents of the H and P but also inhibits the castration-induced change in the receptor binding sites.

## NEUROENDOCRINE REGULATION: PROLACTIN

## 54.1

REGULATION OF PROLACTIN-RECEPTOR AND PROLACTIN-RECEPTOR mRNA BY HUMAN GROWTH HORMONE AND GLUCOCORTICOID IN MOUSE LIVER. J.R. Dave, T. Dang, P. Bednarek, E.W. Mougey\* and E.W. Bernton. Departments of Medical Neurosciences and Bacterial Disease, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Earlier studies have demonstrated an up-regulation of hepatic prolactin binding sites with ovine prolactin (oPRL) or human growth hormone (hGH) treatment and down-regulation with glucocorticoid (GC) treatment in vivo. We have demonstrated that the up-regulation of hepatic prolactin binding following lactogenic hormone treatment may be due to an increase in membrane fluidity. The objective of this study was to determine if hGH and GC treatment had any effect on prolactin receptor mRNA in mouse liver. Adult female C3H mice were treated with vehicle. hGH (24 up/day) or dexamethasone (50 up/day) for 72. with vehicle, hGH (24 μg/day) or dexamethasone (50 μg/day) for 72 hr. Using the reverse transcriptase/polymerase chain reaction (RT/PCR) technique and specific forward and reverse oligonucleotide PCR primers (representing a total of 390 nucleotides including the entire transmembrane region of the prolactin receptor gene), hepatic RNA samples were amplified, and the Southern blots hybridized with a <sup>32</sup>Plabeled oligonucleotide probe. Glucocorticoid treatment decreased both prolactin binding activity and prolactin receptor mRNA levels in liver. However, hGH treatment increased prolactin binding activity without affecting prolactin receptor mRNA levels. These findings suggest that the effect of GC on down-regulation of prolactin binding activity may be at the transcription level, however, hGH mediated up-regulation of prolactin binding activity may be a membrane-associated phenomenon.

## 54.2

EFFECTS OF FEED RESTRICTION ON MAMMARY TUMOR GROWTH AND HYPOTHALAMIC NEUROTRANSMITTERS IN RATS. S. Thyagarajan\* and S.K. Quadri. Kansas State University, Manhattan, KS 66506.

Restriction of feed intake inhibits the growth of dimethylbenzanthracene (DMBA)induced mammary tumor in rats and this effect can be blocked by treatment with estrogen (E) and haloperidol (HAL). Although feed restriction is known to affect the neurotransmitter (NT) metabolism in the brain, the exact mechanism of this effect on mammary tumor growth and its blockade by E and HAL are not known. The purpose of this study was to investigate the long-term effects of feed restriction with or without simultaneous treatment with E and HAL on hypothalamic NT and mammary tumor growth. Sprague-Dawley female rats with DMBA-induced mammary tumor were full fed (FF), half fed (HF), or HF and treated with estradiol benzoate (EB) and/or HAL for a duration of 15 weeks. Mammary tumor diameter was determined every week. The concentrations of NT were determined in the medial basal hypothalamus at the end of the treatment period by HPLC-EC. They are expressed in terms of per μg protein. The average tumor diameter increased by 213±88% (Mean±S.E) in the FF rats during 15 weeks period whereas, it decreased by 81±13% in the HF rats (p<0.001). In contrast to HF rats, the tumor diameter increased by 83±36% in HF+EB, 42±23% in HF+HAL, and 43±11% in HF+EB+HAL rats (p<0.05). The hypothalamic dopamine (DA) concentration increased (p<0.01) in the HF (21.5±0.5 pg) compared to that in the FF (19.1±0.4 pg) rats. In contrast to HF rats, DA concentration decreased to 18.5±0.5 pg in the HF+HAL and to 15.7±0.5 pg in the HF+EB+HAL (p<0.01) rats. The concentration of serotonin was 133.4±17.6 pg in the FF and 78.2±10.7 pg in the HF (p<0.05) rats. Compared to the HF serotonin concentration increased to 120.2±12.2 pg in the HF+HAL rats (p<0.05). These results suggest that long-term treatment with E and HAL increases the growth of mammary tumors in dietary restricted rats through alterations in the concentration of hypothalamic NT. (Supported by NIH grant AG 05980)

STIMULATION OF A PROTEIN TYROSINE PHOSPHATASE (PTP) AS A POSSIBLE INTRACELLULAR MECHANISM FOR DOPAMINE ANTIPROLIFERATIVE EFFECTS. T. Florio. M.-G. Pan. O. Civelli\* and P.J.S. Stork. Vollum Institute for Advanced Biomedical Research, OHSU, Portland, OR 97201, USA. Dopaminergic agonists are largely used in the pharmacological treatment of GH or PRL secreting pituitary adenomas. In this report we studied the possible mechanisms of action of DA in the control of cell proliferation in a transfected tumor nituitary cell

control of cell proliferation in a transfected tumor pituitary cell line, GH<sub>4</sub>ZR7, expressing high levels of the short form of dopamine  $D_2$  receptor. Dopamine (DA) (100 nM-10  $\mu$ M) inhibited DNA synthesis, measured as [3H]-thymidine uptake, in a dose-dependent manner. This effect was completely abolished by pretreating the cells with the D<sub>2</sub> receptor antagonist haloperidol, with pertussis toxin or with vanadate, a selective PTP inhibitor. with pertussis toxin or with vanadate, a selective PTP inhibitor. These results suggest that the stimulation of a PTP activity could be responsible for the DA effects on DNA synthesis. In fact, in GH<sub>4</sub>ZR7 membranes, DA (50 nM-10 μM) stimulated a PTP activity, as measured by using the synthetic substrate parantirophenol phosphate. This effect was also reverted by haloperidol, pertussis toxin and vanadate.

These results show that DA is able to decrease cell proliferation in GH<sub>4</sub>ZR7 cells and suggest that DA activation of PTP activity could represent one of the intracellular mechanisms mediating this

could represent one of the intracellular mechanisms mediating this

### 54.5

QUANTIFICATION OF TYROSINE HYDROXYLASE-IMMUNOREACTIVE TUBEROINFUNDIBULAR NEURONS IN THE HYPOTHALAMUS OF ADULT AND DEVELOPING AMES DWARF MICE. C.J. Phelps, M.Y. Vaccarella, D.L. Hurley\*. Dept. Anatomy, Tulane Univ. Sch. Med., New Orleans, LA 70112. Dopam:nergic (DA) neurons in the hypothalamic arcuate nucleus (ARC) tonically inhibit pituitary prolactin (PRL) secretion. Ames dwarf (df/df) mice, which produce

nimitary prioractin (rex) secretion. After Swari (urba) mice, which produce no PRL, have a reduced number of ARC tyrosine hydroxylase (TH)-immunoreactive neurons (Morgan and Besch, Neuroendocrinology, 1990). In order to quantify whether this deficit in adult dwarfs is present at birth or regresses during development, immunocytochemically stained DA/TH cells were counted in zona a incerta (ZI, A13), periventricular region (A14), and ARC (A12) at 180 µm intervals in coronal sections through the hypothalamus of dwarf and normal sibling (DF/?) mice 7, 14, and 21 days, and 2-16 months, of age. At 7, 14, and 21d, TH+ cell numbers were comparable for DF/? and df/df and increased dramatically (to 2-3X at 21d compared with counts at 7d) in A13, A14, and A12; the developmental increase was smallest in ZI. Between 21d and 2 mos, both DF/? and df/df showed a decrease in A12 TH+ neurons, which was significant in dwarfs (p<0.02), and at 2 mos, ARC TH+ cells in df/df were significantly less (p<0.005) in number than in DF/?. Total ARC TH+ cell numbers are shown below.

| mouse type / age:  | _7d            | 140            | 21 d                | 2-4 mo.         |  |  |
|--|----------------|----------------|---------------------|-----------------|--|--|
| DF/? (n=6-10)  | 918±137        | 2107±311       | 3306±572            | 2387±136        |  |  |
| df/df (n=6-10)   | 1095±200       | 1425±251       | 2707±437            | 1176±277        |  |  |
| In adults (4 -16 m.  | o.), both A14  | (p<0.05) and A | 12 (p<0.001) group  | ps showed fewer |  |  |
| TH+ cells in dwarf   | s; TH cells in | ZI numbers wer | e not significantly | reduced. Gender |  |  |
| differences were not significant. Adult total TH+ neurons are shown below. |                |                |                     |                 |  |  |
| mouse type / neur  | on group:      | Δ13            | Δ1/4                | Δ12             |  |  |

| mouse type / neuron group; | A13      | A14      | A12      |
|----------------------------|----------|----------|----------|
| DF/? (n=17)                | 1818±186 | 4245±485 | 2710±292 |
| df/df (n=13)               | 1443±134 | 2580±434 | 1315±147 |

The results imply that absence of PRL is related to decreased TH expression in A12; A14 may also be involved in this developmental regression in DA PRL-regulating neurons. Supported by PHS grant NS25987 (CJP).

## 54.7

SEROTONIN-INDUCED INHIBITON OF TYROSINE HYDROXYLASE (TH) ACTIVITY AND STIMULATION OF PROLACTIN (PRL) RELEASE ARE ABOLISHED AT MIDPREGNANCY. Joanne R. Mathiasen\* and James L. Voogt Department of Physiology, University of Kansas Medical Center

ABOLISHED AT MIDPREGNANCY. Joanne R. Mathiasen' and James L. Yoogt Department of Physiology, University of Kansas Medical Center Kansas City, KS 66103

We investigated the effect of central serotonin (5-HT) administration on hypothalamic tuberoinfundibular dopamine (TIDA) neurons and related the changes to plasma PRL levels in two physiological models: 1) pregnant rats on days 8, 11 and 16; and 2) ovariectomized (OVX) rats injected under the kidney capsule with rat choriocarcinoma (Rcho) cells, which secrete placental lactogen-I. Rats were given 5-HT (20 μg/6 μl) through a lateral ventricular cannula and blood samples were taken at various times for PRL RIA. NSD 1015 (25 mg/kg 1.a.), a dihydroxyphenylalanine (DOPA) decarboxylase inhibitor, was injected at 20 min. Ten min later, rats were killed and the stalk-median eminence (SME) was dissected. The rate of DOPA accumulation as a measure of TH catalytic activity was determined by measuring DOPA levels in the SME by HPLC. DOPA accumulation in 5-HT-treated rats on day 8 of pregnancy was significantly (p-0.05) reduced to 57% of vehicle-treated controls. This decrease in DOPA accumulation correlated with a 13-fold increase in PRL levels. In contrast, on days 11 and 16 of pregnancy, SME DOPA accumulation and PRL levels were unchanged following 5-HT treatment. In vehicle-treated OVX rats, DOPA accumulation in the SME was 41.9±8.5 ng/mg protein. 5-HT treatment significantly (p-0.05) decreased DOPA accumulation in the SME to 18.2±2.0 ng/mg protein, and increased PRL levels 26-fold. In OVX rats injected with Rcho cells, 5-HT treatment produced no changes in either SME DOPA accumulation or circulating PRL levels compared to OVX controls. These data suggest that the presence of placental lactogens beginning at mid-pregnancy, may terminate the 5-HT-induced decrease in TIDA neuronal activity and corresponding increase in plasma PRL levels present in early pregnancy. present in early pregnancy

PROLACTIN TREATMENT DURING DEVELOPMENT IN AMES DWARF MICE INCREASES DOPAMINE HISTOFLUORESCENCE AND TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN VENTRAL HYPOTHALAMUS. M.I. Romero, C.J. Phelps.\* Neurosciences Training Program and Department Anatomy, Tulane University School of Medicine. New Orleans, LA 70112.

Anatomy, Tulane University School of Medicine. New Orleans, LA 70112.

Under physiological conditions, pituitary prolactin (PRL) secretion is tonically inhibited by hypothalamic dopamine (DA). Dwarf mice (Snell and Ames) do not produce PRL, are nearly totally DA deficient in the median eminence (ME), and arcuate nucleus (ARC) tyrosine hydroxylase (TH) immunoreactivity is reduced compared with normal phenotypic litermates. PRL treatment in adult dwarfs has failed to increase DA levels in the ME (Morgan et al., Endocrinology, 1981) or significantly increase the number of TH neurons in ARC (Morgan and Besch, Neuroendocrinology, 1990). In the present study we tested the possibility that PRL feedforward effect on the DA neurons in the tuberoinfundibular region is essential during development in order for the neurons to synthesize DA. Ames dwarf and normal sibling mice were treated daily with 50 µg of PRL ip. for 30 days starting at 12 days olf; at 42 d anesthetized animals were perfused transcardially with paraformaldehyde (4%)-glutaraldehyde (0.5%) to induce histofluorescence; brains were sectioned coronally at 30 µm using a vibratome. TH immunocytochemistry was performed on floating sections and cell numbers in ARC were recorded. In agreement with previous studies, untreated dwarf mice showed almost no DA fluorescence in ME external zone and TH cells in ARC were about 40% of normal siblings, accompanied by a decrease in TH untreated dwarf mice showed almost no DA fluorescence in ME external zone and TH cells in ARC were about 40% of normal siblings, accompanied by a decrease in TH staining intensity in ME. PRL treatment increased the intensity of DA fluorescence in ARC and ME to a level comparable to normal mice, and TH-positive cell numbers in ARC were similar to normal values. Although TH ARC cell numbers in PRL-treated normal mice did not show a significant change compared with untreated mice, the staining intensity of the TH fibers in ME was clearly increased. No differences according to sex were found. The data suggest that target hormone secretion is necessary for full development of CNS pitutary regulatory neurons. Supported by PHS grant NS25987 (CJP).

### 54.6

USE OF RECEPTOR ANTIBODIES TO CHARACTERIZE PROLACTIN RECEPTORS IN THE RING DOVE BRAIN. <u>C. Li¹, P. A. Kelly², and J. D. Buntin.¹</u> Dept. of Biological Sciences, UW-Milwaukee, Milwaukee, WI 53201¹, and INSERM Unite 344 (Endocrinologie Moleculaire), 75730 Paris Cédex 15, France<sup>2</sup>.

Central administration of prolactin(PRL) has been shown to inhibit gonadotropin secretion and to facilitate food intake and parental behavior in ring doves. In addition, PRL receptors have been mapped in ring dove brain by in vitro autoradiography. In nt study, the characteristics of PRL receptors were examined in binding studies using a polyclonal antiserum generated in rabbits against rat liver prolactin receptors. A purified gamma globulin (IgG) fraction of the antiserum was first obtained using protein A affinity chromatography. Frozen dove brain sections were then slide mounted and incubated with <sup>12</sup>I-ovine PRL plus receptor antibody, <sup>12</sup>I-ovine PRL plus an IgG fraction obtained from normal rabbit serum, or <sup>12</sup>I-ovine PRL plus excess unlabelled PRL and normal rabbit serum IgG. After washing, sections were dried and apposed to Kodak SB-5 film. Densitometric analysis of autoradiographs revealed that receptor antibody concentrations of 1.2x106 M to 5.76x10.7 M inhibited the specific binding of labelled PRL by 40% to 50% in the choroid plexus, lateral septal area, the ventromedial, suprachiasmatic, and paraventricular nuclei of the hypothalamus, and the area surrounding the paraventricular organ. The tuberal region of the hypothalamus showed approximately 20% inhibition of specific binding with the same antibody concentration. No significant inhibition was observed with  $1.2 \times 10^7 \, \mathrm{M}$  or  $5.76 \times 10^8 \, \mathrm{M}$  concentrations of antibody. This study suggests structural similarities between the dove brain and rat liver PRL receptors and offers a methodological tool for examining the action of centrally administered PRL in vivo (supported by NIMH grant MH41447).

## 54.8

EFFECTS OF DOPAMINE (DA) ON PROLACTIN (PRL) SECRETION AND CYTOSOLIC CALCIUM CONCENTRATIONS IN A CLONAL PITUITARY CELL LINE EXPRESSING THE SHORT FORM OF THE D2 RECEPTOR. T.P.Burris\* and M.E.Freeman. Dept of Biol Sci, Fl St Univ, Tallahassee, 32306.

GH<sub>4</sub>C<sub>1</sub> cells are rat somatomammotrophs which lack DA receptors. We have examined the ability of DA to modulate both basal and TRH stimulated PRL secretion and cytosolic calcium concentrations in  $\mathrm{GH_4C_1}$  cells stably transfected with the cDNA for the short form of the rat DA D2 receptor ( $\mathrm{GH_4ZR_7}$  cells). Cells were plated on 96-well microtiter plate and challenged with various concentrations of DA and/or TRH for 6 hrs. Fura-2 was used to estimate changes in cytosolic calcium concentrations by single cell microfluorimetry. Twenty to 30 cells were recorded simultaneously and challenged with various concentrations of DA and/or TRH. DA (0.1 pM - 10  $\mu$ M) had no effect on PRL secretion or cytosolic calcium in GH<sub>2</sub>C, cells. However, DA at concentrations of 1 and 10  $\mu$ M significantly inhibited basal PRL secretion 25% and 36% respectively in GH ZR, cells. Ten  $\mu$ M DA completely reversed the stimulatory effects of TRH (10 nM - 1  $\mu$ M) on PRL secretion and 1  $\mu$ M DA significantly attenuated the effects of TRH in these cells. Concentrations of DA lower than 1 µM had no effect on basal or stimulated PRL secretion. Basal cytosolic calcium concentrations were undisturbed by any concentration of DA. However, DA at concentrations of 100 nM and greater completely inhibited TRH induced increases in cytosolic calcium. A D2 receptor intagonist, Eticlopride (1 µM), completely blocked the ability of DA to inhibit the TRH-induced increase in cytosolic calcium. These data indicate that the short form of the D2 receptor when expressed in GH<sub>4</sub>C<sub>1</sub> cells is able to mediate DAergic inhibition of basal PRL secretion by a mechanism which does not acutely alter basal cytosolic calcium concentrations. This receptor also mediates DAergic inhibition of TRH-stimulated PRL secretion by a mechanism which inhibits TRH-stimulated increases in cytosolic calcium. Supported by NIH, DK-43200.

THE 5-HT<sub>3</sub> ANTAGONIST ONDANSETRON ATTENUATES P-CHLOROAMPHETAMINE-INDUCED ELEVATION OF PROLACTIN, BUT NOT CORTICOSTERONE, RENIN, OR OXYTOCIN SECRETION. A.D. Levy\*, P.A. Rittenhouse, J.E. Kerr, M.S. Brownfield & L.D. Van de Kar, Dept. Pharmacology, Loyola Univ. Chicago, Maywood, IL 60153 and Dept. Comparative Biosciences, Univ. Wisconsin, Madison, WI 53706.

Serotonin (5-HT) containing neurons in brain mediate the secretion of many hormones. The roles of the 5-HT receptor subtypes 5-HT<sub>1A</sub>, 5-HT<sub>1B</sub>, 5-HT<sub>1C</sub> and 5-HT<sub>2</sub> have been previously studied, and have differential influence on the secretion of ACTH/corticosterone, prolactin, renin and oxytocin (see Van de Kar Ann. Rev. Pharmacol. Toxicol. 31:289, 1991 for review). This study examined whether pretreatment with the 5-HT<sub>3</sub> antagonist ondansetron (GR 38032F) would modify the stimulation of corticosterone, prolactin, renin, or oxytocin secretion, induced by the 5-HT releaser p-chloroamphetamine (PCA). Adult, male Sprague-Dawley rats (N=8/group) were administered ondansetron (0, 0.1, or 1 mg/kg i.p.) 30 minutes prior to PCA (0, 3, or 8 mg/kg i.p.) injection. Rats were sacrificed 1 hr after PCA for blood collection. Plasma concentrations of corticosterone, prolactin, renin, and oxytocin were determined by radioimmunoassay. The 5-HT releaser PCA increased secretion of all of these hormones (p<.001). The 5-HT<sub>3</sub> antagonist ondansetron (1 mg/kg) reduced the PCA (3 mg/kg)-induced stimulation of plasma prolactin concentration by 51% (p<.05, Duncan's post-hoc test). In contrast, the PCA-induced stimulation of corticosterone, renin and oxytocin secretions were not altered by ondansetron pretreatment. Furthermore, ondansetron administration alone (i.e. in rats receiving the 0 dose of PCA) did not alter plasma concentrations of any of the hormones examined. The data suggest that the serotonergic stimulation of prolactin secretion is partially mediated by 5-HT<sub>3</sub> receptors. The data also suggest that 5-HT<sub>3</sub> receptors are not likely to be involved in the serotonergic stimulation of corticosterone, renin or oxytocin secretions. (Supported by DAO4865 and MH45812).

NEURONS IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS (PVN) MEDIATE THE SEROTONERGIC STIMULATION OF PROLACTIN (PRL) SECRETION. P.A. Rittenhouse\*, A.D. Levy, Q. Li, & L.D. Van de Kar. Dept. Pharmacology, Loyola University Chicago, Maywood, IL 60153.

These studies examined the hypothalamic site regulating serotonergic (5-HT)

rontrol of PRL secretion in male rats. Initially, we characterized the pharmacology of the drugs utilized. The 5-HT uptake inhibitor fluoxetine significantly impaired the ability of the 5-HT releaser *p*-chloroamphetamine (PCA, 8 mg/kg, ip) to stimulate PRL secretion, demonstrating that PCA increases PRL *via* a 5-HT mechanism. Next, the ability of the 5-HT agonist, RU 24969, (0.5, 1, 5, 10 mg/kg, ip) to elevate PRL secretion was potentiated by pretreatment with the 5-HT synthesis inhibitor, *p*-chlorophenylalanine, suggesting that RU 24969 stimulates PRL secretion through post-synaptic action. RU 24969 was then injected either centrally through chronic intracerebroventricular (icv) cannulae or peripherally (ip). Rats were pretreated with the 5-HT<sub>ICZ</sub> antagonist LY53857 (icv). The PRL response was significantly inhibited by LY53857 if RU 24969 was injected ip, but not icv. However, RU 24969 injected icv significantly stimulated PRL secretion at doses 500 fold lower than the peripherally effective doses (10 μg/kg vs 5 mg/kg), suggesting a role for central 5-HT receptors in the regulation of PRL regulation. Lastly, a series of lesion experiments were performed using the cell-selective neurotoxin ibotenic acid. Ibotenic acid was injected (3 μg/0.3 μl) bilaterally into the hypothalamic PVN, dorsomedial, ventromedial, or supraoptic nuclei lesions. In contrast, rats with histologically confirmed lesions in the PVN had a significantly lower PRL response to both RU 24969 (5 mg/kg, ip) and PCA (8 mg/kg, ip). These data suggest that cell bodies in the PVN are necessary to mediate the 5-HT regulation of PRL. Supported by AHA Chicago, MH45812 and DA04865.

## HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: LHRH AND LH I

#### 55.1

GnRH-GnRH Neuronal Associations in Primate and Rodent Brain. J.W. Witkin.\* M. Ferin and A.-J. Silverman. Dept. Anatomy and Cell Biology, Columbia Univ. Coll.. P&S., New York, NY 10032.
Gonadotropin-releasing hormone (GnRH) is secreted in rhythmic bursts, a mode which is essential to drive the pulsatile secretion of gonadotropins.

There is increasing evidence that GnRH neurons themselves may be intrinsically pulsatile, however the synchronization of their release is not understood. We hypothesize an anatomical substrate. In a light microscopic study the brains of cycling rats (n=17) and ovariectomized rhesus monkeys with gonadal steroid replacement (n=3) were examined for the occurrence of GnRH neurons which were in apposition. In the rats the frequency was between 1.7% and 6.8% and in monkeys, between 3% and 9.3%, with examples throughout the anatomical distribution of GnRH neurons in both species. The frequency was independent of the phase of the estrous cycle. To examine the nature of these appositions, two GnRH neurons from the MBH of one monkey were serially sectioned and examined ultrastructurally. A computerized reconstruction revealed that each cell received a modest synaptic input (5 and 9 terminals,respectively), none of which was GnRH+. There were several regions where other neuronal or glial elements were not interposed between the processes of the GnRH cells. In some of these areas it appeared that cell membranes no longer intervened between the processes, suggesting that the two cells formed a syncytium. A neural network formed by anastomosing processes, highly novel within the CNS (and requiring confirmation), could provide the basis for synchronization of neurohormonal release. NIH DK42323

THE NUMBER OF LUTEINING HORMONE RELEASING HORMONE (LHRH)- CONTAINING NEURONS INCREASES IN RESPONSE TO GLUCOCORTICOID ADMINISTRATION. X, Huang and R, E, Harlan\*. Dept. of Anatomy, Tulane Med. School, New Orleans, LA 70112. Endogenous or exogenous glucocoticoid excess can lead to the development of

Endogenous or exogenous glucocoticoid excess can lead to the development of hypogonadism. The present study investigated the effects of glucocoticoid on the number of LHRH-containing neurons in the central nervous system of 10 adult intact male rats. Glucocorticoid capsules (200 mg releasing 10 mg/day) were implanted subcutaneously in 5 rats and placebo capsules in another 5 rats for 1 week. Immunocytochemistry with the LR1 antibody (gift of R. Benoit) was used to determine the number of LHRH-containing cells in the brain. Sections which contained LHRH neurons were examined and the number of immunopositive neurons per section was determined. It was found that the total number of LHRH-immunoreactive neurons in placebo-treated rats. The increase in the number of immunoreactive neurons in placebo-treated rats. The increase in the number of immunoreactive neurons was predominantly localized in the region surrounding the organum vasculasum lamina terminalis (OVLT), where the cell number doubled. These results suggest that glucocorticoid regulates LHRH content. However, whether the production and/or inhibition of release of LHRH is modified by glucocorticoid has yet to be established. In order to characterize the effects of glucocorticoid on LHRH immunoreactivity in females, 5 pairs of adult female rats were similarly implanted with glucocorticoid or placebo capsules one week after ovariectomy. No differences were found either in the total number of LHRH-containing neurons or the number of neurons in the OVLT regions of females that received glucocorticoid or placebo treatment. While this study is limited to examing these effects in ovariectomized rats, further investigation of this phenomenon in intact female rats may support the differential regulation of LHRH in males and females by glucocorticoids. Supported by Grant NS-24148.

ROSTRAL MEDIAN EMINENCE IS THE SITE OF DYNAMIC CHANGES IN THE ULTRASTRUCTURE OF GONADOTROPIN-RELEASING HORMONE (GNRH) TERMINALS DURING THE GNRH SURGE IN THE EWE. J.-J. Xiong\*S.M. Moenter.F.J. Karsch.and M.N. Lehman. Univ. Cincinnati, Dept. Anat. & Cell Biol., Cinti, OH 45267; Univ. Mich., Reprod. Sci. Prog., Ann Arbor, MI 48109.

Direct measurement of GnRH in portal blood in sheep has shown that the preovulatory gonadotropin surge is due to a simultaneous explosive release of GnRH by axon terminals in the median eminence (ME). We previously found that following the GnRH surge there is a striking decrease in the number and mean diameter of immunoreactive GnRH terminals in the median eminence (Xiong et. al., Biol. Reprod., 42, suppl.1:102). Since earlier studies implicated GnRH terminals in the rostral-mid ME as being specifically required for the surge (Polkowska et al., Cell. Tiss. Res. 208:327), we compared the ultrastructure of GnRH terminals in the rostral, mid, or caudal ME between luteal phase and post-surge ewes. Intact cycling Suffolk ewes were cranially perfused during either days 5-13 of the luteal phase (n=4) or 11-32 hours after the onset of the preovulatory LH surge (n=4). Hypothalami with pituitary stalk attached were embedded in gelatin, and vibratome sections were processed for electron microscopic immunodetection of GnRH. Region-specific ultrastructural differences were observed between groups. In the rostral ME there was a reduction in the mean area of GnRH terminals, the number of GnRH secretory granules per terminal, and the percentage of GnRH terminals containing secretory granules in postsurge compared to luteal phase ewes. In the mid ME the difference was confined to a reduction in the percentage of GnRH terminals containing secretory granules in the post-surge group. In the caudal ME no group differences were observed. These results suggest that dynamic changes in GnRH terminal ultrastructure accompany the GnRH surge, changes that are largely confined to terminals in the rostral ME. EFFECT OF CASTRATION ON PUBERTAL DEVELOPMENT OF GNRH PROJECTIONS TO THE MEDIAL BASAL HYPOTHALAMUS OF THE MALE DJUNGARIAN HAMSTER. K.L. Buchanan\* and S.M. Yellon. Div. Perinatal Biol, Depts. Physiol, Peds, Anat, Loma Linda Univ Sch of Med, Loma Linda, CA 92350.

In the male Djungarian hamster, evidence suggests a decrease with sexual maturation in the number of GnRH neurons that directly project to the medial basal hypothalamus (Biol Reprod 46 Suppl: #499, 1992; Soc Neurosci Abstr 17: #387.15, 1991). To test the hypothesis that the decline in GnRH neuronal input to the medial basal hypothalamus at the onset of puberty does not depend upon the testes, prepubertal males were castrated (n=6) or sham-operated (n=6) at At 25d, hamsters were perfused intracardially with 4% paraformaldehyde. Brains were removed and crystals of Dil, a fluorescent tract tracer, implanted directly into the median eminence. After 8 weeks, brains were sectioned (60  $\mu$ m) and GnRH cells labelled by immunofluorescence. Similar to earlier reports, GnRH-immunofluorescent cells were morphologically bipolar or unipolar and present in a 2:1 ratio; both subtypes were labelled with DiI, i.e., projected to the medial basal hypothalamus. GnRH soma that contained Dil were located primarily in the medial preoptic area (28% of 150), septum (50% of 44), and diagonal band of Broca (51% of 40). Fewer DiI-labelled GnRH cells were found in lateral preoptic and hypothalamic areas. Irrespective of treatment, the number, subtype ratio, and neuroanatomical distribution of GnRH cells and those labelled with Dil were similar in castrated and sham-operated males. The data suggests that both bipolar and unipolar GnRH neurons in the rostral medial forebrain constitute the major GnRH input to directly control pituitary gonadotropin secretion in the male Djungarian hamster. Furthermore, removal of the testes, i.e., absence of gonadal steroid feedback, does not influence the development of GnRH innervation of the medial basal hypothalamus during sexual maturation. (Supported by NIH HD22479)

SOCIAL/BEHAVIORAL REGULATION OF GNRH-IR. E.F. Rissman\* and T.L. Dellovade. Departments of Biology and Psychology, NSF Center for Biological Timing, University of VA, Charlottesville, VA 22901.

Gonadotropin releasing hormone (GnRH) is produced by a small and discreet population of neurons in the brain. Its production and pulsatile secretion from terminals located in the median eminence are regulated by the brain-pituitary-gonad feedback loop. In addition, synthesis and release of GnRH are influenced by environmental variables (eg photoperiod, nutrition, pheromones). We examined the role of the social/behavioral environment on GnRH immunoreactivity (GnRH-ir) in the female musk shrew, Suncus murinus. Virgin females exposed to a male across a screen barrier for 48 hours, had 40% more positive GnRH-ir neurons in the forebrain as compared to control females housed alone. If females mate once and are sacrificed 48 hours later, counts of GnRH-ir neurons differ depending upon whether or not ovulation occurred. Mated females that did not ovulate had 40-50% more GnRH-ir neurons in the forebrain as compared to mated, ovulated females, and virgins. These data suggest that exposure to a male primes the GnRH producing neurons for subsequent synthesis and release of GnRH before ovulation. This degree of environmentally induced plasticity in the production of GnRH has not been observed before in a mammal. Supported by NSF grants BNS 9021226 and DIR 8920162.

ELECTRON MICROSCOPIC STUDIES ON CO-CULTURES OF IMMORTALIZED HYPOTHALAMIC LHRH NEURONS AND PRIMARY OR IMMORTALIZED ANTERIOR PITUITARY CELLS. 2s. Liposits: ½ W. Wetsel², J.J. Reid², I. Merchenthaler², P.L. Mellon², A. Negro-Vilar². Dept. of Anat., Univ. Med. Sch., Pécs, Hungary, H-7643; ²Lab. of Molec. & Integrative Neurosci., NIEHS, Research Triangle Park, NC, 27709; ¹Dept. of Reprod. Med., UCSD, La Jolla, CA 92092.

Recently, genetic targeting of tumorigenesis has been used to immortalize hypothalamic LHRH neurons (CTl-7 cells; Neuron 5:1, 1991) and pituitary cells (QT3-1 cells) which express the α subunit of the glycoprotein hormones (Mol. Endocrinol. 4:597 1990). CTl-7 cells were co-cultured with either primary pituitary or QT3-1 cells to study the architecture, organization and interaction among these cells. All cells contained well-developed, active protein synthesizing apparatus and displayed mature secretory granules. CTl-7 neurons established direct contacts (primarily tight junctions) with gonadotrophs and QT3-1 cells. Co-cultures with GTl-7 cells stimulated hypertrophy of rough endoplasmic reticulum in both gonadotrophs and QT3-1 cells, presumably due to a stimulatory effect of LHRH. These data indicate that (1) immortalized LHRH cells are compatible with both primary and immortalized LHRH cells are compatible with both primary and immortalized LHRH cells stimulate cellular responses within gonadotrophs which are compatible with their underlying physiological role in regulating mammalian reproduction. Co-culture of immortalized LHRH and pituitary cells may provide a useful model to study the morphology, physiology and electrophysiology of cell-to-cell communication between hypophysiotropic neurons and pituitary cells. (Supported by grants from the NIH Intramural Program, and DK44838 & HD20377.)

CHARACTERIZATION OF CYTOSOLIC Ca2+ DYNAMICS IN CULTURED GIRH CHARCIERIZATION OF CYTOSOLIC Ca\*\* DYNAMICS IN COLTURED GIRH SECRETING GT1-7 NEURONS. Martin A. Javors,\* Thomas S. King, Stephen D. Samuelson, Xiaoying Chang and Robert S. Schenken, Departments of Psychiatry, Pharmacology, CSB and OB-GYN, The University of Texas Health Science Center, San Antonio, TX 78284.

Gonadotropin releasing hormone is a decapeptide that is synthesized and released from neurons in the hypothalamus. By regulating the secretion of pituitary gonadotropins, GnRH plays a central role in the regulation of reproductive function. Recently, immortalized GT1-7 neurons containing the promotor of the GnRH gene coupled with the coding region for the large Tantigen of the SV-40 virus have been shown to synthesize and secrete GnRH in response to depolarization (Neuron 5: 1 - 10, 1990). In view of the importance of Ca<sup>2+</sup> in secretion, we sought to characterize cytosolic Ca<sup>2+</sup> dynamics in response to K+-induced depolarization and norepinephrine (NE). GT1-7 neurons were grown and maintained in modified DMEM (Gibco, Grand Island, NY). Twenty four hours prior to the experiments, the neurons were plated on poly-lysine coated glass cover slips. The cells were then loaded with the Ca2+ chelating dye fura-2 for measurement of changes in cytosolic  $\text{Ca}^{2+}$  ([Ca^{2+}]\_c). Our results showed that K+ ranging from 15 to 60 mM increased [Ca^{2+}]\_c in a concentration-dependent manner. Resting [Ca^{2+}]\_c was 69.7  $\pm$  4 nM (n = 69). Fifteen mM K+ increased [Ca^{2+}]\_c by 102  $\pm$  16 nM (n = 10); 60 mM K+ increased [Ca^{2+}]\_c by 367  $\pm$  59 nM (n = 7). Increased [Ca^{2+}]\_c in response to 22.5 mM K+ together with 100  $\mu$ M NE (206  $\pm$  13; n = 13) was greater than 22.5 mM K+ alone (160  $\pm$  18; n = 18). These results suggest that K+-induced depolarization, which stimulates GnRH release from these neurons, increases cytosolic Ca^{2+}. The effect of NE and K+ on [Ca^{2+}]\_c appears to be additive. The relationship between increases cytosolic Ca^2+ and GnRH release in these cells is currently being studied. (Supported by NIDA grant DA 06039.) chelating dye fura-2 for measurement of changes in cytosolic Ca2+ ([Ca2+]c).

IMMUNOHISTOCHEMICAL LOCALIZATION OF cGnRH I AND cGnRH II IN THE BRAINS OF PHOTOSENSITIVE AND PHOTOREFRACTORY EUROPEAN STARLINGS AND JAPANESE QUAIL G.F. Ball\*. T.S. Juss & D. M. Parry Dept of Psychology, Johns Hopkins Univ. Baltimore, MD 21218 USA; AFRC Research Group, Dept. of Zoology, Univ. of Bristol, Bristol, U.K.

The avian brain is known to contain two forms of gonadotropin-releasing hormone (chicken GnRH I and chicken GnRH II). With the use of three antisera, (two that recognize both cGnRH I and II, and one that only recognizes cGnRH II), we examined the distribution of these two peptides in the brains of photosensitive and photorefractory European starlings and Japanese quail. In both species, immunoreactive perikarya for cGnRH II were limited to a region in the mesencephalon just dorsal to N III. In European starlings, in some cases, these cells were present in the ventral part of the midbrain central gray. Immunoreactive fibers for cGnRH II were observed in a variety of areas including the neostriatum, the dorso-medial forebrain, the lateral hypothalamus and diffuse fibers were observed in the lateral and medial parts of the intercollicular nucleus. In no case were fibers for cGnRH II observed in the median eminence, nor were cells bodies observed in regions known to project to the median In no case were ribers for Conkel II observed in the median eminence, nor were cells bodies observed in regions known to project to the median eminence. cGnRH I positive cell bodies were observed in the preoptic area, the lateral septum and the rostral-dorsal part of the paraventricular nucleus. A fiber plexus was apparent in the median eminence. In starlings, as has been previoulsy reported, there was a striking difference in the number immunoreactive cell bodies and in the density of the immunoreactive fiber plexus in the median eminence, between the photosensitive and the photorefractory birds. There was no evidence for such a difference for either fiber tract density or number of immunoreactive cells for cGnRH II. Thus, cGnRH II, as has been reported for other avian species, is not regulated seasonally and does not appear to play a role in the control of the pituitary.

REGULATION OF LHRH GENE EXPRESSION, PRO-LHRH PROCESSING AND SECRETION FROM IMMORTALIZED LHRH NEURONS. W.C. Wetsel\*1, S. Eraly², D.B. Whyte², A. Negro-Vilar¹, and P.L. Mellon<sup>2</sup>, <sup>1</sup>LMIN., NIEHS, Res. Tri. Park, NC 27709 and <sup>2</sup>Dept. of Reprod. Med., UCSD, La Jolla, CA 92093.

Activation of protein kinase A and C stimulates LHRH secreton in vitro. Since this hypothalamic preparation is heterogeneous, other neurons could mediate these effects. Our study sought to determine whether these agents can influence directly LHRH mRNA levels, pro-LHRH processing and secretion from an immortalized hypothalamic LHRH neuronal cell line (GT1-7 cells). Thirty min of 12-0-tetradecanoylphorbol 13-acetate (TPA) stimulated LHRH secretion in a dose-dependent manner; dibutyryl cAMP 500,000 nM) or forskolin (0.5-100  $\mu$ M) produced only a slight enhancement. By contrast, 24 hrs of 100 nM TPA or 10  $\mu\text{M}$  forskolin stimulated secretion of both LHRH and gonadotropin-releasing hormone-associated peptide (GAP). yonaudcropin-releasing normone-associated peptide (ohr). Compared to unstimulated controls, the TPA and forskolin responses were evident within the first 30 and 120 min, respectively. The molar ratio of GAP/LHRH was ~15 with TPA or forskolin; while that from controls reached 60 over 24 hrs. A 4-fold suppression of LHRH mRNA levels occurred at 16 hrs with TPA while forskolin had no effect. These data indicate that relationships among LHRH gene expression, pro-LHRH processing and secretion are complex and that regulation may occur at multiple levels. (Supported by NIH grant DK44838 and the NIEHS Intramural Program.)

# 55.10

PROGESTERONE BLOCKS FOS EXPRESSION IN GONADOTROPIN-RELEASING HORMONE (GnRH) NEURONS DURING THE ESTRADIOL INDUCED GRRH SURGE IN THE EWE. M.N. Lehman . S.J. Berriman, X. H. Gu, A.S.W. Shih, S.M. Moenter†\* N. P. Evanst, G.E. Dahlt, and F.J. Karscht. Univ. Cincinnati Coll. Med., Dept. Anat. & Cell Biol., Cincinnati, OH 45267; †Univ. Mich., Reprod. Sci. Prog., Ann Arbor, MI 48109.

GnRH cells in the sheep express Fos during the estradiol-induced GnRH surge (Moenter et al., Soc. Neurosci. Abstr. 361.6, 1991). Elevated progesterone blocks the GnRH surge in the ewe. We tested the hypothesis that blockade of the GnRH surge by progesterone is associated with an alteration of Fos expression in GnRH cells. To produce a GnRH surge a physiological model for the follicular phase of the estrous cycle was used; an estradiol rise to a late follicular phase level was given after progesterone removal. Animals were cranially perfused with 2% paraformaldehyde either 1) Particular Administration of the Company of the using nickel-enhanced diaminobenzidine (DAB) (black) and GnRH with unenhanced DAB (brown). Fos expression in GnRH cells was seen in 2 of 3 animals of the surge-induction group. Fos expression in GnRH cells was not seen 9 hrs. following the estradiol rise or in animals in which elevated progesterone levels were maintained. These results support the conclusion that a progesterone treatment known to block the GnRH surge alters expression of Fos in GnRH neurons and that the expression of Fos in GnRH neurons is correlated to their increased neurosecretory activity during the surge. [Supported by NIH R01 HD21968 and USDA9102515 to M.N.L., HD18337 to F.J.K., and HD 18258].

ENHANCED AFTERNOON SECRETION OF LH IN MALE SYRIAN HAMSTERS IS NOT ASSOCIATED WITH THE INDUCTION OF OS-RELATED PROTEIN IN LHRH NEURONS. A. Doan\* and H.F. Urbanski. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Although proestrous female hamsters show a pronounced afternoon increase in plasma LH levels, it is unclear whether the

pattern of LH secretion in the male also has a diurnal component. In the present study, male Syrian hamsters were housed under long days (lights on 5:00 - 19:00 h) and blood samples were collected at 3:00, 9:00, 15:00, and 21:00 h. RIA of the plasma revealed a significant peak of LH secretion at 15:00 h. Interestingly, this diurnal pattern persisted after the animals were transferred to short days (lights on 9:00 - 15:00 h), even though the mean daily plasma LH levels had markedly decreased. To investigate whether the afternoon LH peaks reflected activation of LHRH neurons, paraformaldehyde-fixed brains were obtained from male hamsters at 3:00, 9:00, 15:00, 21:00, and 24:00 h. They were sectioned (50) m) using a vibratome and then immunocytochemically-stained, first using a rabbit antibody generated against amino acids 127-152 of the Fos protein (Tom Curran, Roche), and secondly, using a mouse monoclonal LHRH antibody (HU4H); diaminobenzidine and benzidine dihydrochloride were used as the two chromogens. Although intense Fos staining was observed in brain areas such as the cerebral cortex, at no time was staining detected within LHRH neurons. Thus, males appear to differ radically from proestrous females which show an afternoon neuronal coexpression of Fos and LHRH. (Supported by NIH Grants HD-24312 and RR-00163)

## 55.13

DISRUPTION OF ESTROUS CYCLICITY FOLLOWING ADMINISTRATION OF AN LHRH ANTAGONIST TO THE PREOPTIC AREA OF THE RAT. G.D. Weesner and D.W. Pfaff\*, Laboratory of Neurobiology and Behavior, The Rockefeller University, New

We sought to determine if anatomical connections observed between LHRH neurons (Leranth et al., Brain Res 345:332; Witkin et al., Peptides 6:263) in the preoptic area (POA) are of physiological importance for estrous cyclicity. Bilateral cannulae were implanted just dorsal to the POA. Estrous cyclety. Bilateral cannulae were implanted just dorsal to the POA. Estrous cycles were monitored daily by vaginal smears. Antide, a long-acting LHRH antagonist, was infused bilaterally (2.5 µg/side) in the POA or the hypothalamus on the mornings of diestrus I and II. As controls, at separate times, rats also received similar infusions of either vehicle or a bombesin antagonist (Sigma \*B0650). Collection of daily vaginal smears continued, and the number of days from the first infusion to the next day of Estrus which preceded a normal cycle was recorded. Following infusion of Antide into the POA (n=13), rats demonstrated varying durations of interrupted cycles ranging from 11 days to more than 100 days. These periods of disruption were characterized by either linor enian too days. These periods of distribution were characterized by entirel long periods of diestrus, long periods of estrus, or an extended period of diestrus followed by an extended period of estrus. Following infusion of Antide into the dorsomedial (n=4), ventromedial (n=2), or anterior (n=2) hypothalamic areas, rats had either a 4 or 5 day estrous cycle and continued to cycle normally. Likewise, infusions into the septum (n=5) had no effect. Infusion of vehicle (n=24) or bombesin antagonist (n=10) into any of the hypothalamic or preoptic area sites tested also resulted in no interruptions in the cyclic activity of the rats. Therefore, it appears that functional LHRH receptors on POA neurons are important for mediating the LHRH release required to drive the estrous cycle.

STUDIES ON THE ROLE OF ADRENOCEPTOR SUBTYPES IN THE SUPPRESSION OF PULSATILE LH RELEASE. F, Tacconelli & C.W. Coen\*. Division of Biomedical Sciences, King's College, London, UK.

The effect on pulsatile LH release of agonists or antagonists for adrenoceptor subtypes has been studied in bilaterally ovariectomised rats with chronically implanted cannulae; these permitted the administration of drugs into the third cerebral ventricle (ICV) or intraperitoneal cavity (IP) and the removal of blood samples at frequent intervals from the right cardiac atrium without disturbing the animal during the course of the experiment. The pulsatile release of LH was suppressed by treatment with  $\alpha_1$  antagonists (alfuzosine, 0.03 $\mu$ moles, ICV; prazosin, 0.25, 0.5, 1.0mg/kg, IP) or α<sub>2</sub> antagonists (SKF 86466-A, 0.03 or 0.3 $\mu$ moles, ICV; idazoxane, 2mg/kg, IP; piperoxane, 50mg/kg, IP); no effect was observed following treatment with the  $\beta_1$  antagonist atenolol (0.06 or 0.12 $\mu$ moles, ICV) or the  $\beta_2$  antagonist ICI 118551 (0.06 $\mu$ moles, ICV). Treatment with  $\alpha_1$ agonists (methoxamine,  $0.03\mu$ moles; phenylephrine, 0.03 or  $0.3\mu$ moles),  $\alpha_2$ agonists (clonidine,  $0.3\mu$ moles; guanabenz 0.03 or  $0.06\mu$ moles) or the  $\beta_2$  agonist clenbuterol ( $0.15\mu$ moles) suppressed the pulses when administered ICV; no effect was found following treatment with prenalterol (0.3 $\mu$ moles, ICV), a  $\beta_1$  agonist. However, the suppressive effects of an  $\alpha_2$  or a  $\beta_2$  agonist (clonidine, 0.3 $\mu$ moles, ICV or clenbuterol, 0.15 $\mu$ moles, ICV, respectively) were enhanced if the animals were concomitantly treated with a  $\beta_1$  agonist (prenalterol,  $0.3\mu$ moles, ICV). All appropriate vehicle treatments failed to affect the LH pulses. These results suggest that the ability of ICV adrenaline or noradrenaline (both non-selective a suggest that the ability of ICV aurenamie or noracrenamic (both non-selective  $\alpha$  and  $\beta$  agointst) to suppress LH release in ovariectomised rats may involve the concomitant activation of  $\alpha_1$ ,  $\alpha_2$ ,  $\beta_1$  and  $\beta_2$  adrenoceptors. The study also demonstrates that LH pulses can be disrupted by treatment with selective agonists or antagonists of  $\alpha_1$  or  $\alpha_2$  adrenoceptors; the apparent paradox concerning these two receptor subtypes remains to be resolved.

LUTEINIZING HORMONE RELEASING HORMONE (LHRH) ALTERS THE ACTIVITY OF NEURONS IN THE HYPOTHALAMIC ARCUATE NUCLEUS.

The neuronal circuit that generates the episodic pattern of release of LHRH is not understood. Neurons of

the arcuate nucleus (ARC) are known to affect episodic

the arcuate nucleus (ARC) are known to affect episodic LHRH output. To explore the hypothesis that LHRH may alter its own output by acting as a neuromodulator in the ARC, we examined the effects of LHRH on spontaneous electrical activity of ARC neurons in vitro.

Single unit activity was recorded from ARC neurons in coronal brain slices prepared from female guinea pigs in their luteal phase. Stable cells firing at >0.5 Hz were perfused for 5 - 20 min with ACSF containing LHRH. Most ARC neurons (>70%) had a significant change (>30% from baseline) in firing rate during LHRH perfusion. Responses were often complex with neriods of excitation and sponses were often complex with periods of excitation and sponses were often complex with periods of excitation and inhibition that outlasted the period of application. The majority of responders had an overall increase in firing rate. Approximately half of the cells exposed to 100 pM LHRH responded within 4 min of perfusion onset. Other cells responded only after 8-14 min had elapsed. Ten pM LHRH induced only excitatory responses during the first 14 min for perfusion. Subsequently a majority of cells 14 min of perfusion. Subsequently a majority of cells stopped firing. On the basis of these findings, we propose that physiological concentrations of LHRH modulate the activity patterns of ARC neurons.

EFFECTS OF AN ACUTE STRESSOR ON LH AND CORTISOL SECRETION IN RHESUS MONKEYS: COMPARISON TO HORMONE SECRETORY RESPONSES INDUCED BY FASTING. D.L. Helmreich\* and J. L. Cameron, Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

We have previously demonstrated that one day of fasting can cause a suppression of pulsatile LH secretion in adult male rhesus monkeys (Macaca mulatta), and that the slowing of pulsatile LH secretion is apparent within the first 6 h after the missed meal (1100-1700 h). Accompanying this rapid slowing of LH secretion is a moderate increase in adrenal axis activity, indicated by increases in plasma ACTH and cordisol (rising from 17.86  $\pm$  2.3 to 25.14  $\pm$  2.7 µg/dl), and an increase in agitated behavior by the animals. To begin to determine if the rise in adrenal axis activity occurring at the time of the missed meal plays a causal role in the suppression of LH secretion, we used another stimulus to cause a similar rise in adrenal axis activity and determined its effects on LH secretion. The stimulus we chose was presentation of a leather catch glove that is generally used to catch unanesthetized monkeys and causes most animals in our colony to become quite agitated. Blood samples were collected at 15 min intervals from 8 adult male rhesus monkeys with chronic indwelling venous catheters intervals from 8 adult male rhesus monkeys with chronic indwelling venous catheters from 1100-2400 h on a control day, and from 1100-2400 h on a day in which the glove was randomly presented 12 times between 1100 h and 1300 h. On the experimental day, the presentation of the glove caused mean cortisol levels to be significantly elevated from 1200-1600 h, with a rise that was similar in magnitude to that observed on a day of fasting (24.22  $\pm$  2.4  $\pm$  1 $\pm$  1 $\pm$  1 $\pm$  100 h on the day of glove presentation (LH pulse frequency:  $1.5\pm0.38$  pulses/6 h on the control day,  $1.6\pm0.53$  pulses/6 h on the with glove presentation. We conclude that the degree of activation of the adrenal axis observed during short-term fasting is not always associated with a slowing of pulsatile LH secretion. It therefore seems unlikely that the activation of the adrenal axis plays a causal role in fasting-indeed suppression of LH secretion the adrenal axis plays a causal role in fasting-induced suppression of LH secretion.

EFFECT OF PHARMACOLOGICAL DOSES OF NICOTINE ON ANTERIOR

EFFECT OF PHARMACOLOGICAL DOSES OF NICOTINE ON ANTERIOR PITUITARY HORMONES C.A. Hodson, W.K. Bowman, A.T. Davenport and H.W. Burdent. Departments of Obstetrics and Gynecology and Anatomy, East Carolina University, School of Medicine, Greenville, Nc 27858

Previous studies have shown that acute administration of pharmacological doses of nicotine inhibits luteinizing hormone secretion and stimulates prolactin secretion. The present study investigated the effect of nicotine treatment for 7 days on serum and pituitary gland hormone content. Adult male Sprague-Dawley rats were given 1.25 or .312 mg of nicotine per kg bw or the saline injection vehicle for 7 days. On day 7, one hour after the final injection of nicotine, blood samples and anterior pituitary glands were collected for hormone assay. LH, TSH and prolactin concentrations were determined by radioimmunoassay. Data were statistically analyzed using random design analysis of variance and means were compared at the α=.05 level using the Student-Newman-Keul's test.

Keul's test.

Daily nicotine treatment for seven days at .312 but not at 1.25 mg/kg body weight resulted in decreased anterior pituitary gland prolactin TSH and LH content. Serum TSH and LH concentrations were decreased in response to daily administration of 1.25 mg nicotine/kg bw. These results suggest that nicotine has pronounced effects on anterior pituitary gland function. Studies are currently in progress to determine the effect of nicotine on endogenous opioids in the anterior pituitary gland and hypothalamus. We hope to determine whether endogenous opioids mediate the effects of nicotine on anterior pituitary gland hormones.

MONAMINE OXIDASE INHIBITION MODIFIES LUTEINIZING HORMONE BUT NOT PROLACTIN RELEASE. KM ogilvie and MH Stetson. Sch. of Life and Hlth. Sci., Univ. of Del., Newark, DE 19716.

Univ. of Del., Newark, DE 19716.

The female golden hamster is a seasonally reproducing rodent in which anestrus is evoked by exposure to short days (photoperiod-induced anestrus; PIA). PIA hamsters are characterized by low levels of prolactin (PRL) and a daily surge of gonadotropins. We injected animals with saline or pargyline (a mononamine oxidase inhibitor) on diestrus day 1 (DIE), proestrus (PRO) or to PIA animals at 2 hour (h) intervals during the day. Animals were killed 10 minutes after injection and blood collected. We found pargyline affected LH levels in PRO and PIA, but not DIE hamsters. In PRO hamsters (14L:10D), pargyline decreased LH levels at 1800h; in PIA hamsters (12L:12D), LH was decreased at both 1600h and 1800h (lights off at 2000h in both). Conversely, pargyline given to PIA hamsters at 2000h increased LH. PRL levels were not changed, indicating brain dopamine levels were probably unaffected by this treatment. These data support the idea that serotonin, which is dramatically increased by pargyline, plays a role in the control of gonadotropin surges. Supported by NSF research grant DCB87-14638.

EFFECT OF COCAINE ON GRRH-STIMULATED PITUITARY GONADOTROPIN SECRETION IN VIVO. Thomas S. King,\* Ting-Ting Gu, Melin S. Canez, Martin A. Javors and Robert S. Schenken. Depts. of CSB, OB-GYN & Psychiatry, The University of Texas Health Science Center. San Antonio. TX 78284.

University of Texas Health Science Center, San Antonio, TX 78284.

We have shown previously that cocaine administration disrupts estrous cyclicity and normal rates of ovulation in rats (Neuroendocrinology 52: 15 - 22 1990). While the primary effects of cocaine appear to involve the regulation of hypothalamic GnRH release, a direct effect of this drug on pitultary gonadotropin secretion has not been ruled out. Thus, we sought to characterize the effects of cocaine on GnRH-stimulated pituitary LH and FSH secretion. Ovariectomized (OVX), 17β-estradiol benzoate (E2B)-primed rats were injected s.c. every day for one week with saline or 10 mg/kg of cocaine HCI (i.e., "chronic" exposure). On the last day of these injections, a single blood sample was collected from each rat via an indwelling jugular vein cannula. This was followed by i.v. infusion of 100 ng/kg of synthetic GnRH in saline vehicle. Twenty min later a second blood sample was collected. Chronic cocaine had no effect on either basal or GnRH-stimulated LH or on FSH levels. To examine the effects of "acute" cocaine exposure on GnRH-stimulated gonadotropin secretion, a single blood sample was collected from OVX-E<sub>2</sub>B, cocaine-naive rats followed by I.v. injection of (1) 100 ng/kg of synthetic GnRH in saline vehicle, (2) GnRH + 4 mg/kg of cocaine HCl in saline vehicle or (3) GnRH + 1 mg/kg of lidocaine HCl in saline vehicle. Twenty min later a second blood sample was collected. Acute exposure either to cocaine or lidocaine significantly blunted GnRH-stimulated increases in LH, but not FSH, levels. These results suggest that acute, but not chronic, exposure to cocaine attenuates GnRH-stimulated LH secretion. The former effect may reflect cocaine's activity as a local anesthetic, acting on Na\* influx required for GnRH-stimulated pituitary gonadotropin release. (Supported by NIDA grant DA 06039 and NIH grant HD 02012.)

### 55.18

LACK OF EFFECT OF ADRENALECTOMY ON THE PROLACTININDUCED SUPPRESSION OF POSTCASTRATION LH SECRETION. S.-K. Park, D.R. Grattan, L.A. Martin and M. Selmanoff\*, Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559

We contrasted the inhibitory effects of acute hyperprolactinemia on postcastration LH and FSH secretion in adrenal intact and adrenalectomized (ADX) rats with or without physiological corticosterone (B) replacement. Adult male rats were administered purified ovine prolactin (oPRL) every 12h (2,400µg/sc injection) for 10 days, beginning at the time of castration in three groups of rats: orchidectomized (ORCH) rats, ORCH+ADX rats, and ORCH+ADX+B rats. In ORCH rats, oPRL suppressed mean plasma LH and FSH levels from about 18 to 72h postcastration when the effect spontaneously reversed in the face of elevated oPRL levels. In ADX rats. the LH and FSH postcastration increases were delayed as previously reported by Ringstrom and Schwartz (Endo 114:880, 1984), and this delay was not prevented by B replacement. In the case of FSH, the delay of postcastration secretion due to ADX was very striking, and appeared to override any oPRLinduced suppression. Due to this delaying effect, the inhibition of LH by oPRL in ORCH+ADX and ORCH+ADX+B rats was less pronounced than in ORCH rats. We conclude that the oPRL-induced suppression of postcastration LH secretion occurs with or without the adrenal glands. The suppression is most prominent in adrenal intact animals, apparently because the postcastration LH rise is most rapid in these rats and not because of an adrenal-mediated effect of oPRL on the hypothalamic-pituitary axis. (Supported by NIH grant HD21351).

# NEUROENDOCRINE REGULATION: HYPOTHALAMUS/PITUITARY

## 56.1

THE ENKEPHALIN ANALOG [D-MET<sup>2</sup>,PRO<sup>5</sup>]-ENKEPHALINAMIDE STIMULATES MELANOCYTE-STIMULATING HORMONE SECRETION.

J.A. Carr\*, L.C. Saland, A. Samora, D. Tejeda. Dept. of Biol. Sci., Texas Tech Univ., Lubbock, TX 79409-3131 and Dept. of Anatomy, Univ. of New Mexico Sch. Med., Albuquerque, NM 87131 (USA)

We used a combination of in-vivo and in-vitro techniques to investigate enkephalinergic modulation of pituitary intermediate lobe (IL) secretory activity in the rat using the super-active met-enkephalin analog [D-Met<sup>2</sup>, Pro<sup>5</sup>]- enkephalinamide (EA). Plasma titers of alpha-melanocyte-stimulating hormone (a-MSH) were measured by radioimmunoassay to gauge IL secretory activity. Systemic administration of EA resulted in dose- and time-dependent elevations in plasma  $\alpha$ -MSH levels. stimulatory effects of EA were blocked by pretreatment with the  $\mu$ -selective opiate antagonist naltrexone. In-vitro treatment of neurointermediate lobes (NILS) with 10 nM EA caused a rapid 3.7-fold increase in α-MSH release. In-vitro α-MSH release in response to EA was maximal 15 min after administration but had returned to baseline levels 90 min after administration, suggesting desensitization of the response. Treatment with a dose of naltrexone sufficient to block EA-induced secretion of a-MSH had no effect on stress-induced secretion of a-MSH but completely blocked the rise in plasma prolactin levels caused by stress. Our results indicate that systemic administration of EA stimulates  $\alpha ext{-MSH}$  secretion, possibly by acting through  $\mu ext{-selective}$  opiate receptors at the level of the NIL. The inability of naltrexone to reduce stress-induced secretion of  $\alpha$ -MSH suggests that endogenous metenkephalin does not play a role in secretion of  $\alpha$ -MSH during stress. Supported by NIH NS08447 (JAC) and NS21256, GM08139 (LCS).

COLOCALIZATION OF \$\textit{B}\$-ENDORPHIN AND FLUOROGOLD IN THE ARCUATE NUCLEUS OF THE FEMALE GUINEA PIG. J.E. Thornton\*, N. Khaleeli and M.D. Loose, Neuroscience Program and Biology Dept, Oberlin College, Oberlin OH 44074.

Although \$\textit{B}\$-endorphin (BE) is found in the

Although B-endorphin (BE) is found in the cells of the arcuate nucleus (ARC) and in the portal blood, it is unclear which subpopulation of ARC BE cells project to the median eminence (ME). The present study used fluorogold (FG) to determine which BE cells project outside the blood brain barrier, presumably to the ME. Adult ovx guinea pigs were injected ip with 20mg/kg FG. Five days later females were injected with 25ug EB or oil. Females were sacrificed 24h later and brains were postfixed in 4% paraformaldehyde. Cryostat sections (20um thick) were stained with B-endorphin antibody (R13, E. Weber, 1:1000) and with donkey anti-rabbit IgG Texas Red (Jackson, 1:50). Only a small proportion (less than 10%) of BE cells contained FG. However, in parts of the anterior and medial arcuate, approximately 40% of the FG cells also contained BE. B-endorphin released at the median eminence by arcuate cells may have a neuroendocrine role and/or may modify neurosecretion at the median eminence.

MELANIN CONCENTRATING HORMONE (MCH) AND NEUROPEPTIDE-E-I (NEI) ACTIVATE HYPOTHALAMIC CRF NEURONS IN CONSCIOUS RATS. D.G.Parkes. S.Rivest. C.Rivier. P.Sawchenko<sup>+</sup> & W.Vale\*. The Clayton Foundation Laboratories for Peptide Biology and \*Laboratory for Neuronal Structure and Function, The Salk Institute, La Jolla CA 92037.

MCH and NEI are neuropeptides both processed from the MCH precursor hormone and are localized within the dorsolateral region of the rat and human hypothalamus. In teleost fish, MCH acts directly on the pituitary to suppress ACTH release. The physiological relevance of MCH within the mammalian CNS is at present unclear. However, recent studies in rats have suggested contrasting neuroendocrine actions compared to those in fish, as icv injection of MCH into rats produces a CRF-dependent increase in pituitary ACTH release. The present study investigated the effect of acute icv infusion of MCH, NEI and CRF on the neurophysiological expression of the proto-oncogene c-Fos in the rat CNS, as a marker of neuronal activation. Guide cannulae were implanted in the lateral ventricle of adult male rats one week prior to experimentation. On the day of experimentation, lμg of MCH, NEI or CRF was infused over 2 min. Sixty min following infusion, rats were anaesthetized and perfused with 4% paraformaldehyde. Frozen brains were cut into 40μm sections and tissue slices were stained for c-Fos protein, and either CRF or LHRH by means of a double immunocytochemistry method. ICV artificial CSF did not measurably alter c-Fos expression in either the PVN or the MPoA. ICV MCH and NEI significantly increased the expression of c-Fos protein in the parvocellular subdivision of the PVN. In this hypothalamic nucleus c-Fos was mainly located within the nuclei of CRF-like immunoreactive perikarya. In addition, both NEI and CRF markedly increased c-Fos expression within the medial preoptic area (MPoA), although the activated cells were shown not to be LHRH-containing perikarya. This study provides the first evidence of direct activation of hypothalamic CRF perikarya by both MCH and NEI, and together with in vivo findings, suggest that these neuropeptides may be involved in regulating the HPA in mammals. Furthermore, icv NEI and CRF appear to influence activity of neurons located within preoptic regions of the hypothalamus.

INVOLVEMENT OF CALCIUM IN SOMATOSTATIN RELEASE FROM THE BOVINE INFUNDIBULUM. P.G. Harms\*, P.L. Chen, J.P. Walter and N.H. McArthur, Departments of Animal Science and Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX 77843.

Bovine infundibular (INF) explants were cultured to study calcium (Ca) involvement in somatostatin (SS) release. INF were excised,

Bovine infundibular (INF) explants were cultured to study calcium (Ca) involvement in somatostatin (SS) release. INF were excised, mid-sagitally sectioned, and each half randomly assigned to either control or treated (EGTA or Verapamil) groups. Individual halves were incubated in 600 μl of Krebs-Ringer bicarbonate medium (KRB) (4.7 mM K+, 10mM glucose, 0.1% bovine serum albumin, pH 7.3 at 37° C and saturated with 95% O<sub>2</sub>, 5% CO<sub>2</sub>) for 180 min. At 30 min intervals, 500 μl aliquots were removed from each incubate and replaced with fresh KRB. Basal (BAS) and depolarization induced (DEP) (substitution of 60 mM K+ for sodium in KRB) SS release was evaluated by RIA of SS content in the media at 90-120 and 120-150 min of culture, respectively. An analysis of variance was used to determine differences in BAS and DEP SS release between control and treated halves. Differences between BAS and DEP contents were used to evaluate response to depolarization. INF halves from steers treated with 1.25 mM EGTA (Ca binding agent) in the KRB released less (P<.02) SS during DEP than control halves. Similarly, INF halves from steers and heifers treated with 50 or 100 μM Verapamil (Ca L-channel blocker) in the KRB released less (P<.02) SS in response to DEP than control halves. BAS release was not affected (P>.10) by EGTA or Verapamil. These results demonstrate that extracellular Ca is involved in DEP induced SS release and suggest that Ca is involved in the release (exocytosis) of SS from the bovine INF.

INDUCTION OF FOS AND FOS RELATED PROTEINS IN THE RAT PITUITARY FOLLOWING CORRESPONDING RELEASING-FACTOR TREATMENT J. KONONENI, J. HONKANIEMII, L. KIVIPELTO2\*, H. ALHOI, M. PELTO-HUIKKOI 1.) Dept. of Biomed. Sci., Univ. of Tampere, 31101 Tampere 2.) Dept. of Anatomy, Univ. of Helsinki, FINI AND

Transcription factors Fos and Jun might act as intranuclear messengers in the cascade of events concluding in increased pituitary hormone synthesis following releasing factor treatment. In order to test this hypothesis we treated adult male rats with i.p. injections of either CRF, TRH, LHRH, GRF or physiologic saline. Pituitaries were prepared for immunocytochemistry and incubated with antibodies directed against either the N-terminal or M-peptide sequence of Fos.

Injection of CRF resulted in outstanding induction of Fos-immunoreactive (Fos-IR) cells in both anterior and intermediate lobes (AL and IL) of pituitary when compared to animals injected with physiologic saline. Double-labelling verified that majority of cells expressing Fos-IR after CRF treatment contained ACTH-IR. Injections of TRH, LHRH and GRF resulted in induction of Fos-IR in TSH-, LH-, FSH-, and GH- cells of the AL. Injection of physiologic saline induced Fos-IR in AL and IL when compared to untreated animals. Consecutive double staining revealed that these cells also contained ACTH-IR. Similar inductions of Fos-IR were obtained in all experiments with both Fos-antibodies used, although more stained cells were always observed with the Fos antibody directed against the M-peptide. Our results demonstrate the induction of Fos and Fos-related proteins in the rat pituitary after treatment of the corresponding releasing factor, suggesting a role for AP-1 binding proteins in the control of pituitary hormone synthesis.

### 56.4

PRETREATMENT WITH SOMATOSTATIN ANALOG SMS 201-995
POTENTIATES GH RESPONSIVENESS TO GRF. J. Turner, A. Beaudet
and G.S. Tannenbaum\*. Departments of Neurology & Neurosurgery and
Pediatrics, McGill University, Montreal, Quebec, H3H 1P3.

Our recent studies suggest that the temporal pattern of hypothalamic somatostatin (SRIF)/GRF signaling to pituitary somatotropes is an important determinant for pulsatile GH secretion, however the mechanism remains unclear. In the present investigation, we used the long-acting SRIF analog, SMS 201-995, to further elucidate the nature of the SRIF/GRF interaction in GH regulation. Administration of SMS 201-995 (in doses ranging from 25-100 μg iv) to free-moving adult male rats resulted in obliteration of the spontaneous GH pulses for 3-6 h. Rats (n=6) pretreated with SMS 201-995 (25 μg iv) and subsequently challenged with GRF (1 μg iv) exhibited reduced GRF-induced GH release 1 h post treatment; in contrast, preexposure to SMS 201-995 for 3 h markedly enhanced GH responsiveness to GRF (354.7 ± 71.0 vs. 166.0 ± 43.8 ng/ml; P<0.05), compared to controls (n=10) pretreated with normal saline. Animals iv injected with 50 μg SMS 201-995 (n=6) or saline (n=5) 3 h prior to the concomitant administration of native SRIF-14 (50 μg iv) and GRF (1 μg lv) exhibited similar SRIF-14-mediated inhibition of GRF-induced GH release; however, the post-inhibitory rebound release of GH 15 min after SRIF-14 administration was 12-fold higher in SMS 201-995-treated rats than in saline controls (347.8 ± 53.9 vs. 27.6 ± 9.0 ng/ml; P<0.001). These results demonstrate that a 3-h period of exposure to SMS 201-995 is sufficient to enhance pituitary sensitivity to GRF. The findings suggest that this effect is not due to down regulation of SRIF receptors but rather to a SRIF-mediated build-up of pituitary GH stores in a readily releasable pool. Such a synergistic interaction between SRIF and GRF may be necessary to optimize pulsatile GH release;

## 56.6

GALANIN SECRETION FROM PITUITARY CELLS IS REGULATED BY ESTRADIOL AND GHRH. J.F. Hyde\* and A. Hemmer, Dept. Anatomy & Neurobiology, Univ. of Kentucky, Lexington, KY 40536.

The peptide galanin is localized in lactotrophs, somatotrophs and thyrotrophs of the rat anterior pituitary gland (AP). In vivo treatment with estradiol (E2) increases galanin mRNA and peptide levels in the AP, particularly within lactotrophs. Studies using E2-treated AP cells showed that galanin secretion is regulated by dopamine, somatostatin and TRH. Our objectives were to 1) determine if E2 increases galanin release from AP cells in vitro, and 2) examine if growth hormone-releasing hormone (GHRH) alters galanin secretion from cells not exposed to E2. AP cells from male and ovariectomized F344 rats were cultured under low-E2 conditions. The cells were challenged with varying concentrations of 17 $\beta$ -estradiol (.01-10 nM) or GHRH (1-10 nM). Hormone levels were measured by R1A. E2 increased galanin release in a dose-dependent manner. Cells from ovariectomized rats released more galanin than cells from males. Immunocytochemistry was used to quantify the number of galanin-positive AP cells in vitro. E2 (10 nM) increased the number of galanin release, which was greater in cells from ovariectomized rats. Conclusions: 1) E2 increases galanin release from AP cells in vitro in a sex-dependent manner. 2) E2 increases the number of AP cells synthesizing galanin in vitro. 3) GHRH stimulates galanin release from AP cells when E2 is absent. These data indicate that the effects of E2 on galanin synthesis and release are mediated, in part, by a direct action at the level of the AP. Moreover, the regulation of galanin release is dependent on the steroid environment. (Supported by ACS grant #IN-163 and UKMC Research Fund.)

# 56.8

CORTICOTROPIN RELEASING FACTOR GENE EXPRESSION IN JEG-3 CELLS. J.W. Kasckow\*, M.R. Montminy and W.W. Vale, The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92131

Corticotropin releasing factor (CRF) production in the hypothalamus is known to be regulated by activators of the protein kinase A (PKA) and C (PKC) pathway. We have studied CRF gene expression induced by these pathways in transient transfection assays of JEG-3 cells. The rat CRF promoter (base pairs -337 to +25 bp) linked to a luciferase reporter plasmid was transfected into placental JEG-3 cells using standard CaPO4 precipitation methods. Following a 5-6 hour incubation, cells were glycerol shocked and the CRF gene was expressed for 16 hours in the presence or absence of various agents. Following this, cells were harvested, tested for luciferase activity and normalized to  $\beta$ -galactosidase activity. Forskolin enhanced basal CRF gene expression approximately 20 fold. The phorbol ester 12-o-tetradecanoyl phorbol 13-acetate (TPA) was also able to enhance CRF transcription approximately 5 fold. Addition of both TPA and forskolin lead to a synergistic activation. The presence of a palindromic cAMP responsive element (CRE) in the CRF promoter and the lack of a AP1 consensus sequence suggests that both PKA and PKC pathways may act through the CRE to activate transcription. Supported by NIMH 5T22, MH 17140 and DK 26741.

SPONTANEOUS AND AGONIST-INDUCED CYTOSOLIC CALCIUM TRANSIENTS IN FURA-2-LOADED CULTURES OF ANTERIOR PITUITARY CORTICOTROPE CELLS (AtT-20/D16v). J. F. Fiekers', L. M. Konopka¹ and V. May. Dept. Anatomy & Neurobiology, Univ. Vermont Coll. Med. Burl., VT 05405, ¹Hines Veterans Administration Hosp., Hines, IL 60141.

Spontaneous, corticotropin releasing factor (CRF)- and galanininduced changes in {Ca2+}i were examined in cultures of anterior pituitary (AtT-20/D16v) cells. {Ca2+}, was monitored in individual corticotropes by dual excitation microspectrofluorometry using fura-2. Spontaneous Ca<sup>2+</sup> oscillations were observed in >80% of single cells. The frequency, but not the duration or amplitude of Ca<sup>2+</sup> oscillations. was significantly increased with elevated {Ca2+}o. The spontaneous transients were reversibly abolished by Co2+ (2mM) or nifedipine (100uM), but were unaffected by tetrodotoxin (1µM), suggesting that the Ca2+ transients are caused by Ca2+ entry through L-type voltagegated Ca2+ channels. CRF and galanin caused transient increases in {Ca2+}i and increased the frequency of spontaneous Ca2+ transients. Galanin responses were abolished by Cd2+ (150µM) or Ca2+-free solutions. CRF produced a rapid transient increase {Ca2+}, in Ca2+-free solutions. These results suggest that Ca2+ entry through voltage-gated Ca2+ channels is an important pathway for regulating {Ca2+} and that hormonal activation may involve calcium entry and/or calcium mobilization from intracellular store(s). (Supported by NS27319).

## 56.11

THE EFFECT OF GROWTH HORMONE-RELEASING FACTOR (GHRF) ON CYCLIC AMP (cAMP) PRODUCTION AND GROWTH HORMONE (GH) RELEASE FROM PITUITARY CELL CULTURES OF DEVELOPING AND MATURE RATS. L. Cuttler\* and B.J. Collins. Depts. Pediatrics/Pharmacology, Case Western Reserve Univ., Cleveland, OH 44106; Dept. Pediatrics, Univ. of Chicago, Chicago, IL 60637.

Circulating GH levels and the GH response to GHRF are heightened in perinatal mammals, compared with adults. In order to assess the mechanisms underlying this characteristic ontogenic pattern, we tested the effect of GHRF (0.01-10 nM GHRF, for 5-180 min) on cAMP production and GH release by pituitary cell cultures of newborn (2-day-old), juvenile (12-day-old), and adult male (3-4 months) rats (n = 3 experiments/age group). GHRF stimulated intracellular cAMP accumulation in a dose and time- dependent manner in all age groups, with peak cAMP production occurring at 30 min after GHRF application. Although GHRF-induced fractional GH release was greatest from pituitary cell cultures of newborn rats and least from those of adults (ANOVA for age effect: P < 0.001; similar to our earlier observations, Endocrinology 118:69), GHRF-induced cAMP production was similar in all age groups (ANOVA, NS). These findings suggest that GHRF stimulates cAMP production in pituitaries of immature as well as mature rats, and support the concept that cAMP mediates the effect of GHRF throughout development. The dissociation between the ontogenic effects of GHRF on cAMP production from those on GH release suggest that the heightened GH secretory response to GHRF in perinatal animals reflects, at least in part, immaturity of cellular processes distal to the GHRF receptor and cAMP generation.

# 56.13

VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) AND BASIC FIBROBLAST GROWTH FACTOR (bFGF) IN HUMAN PITUITARY ADENOMAS. D.F. Brown, E.G. Stopa, A. Baird, J. Daucher, A. Tatum, D.I.Friedman\* and G.S. Rodziewicz. Depts. of Pathology, Neurology and Neurosurgery, SUNY Health Science Center, Syracuse, NY 13210 and The Whittier Institute for Diabetes and Endocrinology, La Jolla, CA 92037

In addition to the classical pituitary hormones, other proteins have been found to be involved in the regulation and maintenance of pituitary function. Included among these are the heparin-binding proteins Basic Fibroblast Growth Factor (bFGF) and Vascular Endothelial Growth Factor (VEGF). In this study we examined human pituitary adenomas to determine if VEGF and bFGF may be elaborated by these neoplasms. Adenoma specimens and normal gland were fixed in Zamboni's fixative and embedded in paraffin. The tumors varied in their hormonal secretion and included ACTH secreting (n=2 prolactin secreting (n=1), GH secreting (n=1), prolactin and GH secreting (n=2), and non-secreting (n=1) tumors. The immunocytochemical procedures were performed on 5µm sections using the ABC method and specific polyclonal antibodies directed against the amino terminus of VEGF (#61,67) and bFGF (#773). VEGF-like immunoreactivity showed no apparent specificity for adenoma type, and could be found in all specimens examined (n=7). bFGF-like immunoreactivity was observed only within the single non-secreting adenoma. Our data suggest that VEGF is increased and bFGF reduced as a function of pituitary neoplastic transformation. The possibility that bFGF content is reduced due to rapid secretion, however, cannot be excluded. AG10682, DK18811.

CHARACTERIZATION OF ENDOTHELIN RECEPTORS ON THE PITUITARY BY A NOVEL ENDOTHELIN ANTAGONIST, B. Kanyicska and M.E. Freeman. Dept. of Biol. Sci., Florida State University, Tallahassee, Fl. 32306.

Members of the endothelin-like peptide family are capable of modifying hormone secretion of different pituitary cells in vitro: they attenuate prolactin (PRL) and enhance luteinizing hormone (LH), follicle stimulating hormone (FSH) and thyroid stimulating hormone (TSH) release in a dose-dependent manner. Since a remarkable difference has been found in terms of relative potencies of different ET-like peptides on PRL and TSH vs. LH and FSH, we proposed that two different ET receptors are present on lactotrophs and thyrotrophs compared to that of gonadotrophs. In this present on factorrophis and hypotrophis compared to making a study, a new competitive ET<sub>A</sub> receptor antagonist, BQ123 (M. Ihara et al., Life Sci. 50:247, 1992) was used for further characterization of ET receptors in the pituitary. In order to establish the inhibitory potency of BQ123, primary monolayer cultures of anterior pitulary cells or gignated from female rats were preincubated for 30 min without or with 10<sup>-8</sup>, 10<sup>-7</sup>, 10<sup>-6</sup> and 10<sup>-5</sup> M antagonist followed by challenge with ET-1 or ET-3, respectively. After either four or 24 hours of incubation, the media were collected and the amounts of secreted PRL, TSH, LH and FSH were determined by radioimmunoassays. Pretreatment with BQ123 markedly antagonized the effects of ET-1 and ET-3 on PRL and TSH secretion without effecting the ET-induced changes on LH and FSH. The concentrations of ETs necessary for the half maximal responses (EC<sub>50</sub>) with or without the antagonist were calculated using non-linear regression analysis of dose-response curves. In the case of PRL and TSH, the pA<sub>2</sub> values for BQ123 were calculated using Schild's method (Tallarida et al., Life Sci. 25:637, 1979). The  $pA_2$  and  $K_1$  (inhibitory constant) values on PRL and on TSH either with ET-1 or ET-3 were similar  $(pA_2 \rightarrow 9$  and  $K_1 \rightarrow 1$  mM). These data strongly suggest that the lactotroph and thyrotroph cells possess the same type of ET receptors (ET<sub>A</sub>) which mediate the effects of both ET-3 and ET-1. In contrast, the ET's effects on gonadotroph cells are likely involve  $\mathrm{ET}_{\mathrm{B}}$  (or  $\mathrm{ET}_{\mathrm{C}}$ ?) receptors. Supported by NIH, HD-

IMMUNOCYTOCHEMICAL LOCALIZATION OF GAP-43 IN NERVE FIBERS OF THE ADULT RAT NEUROINTERMEDIATE PITUITARY. L.C. Saland\*, N. Perrone-Bizzozero, A. Samora and P. Sanchez. Depts. of Anatomy and Biochemistry, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131.

GAP-43 is a neuronal phosphoprotein associated

GĀP-43 is a neuronal phosphoprotein associated with developing and regenerating nerve fibers. Here, we demonstrate that nerve fibers of rat pituitary neurointermediate lobes (NILS) contain immunoreactive (IR) GAP-43. Male rats were injected I.V. with 150 mg/kg 6-hydroxydopamine (6-OHDA), then halothane anesthetized one week later and perfused intracardially with 4% paraformaldehyde in 0.1M phosphate buffer. Alternatively, NILS were incubated in vitro for 90 minutes in control media or dopamine (DA). Paraffin sections were immunostained for GAP-43 with a polyclonal antiserum (1:1500, Benowitz et al, '88, J. Neurosci. 8: 339). Small numbers of GAP-43-positive fibers were observed in NILS of perfused rats. More intense staining was observed after in vitro DA treatment. GAP-43 is associated with release of DA in PC-12 cells (Ivins et al, '91, Soc. Neurosci. Abst. 17: 576). Here, DA may interact with nerve fibers, perhaps by uptake, to increase GAP-43 IR in pituitary. Support by NIH NS21256, GM08139(LS) and NS30255(NPB).

EFFECT OF ESTROGEN ON IMMEDIATE EARLY GENE EXPRESSION IN THE RAT BRAIN. R.Miyoshi, E.Fujii, T. Muraki and S. Kito, Department of Pharmacology, Tokyo Women's Medical College, Tokyo 162, \*Division of Health Sciences, University of the Air, Chiba 261, Japan. It has been demonstrated that female steroid hormones

can act in the mammalian central nervous system to regulate endocrine functions and sexual and affective behaviors. In this study, we examined the effect of estrogen on c-fos and zif/268 mRNA expression in the rat brain using an in situ hybridization technique. Female Fischer 344 strain rats were ovariectomized and allowed to recover for 2 weeks. &-estradiol was subcutaneously administered. The basal level of c-fos and zif/268 expression was very low throughout the brain. From 30 to 60 min after **\(\mathcal{B}\)**-estradiol injection, c-fos and zif/268 mRNAs were increased in the hippocampus and cerebral cortex. In addition, at 60 or 90 min following the injection, it was detected in the midbrain such as the superior colliculus, central gray matter and interpoducation and the base of the base of the superior colliculus. peduncular nucleus. It has been reported that estrogen receptors richly exist in the hippocampus of ovariectomized rats. It is considered that the induction of c-fos and zif/268 mRNA plays some role in the action of estrogen in the central nervous system.

EFFECT OF MINERAL CORTICOID ON IN VIVO RELEASE OF NEUROTRANSMITTERS FROM THE RAT HIPPOCAMPUS. M.Shimoyama, R.Miyoshi , S.Kito, A.Kimura, M.Hayashi, R.Shimada and Y.Maruyama, Division of Health Sciences, M.Hayashi, University of the Air, Chiba 261, \*Department of Pharma-cology, Tokyo Women's Medical College, Tokyo 162, Japan.

presence and biosynthesis of steroids within the mammalian central nervous system is now accepted. Steroids exert both genomic and non-genomic effects on neurons and the hippocampus contains high densities mineral corticoid receptors of the brain. In order to directly assess changes of release of endogenous acetylcholine (ACh), GABA and aspartate from the rat hippocampus induced by systemic administration of deoxycorticosterone acetate (DOCA), a mineral corticoid. we measured release of these substances using intracerebral dialysis technique. A dialysis probe these substances using an Carnegie Medicine was inserted into the hippocampus of a Wistar strain rat. ACh was assayed by HPLC with an electrochemical detector and amino acids with a fluorescence detector. Subcutaneous injection of DOCA caused short-latency decreases of both glutamate and GABA, and increase of ACh. Aspartate was also decreased. These effects of mineral corticoid are considered to direct actions on neuronal receptors. It is presumed that mineral corticoid is playing roles in regulating hippocampal functions.

DECREASED CORTICOSTEROID RECEPTOR NUMBERS IN THE HIPPOCAMPUS ASSOCIATED WITH DEXAMETHASONE RESISTANCE IN THE PRIMATE. S. Brooke<sup>1</sup>, A. de Haas-Johnson <sup>1</sup>, J. Kaplan <sup>2</sup>, S. Manuck <sup>3</sup> J. Miller 1 R. Sapolsky 1, 1 Dept. of Biol Sci, Stanford University, Stanford, CA 94305 and  $^2$  Bowman Gray Sch Med, Winston Salem, NC. 27103  $^3$  Univ. Pittsburgh, Pittsburgh, PA

Neural corticosteroid receptors and their relationship to glucocorticoid negative feedback regulation have been studied in rats; we present data from the primate brain which support those findings. Subjects were 51 male Macaca fasicularis monkeys with known behavioral histories and who had been given dexamethasone (DEX) suppression tests a few weeks prior to killing. Receptor analysis of tissue from hippocampi of frozen brains consisted of incubating cytosol (stripped of unbound cortisol) at 4 °C with <sup>3</sup>H cortisol (20nM) ± 80nM RU28362 or 250 unbound cortisol) at 4 °C with <sup>3</sup>H cortisol (20nM) ± 80nM RU28362 or 250 nM dexamethasone; pilot studies with this assay showed Type I and II receptors in the monkey brain to have Kd's similar to that seen in the rat. We compared the subset of monkeys who were most DEX responsive (post-DEX cortisol values of 3 ± .2 ug/dl) versus a DEX resistant subset (cortisol values of 9 ± .6ug/dl). DEX resistant monkeys had significantly fewer Type II receptors in the hippocampus; they did not differ in numbers of Type I receptors. Animals had resided for a number of years in social groups that were either stable or were repeatedly destabilized by changing of group membership; the latter has been shown to constitute a sustained stressor. DEX resistant animals disproportionately came from such unstable social groupings. Rodent studies have shown that a depletion of hippocampal corticosteroid receptors is associated with glucocorticoid hypersecretion and feedback resistance, and that sustained stress can bring about such a down-regulatory depletion. The present data demonstrate similar associations in the primate

AGE- AND STRAIN-RELATED LOSS OF mRNA FOR MINER-ALOCORTICOID RECEPTORS IN THE BRAIN. S. Boutelle, A.K. Johnson, S.J. Lewis, W.W. Kaelber\* and B. Kasson. Depts. Pharmacol., Psychol., Cardiovasc. Ctr., Univ. of Iowa, Iowa City, IA

It has been established that mineralocorticoid receptors (MR) that mediate the actions of steroids by functioning as liganddependent nuclear transcription factors exist within the brain. We have previously reported that MR mRNA in the hippocampi of aged 24 - 30 month) old spontaneously hypertensive (SHR) and strokeprone hypertensive (SHRsp) rats is markedly less than in young (5 or 10 week old) rats. This study examined whether the age-related reduction in MR mRNA is due to a loss of MR mRNA production per cell or due to a net loss of neurons within the hippocampi of these rats. Within the hippocampus of young SHR and SHRsp, heavy MR mRNA labelling was found in the pyramidal layer throughout Ammon's horn and the intensity of labelling was higher in field CA3 than in CA1. The aged rats had markedly less MR mRNA throughout the hippocampus. This was evident in areas which were as neuronally rich as the young rats. However, there was a marked loss of cells in some areas of the hippocampi of the aged rats. These results suggest that the loss of MR mRNA in the hippocampi of aged rats is due to both a net loss of MR mRNA per cell and a net loss of neurons per se.

## 57.4

EFFECT OF GLUCOCORTICOID ON IN VIVO RELEASE OF NEUROTRANSMITTERS FROM THE RAT HIPPOCAMPUS. S.Kito,  $\P^{i}$ R.Miyoshi , M.Shimoyama, Y.Kimura, M.Hayashi, R.Shimada, and Y.Maruyama, Division of Health Sciences, University of the Air, Chiba 261, \*Department of Pharmacology, Tokyo

Women's Medical College, Tokyo 162, Japan.

It has been demonstrated that glucocorticoids specifically bind to neuronal receptors in the hippocampus and the hippocampus contains the highest densities of glucocorticoid receptors of the brain. In order to directly assess changes of release of endogenous acetylcholine (ACh), GABA, glutamate and glycine from the rat hippocampus induced by systemic administration of dexamethasone, a glucocorticoid, we measured release of these substances using an intracerebral dialysis these substances using an intracerebral dialysis technique. A dialysis probe of Carnegie Medicine was inserted into the hippocampus of a Wistar strain rat. ACh was assayed by HPLC with an electrochemical detector and amino acids with a fluorescence detector. Subcutaneous injection of dexamethasone caused short-latency decreases of both ACh and GABA and increases of glutamate and glycine. These effects of dexamethasone are considered to be direct actions on neuronal receptors. It has been reported that glucocortineuronal receptors. It has been reported that glucocottricoid has a cytotoxic effect in the hippocampus. The increase of glutamate release and decrease of GABA release induced by dexamethasone may have some relation to neuronal damage by the steroid.

CORTICOSTERONE ALTERS MEMBRANE TIME CONSTANT THROUGH TYPE I RECEPTOR ACTIVATION S.G. Beck\*, T. List and K. Choi,

Department of Pharmacology, Loyola University Chicago Stritch School of Medicine, Maywood, Il 60153. The hippocampus is integral in the feedback inhibitory control of the hypothalamic-pituitary-adrenal axis control of serum corticosterone (CT) levels. The hippocampus contains the highest density of both Type I and Type II CT receptors and mRNA. Standard intracellular recording techniques were used to measure the effects of Type I and Type II receptor activation on CA1 hippocampal pyramidal cell active and passive properties. Rats were adrenalectomized (ADX) or ADX and treated with a 12.5 mg or NAM and treated with a 12.5 mg
CT pellet for two weeks. During the experiment either 1
nM CT and 1 nM RU486 for Type I receptor activation or 10
nM RU 28362 for Type II receptor activation were included
in the perfusion buffer. Type I receptor activation
significantly increased the time constant of cells
recorded from either ADX or ADX+CT treated animals as recorded from either ADX or ADX+CT treated animals as compared to cells from ADX or ADX+CT without Type I receptor activation. Action potential height and duration were significantly increased, fAHP amplitude reduced and the decay time of the sAHP reduced by Type I receptor activation. Type II receptor activation to did not significantly alter membrane properties. These effects of Type I receptor activation result in an increase in pyramidal cell excitability. We conclude that CT has a significant effect on active and passive hippocampal pyramidal cell properties at concentrations normally present during basal conditions. Supported by KO2 MH00880 and NS28512.

CELLS IN THE MEDIAL AMYGDALA ARE ESSENTIAL FOR ADRENAL-STEROID-INDUCED SODIUM INGESTION.
D.M. Zhang, A.N. Epstein and J. Schulkin.\* Departments of Biology and Anatomy. University of Pennsylvania., Philadelphia PA 19104-6048

Mineralocorticoid hormones play an important role in the regulation of body sodium both in terms of physiology and behavior. Adrenal-steroid hormones are known to bind to forebrain sites; including TYPE 1 receptors of the medial amygdala. In previous work with electrolytic lesions we have found that damage to the medial nucleus of the amygdala abolished mineralocorticoid-induced sodium intake. In the present study, cell body damage in the medial amygdala was induced by ibotenic acid in mature Sprague-Dawley rats. Following recovery, the rats were given 3%NaCl in addition to their food and water. They were then treated with either aldosterone alone, corticosterone alone, or both. We found that the lesion abolished both aldosterone-induced sodium ingestion and the potentiation of aldosterone appetite by corticosterone. By contrast,we also later found that sodium depletion-induced and captopril-induced sodium intake were left intact. These results provide further evidence that the medial region of amygdala is importantly involved in both mineralocorticoid-induced and corticosterone potentiation of mineralocoticoid-induced sodium appetite. ## RESPIRATORY REGULATION: CENTRAL NETWORKS/PATTERNS

## 58.1

CARDIORESPIRATORY EFFECTS OF TRIGEMINAL (V) AND SUPERIOR LARYNGEAL NERVE (SLN) STIMULATION IN THE PIGLET. R.A. Darnall\* and D.Berard, Dept. of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

To explore whether sensory inputs from the face and nose can augment the apnea and bradycardia produced by laryngeal stimulation (stim), we evaluated the effects of electrical stim of the maxillary branches of V and the SLNs. Piglets were anesthetized, paralyzed, and respirated either at a constant rate (CV) or were allowed to be ventilated in proportion to their intrinsic phrenic nerve activity (SV). Nerves were stimulated (500 ms train) using constant current during early to mid phrenic inspiration. In the CV animals stim of V increased phrenic amplitude (Pmax) (122.3 ± 3.9 and 150.0 ± 14.4) (intact vs vagotomy, % control ± SEM) whereas SLN stim decreased Pmax (51.3 ± 3.1 and 61.3 ± 4.4). Ttot was decreased by V stim (82.5 ± 3.3 and 98.6 ± 1.9) and increased by SLN stim (134.1 ± 5.3 and 108.9 ± 2.2). There were similar decreases in Ti after both V and SLN stim. When both nerves were stimulated together there was little net change in Pmax, TTot, or Ti. In the SV animals the changes in Pmax and TTot after V and SLN stim were similar to those in the CV animals. Ti, however, increased after V stim and decreased after SLN stim BP changed little after either V or SLN stim in both CV and SV animals. HR fell after both V and SLN stimulation in the SV animals. HR fell after both V and SLN stimulation in the SV animals but not when CV continued despite a decrease in HR when V and SLN were stimulated together. We conclude that stimulation of the maxillary branch of V, augments phrenic activity and decreases the inhibitory effects of SLN stimulation. The HR effects of both SLN and V stim appear to be decreased by chest movement.

PULMONARY C-FIBRE ACTIVATION OF VAGAL MOTONEURONES AND RESPIRATORY CELLS IN THE BRAINSTEM OF ANAESTHETIZED RATS AND CATS.

James F.X. Jones and David Jordan\* Department of Physiology, Royal Free Hospital Medical School, Rowland Hill Street, London NW3 2PF, UK.

The pulmonary chemoreflex is a triad comprising apnoea, bradycardia and systemic hypotension (Coleridge & Coleridge Rev.Physiol.Biochem.Pharmacol. 99: 1-110, 1984). We have recently become interested in the central mechanisms underlying this reflex. The responses of vagal motoneurones and respiratory neurones evoked by right atrial injection of Phenylbiguanide (PBG, 5-50µg/kg) were studied in chloralose/barbiturate anaesthetized rats and barbiturate anaesthetized cats. In the two species PBG evoked a short latency inhibition of both inspiratory (n=5) and expiratory neurones (n=6) located in both dorsal and ventral respiratory groups. In contrast, antidromically activated post-inspiratory laryngeal motoneurones (n=4) were strongly excited by PBG. However, the responses of different vagal motoneurones in the dorsal vagal motor nucleus (n=9) and nucleus ambiguus(n=8) to administration of PBG are less consistent than the responses of the different classes of respiratory neurone. The elicitation of this simple, primitive pulmonary chemoreflex is proving to be useful in dissecting central respiratory and cardiovascular mechanisms. mechanisms.

SOME SIGNS OF SHORT TERM MEMORY AT THE CENTRAL GENERATOR OF BREATHING. J. García Ramos\*. Neuro-physiological Laboratory Medical School. Universidad Autónoma de Querétaro, Wextero, MEXICO.

In pentobarbital anesthetized vagotomized cats

it wes observed that: a) Repeated stimulation of medium threshold vagal afferents (.2 msec 4-lov) applied at the end of inspiration, which have an off-switch effect therefore increasing slightly off-switch effect therefore increasing slightly the breathing rate. This controlled faster rate persisted for several cycles after stopping the stimulation. The effects were not accompanied by correlated changes in end-tidal CO<sub>2</sub>. b) The bradpnea induced by laryngeal distension overlasted also the period of stimulation. c) Brief trains of stimuli (4-6 Hz) applied at the middle of invariant the distributed trains of stimulation reduced trains to the distributed trains of stimulation reduced trains to the distributed trains the distributed trains the distributed trains to the distributed trains to the distributed trains to the distributed trains th spiration reduced transiently the diaphragmatic tension and lengthened the inspiratory movement. By repeating the trains for ten or more successive cycles, a similar pattern of the response appeared at the following inspirations after ceasing the stimuli, extinguishing gradually. Shortly after extinction, one single similar train could induce identical behavior. The results are interpreted as short-term memory mechanisms present at the central generator of breathing. The phenomena were not affected by strychnine, diazepam or amino-phosphono-valeric acid (APV) administration.

NEURONS OF THE PARAPYRAMIDAL REGION MODULATE RESPIRATORY ACTIVITY AND REFLEX RESPONSES TO STIMULATION OF PULMONARY C-FIBER RECEPTORS. B. Erokwu, K.P. Strohl, N.S. Cherniack and M.A. Haxhiu. Case Western Reserve University, Cleveland, OH 44106. It has been shown that ventral meduliary neurons close to the surface and just lateral to pyramidal tract (parapyramidal region-pp) project to spinal cord respiratory and cardiovascular related neurons. However, their role in regulation of cardiopulmonary responses is not well established. In the present experiments we assessed the effects of a) direct activation of pp on breathing activity and b) cardiorespiratory direct activation of pp on breathing activity and b) cardiorespiratory changes induced by stimulation of pulmonary c-fiber receptors, produced by phenylbiguamulate (PBG) given into right atrium (5-30  $\mu_{\rm g}/k_{\rm g})$ . Experiments were performed in  $\alpha$ -chloralose-anesthetized and artificially ventilated cats with  $O_2$  at end tidal CO2 above apneic threshold. Direct activation of pp neurons by topical application or microinjection of N-methyl-D-aspartate (NMDA; 10-100 nmol) increased diaphragm electrical activity from  $16\pm2$  to  $28\pm3$  units (p<0.05; n=12), and caused an elevation of arterial blood pressure (BP) by  $16\pm4\%$  (mean  $\pm$ SEM; p<0.05); but had no effect on heart rate. Activation of pp neurons significantly decreased duration of apnea resulting from stimulation of PBG caused cessation of inspiratory activity, on average lasting  $14.6\pm2.6s$  (p<0.05), decreased systolic blood pressure by  $27\pm5\%$  (p<0.05) and caused slowing of the heart rate, on an average by  $33\pm9\%$  (p<0.05). Activation of pp neurons significantly reduced inhibitory (p<0.05) and caused slowing of the leaft rate, of an average by 35+970 (p<0.05). Activation of pp neurons significantly reduced inhibitory effects on respiratory activity reducing duration of apnea to 4.1+1.7s (control vs NMDA: p< 0.005), but had no significant effects on cardiovascular responses. These data indicate an involvement of pp neurons in control of breathing activity, blood pressure, and respiratory reflex responses. Supp: HL-35830.

RESPIRATORY PHASE-DEPENDENT VARIATIONS IN CORRELATED SPIKE TRAINS OF BRAIN STEM CARDIORESPIRATORY NEURONS. B. G. Lindsey\*, Y. M. Hernandez, A. Arata, K. F. Morris, and R. Shannon. Dept. Physiol. & Biophysics, Univ. South Florida Med. Ctr., Tampa, FL 33612

The regulation of gas exchange requires coordination of the respiratory and cardiovascular systems. One component of this control mechanism may be a central "irradiation" of inspiratory drive from respiratory neurons of the ventrolateral medulla to cardiorespiratory neurons of the brain stem midline (Soc. Neurosci. Abst. 17:339, 1991; Morris et al., these proceedings). We sought evidence for the respiratory phase-dependent modulation of effective connectivity among cardiorespiratory neurons that could reflect one consequence of the irradiation and act cooperatively with baroreceptor feedback. Spike trains were recorded simultaneously in the rostral ventrolateral medulla (RVL) and regions of the medullary raphe nuclei of 10 anesthetized, vagotomized, paralyzed, artificially ventilated cats. Respiratory and cardiac related neurons were identified by cycle triggered histograms. Baroreceptors were stimulated by local pressure changes in the carotid sinus or increased blood pressure caused by occlusion of the descending aorta or i.v. phenylephrine hydrochloride. Correlated spike trains of 52 pairs of neurons were analyzed with the normalized Joint Peristimulus Time Histogram (*J. Neurophysiol.* 61:900, 1989) triggered by the onset of a respiratory phase. Diagonal "bands" of significant bins indicative of impulse synchrony (S) or asynchrony (A) throughout the respiratory cycle were most common. Phase-dependent variations were found in 12 pairs: 4 of 5 S bands were greater during the inspiratory phase; 5 of 7 A bands were more pronounced during expiration. The results provide evidence for respiratory phase-dependent modulation of functional links between baroresponsive and respiratory related midline and RVL neurons. Supported by NS19814 & BRSG S07 RR05749.

RESPIRATORY NEURONS IN THE VENTROLATERAL RETICULAR FORMATION OF OSCILLATING MEDULLARY SLICES FROM NEONATAL RAT. G.D. Funk\*. J.C. Smith. S.M. Johnson. & J.L. Feldman. Systems Neurobiology Lab. Dept. Physiological Science, UCLA, Los Angeles, CA, 90024-1527.

Medullary slices (300-600 µm thick) from neonatal rat containing the pre-Bötzinger Complex (preBötC), generate respiratory oscillations in cranial nerves IX and XII (Smith et al., Science, 254, 91), allowing analysis of mechanisms of rhythm generation in an isolated, active respiratory circuit. We have constructed maps of the spatiotemporal patterns of neuronal activity in the region of preBötC. Extracellular and whole-cell patch-clamp recordings identified 5 major cell types with distinct temporal discharge patterns. Inspiratory neurons (I) discharge coincident with nerve XII output, and receive large amplitude, rhythmic synaptic drive potentials (10-20 mV). Late I neurons discharge starting at the peak of XII output and continuing through I. Tonic expiratory neurons (E) discharge tonically during expiration and receive rhythmic, inhibitory synaptic potentials (2-10 mV) during I. Beating neurons discharge tonically at 3-10 Hz. Oscillatory neurons, proposed to be the kernel of the respiratory rhythm generator, discharge throughout I, and exhibit voltage-dependent pacemaker-like properties, post-inhibitory rebound, and receive small, rhythmic synaptic drive potentials (5-8 mV) during I. Lucifer yellow fills of I and E neurons revealed complex celular morphologies. Dendrites of both cell types extend ventrally 200-300 µm to within 50 µm of the ventral medullary surface. These studies indicate that there are complex, respiratory-related, synaptic interactions in medullary slices in vitro, and provide information essential for understanding the cellular and synaptic processes underlying respiratory rhythm and pattern generation. Supported by NIH Grants HL40959 & HL02204 (ICS) and NSERC of Canada (GDF).

# 58.9

ORGANIZATION OF THE VENTROLATERAL MEDULLA: DISCRETE PROJECTIONS TO TWO RESPIRATORY NUCLEI IN NEONATAL AND ADULT RATS. E.G. Dobbins\* & J.L. Feldman. Systems Neurobiology Lab., Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527.

The medullary lateral tegmental field (LTF) has long been considered critical for the control of respiration. Recent developments suggest a high degree of regionalization among respiratory related LTF neurons (Ellenberger & Feldman, <u>ICN</u> 294 ('90): 202). To establish whether premotoneurons, or afferents to premotoneurons, projecting vertex periodications, of arteriors to principle were located in overlapping populations in LTF, we used the transynaptic tracer pseudorabies virus (PRV). Injections into the phrenic nerve of adult, or the right hemidiaphragm of neonatal, rats labeled premotoneurons in a discrete region of LTF, just rostral to obex. Injections into respiratory modulated musculature at the base of the tongue labeled neurons premotor to the hypoglossal nucleus (XII) predominantly in the medial reticular formation, just lateral to XII. Neurons afferent to either premotor population are contained within rostral regions of LTF, known as the Bötzinger (BötC) and the preBötzinger Complex (preBötC). The populations do not appear to overlap. The density of neuronal label in BötC and preBötC is greater following tongue injections, compared to a more caudal concentration of neuronal label following diaphragm injection. These results indicate that there is a separation of control elements, at least two synapses prior to motoneurons of the tongue and diaphragm, within a highly circumscribed region of the brainstem. We are grateful to J.P. Card, Ph.D., Du Pont Merck Pharmaceutical Co., for his generous gift of PRV and antibody. Supported by NIH Grant NS24742.

MEDULLARY VENTRAL RESPIRATORY GROUP (VRG) NEURON RESPONSES DURING FICTIVE COUGH R. Shannon\*, K.F. Morris and B.G. Lindsey. Physiol. & Biophy., Col. Med., Univ. So. FL., Tampa, FL 33612

The central neural network mechanisms that produce the cough motor pattern are poorly understood. Experiments were conducted to determine if activities of bulbospinal inspiratory and expiratory VRG neurons change appropriately during cough for roles in transmission of cough Anesthetized cats (n=4) were patterns to spinal motoneurons. decerebrated (mid-collicular), thoracotomized, paralyzed and ventilated (phrenic driven). Extracellular single neuron activity and phrenic and lumbar nerve efferent neurograms were monitored during fictive cough, produced by mechanical stimulation of the intra-tracheobronchial tree. Bulbospinal neurons were identified by antidromic stimulation at T1 (collision test). The firing rates of inspiratory (n=10) and expiratory (n=10) bulbospinal neurons increased during the respective phases of the cough cycle. Putative propriobulbar neurons (n=32), active in different phases of the respiratory cycle and located in the caudal and rostral VRG, also responded in ways consistent with roles in cough generation. Altered discharge patterns were similar to those observed during simulated fictive cough generated by enhanced versions of a previously described respiratory network model (Soc. Neurosci. Abst.17:620, 1991). The results suggest 1) that premotor I and E VRG neurons provide descending drive during both eupnea and cough, and 2) that the respiratory network is dynamically reconfigured to generate the cough motor pattern. (BRSG RR05749)

SPATIAL ORGANIZATION OF PREMOTONEURONS IN A LOCAL RESPIRATORY CIRCUIT STUDIED BY TRANSSYNAPTIC NEURONAL LABELING WITH PSEUDO-RABIES VIRUS (PRV). R. Van Bibber. C.L. Barry. E.G. Dobbins. J.C. Smith. & J.L. Feldman\*. Systems Neurobiology Lab, Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527.

Angeles, CA 90024-1527.

We have proposed that respiratory rhyshological science, OCLA, Loss Angeles, CA 90024-1527.

We have proposed that respiratory rhythm is generated in the prebitzinger Complex (pre-BötC) of the ventrolateral medulla, and that rhythmic respiratory drive is transmitted through local interneuronal circuits to cranial respiratory motoneurons including hypoglossal (XII) motoneurons (Smith et al., Science 254: 726, '91). To establish the organization of premotor and interneurons in this local circuit, we used the transsynaptic tracer PRV. Injections of PRV were made into respiratory-modulated musculature of the tongue of neonatal rats, and the neuronal labeling pattern analyzed at different survival times. XII motoneurons were the main population labeled after the shortest survival times (30-35 hrs). With survival times of 48-52 hrs, discrete populations of hypoglossal premotoneurons were labeled predominantly in the tegmental field (TF), just lateral and ventral to XII. With 70 hr survival times, dense neuronal labeling occurred in pre-BötC and more rostral Bötzinger Complex. Less dense neuronal labeling occurred in more caudal ventrolateral reticular formation (rostral ventral respiratory group). These results suggest a spatial segregation of interneurons in the caudal ventrolateral reticular formation (rostral ventral respiratory group). These results suggest a spatial segregation of interneurons in the transmission pathway from pre-BötC neurons through more dorsal TF premotoneurons to XII motoneurons. The results are consistent with our previous studies (*ibid*) which indicate a dense concentration of propriobulbar interneurons within the pre-BötC that are the substrate for transmission of the rhythm (generated locally) to cranial (pre)motoneurons. We are grateful to J.P. Card, Du Pont Merck Pharmaceutical Co. for his generous gift of PRV and antibody. Supported by NIH Grants NS24742, HL.40959 & HL.02204.

FLUORESCENT DYE TRACING REVEALS RECIPROCAL CONNECTIONS BETWEEN RESPIRATORY NUCLEI AND THE MEDIAL PONTINE RETICULAR FORMATION (mPRF).

L.H. Lee, J.G. Veino, and R.Lydic

Department of Anesthesia, Penn.
State University, College of Medicine, Hershey Pa 17033.

Microinjection of cholinergic agonists into the mPRF of intact, unanesthetized cats causes a REM sleep-like state and state-dependent respiratory depression. Since there are no major clusters of respiratory neurons in the mPRF, these potent respiratory effects suggest connectivity between the mPRF and brain stem respiratory nuclei. The present study is characterizing these connections by injecting the mPRF and the pontine respiratory group (PRG) with 50 or 100 nl of the retrograde tracers True Blue (5%), Fluro-Gold (2%), and Diamidino Yellow (3%). To date, we have studied 8 cats following 6 bilateral injections into the mPRF and 2 bilateral injections into the PRG. After mPRF injections fluorescent labeling was observed in nuclei comprising the dorsal, ventral, and pontine respiratory groups. Bilateral mPRF injections produced double labeled cells in the PRG and bilateral PRG injections double labeled mPRF neurons. The mPRF injections consistently labeled cells in the retrofacial, retrotrapezoid and pedunculopontine tegmental nuclei. These data demonstrate connections between cholinoceptive regions of the mPRF and brain stem respiratory groups. Such connections could mediate state-dependent respiratory depression evoked by cholinoceptive mechanisms within the mPRF. Support: Department of Anesthesia, HL47749, HL40881(RL).

SUB-POPULATIONS OF NEURONS IN THE ROSTRAL PONS MEDIATE DISTINCT FUNCTIONS IN THE CONTROL OF RESPIRATION IN CATS. M.-L. Fung. R. A. Maue\* and W. M. St. John. Department of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

The rostral pons has been shown to be involved in difference functional roles in the control of respiration in mammals. Here we examined the hypothesis that sub-populations of neurons in the rostral pons mediate distinct functions in the control of respiration. Experiments were performed on decerebrate, vagatomized and paralyzed animals. Kainic acid (KA) (4.69 mM) was microinjected (10-60 nl) into loci in the rostral pons in which electrical stimulation had caused an on- or offswitch of phrenic activity. Most of the effective microinjections of KA caused changes in the length of different phases of the respiratory cycle. In particularly, microinjections of KA in a medial region (2-3 mm from midline) increased the length of expiratory phase and delayed the onset of expiratory activity of spinal nerves. In a lateral region (4-5 mm from midline), prolongations of the inspiratory phase followed microinjections of KA into the rostral portion (0-1 mm rostral to inferior colliculus). In contrast, KA injections into the caudal portion (1-3 mm caudal to inferior colliculus) increased the length of expiratory phase and changed the onset time of spinal neural expiratory activity. In addition, the frequency response to hypercapnia was diminished significantly after KA was applied in the caudal portion of the lateral region. Results confirmed that the rostral pons plays an important role in the control of the respiration. We conclude that groups of neurons with differential functional roles in the control of respiration are located in the rostral pons. (Supported by HL 26091)

DEVELOPMENTAL CHANGES IN RESPIRATORY NEURAL OUTPUT IN LARVAL FORM OF RANA CATESBEIANA. R. Galante, E. Smith, L. Kubin and A.I. Pack\*. Center for Sleep and Respiratory Neurobiology, Univ. of Pennsylvania, Philadelphia, PA.

Studies have been conducted to examine the changes in respiratory neural output at different stages of development in the larval form of the amphibian Rana catesbeiana. We used an isolated in vitro brainstem preparation superfused with an oxygenated physiological solution. Extracellular multiunit activity was recorded from the 7th motor nucleus at various stages of development, both in normal solution and when chloride ion was replaced in the superfusate by gluconate. When lung ventilation first appeared (stages VI-VII), the neural activity consisted of brief, fast-rising bursts superimposed on the ongoing rhythmic activity reflecting the gill ventilation. During developmental stages XX-XXI, the lung burst rise time lengthened and a distinct oscillation appeared a brief period without gill activity. Still later (stages XXIV-XXV), the gill rhythm disappeared and there was a further lengthening of the bursts for lung breathing. At all stages of development, removal of chloride abolished the bursts corresponding to gill ventilation, while the bursts for lung ventilation persisted, albeit with an increased duration and amplitude. There were no obvious developmental changes in the pattern of lung ventilation bursts in the absence of chloride. These data suggest that chloride ion-mediated inhibition is necessary for generation of the gill but not the lung breathing rhythms. The generator for the latter appears early and shows alteration with development that, at least in part, depend on chloride channels. (Supported in part by HL-39775)

RESPIRATORY RELATED NEURONS SUPPLYING BILATERAL INNERVATION IN THE RAT. R. Pásaro\* and P.A. Núñez-Abades. Dept. of Animal Physiology and Biology, University of Sevilla, 41012-Spain.

The respiratory motoneurons of the nucleus ambiguus and the cervical spinal cord are organized as a bilateral column of cells. These motoneurons project exclusively ipsilateral with no evidence of axonal branching or axons crossing the midline, in the rat. Which cells are implicated in the synchronization of the motoneuronal activity in both pools? To address this issue, we have looked for the neurons supplying bilateral innervation by means of the multiple fluorescent retrograde neuronal labeling technique. Our results indicated that a discrete population of neurons within the rostral Ventral Respiratory Group (rVRG) is the main source (90%) of neurons that sent axonal collaterals to both phrenic nuclei. Furthermore, the rVRG and the Bötzinger Complex concentrate the highest number of neurons (50%) that sent axonal projections by collaterals to both VRG. These results suggested that multiple pathways (instead of only one) could contribute to the synchronization of the bilateral respiratory motoneuronal networks and, that the interconnections of the VRG could satisfy similar purposes.

DYNAMIC RESPIRATORY RESPONSES TO ANTERIOR HYPOTHALAMIC WARMING IN THE SLEEPING CAT. H. Ni\*, J. Zhang, and R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

Local warming of the hypothalamus modifies respiratory rate and clicits panting. This effect is state-dependent, with rapid eye movement sleep greatly diminishing the respiratory response. We examined the respiratory responses following anterior hypothalamic warming during different sleep states; the objective was to determine the mechanisms by which respiratory patterns change to thermal challenge in each state. The anterior hypothalamus was warmed (0.5MHz, 80-150mW) bilaterally by two electrode pairs (2mm inter-tip distance, 2 mm bared tip, and 0.3 mm in diameter). Anterior hypothalamus temperatures were recorded by a thermocouple placed 1 mm deeper than the tip of one heating electrode. Electrodes were also placed 1 mm deeper than the tip of one heating electrode. Electrodes were also placed for recording EEG, ECG, diaphragmatic and neck EMG, and core body temperature. Warming of the anterior hypothalamus by 1-2°C elicited polypnea during awake and quiet sleep states, but not in rapid eye movement sleep. As total respiratory cycle time decreased, the ratio of inspiratory time to expiratory time (Ti/Te), and inspiratory time to total time (Ti/Tio) remained constant, although increased variation in these ratios appeared during the warming period, particularly during REM sleep. The amplitude of diaphragmatic EMG activity decreased with extreme tachypnea. These results suggest that descending thermal influences selectively modify inspiratory/expiratory switching thresholds rather than enhancing inspiratory drive systems. Supported by HD22506.

RESPIRATORY MODULATION OF LOCUS COERULEUS (A6) AND A5 NORADRENERGIC (NE) CELLS. D. Huangfu\*, N. Koshiya, A.J.M. Verberne and P.G. Guyenet. Dept. Pharmacology, Univ. of Virginia, Charlottesville, Va 22908.

The present experiments were designed to test the hypothesis that A5 and A6 NE cells receive central respiratory information from the rostral ventrolateral medulla (RVL), a region of the brain primarily involved in autonomic and respiratory control. A5 and A6 cells were recorded in urethananesthetized vagotomized rats along with the discharge of the phrenic (PND) and splanchnic nerves (SND). Carotid chemoreceptor stimulation (CCSt) was performed with 10 s  $N_2$  inhalation or 3 min hypoxia (12%  $O_2$ ). Both A5 and A6 neurons were activated by CCSt and displayed respiratory patterns of discharge at rest which was enhanced by CCSt. A6 cells displayed one of the two central respiratory patterns found in RVL neurons previously: i) an inspiratory (I) pattern characterized by peak firing coinciding with the PND peak (202±39 ms after PND onset) and nadir during early expiration, or ii) a postinspiratory (post-I) pattern characterized by increased firing probability at the end of the phrenic burst (590 ± 44 ms after PND onset) and a nadir coincident with the peak of PND. Most A5 cells displayed a post-I pattern which was enhanced by CCSt. RVL neurons with direct projections to A6 were identified with antidromic mapping techniques (depth threshold curves). The vast majority of active RVL cells with projections to LC (19/27) also had central respiratory patterns reminiscent of that of AS and A6 cells. The patterns were enhanced by CCSt. These RVL cells were frequently inhibited by raising arterial pressure but were distinct from RVL sympathetic premotor neurons since they did not exhibit detectable pulse synchrony and could not be backfired from the thoracic spinal cord. Support: HL 28785 and HL 39841 from NIH.

CENTRAL NERVOUS SYSTEM NEURONS LABELLED FOL-LOWING THE INJECTION OF PSEUDORABIES VIRUS INTO THE RAT URINARY BLADDER

I Nadelhaft(1-3)\* P.L. Vera(1,2), J.P. Card(4), and R.R. Miselis(5),

VA Med Ctr & Depts of Pharmacology & Neurosurgery, Univ
Pittsburgh Med Sch, Pittsburgh, PA, DuPont-Merck Pharmaceutical Co., Wilmington, DE, Inst of Neurological Sci, Univ of
Penna, Philadelphia, PA

Pseudorabies virus (PRV) was injected into the wall of the urinary bladder and, following incubation times of 2, 3, 4 and 4 1/2 days, central nervous tissue was processed immunohistochemically for the presence of virus. Infected neurons were initially visualized in the sacral parasympathetic nucleus and other parts of the spinal cord (mainly lumbosacral). Following longer survival times, infected neurons were found in the raphe nuclei, reticular area, pontine micturition center (PMC), locus coeruleus (LC), parabrachial nucleus, red nucleus, hypothalamus, preoptic area, amygdala and cortex. Sections from the medullary dorsal tegmental region (DLT) of a three-day animal which included the PMC and the LC were immunohistochemically processed for PRV and acetyl cholinesterase (AChE). Neurons in the locus coeruleus stained for AChE whereas neurons in the PMC stained only for PRV. There were also some neurons medial to the PMC that stained lightly for AChE. There were no doubly labelled neurons. Therefore, since we found no AChE in the PRV-labelled PMC neurons, it is unlikely that PMC neurons are cholinergic. In conclusion, these data define a multisynaptic circuit of neurons whose ultimate output influences urinary bladder function.

## 59.3

Identification of the Central Nervous System Pathways Controlling Bladder Function in the Neonatal Rat Using Transneuronal Tracing with Pseudorabies Virus (PRV). J.R. Roppolo\*, P. Card, K. Sugaya, N. Yoshimura and W.C. de Groat. Dept. Pharm., Univ. Pittsburgh and DuPont Inc., Wilmington, DE

During the early postnatal (PN) period (day 0-6) in the rat, micturition (MT) is mediated by a spinal reflex pathway (SRP), whereas in older animals 12-15 days of age MT occurs via a supraspinal reflex pathway. Axonal tracing studies using PSV were conducted to examine the changes in the MT reflex pathway during the PN-period. PSV  $(1-2~\mu l,~10^6 p/\mu l)$  was injected into one side of the urinary bladder of anesthetized rat pups ranging from 2 to 14 days in age. After transport time of 1-4 days, animals were perfused with fixative and tissues were sectioned and processed using immunocytochemical techniques to identify PSV. In young rats (3-6 days) versus older rats (12-17 days) virus labeled cells in the Le-S1 spinal cord were present in greater numbers and occurred in a wider distribution. In rats of both ages, labelled cells were present in the area of the sacral parasympathetic nucleus (SPN) and in the dorsal commissure (DCM). In young rats, labelled neurons were also present in lamina I of the dorsal horn and in large numbers in medial laminae (V-VII). In older rats, labelled cells were located predominately ipsilateral to the injection site whereas in young rats the cells were distributed bilaterally. Brain stem labelling however was more prominent and had a wider distribution in the older animal. Labelled neurons were seen in the area of the locus ceruleus, iaqueductal grey (PAG), and pontine reticular formation. In young animals (5 days), few or no labelled neurons were seen in these areas. In conclusion, these experiments revealed a more extensive spinal interneuronal system associated with the bladder innervation in day 3 to day 6 rats. The apparent elimination of this interneuronal system in older rat pups is consistent with the reorganization of the micturition reflex and emergence with supraspinal mechanisms during postnatal development.

ANALYSIS OF DENDRITIC END BRANCHES OF NEUROBIOTIN- AND HRP-INJECTED SACRAL PREGANGLIONIC NEURONS (PGN) IN THE CAT. C.W. Morgan\*, L.A. Felkins, and W.C. de Groat Departments of Anatomy and Neurobiology and Urology, Eastern Virginia Medical School, Norfolk, VA 23501; Department of Pharmacology, Univ. Pittsburgh, Pittsburgh, PA 15261.

21 PGN in the sacral parasympathetic nucleus of the cat were filled by intracellular injection of neurobiotin or HRP and were analyzed according to numbers of dendritic end branches (DEB) terminating in nine specific fields in the gray and white matter. Three groups of cells emerged: Type I (N=9) had an avg 17.5 DEB in 6.4 regions and had key dendrites in lam I and the lateral ventral horn. Type IIa (N=8) had an avg 14.2 DEB in 4.9 regions and principal dendrites in the dorsal and lateral funiculus (DLF/LF) but none in lam I. Type IIb (N=4) had an avg 12 DEB in 3.3 regions, no DEB in lam I or the DLF/LF Cells in all three groups had similar numbers of stem dendrites (avg 4.9)

Although the dendritic trees exhibited a predominant transvers orientation, extending up to 1300-2200  $\mu$  m mediolaterally and 2000-2700  $\mu$  m dorsoventrally, further analysis revealed a significant rostrocaudal spread of dendrites of up to 700-1200  $\mu$  m, significantly enlarging the sampling area of

We propose that these separate dendritic patterns exist because of the variety of afferent sources and unique control mechanisms required by functionally diverse groups of PGN. Our hypothesis, to be tested in further experiments, predicts that Type I PGN, with the major lamina I dendritic field, are especially dependent upon the visceral and somatic sensory input to this region and are likely to be involved in sexual function; Type IIa PGN which have many DLF/LF dendrites, but none in lamina I, are likely to be dependent upon bulbospinal pathways which is characteristic of bladder PGN.

ANALYSIS OF THE MICTURITION REFLEX PATHWAY IN THE IN VITRO BRAIN STEM - SPINAL CORD - BLADDER PREPARATION OF THE NEONATAL RAT. K. Sugaya', M.N. Kruse and W.C. de Groat. Dept. Pharmacology, Univ. Pittsburgh, Pittsburgh, PA 15261.

Micturition in the neonatal rat is induced by a spinal reflex pathway activated when the mother licks the perineum of the pup. Experiments were undertaken to determine whether this reflex could be elicited in isolated brain stem-spinal cord-urinary bladder (B-SC-B) preparation of the neonatal rat (1-7 days of age). B-SC-B were removed from hypothermic anesthetized rats and perfused with Kreb's Ringers solution at 26-30°C. Bladder activity was monitored by measuring intravesical pressure with a needle inserted into the bladder lumen. Following distension of the bladder with 0.1-0.2 ml of saline tactile stimulation of the perineal region (PS) induced reflex bladder contractions (mean 9 cm $\rm H_2O$ ) which were almost the same amplitude as the contractions induced by electrical stimulation (ES) of the bladder surface. The response to ES or PS were blocked by TTX  $(1\mu M)$ , however, rhythmic intrinsic contractions of the bladder were unaffected by TTX. Removal of the spinal cord blocked PS-contractions, but enhanced intrinsic contractions. CNQX  $(5\mu M)$  but not MK-801  $(50\mu M)$  decreased the amplitudes of PScontractions but not intrinsic contractions. In some preparations, bicuculline methiodide (BCMI;  $10\mu M$ ) increased the amplitude of PS-contractions. NMDA

 $(10\mu M)$  transiently increased the frequency of rhythmic bladder contractions. It is concluded that glutamic acid acting via AMPA receptors may be involved as a transmitter in the perineal-bladder reflex in neonatal rats. The enhancement of the reflex by BCMI indicates that the reflex pathway is tonically inhibited by a GABAergic mechanism.

## 59.4

THE EFFECTS OF LY-274614, A COMPETITIVE NMDA RECEPTOR ANTAGONIST, ON THE MICTURITION REFLEX IN THE RAT. M. Yoshiyama\*, J.R. Roppolo, K.B. Thor and W.C. de Groat. Dept. of Pharmacol., Univ. of Pittsburgh, Sch. of Med. Pittsburgh, PA 15261 and Lilly Research

Laboratories, Indianapolis, IN 46285.

The effects of LY-274614 (0.1-30 mg/kg i.v.) on bladder and external urethral sphincter (EUS) EMG activity were examined in the following preparations: 1) spinal cord intact rats (SCI), 2) chronic spinal cord (T<sub>6</sub>·T<sub>8</sub>) transected rats, (3) SCI rats with continuous intravesical infusion of 0.1% acetic acid (AA) to produce bladder irritation. Also examined were SCI rats treated with LY-274614 via intrathecal (i.t.) catheter at the L<sub>6</sub>-S<sub>1</sub> segments. All animals were anesthetized with urethane (1.2 g/kg s.c.). In intact rats LY-274614 reduced the maximal amplitude of micturition contractions (MAC) and EUS activity in a dose dependent fashion. In chronic spinal cord transected rats the same doses had no effect on bladder activity but increased MAC at 0.3 and 1 mg/kg, and inhibited EUS activity at 10-30 mg/kg. Intrathecal administration of LY-274614 to intact rats, significantly reduced MAC and EUS activity in doses ranging from 0.12-30 ug. MAC recovered to 50% of control after 3 hrs following i.v. (30 mg/kg) or i.t. (6 ug) administration of LY-274614. AA infusion shifted the dose-response curve to the right for both bladder pressure and EUS EMG. The data suggest that excitatory amino acid (EAA) transmitter mechanisms at the level of the spinal cord are important in modulating bladder activity in the intact animal; but that these mechanisms do not contribute to bladder reflexes following chronic spinal cord transection.

AN IN VITRO NEONATAL RAT PREPARATION FOR THE STUDY OF

PERINEAL-BLADDER REFLEXES. L.Song,B.Schmidt and S.J.Shefchyk\*.

Depts. of Med. and Physiol., Univ. of Manitoba, Winnipeg, Canada R3E 0W3.

In neonatal rats, micturition is evoked by stimulation of the perineal skin (Kruse and deGroat, Am.J.Phys. 1990:258,R1508). In the present experiments, we describe this perineal-bladder reflex in an in vitro neonatal rat preparation.

Neonatal rats, 3 to 13 days old, were anaesthetized with ether and decerebrated. The brainstem and spinal cord dissection was performed in a chamber filled with cold Krebs solution bubbled with oxygen. The bladder, hindlimbs and perineal skin were left intact as were spinal nerves caudal to the L1 segment. One or two 271/2 gauge needles were inserted into the dome of the bladder and connected to a pressure transducer and/or infusion syringe. Bladder reflexes were tested when the bath was warmed to 26°C. A small volume of Krebs solution containing red food colouring was slowly injected into the bladder. The perineum was stimulated by light, fast stroking of the skin with a cotton swab.

The perineal-bladder reflex could be elicited in all ages tested. Ten to twenty five seconds after the start of the stimulation, the bladder pressure increased and one could observe expulsion of fluid from the urethra. The peak pressure reached during stimulation was 5 to 9 mmHg depending on the age of the animal. When stimulation was stopped, the bladder pressure immediately returned to baseline. Sometimes stimulation evoked the bladder contractions which were subthreshold for evoking expulsion of fluid.

This preparation may be useful for further investigations examining physiological and pharmacological properties of perineal reflex pathways involved in micturition or sexual reflexes in the rat.

This research was funded by the Medical Research Council of Canada.

PATCH CLAMP ANALYSIS OF AFFERENT AND EFFERENT NEURONS THAT INNERVATE THE URINARY BLADDER OF THE RAT. Yoshimura and W.C. de Groat, Dept. of

Pittsburgh, Pittsburgh, PA 15261. Axonal tracing techniques were used in combination with patch clamp methods to examine the electrophysiological properties of afferent (AN) and efferent neurons (EN) innervating the urinary bladder (UB) of the adult rat. Fluorescent axonal tracers (fast blue or fluorogold) were injected into the UB 10-14 days prior to the removal of the L<sub>6</sub>-S<sub>1</sub> dorsal root ganglia (DRG) and the major pelvic ganglia (MPG). Ganglia were dissociated with enzymatic-mechanical methods and individual dye-labelled cells were identified with fluorescent microscope. Bladder AN were small (mean;  $27.6 \pm 2.3 \ \mu m$  in size) and the majority (80%) exhibited TTX-resistant action potentials and Na\*currents that had high thresholds for activation (-10 to -30 mV). Bladder EN (mean;  $28.5 \pm 3.1 \mu m$ ) had action potentials with high thresholds (-20 to -40 mV) that were TTX-sensitive. A transient outward current, typical of an A type  $K^*$  current was activated by depolarizing pulses (10-15 mV) from holding potentials equivalent to the resting membrane potential (-60 to -70 mV). This outward current was detected in 75% of bladder AN but not in EN. ACh (10-100  $\mu$ M) applied to EN produced an inward current, membrane depolarization and a prolonged burst of action potentials. A brief application of norepinephrine (1-10  $\mu$ M) elicited a prolonged depolarization and an inward current but no firing in EN. It is concluded that: (1) axonal tracing with fluorescent dyes is useful for identifying specific populations of neurons for patch clamp studies, (2) bladder AN and EN are distinguished by different types of Na\* and K\*channels and (3) the majority of bladder AN have high electrical thresholds for spike initiation which may reflect the large population of unmyelinated chemo-mechanosensitive afferents that innervate the bladder.

## 59.9

HYPERTROPHY OF NEURONS INNERVATING THE URINARY BLADDER OR COLON OF STZ-DIABETIC RATS

B.C. Steinbacher (1), P.L. Vera\*(1,2) and I. Nadelhaft (1-3), <sup>1</sup>VA

Med Ctr & Depts of <sup>2</sup>Pharmacology & <sup>3</sup>Neurosurgery, University
of Pittsburgh Medical School, Pittsburgh, PA

Hypertrophy of smooth muscle occurs as a consequence of various stresses placed upon the organ. For example, partial obstruction of the urethra results in bladder hypertrophy. A concomitant observation was a substantial increase in the size of postganglionic neurons in the major pelvic ganglia (MPG). This finding suggested that urinary bladder hypertrophy observed in the STZ-diabetic rat might also be accompanied by changes in other neurons concerned with micturition or defecation. Using fluoresneurons concerned with micturition or defecation. Using fluorescent dyes injected into the bladder or the colon, we have measured the sizes of various groups of neurons associated with these organs in control and STZ-diabetic rats. These include 1) post-ganglionic neurons in the MPG 2) post-ganglionic neurons in the inferior mesenteric ganglion, 3) dorsal root ganglion neurons 4) sympathetic chain ganglion neurons 5) preganglionic neurons in the sacral parasympathetic nucleus, 6) motor neurons in Onuf's nucleus innervating the external urethral sphincter. In addition we have measured neurons in some of these groups for rats which have measured neurons in some of these groups for rats which have been maintained on a 5% sucrose in water and restricted food diet. Only neurons which make direct contact with the bladder or the colon were hypertrophied (15-70%). We speculate that a trophic factor transported from the organ to the neuron is responsible for this effect.

# 59.11

EFFECT OF INTRATHECAL ADMINISTRATION OF THE NK-1 RECEPTOR ANTAGONIST GR 82.334. ON BLADDER MOTILITY IN ANESTHETIZED

Lecci. S. Giuliani and C.A. Maggi\*. "Menarini" Pharmacol. Res.

Dept., via Sette Santi 3, 50131 Florence, Italy.

It has been proposed that substance P mediates sensory transmission in the spinal cord, however the role of this tachykinin on vesical reflexes has not been determined yet.

Application of capsaicin (4 µg/50 µl) on the serosal surface of the urinary bladder triggers a supraspinal micturition reflex (SMR). GR 82,334 (1 nmol/rat, intrathecal, i.t.) strongly reduced reflex bladder contractions induced by conscient.

reflex bladder contractions induced by capsaicin.

Infusion of saline evoked SMR. I.t. administration of GR 82,334

(up to 1 nmol/rat, i.t.) did not modify either the threshold for activation of the reflex or the amplitude of bladder contractions.

Perineal noxious pinching activated a somatovesical spinal reflex which was reduced by the NMDA antagonist 2-amino-5phosphonovaleric acid (250 nmol/rat, i.t.). GR 82,334 (1 nmol/rat, i.t.) had no effect.

Intraurethral infusion of capsaicin (500 µg/600 µl) inhibited distension-induced SMR. Such inhibition was prevented by the 5-HT1A agonist 8-OH-DPAT (330 µg/kg, i.v.) but not by GR 82,334 (1 nmol/rat, i.t.).

These results suggest that spinal NK-1 receptors mediate excitatory but not inhibitory bladder reflexes induced by activation of capsaicin-sensitive fibers. Other excitatory vesical reflexes, which are capsaicin-resistant, are not affected by GR 82,334.

DIFFERENTIAL EFFECTS OF SPINAL CORD INJURY ON THE MORPHOLOGY OF BLADDER AFFERENT AND EFFERENT NEURONS. M.N. Kruse\*, S.L. Erdman, M. Tanowitz and W.C. de Groat Dept. of Pharmacology, Univ. of Pittsburgh, Pittsburgh PA 15261.

It has been reported that physical obstruction of the urethral outlet in adult rats results in bladder hypertrophy and an increase in size of dorsal root ganglion (DRG) and major pelvic ganglion (MPG) cells which innervate the bladder. Obstruction of the urethral outlet also occurs following spinal cord injury (SCI); this is a functional obstruction caused by simultaneous contraction of the bladder and urethral sphincter (bladder/sphincter dyssynergia). This study tested whether functional obstruction due to SCI also induces changes in bladder weight and bladder neuron size. The bladders of control or chronic spinal (4-9 weeks after transection at T8-T9) adult female Wistar rats were injected with either fluorogold (FG) or WGA-HRP under halothane anesthesia. Several days later, the MPGs and DRGs were removed, processed for either HRP or FG, and the areas of the labelled cells measured. Following SCI, there was a significant increase in bladder weight (400%) and DRG cell size (40%), but no significant change in MPG size. The increase in DRG cell size was observed with both tracers; however, the size of FG-labelled cells was  $\sim\!30\%$  less than the size of WGA-HRP cells. It was shown that both tracers are transported by the same population of neurons; therefore the observed difference is attributed to shrinkage due to the FG-dehydration process. The results indicate that functional and physical obstruction of the urethral outlet elicited similar morphologic changes in the bladder and DRG cells but that only physical obstruction increased the size of MPG cells. This suggests that in spinal injured animals, preganglionic neurons may influence MPG neurons to negate the effect of peripheral trophic substances released from the hypertrophied bladder. Supported by the American Paralysis Association and PVA Spinal Cord Research Foundation.

## 59.10

NEUROANATOMICAL EVIDENCE FOR BRANCHING AXONS FROM THE RAT SACRAL CORD PROJECTING TO THE URINARY BLADDER AND URETHRA. B. CONTÉ, S. STANZANI, S. MANZINI, A. GIACHETTI\*, G. LOPEZ, R. PELLITTERI and A. RUSSO.º Pharmacol Dept Menarini Ricerche Sud, Pomezia (Rome), Italy and °Inst of Physiology, Univ of Catania (Italy).

Previous electrophysiological and functional data provided evidence for the existence of a population of preganglionic axons in the rat pelvic nerve which give rise to two peripheral branches: one providing an input to major pelvic ganglion cells innervating the urinary bladder (UB) and another one projecting distally to the wall of the urethra via the penile nerve (PeN). On the basis of these results a double retrograde axonal tracing technique has been used to ascertain the localization of cell bodies from which these branched axons arise. Fluorescent tracers Fast Blue (FB) and Diamidino Yellow (DY) were injected in postganglionic fibers to the UB or to the urethra (PeN), respectively. Microinjections resulted in the labeling of DY (12.1%), FB (15.6%) and DY-FB (5.7%) small (20-30 µm) neurons located in the dorsal root ganglia (DRG) corresponding to the last segments of the sacral spinal cord. These cells were observed in DRG ipsilateral to the site of injection (n=6), being absent in contralateral DRG or in ganglia taken from higher (lumbar) segments. Transection of the pelvic nerve (10 days before) ipsilateral to the site of tracers administration, resulted in the disappearance of double labeled neurons (n=4). DY, FB or DY-FB positive cell bodies were also found at the level of the last spinal cord segments (S2-S4) in the 'intermediolateral nucleus' and their estimated ratio (%) was 4:5:1. These anatomical data reinforce our previous functional findings and extend the knowledge on the neuroanatomy of the vesico-urethral interrelationships

# 59.12

FOS LABELLING FOLLOWING ELICITATION OF SEXUAL REFLEXES IN MALE RATS Anne M. Peternel\*, Lesley Marson and Kevin E. McKenna Department of Physiology, Northwestern University Medical School, Chicago IL 60611

The proto-oncogene c-fos has been used as a neuroanatomical marker for functional activity. The urethrogenital (UG) reflex represents a reliable model of sexual reflexes in spinalized, urethane-anesthetized rats. After repetitive elicitations of the UG reflex, activity-dependent maps of the lumbosacral cord were constructed from patterns of *fos*-like immunoreactivity with a polyclonal antibody to fos oncoproteins. These maps were compared to patterns of fos labelling in surgically prepared control animals in which UG reflexes were not elicted.

The patterns of fos labelling in experimental animals were different from that of controls. Scant fos-positive neurons were labelled in spinally intact controls or those control animals otherwise not subjected to re intact controls or those control animals otherwise not subjected to repeated elicitations of the UG reflex. From L1-L3, labelled cells were found in the intermediolateral cell column and Lamina X, sites of the sympathetic preganglionic neurons of the hypogastric nerve. Lamina V-VII also contained fos-positive cells as did Lamina VIII of the medial ventral horn. From L4-S1, cells were localized in Laminae V-VII, in the region of the parasympathetic preganglionic neurons of the pelvic nerve. Neurons exhibiting fos labelling were also found in Lamina VIII, near the pudendal motoneurons of the dorsomedial nucleus, as well more laterally in the intermediate ventral gray and in Lamina X. From L1 to L6, numerous cells were found in Laminae I and II of the dorsal horn. Repetitive elicitation of the UG reflex therefore yields distinctive patterns of neurons with fos labelling which provide activity-dependent maps of the neural circuitry fundamental to spinal sexual reflexes.

THE URETHROGENITAL REFLEX EVOKED BY ELECTRICAL STIMULATION OF THE HYPOTHALAMUS AND MIDBRAIN PERIAQUEDUCTAL GREY

Lesley Marson\* and Kevin E. McKenna Department of Physiology, Northwestern University Medical School, Chicago IL 60611

The urethrogenital reflex (UG) is a reflex evoked in the anesthetized rat upon distention of the urethra. This reflex is thought to represent the neural concomitants of ejaculation. Previous work by our laboratory has demonstrated that the UG reflex is under tonic descending inhibition from neurons in the region of the nucleus paragigantocellularis (nPGi) in the ventral medulla. The medial preoptic region of the hypothalamus is known for its role in facilitating sexual reflexes and sexual behavior in awake animals. We examined the effects of electrical stimulation of hypothalamic and midbrain sites on the presence of the UG reflex.

Male rats were anesthetized with urethane and mounted in a stereotaxic

Male rats were anesthetized with urethane and mounted in a stereotaxic frame. The UG reflex was evoked via saline perfusion and brief occlusion of the urethra. As previously reported the UG reflex cannot be evoked in the intact preparation. Bilateral electrical stimulation was performed using bipolar tungsten electrodes (100-400 µA, 0.2 msec, 50 Hz). Trains of stimuli, 1 sec on/off, were initiated and presence of the UG reflex examined. The UG reflex could be evoked upon stimulation of discrete regions of the hypothalamus or midbrain periaqueductal grey. Effective stimulation sites in the hypothalamus ran from the medial preoptic area through the dorsal hypothalamus at 0.5-1.75 mm lateral to the midline. In the midbrain, stimulation of the periaqueductal grey allowed the UG reflex to be elicited. These data indicate that brain regions shown to be important in regulating sexual behavior in awake animals also facilitate sexual reflexes in anesthetized animals.

ERECTION IN RATS MAINTAINED AFTER SECTION OF PELVIC AND HYPOGASTRIC NERVES. Y.-C. Liu\*, S. S. McEldowney, K. Akasofu, and B. D. Sachs. University of Connecticut, Storrs, CT 06269-1020.

Five groups of males received two operations, one week

Five groups of males received two operations, one week apart, resulting in simultaneous or successive transection of the pelvic nerves (PNx), the hypogastric nerves (HgNx) or sham surgeries (SHAM). Four days after each surgery, males were tested for reflexive erections after two min of non-contact exposure to estrous females. Copulatory behavior was tested 5-7 days after the second surgery. Erectile function in both contexts was dramatically impaired by PNx, but at least 30% of males in each PNx group displayed ejaculatory patterns and had reflexive glans erections. HgNx males had more intense glans erections than did SHAM males, possibly due to removal of vasoconstrictor fibers. These data extend the findings of Lucio et al. (SfNS Abstr, 17:1059) and confirm results (Sachs & Liu, J Urol, 146:900) showing that transection of the cavernous nerves, the final common path of erectile fibers in the PN and HgN, does not preclude erection of the glans penis. Sexual excitation may promote sufficient inhibition of vasoconstrictor fibers in the motor pudendal nerve to allow partial erection after all known vasodilator fibers to the penile corpora have been transected. [Supported by HD-08933.]

INHIBITION OF NITRIC OXIDE SYNTHASE IMPAIRS COPULATION AND GENITAL REFLEXES IN MALE RATS. E. M. Hull\*, J. Moses, L. A. Lumley, L. Matuszewich, D. S. Lorrain, and V. P. Markowski. Psychology Dept., SUNY at Buffalo, Buffalo, NY 14260.

The gas nitric oxide (NO) is an intercellular messenger that performs several functions, including promoting vasodilation and mediating glutamate stimulation of cGMP. The inhibitor of NO synthesis, N-nitro-arginine methyl ester (NAME) was administered systemically to male rats prior to testing their copulatory behavior and ex copula genital reflexes. In Experiment 1, NAME (50 mg/kg) profoundly inhibited copulation in a group of extremely proficient male rats. Mean number of ejaculations was reduced from 2.8 (vehicle) to 0.0 (NAME) (p<.001). Only two of 10 animals achieved vaginal intromissions during the 30 min NAME test.

number of ejaculations was reduced from 2.8 (vehicle) to 0.0 (NAME) (p<.001). Only two of 10 animals achieved vaginal intromissions during the 30 min NAME test.

In Experiment 2 the same dose of NAME was injected preceding genital reflex tests in restrained supine males. The mean number of erections following NAME injections was 1.65, compared to 15.75 following vehicle (p<.01). It is likely that a major factor in this reduction is impairment of vasodilation in the penile corpora.

Studies are currently underway in our lab to determine whether NO may also act in the brain to regulate genital reflexes and copulation.

Supported in part by NIMH grant MH-40826.

CNS CELL GROUPS PROJECTING TO THE ISCHIOCAVERNOSUS MUSCLE TRANSNEURONALLY LABELLED WITH PSEUDORABIES VIRUS (PRV)

Kevin E.McKenna\*, Lesley Marson and Marsha S. List Department of Physiology, Northwestern University Medical School, Chicago IL 60611

Previously we reported spinal and brainstem neurons transneuronally labelled following injection of PRV into the penis. Those studies demonstrated labelled autonomic efferents and spinal interneurons in lumbosacral spinal cord regions known to be involved in pelvic function as well as brainstem neurons that project to the these areas. The present study was aimed at identifying CNS neurons controlling the ischiocavernosus muscle, which is involved in penile erection.

Rats were anesthetized with ketamine/xylazine and injected with 2 μl

Rats were anesthetized with ketamine/xylazine and injected with 2 µl PRV (2-3 x 10<sup>7</sup> plaque forming units/ml) into the left ischiocavernosus muscle. Four days later rats were reanesthetized and perfused with 4% paraformaldehyde and spinal cord and brain removed. Sections of the spinal cord and brainstem were cut (30-50 µm) and processed with swine polyclonal antibody to PRV and visualized with avidin-biotin HRP complex. PRV labelled neurons were found in the dorsolateral nucleus (DLN) of L6/L5 ipsilateral to the injection site. Presumptive interneurons were consistently found in the lateral part of lamina V and VI and in lamina X of segments L5-S1. PRV labelled cells were also found in the ventral medulla, in the nPGi and A5.

These results demonstrate some overlap with the circuitry innervating

These results demonstrate some overlap with the circuitry innervating the smooth muscle of the penis but also confirm significant differences in the underlying neuronal connectivity of these two systems.

## 59.16

BILATERAL INHIBITION BY SEGMENTAL AFFERENTS ON PUDENDAL MOTONEURON REFLEX DISCHARGES. R.D. Johnson\* and V.P. Dugan. Department of Physiological Sciences, University of Florida, Gainesville, FL 32610-0144.

In male rats, polysynaptic reflex discharges in pudendal motor axons and perineal muscles can be elicited by stimulating pudendal afferents. Natural or electrical stimulation of these afferents can also produce inhibitory effects. In this study, we investigated the bilateral characteristics of the segmental reflex inhibition produced by afferents in several nerves supplying the pelvic and perineal region. Mature male rats were anesthetized with urethane and acutely spinalized at T7-T8. Recording electrodes were placed on the ipsiand contralateral motor branch (iMB, cMB) of the pudendal nerve. Stimulating electrodes were placed bilaterally on the dorsal nerve of the penis (iDNP, cDNP) and on the ipsilateral pelvic nerve (iPN), superficial perineal nerve (iSP), and motor branch of the pudendal (iMB).

Averaged reflex responses in iMB and cMB to paired electrical shocks (conditioning-test paradigm) to several two-nerve combinations were obtained. Stimulation of iDNP, cDNP, and iPN elicited reflex discharges in both MBs. An iDNP or cDNP conditioning stimulus produced significant bilateral inhibition of iDNP, cDNP, and iPN test stimuli with an ipsilateral predominance. An iPN conditioning stimulus however, only slightly inhibited evoked responses from iDNP, cDNP, and iPN. In addition, iPN evoked reflexes were significantly less vulnerable to high-frequency depression. Stimulation of iSP and iMB produced only slight bilateral inhibition of iDNP and cDNP evoked responses. Of the nerves studied, the DNP produced the most extensive bilateral inhibition. Supported by NS27511.

FUNCTIONAL AND HISTOCHEMICAL EVIDENCE FOR THE INVOLVEMENT OF NITRIC OXIDE IN REGULATION OF PENILE ERECTILE TISSUE. W.G. Dail, B. Galloway, J. Bordegaray and G. Walton. Dept. of Anatomy, Univ. of NM, School of Medicine, Albuquerque, NM 87131.

The present study explores the role of nitric oxide (NO) in vasodilation of the penis of the rat as it has been proposed that this compound is responsible for nonadrenergic-noncholinergic (NANC) neurotransmission in a variety of tissues. Field stimulation of precontracted strips of penile smooth muscle caused marked, transient relaxations which were inhibited by nitroarginine and n-monomethylarginine - compounds which interfere with the synthesis of NO. In some tissues, L-arginine, from which NO is synthesized, enhanced field stimulated relaxations. Penile neurons in the pelvic plexus, identified by the retrograde transport of fluorogold, were intensely positive for nicotinamide adenine dinucleotide phosphate (NADPHdiaphorase); an enzyme purported to be a nitric oxide synthase. These data lend support to the contention that nitric oxide is the NANC transmitter in penile parasympathetic nerves. Moreover, the presence of other populations of non-penile, NADPH + neurons in the pelvic plexus suggests that nitric oxide may be important in neurotransmission in other pelvic visceral tissues. Supported by NIH NS19839-09.

VISUALIZATION OF MAST CELL ACTIVATION BY ACTIVITY-DEPENDENT FLUORESCENT PROBE. J.Y. Wei\*, V.L.W Go and L. Kruger#. Dept. of Medicine, Anatomy & Cell Biology# and Brain Research Institute, University of California Los Angeles, CA 90024.

Activity-dependent fluorescent probes have been used to visualize the endplates of neuromuscular junctions (Nature 314:357, 1985). The purpose of the current study was to determine whether sulforhodamine B (SFRM-B, Molecular Probes Inc) can be used to indicate the active state of peritoneal mast cells. Mast cells in rat peritoneal eluates (PECs) were harvested by peritoneal lavage and plated in tissue culture dishes. PECs were incubated with SFRM-B (200 µg/ml in rat saline) with or without secretogogic compound 48/80 (1 µg/ml). At various intervals, the dish was rinsed with saline and the fluorescence images were observed with a letiz fluorescence microscope equipped with NPL Fluotar water immersion objectives and N2 cube. The images were captured with a sit camera, digitized, acquired and analyzed using large-1 software. After 10 minutes of incubation, a varying number of granular bright red fluorescent spots can be located in individual mast cells, clearly distinguishable from background noise. The spots can be located throughout the cytoplasm. This characteristic image can only be seen in mast cell populations activated by compound 48/80 and correspond to bright field images of mast cell degranulation. These results verify activity-dependent uptake which may be quantitated. This probe has greater photostability and less leakage than acridine orange, its fluorescence persists if the preparation is stored overnight in the dark. Moreover, the dye has no obvious effect on the afferent discharge of mesenteric mechanoresponsive nerve terminals. This enables use of SFRM-B for the study of interactions between mesenteric afferent terminals and surrounding mast cells. (Supported by NIH grant NS28433 & 5685)

JOINT RECEPTORS ANTEROGRADELY LABELLED WITH WGA-HRP. S.M. Madey, A.J. Wolff, R.A. Brand and K.J. Cole. Orthopaedic Biomechanics Laboratory and Dept. of Exercise Science, University of Iowa, Iowa City, IA 52242

We have used WGA-HRP to anterogradely label mechanoreceptors in joint tissue as a prelude to investigating the precise innervation patterns of the cruciate ligaments. This method may also provide a means to clarify distinctions among receptor types, and their distribution, in ligament and joint tissue

Five to ten microliters of 2% WGA-HRP were pressure injected in the L5-S1 dorsal root ganglia of adult cats, anesthetized with IV Sodium Pentobarbital. After a survival time of 24-36 hours animals were sacrificed and joint tissue harvested for histochemical processing and analysis. Nearly complete labelling occurred in cell bodies in the dorsal root ganglia. Tibial nerve sections just distal to the knee showed dense labelling in about half of the axons, as would be expected for this mixed nerve. Receptors in the posterior capsule of the knee joint were densely labelled with reaction product. Using nomenclature for joint receptors introduced by Freeman & Wyke (J. Anat. 101:50, 1967), receptors in the posterior joint capsule resembled Type I and Type II. A third receptor type was consistently seen within the anterior cruciate ligament that could not be clearly distinguished from Type II or Type III. Additionally, nerve bundles and single axons were clearly visible and easily traced through the substance of the joint. Anterograde labelling of joint receptors with WGA-HRP provides a useful method for identifying neural elements in joint tissue, and will allow more accurate determination of the distribution of peripheral afferents to joint and ligament receptors. Supported by NIH grant AR40217.

WHOLE NERVE CUFF ELECTRODE RECORDINGS IN HUMANS. T. Sinkjart\*, M. Haugland, J. Haase, Department of Medical Informatics and Image Analysis, Aalborg University, Fredrik Bajersvej 7D, DK-9220 Aalborg and Department of Neurosurgery, Aalborg Hospital, DK-9000 Aalborg, DENMARK.

During restricted motor tasks, the microneurography technique has been able to provide a detailed picture of single afferent fibres in the peripheral nerves of human subjects. The drawbacks of this technique are that the population of units that one can sample is relatively small and that the recording electrode is easily dislodged if there is any significant movement of the surrounding tissue. These limitations can be circumvented when using nerve cuff electrodes that give a more global picture of the neural activity.

The aim of the present study was to explore the feasibility of adopting the nerve cuff electrode recording technique as a tool to investigate the cutaneous mechanoreceptive innervation in humans.

Whole nerve cuff electrodes were implanted on the sural nerve of three human subjects. The subjects went through a standard neurosurgical nerve-graft procedure and was in general anaesthesia during the experiment. All subjects gave their consents and the study was approved by the Local Ethical Committee.

The nerve signal recorded by the nerve cuff electrode contained clear slip-related information and information about the changes in the force applied perpendicularly to the skin. The activity recorded by the whole nerve cuff electrode corresponds to similar recordings in cats and monkeys, and to what would be expected from the summation of activity of the various types of mechanoreceptors that have been identified by microelectrode recordings in humans.

LONG-RANGE, IN VIVO STAINING OF WHISKER PRIMARY AFFERENTS WITH NEUROBIOTIN: COMPARISONS WITH HRP AND PHA-L. M.F. Jacquin, W.E. Renehan & P.M.E. Waite\*. Anat./Neurobiol., St. Louis Univ. Sch. Med., St. Louis MO 63104; Henry Ford Hosp., Detroit, MI 48202; Anat., Univ. New South Wales, Sydney, Australia.

Conventional means for analyzing the morphology of identified primary afferents are limited by the short distances over which HRP and PHA-L move during the course of a recording session. We have encountered an alternative method that overcomes this limitation. Neurobiotin (NB, Vector) injections into rat trigeminal (V) primary afferents in the brainstem (N=56) provided rapid, long-range staining with recording and electrophoretic parameters that are traditionally used to eject HRP or PHA-L. When NB was injected into brainstem A-beta fibers responsive to whisker deflection. collaterals were darkly stained in each of the 4 V subnuclei and cervical dorsal horn. Labeled fibers were also seen in the V root and infraorbital nerve for a distance up to 15 mm from the injection site. Cell bodies in the ganglion were never labeled. Such long-range staining occurred within 4 hrs of tracer injection and bore no orderly relationship to survival time, but rather reflected the quality, duration and site of the injection. When HRP was injected into primary afferents under equivalent conditions, staining was limited to within 4 mm of the injection site. When PHA-L was injected into V ganglion cells, similar long-range staining occurred, but 1-2 wks of survival was required. Due to its rapid and robust transport, NB is therefore a convenient alternative to PHA-L for long-range staining of the projections of identified ganglion cells. Intracellular NB injection also produces rapid Golgi-like staining of fibers over much greater distances than HRP under equivalent staining parameters. DE07662, DE07734, NS29885, MRC.

USE OF RICIN TO ASSESS NEURONAL CONTRIBUTION TO TOTAL PROTEIN SYNTHESIS IN DORSAL ROOT GANGLIA. H-Z Tang and R Hammerschlag\* Div. Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010

The ability of ricinus communis agglutinin (RCA<sub>120</sub>), a potent protein synthesis inhibitor, to enter the retrograde transport system and cause degeneration of neuronal somata has been exploited previously to establish the origin of peripheral axons (e.g. Science 216:889, 1982). The present study utilizes this lectin to determine the neuronal contribution to the total newlysynthesized protein following incubation of a peripheral ganglion with a radiolabeled amino acid. The method was developed to determine whether the increase in fast axonal transport (FAxT) in hindlimb sensory neurons during tadpole metamorphosis (Trans Amer Soc Neurochem 21:116, 1990) was secondary to an up-regulation of neuronal protein synthesis within the lumbar dorsal root ganglia (DRG). Since the peripheral nerves of pre- and prometamorphic tadpoles are too small and fragile to permit intraneural injection of RCA<sub>120</sub>, lumbar DRG and nerves were placed *in vitro* where the cut end of the nerve was made to swell by brief exposure to chilled distilled water and then placed in test solutions of ricin under hypotonic conditions. After 16 h incubation of the cut end in 2.5 mg/ml RCA<sub>120</sub>, the decrease in incorporation of [ $^{35}$ S]met into DRG varied from 72  $\pm$  12 % at stage V to 42  $\pm$  8 % at stage XVIII. The ricin-treated preparations showed no evidence of FAxT, relative to contralateral controls, as assessed by accumulation of [35S]protein at a ligature 6 mm from the DRG. Ricin inhibition of protein synthesis and FAxT was blocked by preincubation of the nerve trunk in 0.6 mM vinblastine, indicating that axonal transport is required for passage of the lectin to the neuronal cell bodies. [Supported by HD 26956.]

SENSORY NEURONS IN CULTURE ARE DIFFERENTIALLY RESPONSIVE TO BRADYKININ AND CAPSAICIN. C.L. Stucky \* S.A. Thayer² and Y.S. Seybold¹. Dept. Cell Biol. and Neuroanatomy and ²Pharmacol., Univ. of Minnesota, Minneapolis, MN 55455.

Bradykinin (BK) and capsaicin (CAP) are two chemical stimuli that

Bradykinin (BK) and capsaicin (CAP) are two chemical stimuli that are used to define nociceptive sensory neurons. We used primary cultures of rat dorsal root ganglion cells to determine whether receptors for these substances are present on different or overlapping populations of neurons. Cultures were prepared from 1 day neonatal rats; cells were cultured for 3-10 days. Increase in intracellular Ca+\* was used as a bioassay for receptor activation. Changes in intracellular Ca+\* were measured using the Ca+\* sensitive dye, Indo-1. In the initial population of cells examined (N=40, small to medium in size), CAP (500 nM) and BK (100 nM) were selective stimuli for two distinct populations: approximately 50% of the cells were BK-/CAP+, 25% of the cells were BK+/CAP-, but responded to 50 mM K+. Among the CAP-sensitive cells, half exhibited an increase in intracellular Ca+\* in response to CAP was 2800 nM. The response to 50 mM K+ was comparable to that evoked by CAP, although the responses to cold and BK were 25% and 50% as great, respectively. The increase in intracellular Ca+\* in response to BK was not dependent on extracellular Ca+\* in intracellular Ca+\* in response to BK was not dependent on extracellular Ca+\* in response to bak was not dependent on extracellular Ca+\* in response to bak was required for the response to CAP and cold. These data suggest that BK- and CAP-sensitive dorsal root ganglia neurons comprise two distinct populations of cells and a sub-population of CAP-sensitive neurons are responsive to cold. These studies were supported by NS17702 and T32DA07239.

PROTONS ENHANCE THE CAPSAICIN EVOKED INWARD CURRENT IN DORSAL ROOT GANGLION CELLS. M. Petersen\* and R.H. LaMotte, Dept. of Anesthesiology, Yale Univ. School of Medicine, New Haven, CT 06510

Inflammation and ischemia may be accompanied by an endogenous release of algesic chemicals and an increase in the tissue proton concentration. Lowering the pH value of the external medium has been shown to enhance the responses of the peripheral terminals of certain nociceptive neurons (Steen et al. 1991). Our present purpose was to see if an increase in the concentration of protons modulates the responses to the algesic chemical, capsaicin, in dorsal root ganglion cells. Capsaicin is an exogenous substance that excites peripheral nerve endings of certain nociceptive primary afferents by opening a non specific cation channel. Under whole-cell voltage clamp conditions we investigated the effect of externally applied protons on the capsaicin evoked inward current in freshly dissociated dorsal root ganglion cells from adult rats. Low concentrations of capsaicin (200 nM to 300 nM) but not low concentrations of protons (pH 6.9 to 6.3) evoked an inward current in a subpopulation of cells. The amplitude of the capsaicin (pH 7.3) evoked inward current decreased with repeated applications of the drug but increased with increasing proton concentrations (pH 6.9 to 6.3). Increasing the acidification of the external medium from a control pH of 7.3 to a pH of 6.3 enhanced the capsaicin (300 nM) current by about seven times. Exposure of the cell to an acidic capsaicin solution (300 nM, pH 6.3) did not subsequently increase an evoked inward current by capsaicin (pH 7.3) nor lead to a proton (pH 6.3) evoked current where there had been none. Our results suggest that increased proton concentrations play an important modulatory role in the function of chemosensitive sensory neurons. Supported by P.H.S. Grant NS 14624.

NGF INDUCED HEAT AND MECHANICAL HYPERALGESIA IN ADULT RATS. By Gary R. Lewin' & Lorne M. Mendell, Dept. of Neurobiology & Behavior, SUNY, Stony Brook, New York, NY 11794.

Administration of NGF to young animals can lead to the development of hyperalgesia (Lewin et al. Soc. Neurosci. Abst. 17: 546.3, 1991). Here we have investigated the effects of NGF on more mature animals. The behavior of animals to noxious mecahnical and heat stimuli was monitored in animals before and after between 1 and 4 systemic daily doses of NGF (1  $\mu$ g/g I.P). After just one NGF dose a profound mechanical and heat hyperalgesia was apparent for at least 3 days. The threshold for foot withdrawal measured with von Frey hairs dropped from  $162 \pm 70$ g in the control period to  $27 \pm 16g$  24 hours after the first NGF dose (pc.001). The latency for foot withdrawal from a 49°C water bath dropped from  $2.37 \pm 0.4s$  to  $1.48 \pm 0.27s$  after NGF, P<0.0001. Mechanical hyperalgesia developed slowly after NGF treatment (latency 4-6 hours). After 4 daily injections of NGF the mechanical hyperalgesia was maintained and recordings were made from single Aδ nociceptors in these animals. Twenty single Aô nociceptors were recorded and their mean mechanical threshold was  $5.5 \pm 3g$ , not significantly different from control fibers  $(4.3 \pm 2.3g)$ P>0.9, Kolmogorov Smirnov). However, heat hyperalgesia developed within 15 minutes of the NGF injection. Therefore, the heat hyperalgesia may be due to the sensitization of peripheral fibers to heat. In further experiments we investigated whether the heat hyperalgesia which develops after the induction of a CFA (complete freunds' adjuvant) monoarthritis was dependent on NGF. Anti-bodies to NGF (5  $\mu$ l/g, s.c.) prevented the heat hyperalgesia that normally develops after CFA. Thus, in adult animals NGF production in injured peripheral tissues may be necessary for heat hyperalgesia to develop. Supported by NIH, NS 14899, NS16996.

Binding of [<sup>3</sup>H]resiniferatoxin to capsaicin-sensitive sensory neurons: Regulation by nerve growth factor. I.F. James\*, S.K. Hothi I.J. Slack, S. Bevan, J. Donoghue, C.S. J. Walpole and J. Winter Sandoz Institute for Medical Research, Gower Place, London, WC1E 6BN.

Resiniferatoxin (RTX) acts on a subpopulation of primary afferent neurons via the same mechanism as capsaicin, but is at least 100 times more potent. We have measured high affinity binding sites for [<sup>3</sup>H]RTX on membranes from adult rat dorsal root ganglia (DRG). The dissociation constant was 0.42  $\pm$  0.07 nM, and the number of binding sites 54  $\pm$  8 fmol/mg protein (means  $\pm$ SEM, N=4). This confirms an earlier report from Szallasi and Blumberg (Brain Res. 524, 106, 1990). Capsaicin and a series of capsaicin analogues competed for the RTX binding sites, phorbol esters did not compete. There were some anomalies in the competition assays. For example capsazepine (a competitive antagonist of capsaicin action) was a relatively poor competer for the RTX sites. The binding sites were found on membranes from DRG and spinal cord, not cerebellum, midbrain, cerebellar cortex, heart, skeletal muscle, or liver. Binding to DRG membranes from rats pretreated with capsaicin was reduced to  $17 \pm 7\%$  (mean  $\pm$  SEM, N=4) of binding to tissue from control animals. In primary cultures of DRG from adult rats, cells grown in the presence of nerve growth factor (NGF) expressed binding sites for [3H]RTX, whereas binding to cells grown in the absence of NGF was undetectable. The properties, distribution, and regulation by NGF all suggest that the RTX binding sites correspond to the 'capsaicin receptor', but anomalies in the competition experiments suggest that capsaicin may act at more than one site.

REGULATION OF CUTANEOUS C-FIBER HEAT NOCICEPTORS BY NGF IN THE DEVELOPING RAT. By Lorne M. Mendell' & Gary R. Lewin, Dept. of Neurobiology & Behavior, SUNY, Stony Brook, New York, NY 11794.

Here we have asked if NGF is required for the normal physiological development of C-fiber afferents in rats. Animals were treated with NGF  $(2 \mu g/g)$  or anti-NGF  $(5 \mu l/g)$  from post-natal day 0-14 and 2-14, respectively. The latter treatment regime is known not to lead to sensory neuron death (Lewin et al. J. Neurosci. in press, 1992). Mature animals (5-15 weeks) were anaesthetized with urethane (1.25g/kg) and recordings made from single sural nerve C-fibers in thin filaments of dorsal roots. Units were identified by electrical stimulation of their presumptive receptive field in skin (Meyer et al., Brain Res. 561:252-261, 1991). They were subsequently characterized by their ability to respond to noxious mechanical, heat and cold stimuli. The principal finding was that the number of cutaneous C-fibers responding to noxious mechanical and heat stimuli (ie. C-MH fibers) was dependent on the amount of NGF available during development. Thus in control animals 30% (11/37 fibers) were C-MH whereas the proportion increased to 60% (25/42 fibers) in NGF treated animals and decreased to 10% (3/29) in anti-NGF treated animals. In the latter case a novel afferent type with a ve low mechanical threshold  $(1.0\pm0.5\,\mathrm{g}\,\mathrm{cmparet}$  to  $15\pm10\,\mathrm{g}\,\mathrm{fr}$  control C-MH fibers) appeared to replace the C-MH fibers  $(34\%, 10/29\,\mathrm{fibers})$ . Neonatal NGF treatment induced a long lasting mechanical hyperalgesia (Lewin et al. Soc Neurosci. Abst. 17: 546.3, 1991); however, this was not accompanied by a sensitization of C-MH to mechanical stimuli. These results suggest that the availability of NGF during development may regulate the number of C-fibers responding to noxious heat in the adult animal. Supported by NIH. NS 14899. NS 16996.

## 60.10

REARRANGEMENT OF CGRP-IR FIBERS IN SKIN FOLLOWING NEONATAL ANTI-NGF TREATMENT. By James R. Tonra Gary R. Lewin, Stephen B. McMahon', & Lorne M. Mendell, Dept. of Neurobiology & Behavior, SUNY, Stony Brook, New York, NY 11794. 'Dept. of Physiology, UMDS (St. Thomas'), London SEI 7EH.

Treatment of neonatal rats with anti-NGF from post-natal day (PND) 2-14 (5 μl/g, s.c) may force Aδ nociceptors to take on the phenotype of low threshold D-hair afferents (Lewin et al. J. Neurosci. in press, 1992). In adult animals Aδ nociceptor endings are thought to reside in the epidermal layer of skin (Kruger et al. J. Comp. Neurol. 198: 137-154, 1981). Furthermore, these afferents probably contain the neuropetide CGRP. We have used immunohistochemistry to localize CGRP-IR fibers and cells in skin and dorsal root ganglia (DRG) in adult (8-10 week) control or anti-NGF (PND 2-14) treated animals. The hairy skin innervated by the sural nerve was used. The epidermis of controls contained many CGRP-IR fibers (11.8 ± 6.4 fibers/section). Most of these fibers spanned its entire depth. In contrast, the epidermis from anti-NGF animals contained fewer CGRP-IR fibers (4.7 ± 2.3 fibers/section, significantly different from controls p<0.001). Most of these fibers only penetrated half way into the epidermis. The dermal plexus contained many CGRP-IR fibers and there appeared to be no quantitative or qualitative change after anti-NGF. We reconstructed the cell size distribution of CGRP-IR cells in the DRG. In control animals many of these mallest sensory neurons were CGRP-IR. This change may be related to the decrease in the numbers of C-MH fibers after anti-NGF treatment (see Mendell & Lewin, Soc Neurosci. Abst. 1992). The results indicate that subsets of CGRP-IR sensory neurons are the targets of NGF during development. Supported by NIH, NS 14899, NS 16996.

FINE STRUCTURE OF B-HRP TRANSGANGLIONICALLY LABELLED AXONS AND TERMINALS IN LAMINA IIO OF THE ADULT RAT SPINAL CORD FOLLOWING PERIPHERAL AXOTOMY. R. E. Coggeshall\*, P. Shortland and C. J. Woolf. Departments of Anatomy and Neuroscience, University of Texas Medical Branch, Galveston, Texas, 77555-0843, USA, and Department of Anatomy and Developmental Biology, University College London, UK.

Horseradish peroxidase conjugated to the B unit of cholera toxin (B-HRP) transganglionically labels the terminals of large myelinated afferents in the spinal cord (Robertson and Grant, Neuroscience, 14, 895-905, 1985). The labelled axons and terminals are prominent in laminae I and III and conspicuously absent in lamina II, as seen in the light microscope, in normal adult rats. If the sciatic or sural nerves are transected before the administration of the B-HRP, however, label is prominent in lamina II (Woolf et al., Nature, 355:75-85, 1992). One hypothesis to explain this finding is that large myelinated axons in lamina III expand their innervation territories into lamina II, particularly IIo, following axotomy. In accord with this, electron microscopic (EM) examination of the labelled elements in lamina IIo shows numerous labelled axons and presynaptic terminals at times ranging from 1 week to 8 months following the lesion

PREPROENKEPHALIN AND PREPROTACHYKININ GENE EXPRESSION IN MONKEY SPINAL CORD AND SENSORY GANGLIA. S. Numan\*, B.M. Davis, H.H. Traurig and K.B. Seroogy. Dept. of Anatomy & Neurobiology, University of Kentucky, Lexington, KY 40536

Few studies have examined perikaryal enkephalin and substance P localization in primate spinal cord or sensory ganglia. The standard protocol for chemically identifying neuronal somata usually employs immunocytochemistry in colchicine-treated animals. The lack of data in primates is most likely due the concinenter-tracted animals. The facts of usal in primates is most invery due the limited use of colchicine in these vertebrates. As an alternative approach, we used in situ hybridization of <sup>35</sup>S-labeled cRNA probes to examine the cellular expression of mRNAs for preproenkephalin (ppFNK) and preprotachykinin (ppT) in spinal cord, spinal ganglia and trigeminal ganglia of cynomologus and squirrel monkey. In dorsal hom of cervical spinal cord, hybridization for the mRNAs was found in neurons in the superficial laminae as well as scattered throughout was round in neurons in the superioral animale as well as Scattered thoughout mucleus proprius. Labeled cells were also found adjacent to the central canal and sometimes in ventral horn motoneurons, although expression of ppT mRNA was rarely seen in the ventral horn. In cervical dorsal root ganglia (DRG), a major subset of the small, and a few of the large, neurons expressed ppT mRNA. major subset of the smart, and a rew of the tage, neurons expressed pp i mrkva. DRG cells expressing ppENK were restricted to a minor subset (at least 4-fold less than the ppT mRNA-containing subpopulation) of small-sized neurons, although labeled cells were present in higher numbers than previously reported for perikaryal ENK immunostaining in rodent and cat DRG. In trigeminal ganglia, the pattern of ppT mRNA expression was similar to that found in DRG, but expression of ppENK mRNA was restricted to a few lightly-labeled DNO, out expression of ppractices mixed was restricted to a few figure-latered meurons. These results demonstrate that primary sensory neurons and their target regions in dorsal horn of monkey express mRNAs for ppT and ppENK and suggest a role for tachykinins such as substance P and for the opioid ENK in primate somatosensory mechanisms. Moreover, a larger subset of DRG neurons express ppENK in monkey compared to other species.

ULTRASTRUCTURE OF PARATRIGEMINAL NEURONS PROJECTING TO THE PARABRACHIAL REGION: A RETROGRADE EM STUDY WITH WGA-HRP IN RAT. D.W. Saxon\* and D.A. Hopkins. Department of Anatomy and Neurobiology, Dalhousie University, Halifax, Nova Scotia, CANADA B3H 4H7.

The paratrigeminal islands (PTI) in the dorsolateral medulla receive primary visceral and somatic afferent information, and have connections with a number of structures in the medulla, dorsolateral pons and thalamus. Previous ultrastructural analysis of the PTI (Saxon and Hopkins, '89) revealed two distinct populations of PTI neurons based on the number of axosomatic synapses. In order to identify efferent neurons in the PTI projecting to the parabrachial nucleus (PBN), WGA-HRP (1.0%, 0.01 0.03 µl) was injected stereotaxically into the parabrachial region. After 72 hours the medulla oblongata was processed for HRP histochemistry with ammonium molybdate stabilization followed by embedding for electron microscopy. Numerous neuronal somata throughout the PTI were labelled with HRP reaction product ipsilaterally, while a small number were labelled contralaterally. Retrogradely filled neurons were uniform in their morphological features and were characterized by their round or fusiform shape, high nucleus to cytoplasm ratio, sparse Nissl substance and paucity of axosomatic contacts. These neurons corresponded to a previously identified population of PTI neurons which contrasted with a second less numerous population of unlabelled neurons whose most prominent difference was the high number of axosomatic synapses. The present results show that a distinct population of PTI neurons conveys information, possibly convergent primary visceral and somatic information, to the PBN. Supported by MRC of Canada (Grant MT-7369).

5-HT3 RECEPTOR BINDING IN THE DORSAL VAGAL COMPLEX AND OTHER NUCLEI OF THE HUMAN MEDULLA. D.C. Ohuoha, S.S. Wolf, J.E. <u>Kleinman, and T.M. Hyde\*</u>. CBDB, IRP, NIMH, St. Elizabeths Hospital, Washington, D.C. 20032.

The distribution of 5-HT3 receptors in peripheral tissue is well characterized. Much less is known about 5-HT3 receptors in the central nervous system. Previous studies have identified 5-HT<sub>3</sub> binding sites in human dorsal motor nucleus of the vagus (DMN), spinal trigeminal nucleus, nucleus of the solitary tract (NTS), and the area postrema (AP). Binding in the AP has been contested by some investigators. In our study, sections from 3 levels of the caudal human medulla (n=7) were examined using the ligand [3H]LY278584 in receptor autoradiography. We found distinct and consistent binding in the DMN and the commissural subnucleus of the NTS caudally, and the medial and intermediate subnuclei of the NTS and parts of the medial reticular formation more rostrally. Distinct binding in an arc separating the spinal trigeminal nucleus from its tract was apparent at caudal levels. Minimal binding was noted in the inferior olives. No definitive binding was noted in the area postrema. Our findings suggest that 5-HT<sub>3</sub> receptors may play a significant role in the neural network subserving visceral function.

CENTRAL PROJECTIONS OF THE TRIGEMINAL NERVE IN PIGEON. J.M. Wild\* and H.P. Zeigler. Dept. of Anatomy, School of Medicine, Univ. of Auckland, Auckland, New Zealand and Dept. of Psychology, Hunter College, CUNY. In birds, the trigeminal nerve innervates the beaks and periorbital regions, and in

pigeon it is known to play a critical role in both the sensorimotor and motivational control of feeding behavior. In the present study we have used nerve injections of Cholera toxin B-chain conjugated to HRP (CTB-HRP) to trace the central projections of ophthalmic (V1), maxillary (V2) and mandibular (V3) branches, singly or in combination. CTB-HRP was visualized with TMB.

As in mammals, the entering root divides into ascending (TTA) and descending

(TTD) tracts. TTA terminates partly within a pars oralis of nTTD, diffusely within a ventral part of the principal nucleus (PrVV), and densely within a compact, dorsal part ventral part of the principal flucteds (TrVV), and defisely which a Company, dots applied to PrV (PrVd). V1 and V3 projections largely overlap within PrVd, although V3 projections alone occupy the caudal pole and V1 projections a rostro-dorsomedial component. V2 projections are much smaller and scattered, but there is a dense patch of terminations on the medial aspect of PrVd. Within the pars interpolaris and patch of terminations on the medial aspect of PrVo. Within the pars interpolars and pars caudals of nTTD, V3 projections are concentrated dorsomedially, V1 projections ventrolaterally, while V2 projections are scattered between. Within the spinal dorsal horn a medial (V3) to lateral (V1) organization of projections persists. All 3 branches project caudally to between C6 and C9, and all 3 have a small crossed component at caudal medullary and upper spinal levels. Projections from all 3 branches also contribute to a band of descending fibers which appears as the most lateral of several discrete fascicles of TTD (ITTD). ITTD terminates within the ventrolateral part of the external cuneate nucleus in the caudal medulla, and then as very dense "swirls" over cell bodies and mediolaterally extensive dendrites of neurons very denies within 50 ver cein obles and miteriolitaterally exterisive derinates of neurons comprising lamina I of the dorsal horn of upper cervical segments. Both these regions of termination are Substance P-positive. There was no evidence of trigeminal projections to "non-trigeminal" regions (nucleus tractus solitarius, reticular formation, cerebellum) such as have been reported in cat and rat. # SPINAL CORD

PRIMARY CULTURES OF POSTNATAL RAT SPINAL CORD NEURONS: IMMUNOCYTOCHEMICAL AND ELECTROPHYSIOLOGICAL STUDIES. L.J. Kehl\*, G.I. Poliac and G.L. Wilcox. Graduate Program in Neuroscience and Department of Pharmacology, University of Minnesota, Minneapolis, MN 55455, USA

The majority of work studying primary cultures of spinal cord neurons has been performed using fetal and neonatal tissue. We sought to compare characteristics between perinatal and more mature neurons. The objectives of these studies were to (1) culture rat postnatal spinal cord neurons and (2) examine their electrophysiological characteristics. Spinal cords from 10.15 day old Sprague Dawley rats were sectioned (300µm) on a vibratome and dissociated using pronase/thermolysin. Cells were plated onto glial monolayers and incubated (37°C, 10% CO<sub>2</sub>) in DMEM with 10% fetal bovine serum. Neurons survived routinely for 1 to 2 weeks in culture. Immunostaining cultures from 15 day postnatal cord with an culture. Immunostaining cultures from 15 day postnatal cord with an antibody directed against microtubule-associated protein (MAP2, courtesy I. Fischer), which is present specifically in neurons at 2 weeks postnatally, indicates that the cells are neurons. Patch clamp studies using the nystatin perforated patch technique were performed between 4 and 14 days after plating. Neurons maintained in culture for several days had voltage-activated currents (apparently including Na+, K+ and Ca++ components) supporting their neuronal nature. Some neurons were spontaneous action potentials at depolarized membrane potentials; some were responsive to bath application of N-methyl-D-aspartate. These data demonstrate that viable neurons from postnatal rat spinal cord can be demonstrate that viable neurons from postnatal rat spinal cord can be maintained in primary culture. [Supported by grants from NIDR (LJK) K15-DE-00225 and NIDA (GLW) R01-DA01933 & R01-DA04274].

GENETIC DIFFERENCES IN THE OCCURRENCE OF MECHANICAL HYPERSENSITIVITY (ALLODYNIA), MOTOR DEFICITS AND MORPHOLOGICAL DAMAGE AFTER SPINAL CORD ISCHEMIA IN RATS. J.-X. Hao'.1,2, Z. Wiesenfeid-Hailin¹, X.-J. Xu¹, H. Aldskoglus³ and Å. Selger² Depts. of ¹Clin. Neurophysiol., ²Geriatric Medicine and ³Anatomy, Karolinska Institute, ¹,²Huddinge and ³Stockholm, Sweden.

We have previously reported that transient spinal cord ischemia in Sprague-Dawley (SD) rats caused strong mechanical allodynia with minor motor deficits and morphological damage. We report here that the sensory, motor and histological outcome is strain-dependent in rats.

Transient spinal ischemia was induced by a photochemical reaction, leading to platelet aggregation, when a dye, Erythrosin B, injected i.v., is activated by an argon laser irradiating an exposed vertebra at mid-thoracic level. The vocalization threshold of the rats to mechanical stimulation was tested with calibrated von Frey hairs. Motor performance and morphological abnormalities were assessed.

The three strains of rats that were studled were spontaneous hypertensive (SHR), Wistar-Kyoto (WK) and SD. After induction of the Ischemia, WK and SD, but not SHR, rats developed severe allodynia. In contrast, the rank order of the severity of motor deficits and extent of histological damage was SHR-WK>SD.

Genetic variability, which may involve a large number of

SHR>WK>SD.

Genetic variability, which may involve a large number of factors of physiological singificance, can lead to various levels of predisposition for the development of pain and spinal cord damage after ischemia. Such factors may underly the wide variability in clinical outcome after ischemic CNS injury.

DISTRIBUTION OF NEUROKININ A DURING CONTROLLED SUPERFUSION OF THE RAT SPINAL CORD DORSUM.

H. Beck\*, H. Schröck and J. Sandkühler. Physiologische Institute der Universität Heidelberg, 6900 Heidelberg, F.R.G.

Extrasynaptic transmission of information ("volume transmission") mediated by neuropeptides like Neurokinin A (NKA) may play an important role for neuronal plasticity in the spinal dorsal horn. Here we describe the spread of NKA in the spinal cord during controlled superfusion.

Experiments were performed on 7 rats deeply anesthetized with pentobarbital. A femoral artery and vein were cannulated to monitor blood pressure, heart rate and to sustain anesthesia by continuous infusion. The lumbar spinal cord was exposed by laminectomy and the dura mater reflected. For controlled superfusion a pool was formed on the cord dorsum with a specially prepared silicon rubber and filled with 10  $\mu$ l of [125I]NKA (100  $\mu$ M, 2  $\mu$ Ci) for periods of 15, 30 or 60 minutes. The blood pressure increased by 10 to 30 mm Hg during superfusions. At the end of the experiments the spinal cord was removed, frozen immediately, cut into 20 µm sections and exposed to X-ray film for autoradiography. Autoradiograms from the superfused spinal cord showed radiolabel up to a depth of 1.7 mm below the dorsal surface. In spinal cord sections taken from segments rostral or caudal to the pool, the radiolabel diminished rapidly. Thin-layer chromatography of tissue extract from superfused cord revealed a single major peak suggesting that no degradation of NKA took place. Little radioactivity was measured in blood and plasma and all tissues examined independent of superfusion time. Our results show that NKA - and probably other neuropeptides - diffuses well into the dorsal but not ventral horn of spinal cord during controlled superfusion of the cord dorsum.

IN VIVO ANALYSIS OF MONOAMINES IN INJURED SPINAL CORD USING MICRODIALYSIS P.K. Mishra, D.H. Dinh, W.C. Olivero, B.A. Curtis and P.C. Jobe Univ. of Illinois College of Medicine at Peoria and Tulane University School of Medicine, New Orleans.

Since the Osterholm's report of alteration of levels of catecholamines in

injured spinal cord, several authors were unable to replicate his result. A reanalysis of the original finding by Osterholms laboratory in 1980 suggested the increase in the spinal cord norepinephrine after trauma was artifactual. We describe a method for in vivo analysis of biogenic amines in injured rabbit spinal cord using microdialysis and HPLC coupled with elec-

trochemical detector.

New Zealand white rabbits were anesthetized with the Ketamine-Rompun (7:3 by volume, 1 ml/kg) and maintained under anesthesia using halothane; oxygen mixture for the duration of the experiment. Laminoctomy from T7-T10 was performed to expose the spinal cord. A 3mm tip microdialysis probe was inserted into the spinal cord in the midline at T9. The probe was perfused with artificial CSF at a rate of 1  $\mu$ l/min. The dialysate was collected every 20 min and analyzed. After baseline levels of norepine-phrine (NE) and dopamine (DA) were established, the exposed spinal cord at T9 was subjected to a 150 gm-cm force using the Allen weight drop method. A significant increase in extracellular NE, DA and 5-HT was evident during first 20 min after traumatic injury. During the second postinjury 20 min sampling interval, monoamine levels were still elevated, albiet to a lower extent than the 1st postinjury sampling period. The origin of NE, DA and 5-HT remains speculative. We postulate that the elevation of these biogenic amines was secondary to local release from stored vesicles at the injury site and responsible for the initiation of hemorrhagic necrosis process.

# 61.7

IMMUNOHISTOCHEMICAL LOCALIZATION OF CALRETININ IN RAT DORSAL ROOT GANGLIA AND SPINAL CORD. K. Ren\*, M.A. Ruda and D.M. Jacobowitz<sup>1</sup>. Neurobiology and Anesthesiology Branch, NIDR and Laboratory of Clinical Science, NIMH; National Institutes of Health, Bethesda, MD 20892.

Calretinin (CR), a recently identified calcium-binding protein, is present in nervous tissue, including sensory pathways, where it may play an important role in regulation of cellular activity. Using immunocytochemistry, we examined the cellular localization of CR in dorsal root ganglia (DRG) and spinal cord (SC) of normal rats and after multiple unilateral dorsal root ganglionectomies. In the DRG, CR-like immunoreactivity (LI) was found in cell bodies and axons of a small population (~10%) of medium to large sized neurons. In the SC, CR-LI was found in neurons and fibers in all laminae, except for neurons in the motorneuronal groups, and in the lateral spinal and lateral cervical nuclei. Dense fiber networks were also found in Clarke's column. The densest staining of both cells and fibers was in the superficial laminae, especially lamina II. CR-LI fibers were also observed in the fasciculi cuneatus and gracilis. Fasciculus gracilis exhibited the greatest number of labeled axons at the lumbosacral levels, but few labeled axons were found at the rostral thoracic and cervical levels. In contrast, the corticospinal tract at the base of the dorsal column was devoid of CR-LI. Unilateral multiple ganglionectomies resulted in a loss of CR-LI in the dorsal columns ipsilateral to the surgery, without any apparent decrease in the staining intensity in the spinal gray matter. Our observations demonstrate a unique distribution pattern of CR-LI compared to other calcium-binding proteins in the SC and suggest a role for CR in nociceptive and proprioceptive pathways.

AUTORADIOGRAPHIC DISTRIBUTION AND CHARACTE-RIZATION OF NEUROPEPTIDE Y RECEPTORS IN RAT SPINAL CORD. S. St-Pierre<sup>2\*</sup>, S. Kar<sup>1</sup>, Y. Dumont<sup>1</sup>, A. Fournier<sup>2</sup> and R. Ouirion<sup>1</sup>. <sup>1</sup>Douglas Hospital Research Center, Mc Gill University, Montreal, Canada H4H 1R3; <sup>2</sup>INRS-Sante, Pointe-Claire, Canada.

Neuropeptide Y (NPY), an amidated 36-amino acid peptide, is widely distributed throughout the nervous system. In the spinal cord, particularly in the superficial layers of the dorsal horn, a rich system of NPY-like preactivity and NPY receptor binding sites have been described. Recently, we also reported that NPY receptor binding sites localized in the superficial layers of the dorsal horn showed depletion following surgical and pharmacological manipulations (Brain Research, 574: 337-337, 1992). However, the NPY receptor type(s) present in the dorsal horn of the spinal cord has not been characterized so far. In the present study we have investigated this issue by determining the ability of PYY, pNPY, NPY<sub>13-36</sub> investigated this issue by determining the ability of PYY, pNPY, NPY<sub>13-36</sub> and [Leu<sup>31</sup>, Pro<sup>34</sup>]-NPY to inhibit specific [<sup>125</sup>I]PYY binding using quantitative receptor autoradiography. Specific [<sup>125</sup>I]PYY binding is completely inhibited by PYY and pNPY whereas the fragment NPY<sub>13-36</sub> (Y2) and the Y1 agonist [Leu<sup>31</sup>, Pro<sup>34</sup>]-NPY only partly competed for [<sup>125</sup>I]PYY labelling even at 10<sup>-6</sup>M. These results suggest that Y<sub>1</sub> and Y<sub>2</sub> the property of the p receptor subtypes are likely present in the dorsal horn of the spinal cord. At present, the physiological significance of each receptor subtype is unknown but may relate to the modulation of spinal information. (Supported by

## 61.6

HALOTHANE REDUCTION OF AFFERENT INPUT TO THE SPINAL CORD IN DECEREBRATE, SPINALLY-TRANSECTED RATS. Y. Yamamori\*, K. Kishikawa, J.G. Collins. Dept. of Anesthesiology, Yalc Univ. Sch. of Med., New Haven, CT 06510

We have reported that pentobarbital and propofol produce a significant reduction in low-threshold (LT) receptive field (RF) size of some dorsal horn neurons in chronic cat experiments. <sup>1,2</sup> We have recently observed that halothane induced a reduction in LT RF size in acute anesthetized rat experiments. This reduction was maintained in the presence of reversible cold block of the spinal cord, suggesting a spinal site of action. In this IACUC approved study we investigated effects of halothane on LT RF size in decerebrate, spinally transected-animals to eliminate the effect of baseline anesthesia which was discontinued following decerebration and spinal cord transection. Blood pressure and  $PCO_2$  were monitored as LT RFs were mapped. To date 10 LT neurons and 3 wide dynamic range (WDR) neurons have been studied. The mean baseline RF size of LT neurons was  $218.0 \pm 38.2 \text{ mm}^2$  (SE). The mean RF size was reduced by  $66.4 \pm 2.4\%$  SE  $(65.6 \pm 10.0 \text{mm}^2 \text{ SE})$  and  $97.2 \pm 1.3\%$ SE (5.81 ± 3.0mm<sup>2</sup> SE) by halothane to 0.5% and 1.0% respectively. Three WDR neurons also showed the same tendency. Receptive field size returned to baseline values with discontinuation of halothane administration. In 2 to neurons, 50 µg of the GABA<sub>B</sub> antagonist, phaclofen, was administered intrathecally with no effect on the halothane induced reduction of RF size. These results suggest that, in the decerebrate, transected preparation, halothane alters LT afferent input to spinal dorsal horn neurons. This may contribute to anesthetic induced loss of sensation. It is unlikely that a GABA<sub>B</sub> system is involved in the effect of halothane on LT RF size. <sup>1</sup>Brain Res. 525:189-197, 1990. <sup>2</sup>Anesth. 73:A697, 1990. PRIMARY AFFERENT TERMINALS IN BOTH DEEP AND SUPER-FRIMAR I AFFERENT TERMINALS IN BOTH DEEP AND SUPER-FICIAL LAMINAE OF THE RAT DORSAL HORN ARE ENRICHED IN GLUTAMATE-LIKE IMMUNOREACTIVITY. J. Broman\* S. Anderson and O.P. Ottersen. Dept. Cell Biol., Fac. Health Sci., Univ. Linköping, Sweden (JB, SA) and Dept. Anatomy, Inst. Basic Med. Sci., Univ. Oslo, Norway (OPO).

The presence of glutamate-like immunoreactivity (Glu-LI) in primary afferent terminals (PATs) in the dorsal horn was quantitatively evaluated with the electron microscopic immunogold technique. PATs in laminae I and III-V were identified by peroxidase histochemistry following injections of choleragenoid-HRP into spinal ganglion Th 12 or 13. PATs in laminae II were identified by morphological criteria (dense sinusoid axon terminals, DSAs). The density of gold particles over PATs was compared to that over terminals with pleomorphic vesicles in laminae III-IV, that over large neuronal cell bodies in laminae III-V and to the average density of gold particles over lamina II and over laminae III-IV.

average density of gold particles over lamina II and over laminae III-IV. One section through the dorsal hom in each of three rats were analyzed. PATs in laminae I and III-V had similar labeling densities, whereas higher densities were present over DSAs. Expressed in percent of the average density of gold particles over laminae III-IV, the results were as follows: DSAs (n=20 in each section), 420%; PATs in laminae I (n=10) and III-V (III, n=20; IV, n=20; V, n=6-8), 265%; Large neuronal cell bodies in laminae III-V (n=5), 158%; Terminals with pleomorphic versicles in laminae III-V (n=20), 106%; Average density of gold vesicles in laminae III-IV (n=20), 106%; Average density of gold particles over lamina II, 145%

These results show that PATs in all dorsal horn laminae are enriched in Glu-LI, thus supporting a neurotransmitter role for glutamate in PATs throughout the dorsal horn.

NEUROPEPTIDES AND THEIR RECEPTORS IN THE RAT SPINAL CORD: EFFECTS OF SURGICAL AND CHEMICAL MANIPULATIONS. S. Kar\* and R. Quirion. Douglas Hospital Research Center, Dept. of Psychiatry, McGill University, Canada H4H 1R3.

SURVICAL AND CHEMICA MAINTOURIONS, S. Nat. 2 and x. Quitful. Doligas Hospital Research Center, Dept. of Psychiatry, McGill University, Canada H4H 1R3.

The site of the first synapse in pain pathways i.e., the dorsal horn of the spinal cord, is the main center for the integrative processing of nociceptive information. A functional interrelationship between neuropeptides of the primary afferent fibers and the spinal interneurones has been suggested in a variety of experiments. In the present study, following chemical (neonatal capsaicin treatment) and surgical (unilateral sciatic nerve section) manipulations, the possible alterations of immunoreactive Calcitonin gene-related peptide (CGRP), Substance P (Sub P), Enkephalin (ENK), Galanin (GAL) and Neurotensin (NT) and their corresponding receptor binding sites have been studied in rat spinal cord (Lumbar 4) emplyoing immunocytochemistry and quantitative in vitro receptor autoradiography respectively. The capsaicin treated rats, in comparison with controls, showed a depletion of CGRP, Sub P and GAL immunoreactive fibers in the dorsal horn of the spinal cord. The autoradiographic distribution of receptor binding sites on the other hand, showed a relative increase of CGRP, neurokinin 1 (NK1) and GAL bindings, a decrease of μ opioid sites and no alteration of NT receptor sites in the dorsal horn of the capsacint treated rats. Following section of the sciatic nerve, compared to contralateral side, a decrease of CGRP, Sub P, a slight increase of GAL but no visible alteration of the ENK or NT immunoreactive fibers was noticed in the superficial laminae of the spinal cord ipsilateral to nerve section. In keeping with alteration of the immunoreactive fibers, a corresponding increase of CGRP and NK1, a decrease of μ opioid and GAL and no alteration of NT receptor binding sites were noticed in the dorsal spinal cord ipsilateral to nerve section. These results taken together suggest that i) opioid regulates, in part, nociceptive information through a presynaptic inhibition o

SPROUTING AND FUNCTIONAL PLASTICITY OF SPINAL PROJECTIONS OF REGENERATED PRIMARY AFFERENTS. <u>H.R.Koerber\*, <sup>1</sup></u>, <u>K. Mirnics<sup>1</sup></u>, <u>P.B.Brown<sup>2</sup> and L.M.Mendell<sup>3</sup></u>. Dept. of Neurobiol., Anat. & Cell Sci. Univ. of Pittsburgh<sup>1</sup>, West Virginia Univ. <sup>2</sup> and SUNY-Stony Brook<sup>3</sup>.

Tibial primary afferents were impaled with HRP-filled electrodes in the dorsal columns of anesthetized cats 9-17 mos. after transection and self union of the tibial nerve. After determining its adequate stimulus, each fiber was activated with single or pairs of current pulses via the microelectrode to elicit cord dorsum potentials (CDPs), and filled with HRP. The central projections of 13 Group I & II fibers were reconstructed from counter-stained sagittal sections. The longitudinal distribution of boutons was recorded and compared to the monosynaptic CDP amplitudes recorded at the four surface locations. The anatomical projections of 6 afferents resembled those of proprioceptors (most boutons ventral to lamina V); of these, 5 (4 group II and 1 group I) had reinnervated skin and 1 (group I) had reinnervated a subcutaneous structure. Unlike controls, 3 of these fibers elicited measurable CDPs which may be the result of numerous boutons in laminae IV & V supported by these fibers. The other 7 fibers had extensive projections in laminae III-V and elicited CDPs that were characteristic of cutaneous afferents; of these, 2 had reinnervated subcutaneous structures and 5, the skin. However, in some cases the longitudinal distribution of boutons did not match the CDP amplitude profile as closely as in controls. In addition, three of these fibers also had extensive longitudinal collaterals and boutons in laminae I & II and elicited CDPs characteristic of nociceptors in controls. This apparent sprouting of large myelinated fibers into superficial laminae confirms the finding of Woolf et al., Nature, '92 and also suggests that these projections remain functional after ccessful reinnervation of low threshold mechanoreceptors. These results suggest both anatomical and functional plasticity in the central projections of regenerated large myelinated primary afferents. (Supported by the NIH).

DEAFFERENTATION INDUCED INCREASE OF GALANIN IN THE RAT DORSAL HORN. A.A. El-Bohy\*, K.E. Arsenault and C.C. LaMotte. Section of Neurological Surgery, Yale University School of Medicine, New Haven, CT. 06510.

In the spinal cord, intrathecal administration of galanin (GAL) increases the latency of the tail flick and hot plate tests, antagonizes the facilitatory effects of SP on the nociceptive reflex, and potentiates the spinal analgesic effect of morphine. In this study, we examined the light and ultrastructural changes in GAL immunoreactivity following sciatic deafferentation induced by injecting the sciatic nerve of anesthetized rats with proteolytic enzymes (10-20mg Pronase). The effects of this chemical deafferentation were examined in two animal groups, i.e., short term (10-13 days) and long term (4-6 months) after injection, using a computerized densitometry analysis system. In the short term group, we found a highly significant increase in GAL immunoreactivity on the pronase side. This pattern paralleled the distribution of the sciatic nerve, suggesting an association with the terminals of the sciatic nerve. In the long term group, the immunoreactivity on the pronase side was similar to that of the control side. At the ultrastructural level, GAL was localized in simple and glomerular terminals, with or without dense core vesicles, mainly in lamina I and II. On the pronase side, the label was seen in both degenerating and normal terminals as well as some dendrites, somata and nonmyelinated axons. These results suggest that the transient increase may be in part a response of the injured sciatic neurons but other neuronal elements may also be involved. (Supported by PVA Spinal Cord Research Foundation #880, the Eastern Paralyzed Veterans of America, and NIH Grant NS28876)

EFFECT OF PERIPHERAL NERVE CUT ON PEPTIDES IN DORSAL ROOT GANGLIA AND THE SPINAL CORD OF MONKEY WITH SPECIAL REFERENCE TO GALANIN. Z. Xu. G. Ju. R. Elde\* and T. Hökfelt. Dept. of Neurobiology, Inst. of Neuroscience, Xian, 710032, PR. China and Dept. of

Histology and Neurobiology, Karolinska Institute, 10401, Stockholm, Sweden Five adult macaca underwent unilateral sciatic nerve transection. Three of Histology and Neurobiology, Karolinska Institute, 10401, Stockholm, Swéden Five adult macaca underwent unilateral sciatic nerve transection. Three of them and one control animal were studied with immunofluoresence technique. The other two and one control animal were studied with in situ hybridization. Two weeks after peripheral axotomy the expression of peptides in dorsal root ganglia was changed for several peptides. There was a clear reduction in the number of CGRP, SP and SOM positive cell bodies. In contrast, there was a marked increase in galanin (GAL) positive cells. Thus, over 50% of all ganglion cells expressed this peptide after the nerve cut. However, the immunoreactivity and mRNA positivity were almost exclusively confined to small neurons. A few NPY, but no VIP/PHI positive cell bodies could be observed. With regard to fibers in the dorsal horn, there was a small reduction in CGRP- and SP-LI in the ipsilateral dorsal horn. A more pronounced decrease was observed for SOM-LI, where the strong immunoreactivity in fibers in outer lamina II virtually disappeared. Also NT, PHI and CCK-LI were distinctly reduced in the superficial layers of the ipsilateral dorsal horn. A dramatic increase in GAL-LI in the ipsilateral dorsal horn was observed, especially in the inner lamina II, where the GAL immunoreactive fibers formed distinct patches of densely packed varicosities after axotomy. In addition small, weakly GAL immunoreactive fibers could be observed in lamina III. Also the DYN-LI was increased in the ipsilateral dorsal horn with a more extensive distribution of fine fibers into deeper layers. Upregulation of GAL and CGRP in motoneurons on lesion side was also found. These results show, among others that a peripheral nerve lesion upregulates GAL in sensory neurons, not only as previously shown in rat but also in monkey. The analgesic effect of GAL already demonstrated in rat may therefore extend to primate.

# PAIN MODULATION: HYPERALGESIA

ALTERATIONS IN C-FIBER RESPONSE TO MECHANICAL STIMULI IN THE STREPTOZOTOCIN-DIABETIC RAT. S.C. Ahlgren\*, D.M. White, and J.D. Levine Departments of Anatomy, Medicine, and Oral and Maxillofacial Surgery and Division of Neuroscience, UCSF, San Francisco, CA 94143-0452.

Streptozotocin-diabetic rats (STZ-D) demonstrate hyperalgesia in behavioral tests of mechanical nociceptive threshold. This study examined the response to mechanical stimulation in C-fiber afferents in the saphenous nerve of STZ-D rats. There was no difference in the percentage of spontaneously active C-fibers found in 8 STZ-D rats (11.6  $\pm$  1.0%) compared to 8 control (CON) rats (11.3  $\pm$  0.7%) or in the aver age firing frequency of spontaneously active fibers (STZ:  $87.9\pm13.7$  spikes/min, n=81; CON:  $87.7\pm13.8$  spikes/min, n=79). The average mechanical threshold of C-fibers, measured with monofilament von Frey hairs (VFH), was also not significantly different in STZ-D and CON rats (STZ-D: 12.7  $\pm$  4.7 g, n=99; CON: 11.2  $\pm$  2.0 g, n=119). In addition, the average number of spikes elicited by a sustained (one minute) mechanical stimulus of low intensity (threshold VFH) was not different in STZ-D and CON C-fibers (STZ-D:  $51.5\pm9.0$ , n=35; CON:  $52.1\pm8.5$  spikes/min, n=34). However, the application of a mechanical stimulus spikes in C-fibers from STZ-D rats (STZ-D:149.7  $\pm$  18.4; n=44 vs. CON: 84.7  $\pm$  12.2spikes/min; n=45; t(87) = -2.762, p<0.01). This electrophysiological study suggests that changes in activity (firing frequency) to suprathreshold mechanical stimuli contribute to mchanical hyperalgesia in the STZ-D rat. Parallels between joint nociceptor properties and pain report in subjects with pain in the TMJ. Loughner B., Cooper', B. and Heft, M. W., Dept. of Oral and Maxillofacial Surgery, University of Florida, Gainesville, 32610.

Properties of afferents of the carrageenan inflamed (CI) temporomandibular joint (TMJ) were compared to pain report of patients complaining of pain in the TMJ. Recordings were made from the exposed trigeminal root ganglion of the goat, in response to dynamic and static jaw movement. Similar manipulations were made of the jaws of patients. Subjects rated pain using visual analogue scales. Nineteen afferents of the TMJ were characterized prior to and up to 3 hours following injection of 200 ul of carrageenan (CI; n=11) or saline (n=8). Prior to CI, afferents transduced dynamic (9/11 cases). And less frequently static stimuli (4/11 cases). Following CI, transduction of static events was observed in 9/11 cases and transduction of dynamic events 11/11

of static events was observed in 9/11 cases and transduction of dynamic events 11/11 cases. Saline was without effect. Significant reduction of thresholds were also observed (11.2 + 9.9 vs 5.1 + 3.7N) and were significantly greater (t=2.2, df=a5, p<.04) than those observed in saline treated cases (14.1 + 15.0 vs 11.5+7.5N). Six of 9 subjects that had pain on the day of testing reported increased anoiceptor static reactivity, jaw position (degrees of opening) was significantly related to pain report on the static but not on the dynamic test movement. Due to unpredictable voluntary and reflexive reactions to passive jaw movement, the force required to move the jaw was not proportional to jaw pain. Thresholds for pain (10.11 +4.99N and 10.75 +6.2 degrees) were in a range that approximated nociceptor physiology and fell well within the working range of the joint. It was concluded that enhanced static within the working range of the joint. It was concluded that enhanced static transduction in joint nociceptors could play a predominant role in signalling joint pain. Supported by NIDR DE8701.

SYMPATHETIC INNERVATION TO THE RAT TEMPORO-MANDIBULAR JOINT. S.B. Milam, B. Hutchins, R.J. Hinton, and R.E. Dill\*. Depts. of Oral Surgery & Biomedical Sciences, Baylor College of Dentistry, Dallas, TX 75246

Although the innervation of temporomandibular joint structures by branches of the trigeminal nerve has been well-documented, little is known of other sources of innervation (e.g., autonomics) to the joint. To investigate this, a methyl cellulose gel containing 4 % WGA-HRP was placed within the superior joint space unilaterally in growing rats weighing between 200-290 g. After a 24 hour survival period, the rats were killed and the superior cervical (SCG), trigeminal, pterygopalatine, and otic ganglia were harvested. Preliminary results of WGA-HRP histochemistry indicated that labelled neurons were present ipsilaterally in both the superior cervical and trigeminal ganglia. Numerical analysis revealed the percentage of labelled SCG cells to labelled trigeminal ganglion cells ranged between 44 % and 71 %. A small number of labelled cells was noted in the putative pterygopalatine and otic ganglia, but the identity of these ganglia apart from the trigeminal ganglion must be verified further before conclusions can be drawn. These data, although preliminary, suggest that sympathetic innervation to the temporomandibular joint is considerable, and may play a role in neurogenic induction of joint inflammation and pain. (Supported by NIDR DE06982 and NEI EY06977).

HISTOLOGICAL AND ELECTROPHYSIOLOGICAL CHANGES INDUCED BY CARRAGEENAN IN RABBIT LUMBAR FACET JOINT CAPSULE. ACC

HISTOLOGICAL AND ELECTROPHYSIOLOGICAL CHANGES INDUCED BY CARRAGEENAN IN RABBIT LUMBAR FACET JOINT CAPSULE. AC OZAKTAY, JM CAYANAUGH, DC BLAGGEV, AI KING. Bicoengineering Center, Wayne State University, Detroit, MI 48202.

The aim of this study was to investigate effects of carrageenan-induced inflammation of the lumbar facet joint capsule and surrounding muscle. METHODS: Rabbits (3-4 kg, Male) were anesthetized with Na pentobarbital, iv. An L5-L6 laminectomy and ventral ramus rhizotomy were performed. Recordings were made from split L6 dorsal roots. The L6-L7 joint capsule was searched with a glass probe for receptive fields. The units were characterized by their conduction velocities and mechanical thresholds. 0.1 ml of 2% Type II carrageenan (Sigma) in 0.9% NaCl was then injected into the receptive field. The threshold and unit activity were recorded at specific intervals for later computer analysis. At the end of the experiment the tissue was histologically examined with H&E staining. RESULTS: In most of the experiments the spontaneous background discharge rate increased in two phases. Based on average pooled multi-unit data from 8 experiments, the first phase was observed after the first 30 min by a large increase in discharge rate with 45 min duration. The discharge rate then decreased for 30 min. A second smaller increase was then observed with 60 min duration. Group III (n=17) units displayed a prolonged (90 min) first and a shortened (30 min) second phase based on averaged data. Three group IV units showed a first phase after the first 15 min with 40 min average duration. Thresholds of the characterized units ranged from 1.23 grams to glass rod and decreased with time. Unlike the normal joint capsule area, inflamed joints showed vasodilatation and edema in synovial capsule and additionally, leukocyte infiltration in the perivascular space within surrounding muscle tissue. Supported by NIH Grant NS-28994.

# 62.7

CRAMPING PAIN AND DEEP HYPERALGESIA FOLLOWING INTRAMUSCULAR INJECTION OF CAPSAICIN. D.A. Simone\*, G. Caputi, P. Marchettini and J.L. Ochoa. Division of Neuroscience Research in Psychiatry, Univ. Samaritan Hosp. and Oregon Health Sci. Univ., Portland, OR.

Neural mechanisms mediating muscle pain are poorly understood although this is a common symptom associated with various clinical syndromes. Since capsaicin (CAP) has been a useful tool to study mechanisms of cutaneous pain and hyperalgesia, we investigated whether CAP may serve as an experimental model for muscle pain as well.

Injections of vehicle (Tween saline) and (CAP) doses of 0.1, 1, 10 and 100  $\mu g$  in 10  $\mu$ l were given into the gastrocnemius soleus muscles of seven healthy volunte CAP produced immediate cramping pain which radiated around the injection site but was never referred to distant deep tissues or to skin. The magnitude and duration of pain increased monotonically as a function of CAP dose. The sensation of cramping pain from CAP was not due to muscle contractures as evidenced by electromyography. The quality of pain from CAP was witnessed as identical to that produced by intraneural electrical stimulation of small caliber muscle afferents. After injection of CAP, painful muscle tenderness to innocuous pressure developed in an area surrounding the injection. The area of tenderness increased with CAP dose. There was no evidence of hyperalgesia in the skin overlying the injection, confirming that the CAP injection was localized to muscle.

These data indicate that capsaicin may be a useful experimental model of muscle pain and deep hyperalgesia, and should provide valuable information regarding the neural mechanisms of muscle pain in correlative neurophysiological studies. Supported by NIH NS 24766 and 28747.

ADRENERGIC EXCITATION OF CUTANEOUS NOCICEPTORS IN ADJUVANT-INDUCED ARTHRITIC RATS. J. Sato\*,

Neural Regulation, Res. Inst. Environ. Med., Nagoya Univ., Nagoya, 464-01 Japan.

To probe mechanisms underlying sympathetic-mediated pain sensations in some inflammatory diseases, we studied the effects of sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic strivity and comparisons of the sympathetic stripe diseases, we studied the effects of sympathetic activity and norepinephrine on cutaneous nociceptors (C-fiber polymodal receptors, CPMs) in adjuvant-induced arthritic rats. Polyarthritis was induced by intradermal injection into the tail of M. butyricum 0.6 mg/0.1 ml suspended in mineral oil. Two to 27 weeks after treatment, single nerve recording of CPMs was done using fine filaments dissecting from saphenous nerve. In arthritic rats but not in controls, many (70%) CPM units showed sustained ongoing dismany (70%) CPM units showed sustained ongoing discharges. In control animals, lumber sympathetic chain stimulation at 20 Hz for 30 sec (SS) or close arterial injection of norepinephrine 400 ng (NE) by itself did not excite any CPM units tested. On the other hand, SS and NE were excitatory for a subset (35-50%) of CPMs in arthritic rats. Our results suggested that the adrenergic-sensitive CPMs might have a important role in the mechanisms of pain sensations tant role in the mechanisms of pain sensations related to some inflammatory diseases.

REACTIVE OXYGEN SPECIES DO NOT PLAY A MAJOR ROLE IN ACUTE HYPERALGESIA. M. Kress, B. Riedl and P.W. Reeh (SPON: European Neuroscience Association), Inst. f. Physiologie u. Biokybernetik, Universitätsstr. 17, D-8520 Erlangen, F.R.G. The aim of this study was to investigate the contribution of reactive oxygen species, which are massively produced in inflam-

mation, to nociceptor excitation and sensitization.

Receptive fields of single C-fibers (n=78) were separately superfused with test solutions in a saphenous nerve skin in vitro preparation. Solutions containing hydrogen peroxide, pyrogallol (an autooxidzing agent producing superoxide anion), hydroxyl radical (as a reaction product from hydrogen peroxide and ferric EDTA) or nitric oxide at concentrations of up to 10-3M were scarcely efor nitric oxide at concentrations of up to  $10^3\mathrm{M}$  were scarcely effective. 8/17 units were excited by stimulation with synthetic interstitial fluid of ph 6.1. Addition of 1 mM  $\mathrm{H_2O_2}$  did not further enhance responses. In contrast, a mixture of inflammatory mediators (bradykinin, histamine, serotonin, prostaglandin  $\mathrm{E_2}$   $10^3\mathrm{M}$ , ph 7.4) in combination with 1mM  $\mathrm{H_2O_2}$  significantly increased the discharge frequency in 8/16 units as compared to the mediators alone. On average units were neither sensitized nor desensitized to mechanical stimuli although the variability of mechanical responsiveness had increased

mechanical responsiveness had increased.

Extremely high concentrations of reactive oxygen species were needed to excite cutaneous unmyelinated nociceptors, if at all. This does, however not exclude their possible contribution to the development of chronic pain states as they are known to cause changes in lipids and proteins which may be of longer onset. Supported by the DFG, grant Re-A3 in SFB 353.

LASER EFFECTS ON MYELINATED AND NON-MYELINATED AXONS IN RAT PERONEAL NERVE. U. Wesselmann\*, J. M. Kerns and W. Z. Rymer. Depts. of Physiology, Physical Medicine & Rehabilitation, Northwestern University Medical School, Chicago, IL 60611.

We have recently shown that Nd:YAG laser irradiation of rat peripheral nerve

We have recently shown that Nd:YAG laser irradiation of rat peripheral nerve differentially impairs action potential transmission in small, slowly conducting sensory fibers as compared to large diameter afferents (Wesselmann et al., Physiol. Chem. Phys. & NMR, 23, 81-100, 1991). In addition, the number of small sensory neurons of the A-delta and C-fiber group labeled with HRP is significantly reduced after laser irradiation (Wesselmann et al., Exp. Neurol. 111, 251-262, 1991). In contrast the number of labeled large sensory neurons and motoneurons was not affected. To further evaluate this laser induced injury, we examined three distinct regions (site of laser irradiation, 10 mm proximal and 5mm distal) at the ultrastructural level by morphometric methods in the peroneal nerve (n=6). The contralateral side was sham-treated. Our results indicate that the nerve (n=0). The contrainers since was sname-treated, our results indicate that the number of myelinated and non-myelinated axons is not significantly altered at 7 days following laser irradiation. The diameter and the frequency distribution of the myelinated axons was unchanged. There were no consistent ultrastructural changes in the nerves associated with laser irradiation. This study demonstrates that functional alterations in laser irradiated nerves (nerve conduction velocity, HRP transport properties) are not necessarily accompanied by structural changes. Thus, Nd:YAG laser light might be a powerful tool to selectively alter functional properties in small, slowly conducting afferent fibers, without causing structural damage at the ultrastructural level at the site of irradiation.

CHARACTERIZATION OF AN ARTHRITIS MODEL IN RAT:TEMPORAL CHANGES IN PAW WITHDRAWAL LATENCY AND DORSAL HORN GLU. CHANGES IN FAW WITHDRAWAL LATENCE FAIND DORSAL HORN GLU, SP, AND CGRP CONTENT. K.N. Westlund\* and K.A. Sluka. Marine Biomedical Institute, UTMB, Galveston, TX 77555-0843.

An experimental knee joint arthritis was induced by intraarticular injection of 3% kaolin and 3% carrageenan in rats under short acting anesthesia. Side to side differences in paw withdrawal latency (PWL) to radiant heat stimuli and immunocytochemical staining for neurotransmitter/neuromodulator substances (GLU, SP, and CGRP) were determined before and at different time periods after induction of arthritis (4,8,12,24,48,72 hr and 1 wk). The PWL decreased on the inflamed side starting at 4 hr, demonstrating that heat hyperalgesia had developed, and returned to normal by 72 hr. SP content, determined by computer assisted quantitation, was decreased ipsilaterally at 4 hr (52%). However, by 8 hr SP acreased (33%) and remained increased up to one week (24%). Immunoreactivity for CGRP was also elevated at 8 (32%) and 12 (46%) hrs, and 1 wk (25%). GLU content increased at 4 hr (35%) and returned to baseline by 72 hr. The time course changes in GLU content and PWL in the inflamed paw were parallel in the same animals indicating that GLU is involved in arthritic heat hyperalgesia. In 5 rats where hyperalgesia did not develop, there was no change in GLU or SP immunoreactivity, but CGRP increased in the dorsal horn region receiving knee joint afferents. These studies demonstrate that while primary afferents are activated in this arthritis model, more widespread dorsal horn changes in GLU and SP are necessary for the development of heat hyperalgesia. GLU, SP, and CGRP content changes follow different time courses during the development of arthritis and are therefore involved in differential processing of information from the periphery. The persistence of the rise in peptide content may serve a modulatory role in maintaining the increased responsiveness of dorsal horn neurons during arthritic hyperalgesia. (Supported by NS01445, NS11255, and Bristol-Myers Squibb Co.)

A BILATERAL INCREASE IN NADPH-DIAPHORASE ACTIVITY IN THE RAT LUMBAR SPINAL CORD FOLLOWING UNILATERAL HINDPAW INFLAMMATION. R.J. Traub\* 1, A. Solodkin 2 and G.F. Gebhart 1. Depts. of Pharmacology 1, Anatomy and Neurology 2, University

HINDPAW INFLAMMATION. B.J. Traub \(^1, \) A. Solodkin \(^2\) and G.F. Gebhart \(^1\). Depts. of Pharmacology \(^1\), Anatomy and Neurology \(^2\), University of lowa, lowa City, 1A 52242.

Inflammation involves metabolic changes in the periphery and the CNS. Hindpaw inflammation results in the upregulation of \(^2\) for and dynorphin in spinal dorsal horn neurons somatotopically appropriate to the site of injury. In this context it was of interest to determine if there are similar changes in enzymatic activity (e.g. NADPH-diaphorase) in spinal neurons as a result of hindpaw inflammation.

Male Sprague-Dawley rats (300-400 g) were given an intraplantar injection of 3 or 6 mg (100-200 \(^{1}\)) carrageenan. Survival times ranged from 1-24 hrs. Following perfusion with \(^4\)% paraformaldehyde, \(^4\)0 \(^{1}\) msections through the L4-L5 spinal segments were histochemically reacted (60 min, \(^3\)1°C) with \(^6\)-NADPH and nitroblue tetrazolium.

In controls the greatest number of stained neurons were observed in the superficial dorsal horn, including lamina III, with lesser amounts in the neck of the dorsal horn and around the central canal. Varicose axons were scattered throughout the gray matter, but were densest in the superficial dorsal horn and were present in the dorsal and ventral bundles around the central canal. Unilateral hindpaw inflammation resulted in a bilateral increase in: 1) the number of labeled neurons in the dorsal horn; 2) the number of very darkly stained neurons in laminae III-III; 3) the density of axons and varicosities throughout the gray matter. These increases were observed equally ipsi- and contra-lateral to the inflamed hindpaw.

These results suggest the inflammation process modulates NADPH-diaphorase activity within the spinal cord. Since previous studies had shown it coexists with certain peptides and is a putative NO synthase, it could be of interest to determine the neurochemical identity of NADPH-diaphorase stained elements under these conditions. CHRONIC PAIN CAUSES AN INCREASE IN AMINO ACID RELEASE IN THE MIDBRAIN PERIAQUEDUCTAL GRAY. A MICRODIALYSIS STUDY. W. M. Renno.\*F. G. Williams, J. Hautman, and A. J. Beitz. Department of Pathobiology, University of Minnesota, 1988 Fitch Ave. St. Paul, MN 55108.

A. J. Beitz. Department of Pathobiology, University of Minnesota, 1988 Fitch Ave. St. Paul, MN 55108. It has been well documented that systemic administration of opiates or direct injection of opioid peptides into the PAG produces a profound antinociception which is thought to be associated with inhibition of neuronal activity in the PAG. This inhibitory effect has been postulated to result from opiate inhibition of GABAergic neurons in the PAG. Whether this opioid-GABAergic system is affected in chronic pain states has not been investigated. Microdialysis was chosen to perform direct and dynamic studies of amino acid concentrations in the PAG in control rats and in animals subjected to acute and chronic inflammation caused by injection of 120 ul of complete freund's adjuvent (CFA) into the hindpaw. We also examined the effects of acute and chronic pain on amino acid transmitter release from the PAG following depolarization with 75 uM veratridine. Veratridine induced release of aspartate and glutamate in rats treated with CFA 24 hrs prior to dialysis was double that of the control group treated with mineral oil 24 hrs prior to dialysis. GABA release was significantly increased in the group treated with CFA 7 days before dialysis. The increase GABA release was twice that of control groups or the 24 hrs CFA treated group. Based on data from other experiments we believe that this increase in the veratridine induced GABA release may be due to an increased opiate inhibition of GABA resulting from the induction of chronic pain. In sum these data indicate that acute pain (24hrs) causes a net increase in the release of glutamate and aspartate in the PAG, while chronic pain (7days) results in a net increase in GABA in PAG dialysates. This work was supported by NIH grants DA06687, DE06682, NS28016.

AMINO ACID RELEASE IN EXPERIMENTAL ARTHRITIS AND THE EFFECTS OF LIDOCAINE, CNQX, AND AP7 PRETREATMENT. <u>K.A.Sluka\* and K.N. Westlund.</u> Marine Biomedical Institute, UTMB, Galveston, TX 77555.

Amino acid release in the dorsal horn of awake rats was examined by microdialysis during the development of arthritis induced by injection of 3% kaolin and 3% carrageenan into the knee joint. The following amino acids were measured by HPLC at baseline and for the first 8 hr of arthritis: ASP, GLU, ASN, GLN, SER, GLY, and TAU. Four groups of animals were examined: 1) injection of the knee joint with kaolin and carrageenan, 2) pretreatment of the spinal cord with lidocaine 12-24 hours before injection of kaolin and carrageenan, 3) and 4) pretreatment with CNQX or AP7 administered through the microdialysis fiber 1 hr before the injection of kaolin and carrageenan. An initial increase in all amino acids examined was observed on injection of the knee joint in arthritic rats (Group 1). Subsequently, there was a peak increase in ASP (184%) and GLU (188%) by 2.5-3.5 hr which persisted for 8 hr. While ASN showed no changes from control and GLN, SER, and GLY were variable. In lidocaine treated animals (Group 2), only an increase in ASP, SER, and GLY was observed on injection of the knee joint while no change was seen in ASP or GLU. There is a peak decrease in ASP (60%) between 5 and 6 hrs and GLU decreased to 71%. In the CNQX treated animals (Group 3) there was an increase of ASP, SER and TAU on injection of the knee joint. Increases in ASP and GLU seen normally after induction of arthritis, however were delayed by 2 hr. In the AP7 treated animals (Group 4), only an increase in TAU on injection of the knee joint was observed. ASP and GLU were not released on injection. After 4 hr only ASP increased with no change in GLU. This data indicates the induction of arthritis is accompanied by an increased release of excitatory amino acids ASP and GLU which are important in the generation of acute arthritic hyperalgesia. This pattern of release is altered by pretreatment of the spinal cord/dorsal roots with lidocaine, CNQX, and AP7.

REGULATION OF C-FOS AND JUN B mRNA TRANSLATION IN RAT SPINAL NEURONS FOLLOWING CUTANEOUS FORMALIN INJECTION OR UV-B IRRADIATION: INFORMATION STORAGE AT THE mRNA LEVEL?

F. Gillardon, T. Herdegen, R. Bravo and M. Zimmermann. Dept. of Physiology II, Univ. Heidelberg, 6900 Heidelberg, F.R.G. and Bristol-Myers Squibb Pharmaceutical Res. Institute, Princeton, NJ, USA.

Noxious inflammatory stimulation was applied to rat hindpaws by either unilateral plantar injection of dilute formalin (5% in tyrode) or by cutaneous UV-B irradiation (10,7 J/cm<sup>2</sup>). Levels of c-fos (formalin) and junB (UV) transcripts and encoded proteins in the lumbar spinal cord were evaluated by slot-blot analysis and immunocytochemistry,

Compared to vehicle-injected controls, c-fos mRNA was increased in the ipsilateral and (to a minor degree) the contralateral side of the spinal cord 2 h following formalin injection, whereas intense c-FOS immunoreactivity was completely lateralized. In the UV-inflammation model, the significant increase in junB mRNA 6 h after UV-B exposure was not reflected by a corresponding phase at the precipil level.

was not reflected by a corresponding change at the protein level.

We have reported on the potentiated synthesis of c-FOS in spinal neurons following unilateral formalin injection when preceded by an identical stimulation applied to the contralateral paw [Leah et al., Eur. J. Neurophysiol. 415, Suppl.1, R90]. This could now be explained by induction of c-fos expression in contralateral neurons by the first stimulus without subsequent translation. Comparison of formalin and UV related data suggest that translational efficiency may depend on electrical activity in nociceptive afferents.

CORTICAL TONIC FACILITATORY INFLUENCE ON THALAMIC AND DOR-SAL HORN RESPONSES EVOKED BY SURAL N.STIMULATION AND CARRA-GENINE IN RATS. I.Omaña-Zapata\*, F.Pellicer, M.Condés-Lara. Instituto Mexicano de Psiquiatría, 14370 México, D.F.

Cortical action on thalamic centralis lateralis nucleus and dorsal horn cells was studied during electrical suprathreshold sural nerve stimulation (SN) before and after carragenine (CAR) hindpaw injection. Cortical activity was transiently and reversible suppressed by the cortical spreading depression (CSD). Simultaneous recordings were obtained at prefrontal cortex, C1 and lumbo-sacral spinal cord (SC) level. The CSD did not modify the SC responses to SN stimulation in 25(93%) cells and decreased the frequency in 2(7%) cells. After CAR, 12(36%) SC cells increased their spontaneous activity and presented bursting discharges. Nineteen (58%) SC cells were recorded during 3 CSD, 14(43%) cells did not modify their spontaneous or voked responses; five (15%) cells decreased their activity (in around 56%) after 124 ± 33 min. of CAR. In 24(89%) Cl cells, the CSD blocked their responses to SN stimulation. After CAR, 8(53%) C1 cells enhanced their activity; and 12 (80%) Cl cells, the CSD suppressed the CAR evoked activity. These results show that CAR enhanced the basal activity of SC and Cl. The delayed CSD-evoked suppression of activity at SC level suggests a development of a descending cortical facilitatory control. The blockade of this control diminishes the nociceptive effect upon the SC activity evoked by SN stimulation and CAR irritation.

REGULATION OF A CALCIUM/CALMODULIN-DEPENDENT PROTEIN PHOSPHATASE IN THE LIMULUS LATERAL EYE. D.Z. Ellis-Ibidapo and S.C. Edwards\* Dept. of Biology, Inst. for Biomolecular Sciences, University of South Florida, Tampa, FL 33620.

Calcium has been shown to play an integral role in the photoresponse of the photoreceptors in both the vertebrate and invertebrate organisms. For example, in photoreceptors from the horseshoe crab, LIMULUS, increasing Ca2+ levels mediate the state of light and dark-adaptation. In these cells, light, via Ca2+ activates a calcium/calmodulin (Ca/CaM)-dependent protein kinase which increases the phosphorylation of a 46kD protein (46A). Our previous results (Herrera et al., 1992) suggested that the protein phosphatase (PrP) responsible for the dephosphorylation of 46A is a type 1, whose activity is regulated by calcineurin, (PrP 2B, a Ca/CaM-dependent PrP). Using a 32P-labelled peptide fragment of the regulatory subunit of cAMP-dependent protein kinase as a substrate. (Blumenthal et al., 1986) we have identified calcineurin-like (CaN) activity in homogenates of LIMULUS visual and nonvisual neuronal tissues. Comparison of activities present in preparations containing nonphotoreceptor neuronal tissue, photoreceptor cell bodies and their axons demonstrate that Ca/CaM PrP activity is highest in the brain, lateral optic nerve and lateral eye respectively and that these activities are present in membrane as well as soluble fractions. We have shown that this activity is decreased by heparin, protamine and interestingly, okadaic acid (OKA 1,000 to 1 nM). This latter property is significant for it suggests that the LIMULUS Ca/CAM PrP is different from mammalian CaN which is not inhibited at low concentrations. Most importantly, light regulates the Ca/CaM PrP activity in the lateral eye. While there is no significant difference in basal PrP activity for long-term dark or light-adapted preparations,  $Ca^{2+}$  produced an increase in Ca/CaM PrP activity only in long-term light adapted cells. (Supported by NIH EY08765)

# 63.3

AND NON-LINEAR CODING CONTRAST RESPONSES IN FLY PHOTORECEPTORS. M. Juusola, M. Järvilehto, E. Kouvalainen and M. Weckström. Depts. of Physiology and Zoology, University of Oulu, SF-90220 Oulu, Finland. In photoreceptors both long-lasting light stimu-li (background) and changes thereof (contrasts) modulate the cells' membrane potential. We have intracellular voltage responses positive and negative contrast steps of varied duration superimposed on a varied background. The contrast responses are surprisingly linearly dependent on the contrast if the stimulus is of small duration (<2 ms) or the background is low (<100 quanta/s). With longer lasting contrast steps or with higher backgrounds the responses steps or with higher backgrounds the responses to positive contrast (intensity increment) are increasingly smaller than the responses to negative contrast (intensity decrement). These photoreceptor properties are caused partly by kinetic properties of voltage-dependent K\*-channels (Weckström et al. J. Physiol.440:635-57, 1991), but the light-current (recorded with single electrode voltage clamp) rectifies into the same direction as well the same direction as well.

MEASUREMENT OF NEURONAL IMPEDANCE IN FREQUENCY DOMAIN WITH WHITE NOISE MODULATED CURRENT INJEC-SINGLE ELECTRODE TECHNIQUE.

TION USING SINGLE ELECTRODE TECHNIQUE.

M. Weckström, E. Kouvalainen, M. Juusola and
K. Diupsund'. Department of Physiology, University
of Oulu, SF-90220 Oulu, Finland.

The determination of membrane properties of
small neurons is difficult because only one
intracellular electrode can be used. We have
developed a system where, while recording intracellularly current is injected into the cell using discontinuous (switched) technique. The magnitude of the current (0.05-0.5 nA peak-to-peak) is modulated pseudorandomly. The neuron's input impedance is then calculated, via FFT, as the ratio of cross-power spectrum (of input current and output voltage) and input power spectrum. By using time-domain averaged responses to the same pseudorandom sequence we can estimate the linearity of the membrane input-output relation with the coherence.

The described technique can be used to determine the input impedance of invertebrate photoreceptors, and both invertebrate and vertebrate visual interneurons, large monopolar neurons and horizontal cells, respectively.

COMPUTATIONAL ANALYSIS OF THE LIMULUS RETINA: SIMULATION OF VISUALLY-GUIDED BEHAVIOR

E Herzog\* <sup>1</sup>, DR Kipke <sup>1</sup>, M Powers <sup>2</sup>, RB Barlow Ir. <sup>1</sup>

Institute for Sensory Research, Syracuse University, NY 13244; <sup>2</sup>Dept. of Psychology, Vanderbilt University, Nashville, TN

We have developed a computational model of the Limulus retina to investigate the neural representation of the animal's visual world. The model is based closely on the anatomical and physiological properties of the eye and its optics. The visual inputs are transformed via the optical properties of individual corneal lenses to determine the effective photon fluxes that excite the neural units (ommatidia) comprising the retinal network. Each ommatidium is simulated by a compartmental model of its spike-generating neuron that has variable conductances corresponding to light-sensitive excitatory inputs, firing of action potentials, and inhibitory inputs arising from both its own spike activity and that of neighboring neurons. We describe a computationally efficient implementation of the model on a parallel computer (Connection Machine, Model CM-5).

We use the model to investigate the neural representation of real scenes. Specifically, we simulate the spatial and temporal neural code that the eye sends to the brain in response to visual inputs that evoke known behaviors. We have shown that Limulus sights targets at distances between 0.4 and 1.0 meters dependent on the target size and contrast, but independent of time of day. Both day and night, Limulus turn towards objects that subtend as few as 4 ommatidia. We compute the neural responses to targets of various sizes and contrast moving at various speeds and relate these to visually-guided behavior. We also investigate the sensitivity of the neural code to changes in the anatomical and physiological state of the eye

EXPRESSION OF VOLTAGE-GATED SODIUM CHANNEL-LIKE IMMUNOREACTIVITY IN THE CAT AND MONKEY RETINA. C.J. Snider. J.J. Miguel-Hidalgo, K.J. Angelides+, L.M. Chalupa\*. Center for Neurobiology, Univ. California, Davis, CA 95616; +Physiol. & Molec. Biophysics Dept., Baylor Univ., Houston, TX 77030.

Polyclonal and monoclonal antibodies, generated to the  $\alpha$  subunit of the voltage-gated sodium channel ( $\alpha$ VGNaC), were employed to assess the cell types containing these channels in the mature cat and monkey retina. Immunoblot analyses of retinal proteins revealed that these antibodies labeled a band in the 260 KD region which is the expected molecular weight of the aVGNaC. In both the cat and monkey several types of retinal cells were immunolabeled. With the polyclonal antibodies immunoreactivity was observed in ganglion cells, optic axons, horizontal cells, and cones. A smaller number of cells, axons, nonzonial cells, and cones. A smaller number of cells, presumed to be bipolar neurons, were labeled in the inner nuclear layer (INL). With the monoclonal antibody there was staining in the fiber layer, relatively weak labeling of ganglion cell somata, and a continuous band of immunoreactive cell bodies situated in the inner half of INL. By immunolabeling isolated cells dissociated from the cat retina, it was possible to demonstrate unequivocally that bipolar cells were in fact labeled with the antibodies to  $\alpha VGNaC$ . The differences in the labeling observed between the polyclonal and monoclonal antibodies was interpreted as reflecting the presence of different  $\alpha$  subunits in the mammalian retina. Collectively, our findings suggest that  $\alpha VGNaCs$ are expressed on a more diverse population of retinal cells than expected on the basis of previous physiological and immunohistochemical studies. (Supported by NIH and NMSS)

# 63.6

TYPE I NADPH-DIAPHORASE (NADPHd) REACTIVE RETINAL NEURONS SHOW FOS-LIKE IMMUNOREACTIVITY (FOS-IR) AFTER LIGHT EXPOSURE. J. Koistinaho\*and S.M. Sagar. Neurology Service, VA Medical Center, and Dept. of Neurology, Univ. of California, San Francisco, CA 94143.

Nitric oxide synthase (NOS) generates a readily diffusible messenger molecule, nitric oxide, and is responsible for the neuronal NADPHd histochemical reaction. In the rabbit retina, two populations of cells in the inner nuclear layer (INL) are NADPHd reactive: larger, more densely staining cells termed Type I; and more numerous and smaller cells termed Type II. The Type I cells have long processes and are presumably involved in long-distance interactions within the retina. To examine whether these NADPHd reactive cells are stimulated by light, retinas of dark-adapted rabbits that were exposed to flashing light for lh and sacrificed lh later were immunostained for Fos proteins and double labelled for NADPHd. Dark-adapted, control retinas had no Fos-IR, whereas light induced Fos-IR in a minority of cells in the ganglion cell layer and INL, as reported previously (Sagar and Sharp, Mol. Brain Res., 1990). In the INL 25-30% of Fos-IR cells were NADPHd reactive, 70-80% of the Type I and 10% of the Type II NADPHd reactive cells showed Fos-IR. The results indicate that NOS-containing cells are activated by flashing light in the rabbit retina.

GABA ACTIVATES L-TYPE Ca CHANNELS IN THE EMBRYONIC CHICK RETINA. M. Yamashita and Y. Fukuda\*. Dept. Physiol.
Osaka Univ. Med. Sch., Suita 565, Japan.
GABA is present before synapse formation in the chick retina (Hokoç et al. '90). The action of GABA was studied by measuring intraaction of GABA was studied by measuring intra-cellular Ca<sup>#</sup> concentration with Fura-2 in the neural retina of embryonic day 3 chicks. Puff-application of 100 µM-GABA <u>increased</u> the Ca<sup>#</sup> concentration. This response was blocked

by 10  $\mu\text{M-bicuculline}$  and mimicked by muscimol but not by baclofen. The GABA response was abolished in Ca-free medium or in 2 mM-Co, suggesting the involvement of Ca channels. suggesting the involvement of Ca channels. Depolarization with high-K solution also induced the Ca\* increase. This Ca response was completely blocked by 10 µM-nifedipine and enhanced by 5 µM-Bay K 8644, showing the characteristics of L-type Ca channels. The Ca response to GABA showed the same pharmacological properties as the L-type Ca channels.

We conclude that GABA activates L-type Ca channels via GABA, receptors. The depolarization may be caused by efflux of Cl. GABA can regulate the intracellular Ca concentration through L-type Ca channels during the early period of neurogenesis in the chick retina.

## 63.9

RETINA-SPECIFIC BOVINE cDNAs ENCODING HOMOLOGS OF THE norpa AND ninga PROTEINS OF DROSOPHILA. P. Ferreira and W.L. Pak\*. Dept. of Biological Sciences, Purdue Univ., W. Lafayette, IN 47907.

The norpA and ninaA genes encode, respectively, a photoreceptor-specific phospholipase C (PI-PLC) and cyclophilin, which are important in phototransduction and rhodopsin folding, respectively. Mutations in the *norpA* gene also cause photoreceptor degeneration in *Drosophila*. We looked for evidence of retina-specific bovine homologs of these proteins by screening a bovine retinal cDNA library under reduced stringency conditions using probes derived from norpA and ninaA sequences. Among the positively hybridizing clones isolated, we concentrated on two: one isolated with the *norpA* probe and the other isolated with the *ninaA* probe. Sequence analysis showed that the proteins deduced from the two cDNA clones showed strong homology to the norpA (PI-PLC) and ninaA (cyclophilin) proteins, respectively. In Northern analysis, the norpA-like bovine cDNA recognized a 7.4 kb transcript and the ninaA-like cDNA, a 3.1 kb transcript. Both these transcripts were present in blots of retinas but not of any other tissue tested. Results of tissue in situ hybridizations suggest that both transcripts are localized in photoreceptors as well as retinal neurons of the inner nuclear and ganglion cell layers.

# 63.11

Immunolocalization of basic fibroblast growth factor (bFGF) in the rodent outer retina demonstrated with an anti-rodent bFGF antibody Hua Gao. Samuel M. Wu\* and loc G. Hollyfield. Cullen Eye Institute and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030 Despite the fact that bFGF has been isolated from the retina, its retinal localization remains controversial. To establish the precise cellular distribution of bFGF in the C57BL/6J mouse and Sprague-Dawley rat retinas, we have used anti-bovine (AA 1-24, AA 1-15), anti-human (whole molecule) and anti-rat (AA 1-23) bFGF antibodies in immunocytochemical studies. Immunolocalization with these antibodies revealed two distinctly different retinal staining natterns. With antibodies against bovine or human bFGF. some Immunolocalization with these antibodies revealed two distinctly different retinal staining patterns. With antibodies against bovine or human bFGF, some ganglion cells, cells in the inner portion of INL and developing horizontal cells were stained as previously reported in the rat retina. Using the anti-rat bFGF antibody, in the adult mouse, heavy labeling was observed at the level of the photoreceptor outer segment; whereas in the adult rat, Muller's cells and RPE were intensely labeled. In the P5-10 mouse and P5 rat, the staining patterns were virtually identical, with bFGF immunolabeling localized to the outer retina, in the cytoplasm and nuclei of developing photoreceptors and in cells located in the outer portion of INL. From P1 until P5, no difference was observed in the staining intensity between rd and normal mice. From P6 1010, the rd retinas were more intensely labeled in those cells described above observed in the staining intensity between rd and normal mice. From P6 to P10, the rd retinas were more intensely labeled in those cells described above than the normal retinas at equivalent ages. bFGF immunolabeling with anti-rat bFGF antibody could be blocked by preabsorption in rat and mouse retinas with rat bFGF antigen (AA 1-23), and blocked in developing but not in adult mouse retinas with mouse bFGF antigens (AA 1-25, AA 12-25). bFGF labeling with anti-bovine antibody could not be blocked when preabsorbed with the rodent bFGF antigens; and the staining with anti-rat antibody was not blocked by preabsorption with bovine bFGF antigen (AA 1-24) in the rat, but was blocked in the mouse retina. These results indicate that minor species differences in a short segment of the bFGF molecule used to generate these antibodies may result in major differences in apparent bFGF immunolocalization.

DOPAMINE AND PHORBOL ESTER-INDUCED POTASSIUM EFFLUX IN THE

DOPAMINE AND PHORBOL ESTER-INDUCED POTASSIUM EFFLUX IN THE CHICK RETINA: EFFECTS OF MELATONIN. J.T. Laitinen<sup>4</sup>. Dept. of Physiology, Univ. of Kuopio, SF-7D211 Kuopio, Finland. Potassium efflux (assessed as <sup>60</sup>Rb<sup>4</sup> efflux) was studied in retinal suspensions from 1 to 17-day-old posthatched chicken. Dopamine (DA) increased K<sup>4</sup> efflux rate 1.5 fold. This effect was dose-dependent (EC<sub>50</sub> 22 µM), was mimicked by the D1-selective agonist SKF-38393 and reversed by the D1-selective argonist SKF-38393. The DA action was independent of the selective argonist SKF-38390. tive antagonist SCH 23390. The DA action was independent of adenylyl cyclase (AC) activation, as the membrane permeable cAMP analogs showed no potency. Moreover, DA did not affect cAMP accumulation in retinal suspensions. The protein kinase C (PKC) activator, 4 $\beta$ -phorbol 12-myristate 13-acetate (4 $\beta$ -PMA) also stimulated retinal K $^{\dagger}$  efflux in a dose-dependent manner (EC50 4 nM). This effect was mimicked by 4 $\beta$ -phorbol 12,13-didecanoate but not by the inactive isomer 4d-PMA. When added together, DA and  $4\beta$ -PMA behaved in an additive manner suggesting a PKC-independent action for DA. Moreover, DA did not stimulate phosphoinositide hydrolysis, a well-known pathway to generate diacylglycerol, an endogenous activator of PKC. DA also inhibited retinal Na/K-ATPase (assessed as ouabain-sensitive <sup>8</sup> Rb† influx). However, the DA-elicited K† efflux was largely independent on this DA-elicited K efflux was largely independent on this inhibition. As melatonin (MEL) is known to interact with DA in the retina, the effects of MEL on K efflux were studied. MEL affected neither basal nor DA nor  $4\beta\text{-PMA-stimulated }K^t$  efflux. To conclude, DA stimulates K efflux in the chick retina via a D1-receptor mediated action independently on AC and PKC. MEL does not seem to modulate this action of DA.

## 63.10

STEREOSELECTIVE HYDROLYSIS OF RETINYL ESTERS BY CHICKEN NEURORETINA AND RETINAL PIGMENT EPITHELIUM. R.D. Ramirez, L.J. Bustamante, N.L. Mata, and A.T.C. Tsin. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249

The distribution of retinvl esters in the chicken neuroretina and retinal pigment epithelium (RPE) has been reported to be unusual in comparison to other vertebrate species (Rodriguez & Tsin, 1989, Am. J. Physiol. 256, R255-R258). In the present study, retinyl ester hydrolase (REH) activities in neuroretina and RPE tissue homogenates and their subcellular fractions were partially characterized using [7H]-11-cis and all-trans retinyl palmitate as substrates. Ester hydrolysis in both tissues was predominantly stereose-lective for the all-trans isomer and was heat-labile. The rate of hydrolysis was protein, time, pH, and substrate dependent. Maximum hydrolysis occurred at pH 5.0 and in the mitochondrial/lysosomal fractions (63% of total) of both tissue preparations. However, neuroretina homogenates exhibited a significantly higher rate of hydrolysis for all-trans retinyl palmitate ( $V_{max}$  = 111 pmol/min/mg in neuroretina vs. 71 pmol/min/mg in RPE) but little difference in substrate affinity ( $K_{m}$  = 5 uM in neuroretina vs. 4.5 uM in RPE). Since REH activity toward the 11-cis isomer was significantly lower in both tissues (60 pmol/min/mg for neuroretina, 27 pmol/min/mg for RPE) than that observed for the all-trans isomer, and a comparable substrate affinity (5.8 uM for neuroretina, 2.5 uM for RPE), this would suggest that the all-trans retinyl ester in the chicken retina may play an important role in the visual cycle.

IDENTIFICATION OF GAMMA-AMINOBUTYRIC ACID-A (GABA-A) RECEPTOR SUBUNIT TRANSCRIPTS IN RODENT RETINAE. H.M.Valivullah\* and C.M. Waibel. Biology Department, Georgetown University, Washington.D.C. 20057.

Cloning studies have identified six alpha subunits, three beta subunits, three gamma subunits and one delta subunit in rodent brains and two rho subunits in human retina. The biochemical, pharmacological and physiological properties of a given GABA-A receptor seems to be dependent upon the constituent subunit classes of that receptor. Vertebrate retina has GABA as well as GABA-A and GABA-B receptors. As a prejude to the localization of different GABA-A receptor subunit classes in mouse and rat retinae, we have studied the expression of different subunit classes by reverse transcription and polymerase chain reaction (PCR) using rat primers for alpha 1-6, beta 1-3, gamma 1-3 and delta and human primers for rho 1. Our results suggest that alpha 1, beta 1 and 3 and rho 1 mRNA are more prevalent than that of other subunits studied. Alpha 4-6, gamma 1 and gamma 2 long transcripts were not detectable after 35 cycles of PCR. This suggests the expression in retina of a relatively distinct collection of GABA-A subunit mRNAs when compared with the other regions of the CNS. Analysis of the cellular distribution of GABA-A subunit mRNAs may permit the formulation of models relating subunit composition with physiological responses in identified subtypes of retinal neurons.

EFFECTS OF IDPN ON THE STRUCTURE AND FUNCTION OF THE RAT YISUAL SYSTEM. S. Barone Jr. 1. D. Herr 2. K. Crofton 2. METI, RTP, NC 27711; NTD, USEPA, RTP, NC 27709. Short-term repeated administration of 3,3'-imino-dipropionitrile (IDPN) results in a complex neurobehavioral syndrome (cf Cadet, 1989 Neurosci Biobehav Rev 13:39). Adult male Long-Evans rats received IDPN (400 mg/kg i.p.) on 3 consecutive days and were sacrificed 24 hours after the first dose, 24 hours after the third dose, 3 days after the third dose for histological analysis of the eye. IDPN intoxication resulted in opacification of the cornea (3 days) and detachment of the retina (1 week). The corneal changes were transient and were not overtly apparent at 2 wks post-treatment while retinal reattachment took place between 5 and 10 wks. However, early necrosis in the inner nuclear layer (INL) was seen before retinal detachment (3 days post-dosing) followed by progressive retinal degeneration (5 and 10 wks). Retinal detachment was less severe at 10 wks. A dose-response study (0, 100, 200, 400 mg/kg x 3 days) of visual electrophysiology and histology was performed 2 wks post-treatment. Decreased flash evoked potential (FEP) peak N<sub>20</sub> and N<sub>56</sub> amplitudes and increased latencies of peaks P<sub>21</sub> and P<sub>46</sub> were observed in a dose-related manner, with significant decrements at the highest dose. Results indicate that non-neural structures in the eye recover in a time-dependant manner, while neurodegeneration of the visual retina is progressive, even when the retina has reattached. At 2 wks after dosing, retinal detachment in the 400 mg/kg dose group and degeneration in the INL of the 200 and 400 mg/kg dose groups was associated with decreased amplitudes and increased latencies of electrophysiological responses to visual stimulation.

## CIRCADIAN MODULATION OF STRUCTURE IN THE JAPANESE QUAIL RETINA

M.E. Kelly, N.F. Buelow, E.D. Herzog, G.A. Engbretson\* and R.B. Barlow, Jr.

Institute for Sensory Research, Syracuse University, 13244

Retinomotor movements are regulated by light and an endogenous clock in lower vertebrates. Circadian interactions of dopamine and melatonin control cone myoid movement in *Xenopus* (1). Dopamine and its agonists and antagonists modulate structural changes in fish retina (2). Physiological studies in the Japanese quail have shown a circadian rhythm in rod-cone dominance (3 &4).

in rod-cone dominance (3 &4).

Here we report that a circadian clock controls retinomotor movements in the quail. Illumination in the day or night has no detectable effect. Processes of the retinal pigment epithelium (RPE) migrate towards the outer limiting membrane (OLM) during the subjective day, surrounding rod outer segments (ROS) and partially surrounding cone outer segments (COS). At night, the RPE retracts, exposing the COS and ROS. Immunocytochemical staining for tyrosine hydroxylase locates dopaminergic cells in the amacrine layer. Intravitreal injections of dopamine agonists and antagonists do not dispute the structural faythms. dopamine agonists and antagonists do not disrupt the structural rhythms. Structural and functional rhythms do not appear correlated. Circadian control of retinomotor movements and RPE migration may be involved in metabolic stability rather than changes in sensitivity.

CHARACTERISTICS OF LIGHT-EVOKED ALKALINIZATIONS IN CAT RETINA. F. Yamamoto\* and Y. Honda. Dept. of Ophthalmology, Kyoto University School of Medicine, Kyoto, 606 Japan.

Measurements of [H+], by intraretinal ion-selective microelectrodes showed that pH outside dark-adapted rods was relatively acidic in the dark, with maximum acidity (pH 7.04) in the outer nuclear layer (Yamamoto, F. and Steinberg, R.H., Soc. Neurosci. Abstr. 15:206, 1989). Illumination. which was at rod saturation level, produced intraretinal alkalinization that was largest (up to 0.2 pH units) in outer nuclear layer (Borgula, G.A. and Steinberg, R.H., Invest. Ophthalmol. Vis. Sci. Suppl. 25:289, 1984). We studied the effects of various light-stimuli on light-evoked alkalinizations using double-barrel H+-selective microelectrodes in the intact cat eye, in vivo. Stronger lights above rod saturation level made the recovery after light-offset very slow. Short and strong light produced alkalinization as well as the long flash with the intensity of rod saturation level. And the stimulisummation of short flashes induced alkalinizations as well as the long continuous lights. These results suggests that the light-evoked alkalinizations might be concerned with the light adaptation of rods photoreceptors

POSITIVE AND NEGATIVE COMPONENTS OF THE DARK-ADAPTED CAT ERG <u>L.J. Frishman\*, J.G. Robson</u>¹, and <u>L. Du</u>, College of Optometry, Univ. of Houston, Houston, TX 77204; ¹Physiological Lab, Cambridge, UK (CB2 3EG)

Component potentials generated by different retinal processes sum

algebraically to produce the electroretinogram (ERG). We used brief (<1 msec) ganzfeld flashes to re-examine the components of the vitreal ERG in dark-adapted anesthetized cats. We conclude that the ERG reflects activity of several processes whose responses are linearly related to intensity at low intensities, but then saturate at different higher intensities. intensities the significant ERG components are the negative scotopic threshold response (STR) and a positive potential which (unlike PII) saturates at a lower intensity than STR. Below 2-4 quanta/deg2 (incident at the cornea) either this positive potential is the larger (the ERG reaching 1-2  $\mu V$  positive) or the two potentials cancel, making the STR appear to have a threshold. At higher intensities the positive potential stops increasing, and the STR then dominates and increases linearly with intensity up to about 1/3 of its maximum amplitude (of roughly 40 µV). At intensities about 10 times greater, the negative (STR) peak saturates rather abruptly to remain constant up to intensities at least another 100 times higher, and PII emerges as an obvious b-wave. After blocking the small positive and negative (STR) components with 2.5-8.5  $\mu$ Mols of intravitreal NMDLA, the b-wave was evident at intensities 10 times lower than normal, its amplitude was greater than normal, and it was proportional to intensity up to about 1/5 of its maximum amplitude of 1500 μV. This suggests that normally there is significant mutual cancellation of STR and PII over a wide range of intensities, so that amplitudes of STR and PII are greater than indicated by the positive and negative peaks in the ERG and the underlying STR saturates less abruptly. Intraretinal recordings of field potentials showed that only in peripheral retina were onset latencies fast enough to match the ERG components evoked by weak stimuli. Supported by NIH grant EY06671.

Rod-cone dominance exhibits a circadian rhythm in the Japanese

Rod-cone dominance exhibits a circadian rhythm in the Japanese quail retina. In constant darkness (DD), retinal sensitivity (ERG b-wave) is high at night and and low during the day; and spectral sensitivity shifts from rod dominance at night to cone dominance during the day (1). Melatonin and dopamine appear to interact to regulate circadian physiology in the vertebrate retina (2). We hypothesize that dopamine and melatonin mediate the circadian rod-cone shift in the quail retina.

rod-cone shift in the quail retina.

Dopamine antagonists (haloperidol, sulpiride) injected in the vitreous during the day shift the retina to the sensitive, rod-dominated nighttime state. A dopamine agonist (quinpirole) injected at night has the opposite effect. Destruction of dopaminergic cells with 6-OH dopamine leaves the retina in the rod dominated state regardless of time of day. Dopamine, thus, appears to mediate cone dominance. Retinal dopamine synthesis is high during the day and low at night in DD as indicated by DOPA levels following inhibition of DOPA decarboxylase activity in situ. Retinal melatonin synthesis is low during the day, and high at night in DD as measured by tryptophan hydroxylase activity in situ and melatonin levels (3).

The counterphase circadian rhythms of dopamine and melatonin suggest that dopamine mediates cone dominance during the day, and melatonin mediates rod dominance at night.

TRANSGENIC MODIFICATION OF THE MOUSE RETINA. M.A.McCall\*, R.G. Gregg., and L.R. Stanford. The Waisman Center and the Department of Comparative Biosciences. University of Wisconsin, Madison, WI 53706

Genetic ablation has been used to selectively eliminate individual cell populations in a number of somatic organs and tissues. In this study, we have attempted to determine if this technique can be used to eliminate a specific neuronal population, and might thereby prove to be a useful tool in defining the role of these populati in the function of a neural circuit or system. A fusion gene, consisting of the human rhodopsin promoter linked to an attenuated diphtheria toxin gene, was injected into the male pronucleus of fertilized mouse ova, which were then transplanted into pseudopregnant recipients. The animals born from this procedure were then tested, using Southern Blot Analysis, to identify those that had incorporated the fusion gene into their genome. These mice were then used to establish a colony of transgenic animals. Because the transcription of the diphtheria toxin gene is controlled by the rhodopsin promotor, the rod photoreceptors should be selectively eliminated in those animals that inherit the transgene. To determine the functional consequences of the fusion gene, we recorded the electroretinogram from 4 transgenic animals and found that electrical activity could not be evoked from the retinae of any of the affected transgenic animals. Subsequent light microscopic examination of the retinae of these animals showed that both the photoreceptor outer segments and the outer nuclear layer were absent; the remaining retinal layers appeared to be unaffected. These results indicate that the incorporation of a fusion gene can cause the selective elimination of a retinal cell class, and that the effects of this manipulation can be demonstrated both morphologically and physiologically. These results also suggest that this strategy might be used to eliminate other selected elements from neural circuits or systems, possibly providing a very direct method for assessing the contribution of specific neuronal populations to neural processing. Supported by NIH Grant EY 04977 and NSF Grant BNS-9015226.

ENDOGENOUS ADENOSINE DILATES RETINAL ARTERIOLES IN THE NEWBORN PIGLET. J.M. Gidday\*, T.M. Lanius, A.R. Shah, Department of Neurosurgery, Washington

University School of Medicine, St. Louis, MO 63110.

In an effort to test the hypothesis that the purine metabolite adenosine is a metabolic regulator of retinal blood flow (RBF), the present study was undertaken to determine the effect of increased endogenous adenosine concentrations on retinal arteriolar tone. Newborn pigs (<4 d old) were anesthetized (isoflurane) and paralyzed (pancuronium). The iris was dilated (1% tropicamide), and the cornea and lens were excised and replaced with a glass coverslip. The diameter of a retinal arteriole (55-95  $\mu$ m) was measured on-line at 310x using an image processor. A 20  $\mu$ l aliquot of 10  $\mu$ M iodotubercidin, an inhibitor of adenosine kinase, or 5  $\mu$ M NBTI, adenosine transport inhibitor, directly microsuffused onto the abluminal surface of the vessel via a 30 ga intravitreal catheter, increased arteriolar diameter by 24±3% and 30±4%, respectively. Administration of 50  $\mu$ M DPMX, an A2-selective adenosine receptor antagonist, concomitant with NBTI completely blocked the dilatory Thus, resistance vessels of the retina response. possess A2 adenosine receptors that, when activated by increases in endogenous adenosine concentrations, induce retinal arteriolar vasodilation. These findings are consistent with the participation of adenosine in the metabolic regulation of RBF in the newborn.

A Model of a Thalamic Cell Incorporating Voltage-Clamp Data on Ionic Conductances. D.K. Smetters\* Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Thalamic neurons contain an unusually large variety of voltage-and time-dependent conductances, causing them to respond differently to the same pattern of input depending on the past activity of the cell. To understand how thalamic cells respond to sensory input, it is necessary to understand how these currents contribute to their response to current injection, synaptic stimulation, and modulatory neurotransmitters. The complex interaction between these currents confounds a priori understanding of their roles from examination of current- and voltage-clamp recordings. We have therefore constructed a detailed computational model of a thalamic relay cell, based on voltage clamp data obtained from thalamic slices and isolated relay cells. We find that our model reproduces most of the current-clamp behavior of thalamic cells, including tonic and burst modes, rebound low-threshold spikes after hyperpolarization, oscillatory behavior, and extremely long delays to fast spike firing with just-threshold depolarization.

Analysis of the model provides insight into the role of various voltage-dependent conductances in the response of these cells. We are particularly interested in the role of potassium currents in regulation of firing mode, as some of these currents are modulated by a number of neurotransmitters (McCormick and Prince, 1987,1988; McCormick and Williamson 1991), and they have been the subject of several recent voltage-clamp studies (Huguenard et. al. 1991; McCormick 1991). Simulation results lead us to predict that a fast, calcium-activated potassium current similar to Ic (Adams et. al. 1986) can explain the amplitude and time course of the fast after-hyperpolarization, aprediction supported by patch clamp data from cultured rat thalamic cells (Esguerra and Smetters, unpublished). Simulations also suggest that the kinetics of the low-threshold cal

NITRIC OXIDE CONTROLS OSCILLATORY ACTIVITY IN THE THALAMUS.

H.-C. Pape\*. Abt. Neurophysiol., Ruhr-Univ., D-W-4630 Bochum, Germany.

The enzymes for the synthesis of nitric oxide (NO), a possible regulatory molecule in the central nervous system, are specifically co-localized with mesopontine cholinergic neurons. Since these neurons control thalamocortical activity during various states of the sleep/waking cycle, we evaluated the possible modulatory role of NO in the thalamus. Local application to relay neurons of the guinea pig and cat dorsal lateral and medial geniculate nuclei maintained in vitro, of the NO-donating drug 3-morpholinosydnonimine (SIN1; 0.5-2 mM) resulted in a decrease (30 %) in resting input resistance (49 MΩ) associated with a 1-3 mV depolarization from resting potential (-63 mV) in 89 % of the neurons (n=56). Three sets of experiments indicated that this response resulted from the generation of NO: i) The NO-donor nitroprusside (NP; 0.2-5 mM) elicited a very similar response, and the effects of SIN1 and NP were mutually occlusive. ii) The SIN1 derivative molsidomin (10 mM), which requires cellular enzymes generally not present in situ to generate NO, was ineffective. iii) Prior extracellular application of the NO-scavenger hemoglobin (100  $\mu$ M) prevented the action of SIN1. Furthermore, 8-bromo-cyclicGMP (1 mM, local) imitated the action of SIN1, and a near-maximal effect of 8-bromo-cyclicGMP occluded responses to SIN1, suggesting an involvement of the cyclicGMP system. Voltage-clamp experiments demonstrated that the response to NO resulted from a positive

shift in activation by +5 mV of the hyperpolarization-activated cation current, I h The influence of NO dampened rhythmic-oscillatory burst-activity of thalamocortical neurones, but it did not affect the generation of tonic sequences of fast spikes. These findings may indicate a diffusible intercellular signalling mechanism different from that of classical neurotransmitters for controlling the functional state of the thalamocortical network, regardless of any direct connection through synapses.

Relay and Burst Response Modes in the LGN Vary with the Alertness of the Cat. Stephen Lehmkuhle\*, John A. Baro, and William Guidot School of Optometry, University of Missouri-St. Louis, St. Louis, MO 63121 and †Dept. of Neurobiology, SUNY, Stony Brook, NY 11794 Relay cells of cat LGN can respond to visual stimuli in one of two

modes: relay and burst. The burst mode is due to the activation of Low Threshold (LT) Ca<sup>++</sup> spikes only when the cell is hyperpolarized.

Because membrane potential fluctuates with behavioral state, we wished to determine the extent to which response mode would vary with level of alertness. Visual responses were recorded extracellularly in an awake behaving cat, and separated into tonic and LT burst components. LT bursts were recognized as bursts of action potentials with interspike intervals ≤ 4 msec that are preceded by a silent period of ≥ 100 msec

The behavioral state of the cat was classified as alert or drowsy by monitoring the EEG activity of striate cortex. The animal was classified as drowsy when the ratio of the power of the synchronized (4-9Hz) versus desynchronized (10-20 Hz) EEG activity was greater than 5 and the RMS value exceeded a preset value. Spike arrival times were calculated during both pre- and post-stimulus periods, and separated into LT burst and tonic discharge categories.

We found that LGN cells respond in both relay and burst mode during alert and drowsy states. However, LT burst activity was more prevalent during the drowsy state than the alert state. During the drowsy state, LT burst activity increased and tonic activity decreased. During the alert state, LT burst activity decreased and tonic activity increased. This trend occurred for both baseline and stimulus driven activity. One implication is that relay and burst mode may have further significance for sensory processing, perhaps alerting visual cortex to a change in behavioral state. (Supported by NSF BNS-8819706)

MODULATION OF RETINO-GENICULATE TRANSMISSION THROUGH ACTIVATION OF B-ADRENOCEPTORS IN THE CAT. K. Funke, H.-C. Pape and U.T. Eysel. Dept. of Neurophysiology, Faculty of Medicine, Ruhr-University Bochum, W-4630 Bochum, Germany. (SPON: European Neuroscience Association)

The ascending noradrenergic pathway is one candidate for state-dependent modulation of retino-geniculate transmission. Quite non-uniform results were obtained with micro-iontophoresis of noradrenaline in the lateral geniculate nucleus and stimulation of the coeruleo-geniculate pathway in rat and cat. In order to investigate the effect of selective stimulation of adrenoceptors, we micro-iontophoretically applied the B-adrenoceptor agonist isoprenaline (ISO) during simultaneous recordings of lateral geniculate relay cells in the anaesthetized (N2O/O2, 70/30%; halothane, 0.3%; or pentobarbitone 2-4 mg/kg·h), paralysed (alcuronium chloride 0.15 mg/kg·h) cat. ISO effects on spontaneous discharge patterns and visual processing were studied and related to the global state of the animal, as derived from the pattern of electroencephalographic (EEG) activity. We found the following ISO effects: i) the occurrence of rhythmic or non-rhythmic burst discharges during highly synchronized,  $\delta$ -like EEG was significantly suppressed, whereas tonic single spike activity was significantly less affected, irrespective of the pattern of EEG; ii) receptive field center and center-surround responses were not significantly altered when studied during less synchronized, lower amplitude/higher frequency EEG, but we found a significant facilitation of the sustained spot response, when this response component was attenuated during synchronized EEG; iii) late phases (100-400 ms) of binocular and long-range lateral inhibition were significantly reduced, and this effect was similar to the strong reduction of the late inhibitory phase when the EEG changed from a highly synchronized to a less synchronized pattern. Long-lasting inhibitory responses elicit burst discharges during highly synchronized states of the EEG and may also impair retino-geniculate transmission. Our results provide direct in vivo evidence that Badrenoceptor activation attenuates long-lasting inhibitory mechanisms to enable the faithful processing and transmission of visual signals.

ULTRASTRUCTURAL STUDIES OF AFFERENTS TO THE LATERAL

GENICULATE NUCLEUS. S. Felg. D. Van Lieshout. J.Harting\*. Anatomy Dept., Univ. of Wis. Med. Sch., Madison, WI 53706. We have used EM-autoradiagraphy to analyze the morphology and synaptic relationships of six afferents to the lateral geniculate of Galago.

Retinal terminals contain round vesicles, pale mitochondria, and make asymmetrical synapses (RLP's). Terminals arising from cells in area 17, the superior colliculus (SC) and the parabigeminal nucleus (PG) contain round vesicles, dark mitochondria and make asymmetrical synapses (RSD's). The RSD's associated with these three projections exhibit no obvious The HSD's associated with these three projections exhibit no obvious morphological differences. Terminals arising from the pretectum (PT) and thalamic reticular nucleus (TRN) contain pleomorphic vesicles, dark mitochondria and make symmetrical synapses (F1's).

RLP's within the parvi- and magnocellular layers target juxtasomatic regions of geniculate neurons. They share these regions with F profiles; some of the F1 variety arise from the PT and TRN.

some of the F1 variety anse from the F1 and TRN.
The juxtasomatic regions of neurons within the small-celled koniocellular layers are relatively free of retinal terminals. Instead these regions are almost exclusively innervated by F profiles; some of the F1 terminals originate from the the PT and TRN. RLP's within the koniocellular layers innervate intermediate and small sized dendrites, where they occasionally lie adjacent to terminals arising from the SC and the PG.

Labeled corticogeniculate terminals target intermediate to small sized dendrites in all layers and have never been observed adjacent to RLP's. Labeled PT terminals are presynaptic to F2 profiles, and therefore account for at least some of the F1 to F2 synapses. In contrast, labeled TRN profiles have never been observed presynaptic to F2 profiles. Supported by E401277.

THE HISTAMINERGIC INNERVATION OF THE LATERAL GENICULATE COMPLEX. D.J. Uhlrich, K.A. Manning & T.P. Pienkowski. Department of Anatomy, University of Wisconsin, Madison, WI 53706.

Histamine (HA) receptors are present in the lateral geniculate nucleus (LGN), and HA appears to play a role in determining the physiological response characteristics of LGN relay neurons in vitro. However, the anatomy of the histaminergic innervation of the LGN is unclear. In tissue from 3 cats fixed with 1% paraformaldehyde and 4% carbodiimide and processed for immunohistochemistry, we examined the histaminergic projection to the LGN using an antibody to HA.

HA-reactive neurons, now collectively referred to as the tuberomammillary nucleus, were restricted to the hypothalamus. All laminae of the LGN and adjacent nuclei contained fibers with well-labeled *en passant* swellings of varied size  $(0.5\text{-}2.0~\mu\text{m})$  and little branching. Label was dense in regions involved in the retinal W cell pathway, in particular, the ventral lateral geniculate nucleus (vLGN). Parvocellular C laminae of the LGN, the perigeniculate nucleus, and portions of the medial interlaminar nucleus showed intermediate amounts of label. The geniculate A laminae had only sparse labeling. Average varicosity size was greatest in the vLGN. Electron microscopic examination in lamina A revealed HA profiles of unusual morphology. Swellings contained round or elliptical vesicles, many extremely large (diam 20-200 nm, avg 70 nm). Thus far, intriguing appositions are common, but no clear synapses are seen, despite serial reconstruction. HA profiles are not associated with any particular geniculate profile or element. These results support the idea that HA works nonsynaptically as a neuromodulator in the LGN, affecting relay cell responses as a function of behavioral state.

IN THE DORSAL LATERAL GENICULATE BODY OF RATS TWO TYPES OF RECEPTORS SEEM TO MEDIATE THE ACTION OF CHOLECYSTOKININ. H. Davidowa, D. Albrecht, H.-J. Gabriel and U. Zippel. Inst. of Physiology, Charité, Humboldt-Univ., Berlin O - 1040, FRG. (SPON: European Neuroscience Association).

Various transmitters gate the transmission of signals within thalamic relay nuclei. The possible role of CCK has been studied in rats possible role of CCK has been studied in rats anesthetized with urethane. CCK-8S or Boc CCK 4 (0.05 to 1 mM, pH 7.8) as well as CCK A - or B - antagonists were applied iontophoretically. Background and light evoked activity in about one third out of 190 neurons were facilitated, in one sixed inhibited by CCK-8S. The amount of activity change depended on the current (20 to 80 nA). Boc CCK 4 had similar effects, but not so strong as CCK-8S. The effects could partly be blocked by as CCK-8S. The effects could partly be blocked by A- antagonists, partly by B- antagonists. There was no relation of the direction of change to the blocking action of A- or B- antagonists. Cells influenced in their activity by CCK were not uniformly distributed within the dLGB.

The results indicate that modulations of geniculate firing caused by CCK are receptor mediated, and that in the dLGB CCK A- as well as B- receptors seem to be present. Supported by DFG grant Da 275/1-1.

MECHANISMS OF FREQUENCY DEPENDENT FACILITATION OF CORTICOTHALAMIC EPSPs M. von Krosigk\* and D.A. McCormick. Yale Univ. Med. Sch. New Haven, CT

Repetitive activation of corticothalamic inputs to thalamic relay cells is known to result in marked frequency dependent potentiation. Here, we investigate the cellular basis of this potentiation and contrast it with the properties of retinal inputs using an in vitro slice preparation of the guineapig dorsal lateral geniculate nucleus (LGNd).

Delivery of a train of electrical stimuli to corticothalamic inputs to LGNd relay cells resulted in a sequence of EPSPs exhibiting marked, frequency-dependent facilitation, while delivery of similar stimulus trains to optic tract did not. Two mechanisms were found: an increase in neurotransmitter release and GABAergic disinhibition. The frequencydependent facilitation of corticothalamic inputs persisted after the block of GABAergic inhibitory synaptic transmission and was associated with an increase in both NMDA and non-NMDA receptor mediated components, suggesting that this facilitation is mediated by, at least in part, an increase in neurotransmitter release. Examination of GABAA and GABABmediated IPSPs revealed that these synaptic potentials show depression during direct and repetitive activation, suggesting that an additional mechanism in the facilitation of corticothalamic inputs may be GABAergic dis-inhibition.

These results indicate that frequency dependent facilitation of corticothalamic inputs occurs both through an increase in transmitter release as well as through disinhibition.

RESPONSES OF CELLS IN RABBIT LATERAL GENICULATE NUCLEUS TO DRIFTING SINUSOIDAL GRATINGS. S. Molotchnikoff\*an V. Durand. Dépt de biologie, Université de Montréal, \*and C.P. 6128, succ. A, Montréal (Québec) Canada H3C 3J7

Last year we reported an analysis of cortical cell responses to sinusoidal gratings in rabbits. Similarly to cats, rabbit's simple cells respond with a modulatory pattern while complex neuron discharges in a non-modularecorded from the lateral geniculate nucleus with the aim to compare responses of the latter with responses of cortical cells to gratings. Single cell activity was recorded in anesthetized and paralyzed rabbits. Receptive fields were identified as concentric (ON-OFF) and uniform with the help of appropriate stimuli. Ninety-five per cent (N = 37) of geniculate neurons respond to gratings cent (N  $\approx$  37) or geniculate neurons respond to gratings ( $\approx$ 60-65% in cortex). As in the cortex the majority are low-pass (IP) in spatial domain and band-pass (BP) in temporal domain. All proportions between IP, BP, and High Pass cells are equivalent at both levels. The most striking results is the absence of non-modulated discharges to gratings of the geniculate units; indeed all cell responded by a modulation of their evoked firing. Thus in rabbits, the non-modulatory pattern which typically characterizes complex cells, is established at the level of the striate cortex.

THE TEMPORAL PROPERTIES OF RECEPTIVE FIELDS IN THE LGN: A COMPARISON OF KITTENS AND CATS. D.Cat. G.C.DeAngelis. R.D. Freeman and T.E.Cohn\*. Group in Vision Science, School of Optometry, University of California, Berkeley, CA 94720.

Receptive field properties of the neurons in the lateral geniculate nucleus (LGN)

change during normal postnatal development (Mitchell and Timney, 1984). Although changes in spatial properties are well documented, relatively little is known about temporal aspects of receptive field structure during normal development.

We have studied temporal aspects of receptive field structure of LGN neurons in anesthetized and paralyzed adult cats and 4 week old kittens. Orientation, spatial frequency and temporal frequency tuning curves are obtained using drifting sinusoidal gratings. Cells are classified as X or Y based on a linearity test with counterphase gratings. Cells are classified as X or Y based on a linearity test with counterphase gratings. Subsequently, a version of the reverse correlation technique (Jones and Palmer, 1987) is used to obtain a spatiotemporal receptive field profile for each neuron.

Temporal frequency tuning curves from 4-week old kittens show pronounced attenuation at high frequencies, as compared to those from adults. The mean optimal

temporal frequency increases from approximately 3 Hz for kittens to approximately 7 Hz for cats. The mean high cut-off frequency increases from approximately 8 Hz for kittens to approximately 16 Hz for cats. Using the reverse correlation technique, we have analyzed various parameters of the temporal response. Response latency, defined as the reverse correlation delay which produces a maximal response profile, is, on average, 35 ms msec for cells from adults and 60 ms for cells from 4-week old kittens. While most adult LGN neurons show a clearly defined biphasic temporal response, neurons in the LGN of kittens often show a monophasic temporal response under the same conditions of stimulation. No peak latency difference is found between on-center neurons and off-center neurons during development.

Overall, these results demonstrate that the temporal characteristics of receptive fields in the LGN continue to develop considerably beyond 4 weeks of age. Similar findings have been reported for neurons in the striate cortex (DeAngelis et al, 1991, Invest. Ophthalmol. Visual Sci. Suppl. 32:1253). (EY01175)

STATE-DEPENDENT MODULATION OF THE TEMPORAL TRANSFER PROPERTIES OF CAT LATERAL GENICULATE NEURONS.

 P. Mukherjee and E. Kaplan. Rockefeller University, New York, NY 10021
 The activity of the lateral geniculate nucleus (LGN) is affected by changes in arousal during the sleep-wake cycle. Here we report state-dependent effects on the dynamics of cat LGN relay cells associated with the occurrence of low-threshold bursts, which are known to be generated by activation of the T-type Ca<sup>2+</sup> channel. Spikes and retinal S-potentials were simultaneously recorded from single LGN

neurons of anaesthetized and paralyzed cats in response to drifting sinusoidal gratings varying in temporal frequency (TF). Transfer functions were obtained by computing the amplitude ratio and phase difference of the fundamental Fourier components of the LGN response and the retinal response at each TF. Bursts were identified from spike trains as clusters of action potentials with interspike intervals

≤ 4 ms. The electroencephalogram (EEG) was recorded over area 17.
In states of low arousal, characterized by slow-wave EEG activity, LGN relay cells had markedly bandpass temporal transfer functions, with peak transmission between 2-8 Hz. The LGN response phase led that of the retina at low TF, a difference that declined with increasing TF until the LGN response lagged the retinal response at TF > 6 Hz. Neurons in this state frequently fired bursts. However, under higher arousal levels (marked by low-amplitude high-frequency EEG), the same relay cells displayed a flat temporal transfer function with little phase difference between the LGN and retinal responses. In this state, relay cells showed little or no bursting activity. These results demonstrate that the LGN is a temporal filter of retinal information whose dynamics can be modulated by changes in arousal. A neural model of LGN relay cells, incorporating quantitative T-channel kinetics, suggests that this temporal tuning can be explained by a hyperpolarization of these neurons. This alteration in membrane potential may be regulated by brain-stem centers projecting to the LGN.

Retinal Y Axons Contact Interneurons in the Lateral Geniculate Nucleus of the Cat. M. E. Bickford\*, S. C. Van Horn, and S. M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

It is well established that GABAergic interneurons in the cat's lateral

geniculate nucleus (LGN) participate in the modulation of retinogeniculate transmission along the X pathway. However, there has been some controversy concerning the involvement of LGN interneurons in the Y pathway. We investigated this with the electron microscope by anatomically examining the postsynaptic targets of retinogeniculate Y axons intracellularly labeled with HRP. Tissue containing parts of two labeled axons (one innervating lamina A and the other, lamina A1) was serially sectioned, and selected grids were stained for the presence of GABA, using postembedding immunocytochemical techniques. We obtained two lines of evidence that Y retinal axons contact interneurons. First, 31 of the 95 retinal synaptic contacts examined thus far (32%) were made onto profiles that contained vesicles. Reconstructions identified these profiles as small swellings, some of which were identified as GABA-positive. Since the dendritic appendages of interneurons are the only known source of GABAergic, vesicle-containing profiles that receive synaptic input, we interpret this as evidence that some of the output of Y retinal axons is onto the appendages of interneurons. Second, reconstructions revealed that some dendrites that receive Y retinal input give rise to swellings that contain vesicles. We interpret this as evidence that Y retinal axons can also contact vesicles. We interpret this as evidence that I retinal axons can also contact the dendritic shafts of interneurons. These results suggest that although the majority of the synaptic contacts of Y retinal axons are made directly onto geniculocortical relay cells, a portion of their synaptic output is directed to interneurons, providing a possible anatomical substrate for feedforward inhibition in the Y pathway. (Supported by USPHS grant EY03604.)

SPATIAL FILTERING PROPERTIES OF LGN X-CELLS IN CATS. H. Cheng, Y.M.Chino\*, E.L. Smith III, K. Yoshida, and J. Hamamoto, College of Optometry, University of Houston, Houston, TX 77204

Whether spatial filtering properties of X-LGN neurons differ from their retinal inputs is still a matter of debate. We re-examined this issue by directly comparing LGN responses and their simultaneously recorded retinal input, S-potentials (SP). We found: 1) the bandwidths of spatial frequency response functions were narrower in many LGN cells compared to their SPs. 2) In all but two cells, the transfer ratio (defined as the firing rate of LGN cells divided by that of its SPs) was reduced at low spatial frequencies compared to that for the cell's peak or for high spatial frequencies. 3) Transfer ratios in contrast response functions were lowest with low spatial frequency stimuli in the majority of neurons. 4) Differences in contrast thresholds and contrast gains between LGN responses and SPs were greater for the lower spatial frequency range.

Comparisons of receptive field center-surround mechanisms indicated that both the center (Rc) and surround (Rs) sizes are virtually the same for both LGN cells and their retinal inputs. However, the center sensitivity (Kc) was much lower in LGN neurons relative to that of their SPs, whereas the surround sensitivity (Ks) was similar in LGN and SP responses. Our data support the idea that the decreased responses of LGN neurons for low spatial frequency gratings is primarily due to lower sensitivity in the receptive field center mechanism of LGN neurons relative to their retinal inputs rather than increased surround strengths.

Lagged cell responses are more variable in latency than are nonlagged responses in cat LGN cells. S.M. Sherman\*, W. Guido, and S.-M. Lu. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

Lagged responses have been identified for LGN cells of cats, and these differ from more conventional nonlagged responses on a number of criteria. Most distinctions have been made on the basis of histograms from averaged responses to flashing spots. Among other differences, lagged responses as gleaned from these histograms are slower, less sharply defined, and generally poorer. It is not clear whether these slower and poorer lagged responses are present in individual stimulus/response cycles, or whether they are partly an artifact of the averaging process. To answer this question, we recorded lagged and nonlagged responses to flashed spots from a sample of LGN cells in cats and analyzed these on a trial-by-trial basis. We identified the beginning of the response epoch in each trial as the first interspike interval ≤10 msec (or, for some cells, ≤20 msec). As expected, we found that the lagged responses displayed a significantly longer latency for the initial response than did nonlagged ones; however, the variation in this latency among trials was much greater for the lagged responses. Thus any averaged histogram constructed from these responses would artificially smear lagged responses more than nonlagged ones. To control for this, we removed variability in latency among individual trials of both response types by shifting the timing of all responses to each trial by the temporal difference between the first response of each trial by the temporal difference between the first response of each trial toy the temporal difference between the first response of each trial do the temporal difference between the first response of each trial by the temporal difference between the first response of each trial by the temporal difference between the first response of each trial by the temporal difference between honlagged responses, b

PROGRESSIVE CHANGE IN CALCIUM BINDING PROTEINS IN MONKEY LATERAL GENICULATE NUCLEUS AFTER MONOCULAR ENUCLEATION. Neurosci, Prog. <u>Gutierrez and C.G. Cusick\*</u>. Neurosci. Prog. and Dept., Tulane Univ. Med. Sch., New Orleans, LA 70112.

In the lateral geniculate nucleus of monkeys, neurons in magno- and parvicellular layers contain strong parvalbumin immunoreactivity (PV-ir) and little calbindin magno- and parvicellular layers contain strong parvalbumin immunoreactivity (PV-ir) and little calbindin immunoreactivity (CB-ir). To examine the effects of sensory deafferentation on the distribution of these proteins, PV-ir and CB-ir were localized histochemically in enucleation. In each case, PV-ir and CB-ir in fibers decreased within the deafferented parvi- and magnocellular layers. Whereas the numbers of PV-reactive cells did not differ significantly in the deafferented and intact layers, CB positive cells increased in the deafferented layers. At 1-3 months after injury, CB-ir in deafferented cells was very light. At 4-7 months, numbers of CB positive cells increased further (up to 14-fold that of the intact layers and over half the PV cells in the deafferented layers). and over hair the PV cells in the deafferented layers). CB-ir in cells also increased in density, and at 7 months neuropil staining was strong in the deafferented layers. The results suggest that some neurons that normally express only PV co-localize CB in response to deafferentation, and "new" expression of calbindin may increase over several months. Supported by NEI-EY08906.

SPONTANEOUS AND EVOKED GABAERGIC SYNAPTIC CURRENTS IN THALAMO-CORTICAL NEURONES OF THE RAT LATERAL GENICULATE NUCLEUS. N. LERESCHE\* and A. GUYON, Dept. de Neurosciences, Univ. Paris VI, 9 quai St Bernard, Paris 75005, France.

Thalamo-cortical neurones were identified on morphological criteria in slices of the rat dorsal lateral geniculate nucleus and whole cell currents were recorded using the patch clamp technique. Postsynaptic currents occurring spontaneously, or elicited by extracellular stimulation in the vicinity of the recorded neurone, were analyzed. Spontaneous postsynaptic currents were observed in every recorded neurone. At a holding potential of -60 mV, and with a high internal CI', the currents were inward and had amplitudes ranging from less than 10 pA to 425 pA. All the spontaneous currents were blocked by 10  $\mu$ M bicuculline indicating that they were due to the activation of postsynaptic GABAA receptors. The 10-90% rise time of these spontaneous GABAergic currents was 0.86±0.19 ms. Their time course of decay could be fitted to an exponential function with one or two time constants of, respectively,  $18.19\pm3.02$  ms (mean $\pm$ s.d.) or  $4.47\pm0.77$  and  $33.27\pm3.74$  ms. Both the rise and decay time course were independent of the current amplitude. This activity was frequently organized in bursts lasting 1.8 to 4.3 sec.

Stimulus-evoked postsynaptic currents were also recorded. The stimulus-evoked GABAergic currents, recorded under experimental conditions similar to the spontaneous currents, had a 10-90% rise time of 1.93±0.54 ms. Their time course of decay could be fitted to an exponential function with one or two time constants of, respectively, 24.42 ms or 10.26±2.46 and 49.30±10.98 ms. The difference in the time course between spontaneous and evoked GABAergic currents, recorded in the same neurone, suggests that these responses may arise from synapses having different locations

GLYCINERGIC MODULATION OF THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR PLAYS A CRITICAL ROLE IN RETINOGENICULATE TRANSMISSION TO NON-LAGGED X AND Y CELLS. H.E. Jones\*, R.H. Levy, A.M. Sillito and P.C. Murphy. Dept. of Visual Science, Inst. of Ophthalmology, Judd St., London WC1H 9QS, UK.

There is now strong evidence to support the view that NMDA and non-NMDA receptors are involved in the transfer of the visual input from both X and Y retinal ganglion cell afferents to lagged and non-lagged relay cells in the feline dorsal lateral geniculate nucleus (dLGN). Blockade of NMDA receptors effectively eliminates the visual response of dLGN cells. In vitro work shows that activation of the NMDA receptor is subject to allosteric facilitation by glycine acting at a strychnine insensitive site within the NMDA receptor complex. We have examined the extent to which the visual response in the dLGN is influenced by modulation from the strychnine insensitive glycine site in vivo. We examined the effect of iontophoretic application of 2 non-competitive antagonists for the glycine site, 7-chlorokynurenate (7-CK) and 1-hydroxy-3-amino-2-pyrrolidone (HA-966), on the responses of non-lagged X and Y cells recorded in the dLGN of anaesthetized, paralysed cats. Seven barrelled glass micropipettes were used for recording and iontophoretic application of drugs. The visual stimulus comprised a spot of light flashed within the receptive field centre. Iontophoretic application of either 7-CK or HA-966 greatly reduced and in some cases blocked visual responses at ejection current levels of the antagonists compatible with a selective action on the responses to NMDA with respect to agonists acting at non-NMDA receptors. These data provide further support for the view that NMDA receptors are involved in the transfer of retinal input to non-lagged dLGN cells, and demonstrate that factors influencing the glycinergic modulation of the NMDA receptor are capable of exerting a profound influence on sensory processing at the thalamic relay in the visual system

## 64.19

CALCYPHOCINE-IMMUNOREACTIVITY IN THE DORSAL LATERAL GENICULATE NUCLEUS OF THE CAT. F. Vandesande, H. Demeulemeester, W. Van Duffel, G.A. Orban, J.J. Vanderhaeghen\*, and C.W. Heizmann. Lab. Neuroendocrinol., Lab. Neuroendocrinol., Lab. Neuropathol. and Neuropep. Res., U.L.B., Brussels, Belgium, Dep. Pediatrics, Univ. Zürich, Switzerland.

In this study, we investigated wheter the GABAergic neurons in the d. G.M. of the cat can be subdivided by their content of the calcium.

the dLGN of the cat can be subdivided by their content of the calcium binding proteins: calcyphocine (CF), calbindin (Cal) and parvalbumin (PV). Here we report only the results of the A laminae.

(PV). Here we report only the results of the A laminae. In the A laminae about 72% of the neuronal population was CF-IR. Of the CF-IR cells, about 52% contained Cal and 12% contained PV, while about 70% of the Cal and 40% of the PV-IR cells were CF-IR. Areal measurements of the CF-IR neurons in the A laminae revealed a mean soma size of 221  $\mu$ m<sup>2</sup>, with soma sizes ranging from 50 to 700  $\mu$ m<sup>2</sup>. Studies with WGA-Biotin retrogradely transported from the size of the siz from the visual cortex showed that in the A laminae about 58% of the CF-IR cells and 32% of the Cal-IR cells were retrogradely labeled. Retrogradely labeled PV-IR cells were absent.

These and previous results (Demeulemeester H. et al., Exp. Brain Res., 83: 513, 1991) indicate that at least four different IR geniculate cell populations can be identified: (1) cells (+) for PV and Cal; (2) cells (+) for PV and (-) for Cal; (3) cells (-) for PV and (+) for Cal; (4) cells (-) for PV and Cal. The results with WGA-Biotin indicate that populations (1) and (2) are interneurons, and (3) and (4) are relay cells. Each of these populations can again be subdivided by the presence or absence of CF.

POTENTIATION AND DEPRESSION OF THE STRENGTH OF THE TRANSFER OF THE RETINAL INPUT IN THE DORSAL LATERAL GENICULATE NUCLEUS (dLGN), A.M. Sillito, and H.E. Jones, Dept. of Visual Science, Inst. of Ophthalmology, Judd St., London WC1H 9QS, UK.

There is now strong evidence to support the view that both NMDA receptors and non-NMDA receptors are involved in the transfer of information at retinogeniculate synapses. Taking note of the evidence indicating that synapses utilising excitatory amino acid receptors can exhibit long term potentiation (LTP) and long term depression (LTD), we have explored the possibility that it might be possible to modify the strength of the transfer of information at the retinogeniculate synapse. We have recorded from single cells in the A laminae of the dLGN of anaesthetized, paralysed, adult cats with seven barrelled glass micropipettes. Receptive fields were mapped and then stimulated with a small flashing spot located within the receptive field centre. The spot was generated either as an increase in illumination above background (on-centre cells) or a decrease below (off-centre cells). We then explored the effect of pairing the stimulus with either iontophoretic application of NMDA or GABA. Responses were tested systematically at intervals starting five minutes after termination of the pairing procedure. In some, but not all the cells so far studied, the drug pairing resulted in respectively, an enhancement (NMDA) or depression (GABA) of visual responsiveness with respect to control response magnitudes. We also observed response enhancements after visual responses were paired with iontophoretic application of quisqualate which acts at AMPA and metabotropic receptors. The sustained component of the visual response immediately after the onset transient appeared to be particularly susceptible to these procedures. The data suggest the capacity for a long term change in the gain of the transfer of visual information at the retinogeniculate synapse that is not simply linked to the fast dynamics of visual processing or state dependent changes imposed by the extrinsic modulatory systems

EFFECTS OF ACETYLCHOLINE ON THE VISUAL RESPONSE OF LAGGED CELLS IN THE LATERAL GENICULATE NUCLEUS OF THE CAT. E. Hartveit\* and P. Heggelund. Dept. of Neurophysiol., Univ.

of Oslo, Norway.

Relay cells in the cat LGN can be divided into lagged and nonlagged cells based on their visual response properties. Lagged cells are initially suppressed by a flashing light spot and they have longer latency to the visual response than nonlagged cells. There is evidence that the initial suppression is mediated by intrageniculate GABAergic inhibition (Heggelund & Hartveit, J. Neurophysiol., 1990, 63, 1347). The retino-geniculate transmission can be strongly influenced by input from the peribrachial region (PBR) of the brain stem. The cholinergic afferents seem to be particularly important. The response of lagged cells is markedly influenced by electrical PBR stimulation, but the initial suppression is maintained. We have extended these previous findings by examining the direct effects of acetylcholine (ACh) on the visual response of lagged cells.

The response of single cells to a flashing light spot was recorded before, during and after iontophoretic application of ACh. The spot approximately filled the receptive field centre. For comparison some of the cells were also tested by application of the GABA-A antagonist bicucullinemethchloride (BMC).

During the application of ACh there was an increase of both the sponta-

bicucullinemethchloride (BMC).

During the application of ACh there was an increase of both the spontaneous activity and the visually driven response. The latency to onset and half-rise of the response could be reduced. However, the visually evoked initial suppression was resistant to ACh. In contrast, during BMC application the initial suppression was abolished and a short latency initial transient response component occurred.

We conclude that the effects of introphoretic application of ACh on the visual response of lagged cells were markedly similar to the effects of electrical PBR stimulation. The lagged/nonlagged distinction as well as the characteristic response properties of the lagged cells were maintained also during the direct ACh application.

# SUBCORTICAL VISUAL PATHWAYS: RETINA AND COLLICULUS

PARALLEL PROCESSING IN THE RETINOFUGAL PROJECTION OF SYRIAN HAMSTERS. Sonal Jhaveri\* and Gerald E. Schneider, Dept. of Brain & Cognitive Sciences, Mass. Inst. of Technology, Cambridge, MA 02139

The lateral geniculate body (LGB) of anesthetized adult hamsters was

exposed via a lateral approach. Under direct visual guidance, the retrograde cell tracers Fluorogold and rhodamine-labeled microspheres, were pressureinjected, one each in topographically equivalent parts of the dorsal (LGBd) or ventral (LGBv) nuclei of the LGB. After survivals of 1-4 weeks, animals were perfused with 4% paraformaldehyde. The brains were cut and examined for localizing the injection sites, and wholemounts of the ipsilateral and contralateral retinae were analysed with a UV filter and RITC filter for detecting the Fluorogold and the microsphere labeling, respectively

The overwhelming majority of retrogradely labeled retinal ganglion cells (RGCs) in the contralateral retina had either one or the other label; very few cells were double-labeled. Moreover, RGCs back-labeled from the ipsilateral LGBv comprised a predominantly uniform population of medium-sized cells which were distinct from cells projecting to the ipsilateral LGBd. Preliminary experiments combining injections of one retrograde tracer in LGBv and another in the superior colliculus (SC) indicate that the LGBv and SC receive

innervation from many of the same RGCs.

Our results demonstrate that separate populations of RGCs innervate the LGBd and LGBv and suggest that the LGv and SC share more by way of visual input than do the two nuclei of the LGB. These observations support earlier (unpublished) data from our laboratory showing that many optic tract terminals in the LGBv form a fine plexus bearing numerous tiny beads; these terminals are quite distinct from RGC terminals in the LGBd (Erzurumlu et al., Br. Res., 1988)

TRANSPORT OF CALCIUM GREEN DEXTRAN VISUALIZED VIA CONFOCAL MICROSCOPY IN THE VISUAL SYSTEM OF THE RAT. D.M. O'Malley\*, S.M. Lu, W. Guido and P.R. Adams, Howard Hughes Medical Institute and Dept. of Neurobiology & Behavior, SUNY, Stony Brook, NY, 11794.

Fluorescent dextrans can be transported in both the retrograde and anterograde fashion (Nance, 1991). A new calcium indicating dye, calcium green, is available bound to 10,000 molecular-weight dextrans (Molecular Probes). We were interested in whether calcium green dextran (CGD) could be transported and subsequently used as a calcium activity indicator. First, the responsiveness of CGD was tested and found to behave similarly to non-conjugated calcium green; it's fluorescence in an intracellular-like medium increased 7 fold as free [Ca\*\*] was raised from 5 nM to 2  $\mu$ M.

To determine whether the dye could be axonally transported, we injected 1-2 µl of a 20% solution of CGD in distilled water into the visual cortex of young rats. After survival periods of 3 to 7 days, the rats were sacrificed and 300 µm thick coronal stirvial periods of 3 to 7 days, the fats were sacrificed and 300 jill fillick corollal silices of brain were cut on a vibroslicer. The slices were perfused with oxygenated artificial CSF in a chamber mounted on the stage of a Biorad MRC 600 confocal microscope (inverted configuration). Labelling was observed in cortical areas surrounding the injection site as well as in contralateral cortical areas, apparently via callosal projections. Labelled axons and cells were present in the ipsilateral lateral geniculate nucleus (LGN) but not in adjacent thalamic nuclei. Some labelled axons could be followed for several hundreds of microns. Occasional cells in the LGN were

labelled well enough to follow a number of their dendrites for 50 to 100  $\mu m.$  To further support that CGD was axonally transported, we injected 1-2  $\mu l$  of CGD into the eye (vitreous) of young rats. After 3-4 days, extensive fields of punctate labelling were observed within the LGN. This labelling often took the form of rings, suggesting the presence of nerve terminals surrounding cell bodies. The degree and extent of labelling suggest that CGD may have use as a retrograde and anterograde tracer. We are currently testing whether transported dye remains responsive to Ca\*\*.

RETINAL PROJECTION TO THE MESOPONTINE CENTRAL GRAY IN THE RAT. H. Shen, T. Honda, and K. Semba\*., Dept. of Anatomy, Dalhousie Univ., Halifax, N.S. B3H 4H7 Canada.

During the course of a study on the central connections of the retina, we have identified a retinofugal projection to the central gray at the pontomesencephalic junction in the rat. The projection was confirmed with both anterograde and retrograde tracing techniques. Following intravitreal injections of choleratoxin subunit B. immunohistochemically visualized varicose afferent axons were seen in a ventrolateral region of the mesopontine central gray. The labelling was predominantly contralateral. Many of these labelled axons were intermingled with serotonin-immunoreactive neurons in lateral aspects of the dorsal raphe nucleus. Some fibers were also found further laterally, beyond the boundary of the dorsal raphe nucleus but within the central gray. Following injections of the retrograde tracer fluorogold into the mesopontine central gray area (without contamination of previously known targets of retinal projections), ganglion cells in the retina were labelled. Electron microscopic examination of axonal labelling in the central gray is currently underway. These data provide evidence for the existence of a direct projection from the retina to the central gray at the level of pontomesencephalic junction. The direct retinal projection to the mesopontine central gray, including the dorsal raphe nucleus, may have a role in sensorimotor coordination, and/or regulation of circadian rhythms and sleep and wakefulness.

MEDIAN STRIP OF OVERLAP FOR ALPHA CELL DECUSSATION IN

MEDIAN STRIP OF OVERLAP FOR ALPHA CELL DECUSSATION IN PIGMENTED RABBIT RETINA. B. Lia\* & P. Kuthan. Dept. Ophthalmology, RJ-10, University of Washington, Seattle WA 98195
Provis & Watson (81) found large-diameter (220µ) retinal ganglion cells with contralateral projections throughout the rabbit's temporal crescent. These might be presumed to include alpha cells. In the cat, crossed-projecting alpha cells are found in the temporal hemiretina, but mainly within a limited zone near the vertical meridian (Illing & Wässle 81). We wondered whether a qualitative difference exists between these species for alpha cell decussation. Therefore, we examined the decussation pattern of morphologically-identified alpha cells in Dutch belted rabbits. Projection laterality was determined by retrograde labeling following injection of green fluorescent latex microspheres (Molecular Probes) into one optic tract and red into the other. In superfused wholemount preparations, the temporal crescent was first delineated by the median edge of uncrossed labeling. Along sampling transects at various distances parallel to this uncrossed median edge, cells with large somata were injected with carboxyfluorescein to reveal dendritic structure. Ganglion cell classes were distinguished by morphological criteria (Peichl et al. '87; Pu & Amthor '90). Initial findings confirm that large cells with crossed projections can be labeled throughout the temporal crescent. However, the great majority of these did not prove to be of alpha cell morphology. Those few alpha cells within the temporal crescent with crossed projections were found mainly in a narrow zone along the uncrossed median edge and not throughout the temporal crescent. The median edge for crossed alpha cells is situated only somewhat temporal to their uncrossed median edge. Thus, it appears that alpha cells in the rabbit decussate in a pattern quite similar to that in the cat.

ANTEROGRADELY LABELED RETINOCOLLICULAR PROJECTIONS IN THE CAT EXHIBIT HIGH LEVELS OF GLUTAMATE IMMUNOREACTIVITY. Ljubomir Jojich and Roberta G. Pourcho\*. Wayne State Univ., Detroit, MI.

Glutamate-like immunoreactivity has been reported previously in the perikarya of essentially all ganglion cells in the cat retina. This immunoreactivity may represent metabolic pools as well as transmitter glutamate. In order to determine whether elevated levels of glutamate are also present at the terminals of these cells, anterograde labeling was combined with postembed immunostaining of the superior colliculus.

Retinocollicular projections were identified by their content of anterogradely transported WGA-HRP which was visualized with DAB followed gold-substituted silver enhancement. Glutamate immunoreactivity was quantified from post-embed immunogold staining. The mean density levels of gold particles in retinal terminals were 3.2-3.9 times higher in retinal fibers and terminals than in postsynaptic elements, many of which are known to be GABAergic. Parallel sections that were processed for GABA-IR supported the postsynaptic and interneuronal localization of GABA.

The positive identification of retinal terminals by use of anterograde labeling and the high concentration of immunoreactivity in these terminals are consistent with a neurotransmitter role for glutamate in retinocollicular projections of ganglion cells.

RETINAL PROJECTION IN THE RAT BRAIN AS DEMONSTRATED BY CHOLERA TOXIN FOR AN ANTEROGRADE TRACER. Y. Matsumoto¹¹ and M. Kawata². Dept. of Ophthalmol.¹, Dept. of Anatomy², Kyoto Pref. Univ. of Med., Kawaramachi Hirokoji Kamigyo-ku, Kyoto 602, Japan. Retinal central projection pathways have been extensively studied with the aid of degenerative methods and anterograde transport

techniques of tracers such as horseradish peroxidase and fluorescent dyes. We now report new findings of rat retinal projections in the brain by using more sensitive tracers of cholera toxin B-subunit (CTB) in conjunction with immunohistochemistry.

Fifteen adult male rat unilaterally received intravitreal injection of 0.1% CTB. Thirty-six hours later, these animals were perfused with phosphatebottlered saline and a fixative, and their brain sections were prepared in the coronal and sagittal plane at 20µm on a cryostat. These sections were incubated with anti-CTB serum for 3 days at 4°C. Then, immunohistochemical procedure was performed with avidin-biotinperoxidase complex methods.

The immunoreactive products were clearly identified as thin winding

fibers with various-sized varicosities or fine smooth fibers. Terminals of retinal axons were observed in the following regions which have not been reported so far to receive retinal afferents: both sides of the ventromedial hypothalamic nucleus, lateral dorsal thalamic nucleus, visual tegmental relay zone; contralateral side of the vertical limb of the diagonal band nucleus, lateral habenular nucleus, superior geniculate ordivariable and tooleds, heard indoctional indeeds, superior general side of the anterior prefectal nucleus, periaqueductal gray; ipsilateral side of the anterior dorsal thalamus, lateral posterior thalamic nucleus and inferior colliculus. The data described above suggest that the brain contains substantial systems of projection fiber from the retina.

## 65.6

PERIOD FOR REORGANIZATION OF RETINO-GENICULATE PROJECTIONS FOLLOWING ABLATION OF AREAS 17 & 18 IN THE IMMATURE CAT. H. E. Pearson\*, S. G. Lomber, B. R. Payne and P. Cornwell. Temple University School of Medicine, Philadelphia, PA 19140 and Boston University School of Medicine, Boston, MA 02118.

In the cat, ablation of visual cortical areas 17 & 18 within two days of birth is characterized by a reduction in retinal projections to the A

In the cat, ablation of visual cortical areas 17 & 18 within two days of birth is characterized by a reduction in retinal projections to the Alaminae and the maintenance of projections to the C-complex of the dorsal lateral geniculate nucleus (dLGN). Ablation of the same areas in adult cats is characterized by a modest increase in retinal projection density in each layer as the nucleus atrophies. The purpose of the present study was to define the transitional period between newborn-like and adult-like reorganization of retino-geniculate projections following visual cortex ablation (VCA). Areas 17 & 18 were removed from cats between the day of birth (P1) and P30 and from cats 6mo or older. Retinal projections were quantified following the autemporade transport of trijitated. the day of offin (P1) and P30 and from cats ome or older. Retinal projections were quantified following the anterograde transport of tritiated amino acids injected into an eye at least 6mo after the visual cortex ablation. As visual cortex was removed in increasingly older kittens (P1->P30) there was a progressively smaller reduction in retinal projection density in the dLGN A-laminae. Retinal projections to the A-laminae in P30 VCA cats were indistinguishable from those in adult cats that incurred P30 VCA cats were indistinguishable from those in adult cats that incurred visual cortex ablation. In a second group of cats, retinal projections were examined 1, 2 or 3mo after incurring VCA on P1. In all of these cats, the pattern and density of retinal projections were identical to those in P1 VCA cats which were examined in adulthood. These results show: 1) that retinal projections to dLGN can be modified by VCA only during the first postnatal month; and 2) that such reorganizations induced by P1 VCA occur during the first postnatal month. (Supported by NIMH #44647, NINDS #25196, and the Whitaker Health Sciences Fund.)

TRANSECTION OF SUPERFICIAL OPTIC TRACT (SOT) IN HAMSTERS SPARES ANTI-PREDATOR BEHAVIOR BUT ELIMINATES ORIENTING TO VISUAL STIMULI. Gerald E.Schneider\*, Sonal Jhaveri & Amanda S. Battisti, Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Transection of the superficial axons of the SOT at the level of the LGBd spares Internal optic tract (IOT) fibers, which extend <u>through</u> the LGB. Deepest IOT axons project to the olivary pretectal nucleus and superficially in the superficial gray layer (SGS) of the SC (Schneider & Jhaveri, 83). Would selective elimination of the SOT have different consequences for the two types of SC-dependent visually elicited behavior, orienting and anti-predator responses (Merker, MIT thesis, '80; rev. Dean et al., TINS, '89)?

We made unilateral SOT transections in 6 adult hamsters at the level of the LGBd. Control animals had the exposure alone. Testing was done 1-2 times/wk for more than 9 wk, at least 2 hr before the onset of the dark cycle for orienting, and less than 2 hr for anti-predator tests. During a 10 min test, a d stuck onto a 1x1x2 cm piece of black rubber on the end of a wire handle was presented about 6 in from the head, in all parts of the field. Turning responses were recorded on diagrams of the visual field. Antipredator behavior was studied while the animal foraged for seeds on a raised platform: the black rubber object was thrust into the temporal visual field about a meter from the head, and any change in behavior (e.g. freezing, running) was noted. The presentation was repeated on the other side.

For experimental animals with right SOT cuts, freezing, but no orienting responses, occurred for stimulus presentations in the upper temporal field of the left eye. Both types of responses were normal for the (unperturbed) visual field of the right eye. The data, with earlier findings, indicate that anti-predator behavior is subserved by a population of retinal axons terminating in the superficial part of SGS; these axons are not sufficient for orienting. SUPPORT: NIH grants EY00126 (for behavior), and EY05504 (for anatomy).

NMDA AND NON-NMDA EXCITATORY AMINO ACID (EAA) RECEPTORS AND VISUAL RESPONSES OF CAT SUPERIOR COLLICULUS (SC) NEURONES. <u>K.E.Binns and T.E.Salt</u>. Institute of Ophthalmology, University of London, London WC1H 9QS, UK.

EAAs such as L-glutamate may be neurotransmitters of retino-fugal and other visual pathways. We have examined the possible role(s) of NMDA and AMPA/kainate receptors in the responses to visual stimuli of neurones located in the superficial SC. Multibarrel pipettes were used to perform single-neurone recordings and iontophoresis of EAAs and their antagonists in cats anaesthetised with Halothane/Nitrous Oxide/Oxygen.

The antagonist CNQX was found to antagonise responses to iontophoretically applied kainate or AMPA on 14 neurones. Such currents of CNQX were found to antagonise neuronal responses to visual stimuli (drifting bars or gratings, or flashing spots) to 59% of their control values. The NMDA receptor antagonist CPP was applied onto 33 neurones. On 25 of these, visual responses were reduced to 57% of control values. On the remaining eight neurones, CPP either had no effect or potentiated visual responses, even though the antagonist blocked responses to NMDA on the same neurones.

These results indicate that EAA receptors of both the NMDA and kainate/AMPA receptor type may be involved in the mediation of responses of superficial SC neurones to visual stimuli, although the relative contribution of these receptor types may vary between neurones.

## 65.11

EFFECTS OF ANGIOTENSIN-II (AII) ON ACTIVITY OF VISUAL NEURONS IN THE SUPERIOR COLLICULUS OF THE HAMSTER. Y. Zhang\*, R.D. Mooney and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

The superficial layers of the rodent superior colliculus (SC) contain AII receptors in relatively high density, but we have no information about how this hormone may affect the responses of collicular neurons. In this study, extracellular single unit recording and receptive field mapping techniques were used to assay the effects of AII upon the responses of SC cells in vivo. The visual responses of 77 visually responsive SC cells were quantitatively evaluated before, during, and usually after micropressure ejection of AII (10  $\mu M$ ); 71% of these neurons had their visual responses reduced by at least 30% by All and in 13%, responses were reduced by >90%. The effects of All upon responses evoked by electrical stimulation of either optic chiasm (OX) or visual cortex (CTX) were also evaluated. All significantly reduced responses to OX stimulation in 50% of 101 cells tested and to CTX stimulation in 55% of 42 cells. The correlation in response decrements during AII application for 35 cells tested with both OX and CTX was highly significant (linear regression  $r^2$ =.685; p<.0001) indicating that the effect of AII was common to both pathways. We evaluated the ability of the AII-1 receptor antagonist DUP753 to block the effects of AII in 7 cells. When AII alone was applied, the responses of these neurons were reduced an average ( $\pm$  s.d.) of 62.7  $\pm$  28%. During concurrent ejection of AII and DUP753, the reduction was only 9.5 ± 18.4% (paired t-test t=6.6, p<.001). These results indicate that AII has strong suppressive effects upon the responses of visual SC neurons and that these effects might be mediated by AII-1 receptors. EY04170 and EY08015

# 65.13

EFFECTS OF SEROTONIN (5-HT) UPON RETINOTECTAL, CORTICOTECTAL, AND GLUTAMATE-INDUCED ACTIVITY IN THE SUPERIOR COLLICULUS OF THE HAMSTER. X. Huang\*, R.D. Mooney and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

There is evidence that 5-HT<sub>18</sub> receptors are located on retinotectal axons and that other 5-HT receptor subtypes may also be present in the superior colliculus (SC). We used iontophoresis of 5-HT and single cell recording in vivo to test whether the effects of 5-HT on SC neurons were specific to optic inputs or shared by other pathways. Two strategies were used. For neurons activated by electrical stimulation of both the optic chiasm (OX) and visual cortex (CTX), the effects of 5-HT upon these responses were compared. For other cells, we compared the effects of 5-HT on visual responses and upon glutamate-evoked activity during synaptic blockade induced by continuous Mg2+ iontophoresis. Activity evoked by OX stimulation was suppressed by at least 30% in 96% of the cells tested (n=25) and by >90%in 64%; CTX-driven activity was reduced to these levels in 40% and 24% of the neurons, respectively (Wilcoxon matched pairs test: z=4.18, p<.0002). 5-HT suppressed visual activity (>30%) in 97% of the cells tested (n=40) as compared to only 35% of neurons for glutamate-induced activity (z=4.8, p < .0001). There was no correlation between the degree of response reduction for the two types of stimulation in either experiment. This suggests that even though 5-HT did suppress responses to CTX stimulation and glutamate-induced activity, the mechanism underlying these actions may be different and generally less potent than that affecting OX-evoked responses. EY04170 and EY08015.

### 65.10

EFFECTS OF ANGIOTENSIN II (AII) ON SYNAPTIC POTENTIALS IN THE SUPERIOR COLLICULUS (SC) OF HAMSTER. R.D.Mooney\*, M.-Y. Shi, Y. Zhang, S.V. Savage and R.W. Rhoades. Dept. of Anatomy. Medical College of Ohio, Toledo, OH 43699

The superficial layers of the SC have a high density of AII receptors, the function of which is yet unknown. In vivo results which we report in this meeting indicate that many SC neurons are influenced by AII and that the receptors mediating these effects are either postsynaptic or common to both retinotectal and corticotectal afferents. To test whether AII had postsynaptic effects, we made intracellular recordings from superficial SC neurons in vitro using an SC slice preparation to which the entire optic tract (OT) remained attached. To date we have tested 21 neurons, the average resting potential of which was -68.5  $\pm$  9.1 mV (mean  $\pm$  s.d.) and the average input resistance was 129.4  $\pm$  58.5 M $\Omega$ . Electrical stimulation of the OT (500  $\mu$ A, 75  $\mu$ s) produced EPSPs with an average amplitude of 8.4 ± 1.3 mV. Bath-application of AII (10 µM) decreased the EPSP amplitude in 17 cells (81%) by at least 30% and increased the EPSP in one neuron. For the whole sample, AII reduced the EPSP amplitude to 60.4% of control (paired t-test t=8.1, p < .001). Application of AII produced comparatively little change in membrane properties of the neurons: input resistance decreased by only 4% on average and the resting potential increased by 3% to -70.5 mV. Multiple regression analysis showed that changes in EPSP amplitude were not significantly correlated with changes in either membrane potential or input resistance ( $r^2 = 0.15$ , p > 0.1). The lack of a clear postsynaptic effect of AII suggests that it may be affecting some aspect of retinotectal and perhaps also corticotectal synaptic transmission. EY04170 and EY08015.

## 65.12

EFFECTS OF SEROTONIN (5-HT) ON SYNAPTIC POTENTIALS OF NEURONS IN THE SUPERIOR COLLICULUS (SC) OF THE HAMSTER. M.Y. Shi\*, R.D. Mooney, S.V.Savage, Y. Zhang, and R.W. Rhoades, Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

The results of previous studies from our laboratory concerned with the effects of 5-HT in the SC in vivo suggested that this amine influenced the responses of superficial layer neurons by both pre- (i.e. on retinotectal axons) and postsynaptic mechanisms. To better evaluate the relative contributions of these mechanisms, we developed an in vitro slice of the SC with the entire optic tract (OT) attached and recorded synaptic responses intracellularly to electrical stimulation of the OT near the chiasm. To date, we have tested 47 SC neurons. These cells had an average resting potential of -64.1  $\pm$  6.3 mV (mean  $\pm$  s.d.) and input resistance of 135.1  $\pm$  56.6 M $\Omega$ . Electrical stimulation of the OT (500  $\mu$ A, 75  $\mu$ s) produced EPSPs that averaged 7.8  $\pm$  2.3 mV. Bath application of 5-HT (100  $\mu$ M) reduced the EPSP amplitude by at least 30% in 42 neurons (89%) and by at least 50% in 72% of the sample. The average reduction was  $59 \pm 25\%$  (paired t-test, t=-14.8, p < .01). In contrast, the average input resistance of the 47 neurons was reduced by only 5.8% and membrane potential by only 2%. Changes in EPSP amplitude were not significantly correlated with those in input resistance or membrane potential  $(r^2 = .001, p > .36)$ . The profound effect of 5-HT on EPSP amplitude in the absence of any distinct change in the membrane properties of the postsynaptic neurons suggests a presynaptic site of action on retinotectal fibers. However, this does not rule out the possibility that 5-HT may also act postsynaptically on the receptor and/or channels related to the transmitter employed by retinal axons. EY04170 and EY08015.

# 65.14

THE ULTRASTRUCTURAL ORGANIZATION OF PROFILES LABELED BY ANTIBODIES TO GAMMA-AMINOBUTYRIC ACID (GABA) IN THE SUPERIOR COLLICULUS OF THE RABBIT. R.R. Mize\*, R.H. Whitworth\*, B. Nunes-Cardozo\*, and J.J.L. van der Want², 'Dept. of Anatomy, Louisiana State University Medical Center, New Orleans, LA 70112, and \*The Netherlands Ophthalmic Research Institute, P.O. Box 12141, 1100AC, Amsterdam, Netherlands.

At least three types of GABAergic profile have been identified in the superior colliculus (SC) of the cat and monkey. It is not known whether these classes are found in other species. We therefore have studied the organization of GABAergic profiles in the SC of the rabbit. The ultrastructure of profiles labeled by an antibody to GABA was examined with electron microscope post-embedding immunocyto-chemistry using a secondary antibody conjugated to 10-15 nm gold particles that permits the unobstructed visualization of profile morphology.

Three distinct types of profile labeled by the GABA antibody were found in the rabbit SC. One type of putative presynaptic dendrite (PSD) was of large-calibre and had small, discrete clusters of pleomorphic vesicles at sites of synaptic contact with other, conventional dendrites. These PSDs received few synaptic contacts and none from axon terminals of retinal origin. A second type of putative PSD contained pleomorphic vesicles scattered throughout the cytoplasm. These PSDs were found within retinal glomeruli and frequently received input from retinal terminals. In addition, a number of putative axon terminals with more flattened synaptic vesicles were labeled by GABA. These profiles varied in morphology, but had a higher gold particle density than putative PSD profiles. Quantitative analysis of gold particle density revealed a consistent pattern of labeling over different profile types, even when the particle density was quite low. Our results suggest that there are three separate types of GABAergic synapse in the SC of rabbit as is the case in cat and monkey. These synapse types must represent a phylogenetically conserved organization common to many mammals. Supported by USPHS grant EY-02973.

SUPERIOR COLLICULUS NEURONS THAT PROJECT TO THE INFERIOR OLIVE ARE RELATED TO THE CHOLINERGIC PATCHES IN THE INTERMEDIATE GRAY LAYER OF THE CAT. <u>C.J. Jeon\* and R.R. Mize\* Dept.</u> of Anatomy and Neurobiology, Univ. of Tennessee, Memphis TN 38163 and \*Dept. of Anatomy, Louisiana State Univ. Medical Center, New Orleans, LA 70112.

We have previously shown that superior colliculus (SC) neurons which project through the tecto-ponto-bulbar pathway to the cuneiform region of the midbrain tegmentum form discrete cell clusters. These clusters overlap the patches of cholinergic fibers found in the intermediate gray layer (IGL) of the cat SC. In this study, we have examined the relationship of these cholinergic fiber patches to other neuron projection systems in SC, including those that project to the medial accessory nucleus of the inferior olive (IO) and to the dorsolateral pontine gray nucleus (PGN). These neurons were labeled retrogradely with horseradish peroxidase (HRP). Some sections were counterstained with choline acetyltransferase (ChAT) immunocytochemistry. When injections were centered within the dorsal portion of the medial accessory nucleus of IO, two tiers of HRP labeled cell clusters were found in the contralateral SC. One tier was found in the upper IGL and the other in the intermediate white and deep gray layers. These IO projection neurons were mostly small to medium in size (11.4-32.9 µm in average dimater). Three to six clusters were found in each tier. In sections combining HRP and anti-ChAT labeling, the IO projection cells in the upper IGL clusters were distributed just above or surrounding the ChAT immunoreactive patches. Only a few HRP labeled cells were localized within the ChAT patches, although some cells outside the patches had dendrites extending into the patches. Neurons projecting to the PGN did not form any obvious clusters and were scattered both within and outside the ChAT patches. To conclude, the IO projection neurons in the upper IGL must be tightly coupled to cholinergic afferents in this structure. Supported by EY-02973.

OSCILLATORY PROPERTIES OF NEURONS IN A NEWLY DEFINED REGION OF THE PRETECTAL AREA Rowshank Hashemiyoon and John K. Chapin\*. Dept. of Physiology/Biophysics, Hahnemann University, Phila. PA 19102. The pretectal area is typically subdivided into three regions (medial, posterior,

The pretectal area is typically subdivided into three regions (medial, posterior, and anterior) in which only a few nuclei are well-described. Here we provide evidence suggesting the existence of a previously undefined, physiologically distinct nucleus in the medial-most portion of the pretectal area of the rat. This nucleus is almond shaped, measuring about 1.5mm mediolaterally and 1.0mm dorsoventrally at its center. Neurophysiological recordings in this area are obtained either through single, drivable microelectrodes used in mapping studies in the pentobarbital anaesthetized rat, or through chronically implanted bundles of microwire electrodes allowing simultaneous recording of multi-single neurons. The most striking characteristic of the neurons in this area is their synchronous oscillatory behavior which is observed under both anaesthetized and awake conditions. These oscillations are exhibited most strongly in the dark. Increasing luminosity of light stimulation of the whole visual field of the contralateral eye causes a slight decrease in frequency and marked tonic decrease in the intensity of the oscillation. Some neurons in the lateral part of this region exhibit phasic excitatory responses to light stimulation of circumscribed parts of the visual field. The frequency of oscillation depends strongly on anaesthetic state: under deep anaesthesia the frequency occurs at approximately 10 Hz, and bifurcates to 20Hz in light anaesthesia and normal wakefulness. Furthermore, under urethane anaesthesia some neurons in the lateral part of this region exhibit 40 Hz oscillations. Finally, analysis of the dynamic properties of these oscillations indicates that they may exhibit fractal (chaotic) properties. To conclude, the wide-field luminance sensitive oscillatory properties of this subnucleus may play a role in visual processing in the pretectal area. DIFFERENTIAL PROJECTIONS TO TECTAL LAMINAE FROM THE PERIHYPOGLOSSAL NUCLEI IN THE CAT. S. Higo.\*
T.Matsuyama , J.Kawano , and S.Kawamura , Div. of Morphological Neural Science, Kumamoto Univ. Graduate Sch. of Medical Sciences, Kumamoto 860, JAPAN.

Efferent projections of the perihypoglossal nuclei to the superior colliculus (SC) were examined with WGA-HRP method. Following WGA-HRP injection into the hypoglossal complex including the nuclei prepositus hypoglossi(PH) and intercalatus(INT), orthogradely labeled fibers were traced to SC via the reticular formation after crossing the midline. In SC, two terminal zones were found with marked contralateral predominance: one is in the superficial(laminae i and III-2), and the other in the deep(lamina IV)layers. SC injection restricted to the deep layers(laminae IV-VI)led to retrogradely labeled cells only in the caudal PH. By contrast, the injection confined to the superficial layers(laminae I and III-2) produced labeled cells exclusively in the rostral INT. These findings suggest that PH is related to the oculomotor function, whereas INT may participate in the visual sensory function, since the superficial layers of SC receive inputs from only visual sensory structures such as the retina and the visual cortex, and give rise to ascending projections.

### 65.16

THE SYNAPTIC ORGANIZATION OF THE RABBIT PRETECTO-COLLICULAR SYSTEM. AN ULTRASTRUCTURAL DEMONSTRATION OF GABAERGIC AND NONGABAERGIC PROJECTION NEURONS. B. Nunes Cardozo<sup>11</sup>, J.J.L. van der Want<sup>11</sup> and R.R. Mize<sup>21</sup>. P.A. Apkarian<sup>2</sup>. Dept. of Morphology, The Netherlands Ophthalmic Res. Inst., P.O. Box 12141, 1100AC Amsterdam, The Netherlands and Dept. of Anatomy and Neuroscience Center, Louisiana State University, New Orleans, LA 70112.

Neurons in the pretectal Nucleus of the Optic Tract (NOT) which project to the superior colliculus (SC) have been studied using the retrograde transport of Cholera toxin subunit B conjugated to 7 nm gold particles (CTB-AU). Postembedding immunocytochemistry using an antiserum against GABA was applied on the same material to determine whether some or all of these cells contain GABA. A series of small pressure injections of CTB-AU were placed in the superficial layers of SC in a rostral-caudal sequence. Retrogradely labeled cell bodies in the NOT were visualized with silver enhancement of the gold particles. Retrogradely labeled neurons were found throughout the NOT, with slightly increased numbers in the rostral portion of the nucleus. The cells had large to medium sized cell bodies with electron lucent cytoplasm, extensive Golgi apparatus, and stacks of endoplasmic reticulum. Moderate GABA immunoreactivity was observed in some but not all of these labeled neurons. NOT neurons projecting to SC received retinal axon terminals (R) and from synaptic terminals with flattened vesicles thought to be of axonal origin (F profiles) and profiles with pleomorphic vesicles thought to be of dendritic origin (P profiles). These inputs were found on both the cell bodies and dendrites of these cells. Many of the F and P profiles showed GABA immunoreactivity. The GABAergic projection from the NOT to SC in rabbit is similar to that to that previously reported in cat and supports the idea that GABAergic neurons in NOT exert an inhibitory control over SC neurons, some of which may be involved in the relation of eye movements. ## 65.18

IMMUNOCHEMICAL HETEROGENEITY IN THE TECTO-LP PATHWAY OF THE RAT. R.D. Lane\*, D.M. Allan, C.A. Bennett-Clarke, R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, Ohio 43699.

The projection from the rat's superior colliculus to the posterior lateral nucleus (LP) of the thalamus includes neurons which are adenosine deaminase (ADA) positive (Miguel-Hidalgo et al., Brain Res. 476:189, '89). In the stratum opticum of the colliculus, the ADA neurons are primarily wide-field vertical cells. We have recently identified a population of calbindin immunoreactive neurons of similar shape which were likewise located in the To determine if these two populations overlapped and stratum onticum. whether the calbindin immunoreactive neurons projected to the LP, the fluorescent retrograde tracer, true blue was injected in the LP of rats which were subsequently processed for immunofluorescent localization of ADA and calbindin. The expression of ADA and calbindin among the true blue labeled tecto-LP cells was: 64.4 % calbindin, 1.1 % ADA, 14.6 % both calbindin and ADA. On the bases of the distribution of the ADA and calbindin terminal fields in the LP as well as the phenotypic expression of the two markers by the tecto-LP cells, two major tecto-LP subdivisions were defined. The ADAcalbindin positive subdivision, which projects to the rostral-medial portion of the LP, and the strictly calbindin subdivision, which appears to project to a broader area within LP. These results suggest that the rat is more similar to the cat (Abramson and Chalupa, <u>J. Comp. Neuro.</u> 271:397, '88, Hutsler and Chalupa, <u>J. Comp. Neuro.</u> 312:379, '91) than previously though in possessing multiple subdivisions of the tecto-LP pathway. Support: HL36573, EY04170, EY08015.

MORPHO-FUNCTIONAL ORGANIZATION OF PERISTRIATE CORTEX IN DIDELPHIS MARSUPIALIS. S. Martinich\*, C.E. Rocha-Miranda, M.A. Marrocos and M.G.P. Rosa. Instituto de Biofísica, UFRJ, Rio de Janeiro, Brazil.

Didelphis exhibits many general features of the basal mammalian stock in neural and other systems. Thus, it could be an appropriate model for studies of cortical evolution. We have examined the visual cortex of Didelphis marsupialis intending to formulate some general principles of cortical organization.

Multiunitary recordings in the peristriate cortex (PS) indicate that a single visual map specular to V1 exists adjacent to ST, markedly anisotropic and with large receptive fields. PS appears anatomically heterogeneous: patterns of commissural nections, myelin density and cytochrome-oxidase activity reveal periodical bands running rostro-caudally. Besides, three consecutive fields of patchy labelling are obtained in topographically related portions of PS after single WGA-HRP injections in ST, the two more caudal, possibly corresponding to V2 and V3, formed by strings of 3-4 foci. PS-tectal neurons also distribute in consecutive fields. The intervals between foci from the strings of ST-PS connections are much smaller than those between commissural bands, while a commissural belt parallel to the ST-PS border separates the two caudal fields from the rostral one. A postero-lateral PS region adjacent to ST and to the auditory cortex is identified as a separate area by the hodology. The more sensitive tracing with fluorescent dyes injected in PS and ST reveals a much higher degree of dispersion in intra as well as interhemispheric (homo and heterotopic) connections between these regions, but still with rough topographic correspondences.

From these results we suggest that the visual processing in the opossum, as in more specialized mammals, is segregated beyond ST in several cortical fields, some of them organized in a modular fashion. Moreover, the complex requirements of image analysis may impose on a species with few cortical areas more widespread ipsi and contralateral projections than those reported for other mammals.

### 66.3

NEURONS IN V1, V2, V3, AND V4 ENCODE INFORMATION ABOUT COLOR AND PATTERN OF CURRENT AND REMEMBERED STIMULI.

J.W. McClurkin\*, M-N. Chee-Orts, and L.M. Optican. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Responses of neurons in four visual cortical areas (identified by receptive field size and electrode location) were recorded in a monkey trained to choose one of three parafoveal stimuli based on their color or pattern. The discrimination depended on a foveal cue that was turned off 67 msec before the stimuli appeared. The cue was one of 6 colored squares or 6 black & white patterns. The stimuli consisted of all 36 combinations of those 6 colors and 6 pattern

The response of the neuron was modulated by the pattern and color of the stimulus on the receptive field, and by the pattern or color of the preceding cue. The relative amounts of information about pattern and color transmitted by a neuron depended on the discrimination required. When pattern was the cue, 10 of 33 neurons transmitted significantly more information about pattern than about color. When color was the cue, 5 of 33 neurons transmitted significantly more information about color than about pattern (P < 0.05). The other neurons transmitted the sam amount of information about pattern and color.

Information developed continuously, but not uniformly, throughout the timecourse of neuronal responses. A large amount of information was encoded in the initial 50 msec of the response. Most neurons also encoded a large amount of information in a second 50 msec interval, beginning 20-30 msec after the first. Information about pattern also developed more quickly than that about color in each

These results show that neurons in V1-V4 carry information about the color and pattern of both current and remembered stimuli. Furthermore, the relative amounts of information carried by a neuron depend upon the behavioral task. Finally, the development of information over time in different areas suggests that temporally modulated waves of activity may form a code for visual information (next abstract).

# 66.5

SELECTIVITY FOR FEATURES BEYOND ORIENTATION, COLOR, SIZE, AND SIMPLE TEXTURE IN THE PRESTRIATE AREAS V2 AND V4. E. Kobatake\*and K. Tanaka. RIKEN, Japan

To uncover principles of representation of object's image, we have studied the stimulus selectivity of single cells in the latter areas of the ventral visual pathway, TE and TEO. Here, we went back to V4 and V2, to know to what extent and what kinds of integration takes place in these former areas. Recordings were made from anesthetized, immobilized monkeys (Macaca fuscata, n=2). Responsiveness of each cell was examined to both simple responded maximally to a particular object, we determined the critical feature by reducing the complexity of the object, we determined the critical feature by reducing the complexity of the object's image. The responses to the best simple stimulus and to the best complex stimulus (the critical feature if identified) were then compared.

The majority of V4 cells (88% of 82 cells) responded to certain simple stimuli.

No complex stimulus that might activate a cell more strongly could be found in 3/4 of these V4 cells (65% of the total), but for the remaining quarter (23%), response to the best complex stimulus was significantly larger than that to the best simple stimulus. For example, one cell responded to a purple disk, but a best simple stimulus. For example, one cell responded to a purple disk, but a tail view of an eggplant was much more effective. By simplifying the image of the eggplant, we determined the critical feature as white concentric rings on a grey disk base. The remaining 12% of the V4 cells responded only to a particular complex feature but not to any simple stimuli. All but 2 out of 41 cells recorded from V2 were activated maximally by some simple stimuli. One of the 2 cells responded maximally to a tapering bar, which was reduced from a tip of pencil. Though many orientation and width of bars were carefully tested, the response to the best bar was still only 65% of that to the tapering bar (p<0.05). We conclude that integration of object-information takes place in V4 and probably even in V2. Although it is difficult to quantify the complexity of the critical features, it appears that the complex critical features in V2 and V4 were simpler than those in TEO and TE.

FUNCTIONAL SEGREGATION BETWEEN THE LATERAL SUPRASYLVIAN AREAS AND AREAS 7/21A IN THE CAT: PERMANENT DEFICITS FOLLOWING LESIONS K. Krüger A. Groh W. Kiefer Institute for Neuroinformatics, Dept. of Theoretical Biology, Ruhr-University Bochum, ND 04, University Dechum, ND 04, University Bochum, ND 04, Univ tätsstr. 150, D-4630 Bochum, Germany

The behavioural functions of the suprasylvian cortex in the cat were analysed in combination with bilateral lesions of parts of the lateral suprasylvian areas (LSA, lesion 1), area 7 and area 21a (2) and a combination of lesions (1) and (2). We studied the contribution to pattern recognition with detection experiments and the contribution to depth perception, with the cats binocularly or monocularly, in a 2AFC procedure on a jumping stand. Both test series were performed before and after the lesion.

Our results revealed clear functional segregation between the LSA on one hand and areas 7 and 21 a on the other hand. Lesion (1) led to significant deficits in all test situations which were dependent on a relative velocity of moving patterns against the background. Binocular and monocular depth perception was impaired by more or less same degree. Lesion (2) led to modest but significant deficits of more or less same degree in nearly all test situations. A smaller lesion yielded significant deficits only when the background was moved and at the same time a low relative velocity occurred. The monocular depth perception was nearly unaffected, the binocular one was impaired by a factor of about 4. Lesion (3) roughly provoked a combination of the effects of the lesions alone in both

We conclude that the LSA are involved in pattern recognition whenever it is associated with motion in combination with object-background interactions suggesting an involvement in the alnalysis of object- and self-induced motion. Interpretation of the results after lesion (2) is based on the conjecture that the mechanism of vergence movements or of binocular fusion might be impaired

## 66.4

NEURONS IN PRIMATE VI, V2, V3, AND V4 SHARE THE SAME TEMPORAL CODES FOR COLOR AND PATTERN. J.A. Zarbock, J.W. McClurkin, and .M. Optican\*. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

In a discrimination task, neuronal responses were modulated by the color and pattern of both the current stimulus and the preceding cue (previous abstract). The response to each stimulus could be represented as the product of two waveforms, one for color and one for pattern. Feature-specific waveforms for each color and each pattern were isolated from the neuronal responses by a neural net. The product of these feature waveforms predicted the neuronal responses to stimuli with color and pattern combinations not used to train the neural net.

Feature waveforms were often similar for all neurons within a cortical area. To compare these waveforms across cortical areas, all the responses from neurons within each area were pooled. Waveforms encoding pattern were strikingly similar across all areas, irrespective of the behavioral task. Waveforms encoding color differed between cortical areas, depending on the behavioral task. The color waveforms V1 and V4 were different, and showed no task dependence. The color waveforms in V2 and V3 were different from those in V1 and V4 when pattern was the cue, but were identical to those in V1 when color was the cue.

Neuronal responses could also be decomposed into waveforms for the pattern and color of remembered cues, even though the cues did not fall on the receptive field of the neuron. The waveforms for the pattern and color of the cue were similar to those of the receptive field stimuli.

These results suggest that neurons convey information about compound visual features by multiplexing feature-specific messages together. Furthermore, the cuedependence of color waveforms suggests that visual processing in V2-V3 can be altered to help achieve the objectives of different discrimination tasks. Finally, the invariance of pattern waveforms suggests that, at least for these stimuli, the processing of pattern information is completed in V1.

# 66.6

COLOR SPACE TUNING OF MACAQUE AREA V4 NEURONS: CARDINAL DIRECTIONS ARE NOT PREFERRED. Karl Zipser. Robert P. Dolan and Peter H. Schiller\*. M.I.T. Dept. of Brain and Cognitive Sciences, Cambridge MA

The color space tuning of neurons in macaque LGN is clustered along two cardinal directions, but area V1 neurons are tuned to intermediate directions as well (Lennie et al, 1984,1990). Psychophysical experiments suggest that color perception is coded along the cardinal directions of color space, and it is of interest to investigate whether neurons at high levels of color processing reconstruct this cardinal direction specificity. In this work, tuning in the isoluminant color plane was tested for single units in area V4 of the behaving macaque, using color gratings on isoluminant backgrounds. Only 37% of units responded preferentially to cardinal direction stimuli over non-cardinal directions tested, approximately chance for this study. These results provide no evidence for preferential cardinal direction tuning in V4.

As a control for responses to luminance artifacts present in the stimuli, units which responded well to low luminance contrast were not included in the sample. A small fraction of units responded best to color gratings in spatial orientations orthogonal to preferred orientations for black and white gratings.

ATTENTIONAL MODULATION OF RESPONSES IN AREA V4 OF THE MACAQUE. S.J. Luck\*, L. Chelazzi, S.A. Hillyard, and R. Desimone. Lab. of Neuropsychology, NIMH, Bethesda, MD 20892 and Dept. of Neurosciences, UCSD, La Jolla, CA

A previous study of V4 cells found that attending to one stimulus within the receptive field and ignoring another can cause the response to the ignored stimulus to be suppressed beginning 30 msec after response onset. We have now studied V4 cells in a new paradigm modeled after tasks that have demonstrated attentional modulation of evoked potentials in humans using wider separation of attended and ignored stimuli. In this task, sequences of several brief (50 msec) stimuli were presented asynchronously at two locations in the visual field, and the monkey was required to detect a target square among nontarget rectangles in the sequence at one of the locations (i.e., the attended one), ignoring stimuli at the other. Of 28 cells recorded in one rhesus monkey, 16 showed significantly smaller responses to nontargets when they were ignored compared to the same stimuli when attended, consistent with prior studies However, the suppression began much later than in earlier studies, beginning approximately 100 msec after response onset, and was found when both attended and ignored stimuli were located within the receptive field as well as when one set was inside and one outside. The results suggest a new source of late attentional modulation of V4 cells, operating over a wide spatial range. Supported in part by the Human Frontier Science Program Organization.

NEURAL ENSEMBLE MEASUREMENT OF STIMULUS SELECTIVITY IN INFERIOR TEMPORAL CORTEX. P. M. Gochin\*, M. Colombo, G. A. . Gerstein and C. G. Gross . Dept. of Psychology, Princeton University, Princeton NJ 08544.

Inferior temporal cortex (area TE) in the primate appears to represent complex visual stimuli with some type of ensemble code. Thus, characterization of single unit properties is an insufficient approach to measurement of stimulus discrimination capacity. A method for measuring the stimulus discrimination capacity of neural populations was applied to small groups of neurons recorded in posterior area TE of monkeys performing a delayed matching-tosample task. The results show that the shapes tested were well distinguished by a neural population code. The number of neurons and stimuli, type of stimuli, and measurement interval all influence ensemble discriminative capacity. Evaluation of the delay period activity shows that considerable information about stimulus identity persists once the stimulus is no longer visible, but that there is a significant degradation after only 1/2 sec. This leaves some question as to whether the post-stimulus activity in this region of TE is actually part of a short-term memory mechanism. Furthermore, there appeared to be little influence of persisting neural activity from the sample stimuli on the response to the matching stimuli. Thus, the primary function of posterior TE appears to be the representation of shape for objects currently in view.

# 66.11

EFFECTS OF SCOPOLAMINE ON A WORKING MEMORY TASK AND ACTIVITY OF NEURONS IN INFERIOR TEMPORAL (IT) CORTEX. <u>E.K. Miller\* and R. Desimone.</u>
Neuropsychology, NIMH, Bethesda, MD 20892.
Scopolamine, a muscarinic antagonist,

been shown to impair performance in memory tasks. However, the site of action is not known. IT cortex is critical for normal memory and we have reported that responses of IT neurons carry information about stimuli held in memory, even when other stimuli intervene in the retention interval. We therefore tested the behavioral and physiological effects of scopolamine in the same task. The task was delayed matching to sample, with 0-4 intervening items between the sample and final matching stimulus. Two rhesus monkeys received systemic injections of either 10 ug/kg scopolamine or saline. Scopolamine impaired performance of the task with 0 intervening items, but the impairment was not exacerbated with increasing number of intervening items (and delays). In contrast to the striking behavioral delays). In contrast to the striking behavioral deficit, there was little or no effect on either the stimulus selectivity of IT neurons or the mnemonic modulation of their responses. These results suggest that the site of action of scopolamine is not IT cortex or that scopolamine disrupted task performance by interfering with a non-mnemonic mechanism.

ELECTROPHYSIOLOGICAL STUDIES OF COLOR PROCESSING IN HUMAN VISUAL CORTEX. T. Allison\*, A. Begleiter, E. Roessler, G. McCarthy, A. Nobre and D. Spencer. Neuropsychology Laboratory, VA Medical Center, West Haven, CT 06516, and Dept. of Neurology and Section of Neurosurgery, Yale University School of Medicine, New Haven, CT 06510.

Clinical evidence in humans and single-unit studies in monkeys suggest that a

region of prestriate cortex is specialized for the processing of wavelength information. The human homolog of monkey V4 is thought to be located in the lingual and fusiform gyri lateral and inferior to striate cortex. Here we present the first electrophysiological evidence that this region responds preferentially to color

Thirteen patients were studied with electrodes (either subdural electrodes on surface cortex including the lingual and fusiform gyri, or depth probes in the occipital pole superior to the calcarine sulcus) chronically implanted for localization of epileptogenic foci. A 1-sec red or blue "adaptation" stimulus was followed by a red or blue "test" stimulus. We predicted that visual evoked potentials (VEPs) elicited by the test stimulus would be larger when preceded by an adaptation stimulus of the different color than when preceded by the same color.

About 50% of all recording sites on presumptive V4 showed a statistically significant color effect. Other areas had smaller percentages of sites showing a significant color effect: superior occipital pole, 30%; striate cortex, 11%; inferior temporal gyrus, 6%; inferior non-V4 cortex, 5%; all other sites, 6%

Stimulation (5 sec trains of 50 Hz, 0.1 msec duration constant current pulses, 1-10 mA intensity) of some V4 locations elicited negative (desaturation of color) or positive (evocation of color) effects in the contralateral half field, usually crossing the horizontal meridian. By contrast, stimulation of striate cortex evoked quadrantic retinotopic sensations devoid of color change.

Supported by the Veterans Administration and by NIMH grant MH-05286.

## 66.10

THE HETEROGENEITY OF ADJACENT NEURONS IN INFERIOR TEM-PORAL CORTEX. T.J.Gawne\*, E.N.Eskandar†, and B.J.Richmond. Lab of Neuropsychology, National Institute of Mental Health, Bethesda, MD 20892. †HHMI.

There are three possibilities for encoding information in a small area of cortex: 1. Neurons could have identical characteristics, thus conveying redundant information, 2. neurons could give different responses to the same stimuli, thus conveying independent information, or 3. neurons could cooperate with each other to encode more information jointly than they do separately, i.e. synergistically.

We isolated the signals from 28 pairs of neurons from a single micro-electrode, and separated the responses into signal (average response to each stimulus) and noise (deviation from the average). Using linear regression, a mean of only 18.7% of the magnitude of the signal carried by one neuron could be predicted from the magnitude of the signal of the other neuron, and only 22.0% could be predicted by including the temporal modulation of the signal. For the noise, the figures were 5.5% and 6.3% respectively, even less than for the signal.

When we computed the information carried about a stimulus by a neuronal response for each neuron separately and for both considered jointly, we found that adjacent neurons carried information that was an average of only 25.6% away from pure independence, similar to the results seen with linear regression. There was no evidence for strongly synergistic codes.

If adjacent neurons had identical characteristics, and shared the same set of

inputs, then the noise on the outputs of these neurons would be highly correlated, and averaging the outputs would not reduce the signal to noise ratio. We propose that the independence of adjacent neurons both provides a rich description of many stimulus properties, and minimizes the amount of correlated noise, in a local group of neurons. These two principles may be a major constraint on the organization of inferior temporal, and possibly all, cortex

# 66.12

VISUAL RESPONSE PROPERTIES OF NEURONS IN THE TEMPORAL

VISUAL RESPONSE PROPERTIES OF NEURONS IN THE TEMPORAL POLE OF MONKEYS. K. Nakamura, K. Matsumoto, A. Mikamiand K. Kubota. Dept. of Neurophysiology, Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, Japan.

The visual response properties of neurons in the monkey temporal pole (area TG or area 36) were studied in monkeys (Macaca mulatta) by having the monkeys perform a visual discrimination task and a visual fixation task. fixation task. Neurons (n=121) responded well to complex visual stimuli (photographs of human faces, monkeys, food, etc.). However, since simple stimuli (a red circle, a green square, a white bar, etc.) elicited either no or little response (n=24), we were unable to determine properties of their receptive fields with conventional methods with conventional methods using moving or stationary bar stimuli on a display (24 deg height, 34 deg width). Onset latencies of responses ranged from 100 to 300 ms (mean+50, 163+43 ms). In most neurons, only a few stimuli elicited large responses. There was no noticeable effect on the stimulus-selective properties when the color of the visual stimulus was removed. Furthermore, even when only a portion of stimuli (for example, either a right or left half) was presented, the neuronal responses persisted. These findings the neuronal responses persisted. These findings suggest that the temporal pole neurons may be associated with cognitive process rather than with the extraction of some simple feature of visual stimuli, such as color or shape.

FOCAL SPATIAL ATTENTION SUPPRESSES RESPONSES OF VISUAL NEURONS IN MONKEY POSTERIOR PARIETAL CORTEX. M.A. Steinmetz\*, C.E. Connor and K.M. MacLeod, Bard Laboratories

of Neurophysiology, Dept. of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205

We tested the effects of focal spatial attention on the responses of visual neurons in cortical area PG of monkeys performing a spatial match to sample task. Animals were trained to fixate a central target light while directing their attention to a transiently cued spatial location and to respond by releasing a behavioral key when a stimulus appeared at the cued location. In each trial, 1-5 stimuli were presented in random order at fixed locations in a 80° dia. grid centered on the fixation point. The effect of varying the locus of attention was examined by comparing receptive field maps generated with the animal's attention directed toward different grid locations.

Neural responses to stimuli presented at a given location were weakest when the animal's attention was directed toward that location. This suppressive effect was usually confined to one grid location, but occasionally extended over larger regions of the receptive field. These results may explain the "foveal sparing" observed when parietal visual neurons are studied using fixation target dimming tasks, and may reflect a role for PVNs in reorienting attention towards novel stimuli appearing outside the current locus of attention. Supported by NIH RO1 EY09129.

## 66.15

A COMPETITIVE LEARNING MODEL OF THE NEURONS IN AREA 7A G. Ganis\* and K. Zhang. Dept. of Cognitive Science, UCSD, La Jolla, CA

A backpropagation model of how neurons in area 7a represent visual space in head coordinates was put forward in Zipser and Andersen (1988). Such a model was trained to transform retinal coordinates into head centered coordinates by combining retinal and eye position information. After training, the receptive field and spatial gain field of the hidden units were similar to those of 7a neurons. Similar results were obtained by Mazzoni et al. (1990) by using reinforcement learning. Both models have to use error signals for training the network. The objective of our study was to see whether it is possible to obtain similar results by using a biologically plausible hebbian-type learning. The procedure allows to control what the hebbian learning mechanism can learn by controlling the statistical structure of the input, which is similar to the 'errorless' competitive learning procedure discussed by Rumelhart and Zipser (1985). Such a control is achieved by adding a 'teaching' signal that is highly correlated with the features that have to be encoded by the weights. In our model, such teaching signal is provided by units tuned to head position like the ones which have been found in the hippocampus of primates (Rolls et al. 1991). The head position signal can induce a classification of the retinal position and eye position pairs according to a head-centered coordinate system. We found that the visual receptive fields obtained by keeping eye position constant often were very similar to the ones obtained by using backpropagation. We also found that the eye position signal often had a planar dependence on the fixation point (planar spatial gain fields). Finally, we examined the role of the teaching signal (head direction). We found

that the planar spatial gain fields developed even without any teaching signal. Supported by a Fellowship from McDonnell-Pew Center at San Diego. Thanks to M.I. Sereno and D. Zipser for help and advice.

# 66 17

VISUAL RESPONSE PROPERTIES OF SINGLE NEURONS IN POSTERIOR CINGULATE CORTEX OF RHESUS MONKEY. S.Y. Musil\*, C.R. Olson. and M.E. Goldberg. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892, and Department of Anatomy, University of Maryland at Baltimore, Baltimore, MD 21201.

Recent experiments in this laboratory have demonstrated that neurons in posterior cingulate cortex (CGp) of the rhesus monkey carry signals related to the amplitude and direction of saccadic eye movements and to the orbital angle of the eye. They are also sensitive to visual influences as indicated by the fact that eye-movement-related activity is less robust in darkness than in visible surroundings.

We have now investigated the visual response properties of neurons in CGp. We have found that CGp neurons can be driven by large textured stimuli although they do not respond phasically to the presentation of small (0.2°) dim spots even when they are targets for eye movements or shifts of attention. We tested neurons with a variety of visual stimuli varying in size, brightness and spatial frequency. Neurons responded phasically to visual stimuli at a level that increased monotonically with size and brightness. Response strength remained constant across large variations of spatial frequency as long as total luminance was held constant. Neurons responded to the onset or offset of the stimulus regardless of whether it was static or moving and the mean latency of visual responses was 68ms. Response strength depended only to a limited degree on visual-field location. In approximately half of visual neurons, responses could be elicited by presenting a strong stimulus at any location in the visual field.

We conclude that the size and brightness of visual stimuli, rather than pattern, movement or location, are the primary determinants of visual response strength in posterior cingulate cortex.

INTENDED MOVEMENT ACTIVITY OF AREA LIP NEURONS IN DELAYED DOUBLE SACCADE TASKS.
P. Mazzoni\*, R. M. Bracewell, S. Barash and R. A. Andersen

Department of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.
The lateral intraparietal area (LIP) of the macaque's posterior parietal cortex ntains neurons that maintain elevated activity during a delay before a saccade to contains returned in infilial netwated sectivity during a deary before a saccade to the remembered location of a visual target (memory saccade task). This directionally tuned "memory" activity could encode the location of the sensory stimulus or the plan to shift gaze towards it. These alternatives can be distinguished by examining the memory activity while the monkey prepares to make two saccades. Further studies of these neurons in a delayed double saccade paradigm support the hypothesis that the memory activity of most LIP neurons reflects the monkey's plan to make the next intended saccade.

Two targets are flashed briefly while the monkey maintains fixation; after a delay the fixation spot is extinguished and two saccades are made in sequence in darkness to the targets' remembered locations. Most LIP neurons are active in the delay period if the first movement is in the preferred direction. They are much less active if a stimulus appears in the receptive field but the impending saccade is in a nonpreferred direction, and least active if the second stimulus appears in the receptive field but neither saccade is in the preferred direction. In the case where only the second saccade is in the preferred direction, most LIP neurons fire in the period between the two saccades. This activity almost invariably appears tens or hundreds of milliseconds after the start of the first movement, consistent with the

sequence of motor plans in the monkey's behavior.

Many LIP cells are inhibited before memory saccades in the direction opposite their preferred one. We found that this inhibition also appears in the delayed double saccade task, almost exclusively when the next saccade is in the antipreferred direction. Thus LIP neurons maintain their directional tuning in the delay before two saccades, and their activity in general predicts the direction of the next saccade to be made.

RESPONSES OF INFERIOR TEMPORAL AND HIPPOCAMPAL NEURONS DURING AUDITORY-VISUAL AND VISUAL-VISUAL

DELAYED MATCHING-TO-SAMPLE IN MONKEYS.

M. Colombo\* and C. G. Gross, Dept. of Psychology, Princeton University, Princeton, NJ, 08540.

We recorded from 143 IT neurons and 67 H neurons in two monkeys trained to perform both AV and VV DMS tasks with a 5 sec delay. The auditory stimuli wore a birth from your town.

and VV DMS tasks with a 5 sec delay. The auditory stimuli were a high frequency tone and a burst of white noise and the visual stimuli were a 4-lobed pattern and a picture of a monkey face.

More H units (38.7%) responded during the delay than IT units (23.8%). In IT more of the delay units exhibited selective responding, that is, responses in the delay following one stimulus and not the other, whereas in H a greater number of delay units fired nonselectively. The mean absolute spike rate difference from baseline for the IT delay units was 1.75 spikes/sec, compared to 4.56 spikes/sec in H. In examining the correlation between performance (50-75% vs 75-100%) and the occurence of delay units, we found a 220% increase in the number of delay units in the higher performance bracket in IT compared to a 30% increase in H.

The significance of these results for claims of electrophysiological correlates of visual memory will be discussed.

RESPONSES OF SINGLE UNITS IN THE LSO-CIRCUIT TO AMPLITUDE MODULATED SOUNDS. P.X. Joris\* and T.C.T. Yin. Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI. 53706

Binaural cells of the lateral superior olive (LSO) are sensitive to interaural time differences (ITDs) of amplitude modulated (AM) sounds. They receive excitation from the ipsilateral ear through spherical bushy cells (SBCs) and inhibition from the contralateral ear from globular bushy cells (GBCs) relayed through an inhibitory neuron in the medial nucleus of the trapezoid body (MNTB). We compared responses to AM stimuli, in terms of synchronization R as modulation frequency fm and SPL were varied, from the neurons relaying input to the LSO, from LSO cells themselves, and from auditory nerve (AN) fibers.

Cells providing the contralateral input to the LSO showed stronger envelope phase-locking than AN fibers and SBCs of comparable CF. For both SBCs, GBCs, and MNTB cells the decline in R with SPL parallels that of AN fibers. Also the cutoff frequencies of the modulation transfer functions (MTFs) cover the same range as AN fibers. Group delays obtained from the slope of cumulated phase-fm functions were orderly with CF and cell type.

LSO cell responses to ipsilateral AM signals had R values that exceeded those of SBCs. When binaurally stimulated, with modulation of the signal in the contralateral ear only, LSO responses had higher R values than MNTB or GBC responses. On average, envelope synchronization of LSO resonses was less dependent on SPL than was the case for cells of the input pathways. For any given LSO cell the maximal R values and MTF cutoff frequencies for contra- and ipsilateral modulation were similar

These results suggest that the anatomical specializations in this circuit may have evolved to enable interaural time comparisons

## 67.3

FREE-FIELD STATIC AND DYNAMIC SOUND SELECTIVITY OF NEURONS IN PRIMARY AUDITORY CORTEX OF THE CAT. P. Poirier\*, H. Jiang, M. Ptito, F. Leporé, J.-P. Guillemot. Univ. de Montréal and Univ. du Québec, Montréal, Qc, H3C-3J7.

Electrophysiological studies using free-field or dichotic stimuli in the primary auditory cortex of cats have revealed the existence of neurons sensitive to sound-sources in space and to moving stimuli. Similarly, behavioral-ablation studies in the cat suggest that the integrity of primary auditory cortex (A1) is essential for coding contralateral and frontal sound-sources. We report here free-field analyses of the azimuthal selectivity using fixed-sound-sources and stimuli simulating movement in different directions. Azimuthal space representation was obtained from single units in A1 of anesthetized and paralyzed cats. Stimuli, consisting of broad band noise bursts were delivered randomly in a double-wall quasianechoic chamber via 16 loudspeakers each separated by approximately 10°. In the static condition, most cells responded to contralateral hemifield stimulation. However, some cells were strictly ipsilateral. Moreover, two types of omnidirectional cells were found: some responded maximally at all static positions; others showed a clear inhibition in the center of the frontal plane. In the dynamic condition, most cells preserved their azimuthal selectivities. However, a minority of cells responded only to the onset of the dynamic stimulus independent ly of their static azimuthal selectivity. In addition, some cells preferred auditory motion in only one direction (either toward the contralateral or the ipsilateral azimuthal postions). (supported by FCAR and CRSNG).

NEURAL CORRELATES OF INTERAURAL TIME PROCESSING IN THE AUDITORY EVOKED POTENTIALS OF THE BARN OWL. Q. Calvo and A. Moiseff\*. Dept. of Physiology and Neurobiology, Univ. of Connecticut, Storrs, CT

Studies have shown that the barn owl uses interaural time difference (ITD) to localize sounds in azimuth. The present study investigated the neural activity correlated with ITD processing using the brainstem auditory evoked potential (BAEP). In the owl, nucleus laminaris is the first structure where ITD processing takes place. We studied the changes in the short latency complex (first 2 to 6 msec) of the BAEP which is correlated with n. laminaris activity.

Barn owls were anesthetized with ketamine hydrochloride (4mg/kg). Digitized signals (one cycle sound wave) from 5 to 8KHz with ITD ranging from 0 to 1000 usec were delivered through earphones. Averaged BAEPs were recorded in response to monaural (left and right), binaural and spontaneous stimuli, respectively. The sum of the left and right monaural responses was subtracted from the binaural response. The binaural interaction revealed by this calculation was identified as a waveform peak that had a consistent shape.

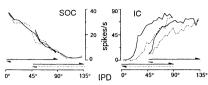

The latency of this binaural component increased by as much as 1 msec as the ITD

increased from 0 to 1000 µsec. The longest latencies were observed in response to ITD >400 µsec. The amplitude of the component decreased as ITD increased. Maximum amplitudes were observed in response to ITD >200 µsec. Finally, the duration of this component decreased as ITD increased. 1000 usec. These results indicate that binaural interaction that occurs at biologically relevant ITDs (i.e., 0-200 usec) can be distinguished from interactions at non-biological ITDs based on BAEPs. This technique provides a non-invasive method of essing ITD processing.

This study was supported by NIH NIDCD DC00277 to AM; OC is sponsored by LASPAU.

RESPONSES TO TIME-VARYING INTERAURAL PHASE DISPARITY IN GERBIL SUPERIOR OLIVE: EVIDENCE FOR HIERARCHICAL PROCESSING M.W. Spitzer\* and M.N. Semple. Dept. of Anatomy & Neurobiology, University of California, Irvine, CA 92717.

Interaural phase disparity (IPD) of low frequency tones is encoded by superior olivary complex (SOC) neurons, which provide a major source of binaural input to the inferior colliculus (IC). For most IC units, the response associated with a given IPD depends on the direction and range of IPD modulation (right), indicating sensitivity to temporal

stimulus features (Spitzer & Semple '90 Soc. Neurosci. Abst. 16: 299.17). Responses to timevarying IPD stimuli were recorded 135° from single units in SOC of anesthe-

tized gerbils. Recording sites were localized histologically with respect to SOC subnuclei. For most SOC units, responses to IPD modulations are symmetric for both directions and contiguous for overlapping ranges (left), indicating insensitivity to temporal stimulus features. These data suggest a hierarchy in which initial encoding in SOC yields a faithful representation of instantaneous IPD. Higher order processing in IC generates sensitivity to changing IPD (Supported by NIDCD grant DC 00364).

# 67.4

NONLINEAR RESPONSES OF SINGLE UNITS IN THE BARN OWL INFERIOR COLLICULUS TO CONTINUOUSLY VARYING INTERAURAL PHASE AND INTENSITY DIFFERENCES. J. Wang\* and A. Moiseff, Dept. of Physiology and Neurobiology, Univ. of Connecticut, Storrs, CT 06269.

Sound stimulus delivered through earphones with changing interaural phase and intensity disparities (IPDs and IIDs) mimics to some degree a moving sound source. We recorded single units extracellularly in the central nucleus of the inferior colliculus of anesthetized barn owls in response to continuously varying IPDs generated by a of ancesticutzer usin owis in response to continuously varying tros generated by a binaural beat (with a few Hertz difference between left and right ears) and continuously varying IIDs generated by a biphasic ramp, as well as to static IPDs and IIDs.

These units commonly demonstrated clear left-right asymmetry to binaural beat stimuli in which a unit showed higher overall sensitivity either when the left frequency

stimuli in which a unit showed higher overall sensitivity either when the left frequency was higher or when the right frequency was higher. These units also showed progressively higher overall firing rates as the beat frequency was increased progressively. The results suggest possible involvement of the neurons in encoding direction (left vs right) and velocity of moving acoustic sources. Responses of these direction-sensitive units showed the following significantly different features in comparison with their responses to static IPDs. First, the IPD tuning curves to dynamic stimuli were much sharper than those to static stimuli (the sharpness defined as IPD bandwidth at 50% maximum discharge rate). Secondly, dynamic stimulus also introduced a large shift in best IPD (the IPD) at the programs, fring rate, with person. introduced a large shift in best IPD (the IPD at the maximum firing rate) with respect to the best IPD under static stimulus conditions. Finally, the maximum discharge rates within an IPD cycle (from -180 to 180 degrees) under dynamic stimulus conditions were higher than under static conditions. In response to continuously varying IIDs, these units each showed a preference to one of the four IID-varying modes (increasing or decreasing IID from left to midline, increasing or decreasing IID from right to midline).

All these nonlinear response properties suggest that these neurons are well suited for processing relative changes in IPDs and IIDs thus they could encode direction and Proceeding to the control of the control of the control of a moving acoustic source crossing a restricted spatial location. FORWARD MASKING PROPERTIES OF NEURONS IN THE DORSAL COCHLEAR NUCLEUS. <sup>1</sup>J.A. Kaltenbach\*, <sup>2</sup>R.J. Meleca, and <sup>1</sup>P. Falzarano <sup>1</sup>Dept. of Audiol., <sup>2</sup>Dept. of Otolaryngol., Wayne State Univ., Detroit, MI 48201

<sup>1</sup>Dept. of Audiol., <sup>2</sup>Dept. of Otolaryngol., Wayne State Univ., Detroit, MI 48201
Forward masking is defined psychoacoustically as a reduction in the audibility of a sound (a probe) which results when that sound is preceded by another sound (a masker). When two sounds occur close together in time the degree of forward masking can provide some measure of the temporal resolution of the auditory system. Previous studies indicate for example, that the response to a sound can be suppressed for periods of up to 250 milliseconds following a masking sound. However, the degree of masking is dependent on both the delay interval as well as the degree of spectral overlap between the masker and the probe. In an effort to describe these spectral and temporal aspects of forward masking neurophysiologically we tested the response of neurons in the DCN of hamsters to probe tones as a function of both the frequency of rons in the DCN of hamsters to probe tones as a function of both the frequency of and time delay following a masker tone. The probe tone was a 10-20 msec tone burst set at CF while the masker was a 30 msec tone varied between 3 and 32 kHz. Both the probe and masker were held constant at 70-80 dB; for each masker frequency the delay between masker and probe was varied between 0 and 500 msecs. The response to the probe was plotted as a bar whose height was proportioned to the number of impulses counted during the period of the probe tone stimulus. The results indicate that the DCN displays a variety of forward masking effects. In some cases the response to a probe is suppressed (i.e. bar heights = 0) over a frequency range which response to a probe is suppressed (i.e. bar heights = 0) over a frequency range which diminishes systematically with increasing delay reaching a well-defined peak at some specific frequency. In others, the masking effect appears as a more circumscribed patch of suppression within the frequency vs. delay space, and many began after 20-30 msecs following masker offset. In either case the frequency at which the response is suppressed over the widest range of delays corresponds to the CF of the masker, and this appears to be independent of the probe frequency, provided the latter falls within the unit's response area. For most neurons the response to the probe can be suppressed out to 250 msecs, although a few can be suppressed out to 500 msecs. Much of this masking appears to be centrally mediated since the bandwidth of suppression commonly exceeds the bandwidth of the neurons response area. pression commonly exceeds the bandwidth of the neurons response area

SPECTRAL INTEGRATION IN TYPE IV UNITS OF DORSAL

SPECTRAL INTEGRATION IN TYPE IV UNITS OF DORSAL COCHLEAR NUCLEUS (DCN): LINEAR AND NON-LINEAR MECHANISMS. I. Nelken, E.D. Young, and B.J. May\*. Center for Hearing Sciences, Johns Hopkins Sch. of Med., Baltimore, MD 21205.

Type IV units in DCN are suppressed by tones, but excited by wide band noise. This fact suggests that nonlinear spectral integration mechanisms are in operation in the DCN. We studied these mechanisms using a variety of stimulus combinations including single mechanisms are in operation in the DCN. We studied these mechanisms using a variety of stimulus combinations, including single tones, pairs of tones, noise bands, pairs of noise bands, and band-reject noise. Our goal was to understand how the inhibitory response to

noise. Our goal was to understand now the inhibitory response to narrow band stimuli becomes excitatory with wide band stimuli.

At low signal level (<10-20 dB re threshold), type IV units sum stimulus energy across frequency in an approximately linear fashion. Narrow noise bands produce the same response as equal-energy tones and the response to a wide band noise can be constructed by adding the response to a band-reject noise and the response to a complementary response to a band-reject noise and the response to a complementary noise band. At higher signal level, nonlinear mechanisms become important and these equivalencies no longer hold. The nonlinearity is demonstrated by facilitatory responses to two-tone stimuli, in which a unit is inhibited less by a two-tone stimulus than by each tone individually. Responses to noise bands show the same effect in that high-level noise bands inhibit units less than equal-energy tones

These data are used to estimate parameters of linear and non-linear models of energy summation from which predictions are made of responses to other complex stimuli. These results form a basis for the study of complex auditory neurons which promises to provide predictive models of neurons' input/output characteristics.

RESPONSES OF SINGLE UNITS IN THE DORSAL NUCLEUS

RESPONSES OF SINGLE UNITS IN THE DORSAL NUCLEUS OF THE LATERAL LEMNISCUS AND PARALEMNISCAL ZONE OF AN ECHOLOCATING BAT. E. Covey\*. Department of Neurobiology, Duke University, Durham N.C. 27710

Connectional evidence suggests that the dorsal nucleus of the lateral lemniscus (DNLL) and the paralemniscal zone (PL) play a role in binaural analysis. Responses of neurons in DNLL and PL were characterized in the echolocating bat Eptesicus fuscus, by presenting sounds monaurally or binaurally to awake animals, and recording responses of single neurons. Binaural responses were not evenly distributed within DNLL. Caudally, 86% of neurons tested were binaural: rostrally, 69% were monaural. This difference suggests binaural; rostrally, 69% were monaural. This difference suggests that the rostral area is a separate functional subdivision, termed here the dorsal paralemniscal zone (DPL). Many binaural neurons in DNLL had complex response functions with inhibition at some interaural sound level differences and facilitation at others, suggesting restricted spatial receptive fields. In DNLL, DPL and PL, neurons with similar best frequencies were clustered together in a mosaic pattern rather than forming a precise tonotopic map.
Discharge patterns in DNLL included phasic, sustained, and chopper types; in DPL, most units were phasic. In PL, the most common discharge pattern was the sustained type. When DNLL neurons were tested with pairs of tones, 26% showed a facilitated response to the second tone, with maximal facilitation at specific delays. Supported by NIH grant DC-00607.

ROLE OF VENTRAL COCHLEAR NUCLEUS IN EYEBLINK CONDITIONING TO AN ACOUSTIC CS IN CONSCIOUS CATS. X.F. Wang, C.D. Woody and E. Gruen. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA

Recordings made from a total of 393 units of the ven-Recordings made from a total of 393 units of the ventral cochlear nucleus showed short latency responses characterized by brief increases in discharge to 70 db click and hiss stimuli. After blink conditioning produced by forward pairing of click as CS with glabella tap and hypothalamic electrical stimulation (570-10ms ISI, see Hirano et al., Br. Res. 1987), followed 2.4 s by hiss as DS, the magnitude of response to both CS and DS increased. After pseudoconditioning, with the UCS preceding the CS, even greater increases occurred.

The results indicate that adaptations occur which pro-

The results indicate that adaptations occur which promote transmission of auditory signals by neurons of the ventral cochlear nucleus. Although the behavior changed after conditioning to support discriminative elicitation of a blink CR by the forward paired acoustic stimulus, the activity at the ventral cochlear nucleus changed with sensitization and did not depend as the behavior on the order of pairing. In contrast the activity of neurons of the dorsal cochlear nucleus depended on the order of pairing and changed in such a way as to support discrimination of and changed in such a way as to support discrimination of the CS from the DS.

FM PROCESSING IN CAT PRIMARY AUDITORY CORTEX (AI): TIMING OF NEURONAL DISCHARGES. P. Heil\*, R. Rajan and D.R.F. Irvine. Dept. of Psychology, Monash University, Clayton, Vic 3168, Australia.

Neurons in cat AI are sensitive to the rate of frequency change (RCF) of frequency-modulated (FM) sweeps. As sweeps of different RCF also differ in their long-term frequency spectra, it is conceivable that spectral rather than temporal sensitivity might underlie the RCF sensitivity of many neurons in AI. To solve this issue the timing of discharges to FM sweeps was analyzed in AI of barbiturateanesthetized cats. Sweeps had a fixed modulation range that included the entire

excitatory frequency response area (EFRA) of the neuron.

In each case (N=350), plots of response latencies to sweeps of different linear RCF for a given direction of modulation versus sweep duration were optimally fitted by a straight line, intersecting the ordinate at a value near the neuron's response latency for high-level characteristic-frequency (CF) tones. Thus, discharges of a given neuron to unidirectional sweeps of different RCF were initiated at the same instantaneous frequency (effective F<sub>i</sub>; derived from the slopes of the linear regressions). In contrast, effective F<sub>i</sub>s were always lower for upward than for downward sweeps, although such sweeps had identical long-term spectra. Discharges were evoked only when the frequency was modulated towards CF and not when modulated away from it, and were initiated before the modulation reached CF. Also, effective F<sub>1</sub>s were unaltered by changes in modulation range, as long as the beginning and ending frequencies fell outside the neuron's EFRA.

These data are incompatible with the idea that sensitivity to the long-term

frequency spectra of FM signals might underlie RCF sensitivity in Al. Further, and in contrast to FM rate and directional sensitivity, the timing of FM discharges of neurons in AI largely reflect properties of auditory-nerve fibers (Sinex, D.G. and Geisler, C.D. Hearing Res.4:127-148, 1981). Supported by the NHMRC of Australia and a Feodor-Lynen scholarship of the Alexander von Humboldt-Stiftung to P.H.

## 67.10

NEURAL PROCESSING BY THE COCHLEAR NUCLEUS. J. R.D. Frisina\*. Otolaryngology Div., Univ. of Rochester Med. Ctr., Rochester, NY 14642-8629.

A crucial first step to auditory processing is to extract signals from background noise. One method is to improve signal-to-noise ratios in higher auditory centers as compared to the auditory nerve. Two mechanisms by which some cochlear nucleus (CN) unit types improve signal gain are: 1) by decreasing a unit's average firing rate in the presence of noise as compared with quiet and 2) by increasing a unit's synchrony in the presence of noise as compared with quiet. It is hypothesized that these mechanisms coexist in cells which receive inhibitory inputs, are unrelated, and are a function of different features of CN cells. The average-rate mechanism may be due to auditory spectral processing and thus a function of off-best frequency (BF) inhibitory input. The synchrony mechanism may be due to auditory temporal processing and thus a function of dendritic and postsynaptic membrane parameters. These mechanisms are being investigated by studying the physiology and anatomy of the CN unit types which receive inhibitory inputs, and by simulating their responses in computer models designed to emulate the neurons. DYNAMIC FREQUENCY TUNING OF CAT AUDITORY CORTICAL NEURONS. H.R. Dinse\* and C.E. Schreiner. Dept. Neuroinformatic, Theoretical Biology, Ruhr-Univ. Bochum, RUB, D-4630 Bochum and Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

We investigated the time dependence of frequency tuning in AI of Pentobarbiturate anesthetized cats. Auditory stimuli consisted of tone bursts of 50 to 200 ms duration and were presented via calibrated headphones. Data analysis was based on PSTHs. Tuning curves (frequency-intensity plots) were constructed on the basis of presentations of at least 10 frequencies around the CF at 10 different sound levels. Time dependence was analysed by time-slice technique, i.e. by computing sequences of frequency-intensity plots for successive time steps. In addition, frequency-time plots were computed for neuron responses recorded at given sound levels. Very similar to what was described for the visual system (Dinse et al. (1990), CINS 1:199), the sequences of tuning curves revealed substantial evidence for a profound time dependence of frequency tuning in auditory cortex. Sharpness of tuning increased over time and the overall shape of the tuning characteristics changed. In the frequency-time plots, frequency transitions from low to high frequencies, or vice versa became apparent. The time scale of these dynamics was in the range of 30 to 50 ms, 3 to 5 times faster than in the visual system. The results are discussed in respect to possible benefits of dynamically based processing of inherently time-variant signals. In addition, comparison between both modalities offer a unique way of differentiating modality specific modes of processing from those that are biased by constraints of cortical architecture and cortical processing principles.

IN VITRO ANALYSIS OF SYNAPTIC INTEGRATION IN THE MEDIAL SUPERIOR OLIVE. B. Grothe\* and D. H. Sanes. Center for Neural Science, New York Univ., New York, NY 10003. The medial superior olive (MSO) is known to be involved in processing interaural time differences, largely due to the coincidence-detection of excitatory inputs from each ear. However, there is now strong anatomical evidence for inhibitory afferents to MSO neurons in all investigated mammals and a clear inhibitory influence on response patterns in the mustache bat's MSO (Grothe et al., PNAS; 1992). Therefore, we investigated the synaptic integration in vitro, using a gerbil Therefore, we investigated the synaptic integration in vitro, using a gerbil (Meriones unguiculatus) brain slice preparation (Sanes, J Neurosci 10; 3494, 1990). Electrical stimulation of either afferent pathway produced an excitatory response that was usually sufficient to evoke an action potential. The latency of synaptically evoked action potentials was level dependent and decreased up to 1 ms with increasing stimulus intensity. The ability to synaptically evoke an action potential during the refractory period was also level dependent. Although these response characteristics can be explained by excitatory interactions, there were clear inhibitory potentials evoked by both ipsilateral and contralateral stimulation. As potentials evoked by obtripstateria and contratateria stinituation. As monolaterial stimulus intensity was increased, the inhibitory influences became more prominent, and finally blocked the evoked action potential. In addition, action potentials and excitatory postsynaptic potentials could be reversibly blocked by delivering the inhibitory transmitter glycine. be reversibly blocked by delivering the inhibitory transmitter glycine. Since these level dependent effects not only influence the probability of an action potential occuring, but also determine the timing of the MSO output, these results have implications for the processing of interaural time differences at higher levels. SINGLE TRIAL AUDITORY MAGNETIC EVOKED FIELDS. J. Stocker, M. Reite\*, P. Teale. Neuromagnetism Laboratory, Dept. of Psychiatry, Univ. of Colo. Health Sciences Center, Denver, CO 80262.

We recorded left anterior (from near the ingoing extrema) auditory evoked fields (EF) and simultaneous C2 evoked potentials (EP) from 7 normal subjects using a 7 channel gradiometer. Stimuli were 20 sec duration 1 kHz tone pips delivered at an ISI ranging from 1100 to 2000 msec. Individual single MEG trials were examined for obvious visual evidence of the 100 msec latency M100 component in that trial, and categorized as yes (obvious single trial response at M100 latency) or no (no apparent response in single trial). Approximately 25 to 50% of single MEG trials contained obvious evoked responses in each subject. No apparent latency variation

was noted. No EEG trials contained obvious N100 responses.

Averages of 25 MEG single trials containing obvious responses produced M100 components with amplitudes ranging from -408 to -730 femptoTesla (fT). Averages of 25 MEG trials containing no apparent responses produced same latency M100 components with mean amplitudes ranging from -36 to -292 fT. Paired t-tests showed the two groups to differ at p<.001. Averages of the corresponding two N=25 EEG trials recorded simultaneously produced N100 components whose amplitudes were the same, and independent of M100 amplitude. The two groups did not differ by paired t-tests.

These findings suggest MEG recordings contain fundamentally different information about temporal lobe auditory processing than do vertex recorded auditory EPs. Supported by USPHS MH47476.

MECHANISMS UNDERLYING THE RESPONSE OF NEURONS IN THE CHICK N. MAGNOCELLULARIS TO STIMULUS TRAINS. Reyes, A.D.,

CHICK N. MAGNOCELLULARIS TO STIMULUS TRAINS. Heyes. A.D.. Spain. W.J\*., and Rubel, E.W. Bloedel Hearing Research Center, University of Washington, Seattle, WA. 98195 and The Seattle VA Medical Center. Neurons of the Nucleus Magnocellularis (NM) relay information about the frequency and timing of auditory stimulus from the VIIIth nerve to higher centers in the chick auditory system. We are interested in the membrane properties of NM neurons that underlie this process.

NM neurons that underlie this process.

Whole cell recordings were performed in transverse slices (50 - 70µm, 37°C) of the chick brainstem containing NM. Patch electrodes were guided onto the cells with the aid of Nomarski optics. Trains of brief (0.1 - 0.4ms), suprathreshold current pulses were injected into the cell at 50 to 500 Hz to mimic the arrival of synaptic current from VIIIth nerve afferents.

The ability of NM neurons to generate action potentials at the stimulus frequency was assessed by dividing the number of evoked action potentials by the number of current pulses in the train. The ratio of action potentials to current pulses decreased to less than 1 at stimulus rates greater than 200 Hz (ratio = 0.5 at 500 Hz). The action potentials were not randomly distributed throughout the stimulus train but occurred in regularly spaced clusters. Substitution of MnCl2 for CaCl2 in the extracellular solution (0 Ca solution) reduced the ratio of action potentials to current pulses to about 0.3 at all stimulus frequencies. In addition, the clusters of action potentials were more widely frequencies. In addition, the clusters of action potentials were more widely spaced. The spikes appeared to remain phaselocked to the current pulses.

There was no change the input conductance and in action potential amplitude, duration, threshold, and afterhyperpolarization.

In voltage clamp, depolarizing steps from -60 mV evoked a fast activated, potassium current (threshold about -55 mV). Perfusion with the 0 Ca solution blocked a persistent component of the potassium current with an activation threshold at about -40 mV.

These data suggest that a Ca<sup>2+</sup> dependent K+ current may be important for sustaining discharge rate of action potentials during rapid VIIIth nerve volleys.

IN TONOTOPIC ORGANIZATION OF AUDITORY CORTEX (AI) OF C57BL/6J (C57) MICE ASSOCIATED WITH SENSORINEURAL HEARING LOSS J. F. Willott\*,

WITH SENSORINEURAL HEARING LOSS J. F. Willott\*, L. M. Aitkin, and S. L. McFadden. Northern Illinois Univ., DeKalb, IL 60115.

AI was physiologically mapped in anesthetized C57 mice by measuring thresholds for tone-evoked multiple-unit activity. Adult C57 mice exhibit sensorineural hearing loss beginning with very high frequencies (>40 kHz) by 2-3 mo. and progressing to lower frequencies (>20 kHz by 6 mo.). One-mo.-old mice exhibited tonotopic organization with high frequencies represented mo.). One-mo.-old mice exhibited tonotopic organization with high frequencies represented dorsocaudally, low frequencies rostroventrally, and middle frequencies (10-20 kHz) in between. As high frequency sensitivity was lost, characteristic frequencies (CFs) in the 10-13 kHz range became more numerous. In 2- and 3-mo-olds these were largely confined to the "middle" region of AI; in 6- and 12-mo.-olds, many units in the dorsal region now had CFs in this range. Because of the "proliferation" of responsiveness to middle frequency tones (for which age-related threshold shifts were minimal), the mean CF threshold for AI units showed little change despite severe loss of sensitivity for high frequencies. frequencies.

INTRACELLULAR RECORDINGS FROM OCTOPUS CELLS IN COCHLEAR NUCLEI OF MICE IN SLICES. N.L. Golding, D. Robertson, R.E. Wickesberg, D. Oertel. Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53711.

Octopus cells of the posteroventral cochlear nucleus carry acoustic information from the cochlear nuclei to the lemniscal nuclei forming one of the parallel pathways out of the cochlear nuclear complex.

We made intracellular recordings from identified octopus cells in slice preparations of the mouse cochlear nuclei. Results from cells injected intracellularly with biocytin revealed large dendrites that typically were oriented perpendicular to the path of auditory nerve fibers. These cells had large axons that could be followed in some cases into the stria of Monokow. Eight of the ten axons that were traced into the stria of Monokow had collateral branches. Of these, five had collaterals in the octopus cell area, four in the granule cell lamina and one in the deep layer of the dorsal cochlear nucleus. Shocks of variable strength to the auditory nerve root evoked EPSPs that were finely graded in amplitude and probably result from the convergent input from many auditory nerve fibers. EPSPs were monosynaptic and brief, with latencies of 0.7 ± 0.1 msec (mean ± SD) and durations of 1.2 ± 0.4 msec (mean ± SD). Inhibitory synaptic inputs were not observed. Input resistances did not exceed 25 Ma and

action potentials recorded in the cell body were small.

The dendritic orientation, the brief and finely graded EPSPs, and the intrinsic electrical properties suggest a role in detecting the coincidence of auditory nerve inputs, and accounts for the precisely timed action potentials at the onset of acoustic stimuli.

RESPONSE PROPERTIES OF SINGLE NEURONS IN THE VENTRAL COCHLEAR NUCLEUS OF AN ECHOLOCATING BAT: COMPARISON WITH HIGHER LEVELS. S. S. Haplea, J. H. Casseday\* and E. Covey. Department of Neurobiology, Duke University, Durham, NC 27710.

Neurons in the ventral nuclei of the lateral lemniscus (VNLL) and the inferior colliculus (IC) of the big brown bat, Eptesicus fuscus, exhibit specializations for analysis of temporal patterns and for fine frequency discrimination. As a first step in determining the origin of these specializations, we recorded from single neurons throughout the anteroventral cochlear nucleus (AVCN) and the posteroventral cochlear nucleus (PVCN) of this species. All neurons in AVCN and PVCN had V-shaped tuning curves. PVCN neurons were more broadly tuned to frequency (average Q10dB of 6.4) than were AVCN neurons (average Q10dB of 10.1); ventral cochlear nucleus (VCN) neurons with phasic discharge patterns were more broadly tuned to frequency (average Q10dB of 4.3) than all other response classes. No level-tolerant filters of the type seen in the IC were present, and no neurons in AVCN or PVCN were as broadly tuned as those in parts of the VNLL. These data indicate that the sharpening or broadening of tuning curves seen at higher auditory levels does not originate exclusively in AVCN or PVCN.

For virtually all neurons in AVCN and PVCN, latency varied as a function of

For virtually all neurons in AVCN and PVCN, latency varied as a function of round frequency or amplitude. However, some neurons in PVCN resembled neurons in the columnar division of VNLL (VNLLc) in that they were more broadly tuned than other neurons in the cochlear nucleus, had phasic discharge patterns, had little or no spontaneous activity, and at best frequency, their avertage latency was small (<0.15 msec). However, their avertage latency varied as a function of frequency or amplitude. In contrast, the latency of VNLLc neurons remained constant over large variations in frequency or amplitude. These data suggest that phasic neurons in PVCN may be an input stage from which temporal resolution is increased in the lateral lemniscus. Research supported by NIH grants DC-00607 and DC-00287.

TEMPORAL AND SPECTRAL CONTRIBUTIONS TO DELAY SENSITIVITY IN AN FM BAT. W. G. Paschal\* and D. Wong. Dept. of Anatomy, Indiana Univ. Sch. of Med., Indianapolis, IN. 46202

Delay-sensitive neurons in the auditory

Delay-sensitive neurons in the auditory cortex of Myotis lucifugus exhibit facilitative responses to pulse-echo pairs at specific delays. In a previous study, the essential echo quarter (EEQ) was determined by dividing the echo (60 kHz in 4 ms) into four equal quarters (15 kHz in 1 ms). These quarters were presented at the same temporal relationships as found when the entire echo was presented at best delay. This study examined how the delay between pulse and EEQ and how the echo frequencies affected facilitation. When presenting the EEQ in the temporal position of the first quarter (or best delay), a decrease in half of the maximum response was observed. Non-EEQs presented in the temporal position of the EEQ did not evoke facilitation. These results demonstrate that not only are specific delays but also that the frequencies found within EEQs were both important for facilitation. By narrowing the FM sweeps of EEQs, the exact frequencies sufficient for maximum facilitation were found to average 8 kHz. These results may provide insight into the temporal and spectral contributions of delay sensitivity.

NEURAL MECHANISM OF DELAY SHIFT WITH AMPLITUDE VARIATION IN DELAY-SENSITIVE CORTICAL NEURONS OF Myotis lucifugus. H. Teng\* and D. Wong, Dept. of Anatomy, Indiana University School of Medicine, Indianapolis, IN 46202

A previous study showed that delay-sensitive cortical neurons were tuned to best echo delay (BD) and best facilitation amplitude (FA) combination. Neurons were categorized into three classes according to how amplitude variation affected the BD. Over the entire range of FAs, delay-shift neurons systematically changed their BD, whereas delay-tuned neurons had a constant BD. Limited delay-shift neurons had a constant BD in a limited FA range, but shifted their BD at the upper and/or lower FAs. This study examined the neural mechanism underlying the BD shift.

Neurons shifted to shorter BD when pulse and echo amplitudes approximated each other, and to longer BDs at relatively high pulse FA or low echo FA. A delay shift often corresponded to a change in response latency which in turn corresponded to the amplitude used. This suggests that the amplitudes in pulse-echo pairs determine delay-tuning of individual neurons. The fact that facilitation latencies to the pulse-echo pairs correlated to latencies to individual sounds of the pair indicates that the synchronization of pulse and echo excitation is the mechanism of facilitation at the BD shift. This study provides further evidence of parallel amplitude channels in the auditory system of this FM bat.

EFFECTS OF FLUOROCITRATE AND CHEMICAL HYPOXIA ON ASTROCYTE FUNCTION IN VITRO. R.A. Swanson\* and S.H. Graham. Dept. of Neurology, Univ. of California San Francisco and V.A.M.C., San Francisco, CA 94121.

Fluorocitrate (FC) and fluoroacetate (FA) inhibit

Fluorocitrate (FC) and fluoroacetate (FA) inhibit the Krebs cycle enzyme aconitase and thus inhibit oxidative metabolism. These agents have been used in vivo to inhibit glial metabolism. We examined the effects of these agents and of the mitochondrial poisons sodium azide (AZ), antimycin A (AA), and 2,4 dinitrophenol (2,4DNF) on glutamate uptake and glutamine production in primary rat cortical astrocyte cultures. After 3 hours pre-incubation with these agents <sup>3</sup>H glutamate uptake was determined by measuring <sup>3</sup>H accumulation during 7 minutes incubation with 20uM unlabeled glutamate in Hank's solution, pH 7.2, 37C. In 5 trials, 25mM AZ, 10ug/ml AA, and 1mM 2,4DNP each reduced uptake by 10-25%.

Glutamine accumulation in the media was determined by HPLC after incubating cultures for 6 or 24 hours with the inhibitors plus 20uM glutamate. In 2 experiments 25mM AZ and 10ug/ml AA each reduced glutamine production by 75%, while 25mM FA and 1mM FC had no effect. No cell death resulted from incubation with the inhibitors for 48 hours. These findings suggest that (1) astrocytes in vitro can survive by glycolysis alone; (2) these astrocyte functions are only partially inhibited by blockade of oxidative metabolism; and (3) FC and FA cause a relatively weak inpairment of these astrocyte functions in vitro.

CHANGES OF CEREBRAL MICROVASCULAR HEMODYNAMICS BY ISOVOLEMIC HEMODILUTION. Shinn-Zong Lin\*, Div. Neurosurgery, NDMC & TSGH, Taipei, Taiwan, ROC.

Changes of local cerebral microvascular hemodynamics by isovolemic hemodilution were investigated in adult Wistar-Kyoto rats. Local cerebral blood flow (LCBF), and microvascular red blood cell (M-RBC) and plasma (M-P) volumes in 14 brain structures were measured using 14C-IAP, 55Fe-labeled RBC's, and 14C-inulin, respectively. The results showed that in the control group the cerebral microvascular hematocrits (mHct) were 26-40% with mean of 35%, which was 69% of the mean systemic hematocrit (sHct = 51%); mean transit time of blood (Tb) through cerebral microvessels were 0.63-1.82 sec with mean of 0.94 sec; transit time of red cells (Tr) were 0.45-1.17 sec with mean 0.64 sec; and transit time of plasma (Tp) were 0.8-2.5 sec with mean 1.26 sec. In the hemodilution group, the mean mHct was 28%, which was 88% of the sHct (32%); LCBF's of the 14 areas were about 60% higher than those of the control animals; Tb was 0.62 sec (66% of the control group); Tr was 0.54 sec (84% of the control); Tp was 0.66 sec (52% of the control). These results indicate that isovolemic hemodilution results in a marked increase in the plasma (not RBC) flow velocity in cerebral microvessels, by which LCBF is increased. The increase in the plasma flow velocity may lower the extraction fraction of glucose and increase the clearance rate of waste products in the brain. Therefor, hemodilution may be feneficial for cerebral ischemia.

# 68.3

INITIAL CONCENTRATION OF BRAIN FREE GLUCOSE DETERMINES RATE OF ISCHEMIC GLUCOSE DISAPPEARANCE FOLLOWING RAPID BRAIN EXTRACTION IN RATS.
T.A. Tishler, B.E. Stoller, J.L. Williams, M.D. Jarvik', and W.H. Oldendorf. Neuroscience Laboratory, Veterans Administration Medical Center, West L. A., Los Angeles, CA 90073. Six groups of male Sprague-Dawley rats were studied for brain free glucose

Six groups of male Sprague-Dawley rats were studied for brain free glucose concentrations present 5 sec. and 30 sec. after bisecting-decapitation. Group 1 was a control group and was untreated prior to decapitation. Group 2 was fasted prior to decapitation, but was otherwise untreated (the other five groups received food ad libitum). Group 3 received i.p. dextrose, 5% in water, 15 min. prior to decapitation. Group 4 received i.v. phioretin, 150 mg/kg, 4 min. prior to decapitation. Groups 5 and 6 received pentobarbital, 50 mg/kg i.p., 10 minutes before bisecting-decapitation. In order to maintain a normal body temperature of 37°C group 5 was externally warmed. Group 6 was not externally warmed and was studied at a hypothermic body temperature of 34°C.

At time of sacrifice, the rat head is simultaneously bisected and decapitated. Details of the method have been described (Oldendorf & Stoller, 1991; Oldendorf, Stoller, Tishler & Williams, 1992). Each half of the in situ brain is aspirated under -250 Hg pressure into a modified small plastic syringe (3 ml) and then extruded through a needle (20 g.) as a fine strand into a multidose sealed vial containing a relatively large volume (10 ml) of 2 M urea at 95°C. This extrusion into the 2 M urea takes place 5 seconds (first brain half) or 30 seconds (second brain half) after bisecting-decapitation. After cooling, sonication, and centrifugation of the brain homogenate, the supernatants are measured enzymatically for brain free glucose concentrations. An ischemic glucose disappearance rate was calculated from each pair of brain halves for each rat.

Results indicate the ischemic glucose disappearance rate is proportional to the concentration of glucose present in brain at time of bisecting-decapitation.

CORTICAL CEREBRAL BLOOD FLOW (CBF) IS STEREOSELECTIVELY ENHANCED BY (+)2-METHYLPIPERIDINE: A MODULATOR OF CENTRAL NEURONAL NICOTINIC RECEPTORS J.L. Raszkiewicz\*, J.W. Turek, and S.P. Arneric. Neuroscience, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL 60064-3500

IL 60064-3500

This laboratory has shown that activation of basal forebrain (BF) neurons elicits marked increases in cortical CBF which are mediated in part by neuronal nicotinic receptor interactions (Linville & Arneric, Neurobiol. Aging 12:503, 1991). Previous work suggested that (+)2-methylpiperidine [(+)2-MP] is a putative positive allosteric modulator of brain receptors labelled by [3+] plicotine (Sloan et al., Life Sci. 37:1367, 1985), since it increased the specific binding of [3+] nicotine. This study sought to determine whether the nicotinically mediated increases in cortical CBF can be further enhanced by a positive allosteric modulator of brain nicotinic receptors.

Male Stragule-Dayley rats (3.5 months) were anesthetized (urethane 1.5).

Male Sprague-Dawley rats (3-5 months) were anesthetized (urethane 1.5 g/kg, s.c.), paralyzed (d-tubocurarine, 0.6 mg/kg, i.m.), and arterial blood gases controlled. Changes in microvascular perfusion were monitored in the fronto-parietal cortex (1.0-2.5 mm rostral: 2.0-3.0 mm lateral to bregma) using laser-doppler flowmetry. The BF received unilateral electrical microstimulation (100 μA; 2 msec pulses; 10 sec. trains) at 12.5, 25 and 50 Hz. Dose response curves were generated following iv. administration of (+)2-MP or (-)2-MP [0.01 - 10 mg/kg] and compared to saline control. (+)2-MP enhanced both the resting (100 ± 10 to 146 ± 28 % control) and BF-elicited increases in cortical CBF (@ 25 Hz: 153 ± 11 to 222 ± 23 % of resting CBF) while modestly increasing mean arterial pressure (MAP) from 76 ± 3 to 92 ± 7 mmHg at 1.0 mg/kg (N=5). In contrast, (-)2-MP appeared to diminish resting CBF, BF-elicited increases in cortical CBF and MAP (N=3).

CONCLUSION: Nicotinic transmission linked to BF neurons regulating

<u>CONCLUSION</u>: Nicotinic transmission linked to BF neurons regulating cortical CBF is stereoselectively enhanced by (+)2-MP.

ENDOTHELIN-INDUCED VASOCONSTRICTION IN BRAIN SLICES: INHIBITION OF ACUTE AND TONIC CONSTRICTION. O. Sagher, W. Szeto, X-Q. Zhang, N.F. Kassell and K.S. Lee\*. Dept of Neurosurgery. Univ. of Virginia, Charlottesville VA 22908.

Cerebral vessels were studied in submerged, in vitro, brain slices using computerized videomicroscopy. cerebrospinal fluid (ACSF) was superfused continuously over the slices during these experiments and drugs were applied by addition to the ACSF. Endothelin-1 (ET-1) was more potent than endothelin-3 (ET-3) in constricting the cerebral vessels, suggesting the participation of an ETA type receptor. Vasoconstriction by ET-1 was characterized by a large, acute phase of constriction followed by a smaller, tonic phase. Pretreatment with the kinase inhibitor, H7, or the lipase inhibitor, bromophenacyl bromide, inhibited both phases of constriction in a dose-dependent manner. Submerged, in vitro, brain slices represent a useful model system for studying the mechanisms of cerebrovascular regulation in pial and penetrating microvessels. The participation of kinase and lipase systems in endothelininduced cerebrovascular constriction will be discussed.

### 68.7

A METHOD FOR MEASUREMENT OF BLOOD FLOW IN SMALL DURAL ARTERIES - EFFECTS OF TRIGEMINAL STIMULATION AND ANTI-MIGRAINE DRUGS. G.A.Lamberi.\* J.Michalicek and V.Gordon. Institute of Neurological Sciences, University of New South Wales, Sydney, Australia.

The pain of migraine and cluster headache is associated with changes in blood vessel dispatch blood. How the state of

The pain of migraine and cluster headache is associated with changes in blood vessel diameter, blood flow and vessel-wall properties, but it is not known whether the vascular changes arise from the pain or cause it. It is possible that ant idromic release of vasoactive peptides from the trigeminal nerve produces the vascular effects. We have found that electrical stimulation of the trigeminal ganglion produces changes in carotid and cortical blood flow. Both responses are mediated via a reflex pathway traversing the greater superficial petrosal nerve, rendering an antidromic mechanism unlikely. However, the cortical microvasculature has little trigeminal innervation and may not contribute to migraine pain. We have therefore extended these studies to measure flow in the middle meningeal artery (mma), a small dural artery richly innervated by trigeminal sensory fibres and a possible source of pain in migraine. Cats were anesthetised with chloralose and electromagnetic flow probes placed around the common carotid arteries. Stimulating electrodes were placed in each trigeminal ganglion (Vg). One trigeminal root was sectioned through a tunnel in the petrous temporal bone. Each mma was exposed, kept surrounded by warm saline and optically temporal bone. Each mma was exposed, kept surrounded by warm saline and optically isolated from the underlying cortex. Meningeal blood flow was measured using infrared photoplethysgmography, using fibre optic probes and a custom-designed detector circuit. Inhalation of CO<sub>2</sub> produced increased signal from the detector circuit and carotid occlusion produced a decrease, confirming that the system gives a measure of blood flow. Stimulation of Vg increased carotid and meningeal flow, ipsilateral to the stimulus site only on the side with an intact trigeminal root. Intravenous injection of dihydroergotamine (DHE, 40 µg/kg) and sumatriptan (80 µg/kg) produced complex changes in carotid and meningeal flow, but no appreciable or prolonged vasoconstriction. Neither drug significantly affected responses to trigeminal stimulation. We conclude that, although the mma is innervated with nerves containing vasoactive peptides, activation of these nerves produces little change in caliber of or flow in the artery.

EFFECT OF ANGIOTENSIN II ON BLOOD FLOW TO THE CHOROID PLEXUSES OF THE RAT. A. Chodobskæ J. Szmydynger-Chodobska. and C.E. Johanson. Dept. Clin. Neurosci., Program Neurosurg., Brown Univ. & RI Hosp., Providence, RI 02902 Blood flow to the choroid plexuses of the lateral (LCPBF), third (IIICPBF), and fourth (IVCPBF) ventricles was measured in male Sprague-Dawley rats anesthetized with pentobarbital sodium (50 mg kg-1, ip) and artificially ventilated. <sup>123</sup>I-N-isopropyl-p-iodoamphetamine (IMP) was used as a tracer with assumption that IMP acts in the brain as a "chemical microsphere". Animals were infused iv with IMP at a constant rate for 30 sec to deliver ~50 μCi of IMP per rat. Reference blood samples were withdrawn using withdrawal pump. Rats were killed blood samples were withdrawn using withdrawal pump. Rats were killed by decapitation. Plexuses were removed separately and weighed on electronic balance before gamma-counting. Angiotensin II (AII) was electronic balance before gamma-counting. Angiotensin II (AII) was infused iv for 10 min before blood flow measurement at the following rates: 10, 30, 50, 100, and 300 ng kg-1 min-1. Under control conditions, LCPBF was 3.19±0.07 ml g-1 min-1. This value was lower (P<0.01) than IIICPBF and IVCPBF (3.90±0.17 and 3.95±0.11 ml g-1 min-1, respectively). LCPBF decreased 15% and 23% (P<0.01) during AII infusion at rates of 30 and 50 ng kg-1 min-1, respectively. IVCPBF decreased 14% (P<0.05) during AII infusion at a rate of 30 ng kg-1 min-1. IIICPBF was not affected by any dose of AII used. It is concluded that AII at moderate doses lowers both LCPBF and IVCPBF. The lack of changes of blood flow to the choroid plexuess with higher The lack of changes of blood flow to the choroid plexuses with higher AII doses suggests a complex interaction of the peptide with these vascular beds. Supported by NIH Grant NS 27601.

ACTION OF PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE-38 ON PIGLET CEREBRAL MICROCIRCULATION. S. Tong, H. Parfenova, M.Shibata, W.M. Armstead, J.B. Schweitzer and C. W. Leffler. Laboratory for Research in Neonatal Physiology, Departments of Physiology & Biophysics, and Pathology University of Tennessee, Memphis,

The purpose of this study was to determine the effects of a synthetic pituitary adenylate cyclase activating polypeptide containing 38 amino acids (PACAP-38) on newborn piglet cerebral microcirculation. a-chloralose-anesthetized newborn piglets(1-5 days old) were equipped with closed cranial windows and diameter of pial arterioles were recorded. Cortical periarachnoid cerebrospinal fluid (PCSF) samples were collected for measurement cerebosphian full (PC3) samples were concerned in measurement of cyclic AMP by radioimmunoassay. PACAP-38 was applied topically for 10 min periods. cAMP levels in PCSF were  $1.7 \pm 0.5$ ,  $3.7 \pm 1.0$ ,  $3.9 \pm 0.9$  and  $4.8 \pm 1.2$  fold of the baseline levels at  $10^{-9}$ ,  $10^{-8}$ ,  $10^{-7}$  and  $10^{-6}$ M of PACAP-38, respectively. PACAP-38 produced dose-dependent dilation of pial arterioles. The maximum increases of pial arteriolar diameter were  $7 \pm 2\%$ ,  $23 \pm 7\%$ ,  $31 \pm 8\%$  and  $36 \pm 6\%$  at  $10^{-9}$ ,  $10^{-8}$ ,  $10^{-7}$  and  $10^{-6}$  M, respectively. The dilation developed slowly reaching a maximum at 7-8 min. Therefore, the vasodilation and increases in cAMP caused by PACAP-38 correlate well. PACAP is a potent dilator of the newborn piglet cerebral circulation and the location of this peptide around cerebral vessels suggests a possible role in control of cerebrovascular tone.

KETANSERIN BLOCKS THE INHIBITION OF CHLORIDE EFFLUX FROM CHOROID PLEXUS INDUCED BY SEROTONIN OR ERGOTAMINE. <u>C. Johanson\*</u>, <u>P. Budhiraja and D. Palm.</u> Dept. Clin. Neurosci., Program in Neurosurgery, Brown U. & R.I. Hospital, Providence, RI 02902

Intraventricularly-administered serotonin decreases CSF secretion rate by a mechanism poorly understood. Because chloride (Cl) transport by choroid plexus (CP) is integral to CSF formation, we tested the hypothesis that serotonin inhibits Cl efflux from choroidal epithelium. Lateral ventricle CP was excised from adult rats and loaded with <sup>36</sup>Cl in artificial CSF (aCSF). The time course of efflux of <sup>36</sup>Cl from CP was measured at 37° C. Cl efflux was determined as a rate coefficient, k (sec-1). The k value for controls was  $0.0251 \pm .002$ . Serotonin in aCSF at a concentration of  $0.1 \mu M$  did not alter Cl efflux, but at 1 and  $10 \mu M$  it decreased the k value for Cl by 18 and 21%, respectively. Ergotamine, decreased the k value for Cl by 18 and 21%, respectively. Ergotamine, like serotonin, induces a potent agonistic response when it binds to the 5-HTic receptor in CP. At  $10 \mu M$ , ergotamine reduced Cl efflux rate by 24%. When the CP was preincubated with ketanserin  $(10 \mu M)$ , neither serotonin nor ergotamine  $(10 \mu M)$  was able to reduce Cl efflux. The antagonist ketanserin alone in aCSF  $(10 \mu M)$  did not significantly alter the k value for Cl. As standard reference inhibitors, acetazolamide  $(0.1 \mu M)$ , DIDS (disulfonic stilbene, 0.1 mM) and nialamide  $(1 \mu M)$ decreased Cl efflux from CP by 40%, 44% and 21%, respectively. We conclude that serotonin can alter Cl release from in vitro CP, and that this inhibitory effect is mediated by way of the 5HT1c receptor. (Supported by NIH NS 27601 and by funds from R.I. Hospital)

THE ROLE OF VASOPRESSIN AND THE SYMPATHETIC NERVOUS SYSTEM IN MEDIATING THE INHIBITORY EFFECT OF ANGIOTENSIN II ON CSF FORMATION IN THE RAT. J. Szmydynger-Chodobska A. Chodobski. and C.E. Johanson, Dept. Clin. Neurosci., Program Neurosurg., Brown Univ. & RI Hosp., Providence, RI 02902

We have previously shown both in the rabbit and the rat that an integration is a company of the providence of the provide

angiotensin II (AII) inhibits cerebrospinal fluid (CSF) production when administered at low doses into the cerebroventricular system. Centrally released AII both activates the sympathetic nervous system and increases vasopressin secretion. The present study was aimed at elucidating the released All obth activates the sympathetic nervous system and increases vasopressin secretion. The present study was aimed at elucidating the role played by the above factors in mediating the effect of All on CSF formation. The experiments were performed on rats anesthetized with pentobarbital sodium (50 mg/kg, ip) and artificially ventilated. CSF formation rate was measured using the ventriculocisternal perfusion method with blue dextran 2000 as an indicator substance. The cerebroventricular system was perfused with artificial CSF at a rate of 5 μl/min through cannulas introduced into both lateral ventricles, and CSF samples were collected from the cisterna magna. Control CSF production was 3.42±0.08 μl/min. Central administration of AlI at a rate of 6.3 pg/min decreased CSF production to 2.70±0.15μ/min (P<0.01). When animals were pretreated with V<sub>1</sub>-vasopressinergic receptor antagonist [d(CH<sub>2</sub>)<sub>5</sub>Tyr(Me)AVP, 10 μg kg<sup>-1</sup> h<sup>-1</sup>], the inhibitory effect of AlI on CSF formation was abolished (3.78±0.30 μl/min). Pretreatment with adrenergic receptor antagonists, prazosin (1 mg kg<sup>-1</sup> h<sup>-1</sup>), did not affect the response of CSF production to AlI. All blockers themselves had no effect on CSF formation. It is concluded that the inhibitory effect of centrally released AlI on CSF formation can be mediated by increased secretion of vasopressin. Supported by NIH Grant NS 27601.

PENTOBARBITAL ALTERS PLASMA AND RED CELL FLOW THROUGH CEREBRAL PARENCHYMAL MICROVESSELS. L. Wei\*, T. Otsuka, D. Bereczki, V. Acuff, K. Pettigrew, C. Patlak, and J.Fenstermacher. Dept. Neurolological Surgery, SUNY/Stony Brook, Stony Brook, NY 11704-8122

Neurolological Surgery, SUNY/Stony Brook, Stony Brook, NY 11794-8122.

Pentobarbital (Ptb) lowers local cerebral blood flow, glucose utilization, and glucose influx throughout the brain and may alter the distribution of plasma and red cells through local parenchymal microvascular systems. This postulation was tested by measuring the distribution volumes of 5Fe-labeled red cells (Vr) and 125I-albumin (Vp) in parenchymal microvessels of the rat brain and combining Vr and Vp to yield blood volumes (Vb) and microvessels hematocrits (mHct). Tissue radioactivity was assessed by quantitative autoradiography. Ptb treatment increased Vr in most brain areas, decreased Vp in some, and raised mHct in most areas; Vb was, however, only changed slightly. Ptb treatment, thus, appears to lower the flow velocities of red cell (Fr) and albumin (Fp) through parenchymal microvessels, makes these velocities similar (in control rats: Fr > Fp), and does not decrease the number of perfused microvessels.

DEVELOPMENTAL CHANGES IN IDENTIFIED CEREBRAL ARTERIOLES AND VENULES IN INDIVIDUAL MICE AT TWO AGES G.D. Foltz, C.M. Rovainen\* and T.A. Woolsey. Depts. Cell Biology & Neuro-

ological Surgery, Washington Univ. Sch. Med., St. Louis, MO 63110 Blood vessels over the left somatosensory barrel cortex in single animals were followed from 1 day after birth (P1) to adult (P30) by in vivo videomicroscopy through cranial windows. Mice were anesthetized with 1-2 mg/gm urethane IP or Metofane. FITC-dextran (200 mg/kg) was injected intracardially or intravenously. Surface vessels were imaged through cranial windows with an epiflourescence microscope and SIT camera at all ages. On P1 vessels were scanned through the transparent, intact dura after which the skull flap over the craniotomy was closed and the scalp sutured. At P8-P30 the same mice were rescanned through enlarged closed cranial windows. Individual vessels were identified at both ages for direct comparison in video montages. In P1 mice surface venules lack prominent deep sources and are small, irregular, and extensively connected with the primordial plexus of pial capillaries. As the cerebral cortex grows, large smooth-walled venules and distal venular branches are molded from the pial capillary plexus. The pattern of the middle cerebral artery and its major branches changes little. Arterial segments lengthen with cortical expansion. Substantial remodeling of collater als in arteriolar loops through growth and regression occurs as flow shifts to supply the brain parenchyma. The pial capillaries so prominent at birth slowly regress by P14 and are absent in the adult. Velocities of flow through the same vessels can be measured during serial in vivo video recordings. This approach provides direct observations of dramatic growth and remodeling of cerebral blood vessels as the cortex develops.

ADENOSINE PARTICIPATES IN THE MEDIATION OF PIAL ARTERIOLAR DILATION INDUCED BY HYPOTENSIVE HYPOGLYCEMIA IN THE NEWBORN PIG. T.S. Park\*, V.J. Ruth, A.R. Shah, E.R. Gonzales, J.M. Gidday. Department of Neurosurgery, St. Louis Children's Hospital, Washington University School of Medicine, St. Louis, MO 63110.

School of Medicine, St. Louis, MO 63110.

Studies in our laboratory and others have documented autoregulatory dilations of pial arterioles and increases in CBF in the newborn piglet in response to either systemic hypotension (HT) or hypoglycemia (HG). The present study was aimed at elucidating the role of the adenosine in mediating the hyperemic response to the combined condition of HT/HG. Anesthetized newborn piglets (n=7) were outfitted with closed cranial windows and the changes in diameter of two sizes of pial arterioles were monitored by videomicroscopy in response to HG (insulin; 25 U/kg i.v.) and subsequent HT to MABP = 30 mmHg. In 10 other piglets, the adenosine receptor antagonist 8-sulphophenyl-theophylline (8-SFT; 10µM) was superfused through the window prior to HG. Results are shown as % increase (meantSEM) in baseline diameters:

25-50 µm Diameter 50-100 μm Diameter 8-SPT Control 8-SPT Control 26±7 # HG 15±5 81±7 \* 51±6 #\* 46±5 \* 31±4 #\* HT/HG f = p < 0.05 vs control group; \* = p<0.05 vs HG alone] Our results indicate that adenosine is involved in mediating the dilatory responses to both HG, and HT/HG.

OPIATE MECHANISMS IN THE REGULATION OF CEREBROCORTICAL BLOOD FLOW DURING HYPERCAPNIC STRESS. N.T. Sandor. I. Horvath. E. Dora. G. Kunos\* and A.C. McLaughlin NIAAA, Rockville, MD 20852.

The mechanisms underlying the increases in cerebral blood flow (CBF) and cerebral oxygen consumption (CMRO<sub>2</sub>) in hypercapnia are still poorly understood. It is generally accepted that intracellular acidosis can be an important factor evoking increased CBF in hypercapnia and central neuronal mechanisms also play a role in regulating the cerebral circulation. The observation that the sympathoadrenal system is activated by hypercapnia suggests that adrenal medulla-derived substances could be involved in regulating the response of cerebral circulation and metabolism to CO<sub>2</sub>.

We investigated the possible role of adrenal medulla-derived opioid peptides in cerebrocortical hypercapnic hyperemia in two groups of ketamine anesthetized rats: intact rats treated with different opiate antagonists and chronic adrenal demedullated animals

CBF was meaured in the cerebral cortex by the Kety-Schmidt technique. CMRO<sub>2</sub> was calculated from the product of CBF and the arterial/venous difference of oxygen.

In intact animals naloxone and the selective ∂-receptor antagonist.

In intact animals naloxone and the selective  $\partial$ -receptor antagonist, naltrindole, but not the  $\mu$  antagonist,  $\theta$ -funaltrexamine, reduced the hypercapnic increase of CBF and CMRO<sub>2</sub> by approximately 50%. Adrenal demedullation also decreased the hypercapnic CBF and CMRO<sub>2</sub> by the same value.

These observations suggest that endogenous opioid peptides, most likely adrenal medulla-derived enkephalins, mediate, at least in part, the increases in CBF and CMRO₂ during hypercapnia, via activation of ∂-opiate receptors.

ANOXIA-RESISTANT TURTLE BRAIN HAS HIGH ASCORBATE LEVELS WITH REGIONAL AND SEASONAL DEPENDENCE.

M.A. Pérez-Pinzón\*, E. Lee and M.E. Rice. Dept. Physiology and Biophysics, NYU Medical Center, New York, NY 10016.

Oxygen free radicals have been suggested to cause neuronal degeneration following an ischemic insult. One factor may be that the antioxidant defense system of mammalian brain is compromised during ischemia, when a decrease in the concentration of key antioxidants such as ascorbic acid occurs. In contrast, anoxia-resistant turtle brain maintains ascorbic acid levels for many hours during anoxia (Rice and Cammack, Neuroscience Let 132:141, 1991). Preliminary studies suggested that ascorbate levels in turtle brain might be higher than mammalian tissues, but with seasonal variability. To confirm this, we have mapped ascorbate content of turtle brain in summer and winter. Ascorbate was determined using reversed phase HPLC with an electrochemical detector set at +0.7 V vs Ag/AgCl. Turtle brain ascorbate levels in either season were significantly higher than those found in mammalian brain. Higher levels were found in the summer- and warm-acclimated turtles. The highest levels were found in olfactory bulb, cortex and dorsal ventricular ridge (DVR) (mean value 5.33 µmol/g). Optic tectum and cerebellum showed intermediate values (mean values 3.37 and 4.06 µmol/g, respectively). Lowest values were found in brain stem and spinal cord (mean value 2.03 µmol/g). A significant 30% decline in ascorbate levels occurred in olfactory bulb, cortex, DVR, optic tectum and cerebellum in winter-acclimated turtles, while no difference was observed in brain stem and spinal cord. These results point toward a metabolic regulation of brain ascorbic acid levels in turtle. Funded by NIH grant NS-28480.

# 68.16

SINGLE INWARD RECTIFIER CHANNELS IN RAT CEREBROVASCULAR SMOOTH MUSCLE CELLS. EFFECT OF HALOTHANE. H. Yan , D.A. Mathers\*and E. Puil Physiology and Pharmacology, University of British Columbia, Vancouver, B.C., V6T 1W5.

The effect of halothane on single inward rectifier channels was investigated in isolated inside-out patches of cerebrovascular smooth muscle cells (CVSMs) derived from the cerebral arteries of adult Wistar rats (200-250 g). CVSMs were enzymatically dispersed from the basilar, middle, posterior communicating, and posterior cerebral arteries and maintained <u>in vitro</u> for 2-4 days prior to use.

Isolated inside-out patch clamp recordings were made at room temperature (21-23 °C) using a List EPC-5 amplifier. Patch electrodes contained external solution (in mM): 140 KCl, 3 EGTA, 0.36 CaCl<sub>2</sub> and 10 HEPES. The cytoplasmic membrane face was bathed in a saline containing (in mM): 140 KCl, 3 EGTA, 3.1 CaCl<sub>2</sub> and 10 HEPES.

Inward single channel currents were ellicited by hyperpolarizing pulses from a holding potential of -30 mV. This channel had a mean conductance of 82pS and a mean open time of 0.7 msec in symmetrical 140 mM KCl solutions. At a holding potential of -90 mV, halothane (3-5% carrier gas, 1 L/min. compressed air) applied internally in 4 patches produced a 40% reduction in mean open probability of these inward rectifier channels.

ATTENUATION OF THE CRE-RESPONSE TO SENSORY STIMULATION BY SYSTEMIC ADMINISTRATION OF THE NO-SYNTHASE-INHIBITOR Nω-NITRO-L-ARGININE (L-NNA). U.Lindauer, A.Villringer, U.Dirnagi. Dept.of Neurology, University of Munich, 8000 Munich 70, F.R.G

We studied the role of the endothelium derived relaxing factor nitric oxide (NO) in the coupling of CBF to local demand. Wistar rats were anesthetized with Halothane in O<sub>2</sub>/N<sub>2</sub>O, tracheotomized, and artificially ventilated. Systemic arterial pressure (SAP), endexspiratory pCO<sub>2</sub>, and body temperature were continuously monitored. The whisker barrel cortex was exposed by thinning the parietal bone and rCBF was continuously monitored through the translucent bone with Laser-Doppler flowmetry. Anesthesia was then switched to i.v. Chloralose. The whiskers were stimulated by deflection (3/s) for 1 minute. 10 mg/KG of L-NNA were injected intravenously. 10 min and 1 h after injection, whisker stimulation was repeated at the NO-blockade induced hypertensive SAP and with SAP reduced to baseline values by exposure of the lower body of the animal to hypobaric pressure. Results see table below. Normalization of the hypertensive SAP did not change the stimulation responses. NO-blockade led to rhythmic CBF-fluctuations (6-8/min). The extreme hypertension disrupted autoregulation in 3 animals after 15 minutes, and no 1 h stimulation was feasible. We conclude that blockade of the endothelial NO-synthase is not sufficient to abolish the CBF response to stimulation. Time dependent blockade of the brain parenchymal NO-synthase may further attenuate but not abolish the response.

|          | ΔrCBF <sub>stim</sub> (%±SD) | SAP (mmHg±SD)      | CBF (%±SD)    |
|----------|------------------------------|--------------------|---------------|

CSE METABOLITES IN RELATION TO SEVERITY AND REVERSIBILITY OF NEUROLOGICAL DYSFUNCTION IN EXPERIMENTAL PORTAL-SYSTEMIC ENCEPHALOPATHY (PSE). G. Therrien\*, J. Butterworth, C. Rose and R.F. Butterworth, Neuroscience Research Unit, André-Viallet Clin. Res. Centre, Höpital Saint-Luc (University of Montreal), Montreal, Quebec, Canada H2X 3J4. Previous studies suggest that PSE results from neurotoxic effects of ammonia and/or alterations of brain amino acids. In order to assess these possibilities,

CSF was obtained using a cisterna magna catheter technique and analyzed for content of ammonia, lactate and amino acids at various stages during the development of (and recovery from) PSE. PSE was induced in portacaval shunted rats by administration of ammonium acetate which led to a reproducible neurological syndrome (loss of reflexes, stupor, coma, followed by recovery). Early PSE was associated with 2-3 fold increases of CSF tyrosine, tryptophan and phenylalanine. Further deterioration of neurological status was closely correlated with increased CSF ammonia, alanine and lactate, all of which returned to normal values following normalization of neurological status. No significant alterations of neurological status nor of CSF lactate or alanine were observed in sham-operated animals nor in shunted animals receiving equimolar amounts of sodium acetate (vehicle). No further increases of tyrosine, phenylalanine or tryptophan were observed at coma stages of encephalopathy. CSF content of GABA, was not altered at any stage during the development of PSE. These findings do not support a pathogenetic role for GABA nor monoaminergic dysfunction (resulting from increased availability of precursor amino acids) in late stage PSE. On the other hand, the observation of increased ammonia and of concomitantly increased lactate and alanine in CSF suggest decreased oxidation of pyruvate in the brains of these animals, implying that alterations of cellular energy metabolism and pH could be involved in the pathogenesis of severe PSE. Monitoring of CSF lactate or of brain lactate by <sup>1</sup>H. NMR could offer a useful means of evaluation of PSE in humans (Funded by

# 68.21

FATTY ACID SYNTHETASE (FAS) IN FETAL RAT BRAIN AND LIVER DURING PLACENTAL ISCHEMIA. Z.Binienda, R.R. Holson, C.S. Kim\*, T. Flynn, W. Slikker, Jr. and R.J. Feuers. NCTR/FDA, Jefferson, AR 72079 and CFSAN/FDA, Washington, DC 20204. The effect of uterine vascular clamping on fetal brain and liver FAS activity was studied in nineteen Sprague Dawley rats in order to identify early and sensitive biomarkers of fetal hypoxia. Ischemic conditions were produced by ligation of uterine vessels at the ovarian and cervical end of one uterine horn for up to 20 min under halothane anesthesia. Fetuses of the other horn served as cervical end of one uterine horn for up to 20 min under halothane anesthesia. Fetuses of the other horn served as controls. Sham operated dams controlled for surgical stress. Fetuses were rapidly frozen in liquid nitrogen at the end of the ligation. Brains and livers were then transferred into dishes placed on dry ice, dissected, and stored at -80°C. FAS and total brain free fatty acids (FFA) were determined in tissue homogenates using a miniature fast analyzer or by gas chromatography. FAS activity rose in fetuses from the control horn (+36%,p=0.055) but did not change in the hypoxic horn (compared to shams). Compared to the fetuses from the control horn, FAS activity was lower in hypoxic fetuses (-34.4%,p=0.015). FFA rose in fetuses of both horns. The (-34.4%,p=0.015). FFA rose in fetuses of both horns. The response of liver FAS to surgery and hypoxia was similar to brain FAS. The association between brain and liver FAS activity and brain FFA concentration may serve as a biomarker of hypoxia; however, the role of surgical stress has to be identified.

EARLY HYPOPERFUSION OCCURS DURING SPREADING DEPRESSION IF NITRIC OXIDE SYNTHESIS IS INHIBITED. R.B. Duckrow\* and D.C. Beard. Department of Neurology, The University of Connecticut Health Center, Farmington, CT 06030.

Nitric oxide may be an endothelium-derived relaxing factor which mediates cerebral blood flow (CBF) responses to neurotransmitters or carbon dioxide. The role of nitric oxide production in mediating CBF changes associated with spreading cortical depression (SCD) was charges associated with spreading corrical depression (SCD) was assessed by inhibiting nitric oxide synthetase with L-nitroso-arginine-methy-ester (L-NAME) and inducing cortical spreading depression in awake rats. Rats were prepared for measurement of regional CBF while awake and restrained by a plaster hip-cast. After recovering from halothane/nitrous oxide anesthesia for one hour, SCD was induced by passing direct current through a bipolar electrode previously implanted in the lateral frontal cortex. CBF was measured using [14C]isopropyliodoamphetamine and quantitative radiography. L-NAME, 30 mg/kg i.v., was given 15 minutes before induction of SCD and CBF was measured 90 seconds later. CBF was compared to rats given L-NAME without induction of SCD and to rats with SCD without treatment with L-NAME. In control rats and rats treated with L-NAME, SCD was accompanied by the usual phases of early brief hyperperfusion and delayed prolonged hypoperfusion. However, an additional brief phase of hypoperfusion (75% flow reduction) appeared before the early hyperperfusion phase in L-NAME-treated rats. This early hypoperfusion should coincide with the depolarization phase of SCD. This suggests that vasoconstriction caused by elevated K+ is normally balanced by simultaneous EDRF-mediated vasodilation involving nitric oxide production. (PHS NS24109)

INCORPORATION OF I<sup>3</sup>HIARACHIDONIC ACID INTO BRAIN PHOSPHOLIPIDS AND RELATIVE SPECIFIC ACTIVITY OF BRAIN PRECURSOR POOLS. D. Purdon. K. Washizaki, Q.R. Smith, J.J. DeGeorge, N.M. Appel\* and S.I. Rapoport, Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892 and Food and Drug Administration, Rockville, MD 20857.

Our aim is to model the incorporation of fatty acid (FA) from plasma into brain phospholipid (PL) including turnover of precurser pools, i.e., free FA and acyl-Coenzyme A (AcCoA). [<sup>3</sup>H]Arachidonic acid ([<sup>3</sup>H]AA) was infused into pentobarbital-anesthetized rats to obtain a high blood level (50 µCi/ml). At varying times the infusion was stopped and animals killed by microwave irradiation. Brains were excised and PL extracted using a modified Folch procedure. PL, free FA and neutral lipid (NL) were purified from the lower organic phase by thin layer chromatography. AcCoA was isolated from the upper aqueous phase using a Sep-Pak and reversed phase HPLC. Brain FA and the FA component of AcCoA were analyzed as methyl esters by gas chromatography; comparison with associated radioactivity allowed determination of specific activities (SA). [3H]AA incorporation into brain PL and NL was linear over the time course of the experiment (1 - 10 min) with most of the tracer being found in phosphatidylinositol and phosphatidylcholine. The SA of precursor pools (brain free FA and AcCoA) increased rapidly to a steady state (t<sub>1/2</sub> <1 min) with brain SA's being considerably lower than in plasma (<10 %). These results suggest that turnover of AA in AA-containing phospholipids is more rapid than previously assumed and that plasma unacylated AA makes only a relatively minor contribution compared to other sources of this FA such as plasma triglyceride and brain recycled AA.

ALTERATIONS IN BRAIN GLUCOSE TRANSPORT PROTEINS, GLUT1 AND

ALTERATIONS IN BRAIN GLUCOSE TRANSPORT PROTEINS, GLUT1 AND GLUT3, FOLLOWING HYPOXIC-ISCHEMIC INJURY IN THE IMMATURE RAT. S.J. Vannucci\*, L.B. Willing, and R.C. Vannucci. Dept Pediatrics, Penn State Univ, Hershey, PA 17033.

Alterations in cerebral energy metabolism and glucose utilization due to perinatal hypoxia-ischemia (H-I) persist into the recovery period. The initial step in cerebral glucose utilization is the transport of glucose across the blood-brain barrier (BBB) and transport into neurons and glia. Two glucose transporter isoforms have been identified in brain: GLUT1 is concentrated in the BBB; GLUT3 is in neurons. The purpose of this study was to correlate known changes in cerebral glucose utilization with changes in GLUT1 and GLUT3 in an experimental model of perinatal H-I brain damage. 7 d postnatal rats were subjected to unilateral common carotid artery ligation followed by hypoxia (8% 02); brains were removed following 24 h of recovery. Samples were removed from the middle of each cerebral hemisphere for Western blot analysis of GLUT1 and GLUT3. GLUT1 was increased by 49.5+11.1% (p<.05) in the ipsilateral hemispheres of brains with moderate to severe damage. GLUT1 in the contralateral (undamaged) hemisphere did not differ from control. Ipsilateral GLUT3 tended to be lower (89.1+10% of control) in these animals; contralateral GLUT3 was slightly increased (111+14% of control). These changes may account for our previous observation of increased brain glucose but decreased control). These changes may account for our previous observation of increased brain glucose but decreased utilization in the damaged hemisphere and increased utilization in the contralateral undamaged hemisphere.

NIGROSTRIATAL ABERRATIONS INDUCED BY WEAVER GENE

ARE PRESENT AT BIRTH. B. Ghetti\* and L. C. Triarhou. Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

The weaver mutation (wv) leads to a loss of mesencephalic dopamine cells in the adult. By breeding female wv/wv mice with either +/+ or wv/wv males (which are occasionally fertile), we obtained respectively adults. either +/+ or wv/wv males (which are occasionally fertile), we obtained, respectively, obligatory weaver heterozygotes and homozygotes, in order to study the effects of the mutation on the nigrostriatal system at birth. The genotype of the animals studied was further confirmed by examination of the cerebellar histology. Using tyrosine hydroxylase immunocytochemistry, a quasi-normal substantia nigra is seen in both genotypes; nonetheless, the characteristic deficit of dopaminergic dendrites previously described in adult carriers and homozygotes is evident at birth. In semi-thin sections of homozygous weaver midbrain embedded in Epon, extensive and diffuse cellular death is seen both in the ventral and dorsal mesencephalon. Moreover, a striking number of neurons are dorsal mesencephalon. Moreover, a striking number of neurons are observed to undergo dark degeneration in the weaver striatum, just beneath the subependymal plate. These results indicate that the weaver effects on the nigrostriatal system are already taking place at birth, which parallels in temporal terms what is known for the cerebellum. Since midbrain dopamine cell loss further progresses in adult life, we conclude that the mesotelencephalic pathology is a combined developmental and degenerative disorder. (Supported by USPHS RO1-NS14426 and PO1-NS27613).

BASIS OF GRANULE CELL LOSS IN THE MURINE CEREBELLAR MUTATION, MEANDER TAIL. K.M. Hamre\* and D.Goldowitz. Dept. of Anat. & Neurobiol., Univ. of Tenn., Memphis, TN 38104

The autosomal recessive murine mutation, meander tail (gene symbol=mea), results in the near-total demise of a highly specific cerebellar population, anterior lobe granule cells. We are seeking to identify the underlying biological basis of mea gene action. Shimada and Langman (Am. J. Anat. 129: 247-260, 1970) have demonstrated that treating neonatal mice with a thymidine analog and mitotic poison, 5-fluorodeoxyuridine (FUdR), resulted in varying degrees of granule cell loss, particularly in the anterior lobe. Thus, we hypothesized that the mea gene works to target anterior lobe granule cells specifically by inhibiting their cell cycle. To test this hypothesis we carried out two sets of experiments. The first experiments used FUdR at varying embryonic and neonatal times to determine which injection regimen most closely mimicked the *mea* phenotype. Mice were injected with FUdR either embryonically (£) or postnatally (P) on £17 alone, £17+£18, £17+P0, P0 alone, or P1+P2. The phenotype of mice exposed to FUdR on £17+P0 most resembled the *mea* mutation. The second exposed to Pour of ETTP that the semined the *mea* initiation. The second experiments used BrdU (5-bromo-2'-deoxyuridine) to label mitotically active granule cells and to determine if alterations in the cell cycle exist in *mea* mice. P0 heterozygous and homozygous mice were injected with BrdU and allowed to survive for 1 hour. Tissue sections were processed for BrdU immunocytochemistry and labeled and unlabeled cells were counted in both the anterior and posterior lobes. The results demonstrated that while there were far anterior and posterior lobes. The results demonstrated that while there were tar fewer cells in the EqLt in the anterior lobe in homozygous mice as compared to heterozygous mice, the labeling index in mea/mea mice is the same or higher than in controls. These results demonstrate that mea and control granule cells have equivalent S-phase dynamics and that inhibition of mitosis is unlikely to be an important factor in the the massive loss of mea granule cells. Thus, while FUdR treatment and the mea gene affect the same population of cells, the underlying mechanisms likely differ between these two developmental perturbations. Support: USPHS GR NS07323.

CO-LOCALIZATION OF TYROSINE HYDROXYLASE AND ZEBRIN IMMUNOREACTIVITIES IN PURKINJE CELLS OF TOTTERING AND TOTTERING-LEANER COMPOUND HETEROZYGOUS MUTANT MICE. L.C. Abbott\* and J. A. Heckroth. University of Illinois, Dept. of Vet. Biosci., Urbana, IL 61801 and Indiana University School of Medicine, Terre Haute Center for Med. Ed., Terre Haute, IN 47809.

Previously we reported that TH-immunoreactive (IR) Purkinje cells in adult tottering (tg/tg) and tottering-leaner compound heterozygote (tg/tg) mice are organized into rostrocaudal stripes through all lobules of the cerebellar vermis and hemispheres (Heckroth, J.A. and L.C. Abbott, Neurosci. Abst. 17:159). This pattern of TH expression in the mutant cerebella bears close similarity to the reported pattern of expression for the Zebrin molecule in the cerebella of normal mice. In the present study we report, using two color immunohistochemistry, that the rostrocaudal stripes of TH immunoreactivity correspond with the rostrocaudal stripes of Zebrin immunoreactivity in both tg/tg and tg/tgia adult mice. The majority of Purkinje cells in the mutant mice that express TH-IR also express Zebrin-IR. However, there are a few cells in the rostrocaudal stripes that appear to express only TH or Zebrin immunoreactivity, but not both. Abnormal Purkinje cell function may be involved in production of the motor system dysfunction exhibited by these mutant mice. The relationship between abnormal gene expression in sagittal stripes of Purkinje cells and the behavioral ataxia and intermittent movement disorder observed in tg/tg and tg/tg\* mutants remains to be determined. (Supported by BRSG Funds to L. C. Abbott (ILLB-44-1230) and J. A. Heckroth (S-507-RR5371).)

GENETIC AND PHYSICAL APPROACHES TOWARD THE ISOLATION OF THE MOUSE MUTANT GENE weaver. Anne E. Mjaatvedt\* and Roger H. Reeves, Developmental Genetics Laboratory, Department of Physiology, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Weaver (wv) is a mouse cerebellar mutant whose phenotype is

characterized by a failure of granule cell migration and is detectable as early as the day of birth (P0). The gene has been mapped to distal mouse chromosome 16, but its product is not known. We are using the phenotype and chromosomal location to isolate wv. wv was previously mapped 1cM proximal to Ets-2 on Chr 16 using a C57Bl/6 wv/wv X (C57Bl/6 wv/wv X MOLD/Rk) backcross. We mapped the Ets-2 related gene, Erg to a position 0.94 cM proximal to Ets-2 on more than 400 progeny of an intersubspecific backcross, and 1 cM distal to wv on the wv backcross, indicating the probable gene order, CEN--wv-Erg-Ets-2 on Chr 16. Since 1 cM on this backcross is equivalent to less Ets-2 on Chr 16. Since 1 cm on this backcross is equivalent to less than 2Mb, chromosome walking using yeast artificial chromosomes (YACs) presents a viable strategy for isolating the wv gene. We obtained 2 YACs with 450kb inserts that hybridized with mouse Ets-2. These YACs were shown to contain Erg as well. The ends of one YAC have been isolated using retrofitted vectors (Hermanson,G.G. et al., '91) and will be used to screen other YAC libraries for overlapping YACs that may contain the wv locus. We have also isolated several cerebellum specific, mouse chr.16 specific genomic clones by screening a reduced somatic cell hybrid library with cDNA made from P0 cerebellum. These clones are currently being mapped and characterized. Using the complementary strategies of positional cloning and biological information, we hope to isolate the wv gene. Supported by PHS grants F32 HDO7501(AEM) and R01 HG00405(RHR).

SUBSETS OF MDX MICE PURKINJE CELLS LACK IMMUNOREACTIVITY FOR CALCIUM BINDING PROTEINS D-28K CALBINDIN AND PARVALBUMIN. F. Rossi, D. Minciacchi, M. Sassoè Pognetto, F. Tempia and P. Strata\*, Dept. of Human Anatomy and Physiology, I-10125 Turin, Italy

It has been recently shown that dystrophin, the protein product of the gene responsible for Duchenne muscular dystrophy, is normally localized at postsysnaptic densities of cerebellar Purkinje cells (PC) in the mouse. Although dystrophin is not present in mdx mutant mouse PCs (Lidov et al. 1990, Nature 348:725), no morphological or functional alteration has been reported, which could be referred to the lack of this protein. We are investigating the structural and functional features of PCs in mdx mice in order to clarify the role of dystrophin in the central nervous system. The cerebellum of young adult mdx mice, aged 30 to 60 days, appears to be fully developed with no abnormalities in foliation and cytoarchitectonics. By contrast, immunocytochemical staining for D-28k calbindin and parvalbumin, which normally stain the whole population of PCs, reveals that subsets of these neurones are not labelled in mdx mice. Immunonegative neurones are grouped in clusters with sharp boundaries, distributed throughout the whole cerebellum, giving a patchy appearance to the labelling of the cerebellar cortex. The lack of immunoreactivity for these calcium binding proteins suggests that an abnormal calcium homeostasis, which has been proposed to play a central role in the pathogenesis of Duchenne muscular dystrophy, is also present in a subpopulation of mdx PCs, and may affect their functional properties. Ultrastructural investigations are now in progress, aimed at determining possible abnormalities in the synaptic investment of mdx mice PCs, which may be related to an altered calcium homeostasis. (Supported by Telethon)

ROSTRAL CEREBELLAR MALFORMATION, A TRANSGENIC INSERTIONAL MUTATION: GENETIC AND HISTOLOGICAL ANALYSIS. L.A. Rund\*, R.T. Bronson, B.B. Boyer and L.P. Kozak University of Illinois, Urbana, IL 61801 and The Jackson Laboratory, Bar Harbor, ME 04609.

of Illinois, Urbana, II. 61801 and The Jackson Laboratory, Bar Harbor, ME 04609. We have identified a transgenic insertional mutation which is allelic to rostral cerebellar malformation (rcm), a spontaneous cerebellar mutation in the mouse mapping to Chromosome 3. Mice homozygous for the transgenic insertional mutation, rcm<sup>1</sup>8 have a tipsy, uncoordinated walk and a structurally altered cerebellum. At the gross level the anterior folia are reduced in size while the posterior folia appear largely unaffected by the mutation. In the adult cerebellum, disruptions in the laminar structure are evidenced by irregularities in the Purkinje cell monolayer, ectopic displacement of the granule cells into the molecular layer and protrusions of molecular layer into the internal granule cell layer. During postnatal development aggregates of external granule cells migrate across the molecular layer, through the Purkinje cell layer and into the internal granule cell layer. Labelling of cells in the 8-phase of the cell cycle with bromodeoxyuridine showed that granule cells which had already that granule cells within the aberrant aggregates as well as cells which had already migrated into the internal granule cell layer were dividing. These characteristics of the abnormally migrating cells in the rcm<sup>12</sup> mutation suggest features of folia development, as if multiple regions in the external granule cell layer have received signals to form folia. Accordingly, one interpretation of the data is that the rcm gene is involved in signalling folia formation and that the mutant phenotype is a genetic

Is involved in signaling formation and that the mutant phenotype is a generic form of cerebellar micropolygyria.

Making use of the molecular tag provided by the mitochondrial uncoupling protein transgene, we have cloned an 8 kb piece of DNA flanking the transgene insertion site. Using an interspecific backcross panel this clone mapped to the distal portion of Chromosome 3, linked to Amy-1 and Mpmv-9. This is the same region to which the spontaneous rcm mutation maps. This insertional mutation provides an excellent opportunity to identify a gene or genes controlling cerebellar development.

RETINAL PIGMENT EPITHELIAL CELL PROLIFERATION RATES IN VITILIGO MUTANT MICE. M. Ruiz, M. Tang and R.L. Sidman\*. Division of Neurogenetics, N.E. Regional Primate Research Center, Harvard Medical School, Southborough, MA 01772-9102.

In vitiligo (vit/vit) mutant mice, the retinal photoreceptor cells begin a life-long progressive degeneration beginning at about postnatal day 60 (P60). However, pigment epithelial (PE) cells appear both functionally (Kosaras, et al., this issue) and histologically (Smirnakis, et al., ARVO, 1991) abnormal much earlier. The present study examines the proliferation behavior of retinal PE cells. Cells in mitosis were selectively stained with R3 antibody (gift of U. Drager) and rhodamine-labelled secondary antibody in Carnoy-fixed PE whole mounts from wild-type (+/+) and vit/vit mice on the C57BL/6] strain background at 5 time points: P0, 2, 4, 6 and 8. For +/+ mice the total counts for R3-labeled PE cells per whole mount were 94, 82, 102, 54 and 2, respectively. Corresponding counts for vit/vit mice were 60, 282, 329, 212 and 8, thus suggesting a shift in the amplitude and timing of peak cell proliferation postnatally in the mutant PE. The rates of DNA synthesis in PE cells were studied by injecting +/+ and vit/vit mice at P0 with 50 mg/kg of bromodcoxyuridine (BrdU) intraperitoneally one hour before sacrifice. PE whole mounts were stained with fluorescein-conjugated anti-BrdU primary antibody. Total number of labelled cells were 816 in +/+ and 1170 in vit/vit, thus resulting in a DNA synthesis to mitosis ratio of 8:1 for +/+ mice and 20:1 for vit/vit. This ratio distortion and the difference in mitotic cell number between mutant and control mice as measured with the R3 antibody, suggest a gene-controlled abnormality in cell cycle kinetics in vit/vit mutant mice.

COCHLEAR DISORDER ASSOCIATED WITH MELANOCYTE ANOMALY IN MICE WITH A TRANSGENIC MUTATION. M.Tachibana<sup>1+</sup>, Y.Hara<sup>2</sup>, D.Yyas<sup>3</sup>, C.Hodgkinson<sup>3</sup>, J.Fex<sup>1</sup>, K.Grundfast <sup>1</sup> and H.Arnheiter<sup>3</sup>. <sup>1</sup>Lab. of Molecular Biology, NIDCD <sup>2</sup>Lab. of Neurochemistry and <sup>3</sup>Lab. of Viral and Molecular Pathogenesis, NINDS, NIH, Bethesda, MD 20892

We have generated eight lines of transgenic mice containing mouse vasopressin-beta-galactosidase fusion constructs. One of these lines, VGA-9, harbors approximately 50 transgene copies at a single chromosomal site. When bred to transgene homozygosity, mice of this line showed a complete loss of skin pigmentation, microphthalmia, and cochlear abnormalities. The vascular stria of the cochlea was thin and deficient in melanin pigment which is normally produced by intermediate cells, i.e. by neural crest-derived melanocytes. The marginal cells of the stria were thin and lacked characteristic basal infoldings. Degeneration of outer hair cells was also observed in homozygous mice, but this alteration was likely secondary to the strial abnormalities. In contrast to homozygous VGA-9 mice, heterozygous VGA-9 mice were pigmented and had no anatomical alterations in either eye or cochlea. Since the integrated transgene provides a marker for cloning an endogeneous gene necessary for normal pigmentation and proper development of the inner ear, the transgene line VGA-9 may become valuable for the study of the molecular genetics of inner ear disorders associated with pigment abnormalities in both mice and humans.

AGE-RELATED CHANGES IN CHOLINERGIC AND GABAERGIC PARAMETERS IN THE BRAIN OF THE SAM P/8 \*SENESCENCE ACCELERATED MOUSE Y. Reddy. J.F. Flood. J.E. Morley and R. Strong. Departments of Pharmacological and Physiological Science and Internal Medicine, St. Louis University School of Medicine, and GRECC, St. Louis VA Medical Center, St. Louis, MO, 63125

Medical Center, St. Louis, MO, 63125
Senescence accelerated prone mouse strains (SAM-P) and resistant strains (SAM-R) were established by Takeda and his colleagues at Kyoto University in the early 1980's. Based on longevity curves and phenotypic changes characteristic of aging, SAM-P strains show an inherited, early onset accelerated advancement of senescence. Moreover, early onset deficits in learning and memory were reported that are not accounted for by age-differences in sensorimotor capabilities. The early onset, irreversible, severe deficits of learning and memory in the SAM-P/8 mice suggest that this may be a useful animal model of human dementia. We therefore performed experiments to determine if blochemical alterations occur in the SAM-P/8 mice significant to those that occur in Alzheimer's disease.

mice similar to those that occur in Alzheimer's disease. We measured ChAT activity in the cortex of SAM-P/8 mice 4, 8 and 16 months of age and in hippocampal regions of SAM-P/8 mice aged 2, 8, and 12 months. ChAT activity was decreased by 33% at 8 months of age and 51% by 16 months of age in the cortex, and 50% in the hippocampus and septal area of SAM-P/8 mice at 12 months. SAM R/1 mice showed no alterations in these brain areas with age. The neurochemical specificity of these alterations is Indicated by the fact that GAD activity, measured in portions of the homogenate used to measure ChAT, was not altered in any brain region examined, except in the septal area, where it increased. These findings raise the possibility that the SAM-P/8 mice might be a useful animal model for at least some aspects of human dementia.

PHAGOSOMES IN RETINAL PIGMENT EPITHELIAL CELLS OF VITILIGO MUTANT MICE. B. Kosaras\*, S.W. Smirnakis, M. Tang and R.L. Sidman. Division of Neurogenetics, N.E. Regional Primate Research Center, Harvard Medical School, Southborough, MA 01772-9102.

The recessive vitiligo mutation maps to chromosome 6, close to or allelic with microphthalmia (Tang, et al., in press). The vit/vit pigment epithelium (PE) is abnormal before birth. Photoreceptor cells differentiate normally, but after postnatal day 60 (P60) their outer segments break up and form lamellar debris between PE and neural retina. Photoreceptor cells degenerate progressively for the next year or more. We ask here whether functional interactions between PE and neural retina are already affected at P23 and P36, when photoreceptor cells are still intact. Wild-type (+/+) and vit/vit mice on the C57BL/6] strain were perfused with aldehyde fixative at 3 time points in the diurnal cycle: in weak dawn light, 1.5 hr after room lights turned on, and 10.5 hr later, just before lights went off. We counted phagosomes in –37 PE cells per specimen in electron micrographs. At P23 +/+ mice averaged 3.3 phagosomes/cell profile at the first two time points, and decrease to 1.9/cell at the third while vit/vit mice averaged 0.5 phagosomes/cell profile at the first two time points and 0.07/cell at the third. P36 +/+ mice showed about 2/3s as many phagosomes as the younger +/+ control. In contrast, phagocytic activity in vit/vit mice was greater at P36 than P23 (x=1.1 /cell in the first two time points, and x=0.75 /cell at the 3rd time). Also, the distribution of phagosomes differed with genotype. In +/+ mice the apical region of PE cells consistently contained more phagosomes than the basal region, while in vit/vit mice the apical zone always had fewer phagosomes than the basal part. The results indicate a functional impairment of vit/vit Pc cells prior to photoreceptor degeneration. Supported by NIH Grant EY06631.

TIMING OF NEURODEGENERATION IN THE MOTOR NEURON DEGENERATION (MND) MOUSE. A. Messer\*, J. Plummer, M. C. MacMillen and W. N. Frankel. Wadsworth Center for Laboratories and Research, N.Y. State Dept. of Health and Dept. of Biomed. Sci., Sch. of Public Health, SUNY, P.O. Box 509, Albany, NY 12201-0509; and The Jackson Laboratory, Bar Harbor, ME.

The mouse mutant *Motor neuron degeneration* (*Mnd*) displays an adultonset progressive degeneration of upper and lower motoneurons, with mild symptoms recognizable at 6 months, leading to spastic paralysis and premature death at 10-12 months on the C57Bl/6 (B6) background. When *Mnd* was outcrossed to the AKR background, 56-63 of 160 affected (*Mndl/Mnd*) F2 progeny of the outcross/intercross showed mild symptoms by 4.5-5 months, and death by 7 months. This accelerated timing effect seems to be strain-specific, since it is not seen in outcrosses to 3 other strains. The gene(s) must be segregating independently of the *Mnd* gene itself, since only 35-39% of the *Mnd/Mnd* mice show early onset. We have eliminated the *Fv* viremia locus, and are mapping the AKR gene(s) responsible.

Even on the later-onset B6 background, abnormally-accumulating lipofuscin-like material can be seen in spinal cord as early as the first month. The material is present in both increasing numbers of cells, and in increasing amounts within individual cells, as the animals age. The level of pathological involvement well before the onset of clear clinical symptoms suggests that the degenerative process is an extremely gradual and protracted one.

The interaction of the timing gene(s), which we hypothesize affects the substrate on which the *Mnd* gene is acting, with the early steps in the degenerative process, should provide a model for delayed neuronal degeneration. (Supported by the ALS Association.)

EFFECT OF CHRONIC TREATMENT WITH TFMPP, A PUTATIVE 5-HT, RECEPTOR AGONIST, ON FEEDING BEHAVIOR AND WEIGHT GAIN, PLASMA INSULIN LEVELS AND HYPOTHALAMIC NEUROPEPTIDE MRNA EXPRESSION IN OBESE ZUCKER RATS. J. Rouru U. Pesonen K. Isaksson R. Huupponen and M. Koulu\*. Department of Pharmacology and Clinical Pharmacology, University of Turku, SF-20520 Turku, Finland.

Obese Zucker rat is a model of genetic obesity characterized by hyperphagia, hyperinsulinemia and insulin resistance. The present

investigation was performed to study long-term effects of the putative 5- $\label{eq:http-receptor} \textbf{HT}_1\text{-receptor agonist trifluoromethylphenylpiperazine (TFMPP)} \ on \ food\ intake$ and weight gain in obese Zucker rats. The influence of chronic TFMPP on expression of hypothalamic appetite regulating neuropeptide mRNAs was also investigated using in situ hybridization. In addition, plasma insulin and glucose levels, and brain  $5\text{-HT}_{1\text{c}}$ - and  $5\text{-HT}_2$ -receptor densities were analyzed. TFMPP (4 mg/kg/day s.c.) significantly reduced food intake during the first seven days, but this effect declined to a non-significant level after 14 and 28 days. Reduced food intake was associated with decreased body weight gains during first and second weeks of treatment, but no effect was found thereafter. Plasma insulin concentration was lowered by TFMPP treatment without impairment of glucose homeostasis. TFMPP treatment did not alter expression of CRF mRNA in the paraventricular nucleus or NPY mRNA in the arcuate nucleus. Chronic TFMPP administration significantly reduced densities of 5-HT<sub>2</sub>-receptors in the claustrum, cingulate and parietal cortex, but not 5-HT<sub>1c</sub>-receptor density in the choroid plexus. It is concluded that the anorectic and weight gain lowering effect of TFMPP deteriorates during long-term treatment in obese Zucker rats. Chronic TFMPP treatment reduces hyperinsulinemia, the potential therapeutic usefulness of which in the treatment of hyperinsulinemic states should be investigated.

HYPOTHALAMIC NEUROPEPTIDE EXPRESSION AFTER FOOD RESTRICTION IN ZUCKER RATS: EVIDENCE OF PERSISTENT NEUROPEPTIDE Y GENE ACTIVATION. U. Pesonen', R. Huupponen, J. Rouru, and M. Koulu. Department of Pharmacology, University of Turku, SF-20520 Turku, Finland

Obese Zucker rat is a model of genetic obesity characterized by hyperphagia, hyperinsulinemia and other endocrine abnormalities. In order to elucidate pathogenetic mechanisms contributing to disturbed feeding behavior in these animals, the effect of food-restriction (50 % reduction in individual 24 h food intake for 2 weeks) on three hypothalamic neuropeptides involved in the control of feeding behavior was studied in lean and obese Zucker rats. The levels of preproneuropeptide Y (preproNPY), preprocorticotropin releasing factor (preproCRF) and preprosomatostatin (preproSOM) mRNAs were determined using in situ hybridization technic. In addition, plasma insulin and corticosterone concentrations were analyzed. Food restriction significantly increased the expression of preproNPY mRNA in the arcuate nucleus in both Zucker phenotypes, while the expressions of preproCRF mRNA in the paraventricular nucleus (PVN) and preproSOM mRNA in the periventricular nucleus (PeV) were not altered. The basal expression of preproNPY mRNA was significantly greater in obese control animals than in lean control animals. Food restriction lowered plasma insulin levels, but did not change plasma corticosterone levels. It is concluded that food restriction activates NPY gene transcription in the arcuate nucleus of lean and obese Zucker rats. The results provide evidence that orexigenic NPY plays a role in the adaptation altered feeding status and reduced caloric intake, and that the enhancement of NPY expression is similar both in lean and obese Zucker rats.

TREATMENT OF W256 TUMORS IN IMMUNOCOMPETENT RATS USING HERPES SIMPLEX VIRUS MUTANTS.J.Tjuvajev<sup>1</sup>,R.G.Blasberg<sup>1</sup>, J.Berk<sup>1</sup>, J.B.Posner<sup>1,\*</sup>, S.D.Rabkin<sup>2</sup>, D.W.Pfaff<sup>8</sup> and M.G.Kaplitt<sup>3</sup>. <sup>1</sup>Dept. of Neurology, and <sup>2</sup>Program in Molecular Biology, Memorial-Sloan Kettering Cancer Center, New York, NY 10021; <sup>3</sup>Laboratory of Neurobiology and Behavior, Rockefeller Univ., New York, NY 10021

Previous studies have indicated that cytolysis by wild-type herpes simplex virus (HSV) can attenuate tumor growth in rats, while HSV mutants have been shown to be effective therapeutic agents against a human tumor grown in nude mice. We have employed two HSV mutants, a thymidine kinase deficient virus (TK-) and a ribonucleotide reductase mutant (RR-). Both mutants efficiently killed 7/7 human tumor cell lines in tissue culture. The TK- HSV also killed the rat RG2 glioma and W256 carcinoma lines as efficiently as the human lines, while the rat C6 glioma was inefficiently killed. For further study, we selected the TK- virus and the W256 line, which is a tumor commonly used as a model of metastatic brain disease. Under conditions of rapid cell growth in tissue culture, the wild-type and TK- HSV infections were similar. In resting cells, however, the TK- was compromised while the wild-type was not. Thus, the proliferative activity of the tumor at the time or site of viral injection may influence efficacy. W256 tumors growing subcutaneously in male Sprague-Dawley rats were then treated with intratumoral injections of TK- HSV, while controls received equal volumes of vehicle. experimental tumors completely regressed, with no recurrence after 6 months, while tumor growth in the remaining animals was significantly attenuated with respect to matched controls. HSV mutants are, therefore, potentially viable therapeutic agents in immunocompetent animals.

NEAR MICROSCOPIC MR IMAGING IN SITU OF BRAIN OF PHENYLALANINE HYDROXYLASE DEFICIENT MICE AT 9.1

TESLA. S. Kornguth\*, A. Shedlovsky, M. Anderson, J. Markley. Univ. of Wisconsin, Madison, WI 53705.

Shedlovsky and colleagues have isolated a mouse strain deficient in phenylalanine hydroxylase (PAH<sup>HPHS.1</sup>), a model for PKU. PKU is associated with mental retardation, hypomyelination and other anatomical and physiological abnormalities. We have successfully imaged the brain of mice and rats in situ at a resolution of 90 X 90 microns in the X,Y plane and 120 microns in the Z plane. The brains of mice that were homozygous for the deficiency, and of control littermates (heterozygous), were imaged in situ using proton spin density imaging parameters (TE 28 ms; TR 3040 ms). The resolution obtained was 400 X 400 microns in the X,Y, plane and 400 microns in the Z plane. The mice were raised on a normal mouse diet and imaged at 3.5, 4.5, 5.5, 6.5, 7.5 weeks postnatum. Following imaging, the brains were removed, fixed, sectioned and stained with cresyl violet. The magnetic resonance images, gross structure and histological appearance of the brains from the homozygous animals and control littermates will be compared. The histology of the mutant mice will be compared with that observed in the brain of a 28 year old patient who died with untreated PKU.

ABERRANT MOSSY FIBER-CA2 CONNECTIONS IN HUMAN TEMPORAL LOBE EPIL EPSY (TLE). A. Williamson\*. G. M. Shepherd and D. D. Spencer. Sects of Neurosurg, and Neurobiol. (Vale Univ. Med. Sch., New Haven, CT 06510. Medial temporal lobe sclerosis (MTS) is the most common form of medically intractable human TLE. A number of anatomical changes occur in the hippocampi of these patients including sprouting of the mossy fibers into the inner molecular layer and up to an 80% loss of specific populations of hilar interneurons and of pyramidal cells in CA1 and CA3. The pyramidal cells of CA2 and the dentate granule cells are relatively spared. These changes do not occur in the hippocampi of a comparison group of patients with TLE produced by extrahippocampal tumors (TTLE). Seizure activity can propagate from the MTS hippocampia even though the primary output paths (CA1 and CA3) have been destroyed. We hypothesize that the sprouted mossy fibers contact CA2 cells in an aberrant fashion, thus providing a route by which seizure activity can leave the hippocampus. Slices were prepared from resected hippocampi of both types of patients and intracellular recordings were made from CA2 pyramidal cells. Cells were filled with neurobiotin to confirm their morphology and location. There were no significant differences in the membrane properties between these two groups. There were, however, a number of differences in the synaptic properties. In TTLE CA2 cells, stimulation of the Schaffer collaterals in stratum radiatum of CA3 produced an EPSP followed by a biphasic IPSP in all cells studied (n=7). In these cells, the amplitudes of the EPSPs varied directly with membrane potential. In the MTS CA2 cells, however, EPSPs were not followed by IPSPs and their amplitudes did not vary significantly with the membrane potential. Even though IPSPs were not present in the sclerotic cells, bursts of action potentials could not be evoked with excitatory synaptic stimulation.

The connectivity of granule cells to CA2 pyramidal cells was examined by stimul

to generalize.

HEAT-INDUCED SEIZURES IN RATS: ANATOMICAL AND FUNCTIONAL REORGANIZATION IN THE BRAIN. N. C. de Lanerolle\*. W. Jiang, and D. D. Spencer. Section of Neurosurgery, Yale Univ. Sch. of

Med., New Haven, CT. 06510
Febrile seizures occur in 3 - 4% of children between 6 months and 5 years of age. About 2% of them progress to epilepsy, especially temproral lobe epilepsy (TLE) in later years. Previous data show that there is a greater degree of neuronal damage in patients with a history of febrile seizures. To study the effect of febrile seizures on pathogenesis in the brain Sprague-Dawley male rat pups (22 days) were exposed for 4 min to warm water (45.0°C) every 4 days. Most rat (22 days) were exposed for 4 min to warm water (45.0°C) every 4 days. Most rat pups had a seizure on the first exposure when the animals core body temperature rose from approximately 38.0 to 44.0°C. The behavioral seizure of these rats varied from facial clonus, head nodding and body jerks to forelimb clonus, rear limb clonus and falling over in full blown tonic clonic seizures. The behavioral seizure lasted from 10 sec to 6 min (median duration 3 min). This was followed by a postictal quiescent period ranging from 10 min to about 1 hour. Epidural EEG recording during a seizure revealed an EEG pattern typical of a seizure, with a post seizure suppression of activity. In rats exposed to 12 such seizures over a period of about 2 to 3 months the Timm stain revealed sprouting of mossy fibers into the inner molecular layer of dentate gyrus. Sprouting was strongest at the tip and angle of the blades of the dentate granule cell layer. After 24-seizures there was increased sprouting. Intracellular recording from 24-seizure rats showed evidence of hyperexcitable granule cells and CA1 neurons. When 12-seizure rats were reexposed to warm water after a period of 6 months since the 12th seizure, many displayed prolonged (10 min) tonic-clonic seizures followed by a long (2 5hr) period of status epilepticus (tooth-chattering). Silver staining for degenerating neurons revealed massive cell loss in the amygdala, pyriform cortex, ventral hippocampus and mediodorsal thalamus. These findings suggests that alteration of neuronal structure and function in this model resemble those by a postictal quiescent period ranging from 10 min to about 1 hour. Epidural that alteration of neuronal structure and function in this model resemble those seen in TLE associated with childhood febrile seizures. [NS27081 & NS06208].

ULTRASTRUCTURAL ANALYSIS OF PEPTIDE SYSTEMS IN THE DENTATE GYRUS OF HIPPOCAMPI FROM PATIENTS WITH EPILEPSY. M. F. Philips\* D. D. Spencer, and N. C. de Laperolle. Section of Neurosurgery, Yale Univ. Sch. of Med., New Haven, CT. 06510.

Light microscopic Studies of immunostained fascia dentata (FD) of hippocampi surgically removed from two groups of patients with medically intractable temporal lobe epilepsy revealed organizational differences with respect to the somatostatin, neuropeptide Y, and substance P like-immunoreactive (SLI. NPYLI, and SPLI respectively) systems (de Lanerolle et al, Brain Res., 495: 387-395, 1989). One group with extrahippocampal temporal lobe tumors (TTLE) demonstrated SLI, NPYLI, and SPLI interneurons in the hilus and peptide specific patterns of immunoreactive fibers in the molecular layer (ML). The other group with no apparent temporal lobe tumors (CTLE) revealed a loss of SLI, NPYLI, and SPLI hilar interneurons and concomitant changes in the fiber-like staining patterns in the ML.

The immunoreactive fiber staining in the FD of the CTLE group. In the TTLE, SLI dendrites were found ramifying from the hilus up through the inner molecular layer (IML). The CTLE FD showed a significant loss of SLI dendrites in the hilus and the IML. SLI terminals, restricted to the outer molecular layer (OML) in the TTLE group, were found throughout the entire ML.

In the TTLE group, NPYLI terminals were most concentrated in the OML, but were found throughout all layers of the FD. Few NPYLI dendrites were found in the ML. Large axon-terminal complexes traversed the OML and the IML and often contacted several dendrites at once. The CTLE FD had more of these terminals in the IML.

In the TTLE group the SPLI fibers in the ML are mostly terminal in nature. They are concentrated mainly in the OML and in a bandlike distribution on either side of the granule cell super (GCL). These small terminals swapse on proximal dendrites of granule cells in the IML. In the CTLE FD the SPLI fibers band on the hilar side of t

### 70.5

HYPEREXCITABILITY OF THE DENTATE GYRUS IN SEIZURE-SENSITIVE MONGOLIAN GERBILS. P.S. Buckmaster<sup>1</sup> and P.A. Schwartzkroin<sup>1,2</sup>, Depts. of Physiology and Biophysics<sup>1</sup> and Neurological Surgery<sup>2</sup>, School of Medicine, University of Washington, Seattle, WA 98195.

of Medicine, University of Washington, Seattle, WA 98195.

Previous studies have revealed anatomical differences in the hippocampi of seizure-resistant (SR) and seizure-sensitive (SS) Mongolian gerbils. SS gerbils have more GABAergic neurons and more GABAergic punctae contacting inhibitory basket cells in the dentate gyrus than SR gerbils. Investigators have hypothesized that inhibition of basket cells in the dentate gyrus of SS gerbils causes disinhibition of granule cells and results in hyperexcitability (Peterson et al., 1985, Brain Res. 340: 384-389). To test this hypothesis we asked, Do SS gerbils have hyperexcitable dentate gyri? Adult gerbils were classified as SS or SR by their response to a novel environment (plastic basket). Animals that seized within 1 min over the 3 testing periods were designated SS; animals that never seized were considered SR. A paired-pulse stimulation paradigm was used to assess excitability of the dentate gyrus. Animals were anesthetized (1.25 gm/kg urethane, i.p.), and recording (glass pipette, 5-15 Mohms, 2 M NaCl) and stimulating (concentric bipolar, 0.25 mm diameter) electrodes were placed stereotaxically in the dentate gyrus and the perforant path, respectively. The ratio of the second population spike amplitude to the first population spike, at stimulus intervals from 10-100 ms, was measured. SS and SR gerbils both showed strong paired-pulse facilitation (ratio < 1) at 10-20 ms stimulus intervals. However, paired-pulse facilitation was greater in SS gerbils (e.g., mean ratios at 60 ms stimulus intervals (i.e., greater than 80 ms) than in SR gerbils. These results confirm the hypothesis that SS gerbils have hyperexcitable dentate gyri and are consistent with the hypothesis of increased inhibition of basket cells.

# 70.7

IN VIVO HYPOXIA CAUSES HYPEREXCITABILITY IN SLICES OF IMMATURE RAT HIPPOCAMPUS AND NEOCORTEX. F.E.Jensen\* and C.E. Stafstrom. Dept. of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115

In vivo, hypoxia is epileptogenic in immature rats (P5-17), but not in adults (Ann. Neurol., 1991;29:629-637). To further examine this age-dependent difference in hypoxia-induced excitability, we prepared brain slices from P10 (n=11) and adult (P60) (n=4) rats immediately after exposure to hypoxia (4% O2) in vivo. Extracellular activity was recorded from hippocampal (n=28) and neocortical slices (n=28) from hypoxic rats. Slices from age matched normoxic rats (controls) were maintained in the same chamber for comparison. In CA1, responses evoked by Schaffer collateral stimulation in slices from hypoxic pups frequently revealed polyphasic field potentials that were not seen in controls at either age or in slices from hypoxic adults. In neocortical layers II/III, the duration of responses to white matter stimulation ere prolonged (48-75 msec) compared to controls (28-60 msec) at P10. Polyphasic responses were more complex and prolonged in both layers II/III and V in P10 slices from hypoxic rats compared to controls. In addition, long latency field potentials with onset > 80 msec from the stimulus were observed in neocortex in some of the slices from hypoxic P10 rats. In contrast, neocortical recordings from layers II/III and V in slices from hypoxic adults were usually similar to control slices, although prolongation of the evoked response was occasionally observed.

These results suggest that slices from immature rats which have undergone hypoxic seizures in vivo are hyperexcitable, and may prove useful as a model system for the mechanisms of seizure ontogenesis in perinatal hypoxia.

ELECTRON MICROSCOPIC VISUALIZATION OF HIPPOCAMPAL MOSSY FIBER BOUTONS IN THE DENTATE MOLECULAR LAYER AFTER STATUS EPILEPTICUS. M.M. Okazaki\*, D.A. Evenson and J.V. Nadler, Depts.

Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

In response to the neuronal degeneration associated with status epilepticus,

hippocampal mossy fibers develop recurrent collaterals that invade the dentat molecular layer. Mossy fiber collaterals have been suggested to form an aberrant recurrent excitatory circuit by making synapses on dentate granule cells. This hypothesis was tested by labeling both mossy fibers and granule cells with biocytin. Status epilepticus was produced by treating adult male rats with 325 mg/kg pilocarpine preceded by 1 mg/kg methscopolamine. At least 4 months later. transverse slices of the caudal hippocampus were prepared and biocytin was ionophoretically applied to stratum lucidum of area CA3b. After allowing 3 h for retrograde transport, the slices were fixed and cut into 50  $\mu$ m-thick sections, biocytin was visualized with avidin/biotinylated HRP/diaminobenzidine and thin sections were prepared for electron microscopy.

Each thin section contained a few labeled dentate granule cell bodies and dendrites. In sections from rats that developed recurrent mossy fibers, but not in sections from control rats, labeled boutons were observed in the dentate molecular layer. Labeled boutons were located mainly in the inner third of the molecular layer, but a few were located farther from the cell body layer. Most were seen to be engaged in synaptic contact with one or more dendrites. A few were contacting labeled dendrites. These results suggest that recurrent mossy fiber collaterals do form synapses and, at least in some cases, innervate granule cells. (Supported by NIH grant NS 17771.)

Characterization of monosynaptic GABAergic IPSPs in hippocampal CA1 pyramidal cells from kainic acid treated rats. S. Williams', P. Vachon and J.-C. Lacaille. Centre de recherche en sciences neurologiques, Département de physiologie, Université de Montréal, Montréal, Québec, Canada H3C 317.

The present experiments assessed whether disconnection of GABAergic sy from interneurons to CA1 pyramidal cells contributed to the hyperexcitability in kainate (KA) lesioned hippocampus. Hippocampal slices were obtained from adult rats 2-4 weeks after bilateral intraventricular injection of KA (0.65 µg in 1 µl saline, pH 7.4) and from sham-treated or control rats. Intracellular recordings were obtained from 47 pyramidal cells of KA-treated animals in areas of slices displaying hyperexcitable field potentials. Following str. radiatum stimulation (0.05 ms, 25-350 µA), 22 cells were hyperexcitable (≥ 2 action potentials) and the remaining cells (n=25) displayed single action potentials (non-hyperexcitable) as control cells (n=20).

A long duration, voltage-sensitive component was associated with subthreshold EPSPs in a majority of hyperexcitable (12/15) and non-hyperexcitable (3/5) but not in control cells (1/10). When excitatory synaptic transmission was blocked with NMDA and non-NMDA antagonists (40  $\mu$ M AP5 and 20  $\mu$ M CNQX, respectively), stimulation of str. radiatum elicited biphasic monosynaptic IPSPs in all hyperexcitable (n=9), non-hyperexcitable (n=9) and control cells (n=8). Monosynaptic IPSPs were not different in terms of amplitude, latency,  $E_{\rm rev}$  or conductance changes between cells in KA-treated and control groups. In hyperexcitable cells, the early component of monosynaptic IPSPs was reduced by the GABA<sub>A</sub> antagonist bicucultine (100-200 µM; n=7). The late component was reduced by the GABA<sub>B</sub> antagonist 2-OH-saclofen (2 mM; n=3). Comparable results were observed in non-hyperexcitable cells (n=4) from KA-treated animals and in control cells (n=5). In conclusion, GABA, and GABA, synapses appear intact and functional in hyperexcitable CA1 pyramidal cells of KA-lesioned hippocampus. Supported by the Medical Research Council of Canada and Savoy Foundation.

RECEPTOR IS INVOLVED IN EXCITATORY SYNAPTIC TRANSMISSION IN THE SUPERFICIAL/MIDDLE LAYERS OF THE EPILEPTOGENIC HUMAN NEOCORTEX. Hwa GGC\*, Mattia D, Avoli M. MNI, McGill Univ., Montreal, Que., Canada.

Intracellular recordings were made from layers II-IV of human neocortical slices resected from the temporal (n = 18), frontal (n = 3) and occipital (n = 1) regions of 22 epileptic patients. The neurons (n = 61) discharged in a regular-spiking fashion and displayed an average resting Vm of -74mV, input resistance of  $30M\Omega$ , action potential amplitude of 92mV. Following synaptic stimulation at subthreshold intensity, the neurons responded with a depolarizing postsynaptic potential (PSP) with fixed latency to onset (0.8-4 ms). At suprathreshold intensities, a single action potential was observed in 95% of the population while an all-or-none bursting discharge was recorded in the remaining 5%. Vm analysis of the PSP evoked by low intensity stimulation revealed an excitatory PSP (EPSP) that increased in size with depolarization and decreased in size with hyperpolarization. This type of anomalous voltage behavior could also be mimicked by an intrinsic response evoked by a brief pulse of depolarizing current. With higher intensity stimulation, inhibitory PSPs were activated and could impose a shunting effect on the EPSP at depolarized Vm. Pharmacological experiments showed that the NMDA antagonist CPP (5  $\mu$ M) could greatly reduce or block the peak amplitude of the EPSP evoked by low intensity stimulation and attenuated the late phase of the bursting discharge. These findings demonstrate that NMDA receptors are operant in the epileptogenic human neocortex and appear to play an important role in the excitatory interaction between neurons. The presence of an all-or-none bursting discharge in some neurons suggests that this interaction might be upregulated, possibly through the activation of NMDA receptors.

CHANGES IN GLUTAMATE RECEPTOR BINDING AND EXCITATORY FIELD RESPONSES IN THE DENTATE GYRUS OF EPILEPTIC PATIENTS. P. McGonigle, A. Dai, M.J. O'Connor and L.M. Masukawa\*. Depts. of Pharmacology, Surgery and Neurology, University of Pennsylvania and Depts. of Neurology and Surgery, Graduate Hospital, Philadelphia, PA.

Although the role of glutamate receptor activation in excitation of the hippocampus is accepted, the contribution of changes in receptor density and responsiveness to electrophysiological abnormalities observed in temporal lobe epilepsy is not well understood. It has been reported that the density of NMDA receptors in the dentate gyrus of patients who have undergone temporal lobectomies either increases (McDonald et al., 1991; Geddes et al., 1990) or does not change (Hosford et al., 1991). We also observed no significant difference in the binding of [3H]-MK-801 to NMDA receptors in the dentate gyrus of epileptic patients (n=28) compared to postmortem controls (n=6). However, we observed that the relationship between the ratio of the early component of the field EPSP (non-NMDA receptor activation) to the longer duration EPSP (NMDA receptor activation) of dentate granule cells (n=5) and a measure of hilar anatomic abnormality (cell density) approached significance (p=.07). We did not observe a significant correlation between the binding of [3H]-MK-801 to NMDA receptors or [3H]-CNQX to quisqualate receptors in the molecular layer of the dentate gyrus or the hilus with hilar cell density. These results suggest that changes in the electrophysiology measured in this study are not due to alterations in the overall NMDA or quisqualate receptor density. Receptor changes in discrete subregions maybe responsible for the differences in physiological responses that were observed. (Supported by GM 34781, NS 23077 and the Pew Charitable Trusts)

INCREASED EXCITABILTY IN THE EPILEPTOGENIC HUMAN TEMPORAL LOBE: A CURRENT STRENGTH ANALYSIS. <u>S.U. KHAN\*C.L. WILSON, E.J. BEHNKE.</u> Dept. of Anatomy and Cell Biology, Dept. of Neurology, and Brain Res. Inst. UCLA School of Medicine, Los Angeles, CA 90024.

In 25 depth electrode patients with medically intractable unilateral

In 25 depth electrode patients with medically intractable unilateral temporal lobe epilepsy, the excitability of hippocampal pathways was investigated by stimulating them with single pulses of ascending current strength from thereshold to maximal response. The measure of excitability was defined as "c50" the current required to evoke a response 50% of maximal amplitude. Hippocampal sites investigated included anterior hippocampus, middle hippocampus, entorhinal cortex, presubiculum, posterior hippocampal gyrus and middle hippocampal gyrus. The pathways joining these structures include perforant path, retrohippocampal path and hippocampal association path. Sites were classified as epileptogenic (EPG) or non-epileptogenic (NEG) according to whether they were on the side where the patient's spontaneous seizures always started or never started, respectively.

(NEG) according to whether they were on the side where the patient's spontaneous seizures always started or never started, respectively. The mean c50 level for 35 EPG hippocampal sites was 2.60 mA (SEM=0.12) while c50 for 63 NEG sites was 3.22 mA (SEM=0.13). In a two way analysis of epilepsy vs. current, the difference in excitability between EPG and NEG pathways was significant at the p<.002 level (df=1, F=10.1) Across the three EPG hippocampal pathways studied, c50 was always lower than in NEG, but there was no significant difference between pathways.

The lower current strength required to evoke 50% response demonstrates greater excitability of the EPG hippocampal principal neurons. Supported by NIH grant NS02808.

EFFECTS OF SEPTO-HIPPOCAMPAL PROJECTIONS ON EXPERIMENTAL GENERALIZED SEIZURES. J.W. Miller\*. G.M. Turner and B.C. Gray. Dept. of Neurology and Neurological Surgery (Neurology), Washington Univ. Sch. of Med., St. Louis, MO 63110.

Epileptic seizures occur less often during wakefulness or paradoxical sleep, two conditions during which septo-hippocampal theta activity is seen. In preliminary studies of this relationship, we have determined effects of different, in vivo, experimental manipulations in the medial septal nucleus of the rat on hippocampal activity and seizures induced

by systemic pentylenetetrazol.

When myoclonic and facial-forelimb seizures were induced by 50 mg/kg intraperitoneal pentylenetetrazol, injections of 1 to 2.5 µg of the cholinergic agonist carbachol in the medial septal nucleus led to a cessation of behavioral seizures and EEG spiking within 15 to 30 seconds, accompanied by the appearance of hippocampal theta activity. Bipolar electrical stimulation of the medial septal nucleus at frequencies of 4-8 hertz produced similar anticonvulsant actions and also induced rhythmic hippocampal activity at the stimulus rate. Electrolytic lesions of the medial septal nucleus resulted in the chronic disappearance of hippocampal theta activity and lowered the thresholds of myoclonic and facial forelimb seizures induced by timed intravenous infusion of pentylenetetrazol, although tonic-clonic seizures were not affected.

Regulation of the physiological state of the hippocampus via septohippocampal projections is likely to be a critical mechanism by which arousal state influences the probability of seizure occurrence. Supported by NIH Grant NS14834.

PRESENCE OF PAIRED-PULSE FACILITATION AND NON-GABA-A PAIRED-PULSE INHIBITION REVEALED BY MODERATE TO LOW INTENSITY STIMULATION IN THE DENTATE GYRUS OF EPILEPTIC PATIENTS. K. Uruno.\*M.J. O'Connor and L.M. Masukawa. Depts. of Neurology and Surgery, Graduate Hospital and Univ. of Pennsylvania, Philadelphia, PA.

Paired-pulse stimulation of dentate granule cells via perforant path input in brain slices from temporal lobe epileptic patients produces inhibition at 20 msec interstimulus intervals at moderate stimulation intensities (40-50% of maximum intensity). The magnitude of the paired-pulse inhibition (PPI) varied from complete to 10% inhibition. In the presence of 15-20 uM bicuculline, the PPI was reduced but in some cases was not affected. Because of the presence of a prolonged EPSP and accompanying population spikes, the PPI after bicuculline was initially attributed to a reduction of action potential generation by voltage-dependent membrane currents. To eliminate membrane depolarization that occurs during bicuculline disinhibition, we measured PPI during low intensity stimulation which reduced the likelihood of NMDA receptor mediated conductances and multiple spiking or during APV (20 uM). Low intensity stimulation in bicuculline led to paired-pulse facilitation (PPF) which suggested that the PPI before bicuculline was mediated by GABAA receptors. During APV at moderate stimuli intensities PPI was not substantially eliminated although multiple spiking and prolonged EPSPs were reduced indicating that the PPI was not due to an increase in membrane conductance. The results suggest the presence of a non-GABA-A mediated PPI that is activated at moderate or higher stimulus intensities. (Supported by NS-23077)

THE INVOLVEMENT OF GABAERGIC TRANSMISSION WITHIN THE POSTERIOR THALAMIC NUCLEI (PO) IN REGULATING SEIZURES IN RATS. S. G. Xued. S. Garant. E. F. Sperber and S. L. Moshé. Departments of Neurology, Neuroscience and Pediatrics, Albert Einstein College of Medicine, Bronx, NY 10461.

There is evidence indicating that specific thalamic nuclei may be

There is evidence indicating that specific thalamic nuclei may be involved in the expression and control of seizures. In the present study, the function of the posterior thalamic nuclei (PO) in the regulation of seizures was investigated in adult rats. Several GABAergic agents were bilaterally infused into the PO via implanted cannulae. The GABAelevating agent, \( \gamma\)-vinyl-GABA (GVG, 20 \( \mu\) g) significantly suppressed clonic and tonic seizures induced by flurothyl. Muscimol (a GABAA agonist, 100 ng) also inhibited clonic and tonic seizures, whereas bicuculline (a GABAA antagonist, 100 ng) facilitated these seizures. Baclofen (a GABAB agonist, 200 ng) was less effective at suppressing clonic seizures, and did not alter the susceptibility to tonic seizures. The findings suggest that GABAergic neurons in the PO may be involved in seizure control. The \( \gamma\)-minobutyric acid (GABA) system in the substantia nigra pars reticulata (SNR) also plays a key role in the control of seizures. Based on anatomical evidence for the nigral GABAergic projections, direct or indirect, to the thalamic nuclei including the PO, we hypothesize that the GABAergic pathway from the SNR to the PO may be involved in the control of seizures.

CHANGES IN EXTRACELLULAR SPACE DO NOT MEDIATE STIMULUS TRAIN INDUCED EPILEPTOGENESIS IN HIPPOCAMPAL SLICES. J. Jing. S. Clark, W.A. Wilson, P.G. Altken\*, Dept. Cell Biology, Duke Med. Center, and VA Med. Center, Durham, NC 27710

Electrographic seizures (EGS) can be induced in hippocampal slices by

Electrographic seizures (EGS) can be induced in hippocampal slices by repeated delivery of stimulus trains to the CA3 region (Science, 245:648-651, 1989). We tested the hypothesis that a decrease in extracellular space (Interstitial Volume Fraction, ISVF) underlies this model of epileptogenesis. Transverse hippocampal slices 0.60 mm thick from 14-22 day old rats were maintained at 32.8°C in an interface chamber. EGS were provoked by stimulating Schaffer collaterals with trains (60Hz, 2 sec, intensity for maximal population spike) every 10 minutes while recording extracellular responses in CA3 or CA1. EGS of 16-35 sec duration occurred after 1-3 trains. ISVF was determined using the method of Nicholson and Phillips (J. Physiol., 321:225-257, 1981) which measures diffusion of tetramethyl ammonium (TMA) through extracellular space from a point source to a TMA-sensitive electrode. 060-.150 mm distant. ISVF was measured in st. radiatum or st. pyramidale of CA3 or CA1 before, and then 2 and 7 minutes after each train during, the induction of EGS (to a maximum of 10 trains). Control slices were maintained identically without delivery of stimulus trains, with ISVF measurements taken at equivalent time points. Control slices showed no ISVF change during 2-2.5 hour experiments. Experimental slices showed an average 14% decrease in ISVF (range -0.3 to 26.9); this change, however, was not correlated with the development of EGS. Full-blown EGS could occur without any ISVF change. These data suggest that while modest changes in ISVF may result from seizure activity, persistent ISVF change is not a major mechanism in this model of epileptogenesis.

INCREASED EXCITATORY RESPONSES IN GENETICALLY EPILEPSY-PRONE RAT HIPPOCAMPUS. T.L. Pencek\*, S. Verma and M. Moran Neurosurgery Laboratory, Southern Illinois University School of Medicine, Springfield, IL 62702.

The genetically epilepsy-prone rat (GEPR) is a well known model for audiogenic seizures of brain stem origin. We wanted to see if there were differences in hippocampal excitability, using the CA<sub>3</sub> to CA<sub>4</sub> pathway for our extra investigation. We recently reported that a marked increase in paired pulse facilitation occurs in the GEPR hippocampus CA<sub>4</sub> pyramidal cell layer, compared to normal Sprague Dawley rats. This is amplified in low K solutions. We have now attempted to separate the excitatory and inhibitory components of hippocampal hyperexcitability. Bicuculline produced a marked increase in paired pulse facilitation in GEPRs. The amount of facilitation in normal rats in a Bicuculline solution resembled that in GEPRs without Bicuculline. This suggests that reduced gamma amino-butyric acid-mediated inhibition may contribute to abnormal GEPR responses. Our results in low K+ solutions show a two-fold increase in facilitation suggesting the involvement of a K+ channel in the enhanced excitation. Intracellular recording from CA<sub>1</sub> pyramidal cells in low K+ medium show an increase in long after hyperpolarization (LAHP) potential. Preliminary studies in GEPR rats showed that the LAHP is greater than in the normal rats. The spike amplitude increases markedly in low K+ and a higher current is required to produce action potentials. Further hippocampus research in GEPRs may provide information on the genetic mechanisms of epilepsy in pyramidal cells.

LOCAL INTERACTIONS OF CARDIAC MODULATED NEURONS OF HUMAN HIPPOCAMPUS AND AMYGDALA. R.C. Frysinger\*, B. Colder, M.F. Levesque and R.M. Harper. Brain Res. Inst., Div. of Neurosurgery, and Dept. of Anatomy & Cell Biology, UCLA Sch. of Med., Los Angeles, CA. 90024
Single-cell activity recorded from hippocampus and amygdala in

patients with epilepsy is reduced in structures ipsilateral to the seizure focus. The number of cells with discharge modulated by the cardiac cycle, however, is relatively unchanged, suggesting that this type of cell may be less vulnerable to epileptogenic changes. We have investigated the degree and type of interaction of cardiac modulated cells with other cells recorded from the same local area to determine the extent to which these cells participate in local networks. Unit recordings were taken from bundles of 9 microwires implanted in amygdala, hippocampus and overlying cortical areas in patients undergoing presurgical seizure monitoring. Up to 8 channels of unit activity from each bundle were simultaneously digitized, and individual spike trains were digitally discriminated off-line for analysis of local interaction. Analysis of 66 cells revealed 9 with significant cardiac modulation and 19 with some form of local interaction. Within this sample, cells with cardiac modulation did not interact with non-cardiac modulated cells. These findings suggest that cardiac modulated cells represent a relatively discrete population within mesial temporal structures, and the relative lack of local interactions may help protect such cells from seizure-related damage. INTRINSIC AND SYNAPTIC PROPERTIES OF RAT SUBICULAR NEURONS. <u>D MATTIA</u>, <u>GGC HWA</u>, <u>M AVOLI</u>, <u>P GLOOR</u>. MNI, McGill Univ., Montreal, Que., Canada.

The subiculum is a region through which most of the hippocampal output is routed. Because of its strategic location, it could play an important role in the spread of epileptiform activity from and within the limbic system. In this study, intracellular and extracellular recordings were made from the subicular region of rat brain slices maintained in vitro. Analysis of the current-voltage relationship revealed membrane inward rectifications in both depolarizing and hyperpolarizing direction. Following the injection of positive current pulses, single action potentials were followed by a fast afterhyperpolarization (AHP), a depolarizing afterpotential and a medium AHP. A slow AHP was discernible after repetitive firing. Synaptic stimulation from the alveus elicited excitatory postsynaptic potentials and doublets of action potentials intracellularly, and double population spikes extracellularly. Hyperpolarizing postsynaptic potentials were not seen. Pharmacological experiments with excitatory amino acid antagonists indicate that the double population spikes were blocked by CNQX (3-5  $\mu$ M), but remained nsensitive to CPP (10-20  $\mu$ M). Our findings demonstrate that the intrinsic membrane properties of subicular neurons are similar to those of other central neurons. Moreover, the excitatory connection between the hippocampus and the subiculum was primarily mediated by non-NMDA receptors. EXCITATORY INTERACTIONS OF BURSTING CELLS IN HUMAN MESIAL TEMPORAL LOBE. B. COLDER\*, R.C. FRYSINGER, C.L. WILSON, M.F. LEVESQUE, AND R.M. HARPER, Dept. of Anatomy and Cell Biology, Dept. of Neurology, Div. of Neurological Surgery, and Brain Res. Inst. UCLA School of Medicine, Los Angeles, CA 90024.

Foilentogenisis in human mesial temporal structures is associated with

Epileptogenisis in human mesial temporal structures is associated with cell loss and changes in electrophysiological function of remaining neurons. We examined the interactive properties of simultaneously recorded spike trains from amygdala, hippocampus, and associated cortical areas to investigate the extent of neuronal intercorrelations as a function of single cell discharge properties. We analyzed recordings of spontaneous activity from epilepsy patients undergoing chronic depth electrode implantation for the diagnosis of focal origion of temporal lobe epilepsy. Individual neurons from multi-unit spike trains were digitally separated and cells were sorted into "bursting" and "non-bursting" on the basis of the auto-correlograms. Cells that displayed an increased probability of discharge near the origin of an auto-correlation histogram were designated as bursting cells. The nature and degree of cell-to-cell interactions were determined by cross-correlation histograms. Cells that fired in bursts were more likely to show an increase in synchronous firing with other cells, whereas non-bursters were more likely to form cross-correlations that showed a decreased probability of discharge of the dependent cell. The amygdala showed a much larger proportion of bursting cells than other areas studied. We speculate that bursting mesial temporal neurons may form physiological networks that play a significant role in the discharge synchrony characteristic of epileptogenesis. Supported by NS 02808

MINIATURE AND EVOKED INHIBITORY POSTSYNAPTIC CURRENTS IN DENTATE GRANULE CELLS OF HUMAN AND RAT HIPPOCAMPAL SLICES. Masako Isokawa\* and Michel F. Levesque. Brain Research Institute and Dept. of Neurosurgery, University of California, Los Angeles, CA 90024-1761

Mhole-cell patch-clamp techniques were used to record inhibitory postsynaptic currents (IPSCs) from dentate granule cells (DGCs) in slices. In rats, hippocampal slices were prepared from normal male Sprague-Dawley (50-100g). In humans, the hippocampal tissue was obtained from epileptic patients who underwent a surgical treatment for intractable seizures. The perforant path stimulation evoked inward postsynaptic currents (PSCs) at a holding potential (Vm) close to the resting. PSCs were biphasic at Vm=-20; EPSCs as a nearly inward component and IPSCs as a late outward component with a reversal potential near -40 mV (CsF electrode). At Vm=0, near the reversal potential for EPSCs, IPSCs were measured as an outward current with the amplitude of 90-100 pA. These findings were similar in both rats and human DGCs. However, when high frequency stimulation (100Hz for 3 sec) was administered, they responded to it in a different fashion. High frequency stimulation temporarily, but significantly, increased the IPSC amplitude in normal rat DGCs (for 10-20 ms at Vm=0). This increase was blocked by 50 µM APV. In human epileptic DGCs, the IPSCs amplitude, measured at Vm=0, was considerably reduced (more than 1/3 of the original) after the 100 Hz stimulation. Spontaneously-occurring miniature IPSCs (mIPSCs) were observed in both rat and human DGCs. Their amplitude varied from 10-100 pA and some of them were as large as evoked IPSCs (Vm=0). They persisted in TTX (1µM) but were blocked in BMI (10µM). DGG (1 mM) and APV (50 µM) did not abolish mIPSCs. However, they altered the frequency of mIPSCs, especially increasing the occurrence of high amplitude mIPSCs in human epileptic DGCs. Supported by NIH Grant NS02808.

LASTING CHANGES IN NEUROPEPTIDE Y (NPY) RELEASE IN THE RAT HIPPOCAMPUS INDUCED BY ELECTRICAL KINDLING OR KAINIC ACID (KA). A. Vezzani\*, M. Rizzi, A. Monno, A. Galli and R. Samanin. Lab. of Neuropharmacology, Mario Negri Institute for Pharmacological Research, Milan, Italy.

NPY release was measured in rat dorsal hippocampal slices during electrical kindling of the hippocampus or one month after KA (10 mg/kg, i.p.). Spontaneous release was increased bilaterally 1.5 times on average (p<0.05) 48 h after preconvulsive stage 2 kindling compared to shams (26.2+5.2 fmo1/ml every 10 min). 25,50 and 100 mM KC1 increased NPY release in shams in a Ca2+-dependent manner (2+0.2, 4.4+0.3 and 6.1+0.9 times baseline. p<0.01)A larger increase (3.0+0.3, 4.1+0.75 and 1.7+0.07 times sham values at 25,50 and 100 mM KCl p<0.05 and 0.01) was found bilaterally at stages 2 and 5. No differences occurred 48 h after a single afterdischarge. An average twofold increase in the 50 mM KC1-stimulated NPY release (p<0.05) was found in the dentate gyrus of rats with behavioral seizures after KA compared to controls. These changes may have interesting functional consequences on hippocampal epileptogenesis.

PERSISTENT ENHANCEMENT OF CALCIUM CURRENTS AFTER KINDLING EPILEPTOGENESIS IN THE HIPPOCAMPUS OF THE RAT. W.J.Wadman\* and M.Vreugdenhil Exp. Zoology, Univ. of Amsterdam Kruislaan 320 1098 SM Amsterdam, The Netherlands.

M.Vreugdenhil Exp. Zoology, Univ. of Amsterdam Kruislaan 320 1098 SM Amsterdam, The Netherlands.

Daily application of a tetanic stimulation (50 Hz, 2 s) to afferent fibres induces in the projection area an epileptic focus characterized by an increased excitability and afterdischarges, ultimately leading to generalized tonic, clonic convulsions (kindling model of epileptogenesis). Stimulation was daily applied through electrodes implanted in the Schaffer collaterals of the hippocampus of the rat, epileptogenesis was monitored through a second bundle straddling the pyramidal cell layer in area CA1. Experimental and implanted control groups consisted of at least 7 animals. Kindling was continued until six generalized convulsions (Racine class 5). Rats were sacrificed and neurons were enzymatically (trypsin) and mechanically dissociated from the focal area. Calcium currents were measured under voltage-clamp in the whole-cell patch configuration. Previously we showed that 24 hours after the last sizure the slow inactivating (SI, time constant 75 ms) and the non-inactivating (NI) component of the calcium current (activated by a depolarization to 0 mV from a 3 s prepulse at 120 mV) were enhanced by 36% and 39% in amplitude, without changes in kinetics or voltage dependency. The fast inactivating component (15 ms) did not change. We now show that this enhancement is persistent at six weeks after the last kindling stimulation (28% and 42% for SI and NI) which relates it to the kindled state instead of being an aftereffect of the epileptiform discharge. From double pulse protocols and repetitive activation of calcium currents we concluded that changes in calcium dependent inactivation can not explain our findings.

Potassium currents were investigated with the same techniques. The noninactivating delayed rectifier was not changed after kindling, Measured 24 hours after kindling the A-current showed a transient enhancement in amplitude (62% higher than control) which disappeared at six weeks after kindling.

The kindled

A POSSIBLE ROLE FOR THE HORMONES OF THE HPA AXIS IN THE DEVELOPMENT OF KINDLED SEIZURES. G. K. Weiss, M. Fernandez, N. Castillo, T. Hoffman, A. Ratner\* and K. Lucero. University of New Mexico School of Medicine, Department of Physiology, Albuquerque, New Mexico.

We are investigating the possibility that hormones of the HPA axis (CRF, ACTH, CORT) may influence the development of kindled seizures. It is known that the HPA axis is activated during kindled seizures. Is there a feedback effect of these hormones on the development of kindled Previous experiments investigating the effect of adrenalectomy on the kindling procedure have been inconclusive. We now report that adrenalectomy decreases the relatively rapid kindling rate when kindling is done in the evening (circadian cort high); increases the relatively slow rate of kindling when it is done in the morning (circadian cort low) and has no effect on mid-day kindling rate. Other experiments using metyrapone to block CORT production produced the same results. Studies in which dexamethasone was injected prior to kindling increased the rate in both the morning and evening kindled rats. We also kindled Lewis rats at the evening time. They have been shown to lack both a circadian and stress response of the HPA axis. They required 16 kindling stimulations to progress through stages 1-2 while the controls (Fisher-344) took 6.8. Is the difference related to the absence of a HPA axis response? Studies are in progress to further investigate this possibility, and determine which hormones of the HPA axis may play a role in the development of kindled seizures. (Supported by NIH Grants RR08139 & NS23262)

TRH mRNA AND FOS-LIKE IMMUNOREACTIVITY ARE CO-LOCALIZED IN LIMBIC STRUCTURES FOLLOWING AMYGDALA KINDLED SEIZURES. Jeffrey B. Rosen\*, Jamie Abramowitz, and Biological Psychiatry Branch, NIMH, Bethesda, Robert M. Post.

Previous studies have shown that both the expression of the immediate-early gene, c-fos, its protein product, Fos, and TRH mRNA are transiently increased in the same limbic structures following kindled seizures. To further elucidate this following kindled seizures. association, the present study examined whether TRH mRNA association, the present study examined whether TRY introduced and Fos-like immunoreactivity (Fos-LI) are co-localized in the same cells following amygdala kindled seizures.

Rats were kindled by once daily electrical stimulation of the amygdala. Five hours following the last stage 5 seizure, the

allyguala. The hours informing the last stage of the rats were fixed and the brains removed and sliced. Sections were sequentially labelled with an oligonucleotide probe for TRH mRNA and an antibody for Fos and Fos-related antigens.

Following kindling, increases in TRH mRNA and Fos-LI were primarily found in the pyriform, entorhinal and perirhinal cortices and the dentate gyrus. The mean percent of Fos-LI labelled cells with TRH mRNA was 62% in the pyriform, 70% in the entorhinal and 80% in the perirhinal. Intense TRH mRNA and Fos-LI labelling were found in the dentate gyrus, but were too dense to measure. Control rats had very low levels of both TRH mRNA and Fos-LI. demonstrates that increases in both TRH mRNA and Fos-LI following kindling are highly co-localized and suggests that Fos may act as a transcription factor for TRH.

EFFECTS OF PARTIAL HIPPOCAMPAL KINDLING IN VIVO ON INTRACELLULARLY RECORDED PAIRED-PULSE RESPONSES AND MEMBRANE PROPERTIES OF HIPPOCAMPAL CAI NEURONS IN VITRO. D. Zhao, Xiao-Wen Fu\* and L. Stan Leung. Depts. Physiology and Clin. Neurol. Sci., Univ. Western Ontario, London, Ontario N6A 5A5 Canada.

Kindled rats received 15 afterdischarges (ADs) evoked hourly, 5 times a day, by 1-sec 100Hz stimulus trains delivered to one hippocampal CA1. Control rats received the same number of pulses at a similar intensity but at 0.17 Hz. One-2 days or 21-23 days after the last stimulation, hippocampal slices were obtained from the rats, with the experimenter blind to the previous history of stimulation. Pairedpulses at 10-200ms interpulse intervals (IPIs) were delivered to the str. radiatum near CA3, and intracellular responses were recorded from the CA1 neurons. Previous studies in our laboratory indicate that the population excitatory postsynaptic potentials (EPSPs) and population spike in CA1 were facilitated by partial kindling. This study confirms the facilitation of paired-pulse EPSPs with intracellular recordings. The intracellular EPSP paired-pulse index (EPI= slope of 2nd EPSP/ slope of 1st EPSP) was significantly larger in 'kindled' than 'control' neurons, on either day 1 or day 21 after kindling (P < 0.001, F(df = 1,22 or 28) > 13). Whether tentier day 1 or day 21 after kinding (F 0.001, F(d1=1,22 of 20) > 15). whether the first pulse evoked a spike or not did not affect the EPI of kindled or control neurons, suggesting that the afterhyperpolarization (AHP) did not affect the EPI. Membrane properties that were not affected by kindling included the resting membrane potential, threshold, height and duration of the action potential, the fast AHP amplitude, input resistance and the EPSP threshold. In other rats, bath perfusion of bicuculline methiodide (25-50 μM) and perfusion of 8mM [K<sup>+</sup>]<sub>0</sub> significantly increased the intracellular EPI. Since paired-pulse facilitation of the EPSP is probably presynaptically mediated, kindling, bicuculline and 8mM [K<sup>+</sup>]<sub>o</sub> may all suppress presynaptic GABA-A inhibition. (Supported by NSERC).

# 71.6

EFFECTS OF AMINOPHOSPHONOVALERIC ACID (APV) ON CARBACHOL-INDUCED KINDLING IN THE RAT AMYGDALA; A PRELIMINARY REPORT. D.Saucier\* and D.P. Cain. Department of Psychology, Univ. of Western Ontario, London, Ontario, CANADA N6A 5C2.

The effects of APV, a competitive NMDA antagonist (7.5 µg in 0.5  $\mu$ l) on carbachol-induced (5nM in 0.5  $\mu$ l) kindling were studied using chemitrodes implanted in the right basolateral amygdala (BLAM) of male rats. An electrode was implanted in the contralateral structure for recording purposes. APV was injected (using an infusion pump) into the BLAM 15 minutes prior to the injection of the carbachol. Control rats were given either injections of saline 15 minutes prior to carbachol injections or carbachol injections only, into the BLAM. Injections were given every 48 hours. The effects of the injections were measured both behaviourally and electrographically. Kindled seizures occurred in the APV + carbachol group, although the overall duration of epileptiform spikes was significantly shorter relative to controls. Behavioural convulsions appeared similar in the two groups. These data suggest that activity of local NMDA receptors is not essential for carbachol kindling. Supported by an NSERC grant to DPC.

LAMINAR PROFILE OF [K+]<sub>o</sub> INCREASES AND EPILEPTIFORM ACTIVITIES IN NEOCORTICAL SLICES FROM PTZ-KINDLED RATS. <u>D.Saar. E. Barkai.</u> and <u>M.J. Gutnick.</u>\* Dept. Physiology, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beersheva, Israel.

University of the Negev, Beersheva, Israel.

In a model of chronic epilepsy - kindling induced by systemic pentylenetetrazole - neocortical slice neurons at different subpial depths responded differently during evoked interictal events. Cells in deep layers generated a paroxysmal depolarization shift (DS) with a reversal potential around 0 mV, similar to neurons at all depths in acute, picrotoxin-induced hypersynchrony. However, in superficial neurons E<sub>DS</sub> was around -50 mV; it gradually shifted in the depolarizing direction during low frequency (.2-1 Hz) stimulation. In recordings with ion-sensitive microelectrodes, largest increases in [K+]<sub>o</sub> during single paroxysmal events were recorded in deeper layers of kindled slices, as opposed to superficial layers of picrotoxin-treated slices. In both the chronic and the acute models, the rise in [K+]<sub>o</sub> began after the onset of the paroxysmal wave, and was correlated with the later part of the DS. In both models, bath application of APV (20 µM) caused a decrease in the duration of the DS, and marked attenuation of the associated rise in [K+]<sub>o</sub>.

Drop application of glutamate in normal neocortical slices bathed in TTX, evoked CNQX-resistant, APV-sensitive focal increases in [K+]<sub>o</sub> which were greatest in superficial layers. By contrast, in slices from kindled rats the [K+]<sub>o</sub> rises were greatest in deep layers.

These data indicate that this form of kindling entails a long-term functional change in synaptic organization of the local neocortical circuitry; they are consistent with the hypothesis that laminar redistribution of NMDA-type receptors is involved.

### 71.9

SITE-SPECIFICITY OF KINDLING ANTAGONISM IN RATS. <u>M. E. Corcoran\*, T. H. Gilbert, & R. D. Kirkby</u>. Dept. of Psychology, U. of Victoria, BC, Canada, V8W 3P5.

With concurrent alternate stimulation of two forebrain sites, one of the sites (dominant) supports typical progressive seizure generalization (kindling), whereas the other site (suppressed) supports only focal or partial seizures (antagonism). Because antagonism may reflect an actual arrest of kindling from the suppressed site (Burchfiel & Applegate, Neurosci. Biobehav. Rev., 1989), we have attempted to replicate these important observations.

We implanted two bipolar electrodes into adult male Long-Evans rats, which were stimulated once per day with 1-sec trains of square-wave pulses (biphasic, 60 pps). Stimulation site alternated daily until six consecutive generalized seizures were provoked from one of the sites.

Kindling antagonism was displayed by animals stimulated in the septum (SE) and either the corpus callosum (6/8) or amygdala (AM) (18/31), with the AM being dominant in all cases. The cingulate cortex, however, was always dominant over the AM (n = 3). Whereas one rat receiving bilateral amygdaloid stimulation exhibited a clear pattern of antagonism, the five remaining rats inconsistently displayed generalized seizures from one or both sites (mutual antagonism; Burchfiel et al., Exp. Neurol., 1982). Surprisingly, antagonism was not observed in any rats stimulated in the SE and either the entorhinal cortex (n = 5), angular bundle (n = 5), dorsal hippocampal commissure (n = 4), or contralateral SE (n = 7).

hippocampal commissure (n = 4), or contralateral SE (n = 7).

We have replicated kindling antagonism, but found that it was sitespecifically less robust than did Burchfiel and Applegate, who applied
monophasic pulse trains (100 pps) to Sprague-Dawley rats multiple times
daily. These methodological differences may account for the somewhat
discrepant findings.

CHANGES IN GLUTAMATE RECEPTOR AND PROENKEPHALIN GENE EXPRESSION AFTER KINDLED SEIZURES. S. Lee, J. Miskovsky, J. Williamson¹, R. Howells, E. Lothman¹¹ and S. Christakos. Dept. of Biochemistry, UMDNJ-New Jersey Med. Sch., Newark, NJ. 07103, ¹Dept. of Neurology, Univ. of Virginia Sch. of Med., Charlottesville, VA. 22908

Changes in gene expression after kindled seizures were examined using microdissection of discrete brain areas and Northern and slot blot analyses. Experimental animals were kindled with either of two protocols: 1) a paradigm in which 50 Hz/10 sec. stimulus trains were delivered every 30 minutes through hippocampal electrodes (12 stimulations every other day for 4 days) and 2) a traditional approach in which 50 Hz/10 sec. stimulus trains were given to the hippocampus three times daily for 16 days. Rats were sacrificed 24 hours or 30 days after the last kindled seizure. We first examined the possibility that kindling may affect transcription of mRNA for neurotransmitter receptors. We found significant decreases (1.7-4.7 fold) in AMPA/kainate activated glutamate receptor mRNAs (GluR-1, -2, -3 mRNAs) in hippocampus, amygdala/entorhinal cortex and in frontoparietal cortex 24 hours but not 30 days after rapidly kindled seizures. However, changes in GABA receptor  $\alpha_1$ ,  $\alpha_2$ ,  $\alpha_4$  or  $\beta_1$  mRNAs were not observed in any brain region 30 days after traditional kindling or 24 hours after rapidly kindled seizures. In addition, we also tested whether changes in the expression of proenkephalin could be detected after kindling. We found a significant 3.5-3.6 fold induction in proenkephalin mRNA in the hippocampus and in the amygdala/entorhinal cortex 24 hours but not 30 days after rapidly kindled seizures. Our findings suggest that changes in glutamate receptor and proenkephalin gene expression are robust, acute sequelae to kindled seizures and may perhaps be involved in kindling. LONG LASTING CHANGES IN TRANSMISSION FOLLOWING REPEATED PERFORANT PATH STIMULATION DEPENDS ON TEST PROTOCOL. N.W. Milgram. M. Khurgel G.O. Ivy. A. Hartawidjojo and R.J. Racine. Univ. of Toronto, Searb., ON MIC 1A4 and McMaster Univ., Hamilton, ON L88 1B92

Recurrent seizures induced either chemically or by repeated electrical stimulation produce a long-lasting increase in inhibition generated in dentate gyrus (DG) by stimulation of the perforant path (PP). This finding has been reported from freely moving and from anesthetized animals, as well as in brain slices. A long-lasting decrease in inhibition has been reported following sustained electrical stimulation of PP in urethane anesthetized animals. In this study, the measure of inhibition was based on a protocol for recording frequency dependent inhibition (FTP) which develops during the delivery of a train of pulse pairs (2Hz).

In an attempt to account for these different long-term changes, we studied paired pulse inhibition produced by sustained PP stimulation in rats which were chronically prepared with electrodes in PP and DG. Baseline measures of paired pulse inhibition and facilitation at a range of interpulse intervals were taken in both the freely moving state, and under urethane. Additionally, we obtained baseline measures of FTP during delivery of 2 Hz trains of pulse-pairs at interpulse intervals of both 40 and 60 msec. Following recovery from the stimulation treatment, the animals were studied at regular intervals over a 2 month period. No consistent changes were noted in paired pulse inhibition at short inter pulse intervals during this period, but every animal showed a decrease in paired pulse facilitation. At the end of this period, the animals were again anesthetized with urethane, and were retested for FTP. This test revealed consistent evidence of inhibitory loss at a 60 msec, but not at a 40 msec interpulse interval. Additionally, there was an increased frequency suppression of the response to the first pulse of the pulse pair. The results therefore provide evidence that frequency dependent suppression is distinct from inhibition produced by presentation of a single pulse.

### 71.10

LONG LASTING CHANGES IN GENETIC EXPRESSION PRODUCED BY KINDLING. R.J. DeLorenzo\*, J.B. Perlin, C. Gerwin, and R. Vick, E.R. Jakoj. Dept. of Neurology, Medical College of Virginia, Richmond, VA 23298.

Kindling is a model of long-term plasticity changes in brain and involves, in part, a potentiation of excitatory amino acid (EAA) synapses, especially the N-methyl-D-aspartate (NDMA) receptors. We have recently shown that EAA and NMDA receptor activation in hippocampal neurons in culture can produce long-lasting and selective regulation of the expression of a gene encoding the membrane associated protein ligatin (Brain Research, in press, 1992). To test the hypothesis that repeated subconvulsant stimulations required to induce kindling can permanently alter gene expression of hippocampal neurons, we measured steady state mRNA levels encoding several phenotypic proteins including ligatin by Northern and in situ hybridization analyses. At six weeks following kindling, hippocampal steady state ligatin mRNA levels were decreased by approximately 30% in comparison to control and sham animals. Northern blot analysis of total mRNA isolated from sham and kindled animals verified selective recognition of the 2.4 Kb ligatin transcript and showed that kindling produced a reproducible decrease in the ligatin transcript. In situ hybridization studies were performed 3 months after the last kindling stimulus showed significantly reduced ligatin mRNA levels bilaterally in specific hippocampal neurons while not effecting the level of a CaM Kinase mRNAs in adjacent sections. A significant decrease in the immunocytochemical labeling of ligatin protein in hippocampal neurons of kindled brains. These results provide the first direct evidence that the physiological alteration in neuronal excitability that occurs in kindling can alter gene expression in a long-lasting manner in identified hippocampal neurons.

# 71.12

CHANGES OF mRNAs ENCODING EXCITATORY AMINO ACID RECEPTORS IN AMYGDALA KINDLED RATS DETECTED BY IN SITU HYBRIDIZATION. M.Hikiji, Y.Fuiiwara\*,H.Tomita,I.Kohira,M.Ono and K.Akiyama. Dept.of Neuropsychiat.Okayama Univ.Medical Sch.,Shikata-cho 2-5-1 Okayama 700, Japan

To investigate lasting changes of excitatory amino acid receptor subtypes at their mRNA level in kinding, we performed in situ hybridization with synthetic oligonucleotide-probes complimentary to NMDAR1 (Moriyoshi et al. 1991), GluR-2 (Keinanen et al. 1990), KA-1 (Werner et al. 1991) and mGluR1 (Masu et al. 1991). Amygdala kindling-established rats were sacrificed 28 days after the last kindled seizure. As a result, kainate receptor mRNA detected by KA-1 probe increased on both sides of hippocampal CA3 region and there were no significant modifications of NMDA (NMDAR1), AMPA (GluR-2) and metabotropic glutamate (mGluR1) receptor mRNAs. This change consists with the report of increase of [3H]kainate binding in hippocampus of amygdala-kindled rat (Represaet al. 1989) and might indicate that new excitatory neural circuit mediated by kainate receptor is formed in hippocampus by kindling.

HUMAN ASTROCYTES CULTURED FROM EPILEPTIC FOCI ARE PHENOTYPICALLY DISTINCT AND EXHIBIT ENHANCED GLUTAMATE TURNOVER. S. N. Magge, M. L. Brines\*, A. Comell-Bell, M. J. During, D.D. Spencer, and N. C. de Lanerolle. Section of Neurosurgery, Yale University School of Medicine, New Haven, CT 06510.

Since astrocytes are important in regulating extracellular levels of excitatory neurotransmitters, neuronal hyperexcitability in epilepsy could arise from primary abnormalities of glial glutamate handling. Surgical specimens obtained from epilepsy patients offer a unique opportunity to test this hypothesis. Therefore, ussue was obtained from tumor-associated neocortical and medial temporal lobe (MTL) seizure foci. Using EEG criteria, neocortex was divided into tumor, adjacent hyperexcitable, and normal regions, while MTL tissue was divided into hippocampus, parahippocampus, and normal temporal neocortex. A series of enzymatic digestions were then used to generate primary astrocyte cultures. Immunohistochemical characterization of these cultures revealed two principle glial types—flat protoplasmic cells that stain weakly for GFAP and strongly for vimentin. In neocortical cultures, the numbers of librous astrocytes were 2-4 fold greater in hyperexcitable and tumor regions compared to normal. Elibrous cell density in MTL-derived cultures varied considerably among different patients.

Fibrous cell density in MTL-derived cultures varied considerably among different patients.

HPLC analysis of conditioned media showed that astrocyte glutamate synthesis was related to in vivo hyperexcitability. Tumor-derived astrocytes produced glutamate concentrations greater than twice that of normal cultures, with some tumor cultures producing glutamate to concentrations over 300µM. In MTL cultures, similar 2-3 fold increases in glutamate were observed from hippocampus and parahippocampus over normal.

Overall glutamate uptake into cells was assessed using depletion of <sup>3</sup>H-glutamate from media over time. Uptake occurred rapidly with hyperexcitable and tumor cultures showing about 1.5 and 2 times the capacity of normal cultures for uptake respectively. MTL cultures also showed a gradation of glutamate uptake capacity with parahippocampus > hippocampus > normal cortex.

These differences in glutamate handling by astrocytes cultured from specific rain regions suggest that in vivo derangements of glial function may contribute to epileptogenesis.

to epileptogenesis.

LASER PHOTOBLEACH-RECOVERY SHOWS INCREASED GAP JUNCTION COUPLING ON ASTROCYTES FROM HUMAN EPILEPTIC FOCI WHICH EXHIBIT HYPEREXCITABLE CA<sup>2+</sup> RESPONSES. <u>S. Lee. S. Magge. D.D. Spencer and A.H. Comell-Bell\*.</u> Cell Biology and Neurosurgery, Yale University School of Medicine, New Haven, CT 06510

Haven, CT 06510

Human temporal lobes obtained from epilepsy surgeries provide hippocampus, surrounding parahippocampus (hyperexcitable EEG activity) and normal cortex (normal EEG activity) for culture. Primary astrocyte cultures reflect their seizure experience for up to 7 weeks in vitro. Sclerotic hippocampal astrocytes have a decreased response to glutamate whereas applications and of the control of the c parahippocampal cells show a dramatic elevation in the frequency of intracellular Ca<sup>2+</sup> oscillations and intercellular Ca<sup>2+</sup> waves. Laser intracetular Car<sup>2</sup> oscillations and intercellular Car<sup>2</sup> Waves. Laser photobleach-recovery was used to quantify the degree of gap junction coupling in the astrocyte syncitium cultured from epileptic and normal tissues. Normal cortical astrocytes refilled (to Time x 1/e) after photobleach to a final level that was 25% of the original cell flourescence within 375.4 sec (n=17). Sclerotic hippocampal cells were somewhat slower (T x 1/e = 428 sec) and refilled to a level 26% of the original flourescence(n=7). 428 sec) and refilled to a level 26% of the original flourescence(n=7). Interestingly,  $Ca^{2+}$  hyperexcitable parahippocampal cells (n=14) refilled in less time (T x 1/e=218 sec) and to a level that was 42% of original cell flourescence indicating a comparatively higher degree of coupling . Astrocyte cultures were loaded with 6-carboxyfluorescein diacetate AM ester (7 ug/ml from Molecular Probes). Fluorescent molecules de-esterified intracellularly are no longer diffuseable. A desired target cell is photobleached with a laser on a Bio-Rad MRC600 that is zoomed to 8 and is focused on a small area. Fluorescence is bleached with 15 scans of the laser taken 1 sec apart. Due refilling is monitored using time-laser confocal. saken 1 see apart. Dye refilling is monitored using time-lapse confocal scanning laser microscopy and is corrected for bleach and offset errors (see Finkbeiner, 1992).

### ALZHRIMER'S-B-AMYLOID II DEGENERATIVE DISEASE:

SUBSTANCE P INDUCES DEPHOSPHORYLATION OF TAU IN RAT BRAIN CEREBRAL CORTICAL SLICES. M.L. Miller and G.V.W. Johnson\*. Department of Psychiatry, University of Alabama at Birmingham,

Simingham, AL 35294-0017.

Substance P belongs to the tachykinin family of neuroactive peptides and is present in neuronal systems in many parts of the CNS including the cerebral cortex, striatum and basal forebrain. Substance P is a potent depolarizing agent, has been postulated to modulate second messenger systems, and appears to protect against certain neurotoxic damage. Interestingly, the \( \beta\)-amyloid protein found in Alzheimer's disease brain contains a conserved domain that is homologous to a conserved region in tachykinins. In this study we examined the effects of substance P on the phosphorylation state of two heat-stable, microtubule-associated proteins, tau and MAP-2.

and MAP-2.

Cortical slices were incubated in the absence or presence of various concentrations of substance P, the reactions stopped and the heat-stable proteins extracted. After determination of protein concentration, the samples were subjected to back phosphorylation with the catalytic subunit of cAMP-dependent protein kinase in the presence of 32P-ATP. There was a significant increase in the in vitro incorporation of 32P into tau which had been treated with substance P compared with controls. This increase was inhibited by the addition of spantide, a specific substance P antagonist. Peptide mapping suggests that the increase in phosphorylation is confined to a single peptide. No significant differences in the phosphorylation of MAP-2 were apparent. These results indicate that substance P induces a selective dephosphorylation of tau.

dephosphorylation of tau.

THE AMNESTIC EFFECTS OF BETA-AMYLOID FRAGMENTS ON PASSIVE AVOIDANCE RESPONDING IN MICE, ARE BLOCKED BY SUBSTANCE P.
M. E. Hall and J. M. Stewart . Dept. of Biochem. and
Neuroscience Training Program, University of Colorad
Medical School, Denver, CO 80262. University of Colorado

Recent findings have strongly implicated the peptide beta-amyloid (bA) in the etiology of Alzheimer's Disease (AD). This peptide and some of its fragments have been shown to have neurotoxic effects in vitro and in vivo. Furthermore, Flood et al, (PNAS, 88:3363-3366, 1991) have reported that acute treatment with bA fragments can cause amnestic effects in mice. Immediate post-training intraventricular injection of the bA fragment bA(18-28) resulted in a dose-dependent impairment of PAR, which was statistically significant at a dose of 10 nanomoles (nmol). Based on reports that substance P (SP) can block the cytotoxic effects of bA, the effects of SP on bA-induced impairment of PAR were examined. Co-injection of several doses of SP resulted in a dose-dependent block of the amnestic effect of 10 nmol of bA(18-28). SP fragments were also co-injected with bA(18-28) to determine whether the N- or C-terminal portion of SP mediates its protective effect. It was observed that the N-terminal SP fragment SP(1-7) was as effective as SP in blocking the amnestic effect of bA(18-28), while the C-terminal SP fragment pGlu-SP(6-11) and the C-terminal SP analog DiMe-C7 were ineffective. These results suggest that the anti-amnestic effects of SP are mediated by its N-terminal region and not its C-terminal, tachykinin region.

MUTATIONAL ANALYSIS OF \$\textit{B}\$-AMYLOID PRECURSOR PROTEIN PROCESSING. Lore Lewis-Higgins\* and Kevin M. Felsenstein. Dept. of Biophysics and Molecular Biology, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492. Alzheimer's Disease (AD) is a debilitating neurodegenerative disorder that afflicts more than 4 million in the U.S. alone. These individuals exhibit progressive cognitive impairments which are predominately associated with degenerating neurons in the basal forebrain, cerebral cortex, and hippocampus. Post-mortem examination of AD brains reveal neurofibrillary tangles, neuritic plaques, and amyloid deposition in meningeal blood vessels. Most cases of AD are sporadic, however, several families with autosomal dominant inheritance patterns have been identified. To date, four single point mutations in the \$\textit{\textit{B}}\$-APP gene have been identified. Three substitutions at amino acid 717 are linked to early onset AD, while a single substitution at amino acid 693 results in hereditary cerebral hemorhage with amyloidosis of dutch-type (HCHWA-D). cerebral hemorhage with amyloidosis of dutch-type (HCHWA-D). The neuritc plaques and cerebrovascular amyloid are composed of The neurite plaques and cerebrovascular amyloid are composed of an ~4.2 kDa protein derived from the proteolysis of the  $\beta$ -amyloid precursor protein ( $\beta$ -APP). The  $\beta$ -protein region of  $\beta$ -APP is normally proteolytically cleaved by the activity referred to as APP-secretase at lysle. This cleavage results in the disruption of the  $\beta$ -protein and would prevent any formation of  $\beta$ -amyloid. Thus, the generation of intact  $\beta$ -protein is the result of alternative proteolytic processing of the  $\beta$ -APP molecule. The goal of the present study was to examine the effects of the HCHWA-D and FAD mutations and mutations at or near the APP-secretase site on normal and alternative processing of  $\beta$ -APP. Using a novel fusion protein expression system data will be presented that suggest certain mutations may lead to changes in the processing pattern of  $\beta$ -APP.

DEVELOPMENT OF A FUSION GENE SYSTEM FOR THE ANALYSIS OF \$-AMYLOID PRECURSOR PROTEIN PROCESSING.

Kevin M. Felsenstein, Susan B. Roberts, Kim M. Ingalls, Darcy A. Grisel, and E. Edward Baetge\*, Dept. of Biophysics and Molecular Biology, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492

Bology, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492.

Alzheimer's Disease (AD) is the fourth leading cause of death and the leading cause of memory loss and dementia in the United States. Throughout the world it accounts for one-half to two-thirds of all cases of progressive dementia. The deposition of β-protein (senile plaques and cerebrovascular deposits) and the formation of neurofibrillary tangles in cortex are the major pathological hallmarks AD. The 4.2 kDa β-protein is derived from the 110-130 kDa β-amylold precursor protein (β-APP). β-APP is differentially processed to yleld both non-amyloidogenic and potentially amyloidogenic products. Non-amyloidogenic processing is defined by a cleavage within the β-protein sequence by a proteolytic activity referred to as APP-secretase. The cleavage releases the protease nexin II domain of β-APP, and a non-amyloidogenic fragment is retained in the cell membrane and degraded by the cell. However, alternative proteolytic pathways exist that process the β-APP protein such that potentially amyloidogenic fragments containing intact β-protein are formed. Neither the cellular pathways nor the proteolytic activities involved are fully characterized.

To study β-APP processing and the generation of β-protein, we have devolved are devolved are applied to the cell for the cellular path of the cellular path of the cellular path of the cellular pathway and the leader of the cellular pathway and the generation of β-protein, we have

involved are fully cnaracterized. To study  $\beta$ -APP processing and the generation of  $\beta$ -protein, we have developed and validated a novel fusion protein expression system that mimics the processing of  $\beta$ -APP. The reporter system has provided extremely sensitive methods for detecting small quantities of products and clearly confirming the existence of multiple processing pathways. We will present data for alternative cleavages and propose a model for  $\beta$ -APP processing.

EVIDENCE SUGGESTING THAT β-PROTEIN IS GENERATED IN CELLS EXPRESSING THE CARBOXYL TERMINAL 100 AMINO ACIDS OF THE AMYLOOD PRECURSOR PROTEIN (APP). T.L. Martin\*, D. Franco and K.M. Felsenstein. Bristol-Myers Squibb, Wallingford, CT 06492.

Alzheimer's disease is characterized pathologically by diffuse cerebral

atrophy and the presence of senile plaques and neurofibrillary tangles in cortex. Data from a series of recent genetic linkage studies has provided powerful support for the notion that the APP gene plays a central role in the pathogenesis of Alzheimer's Disease. The hypothesis that C- terminal fragments of APP may themselves be capable of mediating the cell death characteristic of the AD brain has been proposed on the basis of studies conducted by several groups. Data surrounding a precise definition of the culprit species is mixed; half suggest that the intact or aggregated C- terminal 100 amino acid fragment is toxic while others implicate  $\beta\text{-protein},$  the 42 amino acid molecule coded for by the amino terminus of the larger 100 amino acid fragment described above as the critical moiety. We will present data that will consolidate these apparently variable observations. Cells stably transfected with the APP-C100 fragment were subjected to immunological analysis employing antibodies to the C- terminal domain of APP. Cells expressing this construct were observed to contain two unique bands running at apparent molecular weights of 14 & 9 kD. Based on the uniqueness of these two bands to the transfected cell lines, their reactivity with multiple C- terminal APP antibodies and the relative molecular weights, we hypothesize that the 14 kD parent molecule undergoes proteolytic cleavage resulting in the generation of a 9 kD C- terminal fragment and a ~5kD amino terminal moiety potentially analogous to  $\beta$ -protein.

BETA-AMYLOID PRECURSOR PROCESSING: MULTIPLE LYSOSOMAL

BETA-AMYLOID PRECURSOR PROCESSING: MULTIPLE LYSOSOMAL PROTEASES GENERATE AND DEGRADE POTENTIALLY AMYLOIDOGENIC FRAGMENTS. R. Siman\*. S. Mistretta. J.T. Durkin. M.J. Savage, T. Loh. S. Trusko and R. Scott. Cephalon, Inc., West Chester, PA 19380 Processing of the beta-amyloid precursor proteins (APPs) occurs in both secretory (Weidemann et al., Cell 57, 115 (1989)) and lysosomal/endosomal (Golde et al., Science 255, 728 (1992)) pathways. Secretory processing destroys the beta/A4 domain, but lysosomal proteolysis generates APP fragments that are potentially amyloidogenic, and could be precursors for amyloid deposition. We have examined routes of APP processing in human 293 cells stably transformed to overexpress APP751. Lysosomotropic agents and protease inhibitors of distinct specificities have routes of APP processing in human 293 cells stably transformed to overexpress APP751. Lysosomotropic agents and protease inhibitors of distinct specificities have been used to identify proteolytic events that may form or degrade potentially amyloidogenic fragments. Additionally, subclones of stable transformants were identified which differ markedly in efficiencies of APP secretion. APP fragments were identified by metabolic labelling and immunoprecipitation with antibodies to two different domains near the COOH-terminus, followed by high resolution Tris/Tricine SDS-PAGE. While secretory processing produced a single 9.5 kDa APP fragment, at least 6 fragments were generated within lysosomes, the largest four of which contain the entire beta/A4 domain. Lysosomotropic agents (NH4CI, chloroquine) prevented the appearance of all 6 fragments. However, inhibitors of lysosomal cysteine proteases (E-64, Z-Phe-Ala-CHN2) caused accumulation of 5 of the fragments, suggesting that these fragments are generated by non-cysteine protease(s), and then are cleared by cysteine 64, Z-Phe-Ala-CHN2) caused accumulation of 5 of the fragments, suggesting that these fragments are generated by non-cysteine protease(s), and then are cleared by cysteine protease(s). In the presence of lysosomotropic agents, APP fragments failed to accumulate upon protease inhibitor treatment, confirming that the 5 fragments are formed within lysosomes. Low concentrations of Z-Phe-Ala-CHN2 were used to selectively block the lysosomal cysteine protease cathepsin L, while higher concentrations were used to also inhibit the cysteine protease cathepsin B. Cathepsin L appears to be the major protease responsible for breakdown of potentially amyloidogenic fragments within lysosomes. The finding that a number of potentially amyloidogenic fragments of APP are routinely generated and then degraded by lysosomes suggests that altered lysosomal function could contribute to amyloid deposition. deposition.

β-Amyloid Precursor Protein is Processed by an Alternative Potentially Amyloidogenic Pathway <u>Peter Seubert, Tilman Oltersdorf, Michael G.</u> <u>Lee. Robin Barbour, Cheryl Blomquist, David L. Davis, Karin Bryant.</u> Douglas Galasko\*#, Leon J. Thal#, Lawerence Fritz, Ivan Lieberburg. and Dale Schenk Athena Neurosciences, Inc. South San Francisco CA 94080. #Department of Neurology, Veteran's Administration Hospital, San Diego, CA 92162

Secretion of the  $\beta$ -amyloid precursor protein ( $\beta$ -APP) has previously been shown to be accompanied by cleavage within the  $\beta$ -amyloid protein ( $\beta$ -AP) sequence. Amyloidogenic metabolism of  $\beta$ -APP must then involve a different scheme. To test the idea that an alternative secretory pathway exists, which leaves β-AP intact, the conditioned-medium of human fetal mixed-brain cultures was

intact, the conditioned-medium of human fetal mixed-brain cultures was depleted of  $\beta$ -APP possessing the  $\beta$ -AP 1-15 sequence by use of immuno-affinity methods. Material lacking the  $\beta$ -AP 1-15 epitope, but reactive with antibodies to other  $\beta$ -APP regions was detected. Immunological data suggest this material may be truncated at or near the N-terminal of the  $\beta$ -AP sequence. The apparently truncated  $\beta$ -APP is secreted with a similar time course of maturation and cleavage as  $\beta$ -APP cleaved within the  $\beta$ -amyloid region, suggesting post-secretion events are not responsible for this form. A similarly truncated  $\beta$ -APP was found in CSF and, to a lesser extent, in conditioned medium from 293 kidney cells overexpressing either the 695 or 751 forms of  $\beta$ -APP. We suggest this alternative secretory event may be the first step in amyloid formation.

MUTANT AMYLOID PRECURSOR PROTEIN INCREASES PRODUCTION OF POTENTIALLY AMYLOIDOGENIC FRAGMENTS. L.T. Durkin, T. Loh. S.P. Trusko, M.I. Savage, M.A. Glicksman\*, R.W. Scott and R. Siman. Cephalon, Inc., West Chester, PA 19380

The amyloid plaques deposited in the brains of Alzheimer's disease patients are largely composed of the  $\beta/A4$  peptide. Secretion of the precursor to this peptide, the amyloid precursor protein (APP), involves cleavage within the  $\beta/A4$  domain. Amyloid deposition therefore requires processing of APP by other pathways. We are modeling aberrant processing of APP by expressing APP mutants in cultured cell lines. DNAs coding for mutants of APP751 were inserted into CMV expression vectors and transfected by CaPO4 coprecipitation. Western blots of conditioned media and cell lysates were probed with APP antibodies, and the relative amounts of various forms of APP quantitated by laser densitometry. A double mutation near the secretory processing site, K668E/F671D, was defective in secretion: the ratio (secreted APP in medium)/(fully-glycosylated APP in lysate) was less for the mutant than for the wild-type. Either mutation alone had no detectable effect on secretion. Antisera against the COOH-terminus of APP specifically immunoprecipitated from cell lysates a 9.5 kDa fragment, the mobility of the product of secretory processing. The antisera also precipitated smaller amounts of larger fragments, one of which co-migrated with the COOH-terminal 100 residues of APP (which contain the entire \( \beta / A4 \) domain). Cells transfected with the K668E/F671D construct produced more of these larger fragments, and less of the secretory processing product, than cells transfected with wild-type APP. These results demonstrate that the secretory protease is not sequence-specific, but may be sensitive to disruption of secondary structure near the substrate cleavage site. The mutant APP K668E/F671D is a poorer substrate for secretory processing, and so provides a useful model for elucidating alternate routes of APP processing.

TISSUE DISTRIBUTION IN THE RAT OF A MEMBRANE-ASSOCIATED METALLOENDOPEPTIDASE THAT MAY BE INVOLVED IN METABOLISM METALLJUENDUPERTIDASE THAT MAY BE INVOLVED IN METABOLISM OF THE ALZHEIMER AMYLOID B/A4 PROTEIN (AB P).

T. Yamamoto\*, F. Kametani²and D. Allsop² Lab. of Molecular Recognition, Yokohama City Univ., Yokohama 236, Japan , Dept. of Molecular Biology, Tokyo Institute of Psychiatry, Tokyo 156, Japan , and Division of Biochemistry, The Queen University of Belfast, Northern Ireland, UK.

We have previously reported the processor of a machine.

University of Belfast, Northern Ireland, UK. We have previously reported the presence of a membrane-associated amyloid  $\beta/A4$  protein-cleaving protease(AGP-CP) in rat cerebral cortex (Soc. Neurosci. Abst. 17, 1448, 1991). This enzyme is a metalloendopeptidase that cleaves between His(14) and Gln(15) of a  $\beta/A4$  8-17 synthetic peptide. We have now determined the regional tissue distribution of this enzyme in the adult rat. In the brain, cerebral cortex and hippocampus had the highest level of activity, while the striatum had only modest activity, and no significant activity could be detected in the cerebellum. Also no significant activity was observed outside the brain in peripheral tissues such as kidney, lung and pancreas. These data strengthen the idea that ABP-CP may play a physiological role in the proteolytic processing (degradation?) of AβP or its precursor since the gross regional profile of the enzyme mirrors the distribution of amyloid deposits in Alzheimer's disease.

EVIDENCE THAT THE KPI DOMAIN IS NOT INVOLVED IN THE PROCESSING OF ALZHEIMER PRECURSOR PROTEIN. <u>US Ladror<sup>1</sup>, AM Manelli<sup>1</sup>, TF Holzman<sup>1</sup></u> <u>DE Frail<sup>1\*</sup>, GT Wang<sup>1</sup>, WL Klein<sup>2</sup>, GA Krafft<sup>1</sup>. <sup>1</sup>Abbott Labs. Abbott Park, IL</u> DE Frail<sup>1\*</sup>, GT Wang<sup>1</sup>, WL Klein<sup>2</sup>, GA Krafft<sup>1</sup>. <sup>1</sup>Abbott Labs. Abbott Park, IL 60064. <sup>2</sup> Dept. Neurobiol. Northwestern Univ., Evanston, IL 60208.

The A4 peptide, which accumulates in amyloid plaques in brains of

Alzheimer disease (AD) patients, is the product of proteolytic cleavage of a larger protein called Amyloid precursor protein (APP). In this work we tested whether the Kunitz protease inhibitor (KPI) domain, which is present in 3 of 4 alternatively spliced forms of APP, affects protease activities in extracts from normal and AD brains against substrates that mimic the amyloidogenic cleavage site (AMYL) and the secretory cleavage site (SECR).

APP695 and APP751 were obtained from transfected HEK293 cells. Equal amounts of APP695 and APP751 were obtained from the media after 2 days of growth, suggesting an equal rate of secretion. This result indicates that the KPI domain in APP 751 did not inhibit the SECR cleavage in transfected cells. Protease activities in normal and AD brains were assayed at pH of 7.5 and at pH 6.0, using fluorogenic substrates. APP 695 and the KPI-containing APP751 had no effect on protease activities against the SECR and AMYL sites in extracts from both normal and AD brains. However, KPI-containing APP751, at similar concentrations, completely inhibited the activity of trypsin against these substrates. Activity against the SECR substrate in extract from normal brains at pH 7.5, produced a major cleavage at a site identical to that of trypsin, indicating that the cleavage is identical to the secretory cleavage. Under similar conditions the AMYL substrate was cleaved two positions down-stream from the AMYL site. These results suggest that the KPI domain is not involved in either the secretion of APP or the amyloidogenic cleavage of the APP protein.

CHARACTERIZATION OF ALZHEIMER-RELATED PROTEASE ACTIVITIES IN NORMAL AND ALZHEIMER BRAINS. RE Kohnken 1\*, US Ladror 1, GT Wang 1, TF Holzman 1, WL Klein 2, BE Miller 1, GA Krafft 1. 1 Abbott Labs. Abbott Park, IL 60064. Dept. Neurobiol. Northwestern Univ., Evanston, IL 60208.

Using fluorogenic substrates, we have examined protease activities against the secretory (SECR) site of the amyloid precursor protein (APP, positions 664-671 of APP751) and the amyloidogenic (AMYL) site of APP (positions 649-656) in normal and Alzheimer's (AD) brains. Protease activities in the high speed supernatant against the SECR site had an optimum at pH 3.0-4.0, and another broad optimum at pH 6.0-7.5. Protease activities against the AMYL site had an optimum at or below pH 3.0 and another at pH 6.0. Activities at low pH were significantly higher in AD brains relative to controls, however, at pH 6.0-7.5 nor-

mal brains had significantly higher activities than AD brains, using both substrates. Percent inhibition by TLCK, TPCK and PMSF and by sulfhydryl reagents CuSO<sub>4</sub>, MMTS and PCMB, at pH 7.5 of activities against the SECR and AMYL sites is shown in the table. Pepstatin inhibited both activities at pH 3.5 94%, but did not affect activities

| Inhibitor         | SECR | AMYL |
|-------------------|------|------|
| TLCK              | 16   | 31   |
| TPCK              | 32   | 57   |
| PMSF              | 18   | 25   |
| CuSO <sub>4</sub> | 94   | 89   |
| MMTS              | 79   | 87   |
| PCMB              | 96   | 92   |

above pH 5.5. Apparent KM for the activities against the SECR site at pH 4.0 was 5-8 µM in extracts from normal and AD brains. The activity at pH 4.0 was reversibly stimulated about 3 fold by preincubation at the assay pH. The stimulation was time dependent and was reversed by increasing the pH to 7.0.

These results indicate that multiple activities are present in brain extracts that may be involved in APP processing in vivo. Higher acidic activity and lower alkaline activity in AD brain may result from the pathological state of AD brains.

DESIGN AND SYNTHESIS OF INTERNALLY QUENCHED FLUOROGENIC SUBSTRATES FOR NEURAL PROTEASES. GT Wang<sup>1</sup>, US Ladror<sup>1</sup>, TF Holzman<sup>1</sup>, WL Klein<sup>2</sup>, GA Kraffi<sup>1\*</sup>. <sup>1</sup>Abbott Labs. Abbott Park, IL 60064. <sup>2</sup> Dept. Neurobiol. Northwestern Univ., Evanston, IL 60208.

The formation of  $\beta/A4$  amyloid from its precursor protein (APP) involves at least 2 distinct proteolytic events, and may result from altered processing or trafficking of APP. In order to characterize proteases that may be relevant to normal and amyloidogenic processing of APP, we have synthesized a series of internally quenched fluorogenic substrates that encompass putative cleavage sites for constitutive processing (secretase) and for B/A4 amyloid formation (amyloidogenic). In this paper, we describe experiments, using these fluorogenic substrates, to demonstrate that proteolytic activity in normal brains against the amyloidogenic substrate at pH 7.5 was stimulated by Ca2+, and that the stimulation

| Version  | n Substrate               | No Ca <sup>2+</sup> | 1mM Ca <sup>2+</sup> |
|----------|---------------------------|---------------------|----------------------|
| J=Glutan | nyl-EDANS; B=Lysyl-DABCYL | Rela                | tive rate            |
| 1        | Ac-EJEVKMDAEFBE-NH2       | 1.00                | 2.95                 |
| 2        | Ac-QJEVKMDAEFBQ-NH2       | 0.70                | 1.86                 |
| 3        | Ac-QJQVKMDAQFBQ-NH2       | 2.70                | 3.62                 |
|          |                           |                     | - 21                 |

resulted form an effect of Ca<sup>2+</sup> on the substrate and not on the protease involved cleavage. Activity against substrate version 1 was Ca2+-stimulated 200-400%.

Replacing two Glu's with Gln's (version 2) reduced Ca2+-stimulation to 150-200% and inhibited the activity about 25%. Replacing all four Glu's with Gln's (version 3) reduced Ca2+-stimulation to 30% but stimulated the activity to levels close to the Ca<sup>2+</sup>-stimulated activity of version 1. Substrate version 1 was cleaved by brain extract at the N-side of Ala-8, two positions down stream from the amyloidogenic cleavage. These results suggest that the stimulatory effect of Ca2+ is facilitated by binding to the substrate.

LIPOPOLYSACCHARIDE-INDUCED CYTOTOXICITY PRIMARY RAT HIPPOCAMPAL CULTURES. P.C. May\*, P.M. Robison, R. Berry, D. Waters and B. Gitter, Dept. of CNS

& Molecular Biology, Lilly Research Labs, CNS Division, Ell Lilly and Co., Indianapolis, IN 46285

A key event in the pathogenesis of Alzheimer's disease (AD) may be the transition of B/A4 amyloid deposits from diffuse to compacted neuritic plaques. This transition may involve an inflammatory process as numerous cytokines and acute phase proteins are found associated with the neuritic plaque. We have used lipopolysaccharide (LPS) treatment of primary mixed rat hippocampal cultures to elaborate a cytokine cascade and model the inflammatory process in elaborate a cytokine cascade and model the inflammatory process in AD brain. LPS treatment (10ng/ml-5ug/ml) resulted in cytotoxicity assessed by phase contrast microscopy and LDH release. LPS cytotoxicity follows a slow time course requiring >48 hours to be fully manifested. LPS cytotoxicity may be mediated through release of TNF as direct addition of recombinant murine TNFa produced cytotoxicity. Consistent with a role for cytokines, cotreatment with dexamethasone (10nM-1uM) and other glucocorticoids blocked LPS cytotoxicity in a dose dependent fashion; NSAIDs, EAA-receptor antagonists, and free radical scavengers were ineffective. These results indicate that inflammatory processes initiated by LPS treatment result in direct cytotoxicity in rat hippocampal cultures. Similar inflammatory processes may contribute to pathology in AD.

IN VITRO PRODUCTION OF AMYLOIDOGENIC FRAGMENTS FROM ALZHEIMERS BETA-AMYLOID PRECURSOR PROTEIN (APP) A. M. Brown\* A. Potempska#. A.J. Blume\*\*, D. Miller# and M.P. \*Dept. of Molecular Pharmacology, Lederle Laboratories, Pearl River, NY 10965. #New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

Recently several groups have isolated potentially amyliodogenic C-terminal fragments of APP from normal and AD brains [Estus et al Science terminal fragments of APP from normal and AD brains [Éstus et al Science 255, 726 (1992)]. We have constructed an assay system that allows us to evaluate the ability of isolated proteases or proteolytic activities to generate amyloidogenic fragments of APP from full length APP and then compare them to endogenously produced fragments of APP. The assay employs purified APP from rat brain [Potempska et al. JBC 266, 8464 (1991)] and rat brain extracts that are enriched in C-terminal APP fragments by immunopurification. Using this assay we have demonstated that Cathepsin-G is able to produce both amyloidogenic and non-amyloidogenic C-terminal fragments from full-length APP. Two major C-terminal products of approximately 9 and 11kd were found, which are similar in electrophoretic mobility to C-terminal fragments isolated from rat brain. The identity of these fragments was confirmed and the location of their N-termini was characterized moonily to 0-terminal fragments isolated from rat brain. The learning of these fragments was confirmed and the location of their N-termini was characterized by epitope mapping. The exact location of their N-termini is being determined by sequencing. When the proteolytic fragments were probed with antibodies to the N-terminus of APP we were able to observe conversion with antibooles to the N-terminus of APP we were able to observe conversion of the full length APP to a fragment of molecular weight similar to the extracellular form of APP with kinetics that were comparable to the conversion of the C-terminus to the short (9 & 11kd) forms. We have also begun to characterize the reaction between APP and other proteases whose localization in the brain or association with amyloid deposits make them candidates for the formation of BAP from APP.

BETA AMYLOID PEPTIDE (BAP) IN VITRO TOXICITY: LOT-TO-LOT VARIABILITY. P.M. Robison\*, D. Waters, B. Gitter, L. Simmons, G. Becker, J. Small and P.C. May, Depts. of CNS & Molecular Biology and Biotechnology Research, Lilly Research Labs, Eli Lilly and Co., Indianapolis, IN 46285

BAP is associated with the neuritic plaques of Alzheimer's Disease (AD) and may contribute to the degeneration of neurons. Conflicting observations have been reported about the direct in vitro and in vivo neurotoxicity of BAP. We have compared lots of BAP preparations in high density rat hippocampal mixed primary cultures and found marked lot-to-lot differences. Cytotoxic effects of various BAP 1-40 preparations were assessed in 10 DIV cultures treated in defined media for 4 days and toxicity was measured as LDH released into the media. Repeated experiments using different cell preparations and one lot of peptide obtained from a commercial supplier resulted in dosedependent (1-10uM) direct neurotoxicity. Two other lots from the same supplier were essentially non-toxic at 10uM. Three additional BAP preparations from unrelated sources also did not produce cytoxicity. Initial biochemical characterization of the 3 lots has not yet revealed any marked differences. Low levels of endotoxin contamination (1-2 EU/ml) were detected in several preparations but did not correlate with cytotoxicity. Our observation that some but not all preparations of BAP are neurotoxic in vitro may account for much of the present controversy in this area.

CORTICAL DESTRUCTION IN HUNTINGTON'S DISEASE. H.Braak\*and E. Braak. Department of Anatomy. J.W.Goethe University, D-6000 Frankfurt/M. 70, Germany

Frankfurt/M. 70, Germany
Brains of individuals who had suffered from Huntington's disease (grade 3 and 4 according to Vonsattel et al. 1985) and control brains were examined. Frontal sections through the temporal lobe were stained for Nissl material and lipofuscin pigment. The diseased brains revealed a layer-specific loss of nerve cells in two allocortical areas. The most impressive changes were seen in the entorhinal cortex. The brunt of the destruction was born by the deepest entorhinal layer pri-y which was found to be almost completely depleted of nerve cells. The upper cellular layer pre-a, the layer pre-y and the subiculum showed less severe alterations. The entorhinal cortex and the subiculum are major relay stations of limbic circuits. The specific destruction of these cortical areas is considered to contribute to cognitive dysfunction seen in patients suffering from Huntington's disease. DIFFERENT SURVIVAL PATTERN OF STRIATAL INTERNEURONS AFTER SLOW VS FAST INTRASTRIATAL INJECTIONS OF QUINOLINIC ACID. G.Figueredo-Cardenas\*. Q. Chen and A. Reiner, Dept. Anat and Neurobiol., College of Medicine, Univ. TN, Memphis, TN 38163.

A relative sparing of neurons containing somatostatin (SS) - neuropeptide Y (NPY) - NADPH- diaphorase compared to projection neurons has been tound after intrastriatal injection of quinolinic acid (QA), an excitotoxin acting at NMDA receptors (Beal et al., J. Neurosci., '91). Such findings have been used in support of the excitotoxin hypothesis of Huntington's disease (HD) and to claim that intrastriatal QA produces an animal model of HD. However, other studies have reported that SS/NPY+ interneurons are highly vulnerable to QA (Davies et al., Nature, '87; Anderson and Reiner, Soc. Neurosci. Abstr., '91). Since these research groups used different intrastriatal injection methods, we examined the influence of the speed (3min vs. 15min) and the amount (1µl of 225mM QA vs. 1µl of 50mM QA) injected. After two weeks, alternate brain sections from these animals were processed for diaphorase and cresyl violet stained, and neurons of these types were drawn with camera lucida and counted in both lesioned and nonlesioned sides.

Our results showed a relative preservation of diaphorase neurons compared to NissI-stained neurons after the large fast QA injections (88% of control diaphorase perikarya in areas with 40% of control NissI-stained neurons). In contrast, the slow large QA injections resulted in poorer sparing of-diaphorase neurons compared to NissI-stained neurons (8% of control diaphorase perikarya in areas with 40% of control NissI-stained neurons). Similarly enhanced relative survival of diaphorase neurons compared to NissI-stained neurons was seen with the fast compared to slow small injections. Since rapid injections result in QA efflux, we interpret the results to suggest that brief compared to prolonged QA exposure may produce different patterns of diaphorase vs.projection neuron survival. EXAMINING RAPID RESPONSE GENES IN THE HUNTINGTON'S DISEASE ANIMAL MODEL P. D. Walker' & L. R. Carlock, Departments of Anatomy/Cell Biology & Molecular Biology/Genetics, Wayne State University School of Medicine, Detroit, MI 48201.

Intrastriatal injections of quinolinic acid (QA) produce a selective pattern of neostriatal damage analogous to Huntington's disease (HD), an autosomal dominant disorder localized to chromosome 4. To determine if the rodent model will be useful for identifying and defining HD candidate genes, we analyzed the QA-induced neostriatal expression pattern of a neuron-specific gene, D4S234, which maps adjacent to the HD genetic marker D4S10. The transcriptional response of this gene was compared to several intermediate-early genes (IEGs c-fos, jun-B, zif-268) that appear to be involved in the cellular reaction to excitotoxicity. Within the QA lesion site, D4S234 mRNA levels rapidly increased (161.7± 17.7% of saline controls; p<0.02) within 45 minutes. This early response was analogous to IEG induction and may occur via a Ca+²/cAMP-linked regulatory site identified in the D4S234 promoter which is homologous to a FAP response element in the c-fos promoter.

At 4-12 hours post-QA, a decline in D4S234 expression correlated with the loss of neurotransmitter mRNAs indicative of neuronal death. From 1-7 days, D4S234 mRNA was reduced to  $8.1\pm3.5\%$  (p<0.0001) of saline control neostriata. Interestingly, prior to the decline in D4S234, a second phase of IEG expression occurred between 1.5 - 4 hours and persisted up to 24 hours suggestive of glial response. These results support the use of the  $in\ vivo$  excitotoxic model for examining the expression of genes localized to the HD gene region and underscores the importance of focusing on the early-stage HD brain to determine changes in gene expression that may relate to neurotoxicity. THE QUINOLINIC ACID MODEL OF HUNTINGTON'S DISEASE: AN ELECTROPHYSIOLOGICAL APPROACH. F. Block, M. Schwarz, R. Töpper, J. Noth\*

Besides a diminuition of amplitude of early somatosensory evoked potentials (SEPs) a decreased amplitude in visual evoked potentials (VEPs) has been described as neurophysiological changes in Huntington's disease (HD). The present study investigates whether quinolinic acid (QA) lesions confined to the striatum - an animal model of HD - are sufficient to induce these electrophysiological abnormalities. Two weeks after unilateral intrastriatal injection of QA (240 nmol) SEPs were recorded from the somatosensory cortex in response to electrical stimulation of the contralateral forelimb or VEPs response to a strobe light in rats under light pentobarbital anesthesia. Striatal QA lesion significantly reduced the amplitude of short latency cortical SEPs by about 40% without affecting the latency. The VEPs were not altered at all by QA treatment. The present results suggest that the QA animal model of HD also displays some of the SEP abnormalities of HD patients whereas VEPs are not affected.

TRANSFORMING GROWTH FACTOR α IMMUNOREACTIVE STRIATAL NEURONS DEVELOP PROLIFERATIVE DENDRITIC CHANGES IN HUNTINGTON'S DISEASE. A. Evans\*, R.J. Ferrante, K.M. Harrington, and N.W. Kowall. Massachusetts General Hospital, Boston, MA 02114.

Proliferative dendritic abnormalities affect spiny striatal neurons in Huntington's disease (HD) but the extent to which enkephalin and substance P subsets are involved is not known. It is also not clear if similar dendritic changes affect NADPH diaphorase aspiny neurons which are spared in HD. Transforming growth factor alpha (TGF $\alpha$ ), which colocalizes with enkephalin in the striatum, more clearly labels discrete dendritic processes than either enkephalin or substance P. We therefore examined the distribution of TGF $\alpha$  and NADPH diaphorase in double stained sections of striatum from 6 HD patients and 5 normal controls. In HD, TGF $\alpha$  neurons were depleted in a dorsoventral gradient, similar to that seen with enkephalin and substance P antisera. The staining intensity of individual neurons, however, was somewhat increased over controls. Proliferative dendritic abnormalities and dysmorphic dendritic recurving affected TGF $\alpha$  but not NADPH diaphorase neurons. Our observations show that dendritic proliferation involves enkephalin neurons that contain a growth factor, TGF $\alpha$ , not present in substance P neurons. If TGF $\alpha$  plays a causal role in the development of dendritic proliferation, spiny substance P neurons should not show evidence of dendritic proliferation in HD. Furthermore, TGF $\alpha$  may exacerbate neuronal injury if dendritic proliferation leads to neuronal degeneration in HD.

A SECOND PHASE OF INTERMEDIATE-EARLY GENE EXPRESSION CORRELATES WITH NEURONAL LOSS AND GLIAL/IMMUNE RESPONSE IN THE HUNTINGTON'S DISEASE MODEL. Y. Shan\*, P. D. Walker & L. R. Carlock, Departments of Anatomy/Cell Biology & Molecular Biology/Genetics, Wayne State University School of Medicine, Detroit, MI 48201.

Intermediate-early gene (IEG) induction rapidly occurs within 1 hour following intrastriatal injections of quinolinic acid (QA). Although this early response may trigger neurotoxicity, the successful use of NMDA antagonists to inhibit neuronal death after the initial IEG phase suggests that later signaling events may induce neuronal death and glial response. Therefore, we detailed the acute expression patterns of IEG response after neostriatal QA to determine if additional phases of IEG expression could be correlated with neuronal loss and the activation of glial and immune cells.

Following the detection of the initial phase in IEG induction during the first hour following QA injection, a second and more prominent phase of neostriatal c-fos, jun-B and zif-268 mRNA elevation occurred between 1.5 - 4 hours and persisted up to 24 hours. Because a significant decline in neurotransmitter-specific mRNAs had been detected between 4 -12 hours, this second and larger wave of IEG response extending beyond 12 hours may relate to reactive gliosis. Interestingly, an additional wave of mRNA increases specific for the synthesis of interleukin-1β and heat-shock protein-70 peaked at 12 hours and gradually declined to control levels by 48 hours.

70 peaked at 12 hours and gradually declined to control levels by 48 hours. The identification of a second wave of IEG induction which appears to correlate with neuronal loss and subsequent glial/immune response suggests that a specific window of time (1-4 hours) following brain damage should be targeted in attempts to block neuronal loss and glial response to excitotoxicity. (Supported by NS24236 to L.R.C.)

FUNCTIONAL LOCOMOTOR HETEROGENEITY OF THE STRIATUM IN A RODENT MODEL OF HUNTINGTON'S DISEASE. E. E. Concepcion and W.C. Low. Departments of Neurosurgery and Physiology, and Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN 55455.

Recent studies utilizing a rodent model of Huntington's disease have demonstrated locomotor abnormalities following unilateral lesions of the striatum using neurotoxic analogs of excitatory amino acids. These abnormalities are manifested as an asymmetric rotation ipsilateral to the side of the lesion following apomorphine administration. In the present study we provide evidence for the dependence of rotational direction on the site of the striatal lesion. Sprague-Dawley rats were given lesions of the right striatum using stereotaxic injections of quinolinic acid (150 nmole in 1  $\mu$ l saline). One group of rats received injections at AP 3.0 mm, ML 2.5 mm (with respect to bregma), and DV 4.5 mm (with respect to the dural surface). A second group received injections at AP 1.4 mm, ML 3.3 mm, and DV 4.5 mm. A third group received striatal injections at AP -0.2 mm, ML 4.25 mm, and DV 4.0 mm. The behavioral effects of apomorphine administration (1 mg/kg, s.c.) was examined one month after the lesion. Animals with anterior striatal lesions (AP 3.0 mm) displayed rotational biases contralateral to the side of the lesion while animals with more posterior lesions (AP 1.4 mm or -0.2 mm) exhibited ipsiversive rotations. Analysis of variance revealed significant -0.2 min) exhibited ipsiversive rotations. Analysis of variance revealed significant group effects (p < 0.05). Post-hoc pair-wise comparisons revealed that animals with AP 1.4 mm and AP -0.2 mm did not differ in their rotational bias. Both of</p> these groups, however, differed in their rotational biases in comparison to animals with AP 3.0 mm injections of quinolinic acid (p < 0.05). These results reflect a possible heterogeneity of locomotor function in the rodent striatum along its rostrocaudal axis. (Supported by NIH RO1-NS-24464).

EARLY VULNERABILITY OF STRIOSOMES IN HUNTINGTON'S DISEASE STRIATUM. J.C. Hedreen\* and S.E. Folstein. Neuropathology Lab. and Depts. of Pathology, Neuroscience and Psychiatry, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Psychiatry, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

To define the early vulnerability of components of the neostriatum in Huntington's disease (HD), we have investigated the distribution of neuronal loss and accompanying fibrillary astrocytosis in neostriatal tissue from autopsy cases of HD. The earliest changes are scattered islands of neuronal loss and astrocytosis that occur prior to the previously described ventrally progressing wave of generalized neuronal loss. Examination of serial sections immunocytochemically stained for markers of the striatal patch-matrix system in an early case (Vonsattel grade 0) shows that these islands of early neuronal loss correspond to the striosome (patch) compartment of the neostriatal patch-matrix system, a finding supported by the study of ventral striatal regions in 13 additional grade 1-2 cases.

Connections of striosomes suggest that the early degeneration of striosome neurons may be responsible for some of the early psychiatric and motor symptoms in HD.

# 73.11

ALZ 50 LABELS ASPINY NEURONS IN NORMAL HUMAN STRIATUM THAT RESIST DEGENERATION IN HUNTINGTON'S DISEASE. K.M. Harrington\*, F. Malchiodi Albedi, A.C. McKee, R.J. Ferrante and N.W. Kowall. Massachusetts General Hospital and Harvard Medical School, Boston MA 02114.

ALZ 50 is a monoclonal antibody raised against homogenates of Alzheimer's disease (AD) brain that labels pathological inclusions in AD and other disorders. Immunoblot studies show that ALZ 50 labels normal and hyperphosphorylated forms of the microtubule associated protein tau. Although initially thought to only recognize abnormal structures in AD brain, it is clear that normal neurons in rodent, primate and human brain are immunolabeled with ALZ 50. We noted that a prominent subset of normal appearing medium sized neurons were labelled by the ALZ 50 antibody (courtesy of H. Ghanbari) in normal adult human striatum. We studied the caudate nucleus in 6 normal controls and in 6 cases of HD to determine if ALZ 50 positive neurons were spared. In all HD cases there was dramatic preservation of ALZ 50 neurons that were morphologically identical to somatostatin-neuropeptide Y-NADPH diaphorase-NO synthase neurons. ALZ 50 neurons in normal brain may be enriched in a specific postranslational form of tau protein. Alternatively, ALZ 50 may crossreact with an epitope in an unrelated molecule. In either case, the localization of ALZ 50 immunoreactivity in a subset of striatal neurons in normal adult striatum portends a role for ALZ 50 immunoreactive proteins in normal neuronal physiology.
